1819.
INCREMENTS, Method of, called by the French
Calcule des Differences Finies, is a branch of analysis invented by the learned Dr. Brook Taylor, particularly useful in the summation of series, and applicable to several subjects of mathematical investigation, where hitherto any other method can be successfully employed. Maclaurin observes, that had the human mind always pursued the path which appears the most natural, the theory of increments, or of finite differences, would have preceded that of fluxions, or the differential calculus; as it seems more natural for the mind to be carried from the consideration of finite differences, to that of differences indefinitely small, than that the latter should be the precursor of the former. Such, however, was the fact; for the first distinct notions of the method of increments did not appear till the year 1715, in a work entitled „Methodus Incrementorum.„ &c. by Dr. Brook Taylor, in which both the direct and inverse method of increments are treated of in a very learned manner, and an application of the same to various interesting problems; but the novelty of the subject, and the concise mode of expression employed by its author, together with the very complicated notation, rendered the work nearly unintelligible to any man less skilled in analysis than the author himself; even the enunciation of some of the propositions requires the greatest possible attention in order to comprehend their meaning; but in other respects, the work bears strongly evident marks of the lofty genius of its author, and contains, in the second part, many very excellent applications of the preceding theory to the solution of some of the most interesting and celebrated mathematical problems. Such, however, being the intricacy of the original work, it necessarily follows that it could only be read by the very first rate mathematicians; and it was therefore fortunate that any of them would condescend to illustrate a subject in which they could only act a secondary part; such a person was however found in M. Nichole, of the Royal Academy of Sciences, who, having very early been in possession of a copy of Dr. Taylor’s work, and perceiving, at once, its general utility, he undertook the task of illustrating the principles upon which it rested, and, by simplifying the notation and operations, rendered it intelligible to readers of an inferior order; his first paper on the subject was published in the Memoirs of the Academy for 1717, which was afterwards followed by two others in 1723 and 1724. Dr. Taylor himself also, in the Philosophical Transactions, undertook an explanation of certain parts of his work, and its farther application to some kinds of series beyond those treated of in the original; the fame was also done by M. Montmort, in the Transactions for the years 1719 and 1720; which latter gentleman, it seems, had conceived some idea of the theory before Dr. Taylor’s work appeared; and a trilling altercation took place between them as to the originality of some of the notions which was claimed by both parties. In 1763, Emerson published his „Method of Increments;„ a work which, at least, does this author as much credit as any that he ever produced; but the notation resembles, in a great measure, that of Dr. Taylor, which renders it now almost obsolete. Emerson appears to have been extremely anxious to bring the theory of increments to perfection; and earnestly urged those who were qualified for the task, to pursue the paths he had opened to them. “I cannot,” says he, “promise that I shall have time and leisure hereafter to prosecute this subject any farther. And as I have an earnest desire of advancing truth and improving science, let me here entreat
treat the friendly mathematicians, who are lovers of
tience, to lend their kind affilience for the advancement of
this uncultivated branch of knowledge, yet in its infancy,
or rather, as yet, in the hands of Lucina, either according to
the model I have here laid before them, or some better if it
can be found, so that, by degrees, it may at length be
brought to perfection." Hence it appears that this author
was, in 1763, sensible of the neglect that had been paid to
the theory of increments; and even now, near half a cen-
tury after this date, the subject has not been advanced, may
scarcely touched upon by any English mathematician, while
foreign authors are filling quarto volumes with the theory of
differences finites, and its almost universal application to the
most curious and important of mathematical inquiries. Eu-
ler, whole universal genius led him to the investigation of
every subject that was useful and interesting, did not leave
the theory of increments untouched, but has treated of it,
in his usual masterly style, in a work entitled "Institutiones
Calculi Differentialis," &c. in which he has given a new
form, and much extended the bounds of this important
branch of analysis; and subsequent authors have adopted his
ideas, and rendered permanent the form he gave it. Vari-
rages other works have since appeared to illustrate and render
familiar the principles of this doctrine; the most complete
of which is the "Traité des Différences," &c. by Lacroix.
Baum has likewise a chapter on this subject in his; "Traités
des Calculs Differentiels, one of which the theory is treated in a
very elementary and comprehensive manner; and the same
is still done by Cousin, in chapter 3, of the introduction to his

Having thus given a brief sketch of the history and pro-
gress of the method of increments, we shall now endeavour
to explain the principles and application of it: order to
which, that we may prepare the reader for the more general
theory, it will be best to consider the same in a more limited
form in the first instance, in order not to carry a better model than that of M. Nichole above-mentioned.

The method of this author is extremely simple, but cer-
tainly less general than that of Dr. Taylor; it is, however,
well calculated for conveying the clearest and connected
ideas of this theory, and prepares the reader for more general
refinements, by leading him on, from step to step, with order
and precision.

If we consider $x$ as any variable quantity, which is con-
tinually increased by a constant quantity $n$, so that it becomes
successively $x$, $x + n$, $x + 2n$, &c.; and if $y$ be any func-
tion of $x$, made up of factors, as $y = x (x + n) (x + 2n)
(x + 3n)$, then the difference between this value of $y$, and
that which it becomes when $x$ is again increased by $n$, is the
increment of $y$, or of $x (x + n) (x + 2n) (x + 3n)$; which
increment is readily obtained, by observing that
\[
(x + n) - x = n \\
(x + n) (x + 2n) - x (x + n) = 2n (x + n) \\
(x + n) (x + 3n) - x (x + n) (x + 2n) = 3n \\
(x + n) (x + 2n) - x (x + n) (x + 2n) = 3n \\
(x + n) (x + 2n) - x (x + n) (x + 2n) = 3n
\]

and hence generally, the increment of $x (x + n) (x + 2n)
(x + 3n) ... (x + rn) = (r + 1) n \\
(x + n) (x + 2n) ... (x + rn)$: And hence again con-
versely, the integral of $(r + 1) n (x + n) (x + 2n) ... (x + rn)$
\[= \frac{1}{2} \frac{1}{r + 1} \frac{x^{r+1} - x^n}{(x + n) (x + 2n) ... (x + rn)} \] \[= \frac{1}{2} \frac{1}{r + 1} \frac{x^{r+1} - x^n}{(x + n) (x + 2n) ... (x + rn)} \]

and by means of this general expression, for the increment of
$x^n$, we readily deduce the increment of any function of $x$,
as $x + a x + b x^2 + &c.$ Thus, for example, if $x$ was
required to find the increment of $x^3 + 3 x^2 + 4 x$, we have
increment of $x^3 = 3 x^2 + 2 x + 4 x$ \\
increment of $x^2 = 2 x n + 3 n^2$ \\
increment of $x = 4 x^2$ \\
Hence the increment of $x^3 + 3 x^2 + 4 x = 3 x^2 + 2 x + 4 x$

It is therefore not necessary, when we proceed thus, that
the function proposed should be made up of factors in arith-
metical progression, as in the former rule.

Again, the increment $\frac{1}{x}$ is the difference between $\frac{1}{x}$
and
\[\frac{1}{x + n} = - \frac{n}{x (x + n)} \] ; and in the same way we find the
increment of $\frac{1}{x (x + n)} = - \frac{2 n}{x (x + n) (x + 2 n)}$ ; and
\[\frac{1}{x (x + n) (x + 2 n)} = - \frac{3 n}{x (x + n) (x + 2 n) (x + 3 n)} \] ;
and generally the increment of
\[\frac{1}{x (x + n) (x + 2 n) ... (x + r n)} = - \frac{(r + 1) n}{x (x + n) (x + 2 n) ... (x + r n)} \]

And hence, again, conversely, the integral of
\[\frac{1}{x (x + n) (x + 2 n) ... (x + r n)} = \frac{1}{x (x + n) (x + 2 n) ... (x + r n)} \]

\[= \frac{1}{x (x + n) (x + 2 n) ... (x + r n)} \]

This, as was before observed, is not the most general
mode of considering the subject, but we are much miltaken
if it be not the most obvious and natural; and therefore the
belt adapted for illustration, and for conveying to a beginner
the first ideas of the theory. We will now give the appli-
cation of the above principles to an example or two, by way
of elucidation, and then proceed to a more general and ex-
tended investigation of the method of increments, and its
application to mathematical problems.

Ex. 1.—Let it be proposed to find the sum of 100 terms of
the series
\[1 + 2 + 3 + 4 + 5 + ... + 100 = 101 \]

Each of these terms is of the form $x (x + 1)$, and it is
obvious that the next term to 100, 101, that is 101, 102, is
the increment of the series; or, making 100 = $x$, the lat-
term is $x (x + 1)$, and the following one is $(x + 1) (x + 2)$;
which is evidently the increment of the series, or the dif-
ference between the proposed series in the first case, and
what it becomes when $x$ is increased by the common dif-
ference 1; and the next conversely, the integral of this in-
crement, that is, of $(x + 1) (x + 2)$, will be the sum of
the series sought. Now the integral of \((x + 1) (x + 2)\)
\[= \frac{x(x + 1)(x + 2)}{3};\]
and since \(x\) in the present example = 100, we have \(100 \times 101 \times 102 = 343400\) for the sum required.

\(Ex. 2.-\) Required the sum of \(n\) terms of the series
\[1 \cdot 2 \cdot 3 + 2 \cdot 3 \cdot 4 + 3 \cdot 4 \cdot 5 + \ldots + n(n + 1)(n + 2).
\]
Here, by writing \(n\) instead of \(n + 1\), we shall have for the succeding term \(n(x + 1)(x + 2)\), which is the integral of the series, and therefore the integral of \(x(x + 1)(x + 2)\) will be the sum required; which, by re-establishing the value of \(x = n + 1\), becomes
\[\frac{n(n + 1)(n + 2)}{4} = \text{the sum of } n \text{ terms.}\]

\(Ex. 3.-\) Required the sum of \(n\) terms of the natural series of squares 1 \(^2\), 2 \(^2\), 3 \(^2\), 4 \(^2\), \ldots \(n\) \(^2\).
Here writing \(x\) for \(n\), the succeding term is \((x + 1)\(^2\) = \(x^2 + 2x + 1 = x(x + 1) + (x + 1)\), which is the increment; and it consists of two parts. Now the integral of \(x(x + 1)\) is \(\frac{x(x + 1)}{3}\); and therefore since \(x = n\), we have
\[\frac{n(n + 1)}{2} + \frac{(n - 1)n(n + 1)}{3} = \text{the sum required.}\]

\(Ex.-\) Let it now be proposed to find the sum of the infinite series
\[\frac{1}{1 \cdot 2} + \frac{1}{2 \cdot 3} + \frac{1}{3 \cdot 4} + \frac{1}{4 \cdot 5} + \ldots \frac{1}{n \cdot (n + 1)};\]
Here it will be necessary for us to consider the series as generated from the extreme term, which is \(\frac{1}{n}\), and therefore \(\frac{1}{1 \cdot 2}\) as its last term, which will therefore be the increment of the series
\[\frac{1}{2 \cdot 3} + \frac{1}{3 \cdot 4} + \frac{1}{4 \cdot 5} + \ldots \frac{1}{n \cdot (n + 1)};\]
and consequently, the integral of this will be the sum of the series, wanting only the term \(\frac{1}{1 \cdot 2}\). Make, therefore, \(x = 2\), or
\[x = \frac{1}{x(x + 1)};\]
in which case the increment \(\frac{1}{1 \cdot 2}\) becomes \(\frac{1}{x(x + 1)}\); and the integral of this = \(\frac{x}{x + 1}\) (because the increment is \(-1\)); therefore the sum of the series, beginning at the term \(-\frac{1}{1 \cdot 2}\), is \(\frac{1}{x}\), to which adding the first term \(\frac{1}{1 \cdot 2}\), we have the sum of the whole series = 1.

This will serve to explain the method pursued by M. Nicholson in his first paper, and will be useful as an introduction to what follows; in which case we shall not limit ourselves to considering the continual increase of \(x\) as constant as is done above; but as being variable like \(x\) itself; for it is under this form, that the theory of increments becomes so universally applicable to almost every species of mathematical investigation.

Notation and Definition.

1. As the increment of a variable quantity \(x\) is nothing more than the difference between that quantity in its first state, and what it becomes after a certain increase, this difference may be properly represented by \(\Delta x\), or \(\Delta x\); and in the same manner, if \(y\) be any function of a variable quantity, \(\Delta y\), or \(\Delta y\), will represent the increment of \(y\). And as in the fluxional or differential calculus, \(\dot{y}\) is made the character of integration, so in the present instance, we shall employ it to represent the integral of any increment.

2. The increment of a variable quantity being, as we have observed above, only the excess of this quantity in one state, over the same quantity in the confecutive state, it follows that if a variable magnitude \(x\) becomes successively \(x, x', x'', x''', \&c.\) we shall have \(\Delta x = x' - x; \Delta x'' = x'' - x'; \Delta x''' = x''' - x'';\) &c.

It may happen that an increment may be positive, or negative, according as the variable quantity, of which it is the increment is augmented or diminished. With regard to some other magnitude or magnitudes which we suppose to increase, and of which the increments are therefore necessarily positive.

3. The increments of quantities being themselves quantities, if they be variable, we may take the increments of them, there are called second increments; and if these second increments be also variable, we may in like manner take the increments of these also; which are called third increments, and so on as long as the differences or increments are variable.

In all these cases, the condition of the increments being variable, is necessary, because it, in any case, they become constant, then it is obvious that the increments are 0, whether it be the first, second, third, &c. increment that thus becomes constant or invariable.

Thus the series of squares 1, 4, 9, 16, 25, &c. is an example of a case in which the second differences or increments are constant: for this series may be considered as generated by a variable quantity \(x\); which is such, that if the difference between the successive terms be taken, they will form a series of quantities in arithmetical progression, and consequently the differences of these differences, or the second increment of \(x\), will be constant. If in the same manner we find the third differences of the series of cubes, 1, 8, 27, 64, 125, or the third increment of \(x\), is constant; and therefore the fourth increment = 0; for after any order of increments becomes constant, all the higher orders must, necessarily, become zero.

4. As \(\Delta x\) denotes the first increment of any variable quantity \(x\), so \(\Delta^2 x, \Delta^3 x,\) &c. will represent the second, third, fourth, &c. increments of the same quantity \(x\); which expressions are sufficiently defined from \(\Delta x, \Delta^2 x, \Delta^3 x,\) &c. which represent the powers of their increments; and if it be required to express the power of any increment of the first, or in other words the power of the second, third, &c. increment of \(x\), that will be done thus, \(\Delta x^2, \Delta x'^2,\) &c.

5. In some problems it is necessary to consider a certain order of the increments as constant; thus, in any arithmetical progression the first increments are constant; in the series of natural squares, the second increments are necessarily constant; as also the third increments of cubes, &c. as we have seen above. But there is an in-
INCREMENTS.

finite number of questions, in which, from their nature, it is not necessary that any order of their increments should be constant: yet as we may attribute to a certain quantity whatever variation we please, providing that the variations of the other quantities depending upon the first be such as to accord with the variation we have attributed to it; it follows, that in any problem, we may at pleasure make any order of increments of a quantity chosen at will be constant; observing only, that the other quantities ought to vary in consequence; and, therefore, we cannot make another order of increments also constant, unless from the nature of the problem, some other increment has a certain ratio to that which is so assumed.

6. The whole of the method of increments consists of two problems; *viz.* 1st. Finding the increments of all orders of any variable quantity, raised to any power; the product of different variable quantities, and generally of any function of variable quantities; which problem is always soluble, and presents but little difficulty in any case; and this is called the Direct Method of Increments. The other problem, which is the reverse of the preceding, is that of finding the integral of any given increment, which is frequently insoluble; at least, without infinite series, or some other mode of approximation; and this is termed the Inverse Method of Increments: two problems we will consider under their distinct heads.

Of the Direct Method of Increments.

7. Since the increment of a variable quantity is the difference between the sums in any two consecutive lines, it is obvious in general, that in order to find the increment of any function of variable quantities, we must suppose, that each of those quantities is increased or diminished by its respective increments; and substitute these quantities, thus changed, into the proposed function; and from this result, if there be subtracted the original expression, the remainder will be the increment sought.

Ex. 1.—Find the first increment of the sum \( x + y + z \). Thee quantities, augmented by their respective increments, become

\[
(x + \Delta x) + (y + \Delta y) + (z + \Delta z)
\]

from which subtracting the original expression, there remains \( \Delta x + \Delta y + \Delta z \), as is evident; since the whole increment must necessarily be equal to the sum of each particular one. In the same manner we find the increment of \( x + y - z \), or \( \Delta (x + y - z) = \Delta x + \Delta y - \Delta z \).

And if we had to find the increment of \( a + x + y - z \), we should have, considering \( a \) as a constant quantity,

\[
\Delta (a + x + y - z) = \Delta x + \Delta y - \Delta z,
\]

the same result as before, because the constant quantity \( a \) has no increment, or its increment is equal to zero. Hence it appears, that if to the sum of any variable quantity we add or subtract any constant quantity whatever, the increment of the whole function will still be the same.

Ex. 2. Find the first increment of \( x^m \).

This is, from what is observed above, the difference between \((x + \Delta x)^m\) and \(x^m\); which by the binomial theorem becomes \( x^m \Delta x + \frac{m(m - 1)}{1 \cdot 2} x^{m-2} \Delta x^2 + \ldots \). Thus we find the increment of \( x^3 \), or

\[
\Delta (x^3) = 3 x^2 \Delta x + 3 x \Delta x^2 + \Delta x^3
\]

And if the proposed quantity, of which the increment is required, be \( ax^n \), \( a \) being a constant multiplier, then it is obvious that

\[
\Delta (ax^n) = \left\{ \begin{array}{ll}
\Delta (x) & = \Delta x \\
\Delta x & = \Delta (x) \\
\end{array} \right. 
\]

whence the increment \( ax^n \) is equal to \( a \) times, the increment of \( x^n \).

Ex. 3. To find the first increment of the product \( xy \).

Here \( x \) becomes \( x + \Delta x \) and \( y \) becomes \( y + \Delta y \),

whence the product \( = xy + x \Delta y + y \Delta x + \Delta x \Delta y \); from which, subtracting the original quantity \( xy \), we have

\[
\Delta (xy) = \Delta x + \Delta y + \Delta x \Delta y.
\]

And in the same way we find

\[
\Delta (xyz) = \Delta x \Delta y + \Delta x \Delta y + \Delta x \Delta y.
\]

And in like manner may the increment of any other product be readily ascertained.

If the product was \( ax y, axyz \), etc., \( a \) being a constant quantity, we should have

\[
\Delta (axy) = \Delta (xy), \Delta (axy) = \Delta (xy) + \Delta (x), \Delta (xyz), \text{etc.}
\]

that is, we must find the increment as above, and multiply the result by the constant factor \( a \).

Ex. 4.—To find the first increment of any quantity of the form \( (x + a) \), \( (x + a) (x + 2a) \), \( (x + a) (x + 3a) \), etc. Under which subtitution, the function, of which the increment is required, reduces to \( x u y z \), and, consequently, \( \Delta (x u y z) \) may be found as above. But if, without this substitution, we find the actual product, it is obvious that it will take the following form (where \( A, B, C, D, \text{etc. represent constant quantities} ; \text{viz.} \) \( a^2 + x a^3 + B x^2 + C x^3 + D x^4 \), etc. and hence by finding the increments of each of these terms by example \( 2 \), the sum of them will be the increment of the function proposed. Thus,

\[
\Delta \left( (x + a) \right) = \Delta (x^2 + a x).
\]

Now \( \Delta (x) = 2 x \Delta x + \Delta x, \Delta (a x) = a \Delta (x) = a \Delta x, \) \( \text{whence} \) \( \Delta (x (x + a)) = (2 x + a) \Delta x + \Delta x^2 \).

And in the same manner

\[
\Delta \left( (x + a) (x + 2a) \right) = \Delta (x^3 + 3 a x^2 + 2 a^2 x).
\]

Now \( \Delta (x^2) = 3 x^2 \Delta x + 3 x \Delta x^2 + \Delta x^3, \Delta (3 a x^2) = 6 a x \Delta x + 3 a \Delta x^2 \), \( \Delta (2 a x) = 2 a \Delta x \).

The sum of which particular increments will be the increment of the original function proposed; and in exactly the same way, the increment of any similar function may be ascertained.

Ex. 5.—To find the first increment of the fraction \( \frac{x}{y} \).

Here
INCREMENTS.

Here we have

\[ \Delta \left( \frac{y}{x} \right) = \frac{x + \Delta x - x}{y + \Delta y - y} = \frac{\Delta x}{\Delta y} \]

And therefore from the expansion of \((y + \Delta y)^{-1}\) into a series, we have

\[ \Delta \left( \frac{y}{x} \right) = (y + \Delta y)^{-1} \times (1 + \Delta y/y + \Delta y/y^2 + \&c.) \]

And if the proposed fraction be effected with any constant factor \(a\), the whole of the above increment must be multiplied by \(a^2\).

Ex. 6.—To find the first increment of the quantity \(\sqrt[3]{a + x}\).

It is obvious, on the same principles, that

\[ \Delta \left( \sqrt[3]{a + x} \right) = \sqrt[3]{(a + x + \Delta x)} - \sqrt[3]{(a + x)^3} \]

\[ = \sqrt[3]{(a + x + \Delta x)^3} - \sqrt[3]{(a + x)^3} \]

And if now we consider these two expressions as two binomials, to be raised to the power 3, it is obvious that from the development of the first, there will be cancelled the first term, and the other terms will represent the increment required; and we have

\[ \Delta \left( \sqrt[3]{a + x} \right) = \frac{2 \Delta x \Delta y + (2 \Delta x \Delta y + \Delta y \Delta y)}{2 (a + x)^2} \]

Ex. 7.—Having given the equation \(y = ax + x^3\), which expresses the relation between the constant quantity \(a\), and the two variable quantities \(x\) and \(y\), to find the equation which ought to express the relation between \(a\) and \(y\), and the first increments of \(x\) and \(y\).

Here we must substitute \(x + \Delta x\) for \(x\); and \(y + \Delta y\) for \(y\); which gives

\[ y + \Delta y = \Delta x + 2 \Delta x \Delta y + 3 \Delta x \Delta y^2 + \Delta y^3 = 0 \]

from which, subtracting the original equation, there remains

\[ 2 \Delta y = \Delta x + 2 \Delta x \Delta y + 3 \Delta x \Delta y^2 + \Delta y^3 = 0 \]

which is the equation required.

And in a similar manner the first increments of any quantities whatever may be ascertained, as also of any algebraical equation.

When it is required to find the second, third, &c. increments of any proposed function, it is only necessary to consider the preceding order of increments as variable quantities; and we shall thus pass from the first increments to the second, from the second to the third, from the third to the fourth, &c.; in the same manner as we pass from the original function to the first increment.

Ex. 1.—To find the second increment of \(x^3\).

Here we have, in the first place,

\[ \Delta (x^3) = 2x \Delta x + x^3 \Delta x \]

And if now, in this expression, we substitute \(x + \Delta x\) for \(x\), and \(x + \Delta x\) for \(x\), we have

\[ \Delta (x^3) = (2x + \Delta x)(x + \Delta x) + (x + \Delta x)^3 = 2x \Delta x + x^3 \Delta x + 2x \Delta x \Delta x + x^3 \Delta x \]

which is the second increment required.

And in the same way we find the third, fourth, &c. increments of a quantity or function, by substituting \(\Delta x + \Delta x\) instead of \(\Delta x\); and \(\Delta x + \Delta x\) instead of \(\Delta x\); and so on.

Remark.—If we consider the second increments as being constant, it adds very much to the simplicity of the operation; for, after having found the first increments, viz.

\[ \Delta (x^3) = 2x \Delta x + x^3 \Delta x \]

\[ \Delta (x^3) = 3x^2 \Delta x + 3x \Delta x^2 + x^3 \]

\[ \Delta (x^3) = 4x^2 \Delta x + 6x \Delta x^2 + 4x \Delta x^3 + x^4 \]

&c. &c.

we shall have for the higher order of increments,

\[ \Delta (x^4) = 2 \Delta x^3 + \Delta x^3 = 0, \Delta (x^4) = 2 \]

\[ \Delta (x^4) = 6 \Delta x x^3 + 6 \Delta x^2 x^3 + 6 \Delta x^3 x^3 + x^4 \]

\[ \Delta (x^4) = 6 \Delta x x^3 + 6 \Delta x^2 x^3 + 6 \Delta x^3 x^3 + x^4 \]

\[ \Delta (x^4) = 2 \Delta x x^3 + 2 \Delta x^2 x^3 + 2 \Delta x^3 x^3 + x^4 \]

and if we suppose \(\Delta x\) constant, this expression reduces to

\[ \Delta(x^4) = x \Delta x^3 + 2 \Delta x^2 x^3 + 2 \Delta x^3 x^3 + x^4 \]

And similar methods apply in all cases; it will, therefore, be unnecessary to give any farther examples, except in the case of an exponential expression, which is somewhat different.

Let it be proposed, for example, to find the increment of the hyperbolic logarithm of \(x\).

Let \(y = b.l.x\); then, as \(x\) becomes \(x + \Delta x\), so will \(y\) become \(y + \Delta y\), that is,

\[ y + \Delta y = b.l(x + \Delta x) \]

and hence, since \(y = b.l.x\), we have

\[ y + \Delta y - y = b.l(x + \Delta x) - b.l.x \]

\[ \Delta y = b.l(x + \Delta x) - b.l.x = b.l\left(1 + \frac{\Delta x}{x}\right) \]

Now, by the well-known logarithmic series, we have

\[ b.l\left(1 + \frac{\Delta x}{x}\right) = b.l \left(1 + \frac{\Delta x}{x} + \frac{\Delta x^2}{2x^2} + \frac{\Delta x^3}{3x^3} - \frac{\Delta x^4}{4x^4} + \&c.\right) \]

whence \(\Delta y = b.l(x + \Delta x) - b.l.x = b.l\left(1 + \frac{\Delta x}{x}\right)

whence \(\Delta y = b.l(x + \Delta x) - b.l.x = b.l\left(1 + \frac{\Delta x}{x}\right)\).

3 Now,
INCREMENTS.

Now, expanding \((a^\Delta x - 1)\) into a series, we have

\[
(a^\Delta x - 1) = 1 + \frac{\Delta x (l a)}{1} + \frac{\Delta x^2 (l a)^2}{1 \cdot 2} + \frac{\Delta x^3 (l a)^3}{1 \cdot 2 \cdot 3} + \&c.
\]

Therefore \(\Delta y\), or \(\Delta (a^x) = \)

\[
a^x \times \left\{ \frac{\Delta (l a)}{1} + \frac{\Delta x (l a)^2}{1 \cdot 2} + \frac{\Delta x^2 (l a)^3}{1 \cdot 2 \cdot 3} + \&c. \right\}
\]
as required. And the higher order of its increments may be found by the usual method.

Of the Inverse Method of Increments.

8. In the inverse method of increments, the question is to find the integral, or function, from its increment being given. We must, therefore, examine with attention the steps by which we descend from a variable quantity to its increment; and then, by the reverse operation, we may ascend to the integral, when the increment is known. But this reverse operation is attended with the very same difficulties as the inverse method of fluxions, for, as in that, every fluent may be readily put into fluxions, so may the increment of any function be readily obtained; but it is frequently difficult, and sometimes impossible to find the fluent of a given fluxion; and so in the method of increments, there are many cases that will not admit of integration; we shall, however, give some of the most usual and obvious rules, and which will apply to the generality of examples.

Let us first attend to the powers of a variable quantity \(x\).

1. Since \(\Delta x = \Delta (x)\); therefore, reciprocally, \(\int \Delta x = x\). And if we suppose \(\Delta x\) as constant (a supposition that has place in all that follows), we shall have \(\int \Delta x \times 1 = x\), or \(\Delta x \int 1 = x\); therefore \(\int \frac{x}{\Delta x}\).

2. Since \((\Delta x) = 2 \Delta x + \Delta x^2\), therefore, reciprocally, \(\int (2 \Delta x + \Delta x^2) = x\); or, which is the same, \(\int 2 \Delta x + x = x\); whence again \(\int x + \\frac{\Delta x}{2} = \frac{x^2}{2 \Delta x}\); and hence, by transposition, \(\int x = \frac{x^2}{2 \Delta x} - \frac{\Delta x}{2} \int 1 = \frac{x^2}{2 \Delta x} - \frac{x}{2} - \frac{\Delta x}{2}.

3. Again, since \(\Delta (x^2) = 3 x^2 \Delta x + 3 x \Delta x^2 + \Delta x^3\); therefore, reciprocally, \(\int (3 x^2 \Delta x + 3 x \Delta x^2 + \Delta x^3) = x^3\); or, which is the same, \(\int x^3 + x \Delta x + \frac{\Delta x^2}{3} \int 1 = x^3 - \frac{\Delta x}{3} - \frac{\Delta x^3}{3} - \frac{\Delta x^3}{3} \int 1\); or, which is the same, \(\int x^3 = \frac{x^4}{4} - \frac{\Delta x}{4} \int x = \frac{x^4}{4} - \frac{x^4}{4} \int 1\); whence, again,

\[
\int x^3 = \frac{x^4}{4} - \frac{\Delta x}{4} \int \frac{x^3}{3} + \frac{\Delta x^3}{3} \int 1 = x^3 - \frac{\Delta x}{3} - \frac{\Delta x^3}{3} - \frac{\Delta x^3}{3} \int 1.
\]

We find in a similar manner, by continuing to suppose \(\Delta x\) as constant, and substituting always for the quantities contained under the particular sum their respective values, the following results for the integrals of the successive powers of \(x\), in which we have repeated the two preceding ones, for the sake of uniformity.

\[
\int 1 = \frac{x}{\Delta x};
\]

\[
\int \Delta x = \frac{x^2}{2 \Delta x} - \frac{x}{2};
\]

\[
\int \Delta x^2 = \frac{x^3}{3 \Delta x} - \frac{x}{2 \Delta x} \int \frac{\Delta x}{6} - \frac{\Delta x}{2} = \frac{\Delta x}{2} + \frac{x}{\Delta x} - \frac{x^2}{2} + \frac{x^3}{6} - \frac{\Delta x}{2} - \frac{x^2}{\Delta x} - \frac{x^3}{6};
\]

\[
\int \Delta x^3 = \frac{x^4}{4} - \frac{x^4}{4} \int \frac{\Delta x}{3} - \frac{x^4}{3} \int 1.
\]

where it is only necessary to observe, that if the proposed increment have any constant multiplier, the integral above found must have the same.

Cor. 1. Hence we may find the integral of any function composed of the powers of \(x\), affected with any constant coefficients \(a, b, c, \&c\). For in order to find the integral of such an increment, it is only necessary to find those of the different powers of \(x\), and their sum will be the integral required.

\(\text{Ex. 1.} - \text{Required the integral of the increment } a + b x + c x^2 ; \text{ considering } \Delta x \text{ as constant.}
\]

\[
\int a = a; \int 1 = \frac{x}{\Delta x};
\]

\[
\int b x = b x; \int c x^2 = \frac{c x^3}{3} \int \frac{\Delta x}{6} - \frac{x^3}{6} \int 1.
\]

And hence by addition,

\[
\int (a + b x + c x^2) = \frac{a x + b x}{\Delta x} + \frac{b x^2}{2 \Delta x} + \frac{c x^3}{3 \Delta x} - \frac{c x^3}{6} \int \frac{\Delta x}{6}.
\]

\(\text{Ex. 2.} - \text{Required the integral of } a x^4 - b x^3, \text{ considering } \Delta x \text{ as constant.}
\]

Here we have

\[
\int a x^4 = \frac{a x^5}{5} - \frac{a x^4 \int \frac{\Delta x}{3} - \frac{a x^3 \int \Delta x}{3} \int 1};
\]

\[
\int b x^3 = \frac{b x^4}{4} - \frac{b x^3 \int \frac{\Delta x}{3} - \frac{b x^2 \int \Delta x}{3} \int 1}.
\]

the sum of which expressions will be the whole increment fought.

Cor. 2. - When it is required to find the integral of a quantity of any of the following forms, \((\rightarrow a \text{ being supposed constant}), \&c.
\]

\[
(x + a) \frac{x + a}{x + a} (x + 2 a) \frac{x + a}{x + 2 a} \frac{(x + 3 a)}{x + 3 a} (x + a) \frac{(x + a)}{(x + 2 a)} (x + 4 a)
\]

we arrive at them by taking the partial product of those quantities, and finding successively the increments of each of the terms; thus,

1. \(\int (x + a) = \int x + \int a = \frac{x^2}{2 \Delta x} - \frac{x}{2} + \frac{a x}{\Delta x} \int 1.
\]

2. \(\int (x + a) (x + 2 a) = \int (x^2 + 3 a x + 2 a^2) = \int x^2 \int 1.
\]
INCREMENTS.

1. \( f(x) = \frac{x^3}{3} - \frac{x^2}{2} + \frac{x}{6} \)
2. \( f(3a) = \frac{3a^3}{2} - \frac{3a^2}{2} + \frac{3a}{2} \)
3. \( f(2a^2) = \frac{2a^3}{2} - a^2 \) \\

Whence \( f(x + a) = \frac{x^3}{3} - \frac{x^2}{2} + \frac{x}{6} + \frac{3a^2}{2} + \frac{3a}{2} \) \\

3. Again, \( f(x + a) = \frac{x^3}{3} + \frac{3a}{2} + \frac{3a^2}{2} - \frac{3a}{2} \) \\

\( f(x) = \frac{x^3}{3} - \frac{x^2}{2} + \frac{x}{6} \) \\
\( f(x + a) = \frac{x^3}{3} + \frac{3a}{2} + \frac{3a^2}{2} - \frac{3a}{2} \) \\

\( f(x + a) = \frac{x^3}{3} + \frac{3a}{2} + \frac{3a^2}{2} - \frac{3a}{2} \) \\

Whence by addition, we have \( f(x + a) = \frac{x^3}{3} + \frac{3a}{2} + \frac{3a^2}{2} - \frac{3a}{2} \) \\

\( x + a \) \\
\( x + 2a \) \\
\( x + 3a \) \\

And if it be required to find the integral of quantities of the form \\
\( \int (x + a) (x + 2a) \) \\
\( \int (x + a) (x + 2a) (x + 3a) \) \\
\&c. \\

we have in the same way \\
1. \( \int x \) \\
2. \( \int 3 \Delta x \) \\
3. \( \int 4 \Delta x \) \\

the sum of which will be the increment required. \\

And, in a similar manner, we may find the integral to any other quantity of these forms. 

9. Remark.—Before we proceed any further on this subject, it will be proper to attend to the correction of any integral, when from the nature of the problem under consideration such becomes necessary. 

As the increments of any variable quantities \( x \) and \( x + a \) are both expressed by \( \Delta x \), the constant part \( a \) having no increment, so, reciprocally, the integral of the increment \( \Delta x \) may be \( x \), or \( x + a \); therefore, when we have found the integral of any increment, we must add to it a constant quantity, which will be zero, if the integral need no correction but a real quantity, positive or negative, in other cases, which must be determined from the nature of the problem. This remark will be of considerable importance in what follows. 

10. Let us then consider those products, of which the factors are continually increased by a constant difference; \\
\[ x (x + \Delta x) \] \\
\[ x (x + \Delta x) + (x + 2 \Delta x) \] \\
\[ x (x + \Delta x) + (x + 2 \Delta x) + (x + 3 \Delta x) \] \\
\&c. \\

Here it is obvious that the increment of \( x(x + \Delta x) \); or \( \Delta x \) (\( x + \Delta x \)) = \( x + \Delta x \) \( x + 2 \Delta x \) - \( x + \Delta x \); whence, by multiplication and subtraction, we have \\
\( \Delta x(x + \Delta x) = 2 \Delta x(x + \Delta x) \). 

And thus again, \\
\( \Delta x(x + \Delta x(x + 2 \Delta x)) = 3 \Delta x(x + \Delta x(x + 2 \Delta x)) \) \\
and so on of other similar products. Whence it appears, that in order to find the increment of any product of the above form, we must supress the first factor \( x \), and write in its place the increment \( \Delta x \) expressed with a co-efficient equal to the total number of factors; all the other part of the expression remaining as before. 

Whence again, conversely, the integral to any increment of this form, will be found from the reverse operation. 

Thus for example, 

1. \( \int 2 \Delta x = x(x + \Delta x) \) 
2. \( \int 3 \Delta x = x(x + \Delta x) + (x + 2 \Delta x) = x(x + \Delta x) + (x + 2 \Delta x) \) 
3. \( \int 4 \Delta x = x(x + \Delta x) + (x + 2 \Delta x) + (x + 3 \Delta x) = x(x + \Delta x) + (x + 2 \Delta x) + (x + 3 \Delta x) \) 

and so on of others. 

Whence, in order to find the corresponding integral to any increment of the above form, which may be represented generally by 

\( a \Delta x(x + \Delta x) \ldots (x + n \Delta x) \), 
we must change \( \Delta x \) in the first factor into \( x \), and divide the whole by the number of factors; that is, 

\( \int a \Delta x(x + \Delta x) \ldots (x + n \Delta x) = \frac{a x(x + \Delta x) \ldots (x + n \Delta x)}{n + 1} \) 

This part of the theory has been before considered in the preceding pages, in describing the method employed by M. Nicolson of the Academy of Sciences, published in 1717. 

11. Let us now consider those fractions, the denominators of which are composed of factors similar to those above described, viz. 

\[ \frac{1}{x(x + \Delta x)} \] 
\[ \frac{1}{x(x + \Delta x) + (x + 2 \Delta x)} \] 
\[ \frac{1}{x(x + \Delta x) + (x + 2 \Delta x) + (x + 3 \Delta x)} \] 

in which \( \Delta x \) is constant.
INCREMENTS.

Here, by taking the differences as before, we shall have

1. \[ \Delta \left\{ \frac{1}{x(x + \Delta x)} \right\} = \frac{1}{(x + \Delta x)(x + 2 \Delta x)} - \frac{1}{x(x + \Delta x)} \]
\[ = -2 \Delta x \times \frac{1}{x(x + \Delta x)(x + 2 \Delta x)}. \]

And in the same manner we find the increment, or,

2. \[ \Delta \left\{ \frac{1}{x(x + \Delta x)(x + 2 \Delta x)} \right\} = -3 \Delta x \]
\[ \times \frac{1}{x(x + \Delta x)(x + 2 \Delta x)(x + 3 \Delta x)}. \]

3. \[ \Delta \left\{ \frac{1}{x(x + \Delta x)(x + 2 \Delta x)(x + 3 \Delta x)} \right\} = -4 \Delta x \times \frac{1}{x(x + \Delta x)(x + 2 \Delta x)(x + 3 \Delta x)(x + 4 \Delta x)}. \]

And so on of others. Whence it follows, that in order to determine the increment of any expression of the above form, we must increase the denominator by one factor, and multiply the new fraction by the constant increment taken negatively and affected by such a co-efficient, as is equal to the number of factors in the denominator of the resulting fraction.

And hence, again, conversely, in order to find the integral corresponding to any increment of the form

\[ \frac{a \Delta x}{x(x + \Delta x)(x + 2 \Delta x)(x + 3 \Delta x) \ldots (x + n \Delta x)}, \]

we must suppress the last factor in the denominator, and afterwards divide the resulting fraction, taken negatively, by the product of \( \Delta x \), into the number of factors comprised in the denominator of the said fraction; thus,

\[ \int \frac{a \Delta x}{x(x + \Delta x)(x + 2 \Delta x)(x + 3 \Delta x) \ldots (x + n \Delta x)} \]
\[ = \frac{a}{n \Delta x(x + \Delta x)(x + 2 \Delta x)(x + 3 \Delta x) \ldots (x + n - 1 \Delta x)} \]

12. On the same principles we find

\[ \Delta \left\{ \frac{1}{x + (n + 1) \Delta x} \right\} = \frac{1}{x + (n + 1) \Delta x} - \frac{1}{x + n \Delta x} \]

and, therefore, reciprocally,

\[ \int \frac{1}{x + n \Delta x} - \int \frac{1}{x + (n + 1) \Delta x} = \frac{1}{x + n \Delta x}; \]

The integration of these two latter expressions cannot be effected separately, but the difference of them is evidently equal to the algebraical fraction \( \frac{1}{x + n \Delta x} \).

Whence it appears, that quantities may sometimes admit of integration, by being decomposed into many parts; which, though they will not admit of it in their state of separation, may, notwithstanding, be so combined with each other, that the final result shall be algebraical; a circumstance that commonly happens in practical operations.

**Examples of Integration.**

13. *Ex. 1.—Find the integral of the increment* \( \frac{3 \Delta x + 2 \Delta x}{x(x + \Delta x)(x + 2 \Delta x)} \).

This quantity admits of the following decomposition:

\[ \frac{3 \Delta x + 2 \Delta x}{x(x + \Delta x)(x + 2 \Delta x)} = \frac{1}{x} + \frac{1}{x + \Delta x} \]
\[ - \frac{2}{x(x + \Delta x)(x + 2 \Delta x)} = \frac{1}{\Delta x} \times \frac{1}{x} + \frac{1}{x + \Delta x} \]
\[ - \frac{2}{x(x + \Delta x)(x + 2 \Delta x)} \] : each of which parts is evidently of the form that has been investigated in the preceding paragraph. By making first \( n = 0 \), \( n = 1 \), and \( n = 2 \); thus we have

\[ \int \frac{1}{x} = \int \frac{1}{x + \Delta x} - \frac{1}{x}; \]

by which means the integral of the proposed quantity takes the following form: viz.

\[ \frac{2}{\Delta x} \left\{ \int \frac{1}{x + \Delta x} - \int \frac{1}{x + 2 \Delta x} \right\} = \frac{1}{x + \Delta x}; \]

But the above formula gives also

\[ \int \frac{1}{x + \Delta x} - \int \frac{1}{x + 2 \Delta x} = - \frac{1}{x + 2 \Delta x}; \]

whence the whole integral is

\[ \frac{1}{\Delta x} \times \left( \frac{3}{x + 3 \Delta x} - \frac{1}{x} \right) = - \frac{3 \Delta x - 2 \Delta x}{x \Delta x(x + \Delta x)} \]
as required.

**Ex. 2.—Required the integral of the quantity** \( \frac{3 \Delta x}{x(x + 3 \Delta x)} \).

Here we have \( \frac{3 \Delta x}{x(x + 3 \Delta x)} = \frac{1}{x} - \frac{1}{x + 3 \Delta x}; \)

and, consequently, the integral of the quantity will be

\[ \int \frac{1}{x} = \int \frac{1}{x + 3 \Delta x} \]

Now the above formula gives

\[ \int \frac{1}{x} = \int \frac{1}{x + \Delta x} - \frac{1}{x}; \]
\[ \int \frac{1}{x + 3 \Delta x} = \int \frac{1}{x + 2 \Delta x} + \int \frac{1}{x + 2 \Delta x}; \]

whence the whole integral is expressed by

\[ \int \frac{1}{x} - \int \frac{1}{x + 2 \Delta x} - \frac{1}{x} - \frac{1}{x + 2 \Delta x}; \]

But \( \int \frac{1}{x + \Delta x} - \int \frac{1}{x + 2 \Delta x} = - \frac{1}{x + \Delta x}; \)

by the same formula, and, consequently, we have at length

\[ \int \frac{1}{x} = \int \frac{3 \Delta x}{x(x + 3 \Delta x)} = - \frac{1}{x + 3 \Delta x} - \frac{1}{x + 2 \Delta x} - \frac{1}{x} \]

Such are the elements of the direct and inverse method of increments, and which will be found to embrace a very great number of cases; but those who wish for a more complete development of the principles, cannot consult a work better calculated to convey the necessary information, than the third volume of the "Traité du Calcul Différentiel, &c." par La Croix. We shall now conclude this article,
INCREMENTS.

By showing the application of the foregoing theory a few examples.

Application of the Method of Increments.

14. The summation of series, by the inverse method of increments, is founded generally on this principle; that if we have any series of quantities, as

$$ a, b, c, d, e, \&c. $$

which are derived from each other according to some known law; each term may be considered as the increment of the sum of all those which precede it. Thus,

$$ a + b + c + d + e = z $$

and

$$ a + b + c + d + e + f = z'. $$

then it is obvious, that

$$ z' - z = \Delta z = f ; $$

and therefore, conversely, the integral of any one of those terms, considered as an increment, will represent the sum of all the preceding part of the series.

This being premised, we may proceed to the solution of the following examples.

**Ex. 1.** Required the sum of $n$ terms of the natural series

$$ 1 + 2 + 3 + 4 + 5 + \ldots + n. $$

Here, by writing $x$ instead of $n$, the term next in order will be $x + 1$, which being the increment of the series, we shall have $\int (x + 1) = 1$.

Now $\int (x + 1) = \int x + \int 1$; and by art. 8,

$$ \int x = \frac{x^2}{2} - \frac{x}{2} ; $$

and $\int 1 = \frac{x}{\Delta x}$.

And since in this case $\Delta x = 2$, we have

$$ \int (x + 1) = \frac{x^2 + x}{2} + \frac{x}{2} = \frac{x^2 + x}{2} + \frac{n(n + 1)}{2} $$

by making $x = n$.

But here again, if the series do not begin at unity, it will require a correction, which will be found generally, thus: suppose the series to commence at any term $p$; and let $x = p$; then the above formula gives the sum of the series to the term $p = \frac{p^3}{6} + \frac{p^2}{2} + \frac{p}{3}$, whereas it ought to be $p$: the correction therefore becomes $-\left(\frac{p^3}{6} + \frac{p^2}{2} + \frac{p}{3} - p\right) = e$; and, therefore, the general expression for any number of terms of this series, between the limits $p$ and $n$, will be

$$ \frac{n^3}{6} + \frac{n^2}{2} + \frac{n}{3} - \frac{p^3}{6} + \frac{p^2}{2} - \frac{p}{3}. $$

**Cor.**—This example will also furnis the solution of the problem, when the roots of the squares differ from each other by any constant quantity $m$; for it will only be necessary to make $\Delta x = m$, and the same formula will give $\int (x + m) = \int x^2 + 2m \int x + m^2 \int 1$,

$$ \int x^2 = \frac{x^3}{3} + \frac{x^2}{2} + \frac{x}{\Delta x} $$

$$ 2m \int x = \frac{2mx^2}{2} \int x $$

$$ m^2 \int 1 = \frac{m^2x^2}{\Delta x} $$

And since in this case we have $\Delta x = m$, the sum of these expressions becomes

$$ \int (x + m)^2 = \frac{x^3}{3} + \frac{x^2}{2} + \frac{mx}{\Delta x} + e, $$

the correction; and therefore the general formula for the sum beginning at any term $p$, will be

$$ \frac{n^3}{3m} + \frac{n^2}{2} + \frac{mn}{6} - \frac{p^3}{3m} + \frac{p^2}{2} - \frac{pm}{6}. $$

**Ex. 2.**—Find the sum of the series of squares $1^2 + 3^2 + 5^2 + 7^2 + \&c. n^2$.

Here the general term of the series is $(x + 2)^2$, and therefore the sum required will be expressed by the integral of $(x + 2)^2$.

Now $\int (x + 2)^2 = \int x^2 + \int 4x + \int 4$; and by article 8

$$ \int x^2 = \frac{x^3}{3} + \frac{x^2}{2} + \frac{x}{\Delta x}, $$

$$ \int 4 = \frac{4x}{\Delta x}, $$

And since in this case $\Delta x = 2$, we have

$$ \int (x + 2)^2 = \frac{x^3}{6} + \frac{x^2}{2} + \frac{4x}{2} - \frac{4x}{2} + \frac{4}{2}, $$

by making $x = n$.

But here again, if the series do not begin at unity, it will require a correction, which will be found generally, thus: suppose the series to commence at any term $\mu$; and let $x = \mu$; then the above formula gives the sum of the series to the term $\mu = \frac{\mu^3}{6} + \frac{\mu^2}{2} + \frac{\mu}{3}$, whereas it ought to be $\mu$: the correction therefore becomes $-\left(\frac{\mu^3}{6} + \frac{\mu^2}{2} + \frac{\mu}{3} - \mu\right) = e$; and, therefore, the general expression

**Ex. 3.**—Required the sum of the natural series of cubes $1^3 + 2^3 + 3^3 + 4^3 + \&c. n^3$.
INCREMENTS.

Here the general term is \((x+1)^2\); and the integral of this, that is, \(\int (x+1)^2 \, dx = \int x^2 + 3x + 3 \, dx\), is computed as follows:

\[
\int x^3 = \frac{x^4}{4} + \frac{x^3}{2} + \frac{x^2 \Delta x}{4} \\
3 \int x^2 = \frac{3x^3}{3} + \frac{3x^2}{2} + \frac{3x \Delta x}{6} \\
3 \int x = \frac{3x^2}{2} + \frac{3x}{2} \\
\int 1 = \frac{x}{\Delta x}
\]

And hence, since \(\Delta x = 1\), we have

\[
\int' (x+1)^2 = \frac{x^2}{4} + \frac{x^2}{2} + \frac{x^2}{4} = \left(\frac{x + x}{2}\right)^2
\]

Or, by making \(x = n\), the sum required is \(\left(\frac{n + x}{2}\right)^2\).

Hence a very curious property with regard to the sums of consecutive cubes beginning at 1; viz. that this sum is equal to the square of the sum of all their roots.

Thus,

\[
1 + 2 = (1 + 2)^2 \\
1 + 2 + 3 = (1 + 2 + 3)^2 \\
1 + 2 + 3 + 4 = (1 + 2 + 3 + 4)^2
\]

As to the correction in those cases that required it, it will be found as in the preceding example; as also the sums of any number of cubes whose roots are in arithmetical progression, having any common difference \(m\). And the sums of any powers whatever are attainable upon the same principles.

Ex. 4.—Required the sum of any proposed number of terms in the series of triangular numbers

\[
1, 3, 6, 10, 15, &c.
\]

In this case the general term is \(\frac{x(x+1)}{2}\), and it will therefore be necessary to find the integral of \(\frac{(x+1)(x+2)}{2}\) but (art. 10)

\[
\int \frac{(x+1)(x+2)}{2} = \frac{x(x+1)(x+2)}{6\Delta x} = \frac{n(n+1)(n+2)}{6}
\]

by making \(x = n\), and \(\Delta x = 1\).

The same may be otherwise found from art. 8; thus, if

\[
\frac{1}{2} \int (x+1)(x+2) = \frac{x^2}{2} + \frac{x \Delta x}{3} + \frac{x^2}{2}
\]

\[
\frac{1}{2} \int x^2 = \frac{x^3}{6} - \frac{x^2}{4} + \frac{x \Delta x}{12}
\]

\[
\frac{1}{2} \int x = \frac{3x^2}{4} - \frac{3x}{4}
\]

\[
\int 1 = \frac{x}{\Delta x}
\]

And hence, since \(\Delta x = 1\), this sum becomes

\[
\frac{1}{2} \int (x+1)(x+2) = \frac{x^2}{6} + \frac{x^2}{2} + \frac{x}{3} = \frac{x(x+1)(x+2)}{6}
\]

And the sums of any order of polygonal and figurate numbers may be found in the same manner.

Ex. 5.—Required the sum of any number \(n\) terms of the series

\[
1 \cdot 2 + 2 \cdot 3 + 3 \cdot 4 + 4 \cdot 5 + \cdots + n(n+1)\]

Here the general term of the series is \(x(x+1)\), it is therefore required to find the integral of \((x+1)(x+2)\).

First by art. 10, we have

\[
\int (x+1)(x+2) = \frac{x(x+1)(x+2)}{3\Delta x} = \frac{n(n+1)(n+2)}{3}
\]

The same may also be found, as in the example above, by article 8; but if it is needed to repeat it, as it only differs from that in its constant factor.

We have in neither of the foregoing examples any correction, for it is obvious that when \(x = 0\), the formula

\[
x(x+1)(x+2) = x\]

is evidently true, as it ought to be, and therefore the integral needs no correction.

Ex. 6.—Required the sum of any number of terms \(n\), of the series

\[
1 \cdot 2 \cdot 3 \cdot 4 \cdot 5 \cdot 6 \cdot 7 \cdot 10 + 4 \cdot 7 \cdot 10 \cdot 13 + 7 \cdot 10 \cdot 13 \cdot 16 + \cdots
\]

Here the general term of the series is \(x(x+3)(x+6)(x+9)\), and we have therefore to find the integral of \((x+3)(x+6)(x+9)(x+12)\).

Now, by art. 10,

\[
\int (x+3)(x+6)(x+9)(x+12) = \frac{5}{n+3}
\]

by writing \(x = n\), and \(\Delta x = 3\).

Ex. 7.—Required the sum of the infinite series

\[
\frac{1}{1 \cdot 2 \cdot 3 \cdot 4 \cdot 5 \cdot 6} + \frac{1}{7 \cdot 10 \cdot 13 \cdot 16} + \cdots
\]

Here the general term of the series

\[
x = \frac{1}{(x+1)(x+2)}\]; and the most simple idea is now to consider the series as generated from its extremity, which is infinitely distant; under which circumstances each term will be the increment of all those which follow it in the above arrangement; and therefore, in order to find the sum beginning at any term \(\frac{1}{x(x+1)(x+2)}\), we have simply to find the integral of \(\frac{1}{x(x+1)(x+2)}\), taken negatively, because the increment \(x\) that is, \(\Delta x = 1\).

Now, by art. 11,

\[
\int \frac{1}{(x+1)(x+2)} = \frac{1}{x(x+1)} - \frac{1}{x+1}
\]

because \(\Delta x = 1\); that is, the sum of the above infinite series beginning at any term \(\frac{1}{n(n+1)(n+2)}\) is equal to \(\frac{1}{2(n+1)}\); and therefore when \(n = 1\), the whole series becomes \(\frac{1}{2}\).
INC

Cor. Having thus found the sum of the whole series, we may readily find the sum of as many terms as we please, for we have seen that the sum beginning at the nth term from the first, is \( \frac{1}{2} \left( n + \frac{1}{2} \right) \); and therefore, beginning at the 
(n + 1)th term, the sum will be \( \frac{1}{2} \left( n + \frac{1}{2} \right) \)
which left sum taken from the whole sum \( \frac{1}{2} \), will leave that of the
first \( n \) terms, that is, \( \sum_{n=1}^{n} = \frac{1}{2} \left( n + \frac{1}{2} \right) \left( n + \frac{1}{2} + 1 \right) \).

Thus, if \( n = 1 \), sum = \( \frac{1}{2} \); if \( n = 2 \), sum = \( \frac{5}{12} \); if
\( n = 3 \), the sum = \( \frac{1}{2} \), &c.

Ex. 8.—Find the sum of the infinite series
\[ \frac{1}{\sqrt{5}} + \frac{1}{5.9} + \frac{1}{9.13} + \frac{1}{13.17} + \text{&c.} \]

Here the general term of the series being \( \frac{1}{x(x+4)} \); we shall,
upon the same principles as in the preceding example, have to find the integral of \( \frac{1}{x(x+4)} \).

Now by art. 11.
\[ \int \frac{1}{(x-4)^{2}} \, dx = \frac{1}{x-4} \times \frac{1}{x} = \frac{1}{4x} \]

Making, therefore, \( x = 1 \), we have \( \frac{1}{4} \) for the sum of the
whole series, beginning at the first term. We might have added here a variety of other examples, had the limits of the article admitted of it, but such as are given will be found to apply in a variety of cases; and will indicate to the intelligent reader the method of application in many other, which are reducible to similar principles. It will be proper, however, before we dismiss this subject entirely, to say a few words on the celebrated theorem of Dr. Taylor, the learned
author of this theory. This theorem may be expressed as follows:

Let \( Y \) represent any function whatever of the variable quantity \( x \); then if \( x \) be increased by any difference \( \Delta x \), the value \( Y \), that is \( Y + \Delta Y \), becomes (adopting the differential notation)
\[ Y + \Delta Y = Y + \Delta x \frac{dY}{dx} + \frac{\Delta x^{2}}{1 \cdot 2} \frac{d^{2}Y}{dx^{2}} + \frac{\Delta x^{3}}{1 \cdot 2 \cdot 3} \frac{d^{3}Y}{dx^{3}} + \text{&c.} \]

Where \( \Delta x \) is negative, the terms of the above series must be taken plus and minus alternately; and it will therefore be more generally expressed by
\[ \pm \Delta Y = \pm \Delta x \frac{dY}{dx} + \pm \frac{\Delta x^{2}}{1 \cdot 2} \frac{d^{2}Y}{dx^{2}} + \pm \frac{\Delta x^{3}}{1 \cdot 2 \cdot 3} \frac{d^{3}Y}{dx^{3}} + \text{&c.} \]

In order then to find the increment of any function of a variable quantity, we must take the successive order of its derivatives, by which means all the fluxional parts in both the numerator and denominator will disappear; and we shall have the value of \( \Delta Y \) expressed in terms of \( x \) and \( \Delta x \); and this expression will always be finite, unless the function be transcendental.

Let us propose the function \( Y = a x + b x^{2} + x^{3} \) to find the value of \( Y \), when \( x \) becomes \( x + \Delta x \).

Now these values being substituted in the general series, we shall have for the increment of \( Y \),
\[ \Delta Y = \Delta x \left( a + 2 b x + 3 x^{2} \right) + \Delta x^{2} \left( b + 3 x \right) + \Delta x^{3} \]
Again, given \( Y = a x + b x^{2} - c x + x^{4} \), to find the increment of \( Y \).

\[ \Delta Y = \Delta x \left( a + 2 b x - 3 x^{2} + 4 x^{4} \right) + \Delta x^{2} \left( b - 3 x + 6 x^{2} \right) \]

Whence making these substitutions in the general theorem, we have
\[ \Delta Y = \left\{ \Delta x \left( a + 2 b x - 3 x^{2} + 4 x^{4} \right) + \Delta x^{2} \left( b - 3 x + 6 x^{2} \right) \right\} \]

These examples will explain the method of applying the theorem to any case that may arise, it being as universal in its application in the theory of increments, or differences; as the binomial theorem is in the expansion of roots and powers; but, like the latter, it was left by its author without
demonstration: it has, however, received many since from several able mathematicians, though there is not one of them perhaps that is quite so satisfactory as might be wished.

Maeurin’s rules upon the fluxional calculus, which it would be desirable not to introduce, if it could be obtained from more evident and obvious principles. Another demonstration of this theorem, and which is considered the most satisfactory of any that has yet appeared, is given by l’Huilier of Geneva, in his work entitled “Principiorum calculi diff. et integ. expositio elementaris,” in 4to. published in 1795.

INCROACHMENT, in Law. See ACCROCHING.

INCRUSTATION, the lining or coating of a wall, either with glossy stones, fulcic, marble, pottery, or flucro-work; and that either equably, or in panels and compartments.

INCRUSTATION, in Natural History, is one of the modes in which organic remains are preserved in the earth: the petrifying or incrusting matter, forming a thin coat or crust around the extraneous fossil, that its external form is nearly preserved on the flinty incrustation. Mr. William Martin classifies these among the artificial genera of reliqua, and observes, “Outlines,” p. 177, note, that “the common calcareous incrustations of our rivers, &c. have been ranked as petrifications; but, with more propriety, may be considered as incipient matrices.” If the coat of mineral matter be too thick to exhibit externally the exact figure of the fossil which it covers, such are called by this author sub-incrustations, matrices, of which ironstone nodules including leaves of plants, &c. are well-known examples. The petrifying springs of Derbyshire, (for a list of which, see Mr. Carey’s Report on that county, vol. i.) and other calcareous districts, are well known for the curious and whimsical incrustations which are there in a short time produced.

INCRUSTED, or INCRUSTED COLUMN. See Incrustated Column.

INCUBATION, in Comparative Anatomy, is the term applied to the conduct of most birds in rearing or sitting upon their eggs, in order to communicate to them the necessary degree of warmth for the excitement of their internal parts, and the development of the fetus.

The phenomena produced by incubation are so interesting,
INCUBATION.

In account of their exhibiting in a palpable manner the progress of fetal existence, that they have been studied by almost every respectable physiologist. Writings have been left upon this subject by Aristotle, Hippocrates, Fabricius ab Aquapendente, Aldrovandus, Coper, Velling, Harvey, Langley, Schrader, Theod. Alz, Stenon, Needham, Malpighi, Maitre Jan, Haller, Hunter, Monroe, &c., besides some later observations by Blumenbach, Leveille, and other continental anatomists. Notwithstanding the labours of so many eminent men, some of the most important points in the history of incubation remain still undetermined.

The best treatises are those of Malpighi, Maitre Jan, and Haller, but even in these authors there are many errors to correct, and, except some detached figures that have been published to illustrate particular parts of this subject, we do not possess any tolerably good plates.

The deficiency and doubts that still remain, with respect to several parts of the history of incubation, prove how difficult it is to investigate the subject.

The membranes of the egg, and the organs of the chick, are in general so tender, that they do not admit of being easily or satisfactorily examined; and when prepared by immersion in spirits, acids, or other astrigent liquors, their natural appearances and connections are much obscured.

The progress in the growth of the membranes is found to be in many circumstances unlike what would be expected, and what it appears to be; and the attachments of the membranes to each other are extremely intricate and perplexing. This part of the anatomy of the incubated egg, therefore, principally requires improvement. In the following article we have endeavoured to supply, by our own observations, what was deficient in the history of incubation, but, we must confess, not with as much success as we could wish; there are several anatomical points upon which we are obliged to speak doubtfully, and we have not been able to satisfy ourselves respecting the uses attributed to some of the parts of the incubated egg, although we believe others will be found to be elucidated by the experiments we have made, and which are here related.

Most writers upon incubation, appear to us to have paid too much regard to the dates or periods at which they have observed the different events of incubation to occur. Much exactness with respect to dates is not of material consequence, and if it were, it is not practicable, for the progress of incubation depends so much upon climate, season, and the diligence of the parent, with many accidental circumstances, that hardly any two eggs agree precisely in their rate of growth, at any given period of incubation; we are not, therefore, to wonder at the difference amongst writers upon this subject with respect to chronology.

The proper heat for the hatching of hens' eggs is 104° of Fahrenheit, to which degree the surface of the body of the hen will raise the thermometer when she sits upon her eggs. In those birds that do not sit constantly, but tryst to the heat of the sun, the temperature of the eggs is probably below 100 degrees.

The full period of incubation by the hen, in this country, is well known to be 21 days. In warmer climates it is said to be a day or two less. The periods of incubation vary much in different species of birds: we introduce the following table, which has been compiled from different authors by Count Morozzo, in a letter from him to Lacépède, to shew the periods of incubation compared with those of the life of certain birds.

</table>

Crane and heron, as well as ostrich, hatch their eggs chiefly by the heat of the sun. Journ. de Physique Ventris, an. 10.

The usual mode of examining the progress of incubation, is to gently fracture the shell, and pick it carefully off in pieces with a pair of forceps. This should be done at the large end, as it is there the changes of incubation commence, and at all periods it will be found the most convenient place for breaking the shell, on account of the air-cell being interposed between it and the fluids of the egg. For particular purposes other modes of preparation must be employed. If it be our object to study the formation of the membranes, these must be separated from the humours, and after being cleaned by being passed through several waters, they are to be floated in weak spirits over a blue paper, or some other dark coloured substance. The strongest spirits, distilled vinegar, or a solution of alum, are necessary to render the organs of the fetus sufficiently plain for examination. The only use of boiling the contents of the eggs, is to shew the relative situation and magnitude of different parts.

In many observations, it is necessary to magnify by glassess the subjects of investigation; we would however recommend, that the light be only alighted by the single lens. When a higher power is employed it is liable to deceive.

After the egg has been sit upon for 12 hours, the quantity of air contained between the two layers of the membrane that lines the shell, is found to be a little increased.

No evident change is yet to be observed with respect to the bulk or consistence of the humours.

The white spot on the superior surface of the yolk, which contains the vitellum of the ancient anatomists, or the follicle of Haller, is now somewhat enlarged. There appears, in its interior, a small white body of an elongated and indistinct figure, which is surrounded by a line of a deep yellow or greenish colour. If this part of the membrane be removed and examined with a lens on the under surface, after being a short time immersed in spirits or vinegar, it will be discovered that the elongated white body is the rudiment of the fetus, which is already included in the amnion. The greenish appearance would seem to depend partly upon the existence of the amnion, and partly upon a depression on the substance
INCUBATION.

substance of the yolk, which is the origin of the bed of the chick. We cannot determine whether this depression contains a fluid or not. The part of the white spot which surrounds the depression that contains the fætus, is occasioned by the substance of the yolk having a peculiar organisation. At that point it is white, and has a curdy or coagulated appearance. Malpighi believed that he could discern the fætus as early as the sixth hour, and even before the egg had been fat upon; but most other observers have not been able to see any appearance, which they thought deserved to be considered as the fætus, before the 12th hour. It is, however, probable, that the embryo of the chick is formed after impregnation, although from its extreme tenuity and obscurity of figure, it cannot be detected until it is a little developed by incubation.

The amnion appears to be coeval with the chick. The rings or circles (halomes) that surround the cicatricium, are now somewhat enlarged, and more defined in their outline. They also assume a little of an oval figure. The external circle is undulating, or forms waves, through which the colour of the yolk appears. Maitre Jan describes four halomes, Haller only three; we have found the number vary. This appearance of circles is not easily accounted for. We have thought it arose from the separation of the membranes into their proper layers.

First Day, or after 24 Hours.—Upon opening an egg at this period, it is perceived that the space formed for the admission of air between the layers of the external membrane is a little more enlarged.

The external vesicle appears scarcely diminished; it is fluid and transparent, and runs out at the opening if the egg be inclined to that side.

The yolk is found to float higher in the principal white than before incubation, and appears a little flattened upon the upper surface.

The halomes are more extended, particularly the outer one. The internal one has acquired a little of a heart-shape, and is surrounded by a more defined line of a greenish colour, which is the first appearance of the outline of the venous area. There are also some faint and imperfect traces of green vessels, or rather elongated points, to be detected in different parts of the space enclosed by this line, which are the rudiments of the vesicles that are to compose the area.

The amnion is well formed, and composed of two circles which unite two straight lines, resembling the figure of a pedestal.

The fætus has a more determined figure; it is larger at both extremities than in the middle; but the end which corresponds to its head is larger than the other, and forms an oval mass. Maitre Jan states that if an egg, after being under the hen for 24 hours, be put into water, it will float with the small end downwards, which is a proof that a part of its fluids is lost, and replaced by the admission of air into the air-cell at the great end of the egg.

After 36 hours we have found the greenish line, already mentioned, to have still more plainly the appearance of a vesicle: it encompasses a larger area, and assumes more completely the contour of a heart. The greenish points also are now continued into each, and put on the appearance of vesicles, which are more numerous next the circumference of the area, but present no evident connection with the fætus. Some of these vesicles are seen to contain red blood, more particularly those which pass between the head of the chick and the upper part of the vesicle in shape of a heart. In some eggs, at this period, we have found these red vesicles approach the chick but not join it: in others they were collected by a single branch, which passed behind the head of the chick. This branch Leveille has called the meningo-cardine vein, and others the vena ascendent. There is considerable variety with respect to the period at which red vesicles begin to appear. We have seen them before the 36th hour, but oftener, perhaps, not before the 45th, or even later. Authors differ extremely on this point. Malpighi represents the commencement of the vessels at the 30th hour (Append. figs. 18 and 19.), and even delineates them at the 12th hour. (Epist. 1, fig. 5.) Stenon observed them at the 71st hour; Velling at the 43rd, but saw the points at the 42d hour. Alkorandus found them the third day. Maitre Jan described the first appearance of vessels at the 38th hour, and represented them distinctly formed, and carrying red blood at the 44th hour. (P. 53 and 58, and fig. 10.) Haller noticed some reddish points at the 36th hour, and to the 48th, but did not perceive perfect red vessels before the end of the third day. Memoire sur la Formation du Cœur dans le Poulet, &c. p. 23.

These contradictory accounts depend in some degree upon their authors not having sufficiently attended to the existence of colourless points and vesicles before the formation of red blood.

Haller states, that he observed, at 31 1/2 hours, the head of the fætus to have the appearance of being split, which he attributed to the vessels of the brain having a small degree of opacity, whilst the membranes composing the cranium were so transparent as to be seen through. Malpighi also represented this appearance. We have not noticed it.

Haller likewise describes the head of the chick to begin to form at a right angle with the tail at the 45th hour.

After 48 hours, or two days, the external halomes occupy a considerable extent upon the surface of the yolk, and become fainter in their appearance.

The liquid or external vesicle is somewhat diminished.

The principal vesicle begins to subside to the bottom and small end of the egg.

The yolk-bag appears flatter upon the upper surface, and its contents are a little more fluid than before incubation.

The chalaza, which were originally situated at the two poles of the yolk-bag, are now found somewhat below them, and consequently rather nearer to each other.

The vascula area (figure erinacea of Haller) is now in general completely formed with colourless and red vessels. The number of the latter is very variable. We have found them at this period in very different flates of advancement, but always discoverable by the greenish vessels which precede them. The area has very perfectly the figure of a heart, except that the part corresponding to the bases is formed by the outline of the two fludes being considerably curved before their junction in the middle, at which place the outline of the area forms a pointed projection downwards, which nearly reaches to the head of the fætus. It is this part of the area which receives the branches of the meningo-cardine vein already mentioned. The vesicles are now also connected with the chick by means of their principal trunks.

The pulsation of the heart is evident at this period, and even in some hours before, according to Maitre Jan's observations. It appears to be produced by the alternate contraction and dilatation of two or sometimes three vessels. This appearance is the punctum saliens of the older anatomists, and has been commonly, but erroneously, reputed the first action of life.

One mode of preparing eggs for examination is to remove a portion of the membranes including the fætus and vascula figure around it, and having washed off any pieces of the yolk that may adhere to them, immerse them for a short time in strong spirits or diluted vinegar, by which means the
The pearly substance that composes the chick is rendered opaque and visible, and the structure of the membranes more distinguishable.

If this flap be taken with the egg at the present period, or even before it, a fine glossy transparent membrane will be found upon the external surface of the yolk-bag, which is very readily detached, leaving the fatus and the vascuar area beneath. This membrane, we conceive, is the same which, strengthened by the vessel umbilicus, becomes the one which at last entirely envelopes the contents of the incubated egg.

The membrane, containing the vascuar area at the second day, may be distinguished to be composed of two layers; the external is smooth, and receives the vessels; the internal is a little thickened and fpongy. The remaining portion of the yolk-bag is not separable into different layers. From hence it would appear that the division into layers is the consequence of vessels being distributed to the membrane.

The annia is now found a little larger, and the transparent fluid with which it is filled in greater quantity. The superior circle also, or that which includes the head of the chick, is larger than the lower.

The factus has altered its shape a little. The head has acquired something the figure of the ace of clubs, the anterior prominence of which corresponds to the nose and mouth; and the two other projections are the vessels containing the brain in a very soft pellucid plate. Maitre Jan states that the eyes also are visible at this period. (P. 77.) Haller did not see the eyes before the 5th hour, at which time they had not any colour, and were merely distinguishable from the other parts of the head, by their prominences and situation. Section 13. Second Memoir.

The heart, before the chick is removed from the membranes, and rendered opaque by immersion in spirits, appears to be situated on the outside of the body, and the pulsating points seem unconnected with each other; but upon a close examination it is seen that the heart is not uncovered, although, from its projection, and the natural transparency of the parietes of the shell, it had every appearance of being so. The heart altogether resembles a horse-shoe in form, or a portion of a circle, of which the convexity is turned forwards, and the limbs backwards, one being directed to the upper part of the shell, and the other to the lower. The heart at this time consists of an auricular canal, a ventricle, and a bulbous enlargement belonging to the aorta. The two left are the falient points, and when the chick is so far advanced that the auricle is formed and pulsates, which is sometimes the case at the 48th hour, there are three falient points to be seen. Maitre Jan describes four falient points, and supposes that they are the rudiments of the two ventricles and two auricles of the heart. At other times, he says he has sometimes seen but three pulsating points, or perhaps, only one. Haller, who paid particular attention to the development of the heart of the chick, contradicts Maitre Jan’s account. At the 48th hour he could discover but two falient points; at the 5th hour he saw three, but on no occasion more than that number. He supposes that when there are two falient points the auricle does not pulsate, and when only one the bulb of the aorta is without motion. Memoire 1. p. 53.

The End of the third Day, or Seventy-two Hours.—This is a very important period in the history of incubation.

The separation of the layers of the external membranes for the admission of air continues with increas. The balloon can be scarcely be discovered. The yolk is more extended, and the white continues to gravitate to the lower parts of the egg.

The vascuar area is now generally found to be perfused with red vessels. The contour of the area is more extensive, particularly in the transverse direction. The diameter being now about an inch and a quarter, it has therefore left the shape of a heart; the pulsation of the three vessels, and distribution of the blood-vessels, are very clearly seen through the transparent membrane which covers them.

The annia begins to assume the figure that it is afterwards to possess. The two circles which encompass the head and the tail of the factus become enlarged, principally on the fore-part, or the side next the right-hand of the observer; but the factus is a little contracted on the same side opposite to the umbilicus of the chick, thus tending, in a degree, to give the annia the form of a kidney.

The factus has a curved position forwards, and its body appears larger in proportion to its head, than on the preceding day.

We have forbore to describe particularly the heart and blood-vessels of the chick and area until the present period, when they are more distinctly seen.

In order to discern perfectly these parts, the membrane including the factus and vascuar area should be removed from the yolk-bag, floated in clear water, and examined with a lens. The vascuar area contains four or five principal branches, which ramify upon the membrane, and produce a very close and intricate net-work towards the circumference of the area. These branches appear when the chick is in the natural situation, to be in many distinct trunks. Two of them are seen to come from the sides of the chick, a third from under the tail, and one, or sometimes two, branches from under the head of the chick. The two first are commonly called the umbilical vesseles, as they come out of the chick at the umbilicus: they would, perhaps, with more propriety, be called menteric vessels, as we have much reason for supposing that they are the same which are so plainly branches of the menteric vein in the latter stages of incubation. At the present period they terminate in the vein which corresponds to the vena cava and vena portae. Both the branches which emerge from under the tail and head of the factus are found to be given off from the umbilical veins just outside the body of the chick. This origin is concealed from view until the lower surface of the membranes and chick are carefully examined. Several anatomists seem to have published errors with respect to the inferior or ascending vessels of the vascuar area. They are often described as distinct branches, which are lost on each side of the notch or chink, which has been already mentioned to exit during the first days of incubation in the contour of the vascuar area. They were, therefore, sometimes supposed to be separate vessels. Langley represented them to be at first distinct branches, which united at the 61st hour; but Malpighi, Maitre Jan, Haller, &c. state that these two branches always unite into one behind the head of the factus when they do not fooner. Malpighi, Maitre Jan, and others, however, represent this vessel as coming from the heart: Maitre Jan even supposes it may be the ascending aorta. Our observations, nevertheless, lead us to agree with Haller respecting this vessel, who states it to be a branch of the umbilical vein. It is this vessel to which Leveille has given, as we conceive improperly, the name of meningo-cardiac vein.

The vessel which forms the contour of the vascuar area has been commonly described as a single vein; Malpighi, however, represented it as being composed of an intertexture, or plexus of the ultimate branches of the veins which are spread over the vascuar figure. There appears to be some foundation
INCUBATION.

The ventricle is a single cavity during the first four or five days of incubation; or, rather, the left ventricle exists only at that period. When the two ventricles make their appearance, it is in consequence of the right ventricle being added to that which had already been formed. The left, or single ventricle, arises out of the ring-shaped vessel, which constitutes the first appearance of the heart, and probably is the first point which pulsates. It is an oval vehicle, with transparent parietes in the commencement; but it soon acquires more of a conic figure, with a pointed apex, and greater thickness and muscular power—it is, however, very nearly oval at the present period.

The aorta, as already mentioned, is coeval with the first appearance of the heart, and exists before the formation of the auricle. It is then very long, and its arch is much greater in proportion to the length than in the succeeding periods of incubation, as in the adult bird. It makes an extensive curve backwards, in order to enter the heart, immediately under the head, and compiles a considerable part of the ring which represents the heart. On the left side this artery appears as if cut off by a line which terminates the heart. The auricle, when formed, is surrounded by the arch of the aorta, which is superior, and more forwards.

A few hours after, the part of the aorta which appears to be outside the chest, becomes shorter, and some inequality is perceived in its diameter. The part of the aorta, which immediately arises from the ventricle, is more contracted than any other; and the wave of blood which is seen to pass through it is very slender. Haller gives the name of the first (l. d. seruit) to this part.

The next part of the aorta is a dilatation, to which Haller has given the name of the bulb of the aorta. This portion of the vessel, as already mentioned, constitutes one of the pulsating points, and is seen to beat even before the auricle. The bulb of the aorta has been mistaken by Malpighi for the left ventricle, which, considering its lively and early pulsation, was not unnatural. He likewise was led by the same error to take the single ventricle, which is actually the left for the right, or pulmonary ventricle of the heart.

The third portion of the aorta is cylindrical; its direction is changed, and it represents with the preceding a point or hook. It is smaller than the bulb, but larger than the branches which go to produce the dorsal aorta. Haller calls this part the bris de Paez.

Soon after the present period, and before the end of the fourth day, there are branches seen to arise from the bris of the aorta, in order to form the dorsal portion of that vessel.

The three parts which compose the heart of the foidal chick pulsate so rapidly, when examined immediately after the egg is opened, that the eye cannot follow them; but in proportion as the chick becomes cold and feeble, the intervals between the pulsations become longer. The pulsations may be thus gradually reduced to fifteen, to ten, to five, or to two, or at last even to but one in a minute; nevertheless, the celerity with which each contraction is performed is scarcely diminished.

When the pulsations of the heart are rendered sufficiently slow to be counted, they are perceived to follow each other in a regular succession. The auricle always beats the first of the three vessels. In its systole the point descends, and the sides are approximated; it scarcely ever appears to expel

...
entirely the drop of blood it contains, and therefore it retains almost constantly a degree of red colour.

The wave of blood which proceeds from the auricle appears to vanish, as one cannot see its course into the ventricle unless the heart be held obliquely from above; then the blood will be seen to pass along through the auricular canal, which, as before observed, is concealed by the ventricle.

The contraction of the ventricle succcedes to that of the auricle: it approximates its siphes, and becomes narrower and shorter. The ventricle frequently becomes quite pale during its contraction, owing to the entire expulsion of its contained blood.

After the contraction of the ventricle follows that of the bulb of the aorta, which pulsates as quickly and perfectly as the ventricle itself. It empties itself completely at each contraction, and therefore appears quite pale at these moments.

The pulfatory movement terminates at the origin of the three vessels which go to form the dorso aorta, and this vessel declines very much in bulk opposite to the umbilicus; the branches which go to supply the inferior parts of the heart being very insignificant.

The different membranes become more distinct at the end of the third day than they were before. At this period also the first appearance is seen of that remarkable membrane, which is called by some allantois, and by others vesícula umbilicalis.

When a portion of the membrane is removed containing the vascular area and the chick, and washed and spread out in clear water, it is found to contain four layers. The first is thin, transparent, and shining, and resembles that which forms the yolk-bag before incubation. It very readily separates from the other layers. The second is also transparent, and still thinner than the first, but is more adherent to those underneath it. The third is the membrane in which the blood-vessels are distributed that form the vascular area; and the fourth is the internal or spongy membrane of the yolk-bag. The third membrane seems to grow with the vascular area, by which it appears to be bounded; the internal membrane of the yolk-bag is at this period a little spongy or villous at every part, but much more so under the vascular area than at any other place.

The chick included in the amnion is situated between the two first and two half of these membranes.

The vesícula umbilicalis, when first discovered, makes its appearance as a small spherical transparent bag, which projects out of the opening into the abdominal cavity of the chick, that is left by the reflection of the amnions inwards. At this period, and for some time afterwards, it is distended by a clear fluid.

The end of the fourth day, or ninety-six hours, the appearance of balance is in general no longer to be perceived.

The vascular area is so much extended that it occupies near the half of the superficies of the yolk: the outline has no remains of the heart shape, but has assumed an oval figure, the greatest diameter of which is in the transverse direction of the chick.

The amnion continues to enlarge at the great end of the egg.

The external or liquid white appears to be all consumed.

The principal white is chiefly to be found in the lower parts of the egg, and when poured out is seen to adhere a little to the internal layer of the membrane of the shell at the small end of the egg.

The yolk-bag is still flatter in its figure than before, and its contents are evidently more fluid than they were previous to incubation.

The chalaza continue to approach each other below the poles of the yolk-bag.

The annulus is considerably increased, contains more fluid, and forms a deeper bed for the chick on the membrane of the yolk-bag.

The vesícula umbilicalis has made a rapid progress since the end of the third day. It now projects considerably beyond the fœtus. It appears flatter, and less full of fluid than at first; and at this period, by examination with a magnifying glass, a vessel may be seen to ramify upon it.

Upon opening the yolk-bag, and washing off the yolk, the spongy coat is seen to be elevated in the course of the blood-vessels of the vascular area: this is the first appearance of the valvular structure of the yolk-bag, of which more hereafter.

The fœtus is still more curved in its form, the prominence corresponding to the bill being bent down upon the breast. The rudiments of the upper extremities are apparent: they are two white buds or short projections. The lower limbs are likewise produced, but without any more form. The cerebral vessels are more eminent; and, when opened, their contents are found, though still pellucid, to be mixed with some whitish fibres, which form opaque clouds, and are the commencement of the brain.

Haller found the heart beginning to undergo some changes about this period. The auricles, when viewed in the usual manner on the right side of the fœtus, is seen to contain two oeciemia. The most posterior of these, or the one nearest the vertebras, is the largest, and terminates the auricle. The anterior oeciemia is smaller, and divides the auricle as a kind of septum. This is the first appearance of the distinction of the auricles into two. That which is to be called the left is the larger, and projects over the right posteriorly. The latter, which is the smaller, has a similar termination, which is comprised in the breadth of the left auricle. The vena cava and the auricular canal are infiltrated in the interval of the two auricles.

The distinction of two auricles is likewise to be seen on viewing the heart on the left side. That which is to become the left is oval, wider than the other, and pessies beyond the auricular canal.

At the end of the fourth day, or soon afterwards, the two auricles become more separate from the vena cava and the auricular canal. They project over these vessels, and are elevated from the two sides of the base of the heart into a pointed top. The whole of the auricle, or the united rever-voir of the right and left auricles, appears then as a fasci with two pointed horns, each of these pointed tops has a separate drop of blood. The border of both the auricles appears at this time noted. Mem. 2d sur la Formation du Cœur dans le Poulet, &c. par M. de Haller, p. 70.

The auricular canals, towards the end of the fourth day, paffes more in a direction from below downwards than formerly.

According to Maitre Jan, the rudiments of the lungs are visible at this period; but Haller afferts they do not appear before the 13th hour. The former author describes at this time, in the neighbourhood of the heart, little reddish clouds, apparently of a spongy nature, which appear more or less red, alternately, as the heart moves, and which remain of an uniform colour when the heart has ceased to beat. Maitre Jan admits that the pulmonary vessels cannot yet be discerned, but supposes from the above effect of the heart's motion, that they do exist, although they are not visible. (Observat. sur la Formation du Poulet, par Maitre Jan, p. 115 and 122.)—Not having examined this point, we cannot decide between these authorities, but we should judge it improbable that the pulmonary
pulmonary vessels could regularly transmit blood to the lungs, and yet not be visible.

Both Haller and Maitre Jan agree that the liver makes its appearance towards the end of the fourth day. It is seen as a vivid cloud of a reddish yellow colour, situated between the umbilical vessels and the descending aorta. It is rendered more visible and opaque by moistening it with distilled vinegar.

The eye of the foetus appears black, the chorionic coat being formed; and the superior part of the eye chiefly presenting to view, the pupil is situated in the anterior portion of the eye.

The end of the fifth day, or 120 hours, the vesicular area is so much extended as to cover generally more than half the superficies of the yolk-bag. The trunks of the vessels are proportionally increased in size, but the branches near the circumference are not so much advanced. Some additional vessels are seen to proceed from the umbilicus of the chick towards the left side of the area. These appear to the vesicular umbilicalis, as will be better understood hereafter. All the blood-vessels of the area, which were in the first days of incubation of a fine fuscus, are now commonly found of a dull red colour.

The aorta continues to increase in magnitude, and contains so much fluid, that the chick appears to be surrounded by a green liquor.

The chills, especially when excited by a little external heat, can be perceived to move its limbs.

When the external membrane is removed, the vesicular umbilicalis is found to be considerably larger than it was the preceding day. It is likewise perceived to have contracted some adhesion with the external membrane, which however is undone by a slight force, particularly after the membranes have been a short time immersed in vinegar or spirits.

The branches of blood-vessels which are distributed upon the vesicle, belong to a trunk that comes out through the opening of the abdomen at the umbilicus of the chick. The vesicle is connected with the foetus by means of a neck, or contracted part, which is likewise received into the abdomen at the umbilicus.

Maitre Jan describes at this period a number of fine branches of blood-vessels upon the skin of the chick: we have not, however, observed these so early.

When the internal surface of the yolk bag is examined, it is found that the eminences upon it, already mentioned, have assumed the form of vessels ramifying from the centre, where the chick is situated, to the circumference of the vesicular area. This appearance has been mistaken by many of the older anatomists for real vessels distributed upon the inner surface of the yolk-bag, and were supposed by some to be designed to convey the yolk to the chick. When the appearance of the yellow vessels of the yolk-bag is first presented, it is very difficult to detect the real occurrence of it, but as it advances, it becomes plain that the effect is produced by the inflection or doubling of the inner membrane of the yolk-bag, in the course of the real blood-vessels of the bag. By a careful examination of the matter with a lens, even at this period, we have always perceived the appearance of yellow vessels to arise from the blood-vessels running in grooves, or reflexions of the inner membrane. When the two tunics of the bag are separated, the blood-vessels are found to belong to the external, upon the inner side of which they appear as eminent lines; while upon the external side of the inner coat there are corresponding grooves or impressions.

The heart at this period begins to undergo the changes by which it approximates in structure the heart of the adult bird. It becomes perpendicular, or in the line of the foetus, from being placed in a transverse direction. The point is recurved between the two lobes of the liver.

The auricles become more distinct, and the interval between them white.

The auricular canal is considerably shortened.

The second or right venetile begins to be formed before the termination of the fifth day. It appears as a little sac under the bulb of the aorta. It is much shorter than the original venetile, above which it is placed. Its figure is oval, and it has a red colour. In a short time the new venetile is seen in its proper situation, that is, on the right side of the heart. Haller states that he found it placed on the right as early as the 117th hour. There are then two distinct drops of blood in this part of the heart of the foetus, and a white line is perceived between them.

The aorta arises from the left venetile. The branches, which are furnished in order to form the dorsal aorta, have an inclination downwards, and unite in an acute angle. At this period also the bulb of the aorta begins to diminish, and to retire into the flesh of the heart.

The liver is more distinct than at the end of the preceding day; it is divided into lobes, and is of a pale or yellowish red colour. Its vessels receive blood.

Haller first perceived the rectum at this period, although the ileum and other intestines were not yet formed. It appears in the shape of a trident, the lateral procencies of which are produced by the rudiments of the two coeca.

The End of the 6th Day, or 144 Hours.—Eggs placed so long under the hen are considerably diminished in weight, which is even perceivable on taking them into the hand. The shell begins to appear more dry, and opaque coloured, and is more fragile than before incubation.

The diminution of weight depends upon the enlargement of the air-cell, which now extends over a considerable part of the great end of the egg. Maitre Jan has taken some pains to prove that the air contained in the egg is not derived from the atmosphere. He supposed that the fluids filtered through the inner layer of the membrane which lines the shell, and that by the action of heat, they were volatilized or converted into air. This opinion is not only improbable, but refuted by particular facts. On opening the air-cell, we do not find its surface to possess any moisture; that layer of the membrane which lies next the humours of the egg, although less thick, is smoother, denser, and less porous than the layer immediately in contact with the shell, and therefore less fitted to admit the trranspiration of either fluids or air. The chemical properties of the gaseous contents of the air-cell seem to put it beyond all doubt that the atmospheric air passes into the egg. (See the article Egg.) We shall only add, that when we have varnished the external surface of the shell the air-cell no longer increased in size.

Upon opening an egg at this period of incubation, it is not unusual for the chick turned upon its back, instead of lying as before, upon its left side. This circumstance seems to depend upon the amnion having too much increased in size so that the fetus may roll round within it.

The membranes around the chick begin to acquire more strength and firmness, which is the consequence of the vesicular umbilicalis becoming more closely and extensively united to the external membrane.

The vesicular is now found to be very much increased in magnitude, and to cover a considerable portion of the yolk-bag. When the membranes surrounding it are cut open, and the vesicle exposed, its neck or peduncle may be traced as a fine transparent tube to the rectum, by a careful examination, particularly if the parts have been rendered opaque, by

D being
being a short time steeped in vinegar or strong spirits. Where it opens into the rectum it is diluted.

The connection that exists between the veicula umbilicalis, and the end of the rectum, by means of a tube analogous to the urachus, has induced Haller and others to consider this bag as the reservoir of urine.

We shall find in the subseuent periods of incubation, that the veicula umbilicalis performs very important and other functions than those of a reservoir of urine, in which, nevertheless, it does not perhaps materially differ from the allantois of quadrupeds.

It is necessary here to notice an error which two of the most noted writers upon the subject of incubation have fallen into with respect to the veicula umbilicalis. Both Malpighi and Maitre Jan supposed it to be a part afterwards becoming the stomach of the chick. This mistake appears to have been occasioned by the veicula becoming, as we shall afterwards describe, so much extended as to lose the figure of a bag, and from being united to other membranes, only to be distinguished with difficulty. Its being visible nearly three days before the stomach acquired even then a much greater size than that which possibly, and differing essentially in figure and texture, should however have prevented these two parts from being confounded with each other.

The chick, on the sixth day, has assumed a good deal of its natural form. The extremities are so much developed, that the divisions of these members are visible. The wings have their bent figure, and the legs are added to the thighs.

This period is likewise marked by the first appearance of most of the important organs of the body, besides some changes in those already formed.

Haller states that he could discern the pericardium at this time.

The two auricles are still more distinct than at the end of the preceding day.

The aortic canal, which had before begun to retire within the flesh of the heart, is now not visible.

The ventricles are better formed, and broad at their bases.

The bulb, the bronchi, and the heart of the aorta, which give origin, in the early periods, to the principal arterial trunk, are in general not apparent at the end of the sixth day. This vessel is seen to come forth from the base of the heart itself.

The pulmonary artery was seen by Haller first, about the middle of the sixth day. This vessel is finer and opaque than the aorta; it arises from the left side of the base of the heart with a little bulb. It is usually of 1/40 of an inch in diameter than the aorta. Almost at its exit from the heart it divides into two branches.

The branch on the left side forms an arch, in order to reach the long of that side in passing behind the bronchi; it joins the aorta, towards the third vertebra of the back. The branch of the pulmonary artery, which is inserted into the dorsal aorta, is longer than the dorsal arterioles of quadrupeds, to which it is analogous. It should, however, receive the name of left, as birds have a smaller arterial duct upon the right side. The left lung receives a considerable branch from the ductus while on its way to join the aorta.

The other principal branch of the pulmonary artery passes transversely to the right side, under the aorta; to which it adheres. It supplies the artery to the right lung, and descends behind the bronchi, in order to open into the aorta, higher than the left branch already mentioned. The right arterial duct is much smaller than the left.

These arterial ducts are two of the three branches, which have been described in the preceding days as contributing to form the dorsal aorta. The right duct is later in appearing than the other, and, indeed, when the aorta is first discovered, it is observed to be only formed by two branches.

About this period the lungs have sufficient confidence to be visible. When they are rendered opaque by vinegar, they are found to be not so small, that they might not have been seen some time before if their transparency had permitted it. Their figure is cylindrical if they are attached posteriorly to the back, and connected with the two sides of the heart.

The liver has acquired more of its future form than it had the preceding day.

The femoral is apparent at this time. It is very thin and tender, and resembles a good deal the form of the human femoral; its orifices are, however, nearer to each other. The femoral is received between the lobes of the liver.

The fluid contained in the vesicle of the chick has acquired by this time some confidence.

The kidneys are discovered during this day as long reddish granulated lines or traces in the skin.

The End of the 7th Day, or 108 Hours.—Upon opening an egg at this period, we perceive that the changes already mentioned in the form, confidence, and situation of the humors have continued to increase.

The skin is more fluid, more forced out, and apparently of a larger size than before. Haller nevertheless found it at this date to possess its normal weight.

The blood-vessels which are distributed upon the membranes, and which were in the first days, as before mentioned, of a brilliant scarlet, are now in most eggs found to be all of the purple or venous color. The uniformity of color makes it difficult to distinguish the arteries: they can indeed be only ascertained by dissecting the membranes and pursuing the course of the vessels into the body of the chick.

The aorta is still larger at this than any previous period; it presents its kidney form, and its color is transparent, and cannot be rendered opaque, or congealed by vinegar or spirits.

The utricular umbilicalis goes on increasing in size, and its vessels acquire strength.

The chick has its members more developed. The feet are added to the posterior extremities, and even the eye can be discerned. Observation has commenced. Haller states that he prepared the uterus and thorax at the 14th hour. The two umbilical vessels begin to form at the under part of the head, leaving an aperture between them, which is to be the mouth.

Haller at this period observed the first convolutions of the stomach, which were extremely tender as not to admit of being touched, although the rectum was apparent two days before.

The lungs now first make its appearance. Haller supposes that it could likewise discern the rectal canal and arteries.

The intermediate of the three vessels which arise from the heart to form the dorsal aorta, is, about this time, seen to furnish the two cardias; it is the same vessel which becomes the descending aorta, when the structure of the pulmonary artery is completed. Haller states that the pulsation of the aorta ceases after the 15th hour.

The eye of the fowl is considerably developed at the present period. The three humors exist; the vitreous is
INCUBATION.

extremely abundant, upon which depends the great bulk of the eyes of the chick about this time. The lent is small. The tis is formed, but is very transparent. The trunks of the opic nerves and retina are visible. The latter is transparent and palpitates, and seems to go as far as the lens. The radial black lines which form the corona ciliaris are seen through the retina, placed around the external part of the lens.

The End of the 8th Day, or 112 Hours.—The vascular area has increased so much by this time, that it very nearly covers all the surface of the yolk-bag, except what is in contact with the white. The bulbar veins of this, however, begin to dilate or disappear in some parts, particularly towards the circumference, although the trunks are larger than at any former period.

The blood-vessels belonging to the vesicula umbilicalis are considerably enlarged and extended, and are now seen to turn backwards, or be reflected upon themselves in the direction of the chick. The reflected portion of the vessels of the vesicula appears to be distributed to the superior half of the body only, or, as it were, in contact with the transparent membranes. This membrane, which was in the first period of incubation, as already mentioned, perfectly transparent, by its connection with the vesicula becomes vascular, and acquires strength, and contributes to form a complete sac, which envelopes in the latter days all the humours and the chick, as will be hereafter described.

The vesicula umbilicalis is found at the present period to have a considerable extent, according to our observations, much greater than has been represented by anatomists in general, who do not seem to have been acquainted with the uses of this bag in the later stages of incubation.

The chick is a very pale pink colour, or white slightly tinged with red, in consequence of the vascularity of the surface preparatory to the formation of the skin and feathers.

When the head of the chick is viewed posteriorly, it presents the appearances of four eminences, which are opaque white, and are joined to each other by transparent membranes. Maitre Jan considers them as the rudiments of the bones of the cranium in a cartilaginous state, and the transparent parts as corresponding to the future and fontanel. Haller speaks of these eminences as four lobes of the brain.

We conceive the account of Maitre Jan to be more correct.

The head being opened at this period by Maitre Jan, he finds that he had gained the muscles, the fasciae, and the capillaries of the brain, and that the substance of the cerebro and cedema was well formed, the convolutions even being apparent. This observation, according to our experience, is premature.

The structure of the eye is more perfect than before. The corneal zone, according to Haller, is as perfect at the present period as at any time afterwards. Its defect, then, however, is farther some days later.

The bill of the chick is cartilaginous. The animal occasionally opens it in the water of the annulus as if attempting to swallow.

The brain of the ftrix, which was covered by a thin membrane, that in the first days was so transparent, as to give rise to the mistake of the heart being outside the chick, has at present time some 9th upon it. About this period also the rudiments of the corneum and of the tarsus are discovered.

The first hair makes its first appearance towards the end of the eight day, at which period, and for a few days afterwards, it is very small and without color.

About this time the reflections of the inner tunic of the yolk-bag, which we have described at the end of the fifth day, as putting on the appearance of yellow vessels, acquire more decidedly the form of valves. They fill preserve the same situation and course, commencing under the bed of the feet, and extending outwards in a radiated manner to the circumference of the vascular area, where they terminate. They are made of a number of plate or folds which have a transverse direction, and which are more prominent or have deeper folds in proportion as the vascular bags approach the circumference of the circle. They form mere lines where they commence, and at the present period they are on every part of the yolk-bag much less marked and striking than they become towards the end of incubation.

The End of the 9th Day, or 126 Hours.—Maitre Jan mentions the appearance of some new parts at this period which we have not met with before. He describes the lidgel as forming a milky fluid, which he saw filling the canals. He described about this time the crop and the testa and was not only able to distinguish the principal divisions of the brain, but states that he could discern the cavities with the membranes they contained, and even the papillae choroides. He likewise saw upon the back of the brain the greater number of the nerves that arise there, more particularly the optic and auditory nerves, and found the spinal marrow to be split or composed of two parts at its origin. He dissected the nerves of the spinal marrow, which, although very small, he states to be much more firm than those which take their origin from the brain. Observ. sur la Formation de Poulet, p. 180.

The surface of the factus exhibits now a number of pores; these are principally situated upon the thigh, the back, the neck, and the wings, and are the apertures of the cells in which the feathers are formed.

The eyes are larger than the vessels of the brain; their form is not spherical, but flattened upon the anterior and posterior sides.

The skin is still thin and transparent; but there are seen through it and the transparent cornea five or six white points which form a circle. When the eye is opened carefully with a lancet, these points are found to be elongated, and to form little lines, or ciliary fibres, which at this period are white.

Maitre Jan states that the eyelids to be formed at this time, but to be so transparent as to be invisible, unless after preparation by a strong acid.

The eyelids are now so firm, that they can be examined without danger of breaking them.

The yolk, according to Maitre Jan, begins to form two lobes, a larger and a smaller; but we have not observed this change to take place before the 11th or 12th day.

Maitre Jan made the experiment of killing an egg at this period, after having laid it upon a plate of lead with its beak end downwards. When depoited in the shell, and the chick removed, the depression in which the annulus lay was fully explicable, and found to be very considerable. He then made a section of the egg in the vertical direction, dividing the depression of the yolk through the middle, when there appeared a round space about the eighth of an inch in diameter, filled with a whitish curly matter, and another space around this of a larger extent, containing a denser matter than the hull, and of a pulser yellow than the rest of the yolk. Maitre Jan, very erroneously in our opinion, supposes the white curly substance to be the intilines of the head and
duced to the yolk during the boiling of the egg. This appearance, we believe, arises from the same change of organization in the yolk being continued, which in the early periods of incubation produced the whitish appearance under and around the bed of the chick. The firm, pale yellow texture of the yolk which accompanies that just mentioned, Maitre Jan accounts for by supposing that the fluid parts of the yolk in the neighbourhood of the chick had passed into the amnios. There can be no doubt that different parts of the substance of the yolk are differently constituted, which difference is preferred notwithstanding the motions that eggs may experience; a fact that cannot perhaps be fully explained, but which proves that animal fluids have the same organization, which they can maintain as well as the solids. When the fluids change this composition, it is often by some vital action in themselves, instead of a fermentative process, or the mechanical operation of the solids upon them, as is commonly supposed.

In making the experiment of boiling eggs at this period, Maitre Jan did not find that the amnios was coagulated, although Haller stated that the liquid of the amnios is coagulable at the 19th hour.

The vascular structure upon the internal surface of the yolk-bag is more prominent, and when minutely examined, it is found to receive branches of the blood-vessels which are given off at right angles with the plane of the surface of the bag, and having penetrated towards the edge of each valve, there unite and form a single vessel, which runs within that edge. This structure is better seen a few days afterwards.

The End of the 10th Day, or 240 Hours.—The vascula umbilicales has now a very considerable extent, occupying the greater part of the vascular area, which lately spread over almost the whole of the yolk-bag. The portion of the bag that is applied to the white, is not at this date the 4th of the whole. The chalaza, therefore, are much nearer to each other than when we last mentioned them. The white is confined almost entirely to the lower part of the egg, and its mass continues daily to diminish, while, on the contrary, the bulk and quantity of the yolk appears to be increased.

The external membrane is firm and flexible where it is strengthened by the vascula umbilicales. Some of its vessels are seen to extend to the white, upon which a fine pellicle may be observed to grow, and which is the first appearance of a membrane to this humour, notwithstanding some authors speak of the membrana albuminis as an original structure, and others, amongst whom is Blumenbach, describe the membrane which lines the shell as belonging to the white.

The amnios is larger, its membrane more firm, and the fluid less clear and limpid than before. It has contracted some adhesions with the vascula umbilicales, and by that means, with the external membrane. These adhesions are particularly in the course of the blood-vessels, that are distributed to the vascula and external membrane. One of these vessels is always seen to pass across the back of the chick, at which place it is involved in a reflection of the fine membrane, which is connected with that of the amnios.

The chick is very much curved at this period: its beak is usually doubled down between its feet. The feathers are apparent.

The external form of the head bears a greater resemblance to that of the full-grown bird, except that the eyes are still enormously large.

The eyelids are evidently formed, and are occasionally moved by the chick. The membrana nictitans is likewise to be seen.

Haller prepared at this period the ciliary zone and radiated appearance called the crown, with the membrane on which the latter is full-lined, though he states that these parts are formed on the 6th day, or before it.

He says he has seen on the 7th day the corona ciliaris, or corpus ciliaris of Morgagni. At this epoch the retina, which is in thick folds, appears to go as far forwards as the crystalline lens, behind the corona ciliaris, with which it is covered, and which is dimly seen across it. He believes, notwithstanding, that the retina does not proceed to the lens; that the appearance of its doing so arises from its thickness and folds having to small a space between it and the lens, and that the membrane which supports the ciliary zone and crown, and is attached to the crystalline, is different from the retina.

The corona ciliaris is a row of black lines arranged alternately, long and short, in some degree parallel, but converging as rays proceeding from the external circumference of the eye to the crystalline lens. The ciliary crown is not formed entirely in the same manner in quadrupeds and birds. In the former it appears, when examined by a microscope, to be composed of a plicated membrane, upon which some ramified vessels advance towards the crystalline. In birds there are only some serpentine lines folded upon themselves, which are very numerous in the contour of the ciliary crown, and of which many unite to form single ones: they are joined together by these branches, and are covered with a black pigment.

The figure of the ciliary zone and crown is not a perfect circle, but it is broader on one side than the other.

The greater number of anatomists have described the corona ciliaris as resting immediately upon the membrane of the vitreous humour. Others have believed that the retina extends to the crystalline, and that the corona is supported upon it. Since Zinn's publication upon the anatomy of the eye, the structure of the ciliary body in man and quadrupeds has been well understood; but in birds the lamina, which serves for the base of the corona ciliaris, does not come from the membrane of the vitreous humour.

The membrane, which is placed under the corona ciliaris in birds, is to be seen from the 8th day. It is radiated, opaque, and a little ash-coloured; more thin than the retina, and thicker than the membrane of the vitreous humour. It is of the same dimensions as the corona ciliaris, and in a degree attached to the corona, and much more firmly united in the latter days of incubation; and after the expiration of the chick, it adheres by its posterior extremity to the great circle of the retina, and by the other to the crystalline lens.

The retina terminates by a distinctly formed circle, which is a little strengthened at the circumference of the corona ciliaris, and at that of the zone. The plane of the retina is continued with that of the corona; the zone is placed more posteriorly than the retina. Its external part, which rests upon the vitreous humour, is nearly horizontal, and its internal part becomes straight again in order to be attached to the crystalline lens. It does not adhere to the membrane of the vitreous humour when the chick is but little advanced. It remains often placed upon that membrane without being attached to it, and when the chick is more formed, or after incubation is finished, it quits the membrane of the vitreous humour, in order to remain connected to the corona ciliaris, with which it becomes inseparably united in the end.

The circumference of the ciliary zone, in the latter days of incubation, can be separated from the membrane of the vitreous.
INCUBATION.

vitreous humour without leaving any shred. It is distinguished from the retina by its fineness and being separable from the latter without being torn; but it is continued with the posterior and inferior part of that membrane. It differs still more from the membrane of the vitreous humour; it is thicker, it has more brown and blue in its colour. Acids, when applied to it, affect its colour more than they do that of the vitreous membrane. It is situated anteriorly upon that membrane, in another plane, and evidently sustained by it, and consequently ought not to be confounded with it.

The canal of Petit does not exist. The membrane of the vitreous humour proceeds, without stopping behind the ciliary zone to be attached to the crystalline lens, that it sustains, and which remains in its place even when the corona ciliaris has been raised. The ciliary zone is easy to prepare even in the chick but little advanced. One method is to cut off the cornea and iris; and having washed away the black pigment with which the corona ciliaris is covered, it will appear between the intervals of the ciliary rays; and if some of those rays be elevated, it will be seen in its proper place. It is practicable to make the lens come forth from its depression, and to elevate it with the corona ciliaris, with which it is connected; and sometimes it may be possible to leave the zone rolling upon the membrane of the vitreous humour.

An easier mode of preparation is to cut the sclerotic coat through the middle, and to plunge the anterior half of the eye into vinegar. After some hours immersion in that fluid, if the back of a fine scalpel be inflicted between the retina and the choroid coat, and the vitreous and crystalline humours be removed, one sometimes succeeds in obtaining the ciliary zone alone, the corona remaining attached to the choroid. It is rare to have the zone entire, but a considerable part of it is commonly preserved, and particularly the whole of the external circle. When the experiment fails, it is the interior circle which remains attached to the corona.

In the above account of the ciliary zone and crown, we have anticipated many facts that are observable during the last days of incubation, and even after that process terminates, in order to render the history of those parts more intelligible. We have also been induced to borrow the preceding description from Haller, who made the structure of the ciliary zone and crown in the chick a particular subject of investigation, as we have not much attended to the progress of the eye during incubation. See Mem. sur la Format. du Cœur dans le Poulet, fur l’Œil, &c. Observ. 180. 181, 182, 191, 192, 193, 215, 216, 256. 228, 231, 235, 240, 247, 249, 257, 254, 256, 261, 262, &c. and sect. xii. Mem. second par M. Haller. The small tubercle, from whence the aorta and pulmonary arteries arise, and which appears to have been a remnant of the bulb of the aorta, entirely disappears about the present period.

The right ventricle of the heart is still about the one-fourth of its length shorter than the left.

Those bones of the chick, according to Haller’s observations, which are now formed, are merely in a cartilaginous state; even the cranium, which was apparent some time before the present period.

The umbilical opening, through which the urachus and the blood-vessels communicate with the interior of the body of the chick, forms a projection, or a sort of tube, which in a few days becomes more striking. Some of the convolutions of the intestines may be seen in this opening, but the greatest part of the intestines is contained in the body of the fetus.

The end of the 11th day, or 256 hours, the external membrane goes on strengthening, by its connection with the vitreous humour. The internal coat is now so extensively united to the external membrane and the amnions, that it is only by great care, and after being macerated in spirits, that it can be liberated from its connections, and exposed as a distinct bag, pendent from the umbilicus. When thus separated by dissection, it is seen to be a large sac, composed of a thick fibrous membrane and hardly containing any fluid. The strength of the bag appears to depend upon a reflection of some of the other membranes covering and being inseparably adherent to it, for at the umbilicus the vesica is thin. Haller traced the urachus from the vesica to the rectum after the present period, and even until the last day of incubation; but in our observations it has appeared that the connection of the vesica with the chick, except by means of the blood-vessels, after this time, is very obscure. The whole of the body of the chick is now seen to be covered with feathers.

Haller at this period first discovered the tongue. The fusibility of the brain is still found to be a very soft pulp.

The liver, in most instances, has a yellow colour, but in some the red predominates. Bile is evidently secreted; the gall-bag is green, and a greenish or yellow fluid is commonly found in the florum. The intestines likewise appear to contain bile, or at least a bitter fluid.

The renal capsules are evident; they have, according to Haller, the form of an S.

The tube or sheath which projects at the umbilicus is better formed.

The blood-vessels, which come out at this place, are easily traced from different sources. Those which are distributed to the external membrane and vesica come from the loins, and those belonging to the yolk-bag are from the abdomen.

The end of the 12th day, or 288 hours, the chick has more of the figure of the adult bird than at any preceding period. The extremities are larger, and the head smaller, in proportion to the rest of the body. The bill is more pointed, and of a harder sub stance.

The florum has gained greater strength; it contains a white coagulated or curd-like fusibility.

There is bile found in all the intestines, which is very bitter.

On the outside of the umbilical sheath there are some folds of the intestines, with one of which the yolk-bag is seen to be connected by a short process, which is evidently the continuation of the alimentary canal into the yolk-bag. This part has commonly, and as we shall hereafter see very deferentially, received the name of ductus vitello-intestinalis. Although we have not observed the duct before the present date, there is every reason to suppute that it is coeval with the intestines.

Mapighi states that he saw the florum of the chick on the outside of the umbilical sheath; but this would seem to be an error. The florum, it is true, is situated low down in the belly, but, as far as our observation goes, it never is protruded from that cavity.

The structure of the eye is the same that is described on the 11th day. It is proper to remark, that at no period is there to be found in the chick a membrana papillaris.

The yolk-bag, according to our observations, begins in general to alter its figure. Before this date it was an irregularly round mass, containing two depressions; one for accommodating the chick and amnions at the upper side, and another at the lower part of the yolk, in which the white is partially lodged. The latter is a regular depression, and before this period contracts in breadth, although it becomes somewhat greater.
INCUBATION.

greater in depth; an alteration which arises from the diminution of the white, and from the choanae tending to approach each other, and thereby to bring the two poles of the yolk, at which these bodies were originally attached, together on the lower surface of the yolk. The approximation of the choanae seems likewise to occasion, in the first instance, the division of the yolk-bag into lobes. At the present period the bag forms two lobes, one large and one small. These afterwards, by the compression of the chick, are usually moulded into three, but in the egg of some other birds into a greater number; thus the yolk-bag in the Guinea fowl is divided into six or seven lobes.

The End of the 13th Day, or 312 Hours.—Upon opening an egg at this period, and removing the contents from the shell, the albumen is found to have assumed a greenish hue, and to have more confidence than at any of the former periods; and it is included entirely by a fine film, which retains it in one position, and in strict connection with the depression on the inferior surface of the yolk-bag. The external vessels are distributed over the whole white.

The yolk-bag has still more of the lobulated figure, and the chick lies obliquely across the bag in the superior depression between the two lobes.

The valvular structure on the internal surface of the yolk-bag, which we have noticed before, has now arrived at perfection. The valves are more eminent, form numerous folds or coils, their edges appear to be covered by tubes which are convoluted upon themselves in the manner of intestines. These have been called by Haller the vermis form and interseminariform tubuli, and have been described both by him and other anatomists as real vessels; but they have always appeared, in our examinations, as reflections or procleses of the valvular structure, in the substance of which the real blood-vessels ramify. Maître Jan speaks of them as vessels which collect the fluid of the yolk, and which afterwards terminate in the blood-vessels. Haller considers the blood-vessels which run in the edge of the valves as a distinct order of vessels, that end in the trunks of the veins of the yolk-bag, and which take their origin at the circle, that exists in the latter days of incubation around the line where the yolk and white are joined to each other. We have already said that the vessels upon the edges of the valves have numerous communications with those that run along the roots or bases of the valves, and which belong to the external tunics of the yolk-bag, and were originally the Fatio vessels that formed the valvular area. The venous circle of the yolk-bag, we have no doubt, is the same that in the early stages of incubation has been described as the contour of the valvular area; and the vermis form tubes appear to be the villous or spongy procleses of the external surface of the yolk-bag, which appeared in the first days greatly extended, and grown into the form now described.

The chick, at the present period, has still more of its perfect form; its head is much curved, and the bill is placed under the wing, which position is preferred throughout incubation.

The bill is pointed and has its natural figure. Haller states, that the chick is often perceived to open and shut the bill about this period and afterwards. Maître Jan, on the contrary, although the chick moves its limbs frequently and strongly, affirms, that it does not open its mouth. We have not attended to this circumstance, from considering it of little consequence, and no way explaining the mode in which the chick is nourished.

The internal organs of the chick are considerably advanced towards perfection. The brain, although still soft and pulpy, is well formed. The kidneys and thyir are completed in their figure. The spleen resembles a conglobate gland. The large and greater lobe than the heart.

The first branch that the aorta gives after its exit from the heart is the left carotic, which gives off the subclavian artery of that side. The trunk of the aorta then forms an arch, which turns to the right. It feeds off the right carotic, and approaches the vertebrae in passing behind the right lung, it is united to the ductus arteriosus above the liver.

The right ventricle of the heart is still shorter than the left; it is of an oval figure, but the latter ends in a point.

The end of the 14th day, or 336 hours, the changes in the humours and the formation of the organs of the chick are found to have made progress since the preceding day.

We have already stated that the membrane which is external to the chick and the yolk-bag, and which is scarcely palpable in the first days of incubation, gains strength and receives vessels after the vesicula umbilicalis has acquired some size, and has adhered to it. The magnitude of the vessels, and the thickness of this membrane, increase in proportion as the vesicula umbilicalis grows: we therefore conceive that the development of this membrane depends upon its connection with the vesicula and the blood-vessels which it derives from that bag. We have observed, that some days before the prent period, the external membrane begins to extend over the white, which it usually encloses about the 14th day; it therefore forms a perfect sac, containing the chick in its amnions, the yolk-bag, and the white.

The vesicula umbilicalis about this period has arrived at a very great size; its extent cannot be easily ascertained, as it is so much incorporated with the external membranes, that they cannot be separated or accurately distinguished; but we should conceive that the vesicula exceeds in size the yolk-bag, as there is the appearance of the external membrane being thickened and strengthened by one under it as far as the yolk extends.

The manner in which the vesicula concurs to form a membrane which envelopes all the contents of the egg, appears to be similar to the reflection of the serous membranes of the thorax and abdomen, in order to cover the viscera and line the parietes. It should however be observed, that when it is opened, there is no appearance of its forming an immediate tuftimilar to the pleura pulmonalis; but it seems to be a simple bag, holding the contents of the egg, and only united to them by some reflections of very fine membrane, which are chiefly attached to the back of the amnions, and in the course of the trunks of the blood-vessels. This circumstance has embarrassed other observers, and has led many to overlook the share that the vesicula umbilicalis has in the formation of the common membrane of the parts of the egg.

The blood-vessels, which are distributed to the external membrane are, even at the present period, much larger than those of the yolk-bag. There are four long branches, which send out numerous ramifications, that become in size as to evade the flight; but when this membrane is viewed with a magnifying glass, it presents a beautiful spectacle. The situation of the four great branches is not confinantly the same; as they are dispersed upon a loose membrane, which varies in some degree its position according to circumstances: one of them, if not two, is always seen, however, to cross the back of the amnions. The four branches are arteries, and are formed immediately on the outside of the umbilicus of the chick from the two iliac arteries; they, therefore, correspond to the umbilical arteries of mammiferous animals. The left iliac artery is always of much greater size than the right; it even appears larger than the aorta, of which it is the termination.
nation. The right iliac artery is often a mere filament, and in some instances it seems to be wanting altogether.

The capillary branches which accompany the umbilical arteries are so small that they are hardly distinguishable, although the former are of sufficient magnitude to be injected, and have a visible pulsation. There is, therefore, a quantity of blood sent to this membrane which is not returned to the fetus. The colour of the blood, both in the umbilical arteries and veins, is a purple.

The vascular membrane, above described, has received different names. By the older anatomists it was usually called the chorion, to which perhaps it is most analogous. Haller gave it the name of the umbilical membrane, and Levisle has lately called it the latefused membrane (membrane fusee), from the circumstance of its enveloping all the parts of the egg. We have hitherto called it the external membrane, until it should be described; but hereafter we shall speak of it as the chorion. In the account of the incubated egg, the membrane, on which the shell is moulded, is called the external, which it strictly is. It should not be confounded with the chorion, from which it differs so much in figure, structure, and use. See Egg.

Haller appears to have not distinguished the chorion from the membrane of the yolk-bag, which contains the vascular area. The progress of these two membranes is exceedingly different, and the system of vessels belonging to each is perfectly distinct. The valvar area is confined to the surface of the yolk-bag, and is intimately connected with it, membranes, and the valvar apparatus already described. The vessels of the area are chiefly venous, and preferred independently of the heart of the chick. They are most numerous in the early periods of incubation, although they increase in size along with the other parts of the chick. They go to terminate in a large vein which proceeds directly to the auricle of the heart in the first days, but, after the liver appears, is seen to pass behind it, and when the intestines are formed is found upon the mesentery, and constitutes the largest branch of the vena portae.

The arteries of the vascular area are insignificant, until towards the end of incubation. When first perceived, they are given off from the dorsal aorta, and after the development of the intestines they are discovered to be branches of the mesenteric artery. The vessels distributed to the area appear, therefore, analogous to the omphalo-mesenteric arteries of quadrupeds, although their distribution and functions may differ.

The vessels of the chorion, as we have already said, are branches, or rather, in the fetal state, the trunk of the arteries exterior upon this membrane. They do not exist previous to the appearance of the yolk-bag umbilical, with the growth of which they keep pace. The arteries of the chorion exceed the size of its veins in the same proportion as the veins of the yolk-bag exceed the arteries of that part. The vascular area, therefore, collects and transmits the blood to the fetus, while the arteries of the chorion diffuse a great portion of it in an extraneous circulation, and in the formation of a thick and extensive membrane.

Haller and others have described, at this date, an appearance of white vessels upon the albumen. Maitre Jan remarks five of these white lines or vessels. They arise from a little circle which is in the centre of the white; they divide into branches in advancing toward the vascular circle of the yolk-bag, which forms at this time the boundary of the septum between the yolk and the white. Maitre Jan describes them as passing beyond the septum and extending to the yolk. Haller conjectures that the use of these vessels may be to absorb the white and convey it into the yolk. Obser. 226. Mem. 1.

We have not made such an examination of these white lines, as to enable us to pronounce whether they are vessels or not, or what their use may be.

The yolk of the amnion appears to diminish about this period of incubation. It also becomes gradually less pure. It is stated by Maitre Jan, that when the yolk of the amnion is boiled at this date, the greater portion of it acquires the hardness that the white of the egg possesses after being boiled, although previous to the experiment it is much more fluid than the albumen; from whence Maitre Jan conjectures that some of the fluid of the white is conveyed into the face of the amnion, but he does not pretend to explain the means by which this is effected.

The cord-like substance, already mentioned as being found in the stomach and intestines, is now met with also in the crop and esophagus. According to Haller, boiling water makes this substance hard in the same manner as it does the white of an egg.

The end of 15 days, or 360 hours, the membrane of the chorion continues to increase in strength, and its arteries in size. Haller speaks of having sometimes found the latter of a lighter red than the veins, which does not accord with our observations. We have generally perceived the arteries and veins to be similar in colour, or at least when a difference did exist it was immaterial, and sometimes the arteries and sometimes the veins were the lighter coloured vessels. The vessels of the chorion have always appeared darker in our observations than those of the yolk-bag, but the character of all the blood is venous in the incubated egg during the latter periods. The reflections of membrane which accompany the principal vessels of the chorion, are now more firm than before, and continuous with them appears a fine transparent membrane that envelops the yolk as far as the vascular circle on the edge of the white, and extends over part of the amnion, to which membrane it adheres, for it to cover an irregular triangular portion of the chick in its amnion, and incline more closely the umbilical sheath with the convolutions of the intestines which project from it and the neck of the yolk-bag. This membrane does not appear to have been well understood by the older anatomists.

They sometimes speak of it as a layer of the yolk-bag, and at others as the vesicula umbilicalis, or allantois. The best description of it has been given by Levisle, who has also named it very appropriately entero-chorion, or the membrane containing both intestines and yolk.

The origin of this membrane is still involved in a degree of obscurity. Levisle described it when perfectly formed, but has thrown no light upon the history of its growth. The present date is the first at which it has appeared to us to be perfected, but we conceive that it is one of the original membranes and the second layer, that in the first days comes off the vascular area as a very fine pellicle. It seems to be covered, or rather continued into the peritoneum, lining the... in the late periods of incubation, of which we shall give further proofs hereafter. There is no reason for supposing this membrane to be the vesicula umbilicalis, or allantois, as the vesicula is a stronger membrane in the middle of incubation than this membrane is several days afterwards, when it is completely formed. The proper contents of the allantois also are found, throughout incubation, within the cavity of the chorion, to the formation of which we have supposed that bag contributes, but never under the membrane that includes the intestine and yolk-bag.

Haller states that he examined the yolk upon the inner surface of the yolk-bag with a lens, and distinctly saw the intestines
intestiniform tubes upon the edges of the valves most beautifully curled and folded upon themselves. He failed to see the aperture of these tubes. By maceration in water they were detached from the valves, and swam in the water. The valves themselves, by a longer maceration, were also separated.

The chick increases regularly in size, though not so rapidly as during the early part of incubation. Haller observed the feathers upon the eye-lids at this period, and that the feathers acquired the figure it prefers through life.

The curdy or evagulated substance is now found in the oesophagus and the crop, as well as in the stomach and intestines. Harvey found this substance principally in the stomach: this appears to be the case, and when we meet with other places, it would seem to have proceeded from the stomach to them.

The end of 16 days, or 384 hours, the space between the two layers of the membrane lining the shell, for containing air, is much increased since the period at which we have last mentioned it. About one-sixth of the whole cavity of the egg is occupied by air.

This circumstance depends upon the diminution of the substance of the white, which is at present reduced to a very small size.

The texture of the white continues to become firmer.

Upon removing the chorion, which now completely encloses the white, that humour is found to posses a thin tunica, which is proper to it. This membrane is evidently of a late growth, and appears to be formed by the vesicles of the yolk-bag extending beyond the septum, or that portion of the bag which is bounded by the vascular circle, and which is in contact with the white.

The fluid of the amnios is somewhat diminished.

The yolk-bag in the egg of the hen is generally formed into three lobes, although many authors speak only of two lobes at this time; one, which is the most distinct, but the smallest, lies upon the side of the body of the chick, between the head and the thigh: the other two are placed at the two ends of the chick.

Maitre Jan describes the yolk-bag as being formed only into two lobes, but ready to enter the abdomen, of which he gives a figure at this period, and of a silluar that ascends from the umbilicus, between the two recti muscles of the belly of the chick. He likewise describes the ductus vitello-intestinalis for the first time, which, with the yolk-bag, he finds issuing from the crop of the chick; and he says this part is not to be demonstrated at an earlier period than the end of the 16th day, or, according to his extreme tenderness, but, as already mentioned, we have found the duct on the 13th day.

Haller found the intestines before this period to be irritable. When stimulated, they contracted into knots.

The blood-veils of the yolk-bag appear fewer and smaller, owing, in part, to their being so much more involved in the valvular coat than they were in the middle periods of incubation. The branches of the blood-veils of the yolk-bag are larger than the trunks, and the veins are still vastly greater than the arteries. Haller states that the vein going upon one of the valves, is a larger vessel than the trunk, from whence all the arteries of the yolk-bag take their origin.

The end of 17 Days, or 408 Hours.—Haller admits the appearance of three lobes of the yolk at this date, which we have seen before.

The arteries of the chorion are extremely large; we have succeeded in introducing a pipe into them, and injecting them with coloured size, which makes a beautiful preparation. Haller, in his observation of this date, found both the arteries and veins of the chorion to be a purple colour, and the veins more violet than the arteries.

It now appears that there are two series of vessels belonging to the yolk-bag. The branches, which are spread upon the external membrane of the bag, appear to be the same which formed the valvular area in the early periods of incubation. The vessels of the internal coat are distributed to the valves. Both series contribute to the vascular circle, which, as we have before stated, is the remains of the vein that forms the contour of the valvular area. Maitre Jan finds there are several layers of the membrane which contains the yolk, but it is probable that he mistaken for one that membrane which incloses the yolk-bag, the intestines, and a part of the chick.

Coiter has found the yolk-bag within the belly of the chick at the 17th day; but the ingurritation of the yolk is a later event, according to the observation of other writers.

There is now a circular arrangement of muscular fibres around the opening into the belly of the chick at the umbilicus. This sphincter was not apparent before, and, as we shall soon find, is a very essential structure in the last periods of incubation.

If the yolk-bag be opened, and the valvular membranes cleaned by frequent abruption and floated in clear water, the sides of the valves will be found to be perforated by a great number of foramina, so as to give the valves the appearance of lace. The intestiniform tubes also upon the edges of the valves will be partially detached; the portions that remain resemble pieces of cylindrical tubes.

Many of the blood-veils upon the external surface of the yolk-bag contain apparently but little blood, and have a greenish colour, as if conveying a yellow or green fluid.

The end of the 18th Day, or 432 Hours.—The two layers of the external membrane, which immediately lines the shell, are separate for about one-third of their extent, and can with little pains be detached from each other until near the small end of the egg. The quantity of air contained between these layers, although much increased, is less than might be supposed, as the layers are not far abonder, except at the great end of the egg.

The water of the amnios is a good deal diminished, and its membrane is applied in folds to the surface of the chick. The chorion has attained a very considerable strength, admitting of examination and dissection, without being previously hardened by spirits or vinegar. When this membrane is laid open, there is some tough lymphy substance found under it in layers or strakes, which has been mistaken for a membrane by some anatomists. There is generally mixed with this substance a certain quantity of calcareous matter. It has, therefore, been supposed to be a kind of excrement, or the secretion of the kidneys. These white or pale are what have been called flirea reticulate urina by Malpighi, and were described by him as being found in the allantois.

When the chorion is opened and turned down off the contents of the egg, it appears to be a distinct bag, and only connected to the other parts by the reflection of fine membrane. These are chiefly in the course of the trunks of its blood-veils, and at the junction of the yolk and white.

The yolk-bag is now often found gathered into more lobules than three, some of which have entered the abdomen of the chick, through the aperture at the umbilicus. The forming of the yolk-bag into lobes and lobules, appears to be owing to the contraction of the membrane that contains it, and the intestines of the chick; for, when the yolk-bag is taken out of this membrane, it spreads out into nearly its original figure, except that there is a marked depression where the white is joined with it, and that the neck of the bag is somewhat elongated.
gated. It seems likewise to be the contraction of the same membrane which urges the yolk-bag into the cavity of the abdomen of the chick.

The yolk appears to be somewhat less than in the preceding days; but on the closest examination we have not been able to discover any of it in the intestinal canal. We have observed at this period, although it probably exists much sooner, an appearance of yellow vesicles accompanying on each side the blood-veisels of the yolk in the same manner as the small veins generally attend arteries. We have not been able to determine whether this appearance be caused by real vesicles filled with a yellow fluid, or by the inner coat of the bag being seen through the outer, producing on the edge of the tract of the real blood-veisels an appearance of yellow lines.

The chick has now attained nearly the utmost size that it will possibly while in the egg. Its form is entirely that of the excluded chick, except that its abdomen is enlarged in proportion to the quantity of the yolk-bag which is admitted into that cavity.

The different organs of the chick are very perfect. The convolutions of the intestines which were outflde are taken into the belly with a portion of the yolk-bag, as before mentioned. Maitre Jan states that he found about this period the tympanum and the labyrinth of the ear hard, and nearly of their full size. All the bones have acquired offseous matter and considerable hardness.

The bile contained in the gall-bag is an intense green, and gives that bag a blue colour.

The end of the 19th day, or 456 hours, the air-cell extends round one-half of the cavity of the egg.

The amnion is in some instances found to be ruptured by the bill of the chick.

According to Haller, the chick begins to cry about this period. Harvey and Langly also heard the piping of the chick at this date. Some other authors have not noticed the chick to cry until the twentieth day, which agrees with our observations. Still, however, the time at which the chick begins to cry is subject to vary, according to the degree of heat to which it is exposed. Thus, in an egg from which no found illnes while it is in the nest, if placed upon warm water the piping of the chick will be heard.

The chorion begins to appear a little faded, the circulation of blood upon the membrane being carried on more sluggishly. This change seems to be preparatory to the destruction of that membrane which is about to happen.

More than two-thirds of the yolk-bag and its contents have been received into the abdomen. If that cavity be opened, it will be seen that the bag is prefixed in amongst the different vices, to which its figure is capable of being perfectly accommodated in consequence of its folds and lobules.

The cobite is reduced to a few irregular-shaped knots, which generally contain some calcareous matter that appear to remain after all the liquid parts of the albumen have been removed. The knots are composed of the chalaze, and the membrane of the white compressed together.

Maitre Jan very readily succeeded in distending the yolk-bag and the ductus vitello-intestinalis, by blowing air into the oesophagus, but did not yet perceive that any of the yolk had passed through the duct into the intestine.

Haller describes at this date the effects produced upon the valvular structure of the yolk-bag by maceration in water for some days.

Having first washed the face containing the yolk with several waters, he found the edges of the valves covered with the vermiform tubes before described, which separate and form curves; these elongate and expose the interval of their two curvatures. They break at the end, and the two ends become nearly straight, remaining attached to the edge of the valve. The breadth of these little membranes appears also covered with clyndric tubes, sometimes branched and separated by the reticular intervals. The day after, the yolk-bag having been steeped in water, he saw the appearance of cylindrical tubes forming a net-work upon the membrane which makes the breadth of the valves, and continuous with the vermiform tubes of the edges. He further saw that the valves of the valves, having arrived there, were covered with some very fine small tubes resembling a powder. The following morning, he saw some of the tubes which ascended from the base of the valves, and which were continued with the valves of the edge. They were clyndric as far as he could perceive, and joined in form of a net-work. The straight vessels went evidently as far as the vascular circle of the yolk-bag.

The fourth day many of the tubes had disappeared, and there only remained on the edge of the valves the membrane which covered the trunk of the vessel. With respect to the nature of the tubes on the sides of the valves, he found it difficult to pronounce with certainty. By examination with a strong lens he perceived that there were some real tubes upon the sides of the valves, which ascended in a serpentine manner; but those which are the most numerous, and which form the net-work on the breadth of the valves, were not determined to be tubes, although they are most probably so, as they appear clyndric under every point of view, and are continuous with the tubes of the edge.

The fifth day, the valves of the edge appeared all uncovered; these vessels preferred some breadth, and a round figure at the edge, and an undulating course. It was more easy to distinguish the real vessels which descend from the edge in a serpentine manner, and traverse obliquely the breadth of the membrane, in order to return into the plain between the valves. Haller also saw very evidently some branches which proceed from the vessels between the valves, and which ascend in a serpentine manner by the side of the valves, and communicate with the trunk which runs along the edge. The remainder of the valve was become an open net-work of extreme beauty.

The sixth day many of the valves had disappeared, and others presented only a plaited border, like a masonry, from which the intestines had been removed. Mem. i. p. 379.

The chick at the present date is about the size that it is immediately after exclusion from the shell. It lies coiled round with its head under the right wing.

The blood-veisels in the interior of the chick have attained more of their proper size in proportion to the parts they supply. The left branch of the aorta, however, which forms the principal umbilical artery, is still nearly equal in magnitude to the aorta itself.

Haller observed at this period the vena cava beat between the lobes of the liver.

The end of the 20th day, or 480 hours, the shell is extremely dry, and very fragile, which is occasioned by the more extensive detachment of the membrane which is immediately under it. The brittleness of the shell is a very convenient circumstance at this period, when it is about to be ruptured by the efforts of the chick.

It is usual at the present date to find the greater number of the eggs in a hen’s nest cracked or chipped near the great end. This is attributed by common people to the parent, who is supposéd, by a particular instinct, to know the proper period for the liberation of the young chick. Malpighi likewise supposéd
suggested that the shell was broken by the hen, in which opinion Haller seems to concur. He states that he found a fissure in the shell, and the membranes which inclosed the chick, at the same time entire. Maitre Jan, on the contrary, ascribes the fracture of the shell to the chick. He found the shell had lacereated the membranes before the shell was broken; and having watched the eggs at the time the chicks began to cry, he did not perceive the hen touch them with her bill, but that the shell was ruptured from the inside, and the fractured portions were pulled outwards. This account of the mode in which the shell is opened, exactly accords with our observations. We have seen the shell evidently broken from within; besides, the fact of birds being hatched by artificial heat, proves decidedly, that the afflentance of the hen is not necessary for the fracture of the egg.

After the shell is broken the chick is always heard to cry, and the point of its beak is seen to project out of the egg for several hours before the chick attempts its liberation.

It is reported by common people who have the care of fitting hens, and it is even asserted by some anatomists, that the cries of the chick are heard before there is any aperture made in the shell. Haller relates that he took an egg, in which he discovered the piping of the chick, and which was at the same time unbroken, and having carefully removed the shell, piece by piece, he found that the opaque membrane, which lines the shell, was also entire, but that there was an opening in the chorion opposite to the beak of the chick. He does not state whether the bill had penetrated into the air-cell, but it most probably did, as at this period the two layers of the membrane lining the shell are separated beyond the situation of the beak of the chick. In another observation Haller found the chorion entire under the suffire in the shell, which was on the opposite side of the egg to the bill of the chick; and therefore he supposes the shell to have been cracked by the hen. We cannot positively contradict the assertion of the chick uttering sound before it has the means of freely respiring, but we should conceive it extremely improbable; and upon every occasion where we have heard the piping of the chick issue from the egg, we have found that there was a crack or fracture in the shell.

Where the chorion is lacereated by the beak of the chick there is always some bloodshed, but the edges of the membrane soon dry, which prevents any further hemorrhage; for the circulation is not yet interrupted in the chorion by the contractions of the sphincter at the umbilicus, although Maitre Jan describes the passage of the yolk, and the destruction of the chorion, as events of the same date.

When incubation has proceeded regularly, the whole of the yolk-bag at this period is found within the cavity of the abdomen, which is closed by the contraction of the circular fasciculus, of muscular fibres placed around the umbilicus; but, as already mentioned, this does not, until near the exclusion of the chick, comprefs the umbilical vessels so as to destroy their circulation.

The injection of the yolk causes a great tumefaction of the belly of the chick. The animal resembles one in a gravid state, but the belly is less swollen than might have been suppoed from the bulk of the yolk-bag. The latter does not lie in the front of the cavity, but is pressed in between all the visceræ, and therefore occupies the least possible space.

It is remarked by Maitre Jan, that more chicks die about this period than at any other of incubation, which he attributes to the dilatation of the abdomen by the yolk-bag; but we should suppose that it is the ceflation of the external circulation upon the membrane of the chorion, which causes the great fatality towards the end of incubation.

Maitre Jan states that he discovered the fluid of the yolks at the 48th hour mixed with the contents of the small intestines; but some other anatomists, who admit the passage of the yolk through the ductus vitellus intercallari, do not pretend to have detected it in the intestines so early.

The chick, about this period, is sometimes observed to remain for a while perfectly motionless. Harvey supposes that it was asleep on these occasions. How far he was correct we cannot pretend to say.

According to Haller the weight of the yolk is not sensibly diminished before its entrance into the belly of the chick. He weighed the entire yolk-bag at the 46th hour, and found it to be three drachms and two grains. He states that the weight of the yolk, before incubation, was three drachms and ten grains. This diminution of weight is, therefore, not greater than might have been expected from evaporation, or from an original difference in the bulk of the two eggs that were the subjects of the experiment.

Haller, in seeking for the allantois, or vesicula umbilicalis, at this period, states, that he could not distinguish it from the chorion, or rather from a fine membrane he raised from the internal surface of the chorion by inflation; but he found a little sac in the form of a pear, extremely vascular, full of a yellow mucous, and terminated by a peduncle which was not an inch long. We have already described the vegetal umbilicalis as being lost in the formation of the chorion long before the present period. At midnight, likewise, suppose this part to have the same definition in the latter periods of incubation; and in none of our observations have we met with the pear-shaped bag mentioned by Haller. We have turned back the chorion at the present date, and have found it to be a perfect sac, such as we have previously described it, and connected with the adjoining membranes by reflections of a very delicate texture. These were readily detached, and left the chorion pendent by its vessels from the umbilicus of the chick. Besides the blood-vessels, we could discover a transparent filamente passing to the inverted bag, which appeared to be tubular, and perhaps was the urachus.

The End of 21 Days, or the Full Period of the Incubation of the Hen.—When the progress of incubation has been regular, the chicks are now generally found to have abandoned the eggs, leaving the shells with the threds of the chorion and amnions behind them. It happens, however, occasionally, that some of the chicks have been backward in their growth, from the disadvantageous position of the eggs in the shell, or the negligence of the hen. These are sometimes found about this period within the broken shell, having the remains of the membranes still attached to the umbilicus.

The separation of the membranes does not appear to be effected by a process of slough or ulceration. They appear rather to be torn off, as some threds and a short portion of the trunks of the blood-vessels are seen to project at the umbilicus. The hemorrhage from these vessels also is not entirely suppressed by the contraction of the sphincter muscle, but in a degree by the afflentance of a clot of blood, which forms in the ends of the torn vessels.

We have not been able to observe whether the complete fracture of the shell, previous to the exclusion of the chick, and the detachment of the membranes, are accomplished by the efforts of the chick alone, or with the assistance of the hen.

The belly of the chick, after exclusion, is much enlarged, though less tumid than it was when the yolk-bag was first taken into the abdomen. It would, therefore, appear that the yolk begins to diminish immediately after it is admitted into the belly of the chick, although some observations of Haller...
Haller would lead to a different conclusion. He weighed the egg and its different contents at the 526th hour, and found the entire egg to be 15 drachms and as many grains; the weight of the yolk, with some light membranes that adhered to it, was four drachms. The fetus weighed five drachms and 14 grains. In an egg which had not been fat upon, he found the weight of the entire egg to be 12 drachms and three-sixths, and that of the yolk three drachms and 10 grains. This account of the weight is obviously incorrect. See Egg.

Many anatomists state that they have been able to detect the fluid of the yolk in the intestines at this period, and some supposed that they found it had passed into the alimentary canal, even before the exitation of the chick. Haller found yolk in the intestines at the end of the 21st day, in one instance where the chick had not left the egg. Maitre Jan faw it after 20 days and fix hours. Needham describes the gradual passage of the yolk into the intestines at the end of incubation. Langly also found it in the intestines at the same time. Thoed, Aldes states that before the chick was excluded, he could not press the substance of the yolk into the gut, but that immediately afterwards he was able to do so. Stenson succeeded in prefling the yolk through the ductus vitello intestinals.

Notwithstanding the testimony of many anatomists, we are inclined to believe, that the substance of the yolk is not conveyed into the intestines. We have scrupulously examined the intestines of chicks, both before and after the exitation from the egg, and in no instance could we discover with certainty any yolk in them. In the last periods of incubation, and until the chick has taken its natural food into the stomach, the alimentary canal is filled with a yellow fluid, which it is scarcely possible to distinguish from the yolk; therefore, all direct observations respecting the passage of the yolk into the intestines must be attended with a degree of doubt. There are, nevertheless, many reasons besides actual examination; for supposing that the yolk is not conveyed into the fyllem of the chick by passing first into the intestinal canal, which we shall state in speaking of the uses of the different parts of the egg, we are further supported in our opinion by the authority of Blumenbach, who affirms positively, that the yolk does not pass into the intestine. We might also quote the same opinion held by Levell; but he advances it upon falfe grounds, as he describes the ductus vitello intestinals as a ligament, by which the yolk-bag is suspended to the body of the chick, notwithstanding the tubular structure of this part is so palpable.

The substance of the yolk at the end of incubation is extremely tenacious or gluey in its consistence, and of a deep green colour, particularly in the centre. The net-work of the valves upon the inner membrane is very visible at this period. We have thrown coloured fize into the blood-veilfs of the yolk, and afterwards softened by acetation, and by frequent ablution detached the inner membrane; when we found that the bulbs of the lace-like or reticulated structure of the valves was formed by real blood-veils, which preformed the most beautiful vascular apparatus that we have ever seen. This mode of preparation shews, that the organization of the internal membrane depends upon the growth of the blood-veils of the external membrane of the yolk-bag, and confirms the account we have already given of the formation of the valves. Haller considered the vessels distributed in the valvular structure of the bag as being chiefly, if not entirely, venous; but we found them most easily injected from the aorta of the chick. In the early periods of incubation we know that the branches of the veins of the yolk-bag are larger and more numerous than those of the arteries, but we are inclined to believe the arterial branches predominate towards the end of incubation. Further observations, however, are necessary to explain the vascular sitem of this membrane.

Several anatomists speak of a new membrane being found upon the yolk-bag towards the end of incubation, which is continuous with the skin of the chick. Haller, in some observations, describes this membrane in a manner which leaves no doubt of its being the same that we have already noticed as including the yolk-bag and intestines of the chick, when they are on the outside of the body.

We, as well as others, have found the appearance of a new transparent membrane covering the yolk-bag after it has entered the abdomen of the chick. This membrane seems to be the continuation of the peritoneum. It adheres to the inside of the umbilicus, and to that point of the yolk-bag where the white and chalaza were attached. We have not had it in our power to investigate completely the connections of the yolk-bag with the peritoneal coat of the parietes of the belly, but we believe at present that any appearance of a third tunic to the bag is derived from the peritoneum.

Haller states observations made upon the allantois or vesfcula umbiliculis, even to the last day of incubation. He mentions that he found under the chorion an extremely fine membrane which was incorporated with the tlinle of white filaments or strakes that we have spoken of before. He describes this membrane as giving an immediate covering to the chick: it was so tender that inflation burst it. He supposes it to be either the amnios or the allantois. In the next paragraph he says, he found the centre of the yolk, and found the urachus there without having any connection with the allantois. He inflated it, one part of the air went out at the anus; another elevated the membranes of the rectum. He next passèd an extremely fine probe into the urachus, and found an orifice on the left side, between the anus and that vessel that the urachus produced by inflation in the rectum: the probe would not enter the plicated mucular faco, which is behind the rectum and at the side of the vagina.

This account appears to us to be very inaccurate in some points. The membrane which Haller took for the allantois was most probably that which envelopes the yolk-bag and intestines. The urachus at the periods of incubation, when it can be found, has no connection with the yolk-bag. The foramen on the left side of the anus appears to have been made by the probe, and the muscular faco he speaks of was the buria Fabrini.

Improves which take plaice in the Structure of the Chick after Incubation.—The chiefly relate to the disappearace of the yolk, and the degeneracy of the arterial ducts, in which the fetus conveyed the blood from the pulmonary artery into the aorta.

In two days after exitation from the egg, the yolk is very febibly diminished in quantity, and its consistence is even more tenacious or gluey than it was before.

The right ductus arteriosus, which is the first obliterated, becomes as small as a filament. The left is, according to Haller, diminished three times the size it had during incubation.

In four days after exitation, the yolk is found to be reduced two-thirds of its bulk. In proportion as the substance of the yolk disappears, the membranes forming the bag also diminish. The adhesion which we have mentioned the yolk-bag to have with the internal part of the umbilicus, after its admission into the abdomen, is now undone. It would appear that this attachment is produced by the sinus...
fraction of the sphincter muscle upon the remnant of the vessels and of the membranes connected with the centre of the yolk-bag.

It is now particularly easy to see the origin and course of the proper blood-vessels of the yolk. The veins belong to a single trunk, which is continued along the mesentery, and ends in the vena porta; it is evidently a branch of the mesenteric vein. The arteries are also derived from a single trunk, which is the principal branch of the mesenteric artery. This trunk, in some points of view, appears to be double; it divides, paffes on each side of the intestine, and then unites to form a single vessel previous to its distribution in the membranes of the yolk-bag. These vessels, and the ductus vitellointestinalis, are connected together by some fine folds of peritoneum, which are the continuation of the mesentery.

The cavity of the right ductus arteriosus is completely obliterated, but the left is scarcely more diminished than it was on the second day.

In eight days after exclusion, the yolk is reduced to the size of a hazel nut. The ductus vitellointestinalis becomes thicker, and more resembles the intestine than it did before.

The valvular structure upon the internal surface of the yolk-bag is no longer apparent.

The right ductus arteriosus, although reduced to the size of a filament, is enlarged where it enters the aorta.

The left duct is likewise obliterated at its origin from the pulmonary artery; it is a filament, but is inferiorly white, opaque, and larger. Both these ducts, therefore, decline first at the superior part, where they come from the pulmonary artery.

The gizzard of the chick, especially if the animal has had the opportunity of picking up small stones with its food, is thick and muscular; and the internal coat, which during incubation was soft and spongy, is now become firm and dry.

In 16 days after exclusion, according to Haller, the fluid of the yolk is entirely consumed; there remains but a small thin film, less than a pea, containing a granular substance, which is partly of a calcareous nature, and which is the dregs of the substanice of the yolk.

Twenty-seven days after exclusion, Haller found both the right ductus arteriosus, and the left, still remaining in the form of filaments. The right was smaller than the left. The latter was still open at its junction with the aorta.

In three months after exclusion, the ductus vitellointestinalis is found to be turned down upon the side of the intestine, to which it evidently forms an appendix. At its extremity may still be seen the remnant of the yolk-bag, reduced to nearly the size of the head of a pin. It is usually dark coloured, from the nature of its contents.

In the adult bird, Stenon, Needham, and Maitre Jan, have recognized the ductus vitellointestinalis in the form of a small cæcum. It is situated on the alimentary canal, about midway between the foarnach and the anus.

Needham describes it as being half an inch long, but this is incorrect with respect to any of the gallinaceous tribe, but in some other birds we have found it of a very remarkable size.

In the snipe it exceeds in length the cæca of the large intestines.

In the curlew it is about an inch long, and very capacious.

In the woodcock it is nearly as large.

It is above an inch long, and very slender, in the black

coot: the cæca of the great intestines are also singularly long and slender in this bird.

In all the passerine birds it is small.

In the swan, goose, and duck it is of a moderate size.

It is remarkably small in the heron and in the hawk.

In all the birds we have examined, there exists during life some remnant of the yolk-bag at the end of the cæcum, formed by the ductus vitellointestinalis. This is more particularly remarkable in the passerine and acipitrine birds. The nightingale has a little sac, about the size of a small pea, attached to the end of this process of the intestine.

Although there is so much variety with respect to the figure and size of the cæcum of the small intestines of birds, the structure of this part is constantly the same in every species. It appears to possess but two coats; one is the continuation of the peritoneum, covering the intestine; the other corresponds to the mucous membrane of the gut.

The internal surface of the cæcum exhibits small cells similar to those points of the alimentary canal on which the mucous glands are congregated. This structure exists whether the internal membrane of the intestine be plicated or villous.

We have not found the appendix produced by the ductus vitellointestinalis to receive, in any instance, the contents of the alimentary canal. It is filled with a mucous fluid, which appears to be secreted from its internal surface. There is, therefore, every reason to suppose that this appendix performs the office of a mucous gland in the adult bird. The great size which it possesses in the snipe, curlew, woodcock, and coot is probably dependent upon the nature of the food of these birds, although we cannot at present perceive in what manner this part is so particularly useful to them. See Phil. Trans. part ii. 1811.

In the Plate designed to illustrate the incubation of the eggs, fig. 1. exhibits an egg with a portion of the shell and the membrane underneath it, removed at the great end: a is the first appearance of the fæces as it is seen in the cæcumula, through the membrane which covers it; around it are the concentric circles or waves (balance).

Fig. 2 represents an egg opened in the same manner in order to expose the fæces when it is a little more advanced, with the commencement of the vascular area; a, the fæces somewhat formed with the head like the top of a club; b, the contour of the vascular area assuming the heart-shape: it does not yet circulate red blood, but within it are seen the rudiments of vessels containing a greenish fluid. Some of these points are of a darker colour, and are the first appearance of the real blood.

Fig. 3 is an egg also with the shell of the great end removed; a is the fætal chick; b refers to the pulling points that constitute the heart; c represents the appearance of the vascular area after the circulation of blood is perfected in it.

Fig. 4 exhibits a magnified view of the portion of the membranes at the great end of the egg, including the chick and the vascular area about the fourth day of incubation; a is the thin glistering membrane which readily separates at this period from the shell, turned back; b is the fine transparent membrane imparably under the fæces, also turned a little off; c the chick contained in the amnion; d the vilæcula umbilicales attached to the chick; e the external membrane of the yolk-bag on which the vessels composing the vascular area are seen to spread; f is the internal pulpy membrane of the yolk-bag which afterwards produces the vessels, the preceding membrane being partially removed to expose it.

Fig. 5 exhibits a portion of the yolk-bag with the chick and vilæcula umbilicales considerably magnified; a the chick; b the amnion; c the membranous connection the amnions have with
with the vescula umbilicalis; \(d\) the vescula, the neck of which is seen to enter the opening at the umbilicus of the chick.

Fig. 6. is a magnified view of the heart of the chick as it appears when first formed; \(a\) indicates the horse-shoe dilatation mentioned in the defcription of that organ on the second day.

Fig. 7. shews the heart and large vessefs of the chick magnified after these parts are more perfectly formed; \(a\) is the vena cava; \(b\) the auricle; \(c\) the auricular canal; \(d\) the single vinctule; \(e\) the hub of the aorta; \(f\) the principal artery.

Fig. 8. is a view, also magnified, of the heart, pulmonary arteries, lungs, and aorta of the chick; \(a\) is the heart seen on the posterior side; \(b, b, b\), the two arteries which fend off from the pulmonary arteries, and afterwards concur towards the formation of the abdominal aorta. These vessefs, after parting with their branches to the lungs, are analogous to the ductus arteriosus of mammalia; \(c, c\), are the pulmonary branches of the vessefs left mentioned; \(d\) the third vinctule of the heart, which corresponds to the inferior part of the aorta; \(e\) the abdominal aorta, formed as already described; \(f, f, f\), the two lungs.

Fig. 9. is a view of the internal surface of the yolk-bag after the vessefs have begun to form upon it.

Fig. 10. shews a similar view of the internal membrane of the yolk-bag, when the valvular apparatus is completely formed; \(a, a, a, a\), indicate some of the intelliform tubes upon the edges of the valves; \(b, b\), the appearance of vessefs in the intervals between the valves. The valvular projections themselves are sufficiently evident.

Fig. 11. shews a portion of one of the vessefs of the yolk-bag magnified; \(a\) the basis of the valve, where the principal vinctule runs; \(b\) the plaits or folds upon its side; \(c\) the intelliform tubes upon the edge of the valve.

Fig. 12. is a magnified view of a portion of a vinctule of the yolk-bag after it had been converted into a fine lace, the vessefs injected, and the internal membrane washed, so that the real blood-vessefs alone remain; \(a\) is the principal vinctule that runs along the base of the valve; \(b\) the one which goes along the free edge; \(c\) the lace-like ramification of vessefs between these two.

Fig. 13. represents the yolk-bag, and the portion of the intelline with which it is connected, taken out of the chick a few days after incubation; \(a\) is the yolk-bag very much reduced in size, and of an irregular form; \(b\) the piece of intelline to which the yolk-bag is attached; \(c\) the ductus vitello intellinalis imperfectly seen, as it is partly covered by the blood-vessefs of the yolk-bag; \(d\) the branch of the mepenteric vein, which furnishes, in the early periods of incubation, the veins of the vaucular area; \(e\) the branch of the mepenteric vein, which goes to the yolk-bag. It divides, in the side of the intelline, and unites again before it ramifies upon the yolk-bag.

Fig. 14. shews the chick after the yolk-bag had been taken into the belly; \(a\) the umbilical opening surrounding the aperture, which is closed, in the present instance, by the contraction of this mufcle; \(b\) some lacerated vessefs, and a portion of the chorion hanging from the umbilical aperture; \(c\) the belly of the chick divided in conquence of the admifion of the yolk-bag.

Fig. 15. is a plan of the relative position and magnitude of the contents of the egg about the ninth day of incubation. The view is procured by first boiling the entire egg, and afterwards making an equal fection; \(a\) the edge of the shell; \(b\) the cavity left between the two layers of the membrane that lines the shell to contain air. This cavity is considerable at the present period; \(c\) the chick in its amnios; \(d\) the yolk; \(e\) the cut edge of the yolk-bag; \(f\) the white which has descended to the small end of the egg and diminished; \(g\) the chalazae, much nearer each other than they were before incubation.

Fig. 16. exhibits a view of the contents of the egg, with the chorion cut open and turned down off the other parts; \(a\) the chorion seen obliquely, as it is in some measure covered by the membrane that includes the yolk-bag and intellines, besides being surrounded by the amnios, the fluid of which, at the present period is greenish; \(b\) the amnios seen at each end of the chick; \(c\) indicates the yolk-bag, which is divided into three lobes; one of them is seen to lie upon the side of the chick; the blood-vessefs of the yolk appear small, and are indistinctly seen; \(d\) some folds of the membrane which envelops the yolk-bag, intellines, and a part of the chick; \(e\) the white contained in its proper membrane, and very much reduced in size; \(f\) the chorion turned down, and therefore the surface that is seen is the internal; \(g, f, f, f\), reflections of fine membrane which attach the chorion to the other membranes; \(b, b, b\), the two trunks of the umbilical arteries, which each divide into two branches, and are distributed to the chorion.

Fig. 17. is intended to explain the formation of that membrane which includes the yolk bag and the intellines of the chick, and for this purpose the chorion is entirely removed; \(a\) is the chick contained in the amnios; \(b\) indicates the membrane of the yolk-bag and intellines; it is seen to cover a certain extent of the amnios and chick; it descends posteriorly to be connected to the septum, between the yolk-bag and the white; anteriorly it is laid open, in order to turn out the yolk-bag, which was before contained in this membrane. Within the chik made by the incision are to be seen the intellines of the chick perfectly uncovered and designated by \(c\). The yolk-bag hangs by the ductus vitello intellinalis and its blood-vessefs, and is marked by the letter \(d\).

Fig. 18. shews an egg with the great end fractured previous to the exclusion of the chick: some more pieces of the shell are removed in order to bring into view the membranes that are lacerated by the bill of the chick; \(a\) is that portion of the membrane under the shell which forms the air-cells, and in which there is a small aperture. The chorion and amnios are torn to a greater extent to permit the bill of the chick to appear on the outside of the shell; \(b\) the bill of the chick: beside it are seen some points of feathers projecting out of the opening made in the outer membrane.

Fig. 19. is a portion of the small intelline taken from the adult bird, on which the appendix is placed, that we have described as the remnant of the ductus vitello intellinalis; \(a\) the intelline; \(b\) the appendix or cæcum; \(c\) is a little knot which was, during fetal life, the yolk-bag.

In some of the preceding figures, the form of the chick is represented at different ages, which the reader will understand without the letters of reference.

Of the Use of the different Parts of the Egg during Incubation, and after the Exitus of the Chick.—Although there can be no doubt that the chick derives its nutriment from the humours of the egg, the mode in which this is effected is involved in considerable obscurity. Anatomists have entertained very different opinions upon the subject. Some have supposed that both in mammiferous animals and birds, the foetus is nourished by swallowing or absorbing the liquor amnii.

Heister, in his Compendium of Anatomy, states, that after the contents of the uterus of the cow were frozen, he found...
a piece of ice of the thickness of a finger extended from the concealed amnios into the mouth of the fetus, and down the cæcum as far as the pharynx.

There have been sometimes seen also in the flomach of the 
fatal calf the same kind of fatty concretions, that usually exist in the amnios of this animal. The hairs of the calf have been discovered in the meconium. New-born infants have been observed to vomit a fluid resembling the liquor amnii.

It has been remarked by Harvey, Haller, and several other writers upon incubation, that the fetal chick frequently opens and shuts its mouth while inclosed in the amnios, as if it were performing the act of swallowing.

The preceding facts leave no doubt that the water of the amnios passes into the flomach of the fetus, but by no means proves that it contributes to the nourishment of the young animal, but rather the contrary, as if it were either digested in the flomach, or consumed by absorption, it could not be found towards the end of gelation, or after-birth, in the quantity reported.

Those who give credit to the nutrition of the fetus by

the liquor amnii, cite some remarkable cases in which the umbilical cord is said to have been destroyed before birth, or in which the infant has been born with the cæcum at the umbilicus perfectly formed. See Observ. rarior part pars 1. lib. 39. — Journal des savans, année 1673, p. 69. Observat. communiqu. par Chatton.—F. Hoffmann & Triller Differ. de pinguid. e fucco nutr. superf. p. 10. and Rommel Ephemer. nat. cur. dic. 2 à 7, lib. 299.

It should be remarked, that of these observations, some are related in a manner which makes their accuracy very doubtful; and others, even if correctly stated, do not prove the point they are proposed to establish. Thus the infant with the cicatrized navel was not seen by Chatton until five months after birth; and in some of the cases where the cord was said to be injured or putrid while the child was alive, it does not appear that the circulation had been destroyed.

We should not have noticed the doctrine of the nutrition of the fetus from the liquor amnii, as it is generally discredited, had it not been advanced with some limitation by Lobstein in a modern publication. This author does not pretend that the fluid in the amnios is the principal source of food for the young animal, but that it continues to feed the chick, by means of the umbilical constrictor, which, while still attached to the yolk sac, continues to contain a fluid resembling the liquor amnii. The fluid is absorbed by the chick through the meconium, which is formed by the excretion of the fetal membranes, and the excretion of the fluid is thus converted into a nutritious fluid, which is absorbed by the chick, and which is not injured by the absorption of the contents of the meconium.

Lobstein, however, is not satisfied with this view, but he believes that the fluid in the amnios is not absorbed by the chick, but that it is converted into a nutritive fluid, which is absorbed by the chick, and which is not injured by the absorption of the contents of the meconium.

We should not have noticed the doctrine of the nutrition of the fetus from the liquor amnii, as it is generally discredited, had it not been advanced with some limitation by Lobstein in a modern publication. This author does not pretend that the fluid in the amnios is the principal source of food for the young animal, but that it continues to feed the chick, by means of the umbilical constrictor, which, while still attached to the yolk sac, continues to contain a fluid resembling the liquor amnii. The fluid is absorbed by the chick through the meconium, which is formed by the excretion of the fetal membranes, and the excretion of the fluid is thus converted into a nutritious fluid, which is absorbed by the chick, and which is not injured by the absorption of the contents of the meconium.

It is, therefore, a secretion of the young animal. During several days of incubation it increases as the chick grows, and in the latter periods does not perhaps actually diminish in quantity, but ceases to increase in proportion to the development of the chick; for which reason it appears less than it did when the chick was small. The quantity of the liquor amnii at any given time, even admitting that it is not secreted by the fetus, would be quite sufficient for the formation of the latter. The principal part of this fluid also is lost when the membrane that contains it is ruptured, previous to the liberation of the young animal from the uterus or the egg. We should, on all these grounds, deny that the liquor amnii is designed to sustain the fetus in any circumstances.

In all oviparous animals, there is no necessity for supposing the liquor amnii to be a nutritive fluid, as there are other humours provided for the purpose of nourishing the fetus. The sources of nutrition, during fetal life, are particularly evident in the ovum of birds.

In the history of incubation it will be found, that the albumen begins to diminish as soon as the fetus becomes apparent, that it continues to decrease regularly as the chick grows, and that this fluid is entirely consumed at the end of incubation: there is, therefore, no doubt that the white of the egg is the substance from which the chick is formed. It has been supposed by some writers, that the yolk also contributes to the support of the chick while in the egg.

This opinion rests chiefly upon the circumstance of the yolk becoming larger and more fluid after the white begins to diminish, which has been attributed to the albumen passing into it, that the two fluids might be mixed together, and afterwards converted into the substance of the chick. Maitre Jan, Leveille, and others believed, that the white is absorbed by the chalaza, and thus conveyed into the yolk-bag, and Leveille has even pretended to demonstrate the tubular structure of one of the chalazae. We have already stated, that by the strictest examination we could not perceive the structure described by Leveille; we are therefore led to conclude, that the fluidity of the yolk, during incubation, is occasioned by the organization of that humour undergoing a change from the application of heat. We have found also the yolk become fluid when eggs were fat upon, which had not been fecundated by the cock, and in which the white was not sensibly diminished. The weight of the yolk at the end of incubation, almost proves that it is not concerned in the nourishment of the chick, until after the animal is excluded from the egg.

We confess, however, that we are unable to form a decided opinion with respect to the manner in which the albumen is stored into the body of the chick. Throughout incubation, the white tends to the yolk, and finally, all the white of the egg is absorbed by the chick; the chick is placed at the upper and great end. There is, therefore, no direct communication between the chick and the albumen. The blood-veins of the egg have apparently no immediate connection with the white, until its proper membrane is formed, at which time this humour is already much reduced, and even then there are only a few wandering vessels spread over its membrane. These facts afford reason for the supposition that the white passes into the yolk-bag, through the chalaza; but, on the other hand, it is fearfully credible that the white, after being mixed with the yolk, should alone be absorbed during incubation, and the latter fluid left undiminished.

The chalaza, whether they perform the office of absorbers or not, act as ligaments to the yolk-bag, and have the effect of keeping, throughout incubation, that surface of the bag uppermost on which the chick is situated, in order that it may receive heat from the hen. See Eccl.

The use of the vehicula umbilicalis is a subject on which no satisfactory theory has been yet made out.

The older anatomists supposed this part to be a reservoir of urine, and gave it the name of allantois. Lobstein con-
ders the fluid of the vesicula and the allantois as the nutri-
ment of the fetus during the first periods of its existence.
Sommerring and Plunenbach supposed that the vesicula umbi-
calis is intended for the nourishment of the fetus in the hu-
man subject. Although it does not appear that this use of the
vesicula or allantois has been in any degree proved, the argu-
ments employed are conclusive against it being a reservoir
for urine, and particularly so with respect to birds and the human
subject.

The vesicula umbilicalis attains a considerable size, and is
filled with its proper fluid before the kidneys exit; and
although the membrane continues to increase, the quantity of
the fluid it contains by no means keeps pace with the growth
of the kidneys. We cannot admit the reasoning of Haller,
who contends that the existence of fluid in the allantois is
a proof that the kidneys secrete urine before they are visi-
ble.

It has not yet been ascertained that the fluid contained
in the allantois is urine even in quadrupeds, where this bag
communicates so plainly with the bladder. Leblin found,
after the allantois had acquired a very considerable bulk, that
the kidneys were small and pale, and resembled organs which
had not yet been called into action. The bladder also was
contracted. He very judiciously remarks, that if the allan-
toises were distended to the size that it is known to possess
in the early periods of gestation and incubation by the secre-
tion of the kidneys, it would become before birth a most
prodigious sac. It is extremely improbable that the secre-
tion of urine should diminish or be suspended after the kid-
nies were perfectly formed, by which supposition alone the
smaller relative size of the allantois in the latter periods of
fetal life could be explained.

We may further observe, that there is no reservoir provided
for any of the other secretions of the fetus, and that even
the gall-bag is not remarkably distended, although it evi-
dently contains bile some time before birth, and notwithstanding
the liver is the largest gland in the body.

In describing the progress of incubation, we have mention-
ed, that the vesicula umbilicalis of birds contributes to the
formation of the membrane called the chorion; that its
fluid disapppars, leaving behind it some layers of a soft cal-
careous substance, resembling the excrement of birds, or rather
the solid parts of the urine of those animals. This excrementitious
matter has been considered a proof of the vesicula being the receptacle
of the urine, but it should be observed that the same sort of sub stance is found after the
consumption of all the fluids of the egg.

The functions of the vesicula umbilicalis in birds, if there
be any peculiar to it, are lost in those of the chorion.

By recurring to the history of incubation, it will be found
that the external membrane of the yolks bag, on which the
vascular area is spread, and the chorion, receive a vastly
larger quantity of blood than circulates at any one moment in
the body of the chick. The chorion is not originally a va-
cular membrane; its vessels arise with the vesicula umbilicalis,
by which they are conducted from the body of the fetus.
The vascularity of the chorion in some degree succeeds that
of the vascular area; it appertains chiefly to the arterial
system, whilst that of the area is almost entirely produced by
veins.

The use most commonly ascribed to these two great systems
of extraneous vessels, is the oxidation of the blood of the fetus, for which purpose it is also believed that the air is ad-
mitted into the great end of the egg. We have, however,
been led to entertain a different opinion of the offices of the
vascular area, chorion, and air-cell, in consequence of some
experiments we have made, which we shall lay before the
reader.

**Experiment 1.**—Two eggs of a hen were opened at the
great end by destroying the shell and outer layer of the
membrane composing the air-cell. The blood-vessels were
seen through the membrane of a deep purple colour. Being
exposed to the atmospheric air, they became, in a few
minutes, a vivid scarlet. The same eggs were then placed
in a jar filled with fixed air, and their blood very soon re-
assumed its original purple colour; and upon the eggs being
again brought into the common air, the scarlet colour of the
blood was speedily revived. One of these eggs had its
blood rendered venous and the other arterial, in the manner
above-mentioned. Both were then placed in a vessel of water,
in which they remained all night, and on the next morning
each continued to preserve its proper colour.

**Ex. 2.**—We took an egg which had been fat upon 18
days, and having removed a square portion of the shell and
membrane forming the air-cell, about a quarter of an inch in
size, it was placed in a jar of carbonic acid gas, over a bath
of quicksilver, which was kept throughout the experiment,
as nearly as possible, at the temperature of 104 Fahrenheit.
The motions of the chick ceased when a egg to roll upon a smooth
surface, but in this instance no motion was perceived. After
the egg had remained an hour in the fixed air it was taken
out, and the aperture of the shell was carefully closed with
paper and glue, and two hours elapsed before the egg began
to roll upon the surface of the mercury. Upon this occa-
sion, therefore, the chick appeared to have been submitted
three hours to the influence of carbonic acid gas without
being destroyed.

**Ex. 3.**—An egg, at the 18th day of incubation, was
deprieved of the greatest part of the shell, and of the mem-
brane that lines the shell, so that the vessels of the chorion
were fully exposed. The membrane of the chorion was
moistened to increase the effect. The egg was suffered to
remain for 25 minutes in the fixed air, during which time
the chick flowed no motion; but upon being removed into
atmospheric air it struggled as usual.

**Ex. 4.**—The air contained in the cells, during the latter
stages of incubation, was collected from a number of eggs,
and subjected to experiment in a graduated glass tube. It
afforded, as nearly as may be, the same products that are
obtained from atmospheric air, after it has been spoiled by
respiration; from which it would appear, that it was the presence of undiluted fixed air in the 2d and 3d experi-
ments that caused the motions of the chick to cease, and
not the absence of oxygen gas.

**Ex. 5.**—Being aware of the fatal effects upon the
chick, which have been reported to follow covering the
shell of the egg, so as to stop the further admission of air
into it, we varnished the surface of several eggs at different
periods of incubation. The result of this experiment was
nearly the same in every instance. The chick always died;
not, however, immediately, but in two, three, or four days,
and apparently not in consequence of being supplied with
fresh air, but from being unprovided with any kind of air
to occupy the space caufed by the expenditure of the fluid
contents of the egg in the formation of the chick: for in
these cases, we found the yolks more or less disorganized, the
membranes sometimes ruptured, and the fetus always mal-
formed or imperfectly developed. If the death of the chick
had been occasioned by the deprivation of oxygen, it would
have been immediate, and unattended with any change in the
structure of the fetus.

The gradual admission of air into the eggs of birds takes
place as a matter of necessity, because the shell, being hard and
unyielding, cannot accommodate its form to the bulk of its
contents in proportion as they diminish; for the parts origi-

INCUBATION.
nally contained in the egg occupy a much larger space, as already mentioned, than when the chick is fully formed. The preceding experiments prove that the air does not pass into the egg for the purpose of effecting any change in the blood of the fatal chick, similar to the process of respiration, as has been generally supposed. It is true, nevertheless, that when the blood is frill expelled to the air contained in the great end of the egg, it becomes oxygenated by it; and hence, during the first days of incubation, all the blood-vessels of the vascular area are observed to be of an arterial colour; but as there are no means of expelling the air as it becomes spoiled, and as the supply of pure air afterwards is too small in quantity to produce any effect upon the blood, all the vesseis are of the purple or venous colour in the latter periods of incubation. This appearance of the blood has been observed to exist by many writers upon incubation, and coincides with the experiments we have related above.

It may be asked, what end is answered by the distribution of so much blood to the membranes of the egg, if it be not for its exposure to oxygen gas? This is a question which, perhaps, cannot be solved by direct experiments.

We conceive, however, that it is necessary, during fetal life, to have a greater quantity of blood formed than is employed in the organs of the young animal. The functions of the blood-vessels of the fetus are almost confined to the creation of its body; but in the adult animal the principal part of the mass of blood is consumed in furnishing the various secretions. The vascular membranes of the ovum may be considered as performing the office of the various secretory organs, the actions of which are dormant, at least during the early periods of fetal life. By this means also the organs of the body are accustomed to the preparation and presence of a quantity of blood which is wanted immediately after the young animal leaves the uterus or the egg; indeed, without such a provision, it would seem to be impossible for the fetus to assume, in a moment, the functions of an independent state of existence.

Further, the extraneous circulation on the membranes appears to be the means by which the nutritive fluids of the egg are converted into blood. This is almost demonstrated in the vascular area, in which the red blood appears before its vesseis have any visible connection with the body of the chick.

The membrane containing the vascular area, therefore, we deem the organ of nutriment and assimilation. It corresponds to the different viscera which convert the food into blood in the full-grown or perfect animal. The chorion of birds supplies the place of the viscera, which return the particles of the adult body to the common flock of nature. We could draw many arguments in support of this theory from the anatomy of the lower classes of animals, and from the structure of the vascular system in particular animals of a higher rank; but it does not seem confident, with the nature of the present article, to enter into an extensive physiological discussion.

If it be admitted that the blood of the fetus does not receive that effect from the air which gives the arterial character, it becomes desirable to ascertain the power of the fetus for generating animal heat. With this view we have instituted the following experiments.

Ex. 1.—An egg, on which the hen had sat 17 days, was placed upon a bath of mercury heated to 104° of Fahrenheit, and kept at that temperature for several hours. The heat of the room was 75°. The upper surface of the membranes, when the shell was broken to admit the thermometer, raised the instrument to 92°. The interior of the egg was 95°, and on the instrument being thrust down so as to touch that part of the shell in contact with the mercury, it did not rise higher than 100°. From this experiment, the standard heat of the chick appeared to be about 95°.

Ex. 2.—An egg, at the same period of incubation as the last, had the shell entirely removed, and was placed upon a mercurial bath at the heat of 83°, the air of the apartment being 75°. The centre of the egg preserved the instrument at 88°, and when pushed down upon the membranes next the mercury, it did not fall below 95°.

Ex. 3.—A chick, about 18 days old, was removed from the egg and its membranes, and exposed for some time upon the surface of a bath of quicksilver at the temperature of 79°, and becoming gradually cooler as the heat of the surrounding air was 75°. The thermometer was introduced into the thorax of the chick, and stood at 80° for a short time, even after the chick had died.

The heat of the different parts of the incubated egg cannot be expected to correspond with each other as long as external heat or cold is applied to one surface only, but the three last-mentioned experiments, notwithstanding, appear to us conclusive, with respect to the fatal chick pos- sessing an independent temperature, and being capable of refitting, to a certain extent, both foreign heat and cold.

It is proper to observe, that we have made some experiments with respect to the oxidation of the blood, and the animal heat of the fetus in mammals, which entirely correspond in their results with those above related; and, therefore, fortify our opinion with regard to the absence of any process analogous to respiration during fetal existence, and likewise prove that the young animal has an independent temperature.

We have already mentioned that the yolk loses very little, if any, of its original weight during incubation; but that after the chick is excluded from the shell it is speedily consumed. This humour, therefore, is obviously designed for a provisional nutriment to sustain the chick until it is able to procure a sufficient quantity of its natural food. This disposition of the yolk is particularly necessary to those birds that live in a wild state, but is useful to all.

Anatomists are divided with respect to the manner in which the yolk is conveyed into the vitellum of the chick. Some assert that it passes into the alimentary canal, through the ductus vitello-intestinalis, where it is digested previous to its being absorbed by the lacteals. Others deny that it is to be found in the stomach or intestines, and believe that it is absorbed immediately from the yolk-bag. We are disposed to adopt the latter opinion, both from the natural history of the bird, which indirectly go to disprove the passage of the yolk through the ductus vitello-intestinalis.

In the first place, there does not seem to be any power by which the yolk can be transmitted into the intestines. The yolk-bag itself has no muscular coat, and the mere pressure of the parietes of the abdomen of the chick, even if sufficiently strong, would be exerted as much upon the intestines as the yolk-bag, and might therefore as readily urge the contents of the former into the latter, as the yolk into the gut; for the ductus vitello-intestinalis does not penetrate the coats of the intestine obliquely, so as to produce the effect of a valve, but has merely a slight contraction at the orifice, which must operate equally on both sides.

There would appear to be no necessity for the yolk to pass into the alimentary canal, or to be subjected to any process of digestion or assimilation previous to its entering the
the system of the chick. It is already a vital fluid, which is
proved by Mr. Hunter’s experiments upon the temperature
of eggs. (See Eec.) If the humour of the egg did
not possess vital properties, they would very soon become
putrid from the heat of incubation.
When we contemplate the structure of the yolk-bag, it
must be perceived to be not only continuous with the intes-
ninal canal, but to resemble the latter in organization, ex-
cept that the mucular coat is wanting. The external
membrane of the bag differs in no respect from the peritoneal
cost of the intestines; and the internal membrane is so
analogous to the villous coat, that we cannot hesitate to allow
them the same functions. No advantage, therefore,
would be gained by the palling of the yolk into the in-
testine.
The absorption of this humour, by the valvular or in-
ternal membrane of the yolk-bag, seems proved by the
organization of the yolk undergoing a change upon the
surface which is in contact with the membrane, while
the central part is unaltered. The circumstance also, of a con-
crete subsistence, refembling the residue of the albumen, being
left in the yolk-bag after the nutritious parts of the yolk
are consumed, affords a strong evidence that the latter are
removed by a process of absorption; for if the yolk passed
through the ductus vitello-intestinalis, it would disappear
without diffusion of parts.

The authors who believe that the yolk is carried into
the system without a previous preparation in the alimentary
canal, attribute the office of absorption to the red veins.
In proof of this opinion Blumenbach and others state that
they have detected upon some occasions a yellow fluid in
the veins of the bag, which they have supposed to be the
yolk in its passage. Notwithstanding this appearance, which
we have sometimes also seen, it appears to us most probable
that the yolk is absorbed by the same system of vessels
which take up the chyle from the small intestines. The
yolk-bag and intestinal canal, as already mentioned, are
continuous parts, and similarly organized. The yolk-bag
is, in fact, a process of the intestines, and should be con-
fidered as a portion of the body of the chick. It is sup-
plied by the same blood-vessels as the intestines; why should
we therefore deny it the lactic vessels?

Another argument against the absorbing function of the
veins of the yolk-bag may be deduced from the size of
these vessels at different periods. During the early part
of incubation they are large and numerous; but after the
yolk-bag passes into the abdomen of the chick, where their
absorbing function chiefly, if not entirely, exists, if it does at
all, they become smaller and fewer than the arteries.
The vessels of the yolk-bag, when they constitute the vascular
area, are the organs of fascination for the chick. After
incubation they appear to become the nutritive vessels of
the bag itself.

It may seem not easy to align a use for the ductus vitello-
intestinalis, unless we grant it to be for transmitting the
substance of the yolk into the alimentary canal. If, how-
ever, this should not be the case, still a communication
would probably exist between the yolk-bag and the in-
testine; for it is without example, we believe, for the con-
tinuity to be interrupted by two adjoining cavities that
have a similar organization. The ductus vitello-intestinalis
we think, therefore, would exist as a matter of course,
independently of any offices it might perform. We have
described the purposes this part serves in the full grown
bird; it is not, therefore, without its use.

For the history of foetal life in oviparous animals in ge-
eneral, see Ovum.

*INCBUS*, from the Latin *incubare*, to
lie or sit upon, the same with the English *night-mare*, signifies
a state of imperfect sleep, accompanied with an oppression
of the breathing, and frightful dreams.

By the Greeks this affection was designated by a name
of similar import, *híx, ep calle*, from the verb *híx, ep calle*,
I sleep upon; and it has received various other appellations
expressive of the sense of weight and oppression of the
chest, the laborious respiration, &c. as well as indicative of
the hypostheses by which it is occasioned, was explained.
Thus it has been called *in*cal. *xým*, *eipelleia nóturum*,
*epíhara nóturum*, &c. and by Pliny, *luvinum faunum*, from
the same notion which dictated the more modern appellations
of bag-riding, wizard-freeling, mare-riding; *diev mab*, or *dar
viten der mab*, of the Germans; *cochin?,* of the French;
night-mare, &c.

This disorder seizes persons, while sleeping, who imagine
that they feel an extraordinary compression or weight about
the breast and stomach, which they cannot by any effort
shake off. In this agony they sigh, groan, and utter in-
distinct sounds; sometimes they cry out, but more fre-
quently they attempt to speak, or to move in vain. These
feelings give rise to various frightful suggestions of the
imagination; the patient fancies himself to be struggling
with strong men or devils, or to be in a house on fire, or
in danger of being drowned in the sea or some river; and
in attempting to run away from danger, or climb up a hill,
he fancies he falls back as much after every step as he had
advanced before. At length the sensations of oppression
become intolerable, and the patient awakes; but the terror
excited by the frightful ideas attending the night-mare,
leaves often a palpitation of the heart, with great anxiety
and languor, and sometimes a tingling of the ears, and a
tremor over the whole body.

It is altogether unnecessary to attempt an enumeration
of the numerous hypothetical explanations which have been
attempted to be given of the phenomenon of *incubus*, and
which have been detailed by Awen, Bond, and other writers.
(See Awen, Poét. inaur. de Incubus. Argentorat. 1676.
Bond, Eilay on the Incubus or Night-mare, 1753.)
The disorder has commonly been supposed to proceed from a
famine of the blood in the sinuses of the brain, or in the
vessels of the lungs, or from too great a quantity of blood
being sent to the head. The horizontal posture in time of
sleep, and the pressure of the stomach upon the aorta,
has, in a supine situation, been thought sufficient to occasion
a more than usual dilatation of the *sinales* and other vessels
of the brain; and the weight of the heart, pressing on the left
auricle and large trunks of the pulmonary veins, may, it is
supposed, prevent the easy return of the blood from the lungs,
and thus produce an oppression and sense of weight and ful-
nication in the breast. (See Bond, chap. ii.) But without entering
into a particular examination of these opinions, which are far
from being satisfactorily, we may observe, with Dr. Whytt,
that, if they were true, some degree of the night-mare ought
to happen to every body that lies upon his back, especially
after eating a full meal. Further, if a horizontal situation
could overload the brain with blood, so as to occasion the
incubus, how comes it that people, who remain for some
time in an inverted posture, do not feel this diseased beginning
to attack them? And why does a lighter degree of the
night-mare sometimes seize people who sleep in an erect
situation in a chair? a circumstance which sometimes occurs,
not only after eating, but when the stomach is out of
order,
order, and troubled with wind. As the weight of the
stomach, even when filled with food, can have scarcely any
effect upon the motion of the blood in the aorta, so the
preasure of the heart is by much too small to be able sufficiently
to retard the motion of that fluid in the pulmonary veins,
otherwise, people exhausted by tedious diseases, who gene-

erally lie on their back, would be constantly affected with the
inclusus.

We know that certain medicines or poisons, worms, and
even corrupted bile, or other humours, by disagreeably af-
fecting the nerves of the stomach, produce an oppression
about the breast, wild imaginations, frightful dreams, raving,
and insensibility; and there is no doubt that low spirits,
melancholy, and disturbed sleep, often proceed from a dis-
ordered state of the stomach. It seems, therefore, more pro-
bable that the feat of the night-mare is principally in that
organ. It is well ascertained that some forms of epilepsy,
and of hysteric fits, originate from disorder in that viscus; and
Galæn considered the inclusus as a nocturnal or lighter
epilepsy. People troubled with nervious and hypochondrial
affectations, and who have delicate or flatulent stomachs, are
more peculiarly subject to this disorder; and it is observed,
that a heavy or flatulent fupper greatly aggravates the
night-mare, in those who are predisposed to it. The symp-
pathy of the stomach with the head, heart, lungs, and dia-
phragm, is so remarkable, that there can be no difficulty
in referring the several symptoms of the inclusus to a dis-
agreeable irritation of the nerves of the stomach.

The inclusus is most apt to seize persons when lying on

their back, because, in this position, upon the stom-
ach and other abdominal viscera preffing more upon the
diaphragm, we cannot inspire with the same ease as when
we lift up or lie on one side. Further, in that situation of
the body the food keens to lie heavier on the stomach, and
wind in it does not separate so readily by the eophasus and
pylorus, as in an erect posture, when those orifices are higher
than the other parts of the stomach. The night-mare only
occurs in the time of sleep, because the strange ideas excited
in the mind, in consequence of the disordered feelings of
the stomach, are not then corrected by the external senses
as they are when we are awake; nor do we, by an increased
respiration or other motions of the body, endeavour to shake
off any beginning uneasy fenation about the stomach or
breast. The inclusus generally occurs in the first sleep, and
seldom towards morning, because at the earlier period the
stomach is more loaded with food, and that in a more
crude and indigestible state than in the morning. A lesser
degree, amounting only to frightful dreams, is almost a
constant concomitant of overburdened stomach in some habits.

See Dream.

In fact, if the night-mare were owing to a stagnation of
the blood in the lungs from the weight of the heart, or in
the veins and other vessels of the brain from the horizontal
position of the body, it would become greater the longer it
continued, and would scarcely ever go off spontaneously.
But we know that this disease, after affecting people for
some time, often gradually ceases, and is succeeded by re-
trefhing sleep; for as soon as the load of meat, or wind, or
other cause disagreeably affecting the nerves of the stomach
is removed, the oppression and weight on the breast, wild
imaginations, frightful dreams, &c. vanish; as all these pro-
ceed originally from the disorder of the stomach. It may
be remarked, however, that, as neither flatulency, phlegm,
or crudities in the stomach, ever produce the symptoms of
hypocondriasis, unless the nerves of that organ be indisposed;
so neither a horizontal posture, sleep, nor heavy foppers, ever
produce the night-mare, at least in any considerable de-
gree, unless the person be already predisposed to the com-
plaint, from the particular condition of the nerves of the
stomach.

But although the stomach is the part commonly affected
primarily in the case of inclusus; yet symptoms like those of
the night-mare may sometimes arise without any fault of
the stomach, when the lungs, or even the brain, are affected.
Thus Dr. Whytt observes, that asthmatic patients, whose
lungs are much obstructed, are sometimes disturbed, in time of
sleep, with distressing dreams, and oppressed with a sense of
fussication. Startings and oppressions about the precordia,
with painful dreams, are indeed common occurrences from
hydropothoras, chronic coughs, and other pulmonary obstruc-
tions; but they are not distinctly analogous to the common
night-mare. Dr. Lowr mentions a patient, who, though he
could sleep very easily with his head inclined forward; yet,
in the opposite situation, he was always soon awakened with
horrid dreams and tremors; the cause of which appeared,
after his death, to have been a great quantity of water in the
ventricles of the brain. At all events, a plectoric state of
habit, by rendering the circulation through the lungs less free,
may help to produce, or at least increase, the oppre-
sion of the breast in the night-mare.

The Cure.—As inclusus, then, is only a symptom of dis-
d ordered or loaded stomach, and arises out of the irritation
and morbid feelings which are thus produced during sleep, the
relief of the disease, generally speaking, lies within a nar-
row compass. Temperance in eating and drinking, especially
at late hours; taking, in fact, either extremely light foppers
or none at all; and when the dinner is to late as to be only
a supper with another name, being cautious that that also
should be moderate in quantity, and easily digestible and un-
flaminating in its nature; drinking thin, sub-acute liquors,
where these are agreeable to the constitution; these are
the principal remedies required. Brisk active exercise, by
which the digestive powers may be added and the stomach strengthened, is also advisable. It were useful, too, to sleep
with high pillows, and to lie on the side as much as possible,
in preference to the back. If the functions of the stomach are
much disordered with flatulency, heart-burn, acidity, or
oppression, with pain, or nausea, after taking food, the
remedies recommended for indigestion (which we) must be refor-
ted to. The bowels should be kept open. See Whytt on Ner-
vous Disorders. chap. vi § 18.

INCUMBENT. In Law, a clerk resident on his benefice,
with cure.

He is called incumbent of such church, because he
ought to tend his whole study to discharge his cure. See
RECTOR and VICAR.

INCOMBRAN'T. See QUÆRE INCUMBANT.

INCURABLE. The name of one of the celebrated con-
serveraries or music-schools at Venice, where orphan girls,
or girls of worthy parents in indigence, were to be
well educated and regularly bred to music as a profession.
Galuppi was master of this conservatorio in 1779, when the
composition and performance were exquisite.

INCURVATION, the act of bending a bone, or body,
other body, from its natural shape.

INCURVATION of the Rays of Light. See LIGHT, and
REFRACTION.

INCUS, in Anatomy, one of the small bones contained in
the cavity of the tympanum. See EAR.

INCUSUS, in Geography, a town of Africa, in the king-
dom of Congo; 86 miles S. of St. Salvador.

INDAL, a town of Sweden, in the province of Medel-
pal.
pad, on a river of the same name. N. lat. 62° 34'. E. long. 16° 23'.

INDEA, a town of Africa, in the kingdom of Yemen, on a river of the same name.

INDEBITATUS ASSUMPIT, in Law. See Assumpit.

INDECIMABLE, Indecimablis, is applied to things not titchable, or which by law ought not to pay tithes.

INDEFEASIBLE, or Indefeasable, signifies what cannot be defeated, or made void. As, a good and indefeasible estate. No one, who considers our laws, constitution, and history, without prejudice, and with any degree of attention, will assert, that the doctrine of hereditary right implies an indefeasible right to the English throne. See Right of Crown.

INDEFINITE, Indeterminate, that which has no certain bounds, or to which the human mind cannot affix any. Des Cartes uses the word, in his philosophy, instead of infinite, both in numbers and quantities, to signify an inconceivable number, or number fo great, that an unit cannot be added to it; and a quantity so great, as not to be capable of any addition.

Thus he says, the stars, visible and invisible, are in number indefinite and not, as the ancients held, infinite; and that quantity may be divided into an indefinite number of parts, not an infinite number.

INDEFINITE is also used, in the School's, to signify a thing that has but one extreme: for instance, a line drawn from any point, and extended infinitely.

Thus, what they call eternity a parte ante, or eternity a parte post, are indefinite durations.

INDEFINITE, in Grammar, is underfoot of nouns, pronouns, verbs, participles, articles, &c. which are left in an uncertain indeterminate sense, and not fixed to any particular time, thing, or other circumstance.

INDEFINITE Proposition, in Logic. See Proposition.

INDELAVOY, Indelavoy, or Indelvais, in Geography, a town of Hindoostan, in Gootcord, lying in the route between the Godavery and Hydrabad; 75 miles N. of Hydrabad. N. lat. 18° 26'. E. long. 78° 40'.

INDELIBLE, formed from delere, to blot, with the preposition in, taken negatively, that which cannot be blotted out, or effaced.

Thus baptism, and the order of the priesthood, are said to convey indelible characters.

INDEMNITY, formed from the negative in, and damnum, loss, in Law, an act by which one promises to guarantee, or save harm to some other person from any loss or damage that might accrue to him on any particular account.

When a church is appropriated to an abbey, or college, the archdeacon lotheth his induction money for ever; in recompense whereof he shall have yearly, out of the church so appropriated, one or two shillings, more or less, for a pension, as was agreed at the time of the appropriation; and this pension is called an indemnity.

INDEMNITY, with regard to eftates. See Warranty.

INDEMNITY. See Act of Grace.

INDEN, in Geography, a town of Switzerland, in the Valais; 18 miles E. of Sion.

INDEN-HOTUN, a town of Chinefe Tartary, the capital of the Manchew Tartars, where they began to establish their empire over China. N. lat. 41° 46'. E. long. 124° 26'.

INDENTATIONS of the Coaft of the Ocean, in Geology, or the peninsula, headlands, points, bays, gulfs, cleftures, &c. which occur on the shores of most islands and continents, are phenomena worthy the attentive consideration of geological observers. M. de Luct, in his Geological Travels, vol. i. p. 332 and 336, has considered many of the circumstances attending the headlands and gulfs of the northern coast of Europe, and very properly represents, that they arise from the system of vallies and hills, which are seen inland, continuing down much below the present level of sea, even to the greatest fathomable depths in some inlets: and Mr. Farcy, who has remarked on this part of M. de Luct's work in the Philosophical Magazine (vol. xxxvi. p. 7.), observes, that the hills all evidently ran out in headlands into the sea, just as they would into a sea at a level considerably above the present, of which a perfect idea may be obtained by tracing an extended level line in any country; and that the operations of the tides and waves have a powerful tendency, in most inlets, to leaven the indentations of the coasts, by washing away the projecting points of hills, and throwing up the alluvial matters therefrom in the intervening gulfs, where marshes are accumulated; and that the coasts, where cliffs or precipices occur at the headlands, equally, have not originated, in most inlets, from faults or depressions of the earth under the sea bottom, but are occasioned by the falling and washing away of the points of the hills. It is evident, that where rocky cliffs fringe the borders of the gulfs, as well as the headlands of a district, such cliffs have a different origin from those which are confined to the headlands. See Encroachment of the Sea.

INDENTED, Indentee, in Heraldry, is when the outline of a bordure, ordinary, &c. is notched, in form of the teeth of a saw.

INDENTED Leaf. See Serrated LEAF.

INDENTED Line, in Fortification. See Redens.

INDENTED Medals and Wheel. See Medals and Wheel.

INDENTURE, in Law, a writing which comprises some contract between two, at least; being indented at top answerable to another part, which has the same contents. See Deed.

INDEPENDENT Company and Troop. See Company and Troop.

INDEPENDENTS, in Ecclesiastical History, a sect of Protestants in England and Holland: so called, as desiring not only any subordination among their clergy, but also all dependency on any other assembly.

They maintain, that every separate church, or particular congregation, has in itself radically and essentially every thing necessary for its own government; that it has all ecclesiastical power and jurisdiction; and is not at all subject to other churches, or their deputies, nor to their assemblies, or synods.

Robinson, the founder of the sect, makes express use of this term in explaining his doctrine relating to ecclesiastical government: "Cum unum quinquebat particularem, (says he, in his Apologia, cap. 5. p. 22.) "ut efe totam, integram et perfectam ecclesiam ex his partibus concanatem, immediate et independenter (quod alias ecclesias) sub ipso Christo." It may probably have been from this very paimage that the title of independents was originally derived. The disciples of Robinson, originally called Brownists (which see), because John Robinson, the founder of this sect, was pastor of a congregation of Brownists that had settled at Leyden, did not reject the appellation of Independents. It was certainly utterly unknown in England before the year 1640: at least it is not once mentioned in the ecclesiastical canons and consti-
fullitions that were drawn up during that year, in the synods
or visitations held by the archbishops of Canterbury, York,
and other prelates, in which canons all the various facts that
then subsisted in England are particularly mentioned. See
William's Concilia Magnae Britanniae et Hibertiae, vol. iv.
cap. 5. p. 548.
It is true, that not long after this period, and more par-
ticularly from the year 1642, we find this denomination very
frequently in the English annals. The English Independents
were so far from being displeased with it, that they affir-
mued publicly in a piece, which they published in their
own defence at London, in the year 1644, entitled " Apo-
lyphetical Narration of the Independents." But in process
of time, in order to avoid the odium of sedition and anarchy
charged on this sect, the true and genuine Independents
renounced this title, and called themselves " Congregational
Brethren;" and their religious assemblies " congregational
churches." The first independent, or congregational church
in England, was set up in the year 1616, by Mr. Jacob, who
had adopted the religious sentiments of Robinson. The
Independents, though sprung originally from a congregation
of Brownists, were much more commendable than the latter,
both in the moderation of their sentiments, and the order of
their discipline. The Brownists, as we have already men-
tioned under that article, allowed all ranks and orders of
men prominently to teach in public, and to perform the
other pastoral functions; whereas the Independents had, and
full have, a certain number of ministers, for the most part
regularly educated, chosen respectively by the congregations
where they are fixed; nor is any person among them per-
mitt to speak in public, before he has submitted to a pro-
per examination of his capacity and talents, and been ap-
proved of by the congregation to which he ministers. The
charge alleged against them by our historian Rapin, (Hist.
could not so much as endure ordinary ministers in the
church, &c. is, therefore, evidently false and groundless.
He was led into this mistake by confounding the Indepen-
dents and Brownists. There are other charges, no less un-
justifiable, that have been urged against the Independents by
this celebrated historian, and others of less note. Rapin
says, that, with regard to the state, they abhorred monarchy,
and approved only a republican government. This might
have been true with regard to several persons among the
Independents, in common with those of other sects; but it
does not appear from any of their public writings that repub-
lican principles formed the distinguishing characteristic of
this sect. On the contrary, in a public memorial drawn
up by them in 1646, they declare, that " they do not disaf-
prove of any form of civil government, but do freely ac-
knowledge that a kingly government, bounded by just and
wholesome laws, is both allowed by God, and also a good
accommodation unto men." The Independents, however,
have been generally distinguished by the denomination of
recidives, under a notion that they were chargeable with the
death of Charles I. Whether this fact be admitted or de-
nied, and this is not a place proper for the investigation of
it, no conclusion can be fairly drawn from the greater pre-
valence of republican principles, or from violent proceed-
ings at that period, that can affect the distinguishing tenets and
conduct of the Independents in general; and especially of
the fact that bears this denomination in our times. It is
certain that our Independents are steady friends to a limited
monarchy. Rapin is farther mistaken, when he represents
the religious principles of the Independents as contrary to
those of all the rest of the world. It appears from two
confessions of faith, one composed by Robinson, on behalf
of the English Independents in Holland, and published at
Leyden in 1619, entitled " Apologia pro Exulbis Anglis,
qui Brownifte vulgo appellantur," and another drawn up in
London in the year 1659, by the principal member of this
community in England, entitled " A Declaration of the
Faith and Order formed and professed by the Congregational
Churches in England, agreed upon and confounded unto
by their Elders and Messengers, in their Meeting at the Savoy,
Oct. 12, 1658," as well as from other writings of the In-
dependents, that they differed from the rest of the reformed
in no single point of any consequence, except that of eccle-
siastical government; and their religious doctrines were
almost entirely the same with those that are adopted by the
church of Geneva. During the administration of Crom-
well the Independents acquired very considerable reputation
and influence; and he made use of them as a check to the
ambition of the Presbyterians, who aimed at a very high de-
gree of ecclesiastical power, and who had succeeded, soon
after the elevation of Cromwell, in obtaining a parliamentary
establishment of their own church government. But after
the restoration of Charles II. their cause declined; and in
the year 1691, under the reign of king William, they en-
tered into an association with the Presbyterians refiding in
and about London, under certain heads of agreement, com-
prised in nine articles, that tended to the maintenance of
their respective institutions. These may be found in the se-
cond volume of Whiston's Memoirs of his Life and Writ-
ings; and the substance of them in Mothein, ubi infra.
At this time the Independents and Presbyterians, called
from this association the United Brethren, were agreed with
regard to doctrines, being generally Calvinists, and differed
only with respect to ecclesiastical discipline. But, at pre-
sent, though the English Independents and Presbyterians
form two distinct parties of Protestant dissenters, they are
distinguished by very trifling differences with regard to
church government; and the denominations are more arbi-
trarily used to comprehend those who differ in theological
opinions. The Independents are generally more attached to
the tenets distinguished by the term orthodoxy or Calvinism,
than the Presbyterians.
Independentism is peculiar to Great Britain, the United
States of America, where it was carried first in 1620, and
by successive Puritan emigrants in 1629 and 1634, from
England, and the United Provinces. One Morel, in the
sixteenth century, endeavoured to introduce it into France;
but it was condemned at the synod of Rechel, where Beza
preached; and again at the synod of Rechel, in 1644.
On the subject of this article, see Mellein's Eccl. Hist.
by Mackense, vol. v. p. 398, &c. 8vo. Neal's Hist. of the
p. 40, &c.
INDERGEREE, in Geography, a river on the N.E.
coast of Sumatra, which runs into the sea. S. lat. 0° 33'
E. long. 101° 20'.
INDERGUR, a town of Hindoostan, in Guzerat 15
miles E. of Damarn.
INDERMAU POINT, a cape on the N. coast of Java.
S. lat. 6° 12'. E. long. 108° 18'.
INDERSKAIA, a town of Russia, on the river Urals
71 miles N. of Gurev.
INDERSOUL, a town of Hindoostan, in Baglana
12 miles E. of Bhabhour.
INDER-TAUPLITZ, a town of the duchy of Storia,
on the Enns; 14 miles W. of Rottenman.
INDERVA,
INDERVA, a small island in the Persian gulf; so

fung W. of Ormus.

INDETERMINATE, in Geometry, is understood of a
tothing other than time or place, which has no certain or
definite bounds. See INDEFINITE.

INDETERMINATE Analysis, is a particular branch of
algebra, in which there is always proposed a greater num-
ber of unknown quantities than there are equations; whence,
from what we have seen under the article Algebra, the
questions become unlimited; but in this species of equations,
the solutions must always be given in integers, or rational
fractions; and this condition frequently fixes a limit to the
number of answers that an equation admits of, and even
sometimes renders the problem impossible; though, in the
generality of cases, the number of solutions is inde-
finite. When, amongst the unknown quantities, there are
none that exceed the simple power, the equation is said to
be of the first degree: when the second power enters into the
equation, it is said to be of the second degree: and when the
third power or cube enters, it is of the third degree; and so
on.

Every indeterminate equation of the first degree, as

\[ ax + by + cz + d + \&c. = 0 \]

is solved by means of the more simple equation

\[ ap - bq = \pm 1. \]

And every indeterminate equation of the second degree has
its solution, if not absolutely depending, at least intimately
connected with the solution of the equation

\[ p^2 - N q^2 = \pm 1. \]

Before, therefore, entering upon the general solution of in-
determinate problems, it will be proper to consider more
particularly the two equations above-mentioned.

Prop. I.

To find the values of \( x \) and \( y \), in the equation

\[ ax - by = \pm 1. \]

First, if it may be observed, that this equation is always
possible under either condition of the ambiguous sign \( \pm \),
provided that \( a \) and \( b \) be prime to each other; and without
this, the equation is always impossible; because, in that
case, the first side of the equation will be divisible by the
common divisor of \( a \) and \( b \); whereas the second side, \( \pm 1 \),
has no divisor; and, consequently, no equality can obtain.

But when \( a \) and \( b \) are prime to each other, the solution may
always be obtained by the following rule: Divide the
highest of the two given numbers \( a \) and \( b \) by the other,
and then always the last divisor by the last remainder, as in
the usual method of finding the greatest common measure
of two numbers, and let the successive quotients arising
from this operation be denoted by \( \alpha, \beta, \gamma, \delta, \&c. \) See Commom
Measure.

With these quotients, placed in one horizontal row, make
the following calculation; and the terms of the last frac-
tion but one will be the values of \( x \) and \( y \) required; thus

\[ \frac{a}{1}, \frac{a + \beta}{\beta}, \frac{(a + \beta + \gamma) + \alpha}{\gamma + \delta}, \&c. \]

which may be otherwise expressed in words; thus, having
arranged the successive quotients, as above, the first fraction
will have \( \alpha \) for its numerator, and \( 1 \) for its denominator;
the second will have \( a + \beta + 1 \) for its numerator, and \( \beta \) for its
denominator; and all the other numerators will be found by
multiplying the numerator of the last fraction by the fol-
lowing quotient, and adding thereto the preceding numer-
ator, and the denominators are found exactly in the same
manner, as is evident in the foregoing fractions. See
Ratio.

Ex. 1.—Find the values of \( x \) and \( y \), in the equation

\[ 16x - 41y = 1. \]

First

\[ 2 \times 41(2) \]

\[ \frac{9}{16}(1) \]

\[ \frac{7}{9}(1) \]

\[ \frac{2}{7}(3) \]

\[ \frac{1}{15}(2) \]

quotients \( 2, 1, 1, 3, 2 \)

fractions \( \frac{2}{2}, \frac{3}{1}, \frac{5}{7}, \frac{18}{16} \)

Here the last fraction but one is \( \frac{18}{7} \), and therefore this gives
the values of \( x \) and \( y \); that is, \( x = 18 \) and \( y = 7 \), which
renders \( 16x - 41y = 1 \), as required.

Ex. 2.—Find the values of \( x \) and \( y \), in the equation

\[ 17x - 15y = - 1. \]

First

\[ 15\times 17(1) \]

\[ \frac{2}{15}(7) \]

\[ \frac{1}{12}(2) \]

\[ \frac{1}{15} \]

Quotients \( 1, 7, 2 \)

Fractions \( \frac{1}{1}, \frac{8}{7}, \frac{17}{15} \)

Therefore \( x = 7 \), and \( y = 8 \), which gives

\[ 17x - 15y = - 1. \]

The demonstration of this rule belongs properly to con-
tinued fractions, which the reader will find very ably treated
of, in the English edition of Euler's Algebra; and in most
of the French writers on that subject, particularly in the
"Ellai sur la Theorie des Nombres, par Legendre."

Having thus shewn the general method of solving the in-
determinate equation \( ax - by = \pm 1 \); it only remains to
make a few observations relating to it, and to shew, that one
solution being obtained, an infinite number of other solutions
may be deduced from the one known case.

In the above examples we found \( ax - by = 1 \), and
\( ax - by = - 1 \), as the questions required; but we are
frequently led to the solution \( ax - by = \pm 1 \), when the
question requires \(-1\), and the contrary; which seems at
first to destroy the generality of the rule; but this difficulty
is easily surmounted from the following considerations.

Let \( ap - bq = 1 \), the values of \( p \) and \( q \) being known,
to find, from this equation, the value of \( x \) and \( y \), in the
equation \( ax - by = - 1 \).

Since \( ap - bq = 1 \), we have only to make \( x = bm - p \), and
and \( y = am - q \), and it is obvious that this substitution will give
\[
(a \cdot b - p) - b \cdot (am - q) = -1;
\]
and here, by means of the indeterminate \( m \), an indefinite number of values of \( x \) and \( y \) may be determined.

If from one known case, as \( a \cdot b - b \cdot q = +1 \), the general values of \( x \) and \( y \) in the same equation \( ax - by = +1 \) were required; we should only have to make \( x = ab + p \), and \( y = ma + q \); and we should have futhill
\[
(a \cdot b + p) - b \cdot (ma + q) = a \cdot p - b \cdot q = +1,
\]
where, by means of the indeterminate \( m \), an indefinite number of values of \( x \) and \( y \) may be obtained. We will now illustrate what has been taught by an example, and then proceed to the more general equations; each of which, however, will be found to depend upon the one we have been considering.

Ex. 3.—Find the general values of \( x \) and \( y \), in the equation
\[
13x - 19y = 1.
\]

First, in the equation \( 9p - 13q = +1 \), we have \( p = 3 \), and \( q = 2 \); which gives the same sign with \( 10 \). In the proposed equation, the general values of \( x \) and \( y \) are
\[
\begin{align*}
x &= 13m + 3c, \\
y &= 9m + 2c,
\end{align*}
\]
we have therefore \( p = 3 \), and \( q = 2 \); and this gives
\[
13p - 19q = 1.
\]

Therefore the general values of \( x \) and \( y \) are
\[
\begin{align*}
x &= 19m + p, \\
y &= 13m + q,
\end{align*}
\]
Assuming therefore \( m = 0, 1, 2, 3, 4, \ldots \), we have the following values of \( x \) and \( y \),
\[
\begin{align*}
m &= 0, 1, 2, 3, 4, \ldots, \\
x &= 13, 22, 31, 40, \ldots, \\
y &= 2, 15, 28, 41, 54, 67, \ldots
\end{align*}
\]
which series may be continued at pleasure.

If the proposed equation had been \( 13x - 19y = -1 \), then having found \( p = 3 \), and \( q = 2 \), as above; we must have made
\[
x = 19m - 3 ;
\]
and then, by assuming \( m \) as before, we should have
\[
\begin{align*}
m &= 0, 1, 2, 3, 4, \ldots, \\
x &= -3, 16, 35, 54, 73, 92, \ldots, \\
y &= -2, 11, 24, 37, 50, 63, \ldots
\end{align*}
\]
where it may be observed, that the successive values of \( x \) and \( y \), in both cases, form a series of arithmetical, and may therefore be continued with great facility.

Prop. II.

To find the general values of \( x \) and \( y \), in the equation
\[
ax - by = \pm c,
\]
In the first place we must have either \( a \) and \( b \) prime to each other, or if they have a common measure, \( c \) must have the same, for otherwise the equation will be impossible; and in this latter case, the whole equation may be divided by that common measure, and thus reduced to one in which \( a \) and \( b \) are prime to each other; it will, therefore, only be necessary to consider the quantities \( a \) and \( b \) as prime to each other. Also, after what has been taught in the foregoing proposition, we may always suppose that we know the case
\[
ax - by = \pm 1,
\]
we shall have
\[
ac - b\cdot q = \pm c;
\]
but this furnishes only one solution, and in order to have the general values of \( x \) and \( y \), we must substitute \( x = mb \pm c \); and \( y = ma \pm c \); which give
\[
(a \cdot b \pm c) - b \cdot (ma \pm c) = \pm c;
\]
the ambiguous sign \( \pm \), in the two values of \( x \) and \( y \), being + when \( a \cdot p - b \cdot q \) has the same sign with \( c \), but - when it has a contrary one.

Ex. 1.—Find the values of \( x \) and \( y \), in the equation
\[
9x - 13y = 10.
\]
First, in the equation \( 9p - 13q = +1 \), we have \( p = 3 \), and \( q = 2 \), which gives the same sign with \( 10 \). In the proposed equation, the general values of \( x \) and \( y \) are
\[
\begin{align*}
x &= 12m + 5c, \text{or} \\
y &= 13m + 2c, \text{or}
\end{align*}
\]
And by assuming here \( m = -2, -1, 0, 1, 2, \ldots \), we have the following values of \( x \) and \( y \);
\[
\begin{align*}
x &= -4, 17, 40, 63, 86, \ldots, \\
y &= -2, 15, 28, 41, 54, 67, \ldots
\end{align*}
\]
each of which values has the required conditions, for
\[
9 - 4 - 13 = 10,
\]
Ex. 2.—Find the values of \( x \) and \( y \), in the equation
\[
7x - 12y = 19.
\]
First in the equation \( 7p - 12q = -1 \), we have \( p = 5 \), and \( q = 3 \); where -1 has a different sign from 19 in the proposed equation; therefore the general values of \( x \) and \( y \) are
\[
\begin{align*}
x &= 12m - 5c, \text{or} \\
y &= 13m - 9c; \text{or}
\end{align*}
\]
where, by taking \( m = 9, 10, 11, \ldots \) in order that \( x \) and \( y \) may be positive, we have
\[
\begin{align*}
x &= 13, 25, 37, 49, 61, 73, 85, \ldots, \\
y &= 6, 15, 24, 37, 50, 63, 75, \ldots
\end{align*}
\]
and in a similar manner may any possible equation \( ax - by = \pm c \) be resolved.

Prop. III.

To find the general values of \( x \) and \( y \), in the equation
\[
ax + by = c,
\]
In the foregoing proposition, where the difference of two quantities was the subject of consideration, we found that the number of solutions was infinite, provided that \( a \) and \( b \) were prime to each other; but in considering the sum of two quantities,
QUANTITIES, AS IN THE PRESENT CASE, THE NUMBER OF SOLUTIONS IS ALWAYS LIMITED, AND IN MANY CASES THE EQUATION IS IMPOSSIBLE; IT MAY HOWEVER BE DEMONSTRATED, THAT THE EQUATION ALWAYS ADMITS OF AT LEAST ONE SOLUTION, IF \( c > a - b + a \) AND \( a \) AND \( b \) BEING PRIME TO EACH OTHER; AND IT IS PROPOSED IN THE PRESENT PROPOSITION TO AFFIRM THE EXACT NUMBER OF POSSIBLE SOLUTIONS THAT ANY EQUATION OF THIS KIND ADMITS OF IN INTEGER NUMBERS, AND TO POINT OUT MORE ACCURATELY THE LIMITS OF POSSIBILITY.

THE SOLUTION OF THE EQUATION \( ax + by = \epsilon \), DEPENDS, LIKE THAT IN THE FOREGOING PROPOSITION, UPON THE EQUATION \( \alpha \beta - b \gamma = \pm 1 \), THOUGH ITS CONNECTION WITH IT IS NOT SO DIRECTLY RECOGNIZED.

LET \( \alpha \beta - b \gamma = 1 \); THEN WE HAVE ALSO \( \alpha \epsilon \beta - b \epsilon = \epsilon \), AND IT IS EVIDENT THAT WE SHALL HAVE THE SAME RESULT IF WE MAKE \( x = \epsilon \alpha \beta - m \beta ; \) AND \( y = \epsilon \gamma - m \alpha \) FOR THIS ALSO GIVES \( \alpha (\epsilon \alpha \beta - m \beta) - b (\epsilon \gamma - m \alpha) = \epsilon \), ALLOWING, THEREFORE, FOR \( m \) SUCH A VALUE, THAT \( \epsilon \gamma - m \alpha \) MAY BECOME NEGATIVE, WHILE \( \epsilon \alpha \beta - m \beta \) REMAINS POSITIVE, WE SHALL HAVE \( \alpha (\epsilon \alpha \beta - m \beta) + b (m \alpha - \epsilon \gamma) = \epsilon \), AND CONSEQUENTLY \( x = \epsilon \alpha \beta - m \beta; \) AND \( y = m \alpha - \epsilon \gamma \); BUT IF \( m \) CANNOT BE SO TAKEN THAT \( \epsilon \gamma - m \alpha \) MAY BE NEGATIVE, WHILE \( \epsilon \alpha \beta - m \beta \) REMAINS POSITIVE; IT IS A PROOF THAT THE PROPOSED EQUATION IS IMPOSSIBLE IN INTEGER NUMBERS. AND ON THE CONTRARY, THE EQUATION WILL ALWAYS ADMIT OF AS MANY INTEGER SOLUTIONS AS THERE MAY BE DIFFERENT VALUES GIVEN TO \( m \), SUCH THAT THE ABOVE CONDITIONS MAY OBTAIN.

AND HENCE WE ARE ENABLED TO DETERMINE A PRIORI THE NUMBER OF SOLUTIONS THAT ANY PROPOSED EQUATION OF THE ABOVE FORM ADMITS OF; FOR SINCE WE MUST HAVE \( \epsilon \alpha \beta > m \beta \), AND \( \epsilon \gamma < m \alpha \), THE NUMBER OF SOLUTIONS WILL ALWAYS BE EXRESSED BY THE GREATEST INTEGER CONTAINED IN THE EXPRESSION \( \left( \frac{\epsilon \alpha \beta}{m \beta} - \frac{\epsilon \gamma}{m \alpha} \right) \); AS IS EVIDENT, BECAUSE \( m \) MUST BE LESS THAN THE FIRST OF THESE FRACTIONS, AND GREAT THAN THE SECOND, AND THEREFORE, THE DIFFERENCE BETWEEN THE INTEGRAL PART OF THESE FRACTIONS WILL EXPRESS THE NUMBER OF DIFFERENT VALUES OF \( m \); EXCEPT WHEN \( \frac{\epsilon \alpha \beta}{m \beta} \) IS A COMPLETE INTEGER, OR, WHICH IS THE SAME, WE MUST CONSIDER \( \frac{\epsilon \gamma}{m \alpha} \) AS A FRACTION, AND REJECT IT, BUT NOT \( \frac{\epsilon \gamma}{m \alpha} \); THE REASON FOR WHICH IS OBVIOUS.

EX. 1.—REQUIRED THE VALUES OF \( x \) AND \( y \), IN THE EQUATION \( 9 x + 13 y = 2000 \), AND THE NUMBER OF POSSIBLE SOLUTIONS IN INTEGERS.

FIRST, IN THE EQUATION \( 9 \rho - 13 \gamma = 1 \), WE HAVE AT ONCE \( \rho = 3 \), AND \( \gamma = 2; \) THEREFORE THE NUMBER OF SOLUTIONS WILL BE EXPRESSED BY \( \frac{2000 \times 3}{9} - \frac{2000 \times 2}{9} = 46 ÷ 44 \times 17 \).

AND THESE ARE READILY OBTAINED FROM THE FORMULA \( \{x = \epsilon \alpha \beta - m \beta; \) OR \( x = 6000 - 13 \alpha \}, \) AND \( \{y = m \alpha - \epsilon \gamma; \) OR \( y = 9 m - 4000 \) \)

IN WHICH, ASSUMING \( m = 445 \), WE SHALL HAVE THE FOLLOWING SOLUTIONS, EACH OF WHICH IS DEDUCED FROM THE PRECEDING ONE, BY ADDING SUCCESSIVELY \( \gamma \) TO THE VALUES OF \( y \), AND SUBTRACTING \( 9 \) FROM THOSE OF \( x \); THUS \( x = 215, 202, 189, 176, 163, 150, 137 \&c. \)

\( y = 9, 23, 35, 47, 59, 71 \&c. \)

That is; \( 9 \cdot 215 + 13 \cdot 9 = 2000 \)

\( 9 \cdot 202 + 13 \cdot 14 = 2000 \)

\( 9 \cdot 189 + 13 \cdot 23 = 2000 \)

\( 9 \cdot 176 + 13 \cdot 32 = 2000 \)

\&c. \&c. \&c.

EX. 2.—GIVEN THE EQUATION \( 11 x + 13 y = 190 \), TO FIND THE NUMBER OF SOLUTIONS, AND THE VALUES OF \( x \) AND \( y \).

FIRST, IN THE EQUATION \( 11 \rho - 13 \gamma = 1 \), WE HAVE \( \rho = 6 \), AND \( \gamma = 5 \); THEREFORE \( \frac{190 \times 6}{11} - \frac{190 \times 5}{11} = 87 - 86 \times 1 \) WHENCE IT FOLLOWS THAT THE EQUATION ADMITS OF ONLY ONE INTEGRAL SOLUTION, AND THIS IS OBTAINED FROM THE FORMULA \( \{x = \epsilon \alpha \beta - m \beta; \) OR \( x = 190 \cdot 6 - 13 \alpha \}, \) AND \( \{y = m \alpha - \epsilon \gamma; \) OR \( y = 11 m - 190 \cdot 5 \)

WHERE, BY TAKING \( m = 87 \), IN ORDER THAT \( m \alpha - \epsilon \gamma \) MAY BE POSITIVE, WE HAVE \( x = 91 \), AND \( y = 71 \), WHICH GIVES \( 11 \cdot 9 + 13 \cdot 7 = 190 \), AS REQUIRED.

PROP. IV.

TO FIND THE VALUES OF \( x, y \), AND \( z \), AND THE NUMBER OF INTEGRAL SOLUTIONS OF ANY EQUATION OF THE FORM \( ax + by + cz = \epsilon \).

IN THE FIRST PLACE WE MAY OBSERVE, THAT IF ANY ONE OR MORE OF THE CO-EFFICIENTS \( a, b, \) OR \( \epsilon \), BE NEGATIVE, THE NUMBER OF ANSWERS IS INDEFINITE. FOR IF \( b \) BE NEGATIVE, THEN THE EQUATION MAY BE PUT UNDER THE FORM \( ax + \epsilon z = by + \epsilon \alpha \), IN WHICH, BY MEANS OF THE INDETERMINATE \( \epsilon \), AN INFINITE NUMBER OF VALUES MAY BE GIVEN TO THE SECOND SIDE OF THE EQUATION; AND CONSEQUENTLY ALSO TO \( x \) AND \( y \). WE NEED, THEREFORE, ONLY CONSIDER EQUATIONS OF THE FORM ABOVE GIVEN, IN WHICH THE QUANTITIES ARE ALL CONNECTED WITH THE SIGN \( + \).

NOW IN THIS EQUATION, AS IN THE OF THE TWO FOREGOING PROPOSITIONS, IF \( a, b, \) AND \( \epsilon \), HAVE EACH A COMMON DIVISOR, WHICH \( \epsilon \) HAS NOT, IT BECOMES IMPOSSIBLE; BUT IF ONLY TWO OF THEM, AS \( a, b, \) HAVE A COMMON MEASURE, THE EQUATION IS STILL POSSIBLE, AS WE SHALL SEE IN WHAT FOLLOWS.

THE SOLUTION OF THE EQUATION, \( ax + by + cz = \epsilon \), IS RESOLVED BY MEANS OF THE EQUATION \( \alpha \beta - b \gamma = \pm 1 \), AS WE HAVE SEEN IS THE CASE IN THE PRECEDING EXAMPLES.

For let one of the terms, as \( \epsilon \), BE TRANSPOSED TO THE OTHER SIDE OF THE EQUATION; THEN WE HAVE \( ax + by = \epsilon - \epsilon \gamma \), IN WHICH THE VALUES OF \( x \) AND \( y \), DETERMINED AS IN THE LAST PROPOSITION, WILL BE \( x = (\epsilon - \epsilon \gamma) \beta - m \beta; \) AND \( y = m \alpha - (\epsilon - \epsilon \gamma) \gamma \), THAT IS, BY ONLY SUBSTITUTING \( \epsilon - \epsilon \gamma \) INSTEAD OF \( \epsilon \), WHICH IS THE ONLY RESPECT IN WHICH THIS EQUATION DIFFERS FROM THAT IN THE FOREGOING PROBLEM; AND HERE THE ONLY LIMITS TO BE OBSERVED ARE,

\( 1 \times \epsilon < \epsilon \); \( 2d, \) \( m \beta < (\epsilon - \epsilon \gamma) \beta; \) \( 3d, \) \( m \alpha > (\epsilon - \epsilon \gamma) \gamma \)

BY ATTENDING TO WHICH, ALL THE POSSIBLE VALUES OF \( x \) AND \( y \) MAY
may be obtained. But as these questions generally admit
of a great number of solutions, the object of enquiry is
not so much to find the values of the intermediate quan-
tities, as to determine a priori the number of them that the
equation admits of; and this, therefore, shall form the sub-
ject of our future investigation.

Now we have seen, that in the equation
\[ a + b y = c, \]
the number of solutions is generally expressed by
\[ \frac{c - a}{b} - \frac{c - b}{a}, \]
and \( q \) being first determined by the equation
\[ a + b q = 1. \]
If, therefore, in the equation
\[ a + b y = d - c x, \]
we make successively \( x = 1, 2, 3, 4, \&c. \) the number of so-
lutions for each value of \( x \) will be as below; viz.
\[ \frac{(d - c + 1)b}{a} - \frac{(d - c) b}{a}, \]
\[ \frac{(d - 2 c + 1)b}{a}, \]
\[ \frac{(d - 3 c + 1)b}{a}, \]
&c. &c. &c.

the sum of which will be the total number that the given
equation admits of; and therefore, in order to find the
exact number of solutions in any equation of this kind, we
must first ascertain the sum of all the integral parts of the
arithmetical series
\[ \frac{(d - c + 1)b}{a} + \frac{(d - 2 c + 1)b}{a} + \frac{(d - 3 c + 1)b}{a} + \&c.; \]
and
\[ \frac{(d - c + 1)a}{b} + \frac{(d - 2 c + 1)a}{b} + \frac{(d - 3 c + 1)a}{b} + \&c.; \]
the difference of the two will be the exact number of
integral solutions.

Now in both these series, we know the first and last
term, and the number of terms; for the general term being
\[ \frac{(d - c + 1)b}{a}, \]
we shall have the extreme terms by taking the extreme li-
mits of \( x \), that is \( x = 1, \) and \( x < \frac{d}{a} \); which last value of \( x \)
also expresses the number of terms in the series.

Hence then, having the elements of the progressions
given, the sum of the whole series is readily obtained;
and if therefore we also find the sum of the fractional parts
in each, we shall have, by deducting it from the whole
sums, that of the integral part of the series as required.
The latter part of this problem is readily effected, for the
denominator in each term being constant, the fractions
will necessarily recur in periods; and the number in each
can never exceed the denominator; it will therefore only
be necessary to find the sum of the fractions in one period,
which being multiplied by the number of periods, will give
the sum of the fractional part of the terms; and these
taken from the total sum, will give the sum of the in-
tegral part of the series; and then, from what has been
before observed, the difference of the two sums will be the
number of integral solutions required. It may also be ob-
served, that when the number of terms do not consti-
tute an exact number of periods of circulation, the remaining
terms or fractions must be summed by themselves, which
is also readily effected, as they will be the same as the leading
terms of the first period; and it must also be remembered,
that \( b \) is to be considered as a fraction in the first series;
but not \( a \) in the second, as is explained in the foregoing pro-
position.

Ex. 1.—Given \( 5 x + 7 y + 11 z = 224, \) to find the
number of solutions that the equation admits of in positive
integers.

Here the greatest limit of \( z \) is \( z < \frac{224}{11} = 20; \) also in
the equation \( 3 p - 7 q = 1, \) we have \( p = \frac{3}{7}, \) and \( q = 2, \)
also \( a = 5, \) and \( b = 7, \) and therefore the two series, of
which the sums are required, beginning with the least term
in each, are
\[ \frac{3 \cdot 4}{7} + \frac{3 \cdot 15}{7} + \frac{3 \cdot 26}{7} + \frac{3 \cdot 37}{7} + \&c. \]
\[ \frac{2 \cdot 4}{5} + \frac{2 \cdot 15}{5} + \frac{2 \cdot 26}{5} + \frac{2 \cdot 37}{5} + \&c. \]
the common difference in the first being \( \frac{3 \cdot 71}{7}; \) and in
the second \( \frac{2 \cdot 11}{5}; \) also the number of terms in each \( 20. \)

Whence we have 930 for the sum of the first;
and 868 for the sum of the second.

Again, the first period of fractions, in the first series, is
\[ \frac{5}{7} + \frac{3}{7} + \frac{1}{7} + \frac{6}{7} + \frac{4}{7} + \frac{2}{7} = 4 \frac{1}{7}, \]
and in the second series, the first period of fractions is
\[ \frac{3}{5} + \frac{2}{5} + \frac{4}{5} + \frac{1}{5} = 2 \frac{1}{5}, \]
being considered as a fraction in the first, but not
in the second.

Now the number of terms in each series being \( 20, \) we
have 2 periods and 6 terms in the first series = \( 2 \times \frac{6}{4} \)
\[ \frac{919}{5} \]
\[ \frac{960}{5} \]
which is the number of integral solutions.

Remark.—Simpson, in his algebra, makes the number of solu-
tions to this question 601; but he has evidently intro-
duced one (viz. \( x = 10, y = 14, \) and \( z = 14) \) which
does not obtain.

Ex. 2.—Having given \( 7 x + 9 y + 23 z = 9999, \) it
is required to find the number of its solutions in positive
integers.

Here the greatest limit of \( z < \frac{9999}{23} = 434; \) also in
the equation \( 7 x - 9 p = 1, \) we have \( p = \frac{4}{7}, \) and \( q = 3, \)
\[ a = \]
INDETERMINATE ANALYSIS.

\( a = 7 \), and \( b = 9 \); also \( 9999 - 24 \cdot 434 = 17 \); therefore the series whose sums are required, will be

1st. \( \frac{4 \cdot 17}{9} + \frac{4 \cdot 40}{9} + \frac{4 \cdot 63}{9} + \&c. . . . \cdot \frac{4 \cdot 9976}{9} \)

2nd. \( \frac{3 \cdot 17}{7} + \frac{3 \cdot 40}{7} + \frac{3 \cdot 63}{7} + \&c. . . . \cdot \frac{3 \cdot 9976}{7} \)

the common difference in the first being \( \frac{4 \cdot 23}{9} = \frac{10}{3} \cdot \frac{2}{3} \)

and in the second \( \frac{3 \cdot 23}{7} = \frac{6}{7} \); also the number of terms in each 434; that being the greatest limit of \( z \).

Hence we have the sum of the first series = \( 963769 \frac{3}{9} \)

and of the second - - - - - \( 929349 \)

Also the first period of fractions in the first series, is

\( \frac{5}{9} + \frac{7}{9} + \frac{2}{9} + \frac{4}{9} + \frac{6}{9} + \frac{8}{9} + \frac{1}{9} + \frac{3}{9} \)

and \( \frac{434}{9} \) = 48 periods, and \( z \) terms = \( 5 \cdot 48 + \frac{5}{9} \cdot \frac{z}{9} = 231 \frac{3}{9} \)

And in the second series, the first period of fractions is

\( \frac{2}{7} + \frac{1}{7} + \frac{6}{7} + \frac{4}{7} + \frac{5}{7} + \frac{3}{7} \)

also \( \frac{434}{7} \) = 62 periods; and therefore 62 \( \cdot \frac{3}{7} \) = 186.

Hence \( 963769 \frac{2}{9} = 241 \frac{3}{9} = 963528 \text{ integral terms} \)

and \( 929349 - 186 = 929163 \text{ integral terms} \)

whence the difference \( 34365 \) is the number of integral solutions required.

In the foregoing examples we have had two of the terms prime to each other; but when this is not the case the following transformation will be necessary.

Ex. 3. Let there be proposed the equation,

\[ 12x + 15y + 20z = 100001, \]

to find the number of solutions.

Here no two of the co-efficients are prime to each other, and we must therefore proceed as follows.

Divide the whole equation by 3, and transpose \( z \), and we have

\[ 4x + 5y = 33334 - 7z + \frac{z - 1}{3} \]

which last must be an integer; make therefore \( \frac{z - 1}{3} = \frac{z}{3} \), and we have \( z = 3u + 1 \); substituting now this value of \( z \), the original equation becomes

\[ 12x + 15y + 20 \left(3u + 1\right) = 100001 \]

or, dividing by 3,

\[ 4x + 5y + 20u = 33327 \]

the number of solutions in which will be the same as in the equation proposed, which will be found as in the foregoing examples, except that here the least value of \( u = 0 \), because we shall then still have \( z = 1 \), and by proceeding as in the preceding examples, it will be found that the number of integral solutions that may be given to this question, amounts to no less than 1388611.

Vol. XIX.

Prop. V.

Having given any number of equations, less than the number of unknown quantities that enter therein, to determine those quantities.

Let there be proposed the two equations

\[ \begin{align*}
ax + by + cz &= d \\
a'x + b'y + c'z &= d'
\end{align*} \]

to find the values of \( x, y, \) and \( z \).

Multiply the first by \( a' \), and the second by \( a \), whence, by subtraction, we obtain

\[ \left(a'b - a'b\right) y + \left(a'e - a'c\right) z = d' - d \]

Or, dividing each of these known co-efficients by their greatest common divisor, if they have any, and representing the results by \( b', c', d' \), this equation becomes

\[ b''y + c''z = d' \]

Finding now the values of \( y \) and \( z \) in this equation; and these being substituted for them in the equation

\[ x = \frac{d - cz - by}{a} \]

will give the corresponding values of \( x \), of which, of course, must be rejected that render \( x \) fractional, and also those that give \( (c + b)y > d \).

Ex. Given the equations

\[ \begin{align*}
3x + 5y + 7z &= 560 \\
9x + 25y + 49z &= 2920
\end{align*} \]

to find all the integral values of \( x, y, \) and \( z \).

Multiplying the first by 3, we have

\[ \begin{align*}
9x + 15y + 21z &= 1680 \\
9x + 25y + 49z &= 2920
\end{align*} \]

whence

\[ \begin{align*}
10y + 28z &= 1240, \text{ or} \\
5y + 14z &= 620
\end{align*} \]

And here the values of \( y \) and \( z \) are found to be

\[ y = 110, 96, 82, 68, 54, 40, 26, 12 \]

\[ z = 5, 10, 15, 20, 25, 30, 35, 40 \]

and of these, the only two that give

\[ w = \frac{560 - 7y - 5z}{3} \]

an integer, are as follows,

\[ \begin{align*}
z &= 15, y = 82, x = 15 \\
z &= 30, y = 40, x = 50
\end{align*} \]

which are the only two solutions the equations admit of in integers.

The method above given will never fail of producing all the possible solutions in equations of the above form; but there are other methods that may be followed in particular cases which sometimes shorten the operations. These the reader will find explained in vol. ii, of Euler’s Elements of Algebra.

Prop. VI.

To decompose a given numeral fraction, having a composite denominator, into a number of simple fractions having prime denominators.

This is, in fact, only an application of the foregoing propositions to this particular problem; for let \( \frac{m}{n} \) be the given fraction; and suppose, in the first instance, that its denominator,
INDETERMINATE ANALYSIS.

denominator consists of two prime factors, or \( n = a \cdot b \), it
will then be to find

\[
\frac{m}{a \cdot b} = \frac{p}{a} + \frac{q}{b}, \quad \text{or} \quad a \cdot q + b \cdot p = m,
\]

in which equation, having determined the values of \( p \) and \( q \),
we shall have \( \frac{b}{a} + \frac{q}{b} \) for the fractions required; and as
many different ways may any such fraction be decomposed
into two others, as the equation \( a \cdot q + b \cdot p = m \) admits
of integral solutions. If the given fraction be \( \frac{m}{a \cdot b \cdot c} \), then
we may first resolve it into two fractions, and one of these
into two others; thus, let

\[
\frac{m}{a \cdot b \cdot c} = \frac{p}{a} + \frac{q}{b} + \frac{r}{c};
\]

then we have

\[
a \cdot b \cdot q + c \cdot p = m;\]

and having, from this equation, found the values of \( p \) and \( q \),
we shall have \( \frac{m}{a \cdot b \cdot c} = \frac{p}{a} + \frac{q}{b} + \frac{r}{c}. \)

Again, let \( \frac{p}{a} = \frac{r}{b} + \frac{s}{a} \), or \( a \cdot r + b \cdot s = p \), find \( r \) and
\( s \) in this equation, so shall we have

\[
\frac{m}{a \cdot b \cdot c} = \frac{r}{a} + \frac{s}{b} + \frac{q}{c},
\]

as required; and in the same manner may any fraction that
admits of decomposition be resolved into others of which
the sum shall be equal to the original fraction.

Ex.—What are those two fractions whose sum is equal
to \( \frac{19}{35} \)?

Since \( 35 = 5 \times 7 \), we may make \( \frac{19}{35} = \frac{5}{7} + \frac{4}{5} \), which
produces this equation,

\[
5 \cdot p + 4 \cdot q = 19,
\]

in which the value of \( p = 1 \), and \( q = 2 \) are readily found; and
therefore the fractions sought are \( \frac{1}{7} + \frac{2}{5} = \frac{19}{35} \).

PROP. VII.

To find the least number, that, being divided by given
numbers, shall leave given remainders.

Let \( N \) represent the required number, such that, being
divided by \( a, a', a'' \) &c., the remainders shall be respectively
\( b, b', b'' \) &c. that is,

\[
N = a \cdot m + b = a' \cdot n + b' = a'' \cdot p + b'' \text{ &c.}
\]

and it is required to find the least value of \( N \), that answers
these conditions.

First since \( a \cdot m + b = a' \cdot n + b' \),
we have \( a \cdot m - a' \cdot n = b'' - b \).

Find, therefore, in this equation, the least values of \( m \) and
\( n \) by Prop. II., then will \( a \cdot m + b \), or \( a' \cdot n + b' \), express the
least number that fulfills the first two conditions. Let now
this number be called \( c \); then it is evident that every number
of the form \( a \cdot a' \cdot q + c \) will also fulfill these conditions;
and we must proceed to find \( a \cdot a' \cdot q + c = a'' \cdot p + b'' \) &c.; or,

\[
a \cdot a' \cdot q - a'' \cdot p = b'' - c;
\]

that is, the least value of \( p \) and \( q \) in this equation; so shall
we have \( a \cdot a' \cdot q + c \) for the least number that answers the
first three conditions, and so on for as many others as may
be proposed.

Ex.—Find the least number, that, being divided by 28,
19, and 15, shall leave for remainders respectively 19, 15,
and 11.

Here we have \( 28 \cdot m + 19 \cdot n + 15 \cdot p = 11 \).

Now, in the equation \( 28 \cdot m + 19 \cdot n = - 4 \), the least values
of \( m \) and \( n \) are \( m = 8 \), and \( n = 12 \); whence \( 28 \cdot m + 19 \cdot n +
15 \cdot p = 243 \); and it now remains to find \( 19 \cdot q +
243 = 15 \cdot p + 11 \); or, \( 532 - q - 15 \cdot p = - 228 \).

In which equation \( p = 512 \), and \( q = 14 \), whence
\( 532 + 243 = 15 \cdot p + 11 = 7053 \), which is the least
number having the required conditions.

Having thus treated of the solution of indeterminate equa-
tions of the first degree, to as great an extent as our
limit will admit of, we shall proceed to those, in which one,
at least, of the unknown quantities enter in the square power,
which constitute the class of indeterminate equations of the
second degree; and as we have seen that every equation of
the first class has its solution depending upon that of the
equation \( a \cdot p - b \cdot q = \pm 1 \); so in those that we are about
to investigate, the solution is intimately connected with that
of the equation \( p' - N \cdot q' = \pm 1 \); this, therefore, is what
shall first engage our attention.

PROP. VIII.

To find the integral values of \( p \) and \( q \) in the equation

\[
p' - N \cdot q' = \pm 1,
\]

\( N \) being any given number whatever, not a complete
square.

In order to obtain the general solution of this equation,
which is always possible (at least with the positive sign) we
must shew the method of extracting the square root of
any number \( N \), not a complete square, in continued frac-
tions; but as this operation belongs properly to the latter
subject, we shall only in this place indicate the method, and
must refer the reader for the demonstration to vol. ii.
of Euler's Algebra, and to Barlow's Elementary Investigations.
See also SQUARE ROOT.

The transformation of the \( \sqrt{N} \), to continued fractions,
is performed by means of the following formula.

Let \( a \) be the greatest integer contained in \( \sqrt{N} \); then make

\[
\sqrt{N + o} = a + \frac{m}{N + m} = \frac{a - o}{N - m^2} = \frac{u}{n} = \frac{u' - n}{u'' - n'} = \frac{u'' - n''}{u''' - n'''} = \ldots
\]

In these formulae, \( u, u', u'' \) &c. are the greatest integers con-
tained in the corresponding fractions, which quantities are
the quotients, whence the converging fractions are to be
deduced, by the same rule as is given in Prop. i. for the
quotients \( a, b, c, \) &c.; and by continuing the above
operations, we shall be finally led to a quotient equal to \( 2 \),
at which term we must stop, and the corresponding fractions
to the last quotient before this will give the required values
of \( p \) and \( q \).
Ex. 1.—Required the values of \( p \) and \( q \) in the equation
\[
\rho^1 - 19 q^1 = -1. 
\]
By the above rule,
\[
\sqrt[1]{19} + O = 4 = a \\
\sqrt[3]{19} + 2 = 2 = u \\
\sqrt[3]{19} + 3 = 3 = u' \\
\sqrt[3]{19} + 2 = 2 = u'' \\
\sqrt[3]{19} + 4 = 8 = u''
\]
Required the values of \( p \) and \( q \) in the equation
\[
\rho^1 - 19 q^1 = -1. 
\]
By the above rule,
\[
\sqrt[1]{19} + O = 4 = a \\
\sqrt[3]{19} + 2 = 2 = u \\
\sqrt[3]{19} + 3 = 3 = u' \\
\sqrt[3]{19} + 2 = 2 = u'' \\
\sqrt[3]{19} + 4 = 8 = u''
\]
Having thus arrived at the quotient \( 19 = 2, a \), we have only to compute the fractions by the proposition above quoted; thus, quotients
\[
\frac{3}{1}, \frac{1}{1}, \frac{3}{1}, \frac{1}{1}, \frac{2}{1}, \frac{3}{1}
\]
and fractions
\[
\frac{1}{1}, \frac{3}{1}, \frac{4}{1}, \frac{11}{1}, \frac{18}{14}, \frac{15}{5}
\]
which last fraction gives the values of \( p \) and \( q \); that is, \( p = 170 \), and \( q = 39 \); for
\[
170 - 19 \cdot 39 = -1, \text{ as required.}
\]
Ex. 2.—Find the values of \( p \) and \( q \) in the equation
\[
p^2 - 13 q^2 = -1. 
\]
First,
\[
\sqrt[3]{13} + O = 3 \\
\sqrt[3]{13} + 3 = 1 \\
\sqrt[3]{13} + 4 = 4 \\
\sqrt[3]{13} + 3 = 3 \\
\sqrt[3]{13} + 2 = 2 \\
\sqrt[3]{13} + 3 = 3 \\
\sqrt[3]{13} + 2 = 2 \\
\sqrt[3]{13} + 1 = 1 \\
\sqrt[3]{13} + 3 = 3
\]
And having thus arrived at the quotient \( 2 \), or \( 6 \), we have for quotients
\[
\frac{1}{1}, \frac{1}{1}, \frac{1}{1}, \frac{1}{1}, \frac{1}{1}, \frac{1}{1}, \frac{1}{1}
\]
and fractions
\[
\frac{3}{1}, \frac{4}{1}, \frac{7}{2}, \frac{11}{1}, \frac{18}{5}
\]
that is, \( p = 18 \) and \( q = 5 \), which give
\[
18^2 - 13 \cdot 5^2 = -1, \text{ as required.}
\]
Ex. 3.—Find the values of \( p \) and \( q \) in the equation
\[
p^2 - 17 q^2 = -1. 
\]
First
\[
\sqrt[1]{17} + O = 4 = a \\
\sqrt[3]{17} + 3 = 3 \\
\sqrt[3]{17} + 4 = 8 \\
\]
Here we have, at the first step, arrived at the quotient
\[
2, \text{ whence the first fraction, } \frac{4}{1}, \text{ is the one sought; for}
\]
\[
4^2 - 17 \cdot 1^2 = -1, \text{ as required.}
\]
Ex. 4.—Find the values of \( p \) and \( q \) in the equation
\[
p^1 - 14 q^1 = 1. 
\]
First,
\[
\sqrt[1]{14} + O = 3 \\
\sqrt[1]{14} + 3 = 1 \\
\sqrt[1]{14} + 2 = 2 \\
\sqrt[1]{14} + 3 = 2 \\
\sqrt[1]{14} + 2 = 1 \\
\sqrt[1]{14} + 3 = 2
\]
Whence we have, quotients
\[
\frac{3}{1}, \frac{1}{1}, \frac{11}{3, 4}
\]
which gives \( 15 - 14 \cdot 4 = 1, \text{ as required.} \)

It will be observed, that in the foregoing examples we have obtained for each only one solution; whereas they all admit of an indefinite number of solutions. Moreover, it does not appear, from the first three examples, how we should have found the values of \( p \) and \( q \), if they had been put equal to \( +1 \) instead of \( -1 \). This shall, therefore, be considered in the following proposition.

**Prop. IX.**

To find the general values of \( x \) and \( y \) in the equation
\[
x^2 - N y^2 = \pm 1, \text{ from one known case } p^1 - N q^1 = \pm 1. 
\]
In the first place it may be demonstrated, but our limits will not allow of it, that the equation \( x^2 - N y^2 = \pm 1 \) is always possible for every value of \( N \), providing it be not a complete square; and the values of \( x \) and \( y \) are always deducible, both from \( p^1 - N q^1 = 1 \), and from \( p^1 - N q^1 = -1 \); but if the operation above given does not produce the equation \( p^1 - N q^1 = -1 \), the equation \( x^2 - N y^2 = -1 \) is always impossible. The present problem, therefore, divides itself into three cases; viz., to find the general values of \( x \) and \( y \) in the equation \( x^2 - N y^2 \), under the following conditions:

- 3d, \( x^2 - N y^2 = 1 \), from one known case \( p^1 - N q^1 = 1 \)
- 3d, \( x^2 - N y^2 = -1 \), \( p^1 - N q^1 = -1 \)

**Case 1.**—Resolve \( p^1 - N q^1 = 1 \), and \( x^2 - N y^2 = 1 \) into the factors
\[
\left( p + q \sqrt{N} \right) \left( p - q \sqrt{N} \right) = 1
\]
then we have also
\[
\left( p + q \sqrt{N} \right)^2 = \left( p - q \sqrt{N} \right)^2 = 1
\]
equating these, with the factors in \( x \) and \( y \), we have
\[
\left( p + q \sqrt{N} \right)^m = x + y \sqrt{N} \\
\left( p - q \sqrt{N} \right)^m = x - y \sqrt{N}
\]
whence \( x = \frac{(p + q \sqrt{N})^m + (p - q \sqrt{N})^m}{2} \) and \( y = \frac{(p + q \sqrt{N})^m - (p - q \sqrt{N})^m}{2 \sqrt{N}} \);

which values of \( x \) and \( y \) will always be integral, and will be the general values sought; and these are evidently indefinite in number, because the power \( m \) is indefinite.

**Case 2.**—The same method may be followed here, as in the preceding case, except that the powers must be even,
in order to convert \(-i\) into \(+i\), as is obvious from
inspection; and, therefore, the general values of \(x\) and \(y\)
will be

\[
\begin{align*}
x &= (p + q \sqrt{N})^n + (p - q \sqrt{N})^{n+1} \\
y &= (p + q \sqrt{N})^{n+1} - (p - q \sqrt{N})^n
\end{align*}
\]

Cafe 3.—Here, again, we have evidently the same result as
in the former cases, except that the power \(m\) must now be
odd for every odd power of \(-i\); therefore,

\[
\begin{align*}
x &= (p + q \sqrt{N})^{n+1} + (p - q \sqrt{N})^n \\
y &= (p + q \sqrt{N})^n - (p - q \sqrt{N})^{n+1}
\end{align*}
\]

Let us now propose an example in each of these three
cases.

Ex. 1.—In the equation \(p^3 - 1 = 1\), we have
\(p = 5\) and \(q = 4\), to find a second value of \(p\) and \(q\), or
of \(x\) and \(y\), in the equation \(x^3 - 1 = 1\).

Make

\[
\begin{align*}
x &= (15 + 4 \sqrt{14})^3 - (15 - 4 \sqrt{14})^3 = 449 \\
y &= (15 + 4 \sqrt{14})^{3+1} - (15 - 4 \sqrt{14})^{3+1} = 120
\end{align*}
\]

which gives 449\(^3 - 14 - 120\) = 1; and other values may be
found by assuming any other power above the second.

Ex. 2.—Given \(p = 4\) and \(q = 1\), in the equation
\(p^3 - 17q = 1\), to find the values of \(x\) and \(y\), in the
equation \(x^3 - 17 = 1\).

Here we have, again,

\[
\begin{align*}
x &= (4 + \sqrt{17})^3 + (4 - \sqrt{17})^3 = 33 \\
y &= (4 + \sqrt{17})^{3+1} - (4 - \sqrt{17})^{3+1} = 8
\end{align*}
\]

whence \(33^3 - 17 \cdot 8 = 1\); and other values may be found
by assuming any other power instead of the second.

Ex. 3.—Given \(p = 4\) and \(q = 1\), in the equation
\(p^3 - 17q = 1\), to find the values of \(x\) and \(y\), in the
equation \(x^3 - 17y = 1\).

Assume

\[
\begin{align*}
x &= (4 + \sqrt{17})^3 + (4 - \sqrt{17})^3 = 268 \\
y &= (4 + \sqrt{17})^{3+1} - (4 - \sqrt{17})^{3+1} = 67
\end{align*}
\]

whence, 268\(^3 - 17 \cdot 67\) = 1, and other values may be
obtained, by assuming other odd powers instead of the
third.

Prop. X.

To ascertain the possibility or impossibility of every equa-
tion of the form \(x^3 - N \cdot y = \pm A\); and to find \(x\) and \(y\)
in the former cases, \(A\) being \(\leq \sqrt{N}\).

The rule for this purpose, is to convert \(\sqrt{N}\) into a series
of quotients, as in Prop. VIII.; and if \(A\) be found in the
denominator of any of the quotients, that is, if \(A\) be found
amongst any of the numbers, which in the proposition
above quoted are represented by \(n, n', n'', \&c.,\) the equa-
tion is possible, and the converging fraction corresponding
to the quotient preceding this will give the values of \(a\) and \(y;\)
but if \(A\) be not so found, then the equation is impossible.

This theorem cannot be demonstrated in this place, as it
belongs to the theory of continued fractions, and the reader
is therefore referred for a proof of the rule to Le Gen-
dre's Élai fur la Théorie des Nombres.

Ex. 1.—Required the values of \(x\) and \(y\), in the equation
\(x^3 - 23 \cdot y^2 = 2\).

Here by the rule Prop. VIII.,

\[
\begin{align*}
\sqrt{23 + 0} &= 4 & 1 \cdot 4 - 0 &= 4; & 23 - 4^2 &= 7 \\
\sqrt{23 + 4} &= 1 & 7 \cdot 1 - 4 &= 3; & 23 - 3^2 &= 2 \\
\sqrt{23 + 1} &= 3 & 7 \cdot 3 - 4 &= 10
\end{align*}
\]

Having thus arrived at the denominator 2, it follows that
the equation is possible, and the values of \(x\) and \(y\) are
found from the same calculation as at Prop. VIII.; thus

quotients \(\frac{4, 1}{3, 5}\)

fractions \(\frac{2}{1}, \frac{1}{2}\)

whence \(x = 5\), and \(y = 1\), which gives \(x^3 - 23 \cdot y^2 = 2\).

Ex. 2.—Required the values of \(x\) and \(y\), in the equation
\(x^3 - 19 \cdot y^2 = 5\).

First

\[
\begin{align*}
\sqrt{19 + 0} &= 4 & 1 \cdot 4 - 0 &= 4; & 19 - 4^2 &= 3 \\
\sqrt{19 + 4} &= 2 & 3 \cdot 2 - 4 &= 2; & 19 - 2^2 &= 5 \\
\sqrt{19 + 2} &= 1 & 1 \cdot 1 - 2 &= 1
\end{align*}
\]

Having therefore found the denominator 5, the equation is
possible, and we have

quotients \(\frac{4}{1}, \frac{2}{1}, \frac{1}{2}\)

fractions \(\frac{4}{1}, \frac{2}{1}, \frac{1}{2}\)

whence \(x = 9\), and \(y = 2\), which gives \(9^3 - 19 \cdot 2^2 = 5\)
as required.

Ex. 3.—It is required to ascertain the possibility, or
impossibility, of the equations

\[
\begin{align*}
x^3 - 17y^2 &= \pm 2 \\
x^3 - 17y^2 &= \pm 3
\end{align*}
\]

First

\[
\begin{align*}
\sqrt{17 + 0} &= 4 & 1 \cdot 4 - 0 &= 4; & 17 - 4^2 &= 1 \\
\sqrt{17 + 4} &= 8 & 1 \cdot 8 - 4 &= 4; & 17 - 4^2 &= 1 \\
\sqrt{17 + 4} &= 8 & 1 \cdot 8 - 4 &= 4; & 17 - 4^2 &= 1
\end{align*}
\]

whence it follows, that since only 1 enters into the deno-
mimators of these quotients, no one of the proposed equa-
tions are possible.

Cor.—By means of this proposition, we may demonstrate
generally the impossibility of all equations falling under
any of the following forms,

\[
\begin{align*}
x^3 - (a^3 + 1) \cdot y^2 &= \pm A \\
x^3 - (a^3 - 1) \cdot y^2 &= \pm A \\
x^3 - (a^3 + a) \cdot y^2 &= \pm A \\
x^3 - (a^3 - a) \cdot y^2 &= \pm A
\end{align*}
\]

in which \(A \geq 1\), and \(a < a\).
INDETERMINATE ANALYSIS.

Cor. 2.—It is also deducible from similar principles, that the following equations are always possible; \( N \) being a prime number, of the form placed opposite the respective equations.

\[
x^3 - N \cdot y^2 = -1 \text{ possible when } N \text{ of the form } 4n + 1
\]
\[
x^3 - N \cdot y^2 = -2 \quad \ldots \quad N \quad \ldots \quad 8 \cdot n + 3
\]
\[
x^3 - N \cdot y^2 = 2 \quad \ldots \quad N \quad \ldots \quad 8 \cdot n - 1
\]

And in a similar manner, are deduced the three following theorems:

1. If \( M \) and \( N \) be both of the form \( 4n + 3 \), and not equal to each other, the equation

\[
M \cdot x^3 - N \cdot y^2 = \pm 1
\]
is always possible in integer numbers: that is, under one or other of the signs \( + \) or \( - \).

2. If \( M \) and \( N \) be both of the form \( 4n + 1 \); then one of the equations

\[
\begin{align*}
M \cdot x^3 - N \cdot y^2 &= -1, \text{ or} \\
M \cdot x^3 - N \cdot y^2 &= 1
\end{align*}
\]

will always be reducible in integers.

3. If \( M \) and \( M' \) be two prime numbers of the form \( 4n + 3 \), and \( N \) a prime number of the form \( 4n + 1 \), it will be always possible to satisfy one of the equations

\[
\begin{align*}
N \cdot x^3 - M \cdot M' \cdot y^2 &= \pm 1 \\
M \cdot x^3 - M' \cdot N \cdot y^2 &= \pm 1 \\
M' \cdot x^3 - M \cdot N \cdot y^2 &= \pm 1
\end{align*}
\]

PROP. XI.

To find the general values of \( x \) and \( y \) in the equation

\[
x^3 - N \cdot y^2 = \pm A
\]

from one known case \( p^3 - N \cdot q^2 = \pm A \).

Find the values of \( m \) and \( n \) in the equation \( m^3 - N \cdot n^2 = 1 \), by Prop. VIII.; then it is evident that the product

\[
(p^3 - N \cdot q^2) \times (m^3 - N \cdot n^2) = \pm A \quad \text{and it will be found, upon the development of the following formulae, that}
\]

\[
(p^3 - N \cdot q^2) \times (m^3 - N \cdot n^2) = \left( \frac{(p + m) \cdot n^2 - (p \cdot n + q^2)^2}{(p \cdot n + q^2)^2} \right) - \left( \frac{N \cdot (p \cdot q + m)^2}{(p \cdot n + q^2)^2} \right)
\]

we have, therefore, only to make

\[
\begin{align*}
x &= p^3 + N \cdot q^2 \\
y &= p^3 - N \cdot q^2
\end{align*}
\]

and having before shown to find the general values \( m \) and \( n \) in the equation \( m^3 - N \cdot n^2 = 1 \); it is obvious, that by means of these formulae we may derive different values of \( x \) and \( y \), in the proposed equation, to any extent at pleasure.

Cor.—It appears also from this proposition, that if the rule in the foregoing one give \( p^3 - N \cdot q^2 = -A \), when the equation proposed be \( + A \); that this may be converted to the latter sign by means of the equation

\[
m^3 - N \cdot n^2 = -1.
\]

Ex. 1.—Given the values of \( p \) and \( q \), in the equation

\[p^3 - 7 \cdot q^2 = 21; \text{ viz. } p = 3, \text{ and } q = 1, \text{ to find the general values of } x \text{ and } y, \text{ in the equation } x^3 - 7 \cdot y^2 = 21.
\]

First in the expression \( m^3 - N \cdot n^2 = 1 \), we have \( m = 8, \) and \( n = 3 \); whence by the above formula is obtained

\[
\begin{align*}
x &= p^3 + N \cdot q^2 = 3 \cdot 8 + 7 \cdot 1 = 3 \text{ or } 45 \\
y &= p^3 - N \cdot q^2 = 3 \cdot 3 + 1 \cdot 8 = 1 \text{ or } 17
\end{align*}
\]

so that the second values of \( x \) and \( y \) are, \( x = 45, \) and \( y = 17 \); which give 45 = 7. 17 = 2. And assuming these again as new values of \( p \) and \( q \), other values \( x \) and \( y \) may be found in infinitum; or the original values of \( p \) and \( q \) may be retained, and new values found for \( m \) and \( n \), which answers the same purpose.

Ex. 2.—Find the general values of \( x \) and \( y \), in the equation

\[
x^3 - 11 \cdot y^2 = 5; \text{ the known case being } p^3 - 11 \cdot q^2 = 5, \text{ or } p = 4, \text{ and } q = 1.
\]

In the equation \( m^3 - 11 \cdot n^2 = 1 \), we have \( m = 10, \) and \( n = 3 \), therefore by the formula

\[
\begin{align*}
x &= p^3 \pm N \cdot q^2 = 4 \cdot 10 + 11 \cdot 1 \cdot 3 = 7 \text{ or } 73 \\
y &= p^3 - N \cdot q^2 = 4 \cdot 3 + 1 \cdot 10 = 22 \text{ or } 2 \quad 2 \quad 2 \quad 2
\end{align*}
\]

that is \( x = 7, \) and \( y = 2, \) are two new values of \( x \) and \( y, \) as are also \( x = 73, \) and \( y = 22 ; \) for each of these give

\[
\begin{align*}
x &= 7^3 - 11 \cdot 2^2 = 5 \\
y &= 73^3 - 11 \cdot 22^2 = 5
\end{align*}
\]

and in the same manner, other values may be found to any required extent.

As our limits will not allow of a very full and explicit investigation of the several elegant rules that have been introduced into the indeterminate analysis by Euler, Lagrange, Legendre, and other distinguished mathematicians; we must refer the reader for the investigation of the methods employed in the following propositions to the authors above-mentioned, and must content ourselves with barely stating the operations, without entering into the demonstration of the theorems themselves.

PROP. XII.

Every indeterminate equation of the second degree falls under the general formula

\[
a \cdot x^2 + b \cdot x \cdot y + c \cdot y^2 + d \cdot x + e \cdot y + f = 0,
\]

and this may always be transformed to the more simple form

\[
\begin{align*}
w^2 - A \cdot t^2 &= B
\end{align*}
\]

The method of performing this transformation will be seen from the following partial example, and the formulae we have given it being universally the same in all cases.

Assume \( b \cdot d - 2 \cdot a \cdot e = g; \) \( b \cdot d - 4 \cdot a \cdot f = h; \) \( b \cdot y + d \)

\[
-4 \cdot a \cdot (c \cdot y^2 + e \cdot y + f) = t; \quad b^2 - 4 \cdot a \cdot c = A, \quad A \cdot y + g = u; \quad g - A \cdot b = B.
\]

Then it will be found, by the development of these expressions, that

\[
a \cdot x^2 + b \cdot x \cdot y + c \cdot y^2 + d \cdot x + e \cdot y + f = u^2 - A \cdot t^2 = B = 0,
\]

becomes

\[
\begin{align*}
\begin{align*}
w^2 - A \cdot t^2 &= B
\end{align*}
\]
\]

And having found the values of \( u \) and \( t \) in this last equation, those of \( x \) and \( y \) are readily derived in the equation proposed.

For

\[
\begin{align*}
y &= \frac{u - g}{A}, \quad \text{and } x &= \frac{t - d - b \cdot y}{2 \cdot a},
\end{align*}
\]

or, substituting for \( y \) in the last, we have the following values

\[
\begin{align*}
\begin{align*}
y &= \frac{u - g}{b - 4 \cdot a \cdot c} \\
x &= \frac{(t - d) \cdot (b^2 - 4 \cdot a \cdot c) - (u - g) \cdot b}{2 \cdot a \cdot (b^2 - 4 \cdot a \cdot c)}
\end{align*}
\end{align*}
\]

Ex. 1.—Transform the equation

\[
x^2 + 8 \cdot x \cdot y + 3 \cdot y^2 + 2 \cdot x - 5 \cdot y = 110
\]

to its simplest form.

Here \( a = 3, \) \( b = 8, \) \( c = -3, \) \( d = 2, \) \( s = -5, \) \( f = -110.\)

Whence

\[
\begin{align*}
\begin{align*}
\begin{align*}
&\frac{b^2 - 4 \cdot a \cdot c = A = 100}{} \\
&\frac{b \cdot d - 2 \cdot a \cdot e = g = 46}{} \\
&\frac{d - 4 \cdot a \cdot f = h = 1324}{} \\
&\frac{g - A \cdot b = B = -13284}{}
\end{align*}
\end{align*}
\]

and
and thus the reduced equation becomes 
\[ u' - 100 t' = -130284. \]

In which, having found \( u = 346 \), and \( t = 52 \),
we have \[
\begin{align*}
  y &= \frac{u - g}{A} = \frac{346 - 46}{100} = 3.6 \\
  x &= \frac{t - by - d}{2a} = \frac{50 - 8 \cdot 3 - 2}{6} = 4.5
\end{align*}
\]
therefore \( x = 4 \), and \( y = 3 \), are the values of \( x \) and \( y \) in the original equation.

It will be observed that we have employed here the most general form that equations of this kind admit of, and therefore the formulae are more complex than they usually occur in practical cases, for when any of the coefficients \( a, b, c, \) &c. become zero, the expressions are much simplified, as appears from the following example.

**Ex. 2.**—Reduce 7 \( x^2 + 5xy + y^2 = 67 \) to its simplest form.

Here \( a = 7, b = 5, c = 1, d = 0, e = 0, f = -67 \), whence, omitting those quantities that are zero, we have \[
\begin{align*}
  b^2 - 4ac &= \Lambda = 29; \\
  d^2 - 4af &= b = 1876; \\
  g^2 - \Lambda b^2 &= 29 \cdot 1876^2 = B
\end{align*}
\]
and thus the reduced equation is 
\[ u'' - 29 t'' = 29 \cdot 1876^2. \]

And in a similar manner may any indeterminate equation of the second degree be reduced to the form \( u'' - \Lambda t'' = B \).

Having therefore shown the method of reducing every indeterminate equation to the form \( u'' - \Lambda t'' = B \); it follows that the solution of this simple form involves with it the solution of every equation of this kind that can be proposed; we shall therefore, in the following proposition, attend to the solution of this particular case. But it may be proper to state, that there are an infinite number of equations of this kind that are impossible; and will admit of no solution, either in integers or fractions; and therefore before we proceed farther in the investigation, it will be useful to lay down a rule, whence their possibility, or impossibility, may be ascertained; as we may thus frequently save much unnecessary labour.

Prop. XIX.

To ascertain the possibility or impossibility of every indeterminate equation of the second degree.

**Rule.**—Reduce the proposed equation to the form 
\[ u'' - \Lambda t'' = B, \]
and find all the remainders arising from dividing each of the squares \( 1, 2, 3, 4, \) &c. \( (A - 1)^2 \) by \( \Lambda \);
and also the remainders arising from dividing each of the squares \( 1, 2, 3, 4, \) &c. \( (B - 1)^2 \) by \( B \);
and again, divide the greatest of these numbers \( \Lambda, B, \) by the least of them, and observe the remainder.

Then if \( B \) be greater than \( \Lambda \), this last remainder will be found amongst those of the upper series; and the number \( \Lambda \) will be found amongst those of the lower series, if the equation be possible.

And conversely, if these conditions have not place, the proposed equation will admit of no solution, either in integers or fractions.

Again, if \( A > B \), then the remainder arising from \( \frac{A}{B} \) will be found in the lower series, and the number \( B \) in the upper series of remainders, if the equation be possible; and if these conditions have not place, the proposed equation is impossible.

**Note.**—It is to be observed, that equations falling under the possible form are not always solvable in integers, the proof extending only to their solvability in rational numbers, which may therefore sometimes be fractional; but when they fall under an impossible form, they will admit of no solutions either in integers or fractions.

**Ex.**—Required the possibility or impossibility of the equation 
\[ x'' - 7 y'' = 11 \]

squares \( 1, 2, 3 \) divided by 7
reminders \( 1, 4, 2 \)
squares \( 1, 2, 3, 4, 5 \) divided by 11
reminders \( 1, 4, 9, 5, 3 \)

\[
\frac{11}{7} = 1 \text{ and remainder } 4.
\]
Now 4 is found in the upper series of remainders, but 7 is not found in the lower; therefore the equation cannot have place either in integers or fractions.

And for the same reason, the equation \( x'' - 7 y'' = 11 z'' \) is also impossible, for if this was possible, it would likewise arise from the squares \( \frac{2}{2} - 7 \cdot \frac{2}{2} = 11 \); which we have seen is impossible.

**Ex. 2.**—It is required to ascertain the possibility or impossibility of the equation 
\[ x'' - 13 y'' = 12 \]
squares \( 1, 2, 3, 4, 5 \) divided by 13
reminders \( 1, 4, 9, 3, 10 \)
And the same squares, divided by 12, give for
reminders \( 1, 4, 9, 4, 1, 0 \)
also \( \frac{13}{12} = 1 \) and remainder 1.

And here, since 12 is found in the upper series, and 1 in the lower, the equation is solvable.

**Note.**—If the equation proposed be of the form 
\[ x'' - \Lambda y'' = -B, \]
we must employ, instead of the positive remainders arising from \( \Lambda \), the negative remainders of the same, that is, taking the quotients in excess. And if the equation have the form 
\[ x'' + \Lambda y'' = B, \]
then we must employ the negative remainders of \( B \). Having thus given an idea of the method of judging of the possibility of every equation of the form \( x'' - \Lambda y'' = B \); and having also shewn how any indeterminate of the second degree may be reduced to this form, it only remains to shew the method of solution of the above equation; or, which is still a more general form, of the equation 
\[ x'' - A y'' = B \]
but in this, as in the other propositions, we can only indicate the method, without attempting to investigate the rationale of the operation; as this would carry us much beyond our limits. Now it is shewn under the article Diophantine, that the
the solution of the equation \( x^3 - y^2 = C \) \( z^2 \) is always to be obtained; and in the following proposition, with which we shall conclude this article, it will be seen that every equation of the form \( x^3 - Ay^2 = B \) \( z^2 \), which is possible, may be transformed to another of the form \( x' - y'' = c \) \( z' \); and that \( x', y', \) and \( z' \), in the original equation, will be dependent upon those of \( x', y', \) and \( z' \), in the transformed equation; and therefore the latter being known, the former will be known also.

Prop. XIV.

To transform every possible equation of the form \( x^3 - Ay^2 = B \), to another dependent equation of the form \( x'' = y'' + c \) \( z'' \). 

Ex. 1.-It is required to transform the equation \( x^3 - 5y^2 = 11z^2 \), to another of the form \( x'' = y'' + 3z'' \).

Having first ascertained the possibility of the equation by the foregoing proposition, the transformation may be effected in the following manner.

Assume \( x = n y - 11y' \), and this substituted for \( x \), gives

\[
\begin{align*}
(n^3 - 5) y' - 2 n y y' + 11 y'^2 &= z' \\
\end{align*}
\]

Take \( n \) so that \( n^3 - 5 \) may be divisible by 11; that is, let \( n = 4 \), and our equation becomes

\[
\begin{align*}
y^3 - 8 y y' + 11 y'^2 &= z' \quad \text{or} \\
(y - 4 y')^3 - 5 y'^2 &= z' \\
\end{align*}
\]

or, by making \( y - 4 y = x \), we have

\[
\begin{align*}
x' &= y' + 5 y'^2 \\
x' &= z'
\end{align*}
\]

and, that is, the equation has been reduced from the form \( x^3 - 5y^2 = 11z^2 \), to another of the form \( x' - y'' = c \) \( z'' \); or, at least, to \( x' = z' = 5 \) \( y'' \); which differs from the foregoing solely in the letters.

And, by means of the values of \( x', y', \) and \( z' \), in this last, we readily arrive at those of \( x, y, \) and \( z \), in the one proposition:

for \( x = y - 4 y' \), or \( y = x + 4 y' \)

and \( x = n y - 11 y' \), or \( x = 4 y - 11 y' \)

Now we have seen, under the article Diophantine, that the general values of \( x' \) and \( z' \), in equations of the form \( x' - x'' = 5y'' \), are

\[
\begin{align*}
(x') &= p' + 5 q^2 \\
(z') &= p' - 5 q^2 \\
(y' &= 2 p q \\
\end{align*}
\]

where we have, for the general values of \( x, y, \) and \( z \), in the equation proposed,

\[
\begin{align*}
x &= 4 p + 20 q^2 + 30 p q \\
y &= p' + 5 q^2 + 8 p q \\
z &= z' - 5 q^2 \\
\end{align*}
\]

where \( p \) and \( q \) may be assumed any numbers at pleasure. If \( p = 3 \) and \( q = 1 \), we have \( x = 85, y = 38, \) and \( z = 43 \); which numbers answer the required conditions; for

\[
\begin{align*}
-5 - 5 - 35 &= 11 \cdot 11 \\
\end{align*}
\]

and by giving different values to \( p \) and \( q \), a variety of other integral values may be found for \( x, y, \) and \( z \).

Note.-It may happen that the first transformation will not reduce the equation to the form required, in which case we must again transform this anew, and, by continuing the operation, the reduction to the final form will be ultimately effected.

Ex. 2.—Required the values of \( x, y, \) and \( z \), in the equation

\[
x^3 - 12 y^2 = 13 z^2.
\]

First, we have \( x = n y - 13y' \), and substituting for \( x \) we have

\[
\frac{(n^3 - 12)}{13} y' - 2 n y y' + 13 y'^2 = z' \\
\]

and here \( n = 5 \), whence the equation becomes

\[
-10 y y' + 13 y'^2 = z' \quad \text{or} \\
(y - 5 y')^3 - 12 y'^2 = z'
\]

Make now \( y - 5 y' = x' \), and it becomes

\[
x^3 - z^2 = 12 y^2
\]

and the general values of \( x \) and \( z \), in this equation, are

\[
x' = 3 p^3 + 4 q^2, z = 3 p - 4 q, \quad \text{and} \quad y' = 2 p q.
\]

Whence, by affixing \( p = 2 \), and \( q = 1 \), we have \( x' = 16, \)

\( x = 8, \) and \( y' = 4 \); to that in the original equation, the values of \( x, y, \) and \( z \), are as follow; viz.:—

\[
\begin{align*}
y &= x' + 5 y' = 36 \\
x &= 5 y - 12 y' = 132 \\
z &= \frac{y}{x} = \frac{33}{2}
\end{align*}
\]

the latter values being formed by dividing the former by their greatest common divisor; and either of these sets of numbers answer the required conditions; for,

\[
132^2 - 12 \cdot 36^2 = 13 \cdot 8, \quad \text{and} \quad 33^2 - 12 \cdot 9 = 13 \cdot 2.
\]

and various other values may be obtained by changing the values of \( p \) and \( q \).

We will now give one example in which the required reduction does not take place in the first transformation.

Ex. 3.—Required the values of \( x, y, \) and \( z \), in the equation

\[
x^3 - 5y^2 = 13 z^2.
\]

Assume, as before, \( x = n y - 19 y' \); then the substitution of this value for \( x \) gives

\[
\begin{align*}
\frac{(n^3 - 5)}{19} y' - 2 n y y' + 19 y'^2 &= z' \\
\end{align*}
\]

Whence

\[
\begin{align*}
y &= x' + 5 y' = 10 \quad 19 \\
x &= 5 y - 10 y' = 2z \\
z &= 25 y - 90 y' = 5 z
\end{align*}
\]

Making now, \( 5 y = 10 y' = x' \); we have

\[
x - 5 y' = 5 z
\]

and here, though we have not arrived at the form required, the last co-efficient is reduced from 19 to 5; and thus every succeeding transformation will reduce the coefficients, till we ultimately arrive at that of unity; but without pursuing this reduction further in the present case, we are led to the solution in an easier manner: for we see immediately, that \( z \) may be affirmed \( z = 5, y' = 2z, \) and \( x = 1 \).

And from there we readily ascertain those of \( x, y, \) and \( z \), in the proposed equation; for

\[
\begin{align*}
y &= \frac{x + n y'}{5} \quad \text{or} \quad y = \frac{n + 10 y'}{5} = 5 \\
x &= (y) - 19 y' \quad \text{or} \quad x = 5 y - 38 = 12 \\
z &= 1 \text{ or } \quad z = 1
\end{align*}
\]

which give \( 12 - 5 - 5 = 10 - 1 \), as required.

We shall now conclude this article with a synopsis of indeterminate formulæ, the demonstration and application of which the reader will find in Babbage’s “Elementary Investigation of the Properties of Numbers.”

Synopsis
Indeterminate Analysis.

Form 1. Equation \( ax + by = \pm c \)

\[ \begin{align*}
\text{General value of } x &= m b + c q \\
\text{of } y &= m a + c p
\end{align*} \]

in which expressions \( m \) is indeterminate, and the values of \( p \) and \( q \) result from the solution of the equation \( ap - b q = \pm 1 \).

Form 2. Equation \( ax + by = c \)

\[ \begin{align*}
\text{General value of } x &= c q - m b \\
y &= m a - (d - c) p
\end{align*} \]

Number of solutions \( = \frac{c q - c p}{b} a \)

the quantities \( p \) and \( q \) being ascertained as above, also \( m \) indeterminate.

Form 3. Equation \( ax + by + cz = d \)

\[ \begin{align*}
\text{General value of } x &= (d - cz) q - m b \\
y &= m a - (d - c) p
\end{align*} \]

the quantities \( p \) and \( q \) being found as above, also \( m \) indeterminate, and \( z \) any integer \( \leq d \).

Form 4. Equation \( x^2 - ay^2 = z^2 \)

\[ \begin{align*}
\text{Gen. val. of } x &= p^2 + a q^2 \\
y &= 2 p q \\
z &= p^2 - a q^2
\end{align*} \]

in which expressions \( a \) is given, and \( p \) and \( q \) are indeterminates, that may be ascertained at pleasure.

Form 5. Equation \( x^2 + ay^2 = z^2 \)

\[ \begin{align*}
\text{Gen. val. of } x &= p^2 - a q^2 \\
y &= 2 p q \\
z &= p^2 + a q^2
\end{align*} \]

\( a \) being given, and \( p \) and \( q \) indeterminates as above.

Form 6. Equations \( ax^2 + bxy + y^2 = z^2 \)

\[ \begin{align*}
\text{Gen. val. of } x &= 2 pq + b q' \\
y &= p - a q' \\
z &= p' + b q' + a q',
\end{align*} \]

where \( p \) and \( q \) are indeterminates, and \( a \) and \( b \) given quantities.

Form 7. Equation \( ax^2 + bx = z^2 \)

\[ \begin{align*}
\text{Gen. val. of } x &= \frac{b q^2}{p^2 - a q^2} \\
z &= \frac{b q}{p - a q}
\end{align*} \]

where \( a \) and \( b \) are known quantities, and \( p \) and \( q \) indeterminates.

Form 8. Equation \( m^2 x^4 + bx + c = z^2 \)

\[ \begin{align*}
\text{Gen. val. of } x &= \frac{p - q}{b q - 2 m p q} \\
z &= \frac{m p^2 + m c q - b p q}{b q - 2 m p q}.
\end{align*} \]

where \( m, b, \) and \( c \) are any given numbers, and \( p \) and \( q \) indeterminates.
IND
Synopsis of Indeterminate Formules.

Form. 17. Equation \( m^2 x^4 + b x^2 + c x + d = z^3 \).

\{ Particular val. of \( x = \frac{b^2 - 27 d m^6}{(3c m^3 - b^2)} y m^3 \) \}
\( a, b, c, \&c. \) being given quantities, as above.

Form. 18. Equation \( m x^4 + b x^2 + c x + d = z^3 \).

\{ Particular val. of \( x = \frac{(c^2 - 3 b f^3)}{27 m^3 f^3 - c} y f^3 \) \}
\( Or, \quad x = \frac{(3 c m^3 - b)}{b - 3 m f} y f^3 \),
where also \( m, b, c, \&c. \) are known quantities.

Form. 19. Equation \( x^4 + a x y + b y^3 = z^3 \).

\{ General val. of \( x = t - b t^4 - a b^4 \) \}
\( y = 3 t^2 u + 3 a t u^3 + (a^4 - b) u^3 \)
\( z = i + a u + u^3 \),
t and \( u \) being indeterminate, as above.

Form. 20. Equation \( x^4 + b y^4 = z^4 \).

\{ General val. of \( x = t^4 - 6 b t^4 u^4 + b^4 u^4 \) \}
\( y = 4 t^4 u - 4 b t^4 u^3 \)
\( z = t^4 + b^4 u^3 \),
t and \( u \) being indeterminate, as above.

Form. 21. Equation \( x^4 + b y^4 = z^4 \).

\{ General val. of \( x = t^4 - 8 b t^4 u^4 + 8 b^4 u^4 \) \}
\( y = 16 t^4 u - 16 b t^4 u^3 \)
\( z = t^4 + 8 b^4 u^3 \),
t and \( u \) being indeterminate, as above.

Form. 22. Equation \( x^4 + b y^4 = z^4 \).

\{ General val. of \( x = t^4 - 2 t^4 u^4 + 2 b^4 u^4 \) \}
\( y = 2 t^4 u - 2 b t^4 u^3 \)
\( z = t^4 + 2 b^4 u^3 \),
t and \( u \) being indeterminate, as above.

Form. 23. Equation \( x^3 + c y^3 = z^3 \).

\{ General val. of \( x = 4 t^3 - 4 c t u^3 \) \}
\( y = 8 t^3 u + c u^3 \)
\( z = t^3 + c u^3 \),
t and \( u \) being indeterminate.

Form. 24. Equation \( x^3 + a x y + b x^3 + c y^3 = z^3 \).

\{ Particular val. of \( t = \frac{-a^2 + 2 a u w + (a^4 - b) w^4}{2 w} \) \}
\( \text{Gen. val. of } x = t^3 + 2 c t u w + a c w^2 \)
\( y = 2 t u + 2 b t u w + (a - b - c) w^3 \),
where \( u \) and \( w \) are indeterminate, on which also depends the value of \( t \).

Indeterminate Problems, is that in which there are more unknown quantities than there are equations; and therefore from the principles of algebra the number of solutions is unlimited, unless some other condition enter, such
Vol. XIX.
published an index of the prohibited books, and certain rules, by his letters, in form of a brief. The same Pius IV. in a bull of March 24, 1564, says, that the index was presented to him by order of the synod, that it should not be published before it was approved by him. It was accordingly published by him, with a strict charge that it should be received by all, and the rules prefixed to it observed. Clement VIII. enlarged and confirmed it, together with the rules, and commanded it to be published in 1593. This was called by the name of the Roman index. By the fourth rule, the common reading of the Holy Scriptures is forbid in these words: "Since it is plain by experience, that if the sacred writings are permitted every where, and without difference to be read in the vulgar tongue, men, through their rashness, will receive more harm than good; let the bishop or inquisitor determine, with the advice of the parish priest or confessor, to whom to permit the reading of the bible, translated by Catholic authors in the vulgar tongue, according as they shall judge whether it be most likely that such reading of the scripture may do harm, or tend to the increase of faith and piety. Let them also have the same power as to all other writings. But if any, without such leave, shall presume to read or have them, without first shewing the bible to the ordinaries, he shall not receive the abolition of his sins. And as to all bookellers, who shall sell the bibles translated into the vulgar tongue, without such leave, or by any other method shall publish them, let them forfeit the price of the books, and let the money be given to pious uses by the bishop; and let them be subject to other punishments; at the pleasure of the said bishop, according to the nature of the offence. As to regulars, they shall not read or buy them, without leave first obtained from their prelates." The tenth rule enjoins several restrictive regulations concerning the printing and publication of books. Hardouin's Concil. tom. x. p. 207, &c.

In pope Clement's catalogue is an extraordinary kind of decree, that all the books of Catholic authors, written since the year 1515, which was the year immediately preceding in which Luther began to declaim against indulgences, should be corrected; not only by retrenching what is not conformable to the doctrine of Rome, but also by adding what may be judged proper by the correctors.

After this, the duke of Alva procured another to be printed at Antwerp in 1571, which was published by Francis Julius about the year 1586. There were two others published in 1584. and 1612, by the cardinals Quiroga and Sandoval, and several others by the inquisitors and masters of the aforesaid palace. The most considerable of all the indices is that of Anthony a Sotomayor, supreme prefect and inquisitor-general in the kingdom of Spain, which was made for all the states subject to the king of Spain, and comprehends all the others. This was published, with the advice of the supreme senate of the general inquisition, in 1620, and reprinted at Geneva in 1657. To this there were many rules prefixed; and to the 'Geneva edition was added the index of the decrees which were made by the matter of the holy palace, by virtue of his office, or by the command of the holy congregation, or by the holy congregations for the indices and holy office, after the before-mentioned index of the council of Trent. The rules of the former indices are explained and confirmed by these; and the fifth rule, which enlarges the fourth of the index of Trent, prohibits not only all bibles in the vulgar tongue, comprehending all except those that are Hebrew, Greek, Latin, Chaldean, Syriac, Ethiopic, Persian, and Arabic; but all parts of them, either printed or manuscript, with all summaries and abridgments in the vulgar language or tongue. Limborch's Hist. of the Inquisition by Chandler, book iii. chap. 16.

Of the operation of these indices, the authors of the Encyclopædia observe, that there has been hardly any good book of piety or morality in their language which has not been proscribed. Art. Index.

INDGEH, in Geography, a town of Aftatic Turkey, in Caramania; 12 miles S.W. of Kaifarieh.

INDGEH Su., a town of Aftatic Turkey, in Natolia; 40 miles S.W. of Anguria.

INDIA, an extensive country of Asia, which was divided by Ptolemy and the ancient geographers into "India extra Gangem" and "India intra Gangem," or the peninsula beyond the Ganges and that on this side of the Ganges, to which the appellation of India, according to its original etymology, as the country of the people called "Hindoos," properly belongs. (See HINDOOSTAN.) India on this side of the Ganges was bounded, according to Ptolemy, on the W. by the Paropamisus, Arachedia, and Gedrofia; on the N. by mount Imaus; on the E. by the Ganges; and on the S. and partly on the W. by the Indian sea. The gulf into which the Indus discharged itself was called "Canthiti Colus," and an island in this gulf was named "Barcas." The western mouth of the Indus was denominated "Sagaga." Ptolemy enumerates seven mouths of this river under this and the following names; viz. "Oltium Sinthum, Oreum, Choriphi, Sarapaghes, Sabalaffa, and Lonibare." To the Ganges Ptolemy assigns five months, viz. those of Polura, Oltium Magnum, O. Chambericium, O. Pefudo-Romanum, and Antible." The part of India, which was situated towards the west, was called "Indo-Scythia." India beyond the Ganges had the Ganges on the W., on the N. certain parts of Scythia and Serica; on the E. the country of the Sinn; and to the S. the Indian sea. This, however, is a vague name for wide and various, and till of late very much unknown, regions between Hindoosfan and China. The territory thus denominated is rich and extensive, and includes the Birmcan empire, and the dominions of Pegu, Siam, Laos, Cambodia, Siampa, Cochinchina, Tonquin, and Malaca; which see respectively. See also AREACAN, ASAM, AVA, and THIBET. For an account of "Hither India," or "India Intra Gangem," see HINDOOSTAN and EAST INDIA COMPANY. For an elaborate account of the "Political History of India, from the introduction of Mr. Pitt's bill, A.D. 1784, to the present date," see Mr. Malcolm's "Sketch." Lond. 1811, 8vo.

INDIA, EAST, COMPANY, COINS, SILK, &c. See COMPANY, COIN, SILK, &c.

INDIA, SIGISMONDO DE', in Biography, a musical composer, who was born at Palermo in Sicily, and flourished about the year 1610. In 1611 he published at Venice two sets of madrigals; and in 1627 a book of motettis, which did not go down the stream of oblivion unnoticed.

INDIAN, in a general sense, denotes any thing belonging to the Indies, East or West.

INDIAN ARROW-ROOT, in Botany. See MARANTA.

INDIAN BAY, in Geography, a bay that lies on the W. side of Labrador Bay, in Newfoundland.

INDIAN BREAD, in Botany. See CASSADA.

INDIAN CORN. See MAIZE.

INDIAN CORN-CARES, Petrified, in Natural History. Many of the early writers on extraneous fossil mention ears of Indian corn among their reliquia. Mr. James Parkinson, in his Organic Remains, vol. i. p. 450, flays, that what Emanuel Swedenborg
IND

Swedensborg figured as an ear of Indian corn, is the stem of an
unknown plant, which, at pages 424 and 427, is said to
belong to the series of vegetable remains included in iron-
stone nodules. See plate 14, fig. 4. of W. Martin's Pet.

INDIAN OLD TOWN, a town of America, in Hancock
county, state of Maine, situated on an island in Penob-
cscot river, just above the Great Falls, and about sixty
miles below the Forks. Here are about 100 families of
Roman Catholics, the remains of the Penobscot tribe, and
the only Indians who reside in the district of Maine. They
are in a thriving state, having obtained from the Prov-
cedence congress a tract of land, 12 miles wide, intersected in
the middle by the river, and velted with a right of hunting and
fishing as far as the mouth of Penobscot bay extends. They
have a decent church, and a priest who conducts their reli-
gious service.

INDIAN RED and SHOT, in Botany. See CANDA.

INDIAN RIVER, in Geography, a river of Delaware, which
runs into Rehoboth bay. N. lat. 38° 40'. W. long. 75° 16'.
—Allo, a small arm of the sea, between Chandlín and Plea-
fant river, in the district of Maine.—Allo, a river on the E.
coast of the peninsula of East Florida, rising near the sea-
coast, and running from north to south, and forming a kind
of inland passage along the coast. It is also called Rio Ays.
N. lat. 37° 50'. W. long. 80° 40'.—Allo, a town in Suffolk
county, Delaware, containing 1547 inhabitants.

INDIAN SOUTH, a gulf or bay on the S. coast of Patagonia,
communicating with the Straits of Magellan by St. Jerome's
channel.

INDIAN TOWN, a small town of North Carolina, 32 miles
from Edenton. INDIAN TOWN POINT, a cape on the east coast of the island
of Antigua. N. lat. 17° 15'. E. long. 61° 22'.

INDIAN WOOD, called also Jamaica and Campeachy Wood,
is taken out of the heart of a large tree growing plentifully
in the ises of Jamaica, Campeachy, &c. used in dyeing, its
decoration being very red.

It has been observed, that putting some of this decoration
into two bottles, and mixing a little powder of alum with the
one, it will become of a very beautiful red, which will hold;
the other in a day's time becoming yellow, though both
bottles were dipped from the air alike; and that if a little
of the same decoration be exposed to the air, it will become
as black as ink in the same space of time. See CAMPEACHY
WOOD, BRASIL, and LOGWOOD.

INDIANA, in Geography, a territory on the N. W. side of
the Ohio, and lately formed a part of the N. W. territory.
In January 1801, it was by act of congress erected into a
temporary government, with powers and privileges similar
to other territorial governments. It lies between the Great
Miami river E., the Mississippfti W., the Ohio S., and the.
Illinois N. It is divided into the three following counties:

<table>
<thead>
<tr>
<th>Counties</th>
<th>Inhabitants</th>
<th>Chief Towns</th>
<th>Inhabitants</th>
</tr>
</thead>
<tbody>
<tr>
<td>Knox</td>
<td>2517</td>
<td>St. Vincennes</td>
<td>774</td>

<tr>
<td>St. Clair</td>
<td>1255</td>
<td>Kaskokia</td>
<td>719</td>
</tr>
<tr>
<td><strong>Total</strong></td>
<td><strong>4875</strong></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

This territory has a fine soil, adapted to corn, wheat, rye,
oats, cotton, hemp, tobacco, &c. The two western counties
of Randolph and St. Clair have lately petitioned congress to
be annexed to the Upper Louisiana, in the territorial
government. On the N. W. bank of the Ohio, about twenty
miles southward of the mouth of the Wabash, N. lat. 37°
36', is a remarkable cave, called the 'Great Cave,' which
is one of the most surprising natural curiosities on the Ohio.
The entrance is spacious and uniform; the dome is elliptical,
and the uniformity continues to its termination in the hill.

MORIB. INDIANA, a territory in Virginia, lying between Ohio
river and the Laurel mountain, containing about 2½ millions
of acres; of a form nearly triangular, and extending in
length from the Pennsylvania line to the waters of the
Little Kenhaway.

INDIANA, a new county in the western parts of Pennsyl-
vanian, which, with Wellmoreland and Armtrong, com-
stitute a district for the choice of three representatives.

INDIANE, a small harbour in the island of Cape Breton.

INDIANS, the name given to the aborigines of America.
These people are scattered through the vall extent of the
two prodigious continents, and divided into an infinite num-
ber of nations and tribes, differing from each other but little
in their manners and customs. The Indians are tall and
straight in their limbs; their bodies are strong, and adapted
to endure much hardship. Their features are regular, but
their countenances fierce; their hair long and lank, and the
colour of their limbs a reddish brown. Their only occupa-
tions are hunting and war; agriculture is left to the women,
and for merchandise they have no taste. They are hospita-
table, generous, and good-tempered; but to the enemies of
their country they are implacable: no length of time can
aify their resentment, nor is any distance of place great
enough to protect the object of their revenge. The Indians
seem to have no just notion of a Supreme Being, though they
maintain the existence of such a Being, eternal and incorrup-
tible, who has power over all, to whom however they pay no
worship; but they are exceedingly superstitious; and being
deitiou to look into futurity, they encourage and support a
multitude of diviners, augurs, and magicians, upon whose
predictions...
decisions and advice they rely in all matters that concern them, whether of health, war, or hunting. Liberty is the darling passion of the Indians; it is this which makes life supportable, and to this they are ready to sacrifice every thing. Some tribes acknowledge a head or king, but he is reverenced as a father rather than feared as a monarch. He has no guards, no prises, no officers of justice; in most cases no other qualification is necessary for their chiefs, but age, experience, and ability in conducting their affairs. Every transection is performed with much ceremony; and to fix the remembrance of them in their minds, they have belts of small shells or beads of different colours, which have all a different meaning, according to their colour or arrangement. These belts are carefully treasured up in each town, and serve as the public records of the nation; and to these they occasionally have recourse when any disputes happen between them and their neighbours.

When the ancients among the Indians have resolved upon a war, they do not declare what nation they mean to attack, nor the time when the attack shall be made, in order that the enemy may be off his guard, and unprepared for defence: but the principal captain summons the youths of the town to which he belongs, the war-kettle is set on the fire, the war-fongs and dances begin; the hatchet is sent to all the villages of the same nation, and to all its allies; the fire catches, and the war-fongs are heard in all parts. The prime qualities in an Indian war are vigilance and attention, to give and avoid surprize; likewise patience and strength to endure the intolerable fatigues and hardships which always attend it. The fate of their prisoners is the most severe of all: during the greatest part of their journey homewards they suffer no injury; but when they arrive at the territories of the conquering state, or at those of their allies, the people from every village meet them, and think that they show their attachment to their friends by their barbarous treatment of the prisoners. Many writers have asserted that the Indians, even at the maturest age of their existence, are only furnished with hair on their heads, and that the other parts of the body are always free from it. This, however, is not the truth, for, naturally, their bodies recombine those of the Europeans; but regarding the beard, &c. as deformities, they pluck out each hair by its root, in order to increase their beauty. The men of every Indian nation differ in dress from each other, excepting those who trade with Europeans; these exchange their furs for blankets, shirts, and other apparel, which they wear in such a manner as not to enable any division to be necessary. Tho' among the men who wish to appear gayer than the rest, pluck out the hair from their heads, except from a spot on the top of it, about the size of a crown piece, where it is permitted to grow to a considerable length: on this is fastened a plume of feathers of various colours, with silver or ivory quills. The manner of cutting and ornamenting this part of the head distinguishes different nations from each other. They paint their faces red and black, and their whole bodies when they go to war. Young Indians, who are definitions of excelling their companions in finery, fit the outward rim of both ears, at the same time that they take care not to separate them entirely, but leave the place thus cut still untouched at both extremities; around this spongy substance they twist brass wire, till the weight draws the amputated rim into a bow of five or six inches in diameter, and drags it almost down to the shoulder. It is also a common custom among them to bare their noses, and wear in them pendants of different sorts: shell shellys are much worn by those of the interior, and are reckoned ornaments. Indians in general pay greater attention to their drees, and to the ornaments with which they decorate their persons, than to the accommodation of their hats or tents. They construct the latter in the following method: being provided with poles of a proper length, they cut two of them across near the ends with broads made of bark; having done this, they raise them up, and extend the bottom of each as wide as they purpose to make the area of the tent: they then erect others of an equal height, and fix them so as to support the two principal ones; over the top they spread the skins of beauly. These tents have neither chimneys nor windows; there is only an aperture left in the middle of the roof, through which the smoke is discharged. They have skins also for beds, generally those of the bear, which are placed in rows on the ground; and if the floor is not large enough to contain beds sufficient for the accommodation of the whole family, a frame is erected a few feet from the ground, in which the younger part of it sleep. As the habits of the Indians are thus rude, their domestic utensils are few in number, and plain in their formation. The tools with which they furnish them are so awkward and defective, that it is not only impossible to form them with any degree of neatness, but the time required in the execution is so considerable, as to deter them from engaging in the manufacture of those which are not absolutely necessary. All the trinks are now polished of knives, and laced to strike fire with; these are regarded as essential to the common utes of life, and the Indians usually purchase them with flaves. Indians, by a surprizing facacity, will crofs a forest or plain of the greatest extent, and reach with the utmost exactness the place of their defination without any deviation from a direct line. Their memory is very tenacious, their belts of wampum prepare the substance of treaties which they have concluded with the neighbouring tribes for ages back, to which they will appeal with as much readiness and perfunctility as Europeans can to their written records. Every nation pays great respect to the dictates of age. The advice of a father is regarded; but the decisions of a grandfather create in the minds of the young an awe which they cannot withstand; his words are considered and obeyed as oracles. The Indians are fond of gaming, and often break their arms, their apparel, and every thing of which they are possessed; they are strangers to all diffusion of property, except in articles of domestic use, which every one considers as his own, and increases as circumstances admit. They are extremely liberal to each other, and supply the exigencies of those who belong to the same band, with their superfluities. Of the value of money the Indians, excepting those who live near the European colonies, have no idea, but consider it as a source of innumerable evils. They are equally indifferent to the productions of art. They are ignorant of the sciences, and seem quite unacquainted with the first principles of astronomy, yet they contrive to divide the time in a rational and perfunctory manner. They count their years by winters, or, as they express themselves, by their snows; and they divide the years by the moons, and on the first appearance of each new moon they repeat some joyful sounding, stretching, at the same time, their hands towards it. Every month has with them a name expressive of its fenon: that which answers to our March or April, they call the worm month, because they observe that at this period the worms quit their retreats in the bark of trees, wood, &c. in which they have sheltered themselves during the winter; they have also the month or moon of flowers; the month of corn; the cold month; the snow month, &c. When the moon does not appear above the horizon, they say the moon is dead, and some call the three last days of each moon "naked days." They have no divisions of weeks, but days they count by sleeps; half days by pointing to the fun at noon, and
and quarter by the rising and setting of the sun; to express which, in their traditions they make use of hieroglyphics. Their love knowledge in astronomy consists in being able to point out the polar star, by which they regulate their course when they travel by night. They reckon distances from one place to another by days' journeys, each being about 20 miles. They have no knowledge of arithmetic, and though they are able to count to any number, figures and letters appear to carry with them some hidden mystery, and much above their comprehension. Every separate body of Indians is divided into bands or tribes, and forms a little community within the nation to which it belongs. As the nation has some particular symbol by which it is distinguished from others, so each tribe has a badge from which it is denominated, as that of the eagle, the panther, the tiger, the buffalo, &c. Throughout every nation they particularize themselves in the same manner, and the meanest person among them will remember his lineal descent, and distinguish himself by his respective family. Every band has a chief, who is termed the Great Warrior, and who is elected for his warlike qualifications; besides this there is another who enjoys a pre-eminence as his hereditary Right, and has the more immediate management of their civil affairs. When the chiefs are convened on any public business, they always conclude with a feast, at which felicity and cheerfulness know no limits. Dancing is a favourite exercise among the Indians, they never meet on any occasion but this makes a part of the entertainment; and when they are not engaged in war or hunting the youth both sexes amuse themselves in this manner every evening. The Indians have several kinds of dances which they use on different occasions, as the pipe or council dance, the war dance, the marriage dance, and the dance of the sacrifice. The movements in every one of these are diftin nlar, though it is impossible to give such a description of them as will convey to an European a just idea of the distinctions. Hunting is their principal occupation; they are trained to it from their youth, and it is an exercise which is esteemed no less honourable than necessary towards their subsistence. A destitute hunter is held nearly in as high estimation as a distinguished warrior. Scarcely any device which the ingenuity of man has discovered for envying or destroying those animals that supply them with food, or whose skins are valuable to Europeans, is unknown to them. Every hunter prepares himself by falling during several days: the reason they give for this is, that falling enables them to dream freely, and in their dreams they are informed where they shall find the greatest plenty of game; it is thought also to avert the displeasure of evil spirits, and induce them to be propitious. They seem to have some notion of a future state of existence, and suppose that their employments there will resemble those in which they are engaged here, without the labour and difficulty annexed to them in this period of existence. Among those who have priests, these priests are their physicians and their conjurers: they cure their wounds and diseases, interpret their dreams, give them charms which shall render them superior to external danger, and satisfy their curiosity with regard to future events. The Indian is subject to but very few diseases; the most fatal and destructive is the small-pox, which to them has been the most terrible of all pellagra; this is not, however, continual in their country, as it is in other nations; frequently there are intervals of many years in which it is never heard of; but when it prevails, towns and villages are thinned of their inhabitants. An Indian is said to meet death, when it approaches him in his hut, with the same resolution with which he has often faced it, in the field. If he is a chief, and has a family, he makes a kind of funeral oration, which he concludes by giving to his children necessary advice for the regulation of their conduct. He then takes leave of his friends, and issues out orders for the preparation of a feast, which is designed to regale those of his tribe that come to pronounce his eulogy. After the last struggle the body is drilled in the usual habitations; the face is painted, and it is placed in a sitting posture on a mat in the middle of the hut, with his weapons by his side. His relations being seated round, each harangues the deceased body, in turn, and, if he happen to have been a great warrior, recounts his heroic actions. After this, the body is carried to the burying place, where it is interred with other ceremonies. Such are the general characteristics of the Indians; the peculiarities of each tribe will be found in other parts of the dictionary. The amount of Indian population cannot be precisely ascertained. The newly discovered islands in the South Sea, and part of the N. W. coast, are probably the most populous; as they have suffered less by invaders. The left unformed writers have conjectured the number of aboriginal Indians in America to be under 2½ millions. Since the discovery of America, the decrease, in consequence of labour and oppression, famine and pestilence, has been astonishing. A list of Indian tribes, in Imlay's History of Kentucky, makes the aggregate number less than 60,000 of those who inhabit the country, from the gulf of Mexico on both sides of the Mississippi to the gulf of St. Lawrence, and as far west as the country has been generally explored, that is, to the head water of the Mississippi, and from thence a good way up the Missouri, and between that river and Santa Fe. The population of the Indian nations in the southern parts of the United States is given differently from Mr. Imlay's statement by Mr. Purcell, who refuted among them in 1780, as follows:

Total: 13,516

The above red nations have somewhat increased since the general peace established among them in 1777. The whites incorporated among them are few in number, and lead a vagabond life, connecting themselves with one tribe after another. The increase of population is considerably checked by the use of spirituous liquors, and by a certain complaint introduced among them by the whites. In the northern district of North America, Mr. Hutchins, in 1778, estimated the Indians N. of the Ohio, and E. of the Mississippi, at 13,800, and those westward of lake Superior and the Mississippi, at 10,000.

**INDICATION**, in Physic, signifies the pointing out or discovering what is fit to be done, and what means applied in any case, from a knowledge of the nature of the disease, and the virtue of medicines.

Indications are of four kinds: **preservative**, or **preventative**, which direct how to cut off the cause of an approaching disease; **curative**, which shew how to remove a disease actually formed; **palliative**, which direct how to lessen its effects, or take off some of its symptoms, before it can be wholly removed; and **seducing**, which relate to the strength of the body.

That
That part of physic which treats of indications is called

*Indicative.*

**Indicative**, in Grammar, the first mood or manner of conjugating verbs, shewing either the time present, past, or future, and altering what we think certain; and therefore, sometimes called the *declarative* mood.

I *see* is the present tense; *I saw*, the past; and *I shall see* is the future of the indicative mood.

**Indicative**. See *Column*.

**Indicator**, in Anatomy, extensor or abductor indicis, cubito-ulnare-ouenii; a muscle of the fore-arm, situated on the dorsal surface of the fore-arm. It is a flenser muscle, of an elongated figure, extended from the back of the ulna to the fore-finger. It arises, by short aponeurotic fibres, from the posterior surface of the ulna, beginning about the middle of the bone, and having its attachment extended towards the wrist; and in a slight degree from the interosseous ligament. It is flenser and pointed at its origin, grows gradually larger, and then diminishes again and forms a small flattened tendon. From its origin at the middle of the ulna, it passes obliquely to the carpal end of the radius, and is confined at the surface of that bone in a fibrous sheath common to it with the extensores communis, to which it is here attached by means of the synovial membrane which lines the sheath. Quitting the sheath, it runs along the back of the hand, on the radial side of the tendon, which the fore-finger receives from the extensores communis: these two approach each other, and are united at the articulation of the finger to the metacarpus. The common tendon passes over the back of the first joint of the forefinger, over the first phalanx, and then divides into three portions, which terminate like those of the extensores digitorum communis: it corresponds to them also in every other particular. See *Extensor*.

The posterior surface of this muscle is covered by the extensores carpi ulnaris, the extensores proprius acuidunis, and extensores communis digitorum, and by the integuments. Its anterior surface is in contact with the ulna, interosseous ligament, radius, carpus, interosseous muscle of the second interval, metacarpus, synovial membranes of the digital articulations, and the phalanges. The radial edge is in contact for a considerable space with the extensores tertii internodi pollicis; the ulnar edge is attached to a ridge of the ulna. It will extend the three phalanges of the fore-finger, and move it towards the ulnar edge of the hand, as in pointing to an object. It will extend the wrist, and affect in the supination of the radius.

**Indicavit**, in Law, a writ or prohibition that lies for a patron of a church, whose clerk is sued in the spiritual court by another clerk for tithes, which do amount to a fourth part of the profits of the advowson; then the suit belongs to the king's court, by the flat. *Wilt*. 2. cap. 5.

And the patron of the defendant being likely to be prejudiced in his church and advowson, if the plaintiff recovers in the spiritual court, hath this means to remove it to the king's court. *Reg.* Orig. 35. Old Nat. Br. 31.

**Indicus extensor.** See *Indicator*.

**Indicis extensoris.** See *Indicator*.

**Indication** signifies the conveying of an ecclesiastical assembly as a synod, or council, or even a diet.

**Indication** is applied to the several felions of the same council.

Hence it is, that at the end of the felions of the council of Trent, the decree by which the council appoints the day of the future felion, is called the indication of that felion.

**Indiction**, in Chronology, a term used for a kind of epoch, or manner of counting time among the Romans; containing a cycle or revolution of fifteen years, which, when expired, begins anew, and goes round again without intermission.

This method of computation has no dependence on the heavenly motions. Petavius says, there is nothing in chronology less known than the Roman indiction, he means, than its original and commencement. It is the general opinion, that it was instituted in the time of Constantine, about the year 312; but this is a mere guess. There were indications in the time of the emperor Constantinus, as appears from the Theodosian Code. The learned hold, that indications were originally no other than certain annual taxes, the tariffs whereof were published every year; but why they were so called, why confined to a cycle of fifteen years, when, and on what occasion, instituted, is not known.

We find three kinds of indications mentioned in authors: the indication of Constantine, beginning on the first of September; the Imperial, or Cæsarean indiction, on the fourteenth of September; and the Roman Or Papal indiction, which is that used in the pope's bulls, and which begins on the first of January.

The popes have dated their acts by the year of the indication, which was fixed to the first of January, A. D. 313; ever since Chalemagne made them foreign; before which time they dated them by the years of the emperors.

At the time of the reformation of the calendar, the year 1582 was reckoned the tenth year of the indication; so that beginning to reckon hence, and dividing the number of years elapsed between that time and this by 15, the remainder, with the addition of 19, will be the year of indication, corresponding to the year of our Lord 1811. The indication may also be found by adding 3 to the year of our Lord, and dividing the sum by 15; the remainder is then the year of the indication: if there be no remainder the indication is 15. In either of these ways the year of indication for 1811 is 14.

The word indication comes from *indiciet*, which signifies *establishment, order, or denomination*. The time of the indication, among the Romans, was that wherein the people were summoned to pay a certain tribute; and it is for this reason, that the imperial indication began towards the end of September; because the harvest being then got in, it was supposed the people could more easily pay their tax.

**Indicetive, indicetivus**, an epithet given to certain fast-days appointed by the Roman magistrates, viz. the conful, or pretor.

**Indictment**, derived from the French *edict*, *indict*, or, according to M. Lambard, from *indiciet*, I charge, I inform again; in Law, a bill or declaration, drawn up in form of law, for the benefit of the commonwealth; exhibited as an accusation of one for some offence, criminal or penal, and preferred to a grand jury, and by their verdict found to be true, and preferred before a judge or officer, who has power to punish or certify the same offence.

**Indictment**, in Common Law, signifies as much as accusation among the civilians; though in some points it differs. See *Accusation*.

Lambard says, an indictment is an accusation at the suit of the king, by the oaths of twelve men of the same county where the offence was committed; returned to inquire of all offences in general in the county, determinable by the court into which they are returned, and their finding a bill brought
brought before them to be true. But when such accusatation is found by a grand jury, without any bill brought before them, and afterward reduced to a formed indictment, it is called a presentment; and when it is found by jurors returned to enquire of that particular offence only, which is indicted, it is properly called an inquisition.

Although a bill of indictment may be preferred to a grand jury upon oath, they are not bound to find the bill, if they find cause to the contrary; and though a bill of indictment be brought to them without oath made, they may find the bill if they see cause. But it is not usual to prefer a bill unto them before oath be first made in court, that the evidence they are to give unto the grand inquest to prove the bill is true.

The grand jury (see JURY) are to find the whole of a bill, or to reject it; and not to find it specially in part, &c. If they are satisfied of the truth of the accusation, they then indorse upon the bill of indictment "a true bill," anciently billa vera. But to find a bill, there must at least twelve of the jury agree. The indictment, when so found, is publicly delivered into court.

As indictments are purely for the good and quiet of the commonwealth, they are to be preferred for criminal, not civil matters. They are used in cases of high treason, and petit treason, felony, and trespasses of all kinds, and in all pleas of the crown; though they cannot be used for injuries of a private nature, that neither concern the king nor the public; and therefore all indictments ought to be brought for offences committed against the common law, or against statutes; and not for every flight misdemeanor. A person cannot be indicted of falsification of felony, but of the very crime itself; and then if he be not in custody, the sheriff is commanded to attack his body by a capias, &c. A person indicted for felony may have counsel allowed to speak for him, as to matter of law only; but such as are indicted for treason may have a copy of their indictment before trial, in order to advise with counsel; and such indictments are to be found within three years after the offence committed, unless the treason be directly against the king's person. (7 and 8 W. III. cap. 3, which is extended to trials on impeachments by 25 Geo. II. cap. 30.) Persons indicted of treason must be by the oaths of two witnesses; but in other cases one witness is sufficient. The prisoner, in this case, shall also have a copy of the indictment, but not the names of the witnesses, five days at least before the trial, i.e., upon the true construction of the act 7 W. III. cap. 3, before his arraignment; he shall also have a copy of the panel of jurors two days before his trial; and he shall have the same compellative process to bring in his witnesses for him, as was usual to compel their appearance against him. By 7 Ann. cap. 21. every person indicted for high treason, or misprision of treason, shall not only have a copy of the indictment, but a list of all the witnesses to be produced, and of the jurors impanelled, with their professions and places of abode, delivered to him ten days before the trial, and in the presence of two witnesses. But this last act, so far as it affected indictments for the inferior species of high treason, respecting the coin and royal seals, is repealed by the statute 6 Geo. III. cap. 53. But no person indicted for felony is, or (as the law stands) can be, entitled to such copies, before the time of his trial.

Indictments must be certain in every point, and charge some particular offence; also goods stolen must be particularly set down, and the offence laid positively, and not by way of recital. There must also be expressed the Christian name, surname, and addition of the offender, with the day, year, and place in which the offence was committed, as also the nature of the offence. (1 Hen. V. cap. 5.) In an indictment for murder, the length, depth, or other dimensions of the wound, must be expressed; that a judgment may be formed whether it was mortal; and in this case, the time of the death must be laid within a year and a day after the moral stroke was given. (See Appeal.) And in felony, the value of the things stolen is to be particularly mentioned, in order that it may appear whether the offender has been guilty of grand or petit larceny. A mistake in spelling the defendant's surname is not a sufficient cause for abating the indictment, provided it sounds like it. If a word of confession be omitted in an indictment, it renders the whole naught; but the case is not the same where a word of form is omitted, or where there is an omission of a synonymous word, if the sense is not injured. In some crimes particular words of art must be used, which are so appropriated by the law to express the precise idea which it entertains of the offence, that no other words, however synonymous they may seem, are capable of doing it. Thus, in treason, the facts must be laid to be done "treasonably," and against his allegiance; anciently, prodelicet et contra liganiam sua debiti- tum? else the indictment is void. In indictments for murder, it is necessary to say that the party indicted "murdered," not "killed" or "flew" the other; which, till the late statute, was expressed in Latin by the word "murdrat." In all indictments for felonies, the adverb "feloniously," "felonice," must be used; and for burglaries also "burglariously," or in English, "burglariously;" and all these to ascertain the intent. In rapes the word "rapaciet," or "raufciet," is necessary, and must not be expressed by any periphrasis, in order to render the crime certain. So also in larcenies, the words "felonice cepit et aportavit," "feloniously took and carried away," are necessary to every indictment; for these only can express the very offence. In case one part of an indictment is inconsistent with another part of it, the indictment becomes void; though where the tenor is plain, the court will dispense with a small inconclusiveness. Indictments are amendable the same term they are brought into court, but not afterwards; and in criminal prosecutions, the amendment must be only such as is permitted by the common law. Indictments for crimes committed, ought to be laid in the county where they were done; for otherwise, upon pleading the general issue not guilty, if it appears that the offence was committed in another county or place different from that in the indictment, the defendant will be acquitted. Yet if larceny be committed in any one county, and the goods carried into another, the offender may be indicted in either for the offence is complete in both. (1 Hal. P.C. 507.) Or, he may be indicted in England for larceny in Scotland, and carrying the goods with him into England, or vice verfa; or for receiving in one part of the United kingdoms goods that have been stolen in another. (Stat. Geo. III. c. 31.) But for robbery, burglary, and the like, he can only be indicted where the fact was actually committed; for though the carrying away and keeping of the goods is a continuation of the original taking, and is therefore larceny in the second county, yet it is not a robbery or burglary in that jurisdiction. And if a person be indicted in one county for larceny of goods originally taken in another, and be thereof convicted or found guilty, he shall not be admitted to his clergy; provided the original taking be attended with such circumstances, as would have ousted him of his clergy by virtue of any statute made previous to the year 1691. (Stat. 25 Hen. VIII. 3 W. and M. c. 9.)

An offender is subject to indictment for a felony committed against a person unknown; yet for every thing must be proved to be the proprietor upon the trial, or else the property will
will be presumed to be in the prisoner, he having pleaded not guilty. An indictment being at the king's suit, the
prosecutor is a good witness to prove the charge contained in
it; and no damage can be given to the party aggrieved, ex-
cept it be particularly grounded on some statute. Indict-
ments before judicious of the peace may be removed by cer-
tiorari into the king's bench.

A bill of indictment is said to be an accusation, because
the jury, who inquire of the offence, do not receive it till the
party that offered the bill, appearing, subscribes his name,
and offers his oath for the truth of it.

It is always at the suit of the king, and differs from an
accusation in this, that the preferrer is no way tied to the
proof thereof upon any penalty if it be not proved, except
there appears a conspiracy. But if any one prefer an indi-
cement to the grand jury for any criminal offence, without
probable cause, and the bill is not found, or the party is ac-
quitted, action lies for a malicious prosecution. In order
in which it is necessary that the plaintiff should obtain a copy
of the record of his indictment and acquittal; but in prose-
cution for felony, it is usual to deny a copy of the indictment,
where there is any the least probable cause to found such
prosecution upon. But an action for a malicious prosecution
may be founded on such an indictment whereby no acquittal can be;
as if it be rejected by the grand jury, or be coram non judice,
or be insufficiently drawn.

INDICTMENTS. Demurrer to See Demurrer.

INDICTOR, in Law, he that indicteth another for an
offence: and indictment is the party who is indicted. 1 Ed. III.
cap. 11. 21 Jac. I. cap. 8.

INDICUM. In the writings of the ancients we find this
word very frequently used, as the name of a blue colour,
or pigment used in dyeing, and imported to Rome, Greece,
and other parts of the world, from the East Indies. The
greater number of writers make this the same with our
Indigo, or anil fere; and some fay it was the same with our
wood; but the former opinion seems most probable.

This substance, which the Greeks call indicium, the Ara-
bian writers, Axicea, Serapion, and others, have called
nil; though the same word is also sometimes used by them for
the pigment made from wood. See Indigo-
fera.

INDICUM FOLIUM. See Foliun and Tamalapatra.

INDICUS CALMUS, in Natural History, is a foUil coralline
body, supposethed formerly to represent some species of reed,
beef with flars on the surface.

INDICUS Coccus. See Coccus.

INDICUS Color, a term used by several of the ancient writers
to express black. The generality of the Greek and Roman
physicians of old times have called the black lignum aloeis,
agallochum indicum: and the only black kind of myrobalan
they were acquainted with, was in the same manner called
the indicum; but that there were supposethed particularly the
product of the Indies, in distinction from the paler lignum
aloes, or the other myrobalan; but that they were of that
colour which they called indicus color.

INDICUS Cyclus. See Cortex.

INDIES, EAST, in Geography, comprehends that vaft
tract of country, which is situated in the south of Tartary,
between Peria, and China, as well as the islands in the Eafi
Indian seas, such as Borneo, Sumatra, Ceylon, Java, the
Malays, Celebes, Moluccas, Philippines, &c. See INDIA
and HINDOOSTAN, and each island separathy.

INDIES, WEST, includes islands of the Atlantic, which
extend from the east of Florida, in a curve, to the coast of
Surinam, in South America, from W. long. 58° 20' to
$3° 30'; and from N. lat. 10° to 27° 50'; Cuba being made
the western boundary, and the Bahamas the most northerly;
and fixing the easterly point at the island of Barbadoes,
and the southerly at Trinidad. The name was given by Co-
lumbus, and has not been unfrequently applied to the whole
of America. See each island separately described.

INDIGENOUS, of indigena, denotes a native of a coun-
y; or that which was originally born or produced in the
country where it is found. In this sense, particular species
of animals and plants are said to be indigenous in the country
where they are native, in opposition to exotic.

INDIGESTION, in Medicine, in the acception in
which we employ the term, implies not only the imperfect
performance of the act of digestion, but also an impaired
condition of the functions of the stomach and chylopoetic
vessels in general.

In using the term indigestion in this extensive sense, we follow
the example of Dr. Cullen, who has comprehended, under
the head of Indig. pfla (from &c. ill. and extra, to diger), a
great variety of symptoms, which other nootlogists have con-
dered as distinct diseases, and described under various ap-
pellations, but which, he is of opinion, are all referable to
one common cause, an imbecility, or loss of tone in the
Lines. 5. 1190, and 1193.) Among the symptoms just alluded
to, which stand as distinct genera in other nootlo-
gical-systems, are Anaemia, or loss of appetite; Cardiagia,
or heart-burn; Gaftrocnamia, or stomach-cold; Flatusitis, or
flatulence; Nosea; Vomitus, Seda, &c. (See the Nofol.
System of Sauvages, Vogel, and Linnæus.) To the fame
condition of the digestive organs, when it is sympa-thetic of, or
combined with other complaints, Dr. Cullen likewise referred many of those undefined affections,
which have been confudely clasped together under the
general title of nervous disorders, or under that of chronic weak-
nesses. From the great importance of the stomach in the
animal economy, in which it is, as it were, the laboratory
of health, and from its sympathetic relation to every other
important organ in the body, it is obvious that every de-
rangement to which it is exposed must occasion some
reciprocal derangement in other parts of the system, and
that it must suffer, in its turn, whenever any diffilent
organ is much indisposed; and hence, that indigestion will
most frequently be accompanied with various adventitious
symptoms, and that it will be of two kinds, idiopathic
and sympathetic, according as the stomach itself, or some
other organ, is the seat of the primary disorder. It is
of the idiopathic indigestion, however, that we particularly treat
at present.

The symptoms which characterize idiopathic dyssiphera,
are irregular, but commonly deficient appetite, with oc-
casional flatours and pain, sometimes actual vomiting:—a fente
of load and dilution of the stomach after meals, followed
by eructations of air, or of solid or fluid matter, of various
quantities, acid, pungent, niterous, or infipid,—heartburn,
and pains in the region of the stomach. Some or all of
these symptoms occur at different times or in different in-
dividuals, and are commonly combined with irregularity
of the bowels, which are most frequently colitive, but some-
times lax, or in each of these ilutes by turns. The mouth
and throat are usually dry, especially in the morning, and
the tongue is at the same time furred, and of a white or
yellow colour, and there is a disagreeable taste on the
palate.

These are the direct indications of a deranged condition
of the stomach itself, and the consequent irritation of ill-
digested aliment. The fente of load is occasioned by the
removal
INDIGESTION.

Malaria, and venous grief, this and that fluids, temporary frightful with each other, excites the sensation of heart-burn, and occasional spasmodic and inverted actions of the stomach and gall-bladder, by which eructations are produced, as well as spasmodic contraction of the muscular parts of the stomach, which is accompanied by pain or gaitrodynia; over-dilution of the coats of the stomach, by the flatus, is likewise productive of pain.

But in addition to these morbid sensations and phenomena in the stomach itself, an infinite variety of symptoms occur, in different instances, indicating the sympathtic affection of the constitution at large, or of particular organs. These have commonly been called nervous symptoms, inasmuch as they have originated merely from a sympathy of parts, independently of any disordered state of the circulation, or of any morbid change in the structure of the suffering organs; and they are often more distressing than the primary symptoms belonging to the affection of the stomach. Among the symptoms to which we allude, are languor, dizziness, and indigestion to exertion, either mental or corporeal, but especially the latter; drowsiness, particularly after meals or flight exercice; giddiness, noise in the ears, occasional dimness of sight, or a sense of objects floating before the eyes, with anache under various forms, oft frequently affecting the forehead and temples, sometimes the crown and the occiput; feverish flying pains; palpitations of the heart, or intermissions in its pulsation, with considerable variations in the state of the pulse; total ruffles, or uncommonly equal and slow breathing during the night, with frightful dreams, the incubus, or night-mare, &c.; temporary absence of mind, impaired memory, unual timidity and dependancy; and, in short, all the train of complaints which belong to hypochondria and hysteria in the constitution in which they are liable respectively to occur. See these articles.

The experiments of modern physiologists have shewn that the process of digestion is principally effected by means of the fluids of the stomach, which possess a solvent power over the substances used as aliment; and that it is not a process of cohesion, putrefaction, attrition, or fermentation, as was anciently supposed. (See Digestion.) It would seem, therefore, that the essential cause of idiopathic dyspepsia consists in a change in the quantity or quality of this gastric fluid, or solvent, originating from an impaired condition of the secretory function of the stomach. This, however, can perhaps only be ascribed to the deficiency of its tone and vigour as a muscular organ. Dr. Cullen justly remarks, that, as the peculiar nature of the digestive fluid, the changes which it may undergo, and the causes by which it may be changed, are very little known to us, we cannot found a practical doctrine upon any supposition respecting it; but as, at the same time, the imbecility of the stomach, either as the cause or the effect of the change in the digestive fluid, seems always to be present, and to have a great share in occasioning the symptoms of indigestion, we may still consider the imbecility of the stomach as the proximate and almost sole cause of dyspepsia. He observes, too, that this view of the subject is the more admissible, as it appears to be fully and clearly applicable to the explanation of the practice which experience has established as the most successful in this disease. Four Lines, § 1160.

Causes of Indigestion.—Certain original constitution of the body is obviously connected with a predisposition to this complaint; this is sometimes manifest only in a defective performance of the functions of the stomach itself; but in other cases it is evidently a part of the general want of tone and vigour in the body, and occurs in persons of lax fibre, and languid or languid-phlegmatic temperament. In persons of dark and fallow complexion the stomach itself appears to be often originally weak, in a degree disproportionate to the general condition of the habit.

The exciting causes of indigestion, then, must be looked for among those circumstances which tend either to produce a loss of tone in the muscular fibres of the stomach, or which, in the debilitated state of that organ, tend to oppress its powers and to impede its functions. The causes which contribute to impair the vigour of the stomach are of two kinds; namely, those which operate directly upon that organ, and those which affect it indirectly, or through the medium of the general system.

The vigour of the stomach is impaired by the excessive use of stimulating condiments, and of spiritsuous liquors, as well as by the abuse of certain articles of the digestive or narcotic kind, such as tobacco, tea, coffee, opium, bitters; and by the too frequent and copious use of acid and accecent articles of food, and of warm watry liquids. Frequent vomiting, whether arising spontaneously or excited by art, tends also greatly to debilitating the stomach; and over-dilution of the organ by an excessive quantity of food or drink, or the use of food in itself difficult of digestion, or difficult from the idiosyncrasy of the individual, equally contribute to the same effect. The want of due mastication, and of the proper commixtura of the saliva with the food, by which its tendency to putrefactive decomposition may be diminished, likewise materially enfeebles the digestive powers of the stomach, and adds to the oppression where it is already weakened. Whence the habit of frequent spitting, or rejection of the saliva, is justly enquired among the causes of indigestion. Compersion of the stomach after a full meal, as by particular potions, &c., or violent exercise or overexertion of the body, under the same circumstances, have been found to have a material influence in preventing the process of digestion, and oppressing the powers of the stomach. Hence various occupations and trades, in which compersion and succussion of the diffused stomach are daily produced, occasion habitual dyspepsia in those who are predisposed to the disea.

Many of these occupations, however, debilitate the stomach likewise through the medium of the general system, or by deranging other organs and functions with which the stomach particularly sympathizes. The sedentary and inactive life, connected with many of them, debilitates the body in all its functions, and the stomach most particularly; intense study, or close application of mind to any business, when long continued; grief, anxiety, vexation of mind, and disorderly passions of any kind; venous immodicia; exposure to moist and cold air, when without exercise; and frequent intimation, which belongs partly to this head, and partly to the former,—are all common remote causes of that imbecility of stomach which is connected with indigestion. Dr. Cullen remarks, that, though the disease, as proceeding from the last lot of causes, may be considered as a symptomatic affection only; yet as the disorder of the stomach is generally the first, always the chief, and often the only effect which these causes produce or discover; so the affection of the stomach may be considered as the disease chiefly to be attended in practice; and the more properly so, as in many cases the general debility is only to
be cured by restoring the tone of the stomach, and by remedies first applied to this organ.

On the other hand, however, it is not to be omitted, that the stomach, from its extensive sympathy, by which it is often a partaker of morbid irritation seated in other organs, occasionally displays symptoms of derangement so violent, and apparently so confined to itself, as to make the primary and proper source of the derangement be altogether overlooked. Many instances might be quoted of the successful treatment of seemingly idiopathic dyspepsia, by remedies which manifestly and chiefly operate upon other organs, and exert little or no immediate beneficial influence on the stomach. The visera, more immediately concerned in the function of digestion, especially the liver, and the alimentary canal, are often the seat of the original irritation in such cases; the kidneys and the ureter occasionally produce similar effects.

Treatment of Indigestion.—In attempting to cure this state of the stomach, we may consider the following indications as the principal points to be pursued: first, to avoid, or to remove, or, as far as may be, to regulate those things which have been enumerated above as the ordinary exciting causes of the disease; secondly, to palliate or remove those urgent symptoms, which especially contribute to aggravate and continue the disease; and thirdly, to restore the tone and vigour of the stomach, and of the sytem at large.

The propriety and necessity of the first indication is sufficiently evident, as the continued application, or frequent repetition of those causes, must necessarily tend to continue the disease, to defeat the efficacy of remedies, or to occasion the recurrence of the disorder in spite of the operation of these. Dr Cullen justly remarks, that it is commonly owing to the neglect of this indication, that this disease is so frequently inobitably in its duration. It would be superfluous to enumerate the various modes of fulfilling this indication, which will be sufficiently obvious from the consideration of the several causes; but this circumstance evinces the importance of minutely investigating the origin of the disorder, previous to the administration of remedies, and of ascertaining whether the dyspepsia be constitutional or acquired, whether idiopathic or symptomatic, whether owing to any organic derangement of the stomach, such as tumour, ulcer, or fermentivity, or whether arising merely from errors in diet, or other extrinsic agents. It must be observed, however, that the accomplishment of this first indication is often exceedingly difficult; for, in many cases, the circumstances of the patient will not admit of any material change; his avocations themselves, upon which his subsistence depends, comprehend, perhaps, the principal cause of the mischief. More frequently, the obstructions arise from the difficulty of inducing men to break in upon established habits, or to renounce the pursuit of pleasure; and especially, to persuade them that those practices, which they have often repeated, and even others repeat, with seeming impunity, are in reality prejudicial.

Some allowance, indeed, is necessary to be made for the influence of habit, in all changes that relate to the animal economy, and especially where these habits have been carried to the extreme. For if the stomach have been long accustomed to excessive stimulants, whether from confections or spirituous liquors, the total abstinence of these from the diet might occasion a direct debility, under which the powers of life might sink. Under such circumstances, therefore, some degree of the accustomed stimulants must be for some time indulged in, or some les prejudicial one substituted. But the apprehensions of danger, from great changes in the habits of life, which are generally entertained, are carried to an extent which experience does not justify. Almost all the general rules which can be laid down, in respect to the whole system of certain articles of diet, admit of exceptions from peculiarities of constitution in particular individuals. Some indications on this point, however, may be obtained by attending to the obvious prevailing state of the stomach, as evinced by the acid or sudorous eruptions, &c. The acid state of the stomach implies the necessity of diminishing the proportion of vegetable food; while the sudorous condition may be benefited by augmenting that part of the diet, and lessening the quantity of animal food. It is of much importance that the whole quantity of food should be such as not to overload the stomach, or occasion considerable dilution.

There is a common precept, under which great errors are sometimes committed, in the way of overloading the stomach, or at least of exhausting its digestive powers, namely, that of eating little and often, so that long fasting may be avoided on the one hand, and too much repulsion on the other. With the view of fulfilling this precept, an almost incessant supply of aliment is sometimes thrown into the stomach, so that the digestion of one portion is never completed, before another is combined with it in a crude state, thus aggravating the crudities which the disease itself produces, or preventing their more effectual affimation.

In fulfilling the second indication, of removing urgent symptoms, one of the first objects pursued by some practitioners, is that of removing the crudities of the stomach produced by the disease, by means of emetics: Dr Cullen himself appears to be the advocate of this practice. (First Lines, par. 1204.) Nevertheless, as these crudities are commonly the effect of the disease, and not the cause, the expulsion of them from the stomach by vomiting can afford but a brief and temporary relief; and the same uncles will recur after the first or second meal. And, moreover, experience has shewn us, that frequent vomiting, however excided, tends to weaken the stomach, to diminish its powers of digestion, and to render it less able to retain what is thrown into it, and therefore ultimately to aggravate the symptoms which it was intended to relieve. "They are unhappy," says the same physician in another place, "who trust to this mode of relief, and have frequent recourse to it; for I am certain, from much experience, that frequent vomiting hurts the tone of the stomach, and often makes the symptoms of digestion recur more frequently and sooner than they otherwise would have done." (Cullen on Mater. Medica, vol. i. p. 465. See also Emetics.) We have stated under that article, the circumstances which have led to the erroneous supposition, that the indigestion and its concomitant symptoms originate in the presence of bile and other extraneous fluids in the stomach, and explained how the discharge of bilious and mucous matters from the stomach, under the operation of an emetic, may be the effect of the vomiting, although they might not previously have been lodged there. In short, there are few infallibles of dyspepsia in which the use of emetics can be deemed beneficial.

Of the other urgent symptoms, which require to be palliated, the principal are acidities, and its frequent concomitant, heart-burn,—pain in the stomach,—the ejection of a copious and clear fluid, or water-bubbs (as it is termed in Scotland), and confinement of the bowels. It will not be necessary for us to dilate upon the method of treating these symptoms here, since they will be found amply discussed under their proper heads; as they are often so peculiarly distressing to the patients, as to be considered themselves the principal diseaser, and to be the principal subject of complaint. We may briefly observe, that the presence of acid in the stomach
INDIGESTION.

In a morbid degree is known, not only by its rising occasion-ially into the mouth and throat by eructation, and by the heart-burn which accompanies it (see Cardialgia) ; but also by the occurrence of gnawing pains in the stomach, flatulency, irregular cravings for food, griping and loofenefs of the bowels, &c. The acidity already present in the stomach may be corrected, by neutralizing it by means of a chemical combination with some alkali or absorbent earth. The three alkalis, soda, potas, and ammonia, may be taken for this purpose respectively, either in the pure (or caufic) state, or mild, i.e. in the form of carbonates : on the whole, they seem to be more efficacious in the pure state. The foda-water, now manufactured in the shops, is an agreeable form of antacid ; but the alkali may be taken with advantage in larger quantities than that beverage contains. Magnesia, chalk, and the tafeless powders prepared from crabs-claws and oyster-shells, which are carbonates of lime, likewise combine with the gastric acid, and neutralize it : the magnesia (which is much more effectual in its pure state, or cal- cined, than in the form of carbonate) is often useful, inasmuch as it forms a neutral falt, which is in fome degree laxative, with the acid of the ftomach. It is not, however, fufficient to neutralize the prefent acidity, the difpofition to generate it muft be alfo obviated. This is to be efected partly by avoiding acfent aliment of the vegetable clafs, and using animal food, such as is little capable of afcefeney. But as vegetable food cannot be entirely difcarded, the exces of its acfefeney may be in fome meafeure avoided, by chufing fuch vegetable matters as are leaft difpofed to the vinoif fer-mentation, fuch as leavened bread, and well fermented liquors; and rather than using the frefh native acids, employing vine-gar. But the difpofition to acidity may be further prevented by other means; namely, by fome which invigorate the muf- cular fubjed in the ftomach, to be mentioned prefently. It appears that the acidity occurs in a morbid quantity, either from a change in the digestive fluids, becoming lefs fit to moderate the natural progres to fermentation, or from their not being supplied in fufficient quantity; both of which probably arise from a weakened action of the ftomach. For it is ferved, in fome infances, that fedative or defpeering paffions immediately occasion the appearance of acidity in the ftomach, which did not appear before; and also that the ufe of stimulants, applied to the ftomach, often corrects or obviates an acidity, that would otherwise have appeared.

Of this symptom of the dyspeptic flate of the ftomach, which is a common concomitant of indigeflion, pain, or ftomach-colic, gaftrodynia, we have already treated at length. (See the laft term.) Having there flated the various circum- fiances under which it occurs, and efcpecially in the two opoifite flates of repletion and innutrition, as well as the method of cure, which fucceed in these two conditions repectively, we deem it unneceffary to repeat the obfervations here.

In fulfilling the second indication, another symptom which requires particularly to be obviated is colletenesis. There is too much connection between the feveral portions of the alimentary canal with refpect to the perifalatic motion, that if accelerated or retarded in any one part, the other parts of it are commonly affected in the fame manner. Thus as the briker action of the ftomach muft accelerate the action of the intestines, fo the flower action of the intestines muft in fome meafeure retard that of the ftomach. It is therefore of confequence to the proper action of the ftomach, that the perifalatic motion of the intestines, determining their contents downwards, be regularly continued, and that all colletenesis, or interruption of that determination, be avoided. But an infid- erate ufe of cathartic medicines is much to be deprecated. For it muft be obferved, that, as every confiderable evacuation of the intestines weakens their action, and tends therefore to induce colletenesis when the evacuation is over; to those purgatives which produce a large evacuation are unfit for correcting the habit of colletenesis. The milder cathartics, therefore, are the most fuitable for this purpofe, which do no more than foil the intestines to a more ready discharge of their prefent contents, without either hurrying their action, or increafing the excreitions into their cavity; either of which might produce a purging. Dr. Cullen was of opinion, that medicines which particularly simitize the large intestines, and act little on the higher parts of the intestinal canal, were peculiarly proper for this purpofe, such as the aloetic, and other refined purgatives. These medicines certainly produce a very benefi- cial operation in numerous infances, probably by supplying the place, as it were, of the bile, which appears to be the natural tonic and laxative to the intestines, and which is often both deficient in quantity, and depraved in quality, in dyspeptic habits. The augmentation and correction of this fluid is often an important object in the treatment of indi- geftion, and the changes in the appearance, odour, and con- finence of the ftools, as well as the preference or abfence of griping, tenefmus, heat and irritation in the feat, &c., are among the principal diagnostic symptoms in regard to the condition of the bile, which seems to be the chief caufe of the variations of the alvine discharge. (See Abernethy’s Obfervations on the Diff. of the Health, &c.) For the purpoifes of augmenting and correcting the biliary fecretion, the milder preparations of mercury, which require to be varied according to circumstances, which have not yet been accurately defcribed, appear to be the moft effectual agents. It is pro- bable that the long expected treatifte of Dr. James Curry will contribute materially to elucidate this important fubject; and we refund that we shall be able to avail ourselves of the affiduities of that work, before we compofe our article on the chronic difeafes of the Liver.

The peculiar modification of dyspepsia, called by the Scotch water-brabfs, the Cardialgia flatatoria of Linnaeus, (Gen. Morborum, Clafs iv. Ord. 1.) and the Pyrosis of Cullen, (for which we have no appropriate English name,) is a sufficiently diftinct difeafe to be defcribed in a separate article. See Pyrosis. See alfo Flatulence, Nausea, and Vomiting.

The third indication, which is properly the curative one, is to restore the tone and vigour of the ftomach, the lofs of which is deemed the principal foure of the difeafe. The means of accomplifhing this indication may be referred to two heads; one of which includes thofe means which operate directly and chiefly on the ftomach itslel; and the other, thofe which, operating upon the whole fylem, communicate their tonic powers fecondarily to the ftomach.

The medicines which operate directly on the ftomach, comprife all thohe articles which are denominated tonics, and many of thohe called stimulants, and affiriment.—The bitter vegetable fulbances, or bitders, as they are emphatically called, and efcpecially thohe which combine fome aromatic quality with their bitternefs, are most frequently precribed for this purpofe, and poifeifs very conliderable efficacy. Such are the roots of gentian, columby, and rhubarb; the bark of cinchona, cafebrilla, &C.; the quaffia wood; the flowers of chamomile; and many other vegetable productions. Ex- perience, however, seems to have decided, that these bitders cannot be taken for a great length of time with impunity. Some have imagined that there is a certain quantity of a narcotic power ulnutrant in them which, though defirous of its effects for a conliderable time, ultimately occasions a delerious influence on the constitution. This was particularly learned from the cosequences of a long-continued ufe of the celebrated
INDIGESTION.

celebrated Portland Powder, for the cure of the gout: a very large number of those persons who took that medicine, which consisted of bitters and aromatics, having died of apoplexy, or some other severe disease, after having been apparently much benefited by its use. When these medicines are taken, therefore, with a view to restore the tone and vigour of the stomach, it is advisable not to employ them unremittingly for a great length of time; but to suspend the use of them occasionally for a considerable period, substituting some other corroborant medicines, if necessity require them. Among these the mineral acids are important adjuvants, especially the sulphuric (or vitriolic) and muriatic acids; which have not only a direct tonic power upon the stomach, increase the appetite, and aid digestion, but are requisite to prevent the processes of fermentation in the food taken in. In this way, probably, their efficacy in preventing the formation of acidity in the stomach, and the heart-burn, &c. arising from such acidity, is to be explained. It is certain, that, in many instances, where the alkalis and absorbents have failed to obviate acidity and its consequences, connected with indigestion, the free use of one or other of the mineral acids has effectually remedied the disorder. Aromatic substances stimulate the stomach, and frequently therefore relieve flatulence, flatulence, and colic; e.g. cinnamon, ginger, calphicum, &c. but their stimulus is transitory, and if they are frequently repeated, and taken in large quantities, they may injure the tone of the stomach. Chalybeate medicines, or the various preparations of iron, are often employed as tonics, in the cure of indigestion; and they may be administered in considerable quantities with safety. They have not, however, been found so efficacious in the cure of indigestion, as the remedies above-mentioned; and they are principally taken in the form of chalybeate waters. But it is certain that these waters contain in general a very small proportion of iron; and that other preparations of the iron are administered in much larger quantities without producing these salutary effects, which are often ascribed to the mineral waters; it is, therefore, probable that the benefits, which are observed to accrue during the use of these waters, are generally the result of other circumstances connected with the drinking of them.

For, in fact, the most essential means of fulfilling the third indication are those which strengthen the system at large, and thus indirectly restore the vigour of the stomach; and among these, exercise claims our first notice. We have shewn, in its proper place, the mode in which exercise operates, in promoting the full and perfect circulation of the fluids through all the organs of the body, and therefore in perfecting the performance of all the functions. (See Exercise.) But we may remark, with Dr. Cullen, that it in a particular manner strengthens the stomach by promoting perspiration, and exciting the action of the vessels on the surface of the body, the skin having a peculiar sympathy with the stomach. In this influence, however, as in every other operation of the animal economy, moderation must be the leading rule; for, although the healthy and free circulation through the cutaneous vessels conduces to a sympathetic support of the action of the stomach; yet excessive perspiration, arising from over-action of these vessels, is followed by a languid and partial torpor, which is also communicated to the stomach; in which such reeks, and total loss of appetite are often the immediate results of violent exercise, attended with profuse perspiration. Regular exercise on horseback has been generally found the most effectual means of strengthening the stomach, and of curing indigestion. Cold bathing is another important mode of restoring both general and local vigour; but unless it be resorted to with some discrimination, like other active agents upon the animal frame, it may be productive of much detriment. In order to obtain benefit from the external application of cold, a certain degree of vigour in the circulation, especially in the vessels of the skin, should be present. In the dyspeptic state, the temperature of the skin is liable to be defective, and the cutaneous circulation to be feeble; and under such circumstances, to far from giving strength to the constitution, or to the stomach, the powers of life are depressed by the use of the cold bath, and the digestive organs sympathize in the torpor, produced in the skin. The tepid or warm bath is more beneficial when this condition of the system exists, and the baths of Buxton and Matlock may be resorted to with advantage; the same principle, however, must be kept in view in the use of these; which must not be entered with a chilly and shuddering surface; nor the immersion be repeated, if a glow does not succeed. See Cold, as a remedy.

In consequence of the great sympathy between the stomach and the skin, the proper regulation of the chalybeate is a matter of considerable importance to those who are liable to indigestion; and as the temperature, though variable, is most frequently below the standard of health, in general warmth is a necessary quality to be maintained. This is most particularly required in the extremities, in which the circulation is necessarily most languid, in consequence of the greater distance from the heart; warmth and dryness of the feet, therefore, are peculiarly serviceable in the cure and prevention of dyspepsia; and for those whose whole temperature is easily diminished by external cold, the general stimulus and slow-conducting power of woollen garments, worn next the skin during the winter months, may be considered as affording much security from the attacks of indigestion. But as profuse perspiration is generally accompanied by some degree of sympathetic debility in the stomach, these garments should not be used, during the hot seasons, by those whose skin is readily brought into a perspirable state.

A relaxation of the mind from the anxieties of business and the fatigues of study, and the pursuit of objects of amusement, contribute materially to the well-being of the animal economy, and especially to the proper performance of the digestive functions. This object is more particularly to be considered, when there is a tendency to hypochondria. And as we have already observed, it is probably from the amusements and regular exercise, which are generally enjoyed at waking places, as they are called, that more benefits accrue to the dyspeptic invalids, than from the virtues of the mineral springs, these places of resort may be recommended.

Before we conclude this topic, it may be proper to state, that several contemporary physicians and surgeons have observed, that a deranged condition of the digestive organs, however induced, becomes the cause of many secondary diseases, both general and local; such as superficial evolutions, pains, tumours, &c.; which spontaneously cease, when the disorder of the digestive organs is removed. We may remark, however, that it is not every disorder of digestion which is followed by these consequences; and that it is rather in the morbid condition of the bilious secretion, than of the stomach itself, that the disorder alluded to consists. Its symptoms are thus described by Mr. Abernethy. "This slighter disorder of the chalybeotic organs is, in general, manifested by a diminution of the appetite and digestion, flatulence, and an unnatural colour and action of the excretions, which are generally deficient in quantity. The tongue is dry, whitish, or formed, particularly at the back part; this symptom is most apparent in the morning. The fur is greatest at the back part, and extends along the middle of the
the tongue to the tip, the edges remaining clean. As the
disease advances, a tenderness is felt when the epigastric region
is compressed, and the patient breathes more by the ribs, and
less by the diaphragm, than in the healthy state. The urine
is frequently turbid." (Abernethy on the Conflit. Origin
of Local Dif.) In whichever of the organs concerned in
digestion this morbid condition may be principally seared,
the others participate, and various effects follow, in the
manner thus described by Mr. Abernethy. "It is generally
admitted, that disorders of the chylolpetic viscera will affect
the source of fermentation, and consequently the whole body;
but the variety of diseases, which may result from this cause,
has not been duly weighed and reflected on. It may pro-
duce, in the nervous system, a diminution of the functions
of the brain, or a state of excitation, causing delirium;
partial nervous inactivity and insensibility, or the opposite state
of irritation and pain. It may produce, in the muscular
system, weakness, tremors, and palsy; or the contrary affec-
tions of spasm and convulsions. It may excite fever,
by disturbing the actions of the fanguiferous system; and cause
various local diseases, by the nervous irritation which it pro-
duces, and by the weakness which is consequent on nervous
disorder or imperfect chylification. Or if local diseases occur
in a constitution deranged in the manner which I have
described, they will become peculiar in their nature and
pro-
gress, and difficult of cure. Affections of all those parts
which have a continuity of surface with the stomach, as the
throat, mouth, lips, skin, eyes, nose, and ears, may be origin-
ally caused or aggravated by this complaint." Whenever,
therefore, local diseases are connected with this flight
derangement of the digestive organs, the first care will be to
rectify this derangement, as the most important step towards
the cure of the former. For while the secretion of bile is
either defective, or depraved in quality, (of which the ap-
pearances of the alvine discharge afford the best index,) the
local or general symptoms of disorder, connected with this
condition of the hepatic function, will not yield to remedies
that would otherwise seem to be appropriate, and readily
effect a cure.

INDIGETES, a name which the ancients gave to some
of their gods.

There are various opinions about the origin and signification
of this word; some pretending it was given to all the
gods in general; and others only to the semi-gods, or great men
denominated. Others say it was given to such gods as were
originally of the country, or rather such as were the gods of
the country that bore this name; and others again hold, it
was ascribed to such gods as were patrons and protectors of
particular cities.

Lastly, others hold indigetes to be derived from inde
gemini, or in loco degens, or from inde and ago, for deos, I
live, I inhabit; which last opinion seems the most proba-
ble.

In effect it appears, 1. That these indigetes were also
called local gods, div locales, or topical gods, which is the
same thing. 2. The indigetes were ordinarily men deified,
who indeed were, in effect, local gods, being esteemed the
protectors of those places where they were deified; so that the
second and third opinion are very confinent. 3. Virgil joins
patriis with indigets, as being the same thing, Georg i
ver. 498. Div patriis, indigetes. 4. The gods to whom the
Romans gave the name indigetes were, Faunus, Vesta,
Remus, Romulus, all the gods of Italy; and at Athens,
Minerva, fays Servius; and at Carthage, Dido. It is true,
we meet with Jupiter indiges; but that Jupiter indiges is
Aneas, not the great Jupiter; as we may see in Livy, lib. i.

The ancients were acquainted with the dye, which we call
indigo, under the name of "Indicum." Pliny knew that it
was a preparation of a vegetable substance, though he was
not truly informed concerning the plant itself, and the pro-
duces by which it was fitted for use. From its colour, and
the country from which it was imported, it is denominated
by some authors as "Atramem Indicum" and "Indicum
migrum." Even at the close of the 16th century it was not
known in England what plant produced indigo. Gerard,
in 1597, is wholly silent about it, and so is Johnston in 1632.
Parkinson, however, in 1649, treats largely of it. He
calls it "Indico or Indian woode," and gives a figure of the
leaf from De Laet. He then describes it, first from Fran-
cis Xeres in De Laet's description of America; and se-
condly, from Mr. William Finch, a London merchant, in
Purchas's Pilgrims. Even in 1688 Mr. Ray says it was
not agreed among botanists what plant it is from which
indigo is made; but that the most probable opinion was
that it is a leguminous shrub, allied to Colutea. He
describes it from Hernandez and Margraaff; and subjoins
that of the "Ameri" from the Hortus Malabarium. Nig
or Anil is the American name. In Arabic it is Nila. The
Portuguese have adopted their Anil or Anilera from the
American. The other European nations generally call it
India. In Chinese it is Tien tum, which signifies sky-blue.
Mr. Miller cultivated the dyer's indigo to long ago as the
year 1731; and calls it Guatimala indigo, saying that with
us it is an annual plant. Specimens of the Indigofera trinitaria,
or dyer's indigo, from different parts of India, Madagasca,
Java, Ceylon, &c. vary very much, if they are all really
the same species. Linnaeus says that it is almost an exotic
in Ceylon, but frequent in Paliacea and Coromandel.
According to Loureiro it is spontaneous in China and Cochini-
china, and is cultivated all over those vast empires. Dr.
Patrick Browne, besides the wild indigo already mentioned,
have two others, which he calls the indigo, and the Guatimala
indigo; the former yielding more of the dye than either of
the others, is generally preferred, though subject to many
more mishances.

It has been generally believed, that the indigo plant flour-
ishes only in the climate of the torrid zone, and in those
parts of the temperate zone which are near the tropics. But
experiments lately made in Italy by Bruley, by order of
government,
INDIGO.

government, have proved that, in a suitable soil and exposure, and with good feed, it may be cultivated in a southerly climate. Accordingly, he has obtained the indigo plant in the gardens of the Château de la Vénère, near Turin; and by submitting it to the processes employed at St. Domingo, he has extracted an indigo which might bear comparison with the finest indigo of the colonies. His plantations were made towards the end of February. M. Icard de Batalligni, another colonist, cultivated the plant in 1805, in the department of Vaucluse, in France; and his results confirm the hopes formed with respect to the culture of indigo in Europe.

Labat has given a particular account of the culture of the plant, and the preparation of the indigo. The ground being thoroughly cleared from weeds (one of the principal points in the culture), and, we may add, drained, a number of slashes, ranged in a line, march across, making little trenches of the width of their hooves, and two or three inches deep, about a foot distance from one another every way: then, returning, they drop some seeds in each trench, and afterwards cover them with the earth taken out. The soil, it is observed by others, should be free and rich, and the climate warm; and the leafoil of sowing should be rainy; as the earth must either already have imbibed water, or rain must immediately follow the sowing; otherwise the seed becomes heated, corrupts, and is lost, after all the labour it has occasioned. During the process of vegetation the ground must be carefully weeded, in order to prevent any mixture of herbs, which would injure the indigo in its manufacture. In moist weather, the plant comes up in three or four days; and in about two or three months after, it is fit for cutting: if suffered to stand till it runs into flower, the leaves become too dry and hard, and the indigo obtained from them proves less in quantity, and less beautiful: the due point of maturity is known, by the leaves beginning to grow less sappy, or more brittle. In rainy feasons, the cutting may be repeated every six weeks: cutting in dry weather kills the plant, which, if that is avoided, continues to afford fresh crops for two years.

A large quantity of the herb is put into a vat or cistern of strong mason work, with so much water as is sufficient to cover it; and some wood laid above to prevent its rising up. The matter begins to ferment, foamer or later, according to the warmth of the weather, and the maturity of the plant, sometimes in six or eight hours, and sometimes not in less than twenty. The liquor grows hot, throws up a plentiful froth, thickens by degrees, and acquires a blue colour, inclining to violet. In proportion as the calorics increase, azote is disengaged, the herbaceous mucilage separates, the vegetable is decomposed, and the mixture absorbs oxygen. The fermenting fluid pales from a green to a violet tinge, and this by degrees changes to a blue colour. The great art of the manufacturer is to check the fermentation at a proper degree. If the fermentation is too feeble or too brief, the plant remains impregnated with much effluent salt, which diminishes the quantity of indigo. If it be too long, the tender extremities of the plant undergo a putrefaction which destroys the colour. Some years ago, the following criterion was published at St. Domingo, for ascertaining invariably the correct fermentation of the indigo. It is only requisite to write on white paper with the matter to be examined. If this ink be of very high colour, it is a proof that the fermentation is not yet at its true point. The experiment is repeated every quarter of an hour; till it is perceived that the liquid has lost its colour. This was pronounced an infallible index to shew the true point of fermentation. Others, however, judge of the proper stage of fermentation by means of a silver cup, into which they throw the liquid, shaking it till grains are formed; by their quality, and that of the fluid, they judge of the fermentation. When the feculent particles begin to precipitate to the bottom of the cup, it is then judged, that the herbs have attained the true degree of maceration for obtaining indigo. It has been observed, however, that this procedure often led into error; and, therefore, five or six minutes after the liquid has been put into the cup, it was perceived to form round its sides a cordon of fecula, or sediment, at first of a green colour, and then blue. When the maceration is not at the requisite point, this cordon, or girdle, detaches itself with difficulty from the sides of the cup, but finally precipitates, and concentrates at the bottom, always towards the centre, and the water above it becomes limpid, though of a yellowish tinge. When these signs are perceived, they indicate infallibly the success of the first operation. At this time, without touching the herb, the liquor impregnated with its tincture is let out, by cocks in the bottom, into another vat placed for that purpose, so as to be commanded by the first. The first vat is called the "heaper;" the second and third are called the "beaters."

In the second vat, the liquor is strongly and incessantly heated and agitated, with a kind of buckets fixed to poles, till the colouring matter is united into a body. A good deal of nicety is requisite in hitting this point; if the heating is ceased too soon, a part of the tinging matter remains dissolved in the liquor; if continued a little too long, a part of that which had separated is dissolved afresh. The exact time for discontinuing the process is determined by taking up some of the liquor occasionally in a little cup, and observing whether the blue fecula is disposed to separate and subside.

The facility with which the grain precipitates to the bottom of the beater, is an unequivocal sign that the beating has arrived at the correct point.

The whole being now suffered to rest till the blue matter has settled, the clear water is let off, by cocks in the sides at different heights; and the blue part discharged by a cock in the bottom, into another vat. Here it is suffered to settle for some time longer, then further drained in cloth-bags, or facks, and exposed in shallow wooden boxes to the air, without exposing it to the sun, and carefully keeping it from the rain, till thoroughly dry.

Before it is perfectly dry, it is cut in small pieces of an inch square, which detach themselves readily from the box, when the indigo is entirely dry. Yet, however well drained and dried the indigo may be, it always experiences, in the first months of its fabrication, a diminution sufficiently evident to warrant a hasting of the sale. It is customary to pack the indigo in barrels, and thus to circulate it in commerce. Indigo is packed in facks of coarse linen, and the fack is covered with an ox's hide, so hermetically sewed, that nothing can penetrate it. These packets are called "ceroons."

They are much preferable to barrels, as they are more fold and more convenient for transportation. Two "ceroons" make the load of one animal.

The author above-mentioned, from whom the greatest part of the foregoing account is extracted, observes farther, that the goodnese of the indigo depends greatly upon the age of the plant; that before it has grown fully ripe, the quantity it yields is less, but the colour proportionably more beautiful; that probably the secret of those whole indigos has been most effectually, is no other than cutting the herb at the time when it yields the finest colour; that the superiority of some...
some of the indigo of the East Indies to those of America, is perhaps owing to the former being prepared more curiously from only the leaves of the plant; and that by beating the herb in the steeping-vat, which has been practiced bysome with a view to increase the quantity, great part of the sub-
stances of the leaves and bark is blended with the water along
with the colouring matter, and the indigo extremely debased.
It is said that time, or lime-water, is sometimes employed in
the beating-vat, to promote the separation of the tinting
particles from the water; and that the hardness or finenessystem of some forts of indigo is owing to an over proportion of
this addition.

Pomet says, that the Indians of the village of Sarquee, near Amadabat, use only the leaves of indigo, and throw away the plant and branches; and from these the most esteemed indigo is brought.

Indigo is commonly divided, from the colour which it ex-
hibits upon breaking, into three kinds, copper-coloured, purple, and blue. It is said that the dyers use chiefly the first; and the calico-printers (for this drug gives a durable
faint to linens as well as woollens) the last. On what particu-
lar circumstances these different appearances depend, we
know not; nor is it certainly known whether the real quan-
tity of the indigo has any connection with them. The deep petrol and livid blue indigo, rubbed with the nail, appears like polished copper; and solutions of all the forts, made in alkali
lixivum, assume a copper-coloured skin upon the surface.

Good indigo is moderately light, breaks of a shining sur-
face, and burns almost wholly away upon a red-hot iron.
It is quickly penetrated by water, and reduced into a kind of
paste; a considerable part of this is the same time diffused
through the liquor, and very slowly subides. This is prob-
able what Labat and Hellot mean by its dissolving in water;
for no part of the indigo really dissolves; it cannot
indeed be expected that it should, from the process by which
it is obtained.

Indigo requires an equal quantity or more of fixed alkal-
line salt, to render it totally soluble in water. On digesting the indigo, with a gentle heat, in the solution of the alkaline
salt, a shining copper-coloured skin begins to appear, and
gradually covers the whole surface; on agitating the matter,
a large blue flower or froth arises, and the liquor underneath appears of a deep green. If woollen cloth, without any
other preparation than moistening it with warm water, is
belept in this hot liquor, it comes out perfectly green, and
changes almost instantly in the air to a fine blue. This is
the common procés of dyeing blue.

Mr. Hellot describes two indigo vats with urine; one of
which is used hot, like the foregoing, and the other cold.
The hot vat consists of equal parts of indigo, alum, and tartar, digested in urine till the liquor becomes green. The
cold one is prepared, by digesting powdered indigo with vinegar for twenty-four hours, in the proportion of four
pounds to about three quarts; then mixing the matter with
about fifty gallons of urine, and flirring the whole together
ever night and morning, till the liquor turns green, and
gathers a head like the common vat.

Indigo is fitted for printing on linen, by diluting it with water into the confiquence of a syrup; then adding some
powdered pearl-ashes, green vitriol, and lime newly flaked;
with so much water, occasionally, as will reduce them into
the confiquence of thin paint; mixing the whole thoroughly
together, and flirring the matter every now and then, till it
changes a copper colour on the surface. The proportions used
by the workmen are, two parts of indigo, one of pearl-
ashes, three of vitriol, and two of lime. The same compo-
sition, diluted with a sufficient quantity of water (about six
gallons to a pound of indigo), and boiled, gives a durable
blue to tanned skins, whether dipped in hot or cold.

Indigo digested in a moderate heat with different volatile alkaline spirits, gave only yellowish and brownish red
characters; with rectified spirit of wine, a reddish one; to lime-
water, and to water acidulated with the vitriolic, nitrous,
and marine acids, it gave no tincture at all.

The concentrated vitriolic acid unites with it into a smooth
pall, especially if the indigo is previously well ground with
powdered glafs, sand, or other like substances. The indigo
is thus rendered soluble in boiling water along with the acid,
so as to pass through the pores of a filter; the solution,
whilst hot, appears of a deep bright green colour, like that
made by fixed alkalies, but fades as it grows cold, and
changes at last to a brownish. These experiments, which
were many times repeated with the same event, seem to over-
turn Mr. Hellot’s ingenious theory, which deduces the
green colour of solutions of indigo from the common prop-
erty of blue juices being turned green by alkalies; and the
blue colour which the cloth acquires soon after it is taken
out of the vat, from a separation of the alkali. We here
find, that a green solution of this concrete is obtainable by
the strongest of the acids, and that with volatile alkalies it
discovers no tendency to greenness.

For the method of preparing Saxon blue and Saxon
Green from indigo, see those articles.

Indigo is sometimes used among the painters for paper-
hngs, and such gross urses, who grind and mix it with
white to make a blue colour; for without that mixture it
would paint blackish.

They also mix it with yellow to make a green colour. It
is also used in dyeing, and by the laundrymen, to give a blueish
cast to their linen.

In the Hortus Indus Malabaricus is an account of the
plant whence indigo is drawn; the decoction of whose root
is said to be excellent against nephritic colics; its leaves,
used for the abdomen, good to promote urine; and the
indigo itself is said to be of good use in drying of tumours.

Some physicians have recommended indigo in the quantity
of a drachm, while others look upon it as a poison; and in
Saxony the internal use of it is prohibited.

INDIGO, Baffard. See Anomorpha.

INDIGO Mills. For the purpose of effecting the solution
and union of indigo with the liquid used along with it, for
the purposes of dyeing, mills of various constructions are in
use. In this process of trituration or friction is as much as
possible avoided, and the pulverization is effected merely by
bruising. For this two very sufficient reasons may be al-
igned; the first, in point of economy, and the second, to
avoid chemical inconvenience. On whatever substance the
indigo was triturated or rubbed, a certain proportion of the
stuff would be mixed or incorporated along with the pulv-
erized indigo, and that proportion of indigo which was ab-
orsed by this stuff would be either totally lost, or brought
into union with another substance which might prove ufeless,
and probably injurious in the subfequent procés of dyeing.
If the former only was the cafe, the absorbed indigo would
be totally lost; if the second took place, the whole procés
might be utterly foiled by the combination. In the appropri-
ate plate, fig. 1, reprefents the ground or horizontal plan of
such an indigo mill as is generally used in small dye-works,
and which is occasionally turned by a man’s or boy’s hand.
This is tedious and laborious, for the operation must be
continued for a very long time before the indigo is suf-
icently mixed with the liquid to be fit for use, and only a
small
small quantity can be put into the vesse! at once. Fig. 1. is an elevated section of the same mill.

In this machine the pulverization or granulation of the indigo is effected by the preflure of a number of smooth cast-iron balls, like those used for the shot of great guns, which, being rolled among the indigo, press it into a paste by their weight, until it unit:es with the liquid by which it is to be held in solution.

In fig. 1, A represents the bottom and rim of the vesse! which contains the indigo, and which is of a cylindrical form. B is an upright spindle, which, in this figure, does not appear. Upon the spindle B is fixed a wheel C C, with a convenient number of arms projecting round the vesse!, like the radii of a circle; and below each of these arms are projecting pieces of iron, like the pins or teeth of a harrow, for moving the balls. When this wheel C is moved round its axis, the whole balls in the vesse! A are set in motion, and, by rolling over the indigo, gradually press it, until it unites with the water or liquid with which it is surrounded. If the bottom of the cylinder be flat, a very small part of the surface of each ball can act upon the indigo; but by casting circular hollow grooves, as represented in fig. 2, nearly the semi-diameter of the ball will press upon the stuff. The mill is moved by a handle D, fig. 2, which sets in motion the small bevel wheel E, and this wheel acting upon the horizontal wheel F, fixed upon the spindle B, sets it also in motion, and consequently the wheel C C is moved round its axis, and all the balls roll round upon the indigo. G is a crofs shaft upon the top of the spindle B, loaded at each end with a heavy ball. There is generally another shaft placed at right angles to this, when they affail in regulating and equalizing the motion in the same manner as any other fly wheel. When the indigo is found to be sufficiently dis- solved, and united with the water, the liquid thus formed is drawn off into any other vessel for use by means of a vent and spigot placed in any convenient part of the bottom of the vesse!. The great labour and time which it requires, and the small quantity of stuff which can be prepared at once by a machine of this kind, renders it ill adapted for the use of large works where much indigo is consumed, and where they have generally a horse-power water-wheel, or steam-engine, for raising water, cutting madder, and other purposes necessary in extensive works. Fig. 3. represents an elevated section of one of these machines, driven by any moving power, and capable of preparing a very great quantity of indigo at all times, as it requires no attendance, excepting to empty the vesse! when the indigo is wanted, and add a fresh supply. H is a semi-circular vesse! of cast-iron, placed upon a strong wooden frame O, and of any convenient length. I is a cover made in two pieces, with a circular aperture to admit the upright shaft K working upon the centre, or pivot P. At Q, the upright P is joined to a horizontal shaft of wood M, the other end of which is connected by the joint R, with a crank fixed on the end of a horizontal shaft N driven by the moving power. The circular motion of the shaft and crank N communicates an alternate, or reciprocating motion, by means of the horizontal connecting shaft M, to the upper end of the upright shaft K, which vibrating upon the centre joint P, sets in motion the iron cylinders L, L, in the body of the vesse!, which press upon the indigo, and produce the same effect, but to a much greater extent, as the balls in the machine first described. The cylinders L, L, may be made of any diameter or length which is found convenient. The greater mafs of iron that they contain, the quicker and more effectual is their operation upon the stuff, provided there is a sufficient power to drive them. The frame under the joint P extends the whole length of the semi-circular vesse! H, which may be any length, according to the extent of the power and quantity of work required. As this machine requires no attention whatever, it is found very useful in large dye works, as, by means of it, they can constantly command a large supply of prepared indigo, which may be drawn off when wanted, for the longer it is under the preparing process, the better in every respect, and fresh indigo may be added as the supply gets low.

Gen. Ch. Cal. Petrarch of one leaf, spreading, almost flat, five-toothed. Cor. papilionaceous; standard rounded, reflexed, emarginate, spreading; wings oblong, obtuse, spreading at the lower margin, of the shape of the standard; keel obtuse, spreading, deflexed, marked on each side by an hollow awl-shaped point. Stam. Filaments in two bundles, diposed into a cylinder, ascending at their tips; anthers somewhat roundish. Fig. 7. Germin cylindrical; style short, ascending; stigma obtuse. Peric. Pod roundish, long. Seeds numerous, kidney-shaped. Eff. Ch. Calyx spreading. Keel of the corolla having an awl-shaped spur on each side! Pod linear.

Obf. Till within the last century it was but imperfectly made out what plants produced the dye known to the Romans by the name of Indicum. Mr. Miller, however, cultivated the Indigofera so early as 1731; but he was acquainted with only five species of it; which fame Linnens imperfectly described. Professor Martyn enumerates thirty-five species, and Wildenow fifty-one; but since this genus is particularly known and esteemed for its utility in the arts, and that most of its species yield the blue dye, as well as many other plants of the same natural family, we shall merely give a general outline of the genus, without entering into a long etymological arrangement of the species.

The genus Indigofera is composed of shrubs and herbs, whose leaves are, in certain cases, simple, in the generally ternate, but mostly frequently undivided plan. The flowers in some species are jointed and awned at the base. Stipulae distinct from the leaf-blade. Peduncles axillary, generally manyflowered, in spikes or bunches. Many species are natives of the Cape of Good Hope; for instance, I. filifolia, fericia, d-prefa, erica, pteroloides, caudicant, amens, incanis, procumbens, farina, patauta, denudata, erica, coriacea, fruticosa, fritida, angustifolia, and capillaria. — The rest are either from the East or West Indies, Arabia Felix, New Holland, and the coast of Guinea.

It is said that Pliny was aware that Indicum was a preparation from a vegetable substance, though he was ill-informed both concerning the plant itself, and the proeess by which it is made fit for use. The following is a curious anecdote to that when at the close of the 16th century it was unknown in England what plant produced Indigo, for in a book entitled "Remembrances for Mutter S. by Richard Hakluyt," written in 1582, Mutter S. is instructed "to know if Anule that colour'd blew, be a natural commodity of Turkey, and if it be compounded of an herb—to send the seed or root with the order of towing, &c.—that it may become a natural commodity
commodity in the Realm, as wood is (Sufis tinctoria), that
the high price of foreign woad may be brought down."
I. tinctoria, Dyer's Indigo, is a native of the East and West
Indies, Madagascar, Ceylon, Java, &c. Its item is frutifica
—Louireo says it is cultivated all over the vast empires of
China and Cochinchina. It is figured under the name of
Amert in the Hortus Malabaricus, v. l. 101. t. 54.
INDIGOHERBA. See SOPHORA.
INDIKKOOD, in Geography, a town of Grand Bucharis;
60 miles W. of Balk. N. lat. 36° 38'. E. long. 64° 15'.
INDION, a town of Perzla, in the province of Chorasan,
next to the Masjan; 210 miles N.N.W. of Herat.
INDIRECT Modes of Synthesis, in Logic, are the
five last modes, or moods, of the first figure, expressed by the
barbarous words baraftes, etas, dafbs, sapsms,.SimpleDateFormatations.
It is the conversion of the conclusion which renders the
moods indirect; for instance, a syllogism in darsi, and
another in dabitis, would be perfectly alike, were it not for
that conversion; the propositions having the same quantity,
and the same quality, and the middle term being the subjet
in the major, and the attribute in the minor, in both. It
remains, then, that, to make a distinction, that which is the
subject of the conclusion in darsi, be the attribute in the
conclusion of dabitis; and that which is the attribute in the
first, the subject in the last. See SYLLOGISM.

INDISCERNIBLES, in the Philosophy of Leibnitz.
See LEIBNITZIAN Philosophy.
INDIVIDUAL INDIVIDUAL, in Logic, a particular be
ing of any species; or that which cannot be divided into two
or more beings, equal or alike.
The usual division in logic is made into genera or genera,
those genera into species, and those species into individuals.
See GENUS, SPECIES, and DIVISION.
The schoolmen made a four-fold distinction of individuals;
iz.
INDIVIDUUM Vagum, that which, though it signifies but
one thing, yet may be any of that kind; as when we say a
man, a certain person, or one who is fo and fo; though but one
person is meant, yet that person, for this appears to the
contrary, may be any body.
INDIVIDUUM Determinatum is, when the thing is named
and determined; as Alexander, the river Nile, &c. this is also
called individuum fixatum.
INDIVIDUUM Demonstrativum is, when some demonstrative
pronoun is used in the expression: as, this man, that woman.
INDIVIDUUM ex Hypothesi, or by supposition, when an
universal name or term is restrained, by the supposition, to a
particular thing; as when we say, the son of such a one, and
it be known that he had but one son.
INDIVISIBLES, in Geometry, those indefinitely small
elements, or principles, into which any body or figure may be
ultimately resolved.
A line is said to consist of points, a surface of parallel
lines, and a solid of parallel and similar surfaces; and because
each of these elements is supposed indivisible, if in any figure
Vol. XIX.
indi

connected with the motley history of this persiflage, many volumes thereon are extant among the Hindoos. He is said, in their theogony, to be the offspring of Katyapa and Aditi (see Kasyapa), and has the whole firmament under his regency. In many particulars he corresponds with the Joves or Jupiter's, for there were a great many among the Greeks and Romans; more especially, perhaps, with Jupiter Pluvius, for Indra is the god of showers. The Hindoos fancy the visible heavens to be under the guidance of eight genii, collectively called Maruts, or the Winds. (See Mat-=Rut.) Of these, Indra is the principal, and he rules the eastern quarter. He may be deemed a personification of the firmament, ruling all atmospheric or meteoric phenomena. As god of thunder he is named Vajra Pané, or Lightning Sender; his disk-shaped weapon, vajra, represents lightning. He rides in the celestial city Umravati; his palace, Vaśayatna, is situated in the garden Nandana, which contains also the all-yielding trees Pariyataka, Kalpadruma, and others similarly bountiful. He possesses also all the prolific cow Kamdeu, otherwise called Subebhi; and hence one of Indra's names means the lord of wealth. He has a wont named Indramani; he rides the elephant Iravat, with three probosci, which are said to represent water-spouts, as the bow with which he is armed is the iris. Seated on mount Meru, or the north pole, attended by male and female dancers (Sírana and Úpsírana), he regales the gods with nectar and heavenly music. He is painted with four arms, and spangled with eyes; hence one of his names is the thousand-eyed god. Another of his names is Purendara, or the destroyer of towns; he having, in revenge for supposed neglects, overwhelmed several cities; particularly Ujaini, or Oojein, the capital of Malwa.

Indrapur, the hereditary possession of the family of Sindia. The city has now lain submerged about 1600 years. (See Oojein.) Indra is also named Shatkratu, meaning he whom is made a hundred sacrificers, for this "king of the immortals," another of his names, is very extensively propagated in the numerous ceremonies of libation and sacrifice that Brahmanes, devoted to the service of the altar, are daily called upon to observe. Jealous, however, of the offerings made to other deities, he is represented as frequently interrupting, both by personal interposition and evil counsel, the sacrifice prepared or intended for other deities; in this character of an evil counsellor he is usually called Sakra, and although called and represented as thousand-eyed, he is sometimes painted with but one eye; the cause of which, with many other fables connected with the character and history of this important deity, is related in Moor's Hindoo Pantheon, whence most of the particulars of this article are taken.

Like most of the other Hindoo deities, Indra is represented as immoral and depraved, even to a proverbial degree; but we must refer to the work just mentioned for instances of his profligacy, excessively extravagant if received literally, but which, doubtless, are allegorical concealing of some astronomical or physical facts; for major Moor proves Indra to be a star or a constellation of the northern hemisphere, and that the wars which he sustains against giants, in which he is alternately conqueror and conquered, refer to some cycle or periodical revolution of the heavenly bodies. Metallic images of Indra are rarely seen; he is sculptured in Elephants and other excavations in India, mounted on Iravat, and is often met with in paintings. Several engravings of him are given in the Hindoo Pantheon. Under the words severally referred to above, the foreign names of persons and places that occur, farther particulars of the subjects of this article will be found; for Indra is so important a deity, that his history, like his worship, mixes itself with that of most of his divine associates in the monstros sylem of Hindoo idolatry.

Indranis, the name of the Sakti or comfort (see Sakti) of Indra, the regent of the firmament among the Hindoos. (See Indra.) Her name is sometimes pronounced Aindrani. She is otherwise called Pulomaya, or Powamaya, and Sakti, and is represented in the Hindoo Puranas, or mythological and theogonical romances, as a faithful and virtuous character, which is not always the case with her female divinities: she is also very handlome, and has relitfied many temptations. She is called one of the seven divine mothers of the celestial. (See Matu.) In the sixth volume of the Arctic Researches, is a curious and interesting account by Sir Charles Malet, of the magnificent excavations at Ellora, accompanied by plates; one of them representing Indrani, of lovely form, seated on a lion, with a child in her lap, and a skull and cross bones in her girdle: major Moor, however (Hindoo Pantheon, p. 271), doubts if this elegant figure be really of Indrani, of whom he says he never saw any sculptured representation. See Ellora.

To our account of which may be added, that Mr. Daniel has engraved and published, from materials in the collection of Sir Charles Malet, a series of views, both minute and perspective, of the interior and exterior of these wonderful excavations, that is altogether unrivalled by any work in Europe, as well for the accuracy of oriental scenery and costume, as for its general elegance and splendour.

Indrapour, in Geography, a town on the W. coast of the island of Sumatra, and capital of a country, which has several other towns, where the Dutch have a factory for the purchase of pepper, 100 miles N.W. of Bencoolen. S. lat. 2°. E. long. 100 40'. This was once the seat of a monarchy of some consideration and extent. Its antiquity appears from an historical account given by the sultan of Bantam to Corneille le Brun, in which it is mentioned, that the son of the Arabian prince, who first converted the Javans to Mahometanism, about the year 1400, having got himself declared suzerain of Bantam, married the daughter of the raja of Indrapour, and had, as her portion, the territory of the Sillabares, a people of Banca-joumou. This was probably the first diminishment which the Javan monarchs long availed themselves of; and since, the kingdom of Indrapour has dwindled into obscurity. From its ruins has sprung that of Anafoongey; extending on the seacoast from Mendoota river to that of Oori; the present capital of which, if such towns preserve the appellation, is Moco Moco, Marfleden's Sumatra, p. 254.

Indrapour Point, a cape on the W. coast of Sumatra. S. lat. 2° 16'. E. long. 100 34'.

Indrat, a town of Hindoo-land, in Dowlabadab; 23 miles N.W. of Beder.

Indre, a river of France, which rises about four miles N. N.W. from Doullac, in the department of the Creuse; and joins the Loire at Rigny, between Saumur and Tours.

Indre, one of the departments of the central region of France, formerly Lower Perri, in lat. 46 45', to called from the river which traverses it from S.E. to N.W.; bounded on the N. by the departments of the Loir and Cher, on the E. by that of the Cher, on the S. by the departments of the Creuse and Upper Vienne, and on the W. by those of the Vienne and Indre and Loire, about 54 miles from N. to S., and 5 from E. to W. Its capital is Chateauroux. It contains 362 square leagues, and 287,911 inhabitants; it is divided into four districts, viz. Illoudon, containing 30,344 inhabitants; Chateauroux,
Here, it may be observed, are various assumptions, from the more general species of the animal kind collected into one; which this proposition is supposed to precede; e. g. that every animal is either terrestrial, aerial, aquatic, or reptile.

Suidas reckons three kinds of induction: that just mentioned, which concludes or infers some general proposition from an enumeration of all the particulars of a kind, he calls the *dialectic* induction. The second proceeds by interrogation, and concludes probably, or with a verisimilitude: this is what the Greeks called *παραστάσεις*, and was that which Socrates ordinarily made use of, as Cicero, in his Topics, and Quintilian have observed: and, therefore, called the *Socratic* induction. This, however, is a captious way of reasoning: for while the respondent is not aware of what is designed to be inferred, he is easily induced to make those concessions, which otherwise he would not. Besides, it is not so well suited to continued as to interlocutory discourses.

The third kind of induction is properly *rhetorical*: being a conclusion drawn from some example, or authority. This is a very imperfect induction, all its force lying in a proposition which is concealed, and which will hardly be expressed. Thus, he that says, Codrus did bravely for his country, therefore I must die bravely for my country; proves nothing, unless this proposition be carried in mind, that I must do the same with Codrus. Again, Archimedes, and the other mathematicians, say, the sun is much bigger than the earth; therefore, it must be owned, the fun is much bigger than the earth. Where this proposition is understood, viz. whatever Archimeades, and the other mathematicians, say, is true.

Induction is one of the four forms of reasoning used by orators in confirmation; the other three are syllogism, enthymeme, and example, which last coincides with the third species of induction above enumerated.

Induction, in the English Laws, is usually taken for the giving possession to an incumbent of his church, by leading him into it, and delivering to him the keys, by the就意味着, or bishop's deputy, and by his ringing one of the bells.

When a clerk is inducted into a benefice, he is to exhibit his mandate from the bishop to the archdeacon, or other person to whom it is directed, and hath a right thereby to be induced into his living; and if he be refused induction, he hath a remedy both in the ecclesiastical court, and also an action of the case in common law, against the archdeacon. If the indenter, or person to be induced, be kept out of the church, or house, by laymen, the writ *de vi liae* lies for the clerk, which is directed out of the chancery to the sheriff of the county, to remove the force. And if another clergyman, presented by the same patron, keep possession, a fudation is granted out of the spiritual court, whereby the tethes, &c., shall be fueded, till the right be determined.

The archdeacon rarely inducts a clerk in person, but usually issues out a warrant to the clerks and lettered persons within the archdeaconry, empowering any of them to do it in his stead.

An induction made by the patron of the church is valid, but bishops and archdeacons may induct a clerk to the bensifices of which they are patrons, by prescription. No induction is necessary to a donative, where the patron, by donation in writing, puts the clerk in possession without prescription.

Suidas reckons three kinds of induction: that just mentioned, which concludes or infers some general proposition from an enumeration of all the particulars of a kind, he calls the *dialectic* induction. The second proceeds by interrogation, and concludes probably, or with a verisimilitude: this is what the Greeks called *παραστάσεις*, and was that which Socrates ordinarily made use of, as Cicero, in his Topics, and Quintilian have observed: and, therefore, called the *Socratic* induction. This, however, is a captious way of reasoning: for while the respondent is not aware of what is designed to be inferred, he is easily induced to make those concessions, which otherwise he would not. Besides, it is not so well suited to continued as to interlocutory discourses.

The third kind of induction is properly *rhetorical*: being a conclusion drawn from some example, or authority. This is a very imperfect induction, all its force lying in a proposition which is concealed, and which will hardly be expressed. Thus, he that says, Codrus did bravely for his country, therefore I must die bravely for my country; proves nothing, unless this proposition be carried in mind, that I must do the same with Codrus. Again, Archimedes, and the other mathematicians, say, the sun is much bigger than the earth; therefore, it must be owned, the sun is much bigger than the earth. Where this proposition is understood, viz. whatever Archimeades, and the other mathematicians, say, is true.

Induction is one of the four forms of reasoning used by orators in confirmation; the other three are syllogism, enthymeme, and example, which last coincides with the third species of induction above enumerated.

Induction, in the English Laws, is usually taken for the giving possession to an incumbent of his church, by leading him into it, and delivering to him the keys, by the simulatory, or bishop's deputy, and by his ringing one of the bells.

When a clerk is inducted into a benefice, he is to exhibit his mandate from the bishop to the archdeacon, or other person to whom it is directed, and hath a right thereby to be induced into his living; and if he be refused induction, he hath a remedy both in the ecclesiastical court, and also an action of the case in common law, against the archdeacon. If the indenter, or person to be induced, be kept out of the church, or house, by laymen, the writ *de vi liae* lies for the clerk, which is directed out of the chancery to the sheriff of the county, to remove the force. And if another clergyman, presented by the same patron, keep possession, a fudation is granted out of the spiritual court, whereby the tethes, &c., shall be fueded, till the right be determined.

The archdeacon rarely inducts a clerk in person, but usually issues out a warrant to the clerks and lettered persons within the archdeaconry, empowering any of them to do it in his stead.

An induction made by the patron of the church is valid, but bishops and archdeacons may induct a clerk to the benefices of which they are patrons, by prescription. No induction is necessary to a donative, where the patron, by donation in writing, puts the clerk in possession without prescription.
on the key of the church, which must be then in the door, and to say, "By virtue of this instrument, I induct you in the real, actual, and corporal possession of the rectory or vicarage of , with all its fruits, profits, members, and appurtenances."—This done, he opens the door, and puts the clerk in possession of the church, and shuts the door upon him; who, after he hath tolled a bell (if there be any) to give the parishioners due notice and sufficient certainty of their new minister, comes out, and defines the inducer to issue a certificate of his induction on the archdeacon's warrant, and that all absent will sign it under their hands. If the church-key cannot be had, it is sufficient that the clerk lays hold of the ring of the door, the latch of the church, yea, &c. and, within two months after this, the clerk must read the thirty-nine articles, and all the service of the day, both at morning and evening prayers, in the parish church of his benefice, and in the time of common prayer, and declare his assent and content: he must also then read the ordinary's certificate, in which is the declaration of his conformity, together with the same declaration, and of all this he must have two or three good witnesses, who must sign that they heard him do it, and be ready to attest it, &c. if required; and, within six months after induction, he must also take the oaths of allegiance, supremacy, and abjuration, at the quarter-seas, or in some one of the courts of Westminster.

Induction makes the parson complete incumbent, and fixes the freehold in him. When a clerk is thus presented, instituted, and inducted into a rectory, he is then, and not before, called in law, persona imperfanta, or parson imperfect. 13 Eliz. c. 13 and 14 C. II. c. 4. 1 Geo. flat. 2. c. 13. 9 Geo. II. c. 26. 23 Geo. II. c. 28.

INDULGENCE, in the Remigius Theology, the remission of a punishment due to a sin, granted by the church, and supposed to save the sinner from purgatory.

The Romanists found their indulgences on the infinite treasure of the merits of Jesus Christ, the Holy Virgin, and all the saints; which they suppose the church has a right of distributing by virtue of the communion of saints. See SUPEREROGATION.

These indulgences were first invented in the eleventh century by popes Gregory VII. Victor, and Urban II. as a recompense for those who went in person upon the wild enterprise of conquering the Holy Land. See CRUSADE.

They were afterwards granted to those who hired a follower for that purpose, and in procès of time were bestowed on such as gave money for accomplishing any pious works enjoined by the pope. In the beginning of the twelfth century, the bishops, whenever they wanted a supply of money for their private pleasures, or the exigencies of the church, recourse to the scandalous traffic of indulgences; and when the Roman pontiffs saw that immense treasures were thus accumulated by the interior rulers of the church, they thought proper to limit the powers of the bishops in remitting the penalties imposed upon transgressors, and disfranchised it, almost entirely, as a profitable trade to themselves. They began with granting a plenary remission of all the temporal pains and penalties which the church hath annexed to certain transgressions; and then proceeded to abolish even the punishments which are reserved in a future state for the workers of iniquity.

The Roman jubilees, first instituted by Boniface VIII. A.D. 1300, carries with it a plenary, or full indulgence, for all the crimes committed therein.

The pope also grants bulls of plenary indulgence to several churches, monasteries, and even to private persons; and it is a frequent thing to have general indulgences for the time of the principal feasts of a year. Their causeries say that a plenary indulgence does not always prove effectual, for want of complying with the conditions whereon it was granted.

For the extirpation of heretics, it has been a common practice with the popes to grant indulgences. Thus Clement XII. "That we may stir up and encourage the faithful to extirpate this ungracious crew of forlorn wretches, (the Ceremons, when in arms against Louis XIV.) we fully grant and indulge the full remission of all sins, whatever they may be (relying upon that power of binding and loosing, which our Lord conferred upon his chief apostle), to all those that shall kill themselves in this sacred militia, if they shall happen to fall in battle." See ABSOLUTION.

Julius II. had bestowed indulgences on all who contributed towards building the church of St. Peter at Rome, and pope Leo X. in order to carry on this magnificent structure, published indulgences, and a plenary remission on the same pretences. Finding the project take, he granted the right of promulgating these indulgences in Germany, together with a share in the profits arising from the sale of them, to Albert, elector of Magenta, and archbishop of Magdeburg, who employed Tetzel, a Dominican friar, as his chief agent for retailling them; and he furnished out of other countries to the highest bidder, who to make the bell of their bargains, procured the approbation of their preachers to do the value of the ware: "Happy times for sinners," says a modern writer, "their crimes were rated, and the remission of them set up by auction. The apostolical chamber taxed sins at a pretty reasonable rate; it cost but ninety lives and a few ducats, for crimes which people on this side the Alps punished with death."

These are specified in a book of rates called the Tax-Book of the Holy Apostolic Chancery, first printed at Rome in the year 1514, and ascribed by some to pope Innocent VIII. From a correct edition of this book, printed by L. Banck, professor at Norkopin, in Gotland, in 1651, it appears that the price of abdication for fornication, attended with the most heinous circumstances, was six groffs or gruits; for a layman's murdering a layman, five groits; for laying violent hands on a priest, without shedding blood, nine groits; for committing incest, five groits; for a priest's keeping a concubine, seven groits; for forfing the pope's hand-writing, seventeen or eighteen groits. See the Taxa S. Cancellariae Apostolicae, a L. Banck. Francoeur, 1651, p. 126, &c. It was this great abuse of indulgences, that contributed not a little to the first reformation of religion in Germany; wherein Martin Luther began first to declaim against the preachers of indulgences, and afterwards against indulgences themselves: but since that time, the popes have been more sparing in the exercise of this power; however, they afterwards carried on a great trade with them in the Indies, where they were purchased at two reals a-piece, and sometimes more. See REFORMATION.

INDULGENCE, or Indulce, signifies also a special favour, or privilege, conferred either on a community, or a particular person, by the pope's bull; in virtue thereof the party is licensed to do or to obtain something contrary to the intention and disposition of the common laws.

There are two kinds of indulgences: the one arbitrio, which consists in a power of nominating and prefiguring freely, and without reference, to benefits that are otherwise limited, and restrained by the laws of the apostolical chancery; such are those ordinarily granted to secular princes, cardinals, bishops, &c.

Seal indulgents consist in a power of receiving benefits, and
and expectative graces; of which kind are those of a parliament, of graduates, mandarines.

The Indulo of kings is the power given them of presenting to confidtorial benifees, either by treaty, by favour, or special privilege.

The Indulo of cardinals is a licence for holding regular as well as secular ben-ifices, and for disposing of benefices in commenda, or continuing them, &c.

Indulo of parliament is a right of privilege formerly granted to the chancellor, prelates, councilors, and other officers in the parliaments of France, to obtain a benefice of the colator, upon the king’s nomination directed to him. This was a kind of adowment, or patronage, belonging to the French king; the Indulo being a mandate, or grace, by which he was permitted to name to any colator he pleased a counsellor, or other officer of parliament, on whom the colator should be obliged to bestow a benefice: so that the right of the Indulo redhced radically in the king, the officers being only the objects thereof.

Indulphus, in Biography, the seventy-seventh king of Scotland, began his reign in the year 950. The early years of his reign were peaceable and prosperous, but afterwards his kingdom was invaded several times by the Danes, who were engaged against him for making an alliance with the English. Their first defeat was upon Earl Loudian, whom they fled from and crossed over to Fife. Here they were defeated, and driven out, and so well had Indulphus taken care to guard the coasts, that they could find no other opportunity of invading the country; till, having thrown the Scots off their guard, they made good their landing in Banffshire. Here Indulphus attacked them in their camp, and drove them towards their ships, but was killed in an ambuscade, into which he fell during the pursuit.

Indulito, in Commerce, denotes a duty, tax, or custom paid to the king of Spain for all such commodities as are imported from the West Indies in the galleons.

Indurating, a term applied to such things as give a harder or firmer consistency to others, either by the greater solidity of their particles, or by diluting the thinner parts of any matter, so as to leave the remainder harder.

Induration of Strata, in Geology, denotes the change which all the masses of the earth evidently have undergone since they were deposited in their present situation in a fluid or plastic state; under the article Hardening of Strata, we have noticed some of the facts and theories on this subject, to which we beg to refer.

Indus, or SInd, or, according to the proper Sanscrit name Sundtra, under which name it was not unknown to the Romans (Indus incolis SIndus appellatur, Pliny, v. vi.) a celebrated river of Asia, which is formed of about ten principal streams, that descend from the mountains of Perfa, Tartary, and Hindoostan, on the N.E. and N.W.; all which streams, uniting near Moulten in Hindoostan, form this famous river. The Ayn Acbaroe says, the SInde, according to some, rises between Cauhame and Cufanar, whilst others place its source in Khatari, meaning probably Kotore, the Charge of Teylony, and not China. It is clear, however, that the people of Hindoostan consider the north-eastern branch as the true SInde, though the ancients seemed to have reckoned otherwise; for Pliny says “in jugo Caucani montis, quod vocatur Paropamisis, adversus Solis ortum effusus,” The emperor Bager, indeed, applies the name of SInde to one of its western branches, that springs near Baman, but he appears to differ in this particular from the rest of his countrymen; for the name of Nilab, which was applied to the river that ran by the seat of Attock (long before that city was founded), was applied also to the same river, in its course through Little Thibet; and Nilab is synonymous with Sind. (See NILAB.) The Indus, under the name of Nilab, passes through the country of Little Thibet; and its head must be on the left of the great ridge of mountains called by the ancients Imaus, because on the call of it, the rivers all run in a direction opposite to that of the Indus. About 20 miles above Attock, the periodical rains, which fell on the northern mountains, having considerably swelled the river, its breadth was about a mile; its course rapid and turbulent, and its water extremely cold, with a great quantity of black sand suspended in it.

At Attock the Indus is joined by the Cahul, and very considerably increased by it; so that from Attock downwards to Mountan, or to the conflux of the Punjaub waters, where it has obtained the name of Attock, it is no longer fordable; below that point it is called Soor, or Shoor, until it divides itself into a number of branches near Tatta, where the principal branch takes the name of Meom. This river, however, when spoken of generally, is called Sind; although particular parts of it are known by different names. The Indus, and its branches, admit of an uninterrupted navigation from Tatta, the capital of Sind, to Mountan and Lahore, for ports of near 200 tons. About 170 miles from the sea, by the course of the river, the Indus divides into two branches, of which the westernmost is by much the largest. This branch, after a course of about 50 miles to the S.W., divides into two more: the smallest of which runs in a W.S.W. course, to Larry-Bunder and Dacraway, and the largest, taking the name of Rikelh, runs in a more southwardly course to the town or village of Rikelh, on the sea-coast. The other principal branch is that which bounds the eastern side of the Superior Delta; separation of we have fled, about 170 miles from the sea. It is smaller than the Rikelh river, but larger than that of Larry-Bunder, and according to circumstances and report, it opens into the mouth of the gulf of Cutch, nearly opposite to figg point; its course being somewhat to the eastward of north. Major Rennell refers from various circumstances, that the Delta of the Indus (see DELTA) is about 150 British miles in length along the sea-coast, and about 115 in depth, from the place of separation of the superior branches of the river, to the most prominent point of the sea-coast. The lower part of this Delta is intersected by rivers and creeks in almost every direction, like the Delta of the Ganges, but without trees; the dry parts being covered with bushwood, and the remainder, being by much the greatest part, being noisome swamps, or muddy lakes. The upper part of the Delta is well cultivated, and yields abundance of rice. This Delta is set apart for the breeding of camels, anfwering this purpose by means of the tender parts of its bushwood, which serves them for fodder. The breadth of the Rikelh branch is estimated at one mile, just above the tide; and at Tatta, at only half a mile. It is certain that the Indus is very considerably left than the Ganges. The velocity of its current is estimated at four miles per hour in the dry season; but this is supposed by Rennell to be over-rated. The course of the Indus river is frated by major Rennell at (probably) 45°, that of the Thames being 1. This ingenious geographer mentions the moreable towns or villages that are situated on the banks of the river, noticed by Nar- chus and the Ayin Acbarae; some of which are the habi- tations of fishermen, and others of graziers; which are continually changing their positions like a camp. Few rivers about more with fifth than the Indus does; and among these are some very delicious forts. The mouths of the Indus
Indus are comprehended between N. lat. 23° 20' and 24° 40'.

INDUSTRY. Fruits of. See FRUITS.

INEADA, in Geography, a town of European Turkey, in Romania; 56 miles E.N.E. of Adrianople.

INEQUALITY of Natural Days. See EQUATION.

INEQUALITY, Optical. See OPTICAL.

INERT Vegetable Matter, in Agriculture, is a term lately given to that sort of vegetable matter which, by long and frequent exposure, has been so satureated and combined with the oxygen or pure air of the atmosphere, as to be rendered in a great degree insoluble. The surface of peat moths, and the mould of such foils as have been much expoed to the action of pure air, by falling, are suppotted to be rendered inert in this way by the author of the "Connection of Chemistry with Agriculture." See PLAT.

INERTTIC VIS. See VIS INERITE.

INESCUTCHEON, in Heraldry, a small escutcheon borne in a larger one, as part of some other coat. See ESUCUTCHEON.

Guillem confines the name to an escutcheon borne single in the fefs point or centre.

This is also sometimes called an escutcheon of pretence.

He who marries an heiress, bears her coat of arms on an inescutcheon, or escutcheon of pretence, in the middle of his own coat.

Modern heralds apply the name inescutcheon to those small escutcheons, several of which are borne in a large one.

INESERRHA, in Geography, a town of Africa, in Sennar; 10 miles E. of Giaffin.

INESSE is applied to things which are actually existing.

Authors make a difference between the thing in esse, and a thing in posse. A thing that is not, but may be, they say, is in posse, or potestas; but a thing apparent and visible, they lay, is in esse, that is, it has a real being innotus; whereas the other is casual, and at best but a possibility.

INEVERAM, in Geography, a town of Hindostan, in the circur of Rajamundry; 32 miles S.E. of Rajamundry.

INFLATION, an ancient punishment of felons, by throwing them among the rocks and sands, customarily used in port-towns. It is the opinion of some writers, that inflitatus did imply some capital punishments, by exposing the malefactor upon the sands till the next tide carried him away; of which custom, it is said, there is an old tradition. However, the penalty seems to take its name from the Norman falsite, or falsia, which signified not the sands, but the rocks and cliffs adjoining, or impending on the foal-swore.

"Committ feloniam ob quamquit falsitas, utiacatus, vel alio modo morti damatus, &c. vel apud Dover inflitatus, apud Southampton submersus, &c."

INFLAME, from in, taken privatively, and fluo, I heat, that which cannot decribe or be decribed.

Upon this term stands one of the principal heads of controversy between the Reformed and the Catholicks; the latter of whom maintain, that the church, assembled in general council, is infallible; which the former deny.

The Jesuits, in their disputes with the Jansenists, have expressly asserted that Jesus Christ hath given to all popes whenever they shall speak &c. catholica, the same infallibility which he had, both in matters of right and fact.

The principal reasons alleged for the infallibility, are drawn from the promises of Christ, from the obscurity of the scriptures, the insufficiency of private judgment, and the necessity there is of some infallible judge for the decision of controversies.

The infallibility of the pope is a doctrine of a late standing, and has not been entirely acquiesced in, even in their own communion, and altogether rejected by the Gallican church. See POPERY.

INFAMOUS, derived from in, and fame, fame, report, in the ordinary use of the word, signifies something notoriously contrary to virtue, or honour.

Aulus Gellius uses the word infames materia, for what we ordinarily call paradoxes, i.e. discourses remote from the common opinion; propositions that appear opposite to truth, &c. as the elogy of Theristes, the praise of a quintane, &c.

INFAMOUS, in Law, denotes a person or thing, which is of no repute, or esteem, in the world.

There are two kinds of infamy: some persons being infamous as having been noted by the laws, or fixtagmatized by public judgment.

Infamy, which extends to forgery, perjury, gross cheats, &c. disables a man to be a witness or juror; but a pardon of crimes refores a person's credit to make him a good evidence. Judgment of the pillory makes infamy by the common law, but by the civil and canon law, if the cause for which the person was convicted was not infamous, it infers no infamy.

Others are held infamous, by the exercise of some scandalous profession; as a catchpole, a merry-Andrew, a hangman, an informer, &c.

Heretofore there were crowns of infamy given, by way of punishment, to criminals; they were made of wool.

INFAMY. See INFANT.

INFANT, in a Law sense, a person under the age of one-and-twenty years. Some acts are in many cases either void or voidable. (See AGE.) All gifts, grants, &c. of an infant, which do not take effect by delivery of his hand, are void; and if made to take effect by delivery of his own hand, are voidable by himself and his heirs; and those who shall have his estate.

Although an infant, under 21, can make no deed which is not afterwards voidable; yet in some cases he may bind himself apprentice by deed indented, or indentures for seven years (stat. 5 Eliz. c. 43 Eliz. c. 2. Cro. Car. 179); and he may by deed or will appoint a guardian to his children, if he have any. Stat. 12 Car. II. c. 24. By the custom of London, an infant, unmarried, and above the age of fourteen, may bind himself apprentice to a freeman of London, by indenture, with proper covenants, which shall be binding.

An infant may bind himself to pay for necessaries, as meat, drink, apparel, physic, and learning, but not by bond with penalty; though a bill for necessaries, without a penalty for the very sum due, is paid, will bind him. Infants are not obliged to pay for clothes, unless it be averred for their own wearing; and that they were convenient and necessary for them to wear according to their degree and estate. An infant may buy, but cannot borrow money to buy necessaries; for the law will not bind him with necessaries, but at the peril of the lender, who must lay it out for him in necessaries, or see it thus laid out.

An infant has been adjudged of age the day before his birth-day; for the law will not make a fraction of a day; therefore where a person was born the third of September, and the second of September, twenty-one years after, he made his will, it was held good, and that he was then of age to devise his lands. And it is laid that will shall
INFANTS.

take effect, though the devil dies by fix at night of that day.

An infant eight years of age, or upwards, may commit homicide, and be hanged for it, if it appear, by any other act, that he had knowledge of good and evil; for here malitia supplet atamen: yet Coke on Littleton, sect. 35, says, “An infant shall not be punished till the age of fourteen.” which, according to him, is the age of discretion.

But this depends on the degree of judgment which he possesses. If an infant be infra annums infantis, viz. seven years old, he cannot be guilty of felony, whatever circumstances proving discretion may appear. See Act, in Laze, Executor, Guardian, &c. See also Rape.

An infant en centre sa mere, or in the mother’s womb, is capable of having a legacy, or a surrender of a copy-hold estate made to it. It may have a guardian appointed to it (lat. 12 Car. II. c. 24.) and is enabled to have an estate limited to his use, and to take afterwards by such limitation, as if it were then actually born (lat. 10 & 11 W. III. c. 16.) and in this point the civil law agrees with ours. Though infants cannot alien their estates, yet infant trusts or mortgages are enabled to convey, under the direction of the court of chancery or exchequer, or other courts of equity, the estates they hold in trust or mortgage, to such person as the court shall appoint. By the custom of gavel-kind, an infant, at the age of fifteen, is reckoned at full age to sell his lands; and by custom, in some places, an infant freed of land in focage, may, at the same age, make a lease of years, that shall bind him after he comes of age.

An infant, who has an advowson, may profit to the benefit when it becomes void. (Co. Litt. 172.) An infant is capable of inheriting, and may also purchase lands, but his purchase is incomplete; for, when he comes to age, he may either agree or disapprove to it, without alleging any reason; and so may his heirs after him, if he dies without having completed his agreement. (Co. Litt. 2.) And in case any infant bargain and sell his land by deed, indenture and enrolled, yet he may plead non-age.

If an infant grants leaves for a term of years, he may, at his full age, either confirm the lease, or bring trespass against the lessee for the occupation. Also a lease granted to an infant, may be avoided by waiving the land before the rent-day expressed therein. However, infants are bound in all acts of necessity; as presentations to benefices, admissions, and grants of copy-hold estates, ailing to legacies, and conditions annexed to lands, whether the estate comes by grant or descent. If an infant be the defendant in an action, the plaintiff shall have six years for commencing his action, after the defendant comes of age; and an infant, who is a plaintiff, has also six years after he comes of age, to sue by the statute of limitation.

INFANTS. Difenes of in Medicine. When the extreme delicacy and tenderness of every part of the structure of the infant frame is considered, as well as the extraordinary revolution, which it suddenly undergoes, in passing from its vegetable state, as it were, in the uterus, to that of a breathing animal, it must be obvious that a thousand circumstances, which make no impression on the adult frame, will powerfully influence that of the infant; and that the utmost care will be required to shield it from numerous causes of disease, from the moment of its birth. To the neglect of these circumstances, or to their inability of attending to them, the great mortality that occurs among the children of the poor, in large cities, is perhaps chiefly to be ascribed. But this was formerly much augmented, among all ranks, by the absurd and unnatural interference of art, which was apparently dictated by a notion that the instincts and intimations of nature were to be opposed, as of the most baneful tendency. Fortunately the more rational system of following these intimations, as the bell guides to health, has generally superseded that abuse; and it will only be requisite for us here to speak of some of the accidents attendant on birth, of the more frequent concomitances of disease, and of the diseases peculiarly belonging to the period of infancy and childhood.

Recovery of still-born or weakly infants.—Dr. Hamilton observes, that the occasional recovery of still-born children, under circumstances where experience alone could have encouraged any hopes, ought to teach practitioners the importance of employing, with patience and attention, the means conducive to that purpose. If there is no pulsation in the umbilical cord, the infant should be hastily separated from the mother, the cord being tied by a slip knot, and the body immersed in warm water. The lungs should be then distended with air, by means of a bag of elastic gum; or a common syringe, (the pipe of which is to be inserted into one nostril, while the other and the mouth are carefully closed,) and again emptied by gentle pressure on the breast. In this way an alternate dilatation and compression of the lungs should be continued for some time. Should the action of the heart be now perceived, the same means are to be continued, until the infant exhibit the usual marks of beginning respiration, when the artificial dilatation of the lungs is to be only occasionally repeated, and all pressure on the breast is to be avoided. But if, notwithstanding these means, the pulsation of the heart be not restored, the infant should be taken out of the warm water, placed before the fire, carefully rubbed, and then wrapped in warm flannel. A glycer, consisting of a table-spoonful of spirits, and two or three tablespoonfuls of warm water should then be administered, and the temples, nostrils, and teguments of the face round the mouth, should be gently touched with a feather, dipped in vitriolic aether, or spirits of hartshorn. But, secondly, if the pulsation in the cord of a still-born child is distinct and soft, and the infant has the natural appearance, so long as the placenta remains attached to the uterus, the child ought not to be separated from the mother. The body should be carefully wrapped in warm flannel, the nostrils and faucets should be touched with a feather dipped in vitriolic aether, and a little spirits rubbed on the breast. If the after-birth become detached, (which is known by the lengthening of the cord,) the child must be immediately separated, and the above means employed. Should the process of breathing commence after these means have been used for a few minutes, nothing else is to be done than keeping the infant warm, with its face freely exposed to the air. But should this not take place, the lungs are to be distended and again compressed, as in the first case. See Prof. Hamilton’s Hints on the Diseases of Infants, &c.

Although alive when born, the infant, in some instances, lives only a short time. If the lips be pale, and the pulsation in the heart very feeble or flow, it may be suspected that this originates from some cause which is not cognizable to the senses. On the supposition that it arises from a deficiency of vitality, stimulants have been applied to the surface, as a little brandy, or spirits of hartshorn, rubbed on the ribs and spine, &c. and such means have occasionally proved efficacious, though in the majority of cases they fail. When the extremities are of a purple or blueish colour, and the breathing is impeded or unnatural, it is generally found that there is a defect in the heart or lungs, which is beyond the power of any remedy.
Infants.

§ 1. Congenital Imperfections.—Children are not always born in a state of perfection in respect to the structure of their bodies; for sometimes they have deficient, superfluous, or misplaced parts, natural passages closed, and various marks on the surface. Many of these imperfections admit of no remedy; while others may be easily rectified. The following are those which are most frequently met with.

Fissures in the lips not only constitute a remarkable deformity, but commonly prevent the child from sucking. They appear under various forms. Sometimes the fissure exists only in one lip, generally the upper one, and is occasioned merely by a division of the soft parts: in other cases, there is a considerable loss of substance between the divided parts; in some instances, again, there are two fissures in one lip, or both lips are affected; and in others, the fissure is not confined to the lips, but extends along the roof of the mouth. All these different species of the same deformity receive the generic name of bare lip; which see.

The tongue is naturally bound down to the lower part of the mouth by a membranous cord, to prevent it from too great a degree of motion. Sometimes, however, the cord fixes it so much, that the infant cannot suck, in which case it is commonly said to be tongue-tied. Women very often imagine that their children have this defect, when it does not really exist, and perhaps one infirmity of it does not occur in several hundred of those that are born. The difeafe may be always discovered by putting a finger gently into the child's mouth; for if he be able to grasp it, as he would do the nipple in sucking, or if the tip of the tongue appear disengaged, the membrane does not require to be cut. The operation of dividing the frenum, trilling as it may appear, requires some caution, in order to avoid wounding the sublingual veins, and cutting too deep; for in the first case, a fatal hemorrhage may ensue; and in the second, if the tongue is loosened too much, the tip may be turned back, and close up the throat; an accident that must soon occasion death. It may be discovered by the threatening suffocation or convulsions, and by the introduction of the finger into the mouth, by which also the tongue may be pulled back, and the consequences avoided. This, however, is a very rare accident: it has been ably called “swallowing the point of the tongue.” See Underwood on the Diseases of Children, vol. ii. p. 175th edit.

The natural passages, especially the anus, vagina, and urethra, are sometimes imperfect, preventing alwayso, or in great part, the usual excretions. In some cases, a collection of mucus alone prevents the obifice; but in others, membranous substances close up the passages, in which last instances, an operation will be requisite to open the parts, which must be performed by a skilful surgeon. In respect to the vagina, Dr. Underwood observes that he never found the external parts totally imperfect, there being always a small opening at the meatus urinarius; but the aperture to the vagina itself sometimes requires to be opened, either by the point of a lancet, or by the fingers only, which is generally easily effected, there being always a raphe, or line, where the natural opening should be. The anus is sometimes closed only by a thin membrane, so that the day after birth the meconium may be distinctly felt, and in a manner seen shining through it. A slight puncture with a lancet, and passing a bougie or the point of a finger into the bowel for two or three days afterwards, is sufficient to remove this impediment. But more commonly the imperfect anus is a melancholy cafe, allowing of no effectual remedy, as the gut often terminates in a cul-de-sac; so high as not to be reached. The imperforate penis is not quite so com-

mon a case; but is not unfrequently suppurred, when the aperture of the passage is merely stopped up by a little mucus. Under such circumstances, washing the part with warm milk and water, or at moist a little affilience with a small probe, or any such blunt-pointed instrumen-
}
INFANTS.

Effort of nature to expel some hurtful matter from the fistem, which might otherwise be productive of many complaints at a future period. This opinion, however, is merely a vulgar prejudice, founded neither on reason nor experience. Aphthae appear to be connected with a deranged condition of the alimentary canal, and seem to arise most frequently from the too early or too liberal use of spoon-meal, or improper food; but other causes occasionally produce it, such as exposure to cold, damp weather, &c. In the treatment of this complaint, Dr. Hamilton affirms, that the great object should be to improve the general state, and to counteract the effects of the ailing of the system. The early use of stimulant applications, such as gargles of port-wine and borax, force off the spots before they have undergone the natural changes, and by their irritation keep up the disease. But the proper objects may be obtained by putting frequently into the infant's mouth a tea-spoonful of a liquor, prepared by mixing with the white of an unboiled egg, three table-spoonfuls of cold water, and a little refined sugar, by prohibiting all spoon-meal, and by frequently dousing the natural palates with prepared calamine or titty powder. When the spots become yellow, the borax may be allowed. It is to be mixt with eight or ten times its weight of powdered sugar or of honey, or it may be dissolved in fig-tea in the same proportion. If the spots grow vivid, bark and port-wine should be used as a gargle, while the infant is supported by means of ten or twelve parts of warm cow's milk, mixed with one part of sherry wine. The kind of nourishment is necessary in cafes, where, from the extensive incrustation over the tongue and cheeks, the infant is incapable of sucking, which often happens for a day or two. See APHThAE.

§ 2. DISEASES OF THE SKIN.—Two diseases, of a febrile nature, connected with a morbid condition of the skin, have been described by writers on the disorders of infancy, which merit attention. They are almost unknown, however, except to the physicians of lying-in hospitals, as they have seldom occurred in the private houses of individuals. The first of these is erysipelas inflammation of the skin, called by Dr. Underwood erythela infantilis, which ordinarily occurs within a few days after birth, and sometimes at a later period. It feizes the moi-tu-robust, as well as delicate, children; making its attacks in a very sudden manner, and proceeding rapidly in its course. It most commonly appears first on the sides or fingers, which look swelled and blue, as if from cold; but in the more violent forms, it begins about the palms, and extends upwards on the belly, and down the thighs and legs; or sometimes it commences in the neck, when it is equally dangerous. It appears, indeed, to be always most dangerous when it feizes or spreads to the body, and most mild when confined to the extremities. Suppuration and gangrene are occasionally the consequences; but even where neither of these events takes place, it may terminate fatally from effusion into some of the cavities, or from the inflammation extending to the contents of the abdomen, gluing the parts together, and throwing out upon their surface an exudation of coagulable lymph. On the whole, the treatment of this infantile erythela has too frequently proved unsuccessful. The use of fatuine lotions and poultices, on the first appearance of the inflammation, seemed to check its progress at first; but it was soon found to spread, and to terminate in a fatal suppuration or mortification. A more cordial plan of treatment has been attended with a somewhat greater degree of success; and the application of external stimulants, such as linen compresses wrung out of camphorated spirit, has in some cases checked the inflammation. The bowels should be kept open, and the free admission of pure air enforced: indeed, it is probable that, in proportion to the effectual ventilation employed, the occurrence of the disease will be diminished, and its violence, when it does appear, mitigated.

Another affection of the skin, accompanied by fever, and occurring under similar circumstances, has been called by Dr. Underwood, who was one of the first to describe the disease, the \textit{febrile-bound disease}. This does not happen invariably, like the preceding complaint, within a short time after birth; for it has been known to attack infants above fix months old. It is ushered in with violent fever, with coldness of the limbs, oppressed breathing, and almost confluent moaning. The skin is of a yellowish-white colour, resembling soft wax in its appearance, and not only thickened and hardened, but evidently unyielding; the cellular membrane is found in such a manner that it will not slide over the subjacent muscles, not even on the back of the hands, where it is usually very loose and pliable. This friture often extends over the whole body; but the skin is peculiarly rigid in the parts related to the face, and on the extremities. The child is always cold, and whatever number of days it may survive, has constantly the appearance of being in a dying state. The stools are of a clayey yellow and uneasiness; and the disease seems to be much connected with a disorder of the chylus organs, especially of the liver. The free use of laxatives, together with the warm bath, and some cordial medicines, appears to have been occasionally successful; but in general, where the progress of the disease has not been arrested in the commencement, it has terminated fatally.

The most common affections of the skin, however, that occur in early infancy, are unaccompanied by fever, are productive only of slight inconvenience, without danger, and are, principally of certain rashes, or eruptions of papular or pustular spots. The most common of these is a papular eruption, which appears under a variety of forms, and has been called the gum, or technically \textit{gummi}, Dr. Willan has distributed these varieties of appearance under five heads: the most frequent of which is the red gum (or red gum, as it was formerly denominated, probably because the child's skin, thus variegated, somewhat resembles a piece of red printed linen), the floppulis intermititans. The papulae, or pimples, in this affection, rise febibly above the level of the cuticle, are of a vivid red colour, and commonly distinct from each other: their number and extent vary much in different cases. They appear most conflently on the cheeks, fore-arm, and back of the hand, but are sometimes diffused over the whole body. This eruption not in general any tendency to become pustular, but usually terminates in scurf, or exfoliations of the cuticle. Its duration, however, is very uncertain; the papulae and spots sometimes remain for a length of time without any alteration; sometimes disappear and come out again daily: but for the most part, one eruption of them succeeds another, at longer intervals, and with more regularity. The red gum occurs chiefly within the two first months of lactation; it is not always accompanied or preceded by any disorder of the constilation, but appears occasionally in the strong and diliuent healthy children. In many instances, it is connected with a weak irritable state of the alimentary canal, and consequent indigestion. For it if be, by any means, suddenly repelled from the surface, diarrhoea, vomiting, epistimodic affections of the bowels, and often general disturbance of the constitution, succeed; but as soon as it reappears, those internal complaints are wholly suspended. Dr. Armstrong and others have particularly noticed this reciprocal motion, which makes the red gum at times a disease of
somewhat important, though, in its usual form, it is not thought
to be in any respect dangerous. On their remarks a necessary caution is founded, not to expose infants to a dream of very
cold air, nor to plunge them unseasonably in a cold bath;
the moll violent and even fatal symptoms having often been
the consequence of such imprudent conduct. Little need be
said in regard to the treatment of the red gum: the common
mild appearance of it is being confident with a healthy
state of all the functions of the body, requires no medicinal
application. It is, however, advisable to keep the skin clear
from sores, and to promote equable perspiration. This may
be done best by daily ablutions with tepid water, which
prove useful in most cutaneous disorders, and will be found of
considerable importance with respect to the general health
of the infant.

The other varieties of *Strophalus*, mentioned by Dr. Wil-
lan, are two, the *S. albidos*, or white gum, which differs from
the former merely in the appearance of its papules, which
constitute a number of minute, whitish specks, a little elevated,
and sometimes, though not constantly, surrounded by
a slight redness, occurring chiefly on the face, neck, and
breast, and being more permanent than the papules of the
red gum. 3. *S. conforatus*, or rank red gum, sometimes also
called the tooth-ache, which usually takes place about the
fourth or fifth month after birth, on the cheeks and sides of
the nose, extending sometimes to the forehead and arms, but
rarely to the trunk of the body; and accompanying the state
of dentition; and in the seventh or eighth month affording
a somewhat different form, appearing in one or two large ir-
regular patches, of a high red colour, on the arms, shoulder, or
neck. 4. *S. volitatus*, which is characterized by small, cir-
cular patches, or clusters of papules, arising successively on
different parts of the body, continuing red, with a little
heat or itching, for about four days, when they turn brown,
and begin to exfoliate: the successive patches, however, not
casing to appear in less than three or four weeks. And,
5. *Strophalus candidus*, in which the papules are larger than in
any of the foregoing species, have no inflammation round
their base, and a very smooth and shining surface, whence they
appear to be of a lighter colour than the adjoining
papules; they are diffused, at a considerable distance from
each other, over the loins, shoulders, and upper part of the
arms. This eruption affects infants about a year old, and
most commonly succeeds some of the acute diseases to which
they are liable, such as catarhal fever, or inflamations of
the bowels or lungs: the papules continue hard and elevated
for about a week, and then gradually subside and disappear.

See Willan on Cutaneous Diseases, Order 1. Genus 1.

The *Strophalus volitatus* being sometimes connected with
a disorder of the stomach and bowels, it becomes requisite to
administer a gentle emetic or some laxative medicines;
after which the dejection of Peruvian bark will be found of
advantage. No external application seems necessary. The
*Strophalus conforatus* when the child is otherwise healthy, is
generally ascribed to a state of indigestion, or some feverish
complaint in the mother or nurse; but the eruption is fre-
quently seen when no such cause for it is evident. It may
with more probability be considered as one of the numerous
symptoms of irritation, arising from the inflamed and painful
state of the gums in dentition; since it always occurs
during that process, and disappears soon after the first teeth
have cut through the gums. On this view the eruption
requires no specific consideration in medical practice; it can
only be alleviated by the general treatment proper for the
state of teething, to be mentioned presently.

This species of *Strophalus* appears under other modifica-
tions, which have been mistaken for measles. One very ob-

Some other slight eruptions, to which young children are
liable, chiefly of the papular form, are mentioned by Dr.
Underwood, and require no other treatment than an atten-
tion to the state of the bowels, or the use of some tussive
powders. See his Treatise on Diff. of Children, vol. 1.

There is a very common eruption, says the writer just
quoted, that calls for more attention, and to which medical
writers have given the name of *crysta materia*, (or milk-blotches,
as Dr. Hamilton translates it) "which has a very unpleas-
an appearance, but is, notwithstanding, equally innocent

with
INFANTS.

with the former, and even prevents other complaints. I think I never saw an infant," he continues, "much loaded with it, but it has always been healthy, and cut its teeth remarkably well; indeed it falls to the lot of the sick children, and such as are well nourished; whereas some have imagined it owing only to the richness of the milk. And it is remarkable in this eruption, that howsoever thick and long-continued the scabs may be, the *erysipelates* never excoriate, nor leaves any fear on the parts." It is not attended with any fever, or obvious derangement of the system. The crull appears first on the forehead, and often extends half way over the face in the form of large loose scabs. It is sometimes attended with feverish itching. Practitioners in general affirm that medicines are not required, and are rather injurious than beneficial in this eruption; that mild laxatives, so as to keep the passage of the bowels free, may be employed, but that all active purgatives are to be avoided; and, lastly, that where there is excessive itching, some weak cooling astringent lotion, of the acetate of lead, or sulphate of zinc, should be applied to the parts. Dr. Underwood denies that the *erysipelates* ever degenerates into scald-head, as some authors before him had mentioned. But Dr. Hamilton has pointed out a modification of *erysipelates*, which frequently takes place during teething, and is a most oblique and troublesome complaint. "This," he says, "is characterized by a redness of the skin round the edge of the incurations; by an ichorous or clear-coloured exudation issuing from the surface of the scabs, which concretes, and which tends to carry the disease over every part of the face which it touches. There cannot be a doubt, indeed, that this form of *erysipelates* is contagious, and nothing less than a variety of the scald-head, or *tinea capitis*, the *Porrigo* of Dr. Wilian’s nomenclature, in which this species is called *Porrigo larvaedi*. The cure of this modification of the disea requires conflant ablation with milk and water, thin gruel, &c., to remove the acid fluid which exudes, and the application of some drying ointment. Some alternative preparation of mercury is likewise useful internally, such as the hydrargyrum creta, or the grey oxey, followed by the vegetable and mineral tonics. See *Porrigo*.

Dr. Hamilton has stated the following practical conclusions respecting the eruptions of children in general. They may all be divided into two classes, he observes, the *first* of which are temporary, or of short duration; are commonly ushered in with symptoms of general indisposition, and are owing to some disorder of the stomach or bowels, or to some interruption of the usual excretions or secretions: the *second* are of an indefinite duration; break out gradually without any derangement of the ordinary health; and are, probably, in most infancies, the effects of some diseased condition of the lymphatic system, though, sometimes, they may be occasioned by a local affection of the skin itself. The treatment requisite in these two forms of eruption is thus stated. In the *first*, when symptoms of indisposition, such as heat, restlessness, sickness, or oppression, are followed by an eruption, a brisk dose of calomel should be first ordered, together with the warm bath, and afterwards occasional purgatives, and a suitable regulation of the diet, are to be advised. But, in the *second*, where the appearance of the eruption is unaccompanied by fever or marks of indisposition, some of the medicines called alteratives, and the daily use of warm bathing, particularly in fever, water, should be recommended. The medicines to which an alterative power is ascribed, he continues, are preparations of mercury, of antimony, of sulphur, and of neutral salts; and therefore calomel in very small doses, or antimonial wine, or the sulphuret of antimony, or Harrowgate or Chelsea-
and this is accomplished merely by the preasure of the enlarging tooth, which occasions the absorption of those parts. In favourable cases, the preasure of the teeth on the gums occasions pain, and an increased flow of the fluids furnished by the mouth. Hence the infant is fretful, restles during the night, drives continually; and frequently thrills his little hands, or whatever it can hold hold of, into his mouth, to rub his gums; and he has occasionally ficknels, gripes, and loofens. But at last the corner of a tooth is perceived; but the unpleasannts still continues for some days, when a second one is cut. During the interval between the cutting of the lower and upper teeth, he recovers his strength and usuall good health; but is soon again subjected to the fame unpleasannts.

Were the the only complaints which attend tooth-ding, little danger might be apprehended; but sometimes many very formidable symptoms occur. In robust healthy constitutions, a violent fever frequently precedes the appearance of every tooth; the gums are fwell'd and inflam'd, the eyes much afflected, the belly bound, the skin hot; and there is every now and then continued screaming, with inability to suck, and the flesh is short and disturbed. Weakly infants, where tooth-ding is painful and difficult, are oppressed with ficknels, loath all kinds of food; lose their colour, from perpetually, have a conflent loofens, and become much emaciated. Some, besides these symptoms, are subjeft to convulsions, which recur from time to time, till the tooth or teeth are above the gum. In others, cough, various eruptions on the skin, ulcerations in the gums, extending sometimes over the palate, obilinate inflammation of the eyes, affections of the urinary organs, and sometimes most alarming determination to the head, are occasionally the effects of tooth-ding. All the symptoms are much aggravated, if several teeth be cut at once, or in immediate succession.

It is of great importance to be able to ascertain when any of the distrefling symptoms, thus enumerated, arise from dentition. This is to be done by a careful examination of the state of the gums. Previous to the protrusion of any tooth, the gums, which may be distinctly observed on the edge of each gum, like a doubling of the skin, is done away, and the upper surface of the gum is rendered flat and broad, or is elevated in the form of a small swelling. The gum of the upper jaw is more apt to appear on the fretch than that of the lower. It is not easy to distinguish when the infant suffers pain from any part of the gum being pressed upon; otherwise that might affult in pointing out the advance of some particular tooth or teeth, because such a degree of fretfulness attends tooth-ding, that every attempt to feel the state of the mouth never fails to irritate the child.

An effimate of the danger attending dentition is to be formed chiefly from the nature of the symptoms. Experience proves that puny delicate infants often suffer less than the most healthy and robust. In this climate it has been found that summer is a more favourable season for tooth-ding than winter. Some infants cut their fore-teeth without any pain or difficulty, but are much distrefled while cutting the grinders or eye-teeth; although, when the protrusion of the first two pair of fore-teeth is accompanied or preceded by great uneafiness, there is reason to fear that the individual will suffer during the whole period of tooth-ding; yet the converse of the proposition does not hold good; that is, where little derangement of health attends the first pair or two, it is not to be concluded that all the other teeth are to advance with the same facility. It is well known, that during tooth-ding every acute disease is more than usually dangerous; and it is also a well established fact, that infants, in a crowded city, are more liable to pain and alarming symptoms at that time of life than those reared in the country.

The bterior of the ordinary complaints attending tooth-ding, should conftit in moderating the pain, in regulating the state of the bowels, and in the continued employment of every means calculated to promote the general health of the infant. With these views, small quantities of anodyne balsam may be rubbed on the back-bone at bed-time, when the infant seems to be greatly pained. He ought to be fed with beef-tea twice a-day, if weakly, and if his bowels be loose, and should be kept as much as possible in the open air when the weather is favourable; the cold bath ought not to be laid aside in these cases, unless other concurrent disorders should render it needful, as nothing is more conducive to promote general strength. Loofens, if excessive, must be moderated; and if the belly be bound should be artificially induced by gentle laxative medicines. When tooth-dings during the night, the child should be taken out of bed, and carried about in a cool airy room; and if not relieved in a short time, he ought to be put into a warm bath. Finally, he should be allowed something to rub his gums with, which will both gratify his wishes, and tend to promote the absorption of the parts including the tooth. A piece of wax-candle, or of recent liquorice-root, is preferable to coral; though the latter subsistence is in no other respect injurious than that it may be, by awkwardness, forced into the nostrils or eye.

The management, when alarming symptoms take place, must be varied according to circumstances; but in every case the indications to be fulfilled are, to cut afunder the parts which reft the protrusion of the tooth or teeth, and to palliate distrefling or troublesome complaints. Some of these, which occur also under other circumstances, will be noticed immediately. See also DENTITION. Hamilton's Hints, &c. p. 73, et seq.

Causer of the mouth, sarcum oris, as it has been called, is most commonly connected with dentition; it is sometimes troublesome to remove, but commonly a trivial complaint. It sometimes makes its appearance in the first month, Dr. Underwood says; at others, about the time of teething; and frequently at the age of six or seven years, when children are shedding their first teeth, and the second are making their way through the gums. It consists of little foul fores covering the gums, and extending sometimes to the inside of the lips and cheeks. It is said to occur during teething most frequently where the gums have not been lanced. It is generally easily cured by keeping the body open, and by the use of some mild, saline, or anti-cholagogue to the mouth. As much white vitriol, or rock alum, will give a moderate roughness to a little honey, is usually sufficient for this purpose; or if it should not effect a cure when the complaint makes its appearance at the time of tooth-ding, it will generally go away as soon as the teeth are protruded. The work species of this complaint, witnessed by Dr. Underwood, has occurred during the second period of dentition, when a child has been shedding a number of teeth together, leaving the decayed stumps behind, which have been neglected to be drawn out. Thewhole gums will then sometimes be spongy, or diffuse into foul spreading ulcers; and small apertures will be formed, communicating from one part to another, accompanied with an oozing of a fetid and sometimes purulent discharge. If the stumps of the decayed teeth are easily accessible, they ought to be extracted, and some astringent applications made to the parts, consisting of myrrh, Peruvian bark, alum, or crystals of tartar, made into a paste with honey of roes, or lotions made with the same ingredients, all ringent tinctures, or mineral acids.

§ 4. Bowel Complaints.—Under this head we shall include the
the disorders of the whole of the alimentary canal, and of the organs connected with it, both by function and structure. These constitute, perhaps, the most important tribe of the diseases of children; inasmuch as they not only produce considerable distress by their direct effect in deranging the functions, but are likewise indirectly the source of numerous fever, and even fatal constitutional maladies, both chronic and acute. The disorders of the stomach, indeed, are seldom very formidable or troublesome in early life; but the derangements of the biliary secretion, of the intestinal canal, and of the mæterial glands and absorbers, which are much connected with each other, are productive of much mischief during the whole period of infancy and childhood.

**Sickening and Vomiting.**—A flight degree of sickness is a very common occurrence in infants, as their stomach is so irritable, that it readily rejects any overfood of load. But this spontaneous sickness is attended with little violence to the stomach; the milk, or other aliment, seems to come up without any sensible action of the part, or any reaching effect of the child; and when the food is brought up immediately after sucking or feeding, and in an almost unchanged state, such sickness is observed to be not incompatible with a thriving state. Unless when the sickness is extremely violent, therefore, or long continued, it is seldom necessary to interfere. But when means are required to moderate or to allay it, we must endeavour to ascertain the cause of the sickness, and apply them accordingly. The causes of sickness at the stomach in infants are either some altered condition of the nurse's milk, or the presence of some indigestible substance in the stomach. If the nurse have been under the influence of any violent emotion of the mind, or if the child have been to be out of order, or even to have the feelings preceding that event, it may be concluded that there is some morbid change in the milk. During the progress of teething, the increased quantity of saliva, together with its acrimony, proves occasionally the cause of sickness. In such cases the stomach may require the discharge of its contents by means of a gentle emetic: a little warm water or chamomile tea, or, at the most, some preparation of ipecacuan, will answer this purpose. Antimonials, in doses which excite vomiting, are frequently injurious to infants, and sometimes actually sink, with great rapidity, the living powers. When the vomiting is kept up by irritability of the stomach, which is sometimes the consequence of its actions having been disturbed by a cause already removed, flight corys and aromatic may be given to strengthen the organ and abate its sensibility, and if these fail, some stimulant or anodyne may be applied externally.

It must be observed, however, that habitual vomiting from over-dilatation of the stomach, to which many infants are liable, may lay the foundation for future weakness of the digestive organs, and should therefore be guarded against by every precaution. For this reason, infants ought not to be allowed to suck too much at a time, and large quantities of spoon-food should never be given in the early months.

**Diarrhea or Loofness.**—The natural appearance of the stools of infants should be familiar to every practitioner. In general the colour is that of a bright orange, the consistence is pulpy and curdled, and the smell is not offensive. Any deviation in these respects marks some diseased state of the stomach or bowels. During infancy, from two to four evacuations, within the twenty-four hours, seem necessary and useful; and even when that number is exceeded, it is not to be regarded as injurious, unless the health be impaired, or the stool be rendered flabby. The appearance of the stools, in cases of diarrhea, is very various. When they are green, and at the same time emit a sour smell, which arises from the prevalence of acidity in the first passages, there is generally griping and fretfulness, but the complaint is not dangerous. It generally yields to a laxative, or, in very young infants, to a medicine composed of a little magnesia and rhubarb, with a little distilled water of dill or pennyroyal, with a few drops of ammoniacal spirit, or of the compound tincture of camphor. The nurse's food should be regulated in this case, and the infant ought to have no other food, in addition to the milk, than arrow-root.

Slime stools are generally the effect of exposure to cold, though they occasionally arise from some irritation or accumulation in the bowels. In both cases they are apt to be slightly streaked with blood. If there be violent pain, or symptoms of fever, introduction is to be dreaded. A dose of cold-drawn salt or oil, together with the warm-bath, or fomentation of the belly with flannels wrung out of hot water, are commonly all that are necessary, if the diseased be attended to at the beginning. Where slimy stools are of the colour of clay, and emit a purid smell, the infant soon becomes emaciated, and the disease often terminates fatally, though its progress be slow. Alternatives, with opiate frictions and occasional purgatives, afford the chief means of relief. If the infant be ill at the breast, the milk should be changed, a practice which ought to be adopted in every instance where there is great tendency to looiness.

The most distressing cases of diarrhea are those in which the stools are liquid, brown, black, or clay-coloured, and of an offensive smell. As the disorder proceeds, very unfavourable symptoms occur, such as emaciation and dryness of the skin, swelling or shrinking of the belly, with an altered appearance of the countenance; and there is a constant fretting or peevishness of temper. Swellings of the glands of the groin, and a little uneasiness of breathing, as if there were a flight tendency to cough, are also very unfavourable symptoms. In many of these cases the purging is the effect of a diseased state of some of the digestive organs, or of the mæterial glands; but in others it arises from an irregular action of the former organs. In these disorders some practitioners begin the treatment by the use of enemias; but the advantages of these medicines are not very obvious, while the disadvantages resulting from their debilitating and irritating qualities in the stomach are sometimes unequivocal. On the whole, the continued use of alternative medicines, which maintained a steady but gentle action upon the alimentary canal and the adjoining viscera, seems to be the most successful treatment in these complaints; the physician, at the same time, correcting and modifying their operation according to circumstances, and palliating urgent symptoms. Part of the diet, in these cases, should consist of weak beef-tea or chicken broth, with rice, or boiled low milk with baked flour, or arrow-root. The occasional use of injections of thin starch and laudanum, in the proportion of eight or ten drops of the latter to two tablespoonfuls of the former, may be employed to moderate the discharge when the strength is much reduced.

Of the severe and often fatal species of diarrhea, just alluded to, there is one form which is known in Scotland by the name of the "evening bitches," and which has been well described by Dr Cheyne. (Essay on the Diseases of Children. Ed. 3.) It occurs after weaning a child too suddenly, especially at an unfavourable season, as the autumn. It commences, sometimes two or three days after weaning, but frequently not for three or four weeks, with a purging and griping, and green stools. This, being erroneously ascribed to teething, is perhaps neglected, and the symptoms increase, a retching and vomiting supervene, and are gradually followed by a hoathing of every kind of food, emaciation.
INFANTS.

Emaciation and fatteness of the flesh, redholiness, thirst, and fever of a hectic character. But the most characteristic
symptom of this disease is a constant peevishness, the effect
of unceasing grining pain, expressed by the whine of the
child, but specially by the settled discontent of its features.
In the progress of the disease, the evacuations from the
bowels shew very different actions of the intestines, and great
changes in the biliary secretion; for they are sometimes of
a natural colour, at other times flamy and ait-coloured,
and sometimes hcterlic. The disease seldom proves fatal before
the sixth or seventh week; but sometimes an earlier ter-
mination is suddenly produced by incessant vomiting and
purging, or by convulsions, from the extreme irritation in
the bowels.

By diffusion Dr. Cheyne ascertained the state of the
vifcera in children who had died of this disease. In every
case the intestinal canal, from the stomach downward,
abounded with singular contractions, and had in its course
one or more intus-sufcences; the liver was exceedingly
firm, larger than natural, and of a bright red colour; and
the gall-bladder, which was enlarged, contained a dark-green
bile. In some diffcences the mesenteric glands were found
swelled and inflamed; in others, however, they were scarcely
enlarged, and had no appearance of inflammation. It is
probable, therefore, that this disease is owing to an in-
creased secretion of acrid bile, or rather to the morbid state
of the liver which occasions this; and that the extremely
irritable state of the whole abdominal vifcera, marked by
the spasmodic contractions and intus-sufcences, &c. is
occasioned by the presence and passage of this acrid ex-
cretion.

The exciting cause of this evening sories is apparently
too fudden an alteration of the diet of a child at an urfit
seamen, it follows that children ought at all times, but more
particularly in the autumn, to be weaned gradudally, and
well accustomed to the food on which they are afterwards
to subsist before they are finally taken from the breast.
At the beginning of the diseaee, or even later, when the
attack is slight, Dr. Cheyne recommends a dose or two of
rhubarb, to the extent of five or six grains, at the interval
of two days between each dose; and that, in the mean time,
the child should take half a third part of a grain of
peecan powder, mixed with six or eight grains of pre-
dared chalk, and a small portion of some aromatic powder,
as casta, every four or five hours. A flarch quifter, with five
or six drops of laudanum in it, may be administered at bed
time with advantage, if there be much griping along with
the purging. The success of these remedies, however, will
depend upon a strict attention to diet. An animal diet pro-
duces less irritation than one which is solely composed of
vegetable matter. Eggs, the finer kind of light split-bicuit,
or arrow-root, curfard, the juice of lean meat, plain ani-
mal jellys, broths freed from their oily part, and milk, are
proper articles of nourishment. The breast milk might
perhaps be relieved with advantage. Vegetables of all
sorts, particularly fruits, acids, and compositions of which
sugar or water form a part, and fermented liquors of
every kind should be strictly prohibited. The feet should
be kept warm by woollen stockings, and flannel worn near
the skin; and the warm bath and fomentations may be fre-
cently used to alleviate the continual pains. Dr. Cheyne,
however, taught by subfquent experience, recommends
small doses of calomel as the most effectual remedy against
the weaning pains, and other chronic forms of bilious
diarrhoea. He generally gave half a grain of calomel, morn-
ing and evening, or a grain every night, for a week or ten
days. After the third or fourth dose there is generally a

Great change, he says, in the colour of the alvine discharge;
it becomes of a dark mohogany colour, and is in general
more offensive. When this change takes place it produces a
favourable change in the disorder. Soon afterwards, the
children become free from fever, more placid, and in a
day or two more their appetite returns, with their former
complexion, and every other demonstration of health. He
never found, he adds, in the many cases in which he has
given calomel, that it produced inflammation, or any other
unpleasant effect. Cheyne, Essay ii. On the Bowel Com-
plaints more immediately connected with the Biliary Sec-
cretion.

Costive...—This opposite condition of the bowels, though
seldom occurring in young infants, is productive, in children
a little more advanced, of many distressing complaints.
Some infants, indeed, seem to be habitually costive: and there
is certainly a considerable variety, in respect to the state
of the bowels, in different individuals. But what may be pro-
perly termed costivenes is never to be regarded as a
natural deviation peculiar to any infant: it is always the
effect of disease, or of the nurse's milk, or of the food.
If one copious evacuation take place every twenty-four hours,
and the infant be thriving, there is no occasion for inter-
ference; but if there be any greater torpor of the bowels
than this, suitable remedies are to be employed. It is gen-
erally proper to treat the case at first as if it were the
consequence of disease; and on this account a brisk laxa-
tive may be given every day, for three or five times suc-
cessively. The best laxatives for infants are manna, calci-
ated magnesia, calomel, and cold drawn cider-oil; and Dr.
Hamilton recommends a laxative syrup, prepared with treacle
and a strong infusion of fenna.

Where these means fail, there is reason to attribute the
costivenes to the nurse's milk. Sometimes that peculiar
state of the milk may be altered by regulating the diet,
and opening freely the bowels of the nurse. While proper
means are tried for this purpose, the infant's bowels are
be to kept clear by some mild laxative. But if it be found
that the milk still preserves its injurious quality, the nur-
se should, if possible, be changed. Where this cannot be done,
the infant might be given a small dose of antimonial wine
may be given to the infant every night, at bed-time, and instead of the
ordinary food, panada, made with small beer and treacle, should be
substituted.

Temporary costivenes may be at any time removed by a
suppository, made of a small piece of yellow soap, shaped
like a very large Dutch writing-quill. This may be ren-
dered more powerful, if necessary, by being dipped, previous
to use, into some powdered sea-salt. Suppositories are more
efficacious in infants, and much more easily managed than
glysters, though these latter means are also sometimes use-
ful. In cases of obstinate constipation, attended with symp-
ptoms of great oppression, aloes, suspended in treacle or
syrup, is more powerful than any other laxative; from four
to eight grains may be thus given for a dose. Many prac-
titioners err, Dr. Hamilton affirms, by directing too small
doses of laxative medicines for infants.

At a more advanced period of childhood, a morbid state
of the alimentary canal, of which costivenes is a con-
spicuous symptom, frequently occurs, and is the source of
several varieties of disease, both chronic and acute, which
constitute perhaps the most frequent maladies of the puerile
age. The first of these, to which we shall direct the attention
of the reader, has been called, by Dr. Hamilton, senior,
physician to the Royal Infirmary at Edinburgh, marasmus.
See his Observations on Purgative Medicines, chap. iii.
edit, 2d.

Maresium
Marasmus includes a variety of symptoms which affect children of both sexes. The disease heals on gradually, and the following are the early symptoms by which it is characterized: a languor, and latitude on exertion, depression and loss of appetite, a flabbiness and wasting of the muscular flesh, fulness of the features, and pale or paltry colour of the countenance, swelling of the upper lip, a constant itching of the nose, a fetid breath, with a swelling of the belly, an irregular and generally colicky state of the bowels, and a change in the colour and odour of the feces. When these symptoms have continued for some time other more urgent complaints ensue. There is an alternate paleness and flushing of the countenance, followed by heat and dryness of the skin, feeble and quick pulse, thirst, great fretness, increasing debility, and disturbed sleep, during which the little patients grind or gnash their teeth, and are subject to involuntary startling, and twitching of the different muscles, and, when awake, to a constant picking of the nostrils or lips, or even of the eyes, and to involuntary gesticulations, approaching to convulsions.

Every case of marasmus does not necessarily include all these symptoms; for they occur in different combinations. The disease appears most commonly among weak and infirm children, whether they are so from debility of constitution, or from incident evils. It is particularly prevalent in large and populous cities, where children are deprived of ready access to exercise in pure air, and ficken and pine in the nurseries; or when they are confined in crowded and unsanitary school-rooms, whether they are sent, partly for the purposes of education, and partly, to use a common phrase, with the view of being kept out of harm’s way. Children also, who are employed in manufactories, where their occupation and confinement are such as to weaken and enervate them, are liable to be attacked with this disease. Irregularity in diet and improper food also give rise to marasmus. It is accordingly observed to prevail most in the summer and autumn, the seasons which afford an opportunity of eating unripe fruit and vegetable articles from the garden.

Marasmus has generally been attributed to the prevalence of worms in the alimentary canal. But the afterides, which are often passed in great numbers by children, are not accompanied, except incidentally, by the symptoms of marasmus; and the pellagra, or tape-worm, is altogether unknown in infancy and childhood. The lumbricus, or round worm, must therefore be the generally supposed cause of the symptoms of marasmus. But the disease occurs, in numerous instances, and is cured, when no worms are seen; and, on the other hand, the presence of lumbrici in the bowels is by no means an uniform cause of bad health, and has been frequently noticed when marasmus did not occur. Various anthelmintic medicines, however, have been efficaciously in vogue for the cure of the disease, upon the supposition of the existence of worms, but the possibility of such of them as have been found to be most beneficial, Dr. Hamilton believes to have been in proportion to the purgative powers which they possessed. He says, “when I consider the languor and latitude which precede this marasmus; when I recollect the constitutional or acquired debility of those who are more particularly exposed to be affected by it; instead of adopting the common opinion of its being occasioned by worms, I am more disposed to think, that a torpid slowness, or weakened action of the alimentary canal, is the immediate cause of the disease; whence proceed colic, diarrhea, distemper of the bowels, and a peculiar irritation, the consequence of remora of the faces. I have accordingly been long in the habit of employing purgative medicines for the cure of this marasmus; the object is to remove indurated and fetid faces, the accumulation perhaps of months; and as this object is accomplishing, the gradual return of appetite and vigour mark the prospects of recovery.” Obi. on Purg. Med. p. 511.

Since the practical conclusions are the same, it is not of material importance by what theoretical views they are supported; but we accord with the following observations of Dr. Hamilton, junior, (professor of midwifery at Edinburgh, whose excellent “Hints for the Treatment of the principal Disabilities of Infants, &c.” we have before quoted.)

“Can there be little doubt,” he says, “that neither the mere accumulation of the fleshes, nor the torpor of the bowels, on which it appears to depend, can explain the various symptoms produced by this condition of the digestive organs. There is every reason to suppose that there is an altered action, not only in the stomach and intestines, but also in the liver and lachets, perhaps in all the parts concerned in the digestion of the food. When this has continued for a certain time, the accumulation of seedy matter, which is the consequence, adds greatly to the irritation, and while all this is going on, the circulating juices become deprraved.”

Hints, &c p. 113.

In the treatment of marasmus, then, the leading objects are, to remove the accumulating mafs of morbid and irritating fleses from the bowels, to alter the morbid actions of the digestive organs, and to palliate the distressing symptoms which occur. The two first, which are the curative indications, are both fulfilled by a steady and persevering adminis- tration of purgative medicines.

In the incipient stage, while the dis ease is mild, the bowels are not altogether torpid and inactive, neither are they overloaded with accumulated feces. Mild purgatives, therefore, repeated at proper intervals, effect a cure. They preserve the bowels in proper action, carry off feces which had begun to be offensive and hurtful, and prevent farther accumulation. The disease yields in a few days to this treatment, and all that is farther required is some tonic medicine, which shall strengthen the stomach and bowels, together with a due regulation of diet, and occasionally a purgative at bed-time, the patient being likewise much in the open air. Preparations of iron are found the best remedies in these cases; and children readily take the wine of iron, or the filings covered with sugar. In selecting the purgatives, it is necessary to flatter the taste of our young patients. Powder of jalap is not altogether unpleasant: the mild neutral salts, dissolved in a suitable quantity of beef-tea, are also convenient purgatives: but calomel will prove, on several accounts, the most certain and useful remedy of this kind.

When the incipient stage of marasmus has been allowed to arrive, manifest danger threatens the young sufferer, whose remaining flesh and strength are rapidly wasted by the superimposed fever, while prostration and depravity of appetite withhold necessary nourishment, and at the same time the more inactive state of the bowels, and greater bulk of feculent matter, throw additional difficulties in the way of a cure. Under these circumstances, an active practice should be adopted, with the view of stimulating the intestines, and of putting the collected mafs in motion without delay. Theh ends are best obtained by giving small doses of the purgative medicine, and by repeating thes frequently, so that the latter doses may support the effects of the preceding ones. When the bowels are once opened, stronger purgatives, given at longer intervals, will accomplish the cure.

While the purgative medicines are thus exhibited, it is absolutely
absolutely necessary, in order to have full information of their
effects, to inspect daily what is passed by food. The smell
and appearance of the faces are a criterion of the progress
that is made in the cure, and direct the farther administration
of the purgatives. This inspection is the more neces-
are, as we cannot expect the information we want from
our little patients, and we shall often look for it in vain
from the attendants, whose prejudices, and whole ignorance
of our views, prevent them from seeing the propriety of the
inquiry. During the prevalence of this disease, the faces
are dark, fetid, and varying from a coltive consistence to
that of clay, and are often fluid; and such they appear
upon the first exhibition of the purgative medicines.
It may be observed, that the recovery of the sick keeps pace
with the return of faces of a natural colour, form, and
smell,—a change which the repetition of purgatives does not
fail to produce.

While the purgatives are given in this manner, in the
confirmed state of marasmus, in which the obstinacy of
the disease is sometimes great, and the danger attending it im-
iminent, nourishing food, of light and digestible quality,
and suited to the taste of the patients, and the moderate use
of wine, are much required. For some time after the
symptoms have disappeared, it is expedient to continue a
mild stimulant to the bowels. As they have recently suf-
fere, and have been weakened by over-dilatation, they are
apt to favour subsequent accumulation of faces, the fore-
runner of a relapse, which is to be dreaded the more, as the
patients have been weakened by the previous disease. And
so far from being attended with any danger, this gentle fo-
ilicitation of the alvine discharge, (for it ought to be gentle),
is the greatest promoter of recovery. (Hamilton’s Ob. on
Purg.).

At the close of the disease, strengthening medicines,
such as chalybeates, and the infusions of bitter vegetables,
may be employed with some advantage to complete the
cure.

As marasmus proceeds from symptoms of slight indispo-
fition, which are easily obviated by proper stimulus and eva-
cuation of the bowels, through a series of others which
become daily more and more obstinate and dangerous, the
health of children should be watched with great anxiety.
Prostration and deprivity of appetite, a changing complex-
ion, tumefaction of the abdomen, scanty and unnatural
froths, and fetid breath, indicate approaching danger. When
these, therefore, are observed, the affliction of medicine
should be referred to, by the prompt use of which much
eventual diuresis, and even death itself, may be prevented.
But other considerations call for this affluency. Marasmus
has a close connection with some other formidable diseases,
and either precedes or seems to accompany them; of these
we may notice more particularly two, Hydrocephalus and
epilepsy.

Of the Hydrocephalus internus, the bane of infancy
and of childhood, we have given an ample account under
its proper head. The pathology of the disease has been the
subject of much variety of opinion, and is still involved in
some obscurity. Thus much, however, is known, that it
often heals slowly on, with symptoms resembling those of
incipent marasmus; and that where it has been believed to
exilt, from the presence of some of its most characteristic
symptoms, a diligent exhibition of purgative medicines has
succeeded in reforming this evil. Too much attention, there-
fore, cannot be paid, to prevent the confirmed state of ma-
rasmus. See Hydrocephalus.

Epilepsy, which is a disease most distressing to the patient,
and perplexing to the physician, also often appears in child-
hood. It is confirmed by the repetition of the fits, till their
frequency and the force of habit fix it, and make it a con-
stitutional disease for life. Now it is generally understood,
that the first attacks of epilepsy are not always idiopathic,
but are frequently the effect of particular irritation of the
body or mind. There are numerous inatures, indeed, of
irritation of the body inducing epilepsy; and, in children,
when no other is evident, the loaded intestine, and the
morbid change induced in its contents, in the course of the
marasmus above described, may be suspected of giving
the irritation in question. In fact, worms in the intestines
(or marasmus, for we may thus interpret the language of
medical writers) have been mentioned among the causes of
epilepsy. Surely, therefore, this consideration suggests
another cogent reason for watching the rife and progress of
marasmus: and it will induce us, on the first at-
tack of epilepsy in children, arising from an uncertain
cause, to act on a decided and active course of pur-
gative medicines; and not to incur the risk of allowing
the disease to strike root, while we are idly employed in
the exhibition of inert and useless vermifuge medicines;
or are groping in the dark in quest of other causes of the
disease, or of uncertain remedies for their removal.

Colic pains are not uncommon in infants at the breast;
for the decency of the bowels renders these little likely to be af-
fected by the most apparently trifling causes. Hence expo-
sure to cold, inattention to changing the clothes when they
become wet, too great a quantity of spoon-meat, some
fault in the milk, too large doses of magnesia, and a col-
collection of acid flume, or of air in the stomach and bowels,
may severally be productive of this complaint. If an in-
fant be fretful by fits, or at intervals, if its upper lip look
bluish or livid, if it writhe or contort its body, and draw
up its limbs towards the stomach, and more especially if it
occasionally pass wind, which seems to afford relief, there
is good reason to suppose it is affected with colic. The lesser
degrees of this complaint are of temporary duration, and
so well understood, that a medical practitioner is seldom
consulted on the subject. But the more violent degrees af-
sume an appearance, which seldom fails to occasion much
anxiety and alarm. Excessive and long continued shrieking,
great fever, indicated by the heat of the skin and flushing
of the face, oppressed breathing during the intervals of the
screaming, and the evidence of pain being occasioned by the
flighted preflure on the belly, are the ordinary symptoms
in such cases.

With respect to one of the causes of colic above men-
tioned, the exhibition of too much magnesia, it may be ob-
erved, that many women, from the belit motives, but the
moll improper views, torment their infants with the frequent
administration of this drug; because it has little tate, they
naturally imagine that it can do no injury. But its opera-
tion depends on its undergoing a change, by combination
with acids, in the stomach and bowels, which gives it the
same properties as the laxative salts; and it is obvious, if
too large a dose of these occasion colic pains in grown
persons, the magnesia must, when given in too great quan-
tity, or when there is much predominant acid in the first
passages, produce the same effects in infants. Too much
fugar, put into the meat of children, tends to generate much
acid; whence it gives occasion to these pains, as well
as to the green colour and foul smell of the foles, the
green colour being occasioned by the mixture of an acid
with the bile.

In slight degrees of colic, a few drops of Dalby’s car-
mative, mixed with sugar and water, and a dose of cold
drawn castor-oil, if the bowels be confined, are all that are
necessary. The too common practice of giving spirits and
water
water to infants cannot be reprehended in terms sufficiently strong. Professor Hamilton affirms, from his personal knowledge, that many infants are generally destroyed in Edinburgh by this most unnatural practice; and we have too much evidence that the same practice is constantly reenacted by nurses on this side the Tweed. The best mode of preventing frequent distress of colic, is to take care that the infant do not suck too much at a time; to provide a discharge of any air that may be formed; and with caution, by gently tickling the child new and then, before his hernia will be liable to expand, to prepare the quantity of faeces next to the prop in digestion; and to regulate the dose of the nurse, as it is now well known, that differ cants of food, (such as purple kinds of meat, fish, and vegetables,) a great deal more air than usual is separated during digestion from the milk.

In the more violent degrees of colic, the treatment must be varied according to the circumstances of the individual case. If it seem to arise from the accumulation of风气, or from some fault in the milk, suitable doses of cold drawn calomel, or magnesia and sulphur, together with the warm baths, or fomentations of the belly, are to be employed. But if the bowels be quite open, and the complaint have been evidently excited by exposure to cold, or some external circumstances; along with the warm baths or fomentations, opiates, in the form of aodyne balsam, rubbed upon the belly, may be safely preferred. Preparations of opium should almost never be given internationally to infants, as they may do, and have done, irreparable mischief. Dr. Hamilton recommends the tincture of hyoscyamus as a substitute. When constipation attains colic, the most active means of opening the bowels are to be reenacted. For this purpose even large doses of calomel, followed by cold drawn calomel and laxative glycerins, are sometimes insufficient, and more powerful purgatives must be devised.

Introfuction, or intru-fusception, is a very dangerous dicafe, which often proves fatal to infants, just that it sometimes requires great practical discernment to draw the line of distinc- tion between the two diseases. This disorder consists of the passage or inversion of one portion of the intestines into another, together with a fistula and consequent inflammation in the introfected portion. Sometimes these are such as to close the canal; but in other cases, the passage through the gut, though narrowed, remains free. Introfuction is occasioned by violent irritation and spasmodic action of a part of the gut, and this may be excited by worms, by morbid faces, or undigested aliment, by stricile purgatives, &c.; whence it is sometimes the consequence of colic.

If, along with the ordinary symptoms of very violent colic, the pulse be unusually slow, or if there be no calls to vomit the bowels, and nothing but flatus, or fume tinged with blood be passed, there is much reason to dread the existence of this disease.

When introfuction is discovered at the beginning, it often yields to the use of leches, warm fomentations, and a medicine calculated to excite both vomiting and purging. But if its nature be overlooked or misunderstood, even for a few hours, the fatal result can hardly be prevented. A discharge of blood from the bowels, but more often fluxor and occasional convulsions, proceeds. This disease is "Hamiltons Hernia." See also the surgical article HERNIA, or INTRA-FUSCEPTION.

Prolapsus ani, or falling down of the gut, that is, a partial eversion of the rectum, or slight gut, through the fundament, is a common effect of bowel-complaints in weakly children; and seems to constitute a relaxation of the gut, which is forced downwards by any irritation that excites constant or frequent efforts to expel feces, followed by some degree of spasmodic stridence in the muscles, which prevents it from returning. It is generally of temporary duration only, and is easily replaced by slight pressure. Nurses commonly apply a piece of wooden cloth or a soft frain for this purpose; but Dr. Hamilton says, a better plan is to lay the child upon its face, to separate its thighs, and then to press gently between both its buttocks. If those means fail, it becomes necessary to introduce the fore-finger, previously moistened, into the gut, to remove the striction from the intestine. This is a more safe and speedy method than the application of alluring substances to the protruded parts, which might irritate or injure them. With the view of preventing the frequent recurrence of this most unpleasant, though not dangerous complaint, all irritations of the bowels ought to be guarded against; the stools should be dipped twice a day into a tubful of cold water, in which a red-hot iron had been frequently quenched, and the child ought to be made to sit regularly on a firm hard seat. In some instances the relaxation of the part becomes so great, that the gut descends every time the child goes to stool. In this case, alluring lotions, applied by means of a compot of soft tow, have been referred to with success; or suppositories of various substances have been introduced into the bowel after going to stool, giving a mechanical support to the parts.

Worms in the intestines, although commonly supposed to be the cause of all the varieties of marasmus, are much less frequent causes of disease in children, as we have above stated, than other morbid charges in the digestive organs. None of the three varieties of intestinal worms, however, are peculiar to children; and the tapeworm, or tape-worm, is seldom, if ever, found in infants. Of the ascidice, or small thread-worms, as they have been called, a full account has already been given; and a description of the lumbricus, or round-worm, will be found under its proper head. For the symptoms of worms, as they are commonly related, see the foregoing history of Marasmus.

§ 5. Febrile Disease.—Infants and children are liable to most of the fevers which affect adults, both contagious and non-contagious; although within the first eight or ten months they are not so susceptible of the influence of contagion, as they afterward become. A fucking child will sometimes escape the infection of scarlet-fever, measles, and even the small-pox, which makes the reft of a young family. Each of the diseases just mentioned, as well as the whooping-cough, chicken-pox, and catarrhal fevers, which are among the disorders, which children seldom escape, are sufficiently important for separate consideration respectively. (See Fever, Scarlet, Measles, Small-Pox, Pertussis, Varielia, and Chick; also Cow-Pox.) Our attention, in this place, will be chiefly confined to a form of fever, which is in some measure peculiar to infants, and is now generally known by the name of "infantile remittent fever." The infantile remittent fever, or febris infantum remittens, as it was first denominated by Dr. Butten, might perhaps have been included without impropriety under the foregoing section, among the disorders originating in the bowels; for it is now pretty generally understood, that this fever is connected with a morbid state of the intestines in that canal. As the marasmus, above described, has been commonly attributed to the presence of worms in the intestines; so this fever has been ascribed to the same cause, and has been called the worm-fever; partly, it would seem, from the occasional discharge of worms during the course of the fever, and partly from the fumptoms of irritation in the bowels, from whatever cause it may arise. This fever was called Hectica febris infantum by Sydenham, and Hectica infantilis by Sauvages, from the flow and moderate progress which it commonly

Vol. XIX.
INFANTS.

The fever in question is most commonly preceded for some
days, and occasionally for weeks, by symptoms of indis-
position, much resembling the early symptoms of *mara- 
fus*. The child is observed not to look well, and his colour
often changes. He is indolent, spiritless, and fretful; fre-
quently picks his nose, lips, and fingers, even sometimes 
till he draws blood; his breath is offensive, and he is affected
with a short dry cough. If he can speak, he complains of
pain in his head, or belly, or both: and when still older, he
says also that he is faint and weak. He has a desire for
drink more than for food: is much troubled with wind;
and his belly is sometimes larger than natural. In his
sleep, he startls, moans, and makes a grating noise with his
teeth. His urine puts on a milky appearance almost as soon
as made, and, in a few minutes, deposits a sediment of the
fame colour, leaving the body of the urine with very little
colour. His bowels are generally in the extreme, being
either coltive or loose.

After these symptoms have continued for a longer or
shorter time, the fever makes its appearance, sometimes pre-
ceded by a distinct cold fit, at other times, however, so
gradual in its approach, that the commencement is not ob-
served. It always assumes more or less of the remittent
form, when it is distinctly seen, and the exacerbations are
long, and the remissions short, in proportion to the violence
of the fever. During the exacerbation all the symptoms are
increased: there is great heat of skin, and the patient is drowsy,
and fleeps, but not soundly; for he flarts, moans, talks in-
coherently, and even screams in his fleeps. The wind is par-
icularly troublesome, makes a rumbling noise in the bowels,
and is exploded copiously both upwards and downwards,
with manifest relief. The cough is more frequent,
and the breathing is quickened and oppressed. The patient is
often sick, and sometimes retches, and even vomits phlegmy
fluff of various colours. The pulse beats from a hundred
and forty to a hundred and sixty pulsations in the minute.
In the remissions, all the symptoms abate. The patient is
wakable, is attentive to things around him, often inclines to
be playful, and is in general averfe to lying in bed. What
fleep he has is usually composed. The pulse beats from a
hundred and twenty to a hundred and thirty strokes in a
minute.

These exacerbations and remissions often occur with a con-
fiderable degree of regularity; the exacerbation generally be-
commencing in the evening, and the remission taking place in the
morning: but in the more acute form of the disease, there are
one or two shorter exacerbations during the day. In the
latter cafe, both in the exacerbations and remissions the skin
is commonly dry: when sweats happen, they are partial,
affecting only the head, breast, or palms. The belly and
palms are always warmer than any other part of the body.
Where there is only the nocturnal exacerbation, it is usually
terminated by a profuse sweat: and through the day, the
skin is temperate, but feels dry and harsh. The patient has
no appetite, and scarcely any thirst: so that in many
cases, it is with great difficulty that he can be made to take
either food or drink. The flate of the bowels is uncertain
but the foolds are always unnatural, either as to their colour,
confistency, contents, or smell: most commonly they are
morbid in all these respects: for they are either whiter or
darker than natural; they are always more offensive; are
fleidom without a great deal of flime, and sometimes conflit
of nothing but flime: sometimes they froth and ferment like
youth.

The patients frequently pass worms in the course of this
fever, even when they were never known to void any before.
These worms are not only thrown off by vomitting and foold,
but are sometimes observed to work themselves out of the
body both ways, seemingly unaffected by any exertions on
the part of the patient's organs. But in many cases of
this fever, no worms are ever seen.

When the fever is on the decline, the exacerbations grow
milder and shorter, and at length disappear one after
another; the appetite returns by degrees; the fleep becomes
calm and refreshing, attended with a general moifure of the
skin, and the foolds approach more and more to the natural
state, till they become as in health. The duration of this fe-
ver, in its more acute form, is from eight or ten days to a fort-
night or three weeks; in the more mild and mild form, it
will last for two or three months or more.

That the cause of this remittent fever of children lies in
the alimentary canal, and is of the fame nature with that
from which marasmus, and feveral other infantile difeafes
originate, has not been doubted since it was fo well pointed
out by Dr. Butter. It is proved, in the firft place, by the
fimilarity of the symptoms with which it is preceded and
ubered in, and, secondly, by the nature of the alvine dif-
charges during its continuance, but more especially by the
success of the practice, which is founded upon this prin-
ciple, and consists in carrying off the accumulation of mor-
bid excretions from the bowels, and augmenting their
strength. The fame caufe operating in different constitu-
tions, will produce a different series of symptoms; and
it is probably from the peculiar irritability of habit in
some children, that this fever is produced, by the fame
morbid secretion and accumulation in the *prime vax*,
which give rise to marasmus, and other chronic maladies in
others. "It may be accelerated by cold, fatigue, or the like;" says Dr. Butter, (fpeaking of the remittent fever.)
"but the principal caufes are crude accumulations in the
firt paffages, which, with a very irritable predifpofition,
draw the intestinal canal into fpasm, &c." whence the
irritation is communicated to the rest of the body, and general
fever induced.

Cure of the infantile remittent fever.—The two principal
indications of cure are, to allay the febrile irritation, and to
remove the great irritating caufe; the former of which, although
in a great meafure palliative only, is an object of conliderable
importance. It is extremely defirable, therefore, that from
the firft occurrence of the febrile symptoms, the child shouid
be kept fiff, and quiet, in a chamber which is of a cool
temperature; that all folid food and fecanting drink should
be cautiously abfrowned from; and the fole fupport of the
patient be diluting and nourifhing liquors, fuch as small
broth, gruel, and barley-water.

The fecond, or proper curative indication, is fulfilled by
fuch medicines as keep up a constant gentle action upon the
bowels, and continue the irritation to diffuse the morbid ac-
cumulation, and to correct the morbid condition, of the alvine
excretions. This purpofe may be effected either by the
neutral falls, or by small dofes of mercurial laxatives, es-
pecially in combination with absorbents. Dr. Butter gives
the preference to the former; and commonly employs the
polychrifal fall, which promotes both urine and foolds. For
a child of five years old (and proportionally for a younger
or older {ubje{t) he diffoles a drachm of this fall in a quarter
of a pint of water, sweetening it with two drachms of fugar.
Of this mixture two fpoonfuls are administered every four
hours, or at fuch intervals, when the child is awake, that
the whole may be finifhed in twenty-four hours. This med-
icine is to be repeated daily, fo as to promote one, two,
three,
three, or four foons, according to the circumstances of the case, the larger number in the more acute forms of the disease. When the fever is attended with a loofenes, Dr. Butter interdicts the use of the neutral fats, and prefers the extract of hemlock (Conium, Linn.) the quantity of five grains to be taken in the course of 24 hours, suspended in water with a little sugar. It relieves every symptom of the fever, he says, and at the same time gradually carries off the loofenes. Under similar circumstances, we have been efficient service from small doses of some mercurial, combined with absorbents, as the Hydrargyrum hydroc., of the London Pharmacopoeia; or a grain of calomel united, by rubbing, with a little soda and taffelaceous powder. While the Conium is given as above-mentioned, as much rhubarb may be administered as will keep the body gently open, where the fever is not very acute.

When there is great restlessness and vociferation, the belly should be fomented with flannel cloths, wrung out of a decoction of chamomile, and applied agreeably warm, for twenty minutes or half an hour at a time, as occasion may require; and this operation should be repeated as often as the symptoms return. As the disease declines, the child may be allowed to return gradually to his usual diet and way of life; but some care will be requisite, that he may not have his free liberty as to eating, drinking, and exercise, until he has recovered his full flesh and strength; and the medicines above recommended must be continued till the fever is quite gone.

Cataarrhal fever is not a very frequent disease during infancy, and when it does occur, seldom requires any other treatment, than an emetic at the beginning, an open female of the bowels, and the warm bath every night while it continues. When it extends to the degree of pulmonary inflammation, blistering the chest is often an effectual remedy, or, in strong children, the application of leeches to the chest may be resorted to. The principle of treatment, indeed, is the same in these complaints, whether they occur in the early or later periods of life; except that the infantile constitution is more easily acted upon by remedies, and therefore that a laxative and a blitter will often accomplish a degree of alleviation of fever, which more active measures will be required to produce in adults. See CATARRH and PERIPNEUMON.

Among the fevers incident to children, the acute hydrocephalus, or water in the head, should be described; but we have already given the history of that important disease in its place. (See HYDROCEPHALUS.) It remains for us to say a few words on the subject of convulsions.

§ 6. Convulsive Diseases.—The subject of convulsions, in general, has been treated under its proper head, (see CONVULSIONS,) as well as the most fever modifications of convulsive disease, the epilepsy and St. Vitus's dance. (See EPILEPSY and CHOREA.) It will, therefore, be sufficient to state here some circumstances relative to the convulsions of infants in particular. And first it must be observed, that, in consequence of the peculiar susceptibility of impression in the nervous system of infants, many circumstances excite convulsions at that early age, which have no such effect at a subsequent period of life. Accordingly it is well known, that in general the younger the infant is, the more readily do fits occur, and that some families are more liable to others to the disease, apparently from a weak state of the nervous or vascular system being communicated from the parents. The obvious exciting causes are dejection, mechanical injuries, acute diseases, impurities of the air, passions of the mind, indigestible or poisons substances in the stomach or bowels, over-dilution of those organs, irritations in them from acid matter or worms, the state of the system previous to the appearance of small-pox, measles, &c. All these act by disturbing the nervous system, and altering or deranging the actions of the vessels.

In some cases convulsions come on suddenly; the infant, from being in the most perfect health, turns in a moment livid, his eyes and features are contorted, and his limbs and whole frame are thrown into violent agitations. The symptoms are succeeded by a suspension of the vital powers, as in faintings, which may or may not prove fatal. Sometimes the attack is gradual, and the first symptoms are not easily discerned by the attendants; the infant shows some degree of uneasiness; he changes colour, his lips quiver, his eyes are turned upwards, and he unexpectedly, as it were, stretches himself out; or his hands become clenched. The lesser degrees of these are called by the nurses inward fits. Convulsions commonly precede the fatal termination of most of the diseases of infancy, which explains the reason of their appearing in the bills of mortality to be of such frequent occurrence. Accordingly, where they take place after any considerable indisposition, they are to be regarded as the bar- beginnings of death. But even when the infant had been in perfect health previous to the attack, the event is always to be considered as extremely uncertain, for a single fit may kill. In ordinary cases, the danger is to be estimated by the degree of violence of the fit, and by the cause which had produced it. Thus if the cause be some irritation, which is naturally of temporary duration, or which can be easily removed, a favourable event may be looked for; but if it be not obvious, it may be suspected to be some state of the brain, which admits of no remedy. In many infirns, where it was impossible to discover the cause of the fits during life, an accumulation of water within the ventricles of the brain has been found after death.

There is no medicine possessed of any specific power in suppressing convulsions, although coehinolic, miltoes, musk, and other sublataces, have been at different times extolled for supposited virtues of this nature. One of the most effectual means of alleviating the fits, is to immerse the child, during their attack, in a tubful of water, heated to 96° of Fahrenheit's thermometer, or to a warmth that the hand can easily bear. In very young infants opiates are not always safe, and cannot be trusted in the hands of nurses or inexperienced persons; but in children upwards of eighteen months, where the warm bath does not speedily succeed in abating the convulsions, from one or two to four or five drops of the tincture of opium might be administered, according to the severity of the fits; or a proportionate quantity of the camphorated tincture of opium, or of the extract of poppies diffused in a little water. Professor Hamilton has recommended a substitute for opium, which may be given to younger children; namely, the tincture of hyoscyamus: "twenty drops, evening and morning, have been repeatedly given to infants within six months of age." He remarks, that, when the convulsions have been the effect of hoopingcough, great benefit has been derived from this medicine. Camphor, in the form of glyster, has been found efficacious in some few cases, the same author states, but chiefly in children beyond the second year. He adds, "when a child feems to be suddenly deprived of life by one or two fits, if he appeared previously in good health, he ought on no account to be considered as irrecoverably lost; but the common means for restoring suspended animation should be carefully employed, as long as his colour is not entirely changed." Hints, &c.

Some other diseases, which occur in infancy and childhood, might here have been described; especially the glandular affections, both internal and external; the various disorders

M 2 of
INF

INF

of the scalp, as the calld-head, ring-worm of the scalp, &c.; the ricket, and so forth. But some of these are not peculiar to the age of childhood, and others are sufficiently important to be discussed more at length. See Tables meningitis, or meningeal consumption; Scrofula, Porridge, Rickets.

The prevention of disease in children depends principally on the regulation of the diet and clothing, sleep, exercise, in the open air, and cleanliness. On the subject of the two or three last points we have little to say, as the value of a proper attention to them is now generally understood. In regard to diet, it may be sufficient to state, that, after weaning, preparations of milk, of eggs, of vegetable and animal jellies, should precede solid animal food; that, during childhood, a proper proportion of animal and vegetable matter should be used; and that all condiments, except salt, are unnecessary, and all spirituous fermented liquors pernicious. In respect to clothing, it is important to observe, that the attempts to rear children in a harsh manner, by allowing their legs to be bare, and other parts of the body to be much exposed (a practice sanctioned by some great names) have proved most unsuccessful; for by these means not only has the growth been, in many instances, stunted and perverted, but the constitution has been much injured; and, in some cases, has absolutely destroyed, in consequence of inflammations of the lungs and bowels, or various febrile affections, thus excited. It would appear, indeed, that febrile and consumptive diseases owe their origin principally to the cold and humidity of our climate, and the destitute influence of these causes upon the constitution in childhood was strikingly illustrated in the attempt lately made by the Sierra Leone Company to form an establishment for the education of African children in this country. Mr. John Pearson, who superintended this institution, states that they all died of consumption; they almost uniformly became febrile; they bore the first winter tolerably well, but drooped during the second, and the third generally proved fatal to them; inasmuch that it became necessary to abandon the plan. Now we cannot but deem the situation of a child, who is to be hardened by thin clothing, as analogous to that of these African children, and to believe that, by such delusive attempts to give strength, the perfect and healthy evolution of the fyttem is prevented, and the foundation laid for scrofula, consumption, and other chronic diseases.

INFANTS, Running Eye of. See OPHTHALMY.

INFANTS at Bethlehem, Slaughter of, by Herod, a fact mentioned in the gospel of St. Matthew, chap. ii. 16.; but disputed on account of the silence of Jusephus, who has written the history of the Jews, and particularly the reign of Herod. The fact is not itself improbable nor incredible, if we consider the cruelty of Herod's disposition and other savage acts of which he was guilty (see Herod), and more especially if we recollect, that the slaughter, mentioned by St. Matthew, was perpetrated upon the occasion of tidings brought to Jerusalem, of the birth of one who was called the "king of the Jews." Jusephus, who has given an account of a terrible execution made in Herod's court, and at Jerusalem, about the same time, upon the occasion of some predictions, that God was about to take away the kingdom from Herod, might omit the murder of the infants at Bethlehem from a fear of being charged with a design to load Herod unreasonably, or a fear of rendering his history disagreeable by too particular a detail of cruel actions. The silence of Jusephus, it is said, is no more an objection against St. Matthew, than the silence of other writers with regard to facts mentioned by Jusephus is an objection against him. Jusephus, however, if he was a firm Jew, as most writers have supposed, had a particular reason for passing over this event at Bethlehem, because he could not have mentioned it, without giving great advantage to the Christian cause. If he had written that Herod, at the latter end of his reign, had put to death all the young children at Bethlehem, on occasion of a report spread at Jerusalem, that the "king of the Jews" had been newly born there, he would very much have gratified the Christians; since it was well known, when he wrote, that about thirty years after the death of Herod, Jesus, being then about thirty years of age, had been styled the "king of the Jews," and had been publicly crucified at Jerusalem with that title; and it was firmly believed by all his followers, that he was the great perfom sp.ken of under that character, and was now advanced to eximation and power. If Jusephus did not wish to serve the Christians and their cause, he would therefore be silent with regard to this fact. But it has been alleged, that the Greek and Roman historians are silent with respect to this event; but this may easily be accounted for, if we consider, that the Roman empire was at this time so extensive, that the affairs of many independent princes have been lost in the crowd. Nevertheless, St. Matthew's account is confirmed by the testimony of ancient Christian authors. Fulcran Martyr, Irenaeus, Origen, and other Christian writers have mentioned the fact. Moreover, there is also a noted passage in Macrobins, a heathen author, who flourished in the latter end of the fourth century, who, among other facts of Augustus, has this: "When he (Augustus) had heard that among the children within two years of age, which Herod king of the Jews commanded to be slain in Syria, his own son had been killed, he said, "it is better to be Herod's dog than his son."" Macrob. Sat. ii. c. 4. This passage, if we deduce no other inference from it, shows, that Herod's slaughter of the infants in Judea was a thing well known in Macrobins's time, and was not controlled by the heathens. See Lachner's Works, vol i. chap. 2.

INFANTA, in Geography, a river of Africa, which runs into the Indian sea. S. It. 32.

INFANTE and INFANTA, are titles of honour given to the children of some princes; particularly those of the houses of Spain and Portugal.

It is usually said, that the appellation of infanta was introduced into Spain; on occasion of the marriage of Eleanor of England with king Ferdinand of Castile: and that their son Blanche was the first that bore it. But this is contradicted by Pelagius, bishop of Oliodo, who lived in the year 1100, and who informs us, that the titles infanta and infanta were used in Spain ever since the reign of king Evermond II.

INFANTICE, in Mythology, the name of a deity to whom, according to Lyceus, children were sacrificed by the Greeks. It is not likely that this was originally the name of any separate deity; but from the lamentable frequency of this almost incredible offering, this horrible distortion was appropriated to, most probably, Hecate, or some other form of the goddess Diana, of multifarious names and characters. The subject of infanticide has lately undergone more than usual discussion, and the prevalence of the practice, both heretofore and existing, proved of greater extent than could have been imagined. See the following article.

INFANTICIDE, or child murder, is an enormity that our reason and feelings would lead us to reckon as a crime of very rare occurrence. That it should exist at all, is, at the first view, surprising,—that it should prevail to any extent is difficult of belief,—that parents should be its perpetrators is in a high degree painful to imagine; but that mothers should
In the contiguous countries of Kutch and Sind, infanticide also prevails; but it has not been ascertained to what extent. It is recognized and avowed by the perfons holding the powers of government, who assert the antiquity of the usage, and forbid any interference to our part with a view to its abolition: our endeavours to effect that laudatory end have in these quarters entirely failed.

It is, however, a confounding fact to reflect on, that solely through British interposition this cultum has been put an entire stop to throughout the vast extent of our influence in India. None of the former governments, whether Hindoo or Mahometan, of the countries comprehended within that line appear ever to have made any effort toward working to effect a desirable reform, although the religious tenets of both points of object in this respect.

These particulars we have gathered from a recent publication by major Moor, on “Hindoo Infanticide;” wherein he has given at length all the correspondence and negotiations that led to its discovery and expulsion in India; with notices of a similar cultum, which, and the exposure of children, he proves to have prevailed both in ancient and modern times among many nations in almost every part of the world.

He adduces many speculations on its existence, origin, and effects: extending, indeed, to a lengthened discussion on a subject that, as much as any on record, evinces the most

The infants fland contradistinguished from the male and female, which see, the

INFANTOS, in Geography, a town of Spain, in New Castile; 20 miles W. of Alcaraz.

INFANTERY, the body of foot soldiers, in an army, or other corps. See Foot.

The infantry fland contradistinguished from the cavalry or horse, which see.

Europe is unquestionably indebted to the Swiss for a total change in the military system; particularly so with regard to foot soldiers.

Dr. Robertson, in the first volume of his history of Charles V. p. 105, observes, that the sytem of employing the Swiss in the Italian wars, was the occasion of introducing a total innovation in the military cultum. The arms and discipline of the Swiss were different from those of other European nations. During their long and violent struggles in defence of their liberties against the house of Austria, whose armies, like those of other considerable princes, con- testing chiefly of heavy armed cavalry, the Swiss found that their poverty, and the small number of gentlemen residing in their county, at that time barren and ill cultivated, put it out of their power to bring into the field any body of horse capable of facing the enemy. Necessity compelled them to place all their confidence in infantry; and in order to render it capable of withstanding the shock of cavalry, they gave the soldiers broad-plates and helmets, as defensive armour, together with long spears, halberts, and heavy swords, as weapons of offense. They formed them into large battalions, ranged in deep and close array, so that they could prevent on every side a formidable front to the enemy. (See Machiavell’s Art of War, b. ii. chap. ii. p. 47.)

The men at arms could make no impression on the solid throng of such a body. It repelled the Austrians in all their attempts to conquer Switzerland. It broke the Burgundian Gendarmerie, which was scarcely inferior to that of France, either in number or reputation; and when first called to act in Italy, it bore down, by its irresistible force, every enemy that attempted to oppose it. These repeated proofs of the decisive effects of infantry, exhibited on such conspicuous occasions, re- tended that service to reputation, and gradually re-established the opinion which had been
been long exploded, of its superior importance in the operations of war. But the glory the Swifs had acquired, having inspired them with such high ideas of their own prowess and consecution, as frequently rendered them mutinous and inoffent, the princes who employed them became weary of depending on the caprice of foreign mercenaries, and began to turn their attention towards the improvement of their national infantry.

The German powers having the command of men, whom nature has endowed with that hardy courage and persevering strenth which form them to be soldiers, soon modelled their troops in such a manner, that they vied with the Swifs both in discipline and valor.

The French monarchs, though more slowly, and with greater difficulty, accustomed the impetuous spirit of their people to subordination and discipline; and were at such pains to render their national infantry respectable, that as early as the reign of Louis XII. several gentlemen of high rank had so far abandoned their ancient ideas, as to condescend to enter into their service.

The Spaniards, whose situation made it difficult to employ any other than their national troops in the southern parts of Italy, which was the chief scene of their operations in that country, not only adopted the Swifs discipline, but improved upon it, by mingling a proper number of soldiers, armed with heavy muskets, in their battalions; and thus formed that famous body of infantry, which, during a century and a half, was the admiration and terror of all Europe. The Italian states gradually diminished the number of their cavalry, and in imitation of their more powerful neighbours, brought the strength of their armies to consist in foot soldiers. From this period, the nations of Europe have carried on war with forces more adapted to every species of service, more capable of acting in every country, and better fitted both for conquests, and for preserving them.

Infantry. Exercise. See Exercise.

Infantry, Foreign. The foreign infantry in the service of Great Britain, according to the returns delivered in on the 1st of November 1800, consists of loyal French emigrants, Caftries, Mortemart, Roll and Dillon; Menron ditto; four ditto Dutch, each having a company of artillery attached, and one Dutch rifle with a company of pioncers; Lovenstein's corps, which was not completed, and one corps of foreign invalids. Staff to a foreign hospital. There are besides 16 unattached foreign officers who receive full pay, 166 ditto on half pay, 304 aged and wounded ditto, 46 foreign officers widows, 44 children of foreign officers who have died in the king's service. There is also a small corps of effaiettes, which is attached to the wagon train, and consists wholly of foreigners.

Infantry, Heavy armed, among the ancients, were such as wore a complete suit of armour, and engaged with broad shields and long spears. They were the flower and strength of the Grecian armies, and had the highest rank of military honour.

Infantry, Light armed, amongst the ancients, were designed for skirmishes, and for fighting at a distance. Their weapons were arrows, darts or flings.

Infantry, Light, have only been in use since the year 1659. They have no camp equipage to carry, and their arms and accoutrements are much lighter than the common infantry, or battalion men. Wherever there is light cavalry, there should be light infantry to act in conjunction.

Infarction, in Medicine, infarctus, is of the Greeks, is synonymous with obstruction, and congestion, and denotes that state of any organ of the body, which is tumid, with the blood-vesseils loaded, and is more especially applied to the tumours produced by a chronic inflammation of the parts.

Infarction of the Liver. See Hepatitis, and Liver, Chronic Diseases.

Infarction of the Spleen. See Splenitis and Spleen.

Infarction of the Meility. See Marasmus, and Tafes Mesentericae.

Infatuate, to prepossess any one in favour of some person or thing that does not deserve it, so far as that he cannot easily be disabused.

The word infatuate comes from the Latin fatus, fool, to speak; which is borrowed from the Greek ἑτερος, whence εὐταῖος, which signifies the name with εὐταῖος in Latin, or prophet in English; and the reason is, because their prophets or priests used to be seated with a kind of madness or folly, when they began to make their predictions, or deliver oracles.

The Romans called those persons infatuated, infatui, who fancied they had seen visions, or imagined the God Faunus, whom they called Fatenus, had appeared to them.

Infection, in Medicine, a word used in two acceptations: first, as denoting the effluvium or infectious matter, exhaled from the person of one diseased, and capable of communicating the disease to others who inhale it; in which sense it is synonymous with contagion: and secondly, as signifying the act of communicating such morbid effluvium, by which the disease is transferred. The word comes from the Latin verb inficere, which properly signifies to dye of some other colour, or to cause something to be imbied. See Contagion.

Infecoration of Threes, in Law. See Tithes.

Inferiæ, in Antiquity, sacrifices offered to the dii manes, or the souls of deceased heroes and illustrious persons; or even of any relation or person whose memory was held in veneration.

Inferior, lands opposed to superior.

Inferior Courts of Record, in English Law-writers, is used as a general name for corporation-courts, courts-leet, and sheriffs-torns. See Courts.

Moll courts are subordinate to some other; but for distinction fake the term inferior-court is by Sir Matthew Hale, and others, applied in the manner here mentioned.

Inferior Maxilla, Occan, Planet. See the substantives.

Inferior Penis, in Anatomy, a name given by Spigelius to one of the muscles of the penis, generally called the accelerator by the moderns; and by Vellthus, and others of his time, primary penis.

Inferior Obliquus, Serratus, Subcapularis. See the several articles.

Inferioris labii depressor, labii elevator. See Depressor, and Elevator.

Infernal Glass, in Chemistry, is a name given to the bolt-head, when its stem is continued downward into the body of the glafs vessel, and left open only by a very small orifice.

Infernal Salt, a name given by Hoffmann, and some other of the chemical writers, to nitre; they have also called it corbusus chemicus.

Infernal Stone. See Lapis Infernalis, Caustic, and Crystals of Silver.

Infernals, in Artillery, floating mines constructed in the bodies of ships or boats. The first inventor of them, or at least the first who put them in practice, was Frederick Jambelli, an Italian engineer, at the siege of Antwerp by the Spaniards under Alexander, prince of Parma, in the year 1585. A very particular and interesting relation of their wonderful effects is given by Strada, in his "History of the Belgic
Dunkirk and St. Maloes they were tried by the English; at Havre de Grace by the English and Dutch, under king William; and one was constructed by the French to be used against Algiers, in 1688, but it was not employed. St. Remi, in his Memoirs of Artillery, has given a lection and view of the internal used at St. Maloes. See a description and figure of it in Grofe's Military Antiquities, v. i., p. 410.

INFERTILITY. See Fertility.

INFIBULATION, in Antiquity. It was a custom among the Romans, to infibulate their singing boys, in order to preserve their voices: for this operation, which prevented their retracting the preface over the glans, and is the very reverie to circumcision, kept them from injuring their voices by premature and preposterous venery: serving as a kind of padlock, if not to their inclinations, at least to their abilities. It appears by some passages in Martial, that a lea decent use was made of infibulation among the luxurious Romans; for some ladies of distinction, it seems, took this method of confining their paramours to their own embraces. Juvenal also hints at some such practice. Celsus, a chaste author, says, infibulation was sometimes practiced for the sake of health; and nothing destroys it more than the filthy practice this operation seems intended to prevent. This practice is not perhaps likely to be revived; if, however, any one who has suffered in his constitution by preposterous venery, should be able to get children, and should be inclined to prevent the same misfortune in them, by infibulation; the method of doing it is thus:

The skin which is above the glans is to be extended, and marked on both sides with ink, where it is perforated, and then suffered to retract itself. If the marks recur upon the glans, too much of the skin has been taken up, and we must make the marks farther; if the glans remain free from them, they fhew the proper place for affixing a fibula: then pass a needle and thread through the skin where the marks are, and tie the threads together: taking care to move it every day, until the parts about the perforations are cicatized; this being effected take out the thread, and put in the fibula; which the tighter it is the better. Celsus, lib. vii. cap. 25.

Authors have not determined what the fibula of the ancient Egyptians was, though no doubt they were for different purposes. In the present cafe, the fibula seems to mean a ring of metal, not unlike what the country people put through the noses of swine.

INFIDEL, a term applied to such persons as are not baptized, and that do not believe the truths of the Christian religion. See Deist.

INFIERTO, in Geography, one of the smaller Canary Islands, between Lancerotta and St. Clara.

INFIESTO, a town of Spain, in the province of Al- tarrias; 20 miles E. of Oviedo.

INFILTRATION, in Geology, is one of the processes of nature, by which thiny harden's seem to be have been given or increased in mineral substances or strata, in certain situations, effected by the infiltration or soakage of water laden with thiny particles, through porous substances, and then depositing their limpidiferous contents: Mr. Kirwan, in his "Geological Essays," pages 145, 128, 131, and 412, has considered this mode of indurating the terrihial strata, and quoted a number of curious mineral changes and appearances ascribed to this agent.

INFINITE, that which has neither beginning nor end: in which fere no God alone is infinite.

INFINITE is also used to signify that which has had a beginning, but will have no end: as angels, and human souls.

This makes what the schoolmen call infinitum a parte privata, as, on the contrary, by infinitum a parte ante, they mean that which has an end, but had no beginning. See INDEFINITE and Finite.

INFINITE, in Mathematics, is applied to quantities which are either greater or smaller, than any assignable ones. In which sense it differs not much from what we otherwise call indefinite or indeterminate. Thus, an

INFINITE, or Infinitely great line, in Geometry, denotes only an indefinite or indeterminate line; to which no certain bounds or limits are preferred.

INFINITE Quantities. Though the idea of magnitude infinitely great, or such as exceeds any assignable quantity, does include a negation of limits; yet all such magnitudes are not equal among themselves; but besides infinite length and infinite area, there are no less than three several sorts of infinite solidity; all of which are quantities fictitious; and those of each species are in given proportions.

Infinite length, or a line infinitely long, is to be considered, either as beginning at a point, and so infinitely extended one way; or else both ways from the same point: in which case the one, which is a beginning of infinity, is one-half of the whole, which is the sum of the beginning and extending infinity, or infinity a parte ante, and a parte pos, which is analogous to eternity in time or duration; in which there is always as much to follow, as is past any point or moment of time.

Nor does the addition or subtraction of time, length or space of time, alter the case, either as to infinity or eternity; since neither the one nor the other can be any part of the whole.

As to infinite surface or area, any right line infinitely extended both ways on any infinite plane, divides that plane into equal parts, the one to the right, and the other to the left of the said line; but if from any point in such a plane, two right lines be infinitely extended, so as to make an angle; the infinite area, intercepted between these infinite right lines, is to the whole infinite plane, as the arc of a circle drawn on the point of concourse of those lines as a centre, intercepted between the said lines, is to the circumference of the circle; or as the degrees of the angle to the 360 degrees of a circle.

For an example—Two infinite right lines meeting at a right angle on an infinite plane, do include a quarter part of the whole infinite area of such a plane: if two parallel infinite lines be supposed drawn on such an infinite plane, the area intercepted between them will be likewise infinite; but at the same time it will be infinitely less than the space intercepted between two infinite lines, that are inclined, though with never so small an angle, because in the one case the given finite distance of the parallel lines diminishes the infinity in one degree of dimension; whereas in the other, there is infinity in both dimensions; and consequently the quantities are one infinitely greater than the other, and there is no proportion between them.

From the same consideration arise three several species of infinite space or solidity; for a parallelopiped, or a cylinder infinitely long, is greater than any finite magnitude, how great soever; all such solids supposed to be formed on a given basis, are in proportion to one another as those bases. But if two of those three dimensions are wanting, as in the space intercepted between two parallel planes infinitely extended, and at a finite distance; or with infinite length and breadth,
Breadth, it have a finite thickness; all such solids shall be as the given finite distances one to another.

But these quantities, though infinitely greater than the other, are yet infinitely less than any of those wherein all the three dimensions are infinite—such are the spaces intercepted between two inclined planes infinitely extended; the space intercepted by the surface of a cone, or the sides of a pyramid, likewise infinitely continued, &c. all which, notwithstanding the proportion of one to another, and to the >, or vast abyss of infinite space (wherein is the locus of all things that are, or can be) to the solid of infinite length, breadth, and thickness (taken all manner of ways) are easily affimitable. For the space between two planes is to the whole, as the angle of those planes to the 360 degrees of the circle. As for cones and pyramids, they are as the spherical surface intercepted by them, to the surface of the sphere; and therefore cones are as the vered lines of half their angles to the diameter of the circle; these three sorts of infinite quantity are analogous to a line, surface, and solid; and like them, cannot be compared or have any proportion one to another.

INFINITES, Arithmetic cf. See Arithmetic.
INFINITES, Characters in Arithmetic of. See Character.
INFINITE Decimals. See Repetend.
INFINITE Dilations, in Laws. See Distress.
INFINITE Proposition, in Logic. See Proposition.
INFINITE Series. See Series.
INFINITELY small quantity, called also an infinite
field, is that which is fo very minute, as to be incomparable to any finite quantity; or it is that which is less than any affimitable quantity.

An infinite quantity cannot be either augmented or lessened, by adding or taking from it any finite quantity, neither can a finite quantity be either augmented or lessened, by adding to, or taking from it an infinitely small quantity.

If there be four proportionals, and the first be infinitely greater than the second; the third will be infinitely greater than the fourth.

If a finite quantity be divided by an infinitely small one, the quotient will be an infinitely great one; and if a finite quantity be multiplied by an infinitely small one, the product will be an infinitely small one; if by an infinitely great one, the product will be a finite quantity.

If an infinitely small quantity be multiplied into an infinitely great one, the product will be a finite quantity.

In the method of infinitesimals, or of infinitely small quantities, the element by which any quantity increases or decreases, is supposed to be infinitely small, and is generally expressed by two or more terms; one of which is infinitely less than the rest, which being neglected as of no importance, the remaining terms form what is called the difference of the proposed quantity. The terms that are neglected in this manner, as infinitely less than the other terms of the element, are the very same which arise in consequence of the acceleration, or retardation of the generating motion, during the infinitely small time in which the element is generated; so that the remaining terms express the element that would have been produced in that time, if the generating motion had continued uniform, as is farther explained under Fluxion.

Therefore these differences are accurately in the same ratio to each other as the generating motions or fluxions. And hence, though infinitesimal parts of the elements are neglected, the conclusions are accurately true, without even an infinitely small error, and agree precisely with those that are deduced by the methods of fluxions. In order to render the application of this method easy, some analogous principles are admitted, as that the infinitely small elements of a curve are right lines, or that a circle is a polygon of an infinite number of sides, which being produced, give the tangents of a curve, and by their inclination to each other measure the curvature. This is as if we should suppose that when the baze flows uniformly, the ordinate flows with a motion which is uniform for every infinitely small part of time, and increases, or decreases, by infinitely small differences at the end of every such time.

But however convenient this principle may be, it must I applied with caution and art, on various occasions. It is usual, therefore, in many cases, to resolve the element of the curve into two or more infinitely small right lines; and sometimes it is necessary (if we would avoid error) to resolve it into an infinite number of such right lines, which are infinitely smalls of the second order. In general it is a postulatum in this method, that we may defend to infinitesimals of any order whatever, as we find it necessary, by which means any error that might arise in the application of it may be discovered and corrected by a proper use of the method itself.

It is also to be observed, that when the value of a quantity that is required in a philosophical problem becomes, in certain particular cases, infinitely great or infinitely little, the solution would not be always just, though such magnitudes were admitted. As when it is required, to find by what centripetal force a curve would be described about a fixed point that is either in a curve, or is so situated that a tangent may be drawn from it to the curve. The value of the force is found infinite at the centre of the forces in the former case, and at the point of contact in the latter; yet it is obvious, that an infinite force could not inflect the line described by a body that should proceed from either of these points into a curve; because the direction of its motion in either case pasts through the centre of the forces, and no force, how great soever, that tends towards the centre, could cause it to change that direction. But it is to be observed, that the geometrical magnitude by which the force is measured, is no more imaginary in this than in other cases, where it becomes infinite; and philosophical problems have limitations that enter not always into the general solution given by geometry.

But although by proper eare errors may be avoided in the method of infinitesimals, yet it must be owned that to such who have been accustomed to a more strict and rigid kind of demonstration in the elementary parts of geometry, it may not seem to be consistent with perfect accuracy, that, in determining the first differences, any part of the element of the variable quantity should be rejected, merely because it is infinitely less than the rest; and that the same part should be afterwards employed for determining the second and higher differences, and resolving some of the most important problems. Nor can we suppose that their scruples will be removed, but rather confirmed, when they come to consider what has been advanced by some of the most celebrated writers on this method, who have expressed their sentiments concerning infinitely small quantities in the preceding terms, while some of them deny their reality, and consider them only as incomparably less than infinite quantities, in the same manner as a grain of sand is incomparably less than the whole earth; and others represent them in all their orders, as no less real than finite quantities. And although it appears, from what has been said in this article, that a satisfactory account may be given for the brief way of reasoning that is used in the method of infinitesimals; while nothing is neglected without accounting for it; and then the harmony...
between the method of fluxions, and that of infinitesimals thus appears more perfect.

And however safe and convenient this method may be, yet some will always be reluctant to admit infinitely little quantities and infinitely small orders of infinitesimals, into a science that

boasts of the most evident and accurate principles, as well as of the most rigid demonstrations. It is therefore proper, that this extensive and useful doctrine should be established on unexceptionable principles. See the articles Fluxions and Limit.

See also Mr. Machin's Treatise of Fluxions, in the Introduction, p. 39, 40, &c. and book i. art. 495 to 502.

Infinitemly Infinites Fractions, or all the powers of all the fractions whose numerator is one, are together equal to an

unit. See the demonstration hereof given by Dr. Wood, in

Hence, it is deduced, 1. That there are not only infinite progressions, or proportions in infinitum; but also infinitely farther than one kind of infinity. 2. That the infinitely infinite progressions are not withstandable, and to be brought into one form; and that not one, but finall as to be less than any assignable number. 3. That of

infinite quantities, some are equal, others unequal. 4. That one infinite quantity may be equal to two, three, or more

other quantities, whether infinite or finite.

INFINITELY, in Grammar, the name of one of the

moods, which serve for the conjugating of verbs.

The infinitive does not denote any precise time, nor does it determine the number, or persons, but expresses things in a loose indefinite manner; as, to teach, &c.

Hence the Latin and modern grammarians have called verbs under this mode, from this their indefinite nature, infinitives.

Sancius has given them the name of imperfons; and the Greeks that of \( \sigma \tau \pi \gamma \mu \delta \) αλοικας from the same reason of their not discovering either person or number.

Infinitives, says Mr. Harris, not only lay aside the character of attributes, but they also affect that of substantives, and are distinguished with their several attributes; e.g.

"Dolcis & decorum est pro patria morti; seire tuum nihil eft, &c."

Hence the infinitive has been sometimes called \( \sigma \nu \mu \xi \phi \gamma \zeta \alpha \tau \iota \) a verbal noun; sometimes \( \sigma \omega \mu \zeta \phi \gamma \zeta \alpha \tau \iota \) the verb's noun. The reason of the appellation is evident in Greek, by its taking the prepositive articles before it in all cafes: e.g.

\( \tau \rho \chi \mu \alpha \iota \nu \tau \iota \chi \mu \alpha \iota \) to \( \tau \rho \chi \mu \alpha \iota \nu \tau \iota \chi \mu \alpha \iota \) the fame construction is not unknown in English. Thus Spencer,

"For not to have been dipped in Lethe's lake

Could save the son of Thetis from to die." i.e.

The Sages.

The poe tie hold the infinitive as the genuine \( j \mu \omega \zeta \), or verb, a name which they denied to all other modes; because the true verbal character was conceived to be contained in the

imperfect and unimperfect in the infinitive only; thus, to walk, means simply that energy, and nothing more; the other modes, besides expressing this energy, superadd certain affections which respect persons and circumstances. The infinitive, says Priscian, "significat ipsum rem, quam continet verbum." The infinitive, in the application of it, naturally coalesces with all these verbs, that denote any tendency, desire, or volition of the soul, but not readily with others. See

Harris's Hermes, p. 103, &c.

In most languages, both ancient and modern, the infinitive is distinguished by a termination peculiar to it; as 

\( \sigma \nu \mu \xi \gamma \zeta \alpha \tau \iota \chi \mu \alpha \iota \) in the Greek, \( j f b i b a r e \) in the Latin, \( c e r i e \) in the French, 

\( j f r \alpha t c e r e \) in the Italian, &c. but the English is defective in this point; so that to denote the infinitive, we are obliged to

have recourse to the article to; excepting sometimes when

two or more infinitives follow each other.

The practice of using a number of infinitives successively, is a great but a common fault in languages; as he offered to go to teach to write English. Indeed, where the infinitives have no dependence on each other, they may be used elegantly enough; as to mourn, to fish, to find, to saw, to die.

INFINITO, in the Italian Mufic, is used for such canons or fugues, as may be begun again and again; whence they are also called perpetual fugues. See Fugue.

INFINITY, the quality which denominates a thing infinite.
The idea signified by the name infinity is best examined by considering to what things infinity is by the mind attributed, and how the idea itself is framed: finite and infinite are looked upon as the modes of quantity, and are attributed primarily to things that have parts, and are capable of increase or diminution, by the addition or subtraction of any parts.

Such are the ideas of space, duration, and number. When we apply this idea to the Supreme Being, we do it primarily in respect of his duration and ubiquity: and more figuratively, when to his wisdom, power, goodness, and other attributes, which are properly inexhaustible and incomprehensible; for when we call them infinite, we have no other idea of this infinity but what carries with it some reflection on the number, or the extent of the objects or parts of God's power and wisdom, which can never be fully or so great, or so many, that these attributes will not always exceed and exceed, though we multiply them in our thoughts with the infinity of endless number. We do not pretend to say, how these attributes are in God, who is infinitely beyond the reach of our narrow capacities: but this is our way of conceiving them, and these are our ideas of their infinity.

We come by the idea of infinity thus: every one that has any idea of any finite length or space, as a foot, yard, &c. finds that he can repeat that idea, and join it to another, to a third, and so on, without ever coming to an end of his additions. From this power of enlarging his idea of space, he takes the idea of infinite space, or immensity. By the fame power of repeating the idea of any length or duration we have in our minds, with all the endless addition of number, we also come by the idea of eternity.

If our idea of infinity be got by repeating without end our own ideas, it may be asked, why do we not attribute it to other ideas, as well as those of space and duration; since they may be as easily, and as often repeated in our minds, as the other? yet nobody ever thinks of infinite sweetnefs, or whitenefs, though we can repeat the idea of sweet or white, as frequently as those of yard or day? To this it is anwered, that those ideas which have parts, and are capable of increafe by the addition of any parts, afford us by their repetition an idea of infinity; because with the endless repetition there is connected an enlargement, of which there is no end; but it is not fo in other ideas; for if to the most perfect idea I have of white, I add another of equal white-parts, it enlarges not my idea at all. Those ideas, which confift not of parts, cannot be augmented to what proportion men please, or be stretched beyond what they have received by their senses; but space, duration, and number, being capable of increafe by repetition, leave in the mind an idea of an endless room for more; and fo these ideas alone lead the mind towards the thought of infinity.

We are carefully to distinguish between the idea of the infinity of space, and the idea of the space infinite. The first is nothing but a supposed endless progression of the mind over any repeated idea of space; but to have actually in the mind the idea of space infinite,—it is to suppofe the

mind
mind already paled over all these repeated ideas of space, which an endless repetition can never totally represeent to it; which carries it in a plain contradiction. See Space.

This will be plainer, if we consider infinity in numbers; the infinity of numbers, to the end of whose addition every one perceives there is no approach, easily appears to any one that reflects on it: but how clear ever this idea of the infinity of numbers be, there is nothing yet more evident than the absurdity of the idea of an actual infinite number. Locke's Essay, vol. i. chap. xvii.

Infiniety of Actions, in Law; the lord of the foil may have a special action against him who shall dig foil in the king's highway: but one subject cannot have his action against another for common nuisances; for if he might, then every man might have it, and so the actions would be infinite. &c. 1 Co. Inst. 56. 9 Rep. 113.

Infirmary, a place where the sick and weak belonging to any society, or community, are disposed, either for nursing or cure. See Hospital.

Inflammability, is that property of bodies which disperses them to kindle, or catch fire. See Flame, Heat, and Phlogiston.

Inflammability of Oils. See Oil. 

Inflammarble Air. See Hydrogen.

Inflammable Springs. About the middle of the last century, a spring or well at Brodley in Shropshire, was much noticed on account of the inflammable exhalations or gasses which it emitted, so that when a cover was adapted to it, that contracted the stream of air, and a candle was applied, it continued to burn with a lambent blue flame for a long time; but the coal-works in the neighbourhood have long since drained this well. During the driving of Stoke fough, to drain the lead mines near Eyam in Derbyshire, such a quantity of liquid bitumen or rock oil was liberated from the small cavities in the limestone, and from godes of limestone in the face above it, that it frequently swam on the water in the fough, in sufficient quantities to take fire and burn for a time, after the application of a lighted candle: this was called by Mr. Brir, in his "Tour" (p. 176.) a burning spring, but improperly, seeing that the bitumen was only let free by the tools of the workmen, and was spontaneously discharged from the rock, a condition which seems essential to a spring of any kind. See an account of this fough, in Mr. Farley's Report on Derbyshire, vol. i. p. 330.

Inflammation is concerned, either as a cause, symptom, confluence, or complication of the greater number of diseases, to which the human body is liable, and hence it has always been confidered by the most enlightened pathologists as a subject which, in point of importance, is inferior to none in the whole circle of medical science. It interests the physician, the surgeon, the accoucheur, and, in short, every individual, who is in the habit of being entwined with the treatment of any kind of disorder, or accidental injury. A knowledge of the nature and laws of inflammation, and just ideas respecting the means of checking and curing this affection, may be laid to constitute a key, or introduction, to the comprehension of diseases in general; for some may be alleged to consist of it, and very few are entirely unattended with it in one stage or another. It is for such reasons, that systematic authors mostly treat of it at the very beginning of their works.

The term inflammation, which is derived from the Latin word inflammatio, probably owes its origin to an ancient opinion, that there was fire in the part affected, and, if we advert to the confiderable sensation of heat, which the patient experiences in the heat of the complaint, the use of such an expression seems almost natural. The Greeks appear to have employed terms of similar import, as θύπνημα, or θύπνημα, from θύπνος, I burn.

Inflammation is divisible into several species. The distinctions chiefly inflected upon by surgical writers, are the acute and chronic. When inflammation is unattended with any particular disease, it is sometimes called simple or healthy, of which there can only be one kind. But the morbid inflammmations, or such as are influenced by the presence of a diseased action, are as numerous and various as diseases themselves, each disease, in fact, having its own specific kind of inflammation; as, for instance, the small-pox pustule, the cow-pox vesicle, the carbuncle, erythelas, icterola, the venereal disease, &c.

When common inflammation is spoken of, the acute healthy species is usually implied, or that which is so well known by the name of phlegmon. It is attended with four remarkable symptoms in the part affected, namely, pain, redness, swelling and heat: "nec vero inflammations sunt quatuor: rubor et tumor, cum calor et dolore." Celsus, lib. iii. cap. 10.

The pain which accompanies the various forts of inflammation, differs very materially both in its degree and kind. In many instances, indeed, it might be more proper to say, that there is an alteration in the natural sensations and sensibility of the part, than that there is pain, which latter term leads one to understand a degree of agony. Numerous chronic inflammations produce very trivial uneasiness in the part, the patient feeling, perhaps, in the seat of the disease, merely a sensation of weight and heaviness, which is likewise remarked by Richerand, that the puritus, which precedes and attends certain cutaneous eruptions, so far from being painful, occasions rather an agreeable sensation. It is only when the sensibility is carried beyond a particular pitch that it amounts to pain. In phlegmonous inflammation the pain is of a throbbing description, and the sufferer is joined with an annoying sense of weight. In erythelas the pain is of a burning kind. In anthrax it is accompanied by a feeling of stiffness. The severity of the pain is generally in proportion to the vehemence of the inflammation, the sensibility of the parts, and the resistance which their structure makes to the tumefaction.

It is a curious fact, of which the practice of surgery affords many proofs, that parts which, in their natural healthy state, are not remarkable for their great sensibility, are frequently affected when inflamed with an exquisite degree of tenderness and pain. The gums, in the found flute, are not very sensible; they may be divided with a lancet, without any great deal of pain being occasioned; and the pressure of hard substances against them in mastication is not productive of injury. When inflamed, however, in confluence of decayed teeth, a cold, or any other causes, they are affected with extreme sensibility, swell with a considerable degree, and cannot be touched or pressed, in the slightest manner, without much suffering being excited. The ligaments are naturally almost insensible; but, in several diseases of the joints, they are even much more painful, than some other inflamed parts, which, when found, possess a vast deal of sensibility.

A preceding remark, therefore, that the pain is in proportion to the natural sensibility of the parts affected, is not to be received without exceptions. With respect to the immediate way, in which pain is excited in cases of inflammation, it seems most rational to impute the degree of suffering to the augmented sensibility of the nerves, and the unnatural condition in which they are placed. In chronic inflammation, the changes which the parts undergo are slow, and the nerves seem to have time to adapt themselves to the alteration;
INFLAMMATION.

Inflammation is a subject which has been treated of with great abundance of matter in medical works; but in acute inflammation, the mutations are quick, and the pain is, for the most part, considerale.

The swelling appears to be occasioned by several circumstances, yet principally by the increased determination of blood to the vessels of the part, and by an effusion of coagulating lymph in the interfaces of the cellular substance. The dilatation of the blood-vessels, and the interruption of absorption, probably have also a share in producing the effect.

The considerale injection of the small vessels with red blood, and their great increase of diameter, afford some explanation of the manner in which the preternatural redness arises. It has been a prevailing sentiment, that the redness of common inflammation is partly owing, not merely to a dilatation, but at the same time to an actual increase in the number of the blood-vessels of the inflamed part. New vessels are supposed to be generated. This doctrine, however, is far from resting upon unquestionable evidence. When coagulating lymph is extravasated upon the surface of a wound, an inflamed membrane, &c. it is beyond a doubt often rendered vascular, or, in other words, becomes furnished with new vessels. But, in the extravasated lymph of a phlegmonous tumour, we have no evidence to prove that there is any generation of new vessels. If the vessels have the appearance of being more numerous, it is because their diameters are enlarged, and many, which previously contained only a colourless fluid, are now filled with visibly red blood. Were the extravasated lymph of a phlegmonous swelling to be rendered organized and vascular, the tumefaction and redness would probably be more permanent, and not admit (at least so easily as they often do) of refutation.

When adhesions form between two inflamed surfaces, the organized substance, forming the connection, lives after the subsidence of the inflammation, and is a permanent effect. (Dict. of Pract. Surgery.) According to Mr. Burns, the supposition easily admits of refutation; for heat, and many other causes of inflammation, operate so quickly, that there can be no time for the formation of any new vessels; and yet the redness is as great, and the inflammation as perfect, in a minute, as in an hour, or a day, after the application of the exciting cause. (Differt, on Inflammation.)

Now that we are noticing the redness of inflamed parts, it may be as well to mention the circumstance of red blood itself being sometimes extravasated, in consequence of inflammation. The occurrence generally indicates, that the inflammatory mischief has been rapid and violent. The most striking instances, which just now present themselves to our mind, are, first, that plate of an inflamed eye, termed *the-plate,* for an account of which we refer to *Ophthalmology;* and, secondly, the spots, produced by effused blood, on the inner coat of the foimach, when this viscous has been inflamed, in consequence of poison. There is still another circumstance, which has been mentioned by the celebrated Mr. John Hunter, as constrictive to the red appearance of inflamed parts, &c. the blood, after it has become venous, retaining a certain degree of the bright scarlet colour, which it possessed in the arteries. We cannot offer any opinion concerning the truth of the latter suggestion; as coming from Mr. Hunter, it cannot fail to deserve attention.

The experiments which Mr. Hunter made with the thermometer, tend to evince, that the real augmentation of the heat of an inflamed part is incomparably, although it seems to be very great, when a judgment is derived from the patient's feelings. If we recollect, that the sensibility of the nerves is augmented, we can no longer be surprised, that they should convey to the sensorium false impressions. With regard to the manner, in which the increased temperature of inflamed parts is produced, this subject is explicable on the principles, which apply to the production of animal heat in general. We shall merely observe, that there is always a greater determination of blood to a part which is in a state of inflammation, than to the same part when it is not inflamed. The blood flows through it with augmented velocity, and we always find, that the heat of the whole body, as well as of any portion of it, is always in a ratio to the accelerated rate of the circulation. When a pain runs, he hurries the current of the entire mass of blood, and his whole body is thrown into a heated state. In fevers, the circulation is quickened, and there is likewise general heat. But in inflammation, accompanied with febrile disorder, the blood flows only through the inflamed part with increased impetuosity, and, of course, the augmentation of heat is local and circumcised.

Phlegmon, or what may be called common inflammation, has been regarded by many writers as an affection of the cellular membrane. Its frequent occurrence in every situation, both internal and external, has been accounted for by the way, in which the cellular substance pervades the texture of almost every part of the body. Phlegmon is represented as being attended with more swelling than any other species of inflammation. The bright red colour in the centre of the tumour gradually extends towards the circumference, and is insensibly lost on the surrounding skin. The swelling, on the other hand, is distinctly circumcised. The heat has been compared with that arising from the flame of boiling water. The throbbing, to which we have already adverted, manifestly depends upon the pulsation of the arteries, and is synchronous with the pulse of the whole system. The throbbing particularly affects the patient himself, and the surgeon may plainly perceive it when he touches the part, all the small vessels of which are dilated, and heat in a preternatural degree. In a common whitlow, this vehement throbbing is not confined to the finger, but extends to the larger arteries, a considerale way up the arm.

The active mind of the late Mr. John Hunter led him to pay much attention to the interesting subject before us, and from him we have many fertile and original observations. The principles and laws of inflammation were better explained by this philosophical observer, than by any of his professional predecessors. He has noticed the well established circumstance, attending phlegmonous and other inflammations, wherever it is attended, namely, their being always most violent on the side next to the external surface of the body. Thus, when inflammation invades theocket of a tooth, it chiefly takes place towards the cheek, and not on the inside of the alveolar processes. He points out, that the situation, position, structure, functions, and dilatation of the part affected from the source of the circulation, causes a considerale variety in the progress and termination of all inflammation. He maintains, that parts, naturally enjoying a vigorous circulation of blood then can bear inflammation better than others in the opposite condition. From this observation, however, he excepts vital parts, which, though they may be exceedingly vascular, do not undergo inflammation favourably, because the natural operations of universal health depend so much upon the found-
INFLAMMATION.

other parts, which constitute a portion of the original fabric of the body; hence, when inflamed, they are exceedingly apt to be destroyed by ulceration, or mortification.

When an inflammation is of trivial extent, and not severely painful, the effects of the complaint are altogether local. In the contrary case, the whole circulation partakes in the excitment, and the inflammatory fever occurs.

The blood, taken from a patient labouring under inflammation, is well known by all medical practitioners to exhibit peculiar appearances. The blood, when it has escaped out of the living vessels, spontaneously separates into two distinct parts, the serum and the clafnamment. The left is a compound substance, consisting chiefly of coagulating lymph and red globules, the most heavy ingredients in the blood. Now, it is to be observed, that blood, taken away from persons affected with inflammation, is longer in coagulating, and coagulates more finely, than when drawn from people in other circumstances. Hence the red globules, which are very heavy, not being to form entangled in the lymph, defend by their gravity more deeply from its surface, which, being in this manner more or less divided of the red colouring matter, is, from its appearance, termed the buffy coat, or inflammatory crust. The finer and more compact coagulation of the lymph comprefles out an unusual quantity of serum from it, and the surface of the fley blood, as it is frequently called, is often formed into a hollow, the edges being drawn inwards. These changes in the blood are, in some cases, a more infallible proof of the existence of inflammation than the pulse itself. At the same time, it is probably only a criterion of some unusual operation going on in the system; for, the blood, taken away from pregnant women, is always found to exhibit the above appearances, a circumstance which should always be re-collected. In peritoneal inflammation, the patient sometimes seems to be in the most fcale state, and the pulse, abstractedly considered, would rather induce the practitioner to employ tonics and stimulants, than evacuations; but should the continuance, or exacerbation of the disorder, or any other reason, lead the surgeon to use the lancet, then the buffy coat, the concave surface of the blood, and the large quantity of serum, will serve as clear evidence of the existence of inflammation. But every practitioner ought to bear in mind, that, besides pregnant women, there are a few anomalous constitutions met with, where the blood, taken away by the lancet, always exhibits the foregoing peculiarities, though inflammation may not prevail.

We see three very remarkable effects follow the prevalence of inflammation; viz. adhesions of parts of the body to each other; the formation of pus, or suppuration; and ulceration, a process in which the lymphatics are more concerned than the blood-veils. Hence Mr. Hunter termed the different stages of inflammation the adhesive, the suppurative, and the ulcerative.

All parts of the body are not equally liable to each of the preceding consequences. It was remarked by Mr. Hunter, that in the cellular membrane, and in the cutaneous cavities, the adhesive stage takes place more readily than the others; suppuration may be said to follow next in order of frequency; and, lastly, ulceration. Whenever mucous membranes are affected, the suppurative inflammation comes on more readily, than either the adhesive or the ulcerative. Here adhesions, which originate from the slightest degree of inflammation in other situations and structures, can only be produced by the most violent kind. Indeed, ulceration is much more frequently met with upon mucous surfaces than adhesions. The cellular membrane appears to be much more susceptible of the adhesive inflammation than the adipose, and much more readily passes into the suppurative. Thus, we see the cellular substance, connecting the muscles together, and the adipose membrane between the muscles, inflaming and suppurating, and the matter separating the muscles from their lateral connections, and even the fat from the muscles. While the adipose substance and the skin are only highly inflamed. Yet, it must be allowed, that in situations where fat abounds, we are frequently meet with abscesses. This is so much the case, that Mr. Bromfield accounted the fat a more common nidus for collections of matter, than the cellular substance itself. Thus abscesses about the anus, mammary, &c. are remarkably frequent. When we speak of the fat inflaming and suppurating, we should rather say, that the membranous cavities containing this secretion are to affected; for, fat itself has no vessels, principle of life, nor action of its own, and, consequently, cannot be supposed to be capable of undergoing inflammation and suppuration.

Parts of the body, which lie deeply from the surface, but more particularly such as are known by the name of vital, are readily affected with the adhesive inflammation. That they are not so much disposed to suppurate as the superficial parts are, is strikingly illustrated in cases of extraneous bodies, which, if deeply lodged, only produce the adhesive inflammation. By this process a cyst is formed, in which the foreign body lies, without much inconvenience to the patient, and may even change its situation, without fe-niously disturbing the parts through which it passes. But no sooner does it approach the skin, than abscesses immediately arise.

Much might be said concerning the difference of the pulse in the various cases of inflammation. Thus, when any part of the surface of the body is affected with a certain degree of phlegmonous inflammation, the pulse is generally full, frequent, and strong. When the peritoneum and bowels are inflamed, it is very quick and small, &c. We shall not, however, enlarge upon this topic, as the pulse is, in the several cases, will be noticed in the many articles of this work appropriated to the consideration of inflammatory diseases.

According to Mr. Hunter, the susceptibility of the body for inflammation is of two kinds; the one original, constituting a part of the animal economy, and beyond the reach of human investigation; the other acquired from the influence of climate, habits of life, and state of the mind over the constitution. The first kind of susceptibility, being innate, cannot be diminished by art; the second may be lessened by the mere avoidance of the particular causes upon which it depends. These latter might be named predisposing.

With regard to the remotes, exciting, or occasional causes of inflammation, they are infinite in number; but very easy of comprehension, because most of them are referable to two general classes. The first includes all such as operate by their irritant or chemical qualities, as, for instance, heat, caustics, sulphurous acid, aqua ammonia pura, &c. The second embraces such as act mechanically, as bruise, wounds, fractures, &c.

The principle on which cold becomes an exciting cause of inflammation, is yet contended among surgical writers, and may still be considered as not decidedly known. Fevers would sometimes appear to be the exciting causes of inflammation. The local affection, thus originating, is often called critical, and is supposed by many to be the means, by which a stop is put to the constitutional indisposition.
INFLAMMATION.

The peculiar nature of the swelling thus occasioned was supposed, by the ancients, to depend upon the kind of humour. Blood produced the true phlegmon, bile, erysipelas, &c.

The ancient physicians also entertained an idea, that the blood and humours might flowly flagmatize in a part, from a want of expansive power, and this affection was termed a 

\( \text{congestion} \), while the expression \( \text{fluxion} \) or \( \text{defluxion} \) was used to denote any swelling arising from the sudden flow of humours from a distant part. The first was formed gradually without much pain, or the feeling of pulsation, and ran its course slowly; the second appeared suddenly, was very painful, had a pulsatory feel, and was rapid in its progress. The ancients, who supposed that the blood had very little motion, and that its course could be easily directed or changed, recommended bleeding from some part which was remote from a recent inflammation, by which they imagined that the current of blood was altered, and a \( \text{resolution} \) made.

A resolution was also made by raising a tumour in some other part, by means of ligatures, cutting, glades, &c. or by giving nature an opportunity of discharging the humours from distant parts, by applying leeches or blisters. Hence the parts were applied to the feet in diseases of the superior parts.

When blood was drawn from the vicinity of the fluxion, or congestion, the mode was called \( \text{divulsion} \), which only differed from \( \text{resolution} \) in the distance to which the humour was drawn being less.

We shall not enter further into an account of the practice of the ancients in the treatment of inflammation; but shall refer the reader to what Mr. Burns has written on the subject. Our present object is only to trace the leading doctrines which have at different times prevailed, respecting the proximate cause of inflammation.

From the theories of \( \text{fluxion} \) and \( \text{congestion} \), which were quite incompatible with the laws of the circulation of the blood, we turn our attention to the doctrine of \( \text{obstruction} \).

Boerhaave inculcated, (Aph. 375 et seq.) that inflammation was caused by an obstruction to the free circulation of the blood in the minute vessels, and this obstruction, he supposed, might be caused by heat, diarrheas, too copious flow of urine and feces, or whatever could dissipate the parts of the blood and produce a thicker or viscosity of that fluid. When the leucorhoea did not exist before the production of inflammation, he imagined, that the larger globules of the blood got into the small vessels, and thus plugged them up. When, for instance, the perpiration was stopped, the fluid being retained, diluted the vessel, and allowed some of these mulchious globules to enter, and produce a more permanent obstruction. This circumstance was termed an \( \text{error loci} \), and was one of the chief causes assigned for inflammation. The obstruction, whether caused by \( \text{viscidity} \) or an \( \text{error r loci} \), was imagined to occasion a resistance to the circulation in the part affected; hence increased it in the other vessels, proving an irritation to the heart, and augmenting the force or attraction of the blood in that part of the vein which was behind the obstruction. This caused heat and pain, while the accumulation of the blood produced redness; which three symptoms are the essence of the disease. Besides \( \text{obstruction} \), Boerhaave also brought into the account an \( \text{acrimonious state of the fluids} \), which rendered resolution out of the question, and gangrene likely to follow. Aph. 388.

The viscosity of the blood cannot be admitted as the proximate cause of inflammation; because we have no proof that this state ever exists; or, granting that it did, it would not explain the phenomena. Were a viscosity to occur, it would exist in the whole mass of blood, would affect every part of the body alike, and could not be supposed to produce only a local disorder. How also could such a leucorrhoea be produced by causes which bring on inflammation sudenly, without there being time for changes of the fluids to take place?

With regard to the doctrine of \( \text{error loci} \), or of red globules going into vessels, which did not formerly transmit them, the fact must be admitted, at the same time, that the conclusion is denied. When the eye becomes inflamed, the tunic conjunctiva is seen with its vessels full of red blood, which in health is not the case; but this redness never appears until the inflammation has commenced; and mild, therefore, be considered as an effect, not a cause. Nor can this \( \text{error loci} \) occasion any obstruction in these vessels; for if they be divided, the blood flows freely, which shows, that they are large enough to allow an easy circulation.

Boerhaave's theory of obstruction was too circumstanced, and too mechanical; it reduced all inflammations to one species. The only distinctions which could have arisen, must have proceeded from the nature of the obstruction itself. This doctrine could never account for the action of many specific diseases and morbid poisons.

As for the supposition of the co-operation of an \( \text{acrimony of the fluids} \), the proportion of the saline matter of the blood has never been proved to be greater in this, than in any other state of the body. Even were a general disorder of this kind to be admitted, no rational explanation of the proximate cause of local inflammation could be deduced from it.
INFLAMMATION.

Dr. Cullen attributed the proximate cause of inflammation to a "spasm of the extreme arteries supporting an increased action in the course of them." This theory only differs from that of Boerhaave in the cause which is assigned for the obstruction. Some causes of inequality in the distribution of the blood, may throw an unusual quantity of it upon particular vessels, to which it must necessarily prove a stimulus. But, further, it is probable that, to relieve the congestion, the vis medicatrix naturae increases still more the action of the vessels; and which, as in all other febrile disea-ses, it affects, by the formation of a spasm on their extremities. "A spasm of the extreme arteries, supporting an increased action in the course of them, may, therefore, be considered as the proximate cause of inflammation; at least, in all fevers not arising from direct flimmu applied; and even in this case, the spasm may be supposed to produce a spasm of the extreme vessels." The inconsistencies in Cullen's theory are very glaring. The congestion or accumulation of blood, which is only an effect or confluence of inflammation, is set down as the cause of the spasm of the vessels, to which spasmodic constrictions Cullen, strangely enough, affixes the name of proximate cause. The spasmodic contraction of the extremities of the vessels, instead of propelling the accumulated quantity of blood, would render the passage of the blood from the arterial into the venous system still more difficult. Spasmodic constriction of the small vessels is so far from being a satisfactory explanation of the proximate cause of inflammation, that even tying a large vessel does not of itself bring on the affection. Phlegmon is also attended with an effusion into the cellular substance from the extremities of the arteries; a circumstance not easily explained upon the principle of obstructed circulation. See Burns on Inflammation.

We shall now notice the celebrated, and very original opinions promulged on this subject by the famous John Hunter. According to him inflammation is to be considered only as a disturbed state of parts, which requires a new, but salutary mode of action, to restore them to that state, wherein a natural mode of action alone is necessary. From such a view of the subject, therefore, inflammation, in itself, is not to be considered as a disease, but as a salutary operation, consequent either to some violence, or some disease. Elsewhere, the author remarks, the act of inflammation is to be considered as an increased action of the vessels, which, at first, consists simply in an increase or dilatation beyond their natural size. This increased action to depend upon a diminution of the muscular power of the vessels, at the same time that the elastic power of the artery must be dilated in the same proportion. This is, therefore, something more than simply a common relaxation; we must suppose it an action in the parts to produce an increase of size, to answer particular purposes, and this Mr. Hunter would call an act of dilatation. The whole is to be considered as a necessary operation of nature. Owing to this dilatation, there is a greater quantity of blood circulating in the part, which is according to the common rules of the animal economy; for, whenever a part has more to do than simply to support itself, the blood is there collected in larger quantity. The swelling is produced by an extravasation of coagulable lymph, with some serum; but this lymph differs from the common lymph, in consequence of passing through inflamed vessels. It is this lymph which becomes the uniting medium of inflamed parts; vessels shoot into it, and it has even the power of becoming vascular itself. The pain proceeds from spasm. The redness is produced either by the arteries being more dilated than the veins, or because the blood is not changed in the veins. When, after an injury, a part cannot be restored to health by inflammation alone, or by adhesion, then suppuration, as a preparatory step to the formation of granulations, and the consequent restoration of the part, takes place. The vessels are nearly in the same state as in inflammation; but they are more quiescent, and have acquired a new mode of action. See Hunter on the Blood, Inflammation, &c.

An increased action of the vessels is now almost universally regarded as the proximate cause of inflammation. This opinion derives strong support from a review of the several exciting causes of the affection, which, being in general of an irritating nature, must, when applied to living or sensible parts, occasion a preternatural exertion of their vessels. The method of cure tends also to confirm the common sentiment concerning the proximate cause of inflammation. See Dictionary of Practical Surgery.

Treatment of Inflammation.—According to the preceding views of the subject, the first and principal object to be aimed at in the treatment of inflammation, is to diminish that immoderate action of the arteries, which exists in so conspicuous a degree. There are several means conducive to this end; but that which demands primary attention, and, indeed, which seems to be indicated by common sense, is to remove, if possible, whatever constitutes the remote or exciting cause of the inflammation. Thus, supposing the eye were to inflame in consequence of a small infect lodging under the eyelids, how obvious would be the propriety of immediately taking away the source of irritation? If the irritation of a thorn or splinter should excite inflammation, who would not of his own accord endeavour to extract the extraneous substance? When the affection is excited by extravasated urine, by pressure, friction, stimulating applications, &c, the surgeon often has it in his power to render most essential service, by removing at once what excites and keeps up the complaint. Frequently, the exciting cause is transient in its operation, and yet, the inflammation cannot be prevented from running a certain course. Then, many kinds of external violence are inflicted in a moment; but inflammation must follow, and go through its operations, though the duration of the circumstance which gave rise to the process has ceased. The living solids demonstrate, in these instances, a kind of reaction. Since, therefore, the removal of the stimulus which excites inflammation will not always put an immediate stop to the complaint, however it may tend to alleviate it, we are generally called upon to moderate, by other means, the increased vascular action.

There are few persons so entirely ignorant of the subject before us, as not to know that bleeding is one of the most powerful means of counteracting inflammation. This well known fact, which has obtained the applause of the most celebrated physicians and surgeons in every age and country, can hardly fail to be quite congenial with such ideas and expectations as are naturally impressed upon the mind by a description of the disorder. Indeed, one principal effect of the increased action of the vessels, is the translation of a larger quantity of blood through the inflamed part. The propriety of endeavouring, therefore, in most cases, to diminish this determination of blood to the seat of the inflammation, cannot be doubted. The chief mode of accomplishing this object is by general and topical bleeding. This evacuation is called general, when the blood is taken from a large vessel, at a distance from the inflamed part; local or topical, when the blood is evacuated by leeches, scarifications, or cupping, from the vessels which are near, or belong to the inflamed part. General bleeding is not so invariably proper as topo-
INFLAMMATION.

cal. Inflammation is a local affection, and therefore must particularly require local curative means. Objections have been urged against topical bleeding, except when the skin, over and near the inflamed part, is left free from the inflammation. However, most surgeons in this country think otherwise; they put leeches on the inflamed skin, and even see many dilated veins of the conjunctiva, and cases of ophthalmia, in which we think, with decided good effect. It is also an incontrovertible truth that bleeding is generally more effectual, the nearer the evacuation is made to the seat of the inflammation. But it is not always in our power to take away a sufficient quantity of blood in this manner. Many inflammations must be immediately checked, or the patient is destroyed. Therefore, when inflammation affects a part of such consequence in the animal economy that it cannot undergo much disturbance, without life itself being endangered, the furgon on is not to be satisfied with local measures. Thus, when the brain, the lungs, the stomach, the bowels, &c. are inflamed, the inflammation, unless suddenly arrested, will inevitably end in death. Also, when the inflamed parts are ended with inferior powers of recovery, it is often necessary to have recourse to general as well as topical bleeding; as in inflammation of a joint. When inflammation is situated in an organ, where suppuration would certainly destroy its nefs, it is likewise advisable to moderate the local affection, even at the expense of the whole system. Ophthalmia is a case of this kind. Moreover, it ought to be well understood that every considerable and extensive phlegmonous inflammation, wherefoever situated, ought always to be relieved by general bleeding.

There is no utility in bleeding, when the inflammation and fever are trivial, and the cause of the disorder can be entirely removed. Such evacuation must often be hurtful and dangerous, when the patient is much debilitated by previous indisposition, extreme age, or any other circumstances. The symptomatic fever, attendant on inflammation, can seldom be of itself a just ground for bleeding, as it constantly increases and abates with the local affection. We are, therefore, to be principally guided by the state of the inflammation. Bleed with a view of diminishing this, but never for the sole purpose of lessening the fever.

It is a principle very generally acknowledged by surgeons, that the efficacy of bleeding is greater the sooner it is practised, the nearer it is done to the part affected, and the more suddenly the blood is discharged. Hence, when an organ, like the brain, is inflamed, and it is an object of infinite moment to put an immediate check to the inflammation, the surgeon should take away in the first instance fifteen or twenty ounces of blood, if possible, from the temporal arteries; but if that quantity cannot be thus procured, the deficient proportion ought to be taken from the arm. Another plan, calculated to check and diminish inflammation, and which is necessary in all inflamed cases, is to give the patient mild aperient medicines, such as Epsom salt, Glauber's salt, magnesia sulphates, &c. Strong draughts purgatives, by their irritation on the constitution, are seldom allowable, and almost always prove hurtful. Gentle purging is even more invariably proper, in all cases where inflammation already exists, or is to be apprehended, than bleeding; for this latter evacuation is productive of more lasting weakness, and therefore, in flight cases, and weak habits, is generally dispensed with. Purging probably counteracts inflammation, first, by increasing the secretion of the bowels, so as to lessen the quantity of the circulating fluids; and secondly, by specifically diminishing every operation going on in the body, and among others, inflammatory action.

In many inflames, the effect of the aperient medicines is to be promoted with clysters. Indeed, there are some examples, where the latter are safer than purgatives given by the mouth: when the peritoneum and bowels are inflamed, the prudent surgeon is often afraid to prescribe any very active opening medicines. Perhaps he ventures to exhibit half an ounce of the oleum ricini, which frequently does not take effect, although the dose be repeated, until dilated with a clyster.

Antimonial medicines have acquired considerable reputation in numerous cases of inflammation, and, as far as we can judge, they are really of eminent service. Nanosating doses of antimony tartarizatum prove advantageous in several ways; they relieve that oppressive dryness of the skin, which accompanies the fever attendant on severe local inflammation; they promote all the evacuations; and they diminish the increased action of the inflamed part. The latter effect is produced, because, whenever an inclination to swellings prevails, the sympathy of the whole constitution with the stomach is to intimate, that the system is immediately thrown into a temporary state of debility, every considerable operation in the machine becoming lowered, and, among others, the process of inflammation. When the inflammation is dangerous, and there is urgent reason for putting an immediate check to it, the employment of antimonials ought never to be neglected. Thus, when the brain or its membranes are affected with inflammation, it is usual to exhibit small doses of antimony.

Opium is not prescribed in cases of common inflammation, unless the severity of the pain render this medicine indispensably necessary; for it is generally considered as a powerful stimulant, and therefore hurtful in regard to the local complaint. Inflames, however, certainly do present themselves, in which opium is proper. Procuring the patient ease and sleep, during the violence of many severe inflammations, is an object of the highest importance; and, it may be questioned whether the inflammation itself would not be aggravated more by leaving the patient to all his pain and restlessness, than by making an attempt to diminish his sufferings, and call him to sleep by opiums. One thing seems certain, that if opium is to be given in cases where pain and inflammation exist, it should be prescribed in an adequate dose. Thus, after any great operation, such as an amputation, the removal of a brest, &c., the surgeon should give from twenty-five to forty drops of the tinctura opii; small doses of opium, in such cases, always have the effect of seriously increasing the restlessness, fever, &c. instead of affording rest, and procuring sleep.

The patient's regimen and diet are to be low; no spirits nor fermented liquors are allowable; and when the inflammation is at all extensive, or such as to be of consequence, the patient should abait from eating meat, and live on thin broths, barley-water, tea, &c. The practitioner would in vain make depletions in order to flop an inflammation, while his patient was living upon grofs, hot, stimulating dishes. On the contrary, when the regimen and diet are such as they ought to be, the patient will do with less evacuations, and his health will not be so much injured by the requisite treatment.

He should be advised to drink plentifully of diluent cooling beverages, like lemonade and acidulated barley-water. Oranges, strawberries, saline draughts, &c. may be permitted, as being exceedingly grateful to patients, who are feverish and thirsty, from being affected with any serious degree of inflammation. The patient's chamber should be kept cool, nor ought he to be covered with two much bedding. The antiphlogistic regimen, moreover, requires perfect repose both of body and mind.

With
With regard to the topical applications, these are generally either cold astringent lotions, or else warm relaxing emollients. Heat is well known to promote and increase all animal actions, and must therefore tend to keep up and augment the processes of inflammation. Hence arises the indication to diminish the heat of the part affected, by making use of cold topical applications, and maintaining a continual evaporation from the inflamed surface. The common plan is to dip linen in the fumarine lotion, and after folding it once or twice, lay it all over the part affected, taking care afterwards to keep it constantly wet with the application. In some instances cold water will answer every purpose; in others the aqua ammonis acetate, or lotions of the sulphate of zinc, alum, &c. may be employed. Poultices made with linseed-meal and water, or with bread and milk, are the ordinary emollient applications when such are considered proper. Those of the first kind are frequently preferable to the latter, which are apt to turn sour and acquire an irritating quality, a circumstance of high importance where the cuticle is detached, ulceration is present, or the part is exquisitely sensible. When poultices are used, fomentations are also frequently proper, as having in all severe cases a great effect in lessening the pain. Likewise, when suppuration is unavoidable, they accelerate the cure by promoting the formation of matter, and hastening its approach to the surface of the body. The common method is to dip flannels in a decoction of chamomile flowers, or white poppy heads, wring them, and apply them very warm to the inflamed part.

In discriminating the cases which require cold applications from others to which warm ones are most serviceable, the practitioner should always bear in mind, that when suppuration is inevitable, it is invariably most advantageous to discontinue cold astringents without delay. In general, where the chance of the inflammation being resolved is great, the applications are best; but sometimes the choice of the topical remedies must be partly regulated by the patient's feelings. There are some patients who seem to derive more comfort from cold applications: there are others who appear to experience most comfort from cold ones. The latter remedies ought perhaps rather to have the preference, when the prospect of preventing suppuration is fair and rational, and when at the same time they afford as much ease as poultices.

In technical language, inflammation is said to have different terminations. When the redness, swelling, heat, and pain, all gradually subside, and the affection subsides without formation of matter, the case is said to end in what is termed resolution, which is the most favourable event which can happen. In some instances, a change takes place in the action of the secretory glands of the inflamed part, and they assume the power of secreting pus, or matter. Thus an abscess is formed, and the case (in a surgical sense) terminates in suppuration. In certain examples, ulceration is a direct consequence of inflammation, but in general an abscess precedes the former.

The latter termination of inflammation, to be noticed here, is known as mortification, which is the world, but happily the least frequent result of common cases. See GANGRENE, SUPPURATION, &c.

For an account of particular kinds of inflammation, see Erysipelas, Anthrax, Carbuncle, Furunculus, Scofula, Lues Venerea, &c.

The inflammations of various parts of the body are also treated of under distinct heads: For inflammation of the eye, see OPHTHALMY; for that of the parts about the anus, see Fistula in Ano; for that of the dura mater, see INJURIES OF THE HEAD; for that of the teeth, see HERNIA Hemorrhoidis; for that of the finger, see Whitlow, &c. See Inflammation of the Bladder, See Cystitis.

Inflammation of the Pericardium. See Pericarditis, and Carditis. Inflammation of the Peritonium. See Peritonitis. Inflammation of the Spleen. See Splenitis. Inflammation of the Stomach. See Gastritis. Inflammation of the Throat. See Cystitis. Inflammation of the Tenets. See Cystitis Testicularis. Inflammation of the Womb. See Nystagmus. Inflammation, Spontaneous, of earthy matters, in Mining. It is a curious and important fact, that several pyritic and bituminous thin strata which are found accompanying the coal-forms in some situations, will, on being thrown out or exposed to the air in the works, heat and take fire. This seems particularly the case in the thick coal-strata about Dudley in Staffordshire, as mentioned by Mr. Keir in Shaw's History of Staffordshire. In different parts of Derbyshire there are also thin strata of dusts, tars, &c. which thus become a source of danger to the coal-works, as at Hennon, Derby-hall and other pits, which are particularized by Mr. F. C. in his Report on this county, vol. i. p. 348.

Inflammatory Diseases, in Medicine, are all those diseases in which any part or organ of the body is affected with inflammation, as above described; but these terms, in the general acceptation, imply more particularly those acute and severe inflammations which excite a degree of febrile commotion in the system. In addition to those just enumerated, with references, the gout, acute rheumatism, erysipelas, &c. may be included under the class of inflammatory diseases, and, together with them, constitute, in fact, a distinct Order, in the system of our best nomenclature, Dr. Cullen, under the title of Phlegmosis; namely, the second order, of the first class, Pyrexia, or Febrile Diseases. See his Nomenclature. Method.

We judge of the presence of an internal inflammatory disease by the occurrence of the following congeries of symptoms; namely, when, together with a state of fever, there is a fixed pain in any internal part, attended with some interruption in the exercise of its functions. It is to be observed, that the occurrence of all these symptoms is necessary to prove the existence of active inflammation in any organ, and that the occurrence of any one or two of them may originate from other causes than inflammation. Thus pain may arise from a spasmatic contraction of the muscular fibres of the part, and it may be movable, and pass from one part to another; fever may arise with or without pain; and the functions of an organ may be impeded without either pain or fever. In none of these cases are we to conclude that active inflammation is going on. We may illustrate this respect to inflammation of the lungs, or peritonitis. This disease is known to be present, when, together with general fever (i.e. a frequent pulse, hot skin, thirst, etc,)
INFLAMMATORY DISEASE.

thief, &c.), there is a fixed pain in some part of the chest, cough, and difficulty of breathing; (Cullen, Nosol. Meth. Clafs i. Ord. ii. Gen. 11.) Now fever occurs from many other causes, and without these other symptoms; in which case no pulmonary inflammation is judged to be present. Pain may be felt in the chest when there is neither cough nor fever, nor difficult respiration, as in the case of rheumatism in the intercostal muscles, the diaphragm, or perhaps the mediastinum, or in the case of partial or general pain in these muscles. It may be also felt with difficulty of breathing, but without fever, as in the case of pain in the diaphragm, in hydrothorax, or in the pericardium; or it may occur with fever when there may be no cough, as sometimes happens when the liver is inflamed on the surface contiguous to the diaphragm. Again, there may be an impeded function (i.e. in this case difficulty of respiration) without fever or pain, as in many cases of asthma and chronic dyspnoea, connected with a spasmodic contraction of the bronchial passages, or a considerable secretion of mucus into the cells and bronchial tubes. But where there is inflammation in the lungs, there is necessarily, in the first place, a symptomatic fever; in the next, from the congestion and over-dilatation of the vessels of the inflamed organ, there is a fixed pain, and also a difficulty of admission of air into the compressed cells, i.e. difficult breathing; and the irritation upon the nerves of the bronchi, by this congestion, as well as by the mucus secreted, necessarily excites cough.

Thefe concurring phenomena, then, of pain and impeded function in any organ, with general fever, are the diagnostic symptoms of all internal inflammatory diseases. But there are still other phenomena which indicate the degree of violence of the inflammation which is going on. These are principally the other conditions of the pulse, besides its frequency, and the appearance of the blood drawn from the veins. Where an acute inflammation subsists, the pulsation of the heart and arteries is generally very vigorous; so that the pulse at the wrist strikes against the finger with a considerable force, and with a sharpness of stroke which elevates the finger, compressing the artery, even when firmly held on it. The terms hard, throb, and thump, have been used to denote this vigorous pulsation of the artery. The degree of hardness, strength, or sharpness of the pulse, however, varies greatly, not only according to the violence of the disease, but to the vigour of the patient's natural constitution; and it differs also according to the peculiar structure of the organ inflamed; all of which circumstances must be taken into the consideration of the physician before he decides upon the practical treatment which he shall adopt. Even in the most fever inflammation, which a very delicate habit is capable of and going, the pulse may be full and strong, but in a light, febile affection in a robust habit; but there is generally a degree of sharpness in the stroke of the pulse, even in a feeble habit under the excitement of acute inflammation, which the term, acquired by a little experience, enables the physician to estimate. Besides, in such cases, the degree of pain of and impeded function and the state of the heart, are mutually illustrative of each other. If the pain has remained fixed and severe for many hours, and the function of the suffering organ is greatly deranged, although the pulse may betray but a moderate degree of sharpness or hardness in a habit not originally strong, the proper evacuations for the cure of inflammation must be considered as indicated. This is particularly necessary, as we have just hinted, in respect to certain organs. When there is an acute inflammation in the lungs or liver, and especially when the enveloping membranes are affected, the pulse is perhaps invariably characterized by hardness and strength. (See Hematites and Pleurisy.) But when the stomach is inflamed, the pulse is often without any considerable hardness, and generally small, but very frequent. In this case, therefore, the existence of acute inflammation might be overlooked, if we judged principally from the pulse; and it is necessary to compare the state of the pulse with the degree of fixed burning pain in the stomach, and the sudden increase of that pain, as well as the vomiting which is excited by any thing whatever that is taken into the stomach, in order to ascertain the nature of the disease. See Cautery.

The other circumstances, which has been mentioned as aiding us in determining the degree of violence of any internal inflammation, is the appearance of the blood drawn from the veins. When the blood is used in inflammatory diseases, the blood, which is drawn, after standing some time in any vessel until coagulation has taken place, exhibits, on the surface of the coagulum, a thick gelatinous substance, without any admixture of red blood; this has been variously termed the buffy coat, or simply the buffy, the inflammatory crust, &c.; and has been considered as a proof of the existence of inflammation and, as a test, in a great measure, of the severity of the disease. It is certain, that this buffy crust is commonly found in pleurisy, peripneumony, hepatitis, acute rheumatism, &c., and is not seen where blood flows from a person in ordinary health. It seems to arise from a difference in the mode of coagulation, so that the red particles subside and leave the upper portion of the coagulating lymph untinged; and not to consist of a morbid humour in the blood, as the humoral pathologists believed. But experience has taught us, that the buffy flake of the blood is not a criterion, by which the necessity or propriety of blood-letting can be determined in diseases. For, not to mention the absurdity of relying upon a test, which requires the practice to be adopted, to some extent or other, before its propriety can be ascertained, (a doctrine which has often led to the folly of taking away a little blood, "to see how it looked," observation has proved, that the blood is actually often in the condition to flew the buffy coat, where no inflammatory action is going on, and where, although a certain degree of inflammatory action may be present, yet it will not be removed by blood-letting; but if the blood-letting be repeated, the patient may be destroyed before the buffy coat on the blood will disappear. Thus the buffy coat is almost invariably seen on blood drawn from women in a state of pregnancy; it is likewise seen on that, which is taken from persons labouring under hectic fever, from pulmonary consumption; may, it has been observed on the blood drawn from patients affected with the typhus fever, and with sepsis (see Fourcroy, Connois, Chimiques, also Blood, morbid alterations of); in all which cases we should occasion infinite mischief, were we to conceive that this appearance indicated the necessity of repeating the use of the lancet. But, further, it is a fact, which has not hitherto been satisfactorily explained, that in a violent attack of unequivocal inflammation, as of pleurisy, if, during one bleeding, the blood be received in two or three different vessels, the coagulum in one or two of the vessels shall precipitate the buffy coat, while that of the subsequent drawing shall flow it in large quantity. This variety has been principally attributed to the velocity with which the blood flows from the vein; thus it would appear, that the blood which trickles slowly down the arm, seldom flows so much buff, as that which flows in a full and copious stream. In a word, then, the appearances of the blood drawn in the cure of diseases, is to be considered as a very imperfect guide
in directing the farther use of the lancet, and is only to be deemed a secondary adjutant in determining the proper mode of practice, in conjunction with a careful investigation of the violence of the symptoms of the disea;e, its duration, and tendency, and of the age, strength, and constitution of the patient.

In attempting to form an accurate diagnosis, in regard to inflammatory diseases, two difficulties present themselves: the first of these is the difficulty of distinguishing the inflammation of one organ from that of another, which is contiguous to it, or in its vicinity. For instance, the leading symptoms of inflammation of the lungs, in very many cases, are present in hepatitis, or inflammation of the liver, on the one hand, and in carditis, and pericarditis, or inflammation of the heart, and of the pericardium, on the other. The distinction, which is commonly supposed to exist between the inflammation of the heart and its membranous bag, and inflammation of the lungs, confints in the occurrence of palpitation, syncope, and an irregular pulse, in the former disea;e, in addition to the symptoms of the latter; but Dr. Cullen admits that these three symptoms are occasionally absent in pericarditis, and accords with the observation of Vogel, that "the symptoms of carditis are nearly the same as those of peripneumony, but more severe!" i.e. fever, with pain in the left side of the chest, difficulty of breathing, and cough. (See Cullen, Nofol. Meth. Clafs i. Ord. ii. Gen. 13 and 11.) In like manner, those four diagnostic symptoms of peripneumony and pleurisy are commonly present in inflammation of the liver, especially when the convex side of that viscus, which lies in contact with the diaphragm, is the seat of the inflammation: for in addition to fever, and pain in the side, a difficulty of breathing is occasioned by the suffering, which any attempt to depress the diaphragm in the act of inspiration, excited by compressing the inflated liver; and a cough, which, however, is commonly dry, or unaccompanied by expectoration, but not always, and which is excited probably by the vicinity of the seat of irritation to the lungs. As the hepatitis proceeds, the other symptoms belonging to it, especially the bilious tinge of the skin and eyes, point out clearly the seat of the inflammation.

It is satisfactory, however, to know that, in such cases of extreme similarity of symptoms, no practical evil can arise from the inability to decide as to the seat of the disease: for, in the first place, the inflammation actually spreads, in some instances, to the contiguous organs, so that the symptoms indicative of the disorder in both must necessarily co-exist; and, in the second place, the inflammation requires the same practical measures to be adopted for its removal, in whatever viscus it may be seated; namely, evacuations proportioned to its violence, and to the vigour of the patient.

The second difficulty, in distinguishing inflammatory diseases, to which we have alluded, arises from the occasional severity and fixed seat of the pain, which is attendant on cramps or spasmodic diseases, more especially in the stomach and the bowels. Hence it is often extremely difficult to pronounce, whether an acute pain in the belly, for instance, is occasioned by the colics, or by enteritis (inflammation of the bowels), for colikation accompanies both; and although a mere spasmodic pain is very commonly present, without any acceleration of the pulse, or fever heat; yet when such pain is extremely acute, and has continued for some length of time, the colikation begins to suffer from excessive irritation, and the pulsations of the heart and arteries are quickened; and if it still continues, actual inflammation in the part is liable to ensue, so that what was colic in the commencement, becomes finally enteritis. It is important to discriminate accurately in the outlet between these two flates of pain; because that, which is spasmodic, may be removed by large doses of opium, and other antispasmodics; whereas the inflammatory pain would be augmented, and the disease itself rendered more dangerous, by the exhibition of such medicines. In making this discrimination, the practitioner is principally guided by the hardenss and force, or the softness and weakness of the pulse;—by the rigidity of fibre and robust habit, or the contrary condition of the patient;—by the unvarying intensity and seat of the pain, or its occasional remissions and slight change of place;—and by a knowledge of the nature of former attacks, of a similar kind, where such have occurred.

The experienced and accurate observer of the phenomena of disea;es, therefore, will seldom be at a loss in selecting the proper mode of treatment in such cases: and it is fortunate here also, that the evacuation of blood-letting, which is absolutely necessary to subdue a violent inflammatory affection of the bowels, often succeeds in removing a fixed and severe spasm in the same organs. And as a spasmodic affection, of considerable duration, is liable to terminate in inflammation and its fatal consequences, the depletion of the blood-vei;els is indicated, under such circumstances, both as a preventive and as a cure, where the age, strength, and constitution of the patient do not render the safety of such a depletion very equivocal.

In regard to the treatment of inflammatory diseases, we have already in part anticipated the discussion. The great decisive remedy for such disea;es is found, in diminishing the quantity of the circulating blood. This operation of blood-letting is supposed to produce its beneficial effects upon the disea;e, by removing the "flatus of dilution" from the blood-vei;els: for it is an ascertained property of the living solid, to contract more forcibly after a great extension of its fibres. It cannot operate by letting out the morbid matter or humour from the circulating fluids, as the older pathologists imagined; for if we suppose the whole mafs of fluids to be impregnated with a morbid humour, how can we, by abstraining a part, purify the condition of the remainder? The fact, however, is fully established, and cannot be invalidated by any error in the hypotheses, which may be framed for the purpose of explaining it. The depletion of the vei;els may be effected by opening the smaller branches of the arteries, where they are superficial, and easily subjected to pressure, as in the temples;—or by opening the external veins by the lancet; or by a more limited and topical discharge by means of leeches, and cupping. The circumstances, under which one or other of these modes of depletion is to be preferred, vary materially according to the seat and degree of inflammation, and will be mentioned under the head of each disea;e. While this mode of reducing inflammatory action is resorted to, it is generally necessary, also, to employ other concurring means; such as purging, exciting a diaphoresis or gentle perspiration, procuring a discharge from the skin in the vicinity of the inflamed organs, by blisters, &c; and, at the same time, to employ all the negative means of diminishing excitement, which constitute the antiphlogistic regimen; such as avoiding heat, noise, exertion of body or mind, and flushing all the solid animal food, condiments, spirituous, vinous, or other fermented liquors, which increase the action of the vasculat system.

INFLATION, formed from in, and fluere; of fluo, to blow; blowing up, the act of stretching or filling any fluid or diffusible body, with a flatulent or windy fluid.

INFLATION, called also diffusion, and defequation, in Optics, is a property of light, by reason of which, when it comes within a certain distance of any body, it will either be bent...
INFLECTION.

Bent from it, or towards it: which is a kind of imperfect reflection or refraction. See Diffraction.

This property was first taken notice of by Dr. Hooke; who shews that it differs both from reflection and refraction, and seems to depend on the unequal density of the constituent parts of the ray, whereby the light is dispersed from the place of condensation, and rarified or gradually diverged into a quadrant: and this deflection, he says, is made towards the superficies of the opaque body perpendicularly. Some writers ascribe the first discovery of it to Grimaldi, the Jesuit. He first published an account of it, in his treatise "De Lumine, Coloribus, et Iris," printed in 1666; nor did any other person lay claim to the discovery, except Dr. Hooke, who communicated his observations on this subject to the Royal Society, in 1672. It appears, however, that Dr. Hooke had not heard of the discoveries of Grimaldi; for he speaks of his own as a discovery of a new property of light, not mentioned by any optical writer before him.

Sir Isaac Newton discovered also, by plain experiment, this refraction of the rays of light; and M. de la Hire assures us, that the beams of the flares being observed, in a deep valley, to pass near the brow of a hill, are always more refracted than if there were no such hill; or the observations were on the top thereof; as if the rays of light were bent down into a curve, by passing near the surface of the mountain.

Sir Isaac Newton, in his Optics, makes several experiments and observations on the refraction of the rays of light; which see under Light, and Rays.

Although Sir I. Newton particularly examined the phenomena, relating to this subject, under a considerable variety of circumstances, his observations were not quite correct; nor was his hypothetical explanation very plausible. Subsequent experiments and observations seem to reduce the phenomena of refraction to a single principle, viz. to the attraction of bodies towards light; which attraction becomes conspicuous when the rays of light pass within a certain distance of their surfaces. Besides their being bent, the rays of light are likewise separated into colours by the vicinity of bodies, and this produces the singular phenomenon of the coloured fringes that accompany the refraction. Various experiments have been made relative to the refraction of light by Maraldi, Grimaldi, Delille, Maisan, Du Tour, Muschenbroek, and others, as well as Newton; an account of which experiments the reader may see in Pecile's History of Vifton, Light, and Colours, part vi. § 6.

M. de la Hire observed, that when we look at a candle, or any luminous body, with our eyes nearly shut, rays of light are extended from it, in several directions; to a considerable distance, like the tails of comets. The true occasion of this phenomenon, which has exercised the sagacity of Des Cartes, Rohault, and others, seems to be, that the light passing among the eye-lashes, in this situation of the eye, is infected by its near approach to them, and therefore enters the eye in a great variety of directions.

Inflection, in Grammar, the variation of nouns and verbs, in their several cases, tenses, and declensions. Inflection is a general name, under which are comprehended both conjugation and declension.

Inflection, Point of, of a curve, in Geometry, is a point or place where the curve begins to bend, or turn a contrary way.

If a curve line, as A F K (Plate X. Analysis, fig. 2.) be partly concave, and partly convex towards a right line, as A B, or towards a fixed point, the point F, which divides the concave from the convex part, and consequently is at the beginning of the one and end of the other, is called the point of inflection, as long as the curve, being continued beyond F, keeps its course the same: when it returns back again towards that part or side from whence it took its origin, it is called the point of retrogression.

To conceive this, it is to be considered, that any quantity, which goes on continually increasing or decreasing, cannot change from a positive to a negative expression, or from a negative to a positive one, without first becoming equal to an infinite, or nothing. It becomes equal to nothing, if it continually decrease; and equal to an infinite if it continually increase.

Now, if through the point F be drawn the ordinate E F, and the tangent T L, and from any point, as M, on the same side of A F, be drawn the ordinate M P, and the tangent M T; then in curves which have a point of inflection, the abscissas A P continually increase, and the part A T of the diameter, intercepted between the vertex of the diameter, and the tangent M T, increases also, till the point P fall into E; after which it again begins to diminish: whence the line A T must become a maximum A L, when the point P falls into the point F.

In those curves which have a point of retrogression, the part A T increases continually, and the abscissas increase, till the point T falls into L; after which it again diminishes: whence A P must become a maximum, when the point T falls into L.

If A E = x, E F = y, then will A L = \frac{y}{x} - x (see Tangent), whose fluxion, which is \frac{y}{x} \cdot \frac{y}{x} - \frac{j}{x} \cdot \frac{y}{x} = \frac{y}{x} \cdot \frac{y}{x} - \frac{j}{x} \cdot \frac{y}{x} = \frac{y}{x} \cdot \frac{y}{x} - \frac{j}{x} \cdot \frac{y}{x}, supposing \frac{y}{x} constant, being divided by \frac{y}{x}, the fluxion of A L must become nothing: i.e. \frac{y}{x} = 0: so that multiplying by \frac{y}{x}, and dividing by - x, \frac{y}{x} = 0; which is a general form for finding F, the point of inflection, or retrogression, in those curves whose ordinates are parallel to one another. For the nature of the curve A F K being given, put the equation of the curve into fluxions; from which, or from other properties of the curve, find the value of \frac{x}{x} or \frac{j}{x}, and put this \frac{x}{x} or \frac{j}{x} and its value into fluxions, making both \frac{x}{x} and \frac{j}{x} = 0: then by expunging the rest of the fluxional quantities, we shall determine the value of \frac{x}{x}, i.e. A E or \frac{j}{x}, i.e. E F, at the point of inflection sought.

To distinguish the points of inflection from those of retrogression, which arise indiscriminately according to the above method, it will be sufficient to attend to the progress of the curve, by taking any ordinate very near the point; which will always serve to remove any doubt on that head.

Ex. 1. To find the point of inflection B in the curve A B Y (fig. 3.) whole equation (putting the abscissas A C = \frac{x}{x}, ordinate C B = y, and the perpendicular A E = a) is a \frac{x}{x} + a \frac{x}{x} = a \frac{x}{x} + y. From the fluxion of this equation, viz. 2 a x \frac{y}{x} = \frac{x}{x} + 2 a x \frac{y}{x} + a \frac{x}{x} \frac{x}{x} + a \frac{x}{x} \frac{x}{x} + a \frac{x}{x} \frac{x}{x} + a \frac{x}{x}, we deduce \frac{x}{x} = \frac{2 a x \frac{x}{x} - 2 a x \frac{x}{x}}{a \frac{x}{x} + a \frac{x}{x}} i.e. by substituting for y its value \frac{x}{x} = \frac{2 a x \frac{x}{x} + a \frac{x}{x}}{a \frac{x}{x} + a \frac{x}{x}}, and the fluxion of this equation, making both \frac{x}{x} and \frac{j}{x} = 0, is \frac{x}{x} = \frac{2 a \frac{x}{x} \frac{x}{x} (a \frac{x}{x} + a \frac{x}{x}) - (4 a \frac{x}{x} \frac{x}{x} + 4 a \frac{x}{x} \frac{x}{x} + 2 a \frac{x}{x} \frac{x}{x}}{a \frac{x}{x} + a \frac{x}{x}} which,
which multiplied by \((a' + x^2)\) and divided by \(2a' x\), gives
\[ o = (a^3 + x^3) - 4 a' x^2 - 4 x^4; \] therefore, \(4 x^4 + 4 a' x^3 = (a^2 + x^2)\), which equation divided by \(x^2 + a'\) makes \(4 x^2 = a^2 + x^2\); therefore \(3 x^2 = a' x\), and \(x = a' \sqrt{3} / 4\); and if this value be substituted for it in the given equation of the curve, we shall have \(y\), or the ordinates at the point of inflection
\[ = \frac{a x^2}{a' x} = \frac{1}{3} a^3 = \frac{1}{3} a. \] Let
\[ A C \] be equal to \(A E\), and with the radius \(E\), describe the arc \(C\); then will \(C\) be the point from which the ordinate to the point of inflection must be drawn: for \(E = \frac{1}{3} a\); and \(C E = a \Lambda = A C, \) i.e. \(\frac{1}{3} a = \frac{1}{3} a' = \frac{1}{3} A = \Lambda C\), or \(x = a' \sqrt{3}\).

Another method of finding the point of inflection, or retrogression, is as follows. From the nature of curvature it is evident, that while a curve is concave towards its axis, the fluxion of the ordinate decreases, or is in an increasing ratio, with regard to the fluxion of the absciss; and on the contrary, this fluxion increases, or is in an increasing ratio to the fluxion of the absciss, when the curve is convex towards the axis; and hence it follows, that these two fluxions are in a constant ratio at the point of inflection, or retrogression, where the curve is neither concave nor convex; that is, \(\frac{x}{y}\) or \(\frac{y}{x}\), is a constant quantity. But constant quantities have no fluxion, or their fluxion is equal to 0; whence we derive this general rule.

Put the given equation of the curve into fluxions; from which equation of the fluxions, find either \(\frac{x}{y}\) or \(\frac{y}{x}\), and take again the fluxion of this fraction, and make it equal to 0, and from this last equation find also the value of the same expression \(\frac{x}{y}\) or \(\frac{y}{x}\); and by equating these two, and the given equation of the curve, \(x\) and \(y\) will be determined, being the absciss or ordinate answering to the point of inflection.

Or, otherwise, putting the fluxion of \(\frac{x}{y}\) equal to 0, that is
\[ \frac{x}{y} - \frac{y}{x^2} = 0; \] or \(\frac{x}{y} = \frac{y}{x^2}\), whence \(\frac{y}{x} = \frac{y}{x^2}\), or \(\frac{x}{y} = \frac{x}{y}\); that is, the second fluxions have the same ratio as the first fluxions; and therefore if \(x\) be constant, or \(x = 0\), then shall \(y = 0\), which gives the following rule, viz.

Take both the first and second fluxions of the given equation of the curve; in which make \(x = 0\), and \(y = 0\), and the resulting equations will determine the values of \(x\) and \(y\), or the absciss and ordinate answering to the required point.

Thus repeating again the preceding example, in which the given equation is \(a x^2 = a y + x y\); and of which the point of inflection is required.

By the first rule, the fluxion of \(a x^2 = a^2 y + x^2 y\), is
\[ 2 a x x = a^2 y + x^2 y; \] whence \(\frac{x}{y} =
\] And now making again the fluxion of this quantity \(= 0\), we have
\[ 2 x x (a x - y) = (a^2 + x^2) (a x - y x - x y), \] whence
\[ \frac{x}{y} = \frac{a + x - x y - x x}{a - y - y x} \]

And now equating these two expressions, we have
\[ a^2 + x^2 \times \frac{x}{y} = \frac{a^2 + x^2}{a - y} \]
which being reduced, gives \(2 x^2 = a' x - x^3\), or \(x^3 + a^2 = x'\), and \(a = a' \sqrt{3}\), the same result as before; and this value of \(x\) substituted in the original equation of the curve, becomes
\[ y = \frac{a x^3}{a^2 + x^2} = \frac{1}{4} a, \text{ the ordinate at the point of inflection.} \]

The second method differs from the first rather in contrariety than in principle, the application of it is therefore omitted.

Ex. 2. Again, let it be proposed to find the point of inflection in a curve whose equation is \(b x = a x^2 - x^3\).

The fluxion of this expression gives
\[ b x = 2 a x x - 3 x^3\]
Taking again the fluxion of this expression, and making it equal to \(0\), we have
\[ 2 a b x - 6 b^2 x = 0\]
becaus \(b\) does not enter; whence \(x = \frac{1}{3} a\), which is the absciss answering to the point of inflection found.

Ex. 3. Let it be proposed to find the point of inflection, or retrogression, in the cubic parabola, with the equation
\[ y = a + \sqrt{a - 2 a' x + a x}\]
By taking the fluxion, we have
\[ y = \frac{(-2 a a' + a x)}{3 (a - 2 a x + a x)} \times \frac{a + \sqrt{a - 2 a' x + a x}}{a' - 2 a a' + a x}\]
Taking again the fluxion of this expression, and making it equal to \(0\), according to the above rule, we have \(a x\)
\[ (a - 2 a x + a x) \times 2(2 a a' + 2 a x x) \]
\[ 3 (a - 2 a x + a x) \]
because \(y\) is not found in the second fluxion, which expression being reduced, gives \(x = a\); and this value substituted for \(x\), gives also \(y = a\); hence the point required is, that answering to these conditions of the absciss and ordinate, which is a point of retrogression, as will appear from considering the nature of the curve.

Ex. 4. Let it be proposed to investigate the point of contrary fluxure in the curve commonly called the witch; of which the equation is \(y x = a - a x\).

Taking the fluxion of this expression, we have
\[ 2 y x + y x = -a x; \]
Taking again the fluxion of this expression, we have
\[ -a y + a y = \frac{(a^2 + y')}{2 x y x}\]
Now, again, making the fluxion of this expression \(= 0\), we have
\[ -4 y^2 \times \frac{x}{y} + (2 x^2 - y x) \times (a^2 + y) = 0, \]
whence
\[ \frac{x}{y} = \frac{(a^2 + y')}{2 x (a^2 + y') - 4 y^2 x} \]
And now equating this value of \(\frac{x}{y}\) with the foregoing, there
there is obtained
\[
\frac{2y}{a^2 + y^2} = \frac{a^2}{a^2 + y^2} - 2y.
\]

or, \[4y^2 x = 2(x^2 + y^2) - 4y^2,\] or \[4y^2 = a^2 + y^2;\]
whence \[y = a/\sqrt{2},\] which being substituted in the original equation, gives \[x = \frac{x}{2};\] which are therefore the values of \(x\) and \(y\) answering to the required point of inflection.

At present we have only considered those curves that have parallel ordinates, and which are referred to one common axis; but it is necessary to employ a different method when the curves are referred to a common focus: it will therefore be proper now to attend to this latter case, observing only, with regard to the former, that in order to know whether any curve be concave or convex towards any point assigned in the axis, find the value of \(y\) at that point; then if this value be positive, that curve will be convex towards the axis, and if it be negative, it will be concave. The rule for determining the points of contrary flexure and retrogression of curves, which supposes the second flexure of the ordinate to be nothing or infinite, i.e., \(y = 0\) or \(y = 0,\) is liable to several exceptions, as if it were very fully and clearly by Maclaurin in his Treatise of Fluxions, book i. chap. 9. book ii. chap. 5. art. 896 and 867.

The ordinate \(y\) paffes through a point of contrary flexure when, the curve being continued on both sides of the ordinate, is a maximum or minimum. But this does not always happen when \(y = 0,\) or \(\infty.\) Maclaurin observes, in general, that if \(y, y, y, \&c.\) vanish, the number of these flexions being odd, and the fluxions of the next order to them having a real and finite value, then \(y\) passes through a point of contrary flexure; but if the number of these fluxions that vanish be even, it cannot be said to pass through such a point; unless it should be allowed that a double indefinitely small flexure can be formed at one point.

The curve being supposed to be continued from the ordinate \(y,\) on both sides, if \(y\) be infinite, the extremity of the ordinate is not therefore always a point of contrary flexure, as \(y\) is not always, in this case, a maximum or minimum; and the curve may have its concavity turned the same way on both sides of the ordinate. But these cases may be distinguished by comparing the signs of \(y\) on the different sides of the ordinate; for when these signs are different, the extremity of the curve is a point of contrary flexure.

The suppositions of \(y = 0,\) or \(\infty,\) and of \(y = 0,\) or \(\infty,\) serve to direct us where we are to search for the maxima and minima, and for points of contrary flexure; but we are not always sure of finding them. For though an ordinat or fluxion that is positive, never becomes negative at once, but by increasing and decreasing gradually, yet after it has decreased till it vanishes, it may thenceafter increase, continuing still positive; or after increasing till it becomes infinite, it may thereafter decrease without changing its sign.

Of the points of inflection and retrogression of curves referred to a common focus.

Let \(A D E\) (fig. 4 and 5) represent a curve referred to the focus \(Q,\) from whence the ordinates \(Q D, Q D\) proceed; and let \(Q D\) be indefinitely near to \(Q D.\) Draw \(Q T\) perpendicular to \(Q D,\) and \(Q T\) perpendicular to \(Q D.\) Draw \(D T\) a tangent to the point \(D,\) and \(d\) a tangent in the point \(d.\) Let \(Q T\) (produced if necessary) meet \(D T\) in the point \(o.\) Now it is plain, that as the ordinates increase, if the curve be concave towards the focus \(Q\) (fig. 4),

\[Q t\] will be greater than \(Q T;\) but if the curve be convex towards the focus \(Q\) (fig. 5) \(Q t\) will be less than \(Q T;\) and therefore, as the curve changes from being concave to convex, or vice versa, that is, in the point of inflection, or retrogression, the line or quantity \(a,\) from being positive, ought to become negative, or the contrary; and therefore must pass through nothing or infinity.

Therefore make \(Q D = Q D = D M = x,\) and with the centre \(Q,\) let the indefinitely small arcs \(D M, T H,\) be described; then the two triangles \(D M, D Q T\) will be similar, as also \(D Q o, T H o;\) and therefore it will be

\[d M : MD : = d Q (or DQ) : Q T,\]

or \(x y）\]

But the two sectors \(D Q M, T Q H\) are also similar; whence

\[D Q : D M : = Q T : T H,\]

and because of the similar triangles \(D Q o,\) and \(T H o,\) it will be \(d Q (or D Q) : Q T (or Q T) : T H : H o;\) that is,

\[y : v = e : \frac{v}{a}, \quad \frac{v}{a} = H o.\]

But \(H t (fig. 5)\) represents the fluxion of \(Q T,\) that is, \(H t = \frac{x}{x^2} - \frac{x}{v^2}\)

by taking \(x\) as constant. Therefore \(o = t H + H o = \frac{v}{a^2} - \frac{x}{v^2} + \frac{x}{a^2},\)

which must be equal to \(o,\) or to \(a,\)

infinite; and consequently multiplying by \(v^2\), and dividing by \(v^2,\) it will be \(v^2 - v^2 + x^2 = o, \text{ or } \infty.\)

In \(fig. 4\) \(a t\) becomes negative, and therefore \(o t = \frac{x^2 - y^2}{y^2},\)

and multiplying and dividing this expression as above, we have again

\[x^2 - y^2 + a^2 = o, \text{ or } \infty,\]

wherefore is the general formula for finding the point of inflection or retrogression in curves that are referred to a focus.

Let us now make an application of this formula to an example, by proposing to find the point of contrary flexure in the curve, which is generated as follows:

A E D being a circle described from the centre \(B,\) let \(A F K\) be such a curve, that, drawing any radius \(B F E,\)

the square of \(E F\) may be always equal to the rectangle of the corresponding axes \(A E,\) into a right line \(b.\) See fig. 6.

Let the arc \(A E = a, B A = B E = a, B F = y,\) and \(F G = x,\) drawing \(B E\) indefinitely near to \(B E,\) and with the centre \(B,\) and radius \(B E\) describe the small arc \(F G;\) then by the nature of the curve, it will be \(b = a^2 - 2 a y + y^2;\) and taking the fluxions we have \(b x = -2 a y + 2 y^2;\)

whence \(z = \frac{2 y^2 - a^2}{b} = B E.\) But because of the similar factors \(B E E,'\) and \(B F G,\) it will be as \(B E ; B F:\)

\[E E : F G;\]

that is, \(a : y = \frac{2 y^2 - a^2}{b} : x;\) whence \(x = \frac{2 y^2 - 2 a y^2}{a} a\) and now taking the fluxions again

and making \(a\) constant, we have \(4 y^2 + 2 y^2 - 2 a y^2 - 2 a^2 = 0;\) therefore \(y = \frac{a^2 - 2 y^2}{y^2} - a = 0.\)

Now the general formula above is \(x^2 - y^2 = o,\) and therefore, substituting for the above quantities their respective values, the expression becomes

\[4 y^2\]
\[
4y^4 + 12a^2 y^2 + 12a^2 y^4 - 4a^4 y^2 + 3a^2 b^2 y - 2a^2 b^2 \frac{\frac{y}{\sqrt{y-a}}}{a b^2} = c_0, \text{and these again reduced to a common denominator will be}
\]
\[
4y^4 + 12a^2 y^2 + 12a^2 y^4 - 4a^4 y^2 + 3a^2 b^2 y - 2a^2 b^2 \frac{y}{a b^2} = c_0 \text{ or } \infty; \text{ the roots of which equations will give those values of } y, \text{ or of } B F, \text{ that answer to so many different points of inflection or retrogression belonging to the curve which is the subject of investigation; and consequently, in those curves that have but one such point, it is determined by a simple equation.}
\]
Curves may also have another kind of retrogression different from that we have been considering; which is, when the curve returns backwards towards its origin, turning its cavity the same way that it did before its retrogression, as in the following case.

Let the curve be \( \text{BAC} \left( \frac{\text{fig.}}, \gamma \right) \), with a contrary flexure at \( \Lambda \), and let it be evolved by a thread beginning at any point \( D \), different from the point of contrary flexure \( \Lambda \); the evolution of the portion \( \text{DC} \) generates the curve \( \text{DG} \), and that of the portion \( \text{AB} \) generates the curve \( \text{EF} \); in such manner that the evolution of the whole curve \( \text{BAC} \) will form the entire curve \( \text{FEDG} \), which has two retrogressions, one at \( D \), the other at \( E \), two branches \( \text{DE}, \text{DG} \), to turn their convexity; the other at \( E \) of the second fort, because the branches \( \text{ED}, \text{EF} \), are concave towards the same parts. Let now \( N, N_{m}, \text{he any two radii, indefinitely near, of the evolute } \text{DA}; \text{ and } N_{H}, \text{and } \infty \text{H}, \text{two perpendiculars to the same; the two indefinitely small factors } N_{m} M, H N_{n}, \text{will be similar, and therefore } H N : N_{M} = : N_{n} : M_{m}. \text{ But in the point of contrary flexure } \Lambda \text{, the radius } H N \text{ ought to be either infinite, or nothing; and the radius } N_{m} M, \text{which becomes } A \infty, \text{continues finite. Therefore, in the case of contrary flexure } \Lambda, \text{that is, the point of retrogression } E_{s}, \text{of the second fort, the ratio of } N_{n} M, M_{m} \text{, or the ratio of the fluxion of the radius } N_{M}, \text{to the element of the curve, ought to be either infinite great, or infinitely small. But the formula of the radius } N_{M} \text{ is } \left( \frac{\text{y}^2 + \gamma y}{x} \right)^{\frac{1}{2}} - \frac{\gamma y}{x} \text{ considering } x \text{ as conflant; the fluxion of which is } -3 x \frac{\text{y}^2 + \gamma y}{x} \text{, or } \left( \frac{\text{y}^2 + \gamma y}{x} \right)^{\frac{1}{2}} \frac{\gamma y}{x}, \text{ and } M_{m} = \sqrt{x} \left( \frac{\text{y}^2 + \gamma y}{x} \right) \text{; therefore } N_{n} M_{m} = \frac{\text{x}^2 y + \gamma y^2 - 3 \gamma y^2}{\text{x}^2} \text{ is } c_0 \text{ or } \infty; \text{ which is the formula for points of retrogression of the second order.}
\]
For other methods of finding the points of inflection and retrogression of curves, the reader is referred to Simpson's and Maclaurin's Fluxions; Donna Agnelli's Analytical Institutions; and to the Traité Élémentaire de Calcul Differential, par La Croix.

INFLUENCE, in Botanical Phlegmology, inoffensive to Linnaeus, is used to express the particular manner in which flowers are disposed upon a plant, and which preceding writers denominated the modus florandi, or "manner of flowering." The several kinds of inoffensiveness come under the heads of \text{Verticillius, Racemus, Spica, Corymbus},

\[Fasciculus, Capitulum, Umbello, Cynum, \text{Pediculus and Thrift,} \text{ which the reader will find in their proper places. A flight correction of the definition which finds under our article \text{Capitulum is necessary, the Statice Armeria and thrift, and Gomphrena globo}^{\text{flex}}\text{a} \text{or Gloire amarantinus, being better examples of that kind of inoffensiveness than any compound flower.}
\]
For the reasons against taking generic characters from the inoffensiveness, see \text{Cyume and Genes.}

INFLUENCE, a quality supposed to flow from the bodies of the flars, either with their heat or light, to which alchemists vanye attribute all the events which happen on the earth.

Alchemists, also, who to this ascribe the philosopher's stone, tell us that every thing in nature is produced by the influences of the flars, which, in their passage through the atmosphere, imbibe many of its most parts, the greatest whereof they deposit in the sands and earths where they fall; that these, filtrating through the pores of the earth, defend even to the centre, whence they are driven, by the central fire, back again to the surface; and in their ascent, by a natural kind of sublimation, as they find earths duly disposed, they form natural bodies, as metals, minerals and vegetables, &c. Thus it is pretended, that chemistry, confounding of an artificial imitation of these natural operations, and in applying active principles to passive principles, can form natural bodies, make gold, &c. See \text{Transmutation}, and \text{Philosopher's Stone.}

INFLUENT, a term used where a liquor or juice, by the contrivance of nature, and the laws of circulation, falls into a current or receptacle.

Thus with respect to the common receptacle, the chyle is its fluent juice; and so is the bile to the gall-bladder; the renal blood to the heart in its diastole; and the like.

INFLUENZA, in Medicine, a term generally employed to denote an epidemic catarrh, which has at different times spread more rapidly and extensively than any other epidemic disorder. For it has seldom occurred in any one country of Europe without appearing successively in every other part of it; it has sometimes apparently traversed the whole of the old world; and, in some instances, it has been even transferred to America, and has spread itself over that continent likewise. The French give it the name of \text{La Grippe}.

In truth, this extensive prevalence of the disease constitutes its most remarkable peculiarity; for in all the influences of its occurrence, from the fourteenth century down to the present day, its phenomena have not only been pretty uniformly the same, but have differed little, except in severity, from those of the common febrile catarrh. (See \text{Catarrh}.) This will appear from the following description of the disease, when epidemic in 1782, which is taken from a comprehensive view of it, compiled by the late Dr. Gray, of the British Museum, from a number of accounts given by physicians, in various parts of Great Britain, from their own personal observation (see Medical Communications, vol. i. art. 1. Lond. 1784); and from similar accounts published by the College of Physicians. Med. Transact. Inns. art. 8.

Very little authentic information was procured respecting the history of this epidemic, before the time of its appearance in London; all that was related, on good authority, was, that it prevailed at Moscow in the months of December 1781, and January 1782, and at Peterburgh in February 1782; and it was traced to Tobolisk, to which place it was supposed to have been brought from China. In confirmation of this opinion it was observed, that several accounts from different parts of the East Indies made mention of a disorder, similar in its symptoms, which prevailed in those parts in the months
months of October and November 1781. At all events, its course was in the beginning wellward; for it was in Denmark in the latter end of April 1782, or the beginning of May, and many people were said to have died of it at Copenhagen before the 1st of May. It appeared at Newcastle-upon-Tyne about the end of April, and in the second week in May it was certainly in London; some persons indeed thought that it had reached the metropolis sooner. According to the accounts received from various parts of England, it did not begin to appear in most of them until after its prevalence in London, namely, until the latter end of May, or the beginning of June. In Scotland and Ireland it seems to have been rather later, and in the south of Europe rather still; for it prevailed in France in the months of June and July; in Italy, in July and August; and in Portugal and Spain, in August and September. The fourth week in May was the period of its most general prevalence in London: from that time it began to decline, and in the space of two or three weeks ceased to exist as a general disorder; but it did not altogether leave the city till the month of September.

No attempt was made to ascertain with accuracy the proportion of persons attacked by this influenza; the number was everywhere very great; the proportion of the inhabitants affected in some places being estimated at three-fourths, in other places at four-fifths of the whole: and in London it was affected, from a pretty competent view of the matter, that the number of those attacked by it was much greater than that of those who escaped it. Both sexes appeared to be equally liable to it; but persons of the middle age were more subject to its attacks than old people, and these more than children; while infants were considerably less affected than by the epidemic which its symptoms came on, (which in some instances was truly wonderful,) seem to have been the most remarkable characters of it. Persons, apparently in perfect health, were seized instantaneously, as it were, with a violent cold, to which succeeded headache, running at the nose, &c.; while others were as suddenly seized with giddiness, giddiness, and cold sweats, which were speedily followed by the pectoral symptoms. The most common course of the symptoms, however, was the following:

The disease generally began with fits of chilliness and heat alternately succeeding each other; sometimes with a flight shivering, followed by more or less of fever; anxiety of the precordia; pain in the back and limbs; hitch and cramps in the muscles labruntient to respiration; a very great discharge of their lymph from the eyes and nose; a fenaena in the eyes as if they were about to start out of the head; freezing, hoariness, and frequently an incoherent cough, forcing up large quantities of mucus, and sometimes attended with a sense of the breath. In many instances the appetite and sense of taste were lost or much impaired, with some degree of nausea; and a few vomited. Most of the patients laboured under great latitude and restlessness. The sleep was generally much broken; and many could hardly sleep at all. The pulse was frequent, but seldom hard or tense. Langour, debility, and deposition of spirits were general, and very great in all; far beyond what might have been expected from the degree of all the other symptoms.

But the symptom which universally prevailed, and which appeared to be almost a pathognomonic of the disease, was a dastreling pain and sense of constriction in the forehead, temples, and sometimes in the whole face, accompanied with a sense of a sense of the eyes, and often even the inner extent. The cough was some-

times
INFLUENZA.

times troublesome for a considerable time after the febrile state of the disorder had ceased; and a great weakness often remained after the disease.

The influenza, as above described, may be taken as an example of the epidemic at all times of its appearance; but it has sometimes assumed a more violent and inflammatory type, been more frequently accompanied with symptoms of pleurisy and peripneumony, and therefore more frequently fatal, and also laid the foundation for more numerous cases of pulmonary consumption, than in the influenza of 1762. Such was the fact, in regard to the influenza of 1762 in particular; which, indeed, appeared to be far more fatal, both at the time of its raging, and in its consequences, as several persons continued languishing under the remains of it for one or two years, and never recovered.

The causes of the influenza have been the subject of much difference of opinion; and all that has been said in respect to them rather tends to prove the difficulty of obtaining a sufficient number of unquestionable facts to found a clear opinion upon, than to fix the subject at rest. Three different views of the matter have been taken by different physicians: 1. Some attributed the disease solely to the state of the weather; i.e. they believed it to be a common catarrh, occasioned by changes in the sensible qualities of the atmosphere, such as cold, moisture, &c.: 2. Others ascribed it to a particular and specific morbid principle, totally different from and independent of the sensible qualities of the atmosphere, but resident in and conveyed by the air; 3. While the greatest number concurred in the opinion, that the influenza was contagious, in the ordinary acceptance of the word, i.e. was propagated only by the contact, or at least by the sufficiently near approach, of an infected person. The first opinion, however, that it originated in the sensible variations of the air, seems to be untenable: for not only was there no peculiarity of the atmospheric temperature, moisture, &c., which was common to the different periods when the influenza prevailed, or was obviously different from that of other seasons, when it had not appeared; but the sensible state of the air preceding, and accompanying the same epidemic was different in different places. Thus, though in most parts of England it had been uncommonly cold and wet, yet in the other parts of the world, as in Germany, where the disorder was equally general, it had been very dry. Again, it was observed in several places, that great alterations happened in the weather during its prevalence, without any sensible change in the symptoms of the disorder.

The second opinion, that the cause of the disease, though not connected with the sensible qualities of the atmosphere, was yet resident in it, and thus conveyed from place to place, was supported upon the following grounds: 1st. That those who were most exposed to the air were generally the first persons attacked: 2dly. That many had the disorder without having had any communication with a diseased person: 3dly. That several escaped though surrounded by persons ill of the disease: 4thly. That some whole families were seized at once: and, 5thly. That some persons had the disorder a week or a fortnight before it began to be taken notice of as a general one. Without preferring to decide upon so difficult and intricate a question, we may state the following objections to these arguments:

The first argument, that those who were most exposed to the air were generally the first persons attacked, (which, by the way, was altogether denied by many observers,) is surely by no means in favour of the opinion, that the cause of the disorder resided in the atmosphere; for if it had resided there, what should have prevented those who stood at home from being infected? since the air which they breathed must necessarily have been the same as that breathed by those who went out. But if, on the other hand, a communication with some infected persons was necessary to produce the disease, it is very clear that those who went out of doors, and mixed with the world, were more likely to get it than those who did not stir from home.

Before the second argument, namely, that many were attacked without having had any communication with a diseased person, can be allowed to have any weight, it must be clearly proved, not only that the persons themselves had not had such communication, but also, that no person, who had been near them, had previously been where the disorder existed, for it is pretty clearly established, with respect to other active contagions, such as the small-pox, &c. that a person, who has already suffered the disease, may nevertheless convey the contagion from one place to another.

From the third argument, that many escaped though surrounded by persons affected with the disease, no inference of any consequence to the present question can be drawn; it being certainly not less difficult to account for their escape when surrounded by diseased persons, than when surrounded by the same air, which had (according to the hypothesis) caused the disease in those persons.

With respect to the fourth argument, that some whole families were seized at once, without having been exposed to infection, it may be remarked that, when we consider what has been said in answer to the second argument, it will be very difficult to prove that they were not exposed to it; and equally difficult to give any reasons why, if the exciting cause of the disorder resided in the air, any whole family should have been affected by that cause, rather than an equal number of persons in divers families; but if we suppose the disease to have been propagated by personal intercourse, it is very easy to conceive in what manner it may have been communicated to some whole families at the same time. And, in answer to the last argument, that some persons had the disorder a week or a fortnight before any others were known to have it, it may be sufficient to remark, that, admitting these cases to have been really influenza, the supposition, that the cause of it existed in the air, will not render it more easy to explain why those persons only should at that time have been affected by this cause.

These considerations tend to favour the third opinion above-mentioned, that the disease was propagated by contagion, in the common acceptance of the term, that is, by personal communication with the diseased; but they are very far from being decisive of the question. Indeed, the question of contagion, as connected with any particular epidemic, in which there is no palpable matter produced, by which the disease can be communicated, is always difficult, and has been agitated even with regard to the plague itself. (See Contagion and Epidemic.) But it has been satisfactorily demonstrated, that the contagion of all malignant and eruptive fevers cannot be conveyed through the air to any distance (even many feet) from its source. If the contagion of the influenza, therefore, could be suspended and conveyed through the atmospheric air, so as to spread the disease far and wide, it would form an exception to the general properties of known contagions. Several facts, recorded during the epidemic of 1782, militate strongly against such a supposition. It was remarked, for example, that the disease was prevalent in one place a week or two before it appeared in another, only a few miles distant from the first. Thus it flourished itself at Edinburgh on the 20th of May, and soon raged very much, and was prevalent at Glasgow in the first week in June; yet it did not appear at Musselburgh, a village
INFLUENZA.

village about five miles south-east of Edinburgh, until the
9th or 10th of June. Again, it was prevalent at Dartmouth
much sooner than at Exeter, and yet is appeared at Exeter
much sooner than at Tinmouth, although the last mentioned
place is situated between Dartmouth and Exeter.

The opinion, that it was propagated by personal inter-
course, was also favoured by its progress in numerous in-
fiances. Thus it was frequently observed, that some one
individual in a family was first attacked, and that then
several more, and sometimes the whole of the same family,
were very soon afterwards seized with it, in some instances
all at once, but in others successively. Very early in June,
three families, consisting of seventeen persons, came on the
same day to the hotel in the Adelphi buildings; they were
all in perfect health when they arrived; and they were all
affected the next day with the symptoms of the illness
then reigning in London. In some cases, it seemed to be propa-
gated, like contagious diseases in general, by _fomites_, that
is, by articles of clothing or furniture impregnated with the
morbid effluvia. One physician, Dr. Meade of Strabane,
in Ireland, says, "I have no shadow of doubt that the
disorder was contagious; and am certain, I myself received
the infection from a small trunk of wearing apparel, which
came from Dublin, where it then raged. I may add, that
this was the first introduction of it into this town." The
disease appeared to be carried on board two ships of war, on
their arrival at Gravesend from the West Indies, by three
custom-house officers, who were put on board; in a few
hours, the crews of both ships, till in good health,
were seized with symptoms of the influenza; hardly
a man in either ship escaped, and some had it very severely.
In some instances it was observed, that the epidemic did
not shew itself in certain places, until some one or more ar-
ived at those places, either actually labouring under the
disease, or coming immediately from other places, whose
inhabitants had been affected by it for some days. In ge-
neral the disease appeared earlier in towns, than it did in the
surrounding villages, and in villages earlier than in the
distressed houles in the neighbourhood.

On the whole, the progress of the disorder is perhaps
more easily explained, upon the supposition that it was propa-
gated by personal communication, than by any other. In
objection to this hypothesis, however, it is credibly affirmed,
that the crews of several ships were seized with the influ-
enza many miles distant from land, and came into various
ports of England labouring under it; and the same thing is
said to have happened to ships in the East Indies, and other
parts. But great caution is requisite in admitting such
statements as facts, from which any satisfactory inference
can be deduced.

A familiar epidemic catararrh, or influenza, is recorded as
having visited Europe, and even other parts of the globe,
two or three times in the fourteenth century, and at se-
veral subsequent periods; namely, in the year 1347, 1375,
and 1380, the last of which is said to have originated, like
several of those which succeeded, in Asia; and again in 1591,
in 1638, in 1675, in 1679, in the latter end of 1732, and in
the beginning of 1733, in 1743, in 1762, in 1767, in
1775, in 1782, and in 1803. Those who are desirous of in-
vestigating the records of these epidemics, will find refer-
cences to the works in which they are contained, arranged
in chronological order, in Dr. Cullen's Synopsis Nosologica
Method. under the head of Catarrhæs, Gen. xl. and species
2. C. a contagio.

Cure of the Influenza.—Since the effects of this disease
were different in different individuals, no general method of
cure could rationally be followed. Many, indeed, were to
slightly indisposed, as to require but little or no medicine.
Nothing more was wanted for their cure, than to abstain for
two or three days from animal food and fermented liquors,
and to use some diluting tepid drink. A tonic purgative,
given at the beginning of the disease, was useful in mo-
derating the fever; and nature sometimes seemed to point
out the repetition of it afterwards, when there were pain
in the stomach and bowels, and a tendency to a diarrhoea.
The same was observed in the epidemics of 1732 and 1762.
Nothing likewise was observed to successfully mitigate the
cough, as to open the bowels with a gentle purgative, and
afterwards to give a light opiate at night. It was observed
by numerous practitioners, that emetics, exhibited upon the
first attack, were evidently of use in relieving the head
and breast, and also in producing a speedy and free periphrasia.
All attempts to force much sweating appeared to do harm,
especially by means of the stimulatting diaphoretics, such as
contrareps, ammonia, wine, &c. In fact, in most of the mild
and simpler forms of the disease, an early periphrasia
generally came on spontaneously, which seldom failed to
relieve the symptoms materially, and it was only necessa-
ary to give tepid aqueous liquors, the neutral salts, or antimonials
in small doses, to keep up a regular and gentle moisture
upon the skin.

But in the more severe forms of the disorder, other re-
medies became necessary, according to the severity of the
symptoms. Whenever symptoms of pleurisy or peripneum-
ony appeared, the propriety of blood-letting was com-
monly admitted, notwithstanding the languor and depression
connected with the disease. There was, however, consider-
able difference of opinion upon the subject of blood-letting.
Several learned and experienced physicians, if called at
the beginning of the disease to a person strong and plethoric,
and labouring under great heat and inquietude, even in cases
where no direct symptoms of pneumatic inflammation ap-
ppeared, ordered bleeding without hesitation; and under
such circumstances, they several times observed, that the
languor, oppression, and feverish anxiety, were abated by
the loss of a few ounces of blood; that both the head
and the breast were relieved; and that the disease proceeded
to its termination with fewer difficulties both to the patients
and to themselves, and without any subsequent inconvenience.
Yet others were of opinion that the blood-letting, although
indicated by the symptoms, and also by the appear-
ance of the blood drawn, not only failed to procure that
relief, which might have been expected from it under
ordinary catarrhal or pneumatic symptoms, but in some
cases even proved prejudicial. Drifters were applied to va-
rious parts with good effects: when there was pain in the
breast or side, the application of them to the part affected
was found very beneficial; and it was frequently thought
proper to keep them open for some time. In some cases, it
was remarked, that a second blister, applied a few days after
the first, produced great relief, while the first had failed to
do so. On account of the great debility, which seldom
failed to accompany or follow the disorder, bark and cor-
dials were often deemed necessary, especially towards the
close of the disease; but they would probably be deemed
less necessary by the practitioners of the present day; for
when a diseased condition is removed, the constitution com-
monly recovers its strength with rapidity, when care is
taken the food be light and nutritious, and there is a free
access to pure air. See Medical Transact. vol. iii. art. p.
Medical Communications, vol. i. art. I.—Hill. de la Doc.
Royale
INFORMED.
INFORMED.

INFORCEMENT. See REINFORCEMENT.

IN FORMA PAUPERIS, in Law. See FORMA PAUPERIS.

INFORMATION, for the king, is much the same with what is called declaration for a common person: it is not always done directly by the king or his attorney, or the clerk of the crown-office; but sometimes by another, who sues as well for the king as himself, on a breach of some penal law or statute, wherein a penalty is given, one part to the use of the king, and another to the use of the informer. And it differs from an indictment, which is found by the oaths of twelve men; and is only the declaration of the officer who exhibits it. The latter sort of informations, which are partly at the suit of the king, and partly at that of a subject, is a species of qui tam actions, to be used because they are brought by a person qui tan pro domino rege, &c. quam pro se in hac parte sequitur, and carried on by a criminal instead of a civil process. By 31 Eliz. c. 5, no prosecution of this kind can be brought by any common informer, after one year is expired since the commission of the offence; nor out of the country where the offence was committed; nor on behalf of the crown after the lapse of two years; nor, where the forfeiture is originally given to the king alone, can such prosecution be had after the expiration of two years from the commission of the offence. It is also enacted by 18 Eliz. c. 5, that if any person, informing under pretence of any penal law, makes any composition without leave of the court, or takes any money or promise from the defendant to excuse him, he shall forfeit ten pounds, stand two hours on the pillory, and be for ever disbarred to sue in any popular or penal statute. And by the same statute, if a person exhibits his information only for vexation, the defendant may bring information against the informer. See COMPOUNDING OF INFORMATIONS.

Informations that are exhibited in the name of the king alone are of two kinds; those which are truly and properly his own suits, and filed ex officio by his own immediate officers, the attorney-general; and those, in which, though the king is the nominal prosecutor, yet it is at the relation of some private person or common informer; and they are filed by the king’s coroner and attorney in the court of king’s bench, usually called the master of the crown-office, who, for this purpose, is the standing officer of the public. The objects of the king’s own prosecutions, filed ex officio by his own attorney-general, are properly such enormes misdemeanors as particularly tend to disturb or endanger his government, or to molest or affront him in the regular discharge of his royal functions. The objects of the other species of informations are any gross and notorious misdemeanors, riots, batteries, libels, and other immorals of an atrocious kind. And when an information is filed in either of these ways, it must be tried by a petty jury of the county where the offence arose; after which, if the defendant be found guilty, he must be referred to the court for his punishment. These informations, which are as ancient as the law itself (1 Show, 118.), of every kind, are confined by the constitutional law to mere misdemeanors only, without extending to any capital offence. The oppressive use of information by the court of Star-chamber, &c. in the times preceding the Revolution, occasioned a struggle soon after the accession of King William, to procure a declaration of their illegality by the judgment of the court of king’s bench. But John Holt, who then presided there, and all the judges, were of opinion, that this proceeding was founded on the common law, and could not then be impeached. However, in a few years afterwards, it was enacted by 4 & 5 W. & M. c. 18, that the clerk of the crown shall not file any information without express direction from the court of king’s bench; and that every prosecutor, permitted to promote such information, shall give security by a recognition of twenty pounds (a sum now too small), to prosecute the same with effect; and to pay costs to the defendant, in case of his acquittal, unless the judge, who tries the information, shall certify there was reasonable cause for filing it; and, at all events, to pay costs, unless the information shall be tried within a year after it is joined. But there is a proviso in this act, that it shall not extend to any other informations than those which are exhibited by the master of the crown office; and, consequently, informations at the king’s own suit, filed by his attorney-general, are no way restrained thereby.

There is one species of informations, still farther regulated by 0 Ann. c. 26, that the nature of a writ of quo warranto, which is a remedy given to the crown against such as had usurped or intruded into any office or franchise. The modern information tends to the same purport as the ancient writ, being generally made use of to try the civil rights of such franchises; though it is commenced in the same manner as other informations are, by leave of the court, or at the will of the attorney-general: being properly a criminal prosecution, in order to fine the defendant for usurpation; as well as to oust him from his office; yet usually commuted at preferment as merely a civil proceeding.

An information on behalf of the crown, filed in the exchequer by the king’s attorney-general, is a method of suit for recovering money or other chattels, or for obtaining satisfaction for damages in any personal wrong committed in the lands or possessions of the crown. (Moor, 375.) The most usual informations are those of intrusion and delit; the former being for any trespass committed on the lands of the crown (Cro. Jac. 212. 1 Leon. 48. SVM. 49), as by entering thereon without title, holding over after a lease is determined, taking the profits, cutting down timber, or the like; and the latter, upon any contract for monies due to the king, or for any forfeiture due to the crown upon the breach of a penal statute. There is also an information in rem, usually filed in the exchequer, where any goods are supposed to become the property of the crown; if no man appears to claim them, or to dispute the title of the king. There is also another information, filed ex officio by the attorney-general, in the court of chancery, at the relation of some informer, called the relator, for the proper establishment of charities, of which the king has the general superintendence. Blackil. Com. b. iii. and iv.

INFORMATUS NON SUM, or Non sum informatus, a formal answer made of course by an attorney, who is commanded by the court to say anything he thinks good in behalf of his client; who having nothing material to urge, makes answer, he is not informed: on which judgment passes for the other party.

INFORMER, INFORMATOR, a person that informs against, or prosecutes any of the king’s courts, tho’ that offend against any law or penal statute. See INFORMATION.

INFORMIS, UNINFORMED, that which has not the form or perfection it should have.

INFORMES Stultae, in Astronomia, are such stars as have not yet been reduced into any constellation; otherwise called forades.
Of this kind there was a great number left by the ancient astronomers; but Hevelius, and some others of the moderns, have provided for the greater part of them, by making new constellations.

INFORTUNIUM, HOMICIDE BY. See HOMICIDE.

INFRA, l. ait. below. See HYPO.

INFRATION, formed from in and the sujpine of franga, a rupture or violation of a treaty, law, ordinance, or the like.

INFRALAPSIARI, in Ecclesiastical History, the name of a sect of Pseudofarianians, who maintain, that God has created a certain number of men only to be damned, without allowing them the means necessary to save themselves, if they would; and they are thus called, because they hold that God's decrees were formed inra lapsis, after his knowledge of the fall, and in consequence thereof; in contradistinction to the Supralapsarians.

INFRASTAPULARIS, in Anatomy, a name of the infraspinatus muscle. See the following article.

INFRASTAPINATUS, is a muscle of the shoulder, called by the French sous-épineux, and sous-capula-truchtière. It is placed at the back of the shoulder, covering that division of the dorso of the scapula, which is below the spine, and extends from the basis of the scapula to the great tubercle of the humerus. It is thick, broad, and triangular.

Its posterior surface is covered above and on the outside by the deltoid; above and within by the trapezius, and below by the latissimus dorsi; in the rest of this surface it is covered by the skin. A thin aponeurosis, common to this muscle and the teres minor, immediately invests its posterior surface. This aponeurosis is continuous above with those of the trapezius and deltoid, it is attached on the inside to the basis of the scapula; is continuous below, with a septum placed between the two teres muscles and the infraspinatus; and is fixed on the outside to the posterior edge of the inferior margin of the scapula.

Its anterior surface covers the scapula below the spine, to the posterior three-fourths of which it is attached. It is separated from the anterior fourth of this lower division of the scapula by the superior and external scapular vessels, by the scapular nerve, and by cellular substance. Beyond the scapula this surface of the muscle covers the shoulder joint; to the scapular ligament of which it is strongly connected. The inner edge is fixed to the basis of the scapula, from the spine almost to the inferior angle. Its upper edge is attached to the lower surface of the spine of the scapula, and to the aponeurosis of the deltoid; the outer portion of this margin is parallel to the inferior edge of the supraspinatus. The lower border is oblique from below upwards, and from within outwards. This is united to the teres major by an aponeurotic septum, which is soon divided into two layers: one of these passes between the two teres muscles, the other between the teres minor and infraspinatus. The lower border of the latter is then united to the teres minor through about half its length; for the rest of their extent they are separated by a cellular line. In many subjects the fibres of these two muscles are so confounded at this part, that they cannot be separated.

The superior and inferior edges are united at a truncated angle, which is large and thick, and attached to the middle of the great tubercele of the humerus.

The infraspinatus muscle is composed of teninous and muscular parts. It is attached to the humerus by a broad and thick tendon, which expands into an aponeurotic plane continued into the substance of the muscle beyond its middle, and nearer to the posterior than to the anterior surface of the muscle. The muscular fibres arise from the dorsum of the scapula, from the under surface of its spine, from the aponeurosis of the deltoid, and from the aponeurotic septum, which separates this from the two teres muscles. They join the common tendon, which they accompany nearly to the humerus, pursing, however, very different directions. The superior fibres proceed nearly horizontally from within outwards: all the others are oblique from within outwards, and from below upwards, and their obliquity increases as they are placed lower down. Those fibres, which arise from the aponeurosis of the deltoid, and from the lower surface of the spine of the scapula, descend slighted, and terminate on the posterior surface of the tendon, on which they are extended almost to its attachment to the humerus.

The motions which this muscle can produce in the humerus, differ according to the position of that bone. When the arm is hanging by the side, the humerus will be moved on its axis, as to be turned from before outwards and backwards. If the humerus has been previously elevated, the infraspinatus will carry it backwards. When the arm is fixed, this muscle will draw the scapula, and through it the trunk also, forwards. The strength and breadth of its tendon enable it to support the head of the humerus, and to prevent it from being thrown out of the glenoid cavity, when the arm is moved sudenly forwards.

INFULA, a name anciently given to one of the pontificial ornaments worn on the head. Petrus tells us that the infula were filaments or fringes of wool, covering that part of the head where the hair grows as far as the temples, whence, on each side, hung down two fringes called vittae, for binding it, where with the ancients used to adorn their priests, their victims, and even their temples. The infula was the same thing to priests that the diadem was to kings; viz., the badge of their dignity and authority. The difference in shape between the diadem and the infula consisted in this, that the diadem was flat and broad, and the infula was rounded and twisted.

INFUMA, or DIJESCHOPT, in Geography, a town of Africa, in the kingdom of Anté, where the English built a fort in 1601.

INFUNDIBULUM, a Latin word signifying a funnel; whence divers parts in the human body, having a resemblance thereto in shape, are called by the same name. Hence also certain parts of plants are called infundibuliformes.

The word infundibulum is also used by the metallurgic writers to signify a vessel of a conic shape, used to pour a melted metal out of the crucible into.

INFUNDIBULUM, in Anatomy, a small procub in the brain. See BRAIN.

INFUSION, in Pharmacy, an operation whereby the virtues of plants, roots, and the like are drawn out by letting them steep in some convenient fluid menstruum without boiling them therein; since boiling is found to dilate the inner parts of many bitter and aromatic substances, without carefully extracting their medicinal principles.

Infusion is used in bodics of a lax texture, whose parts are so light as not to admit of a greater motion without hazard of flying away in vapour.

Its chief use is to communicate the virtues of bodis to liquors.
Infusion.

Infusion of Culparia is procured by macerating for two hours, in a covered vessel, two drams of bruised Culparia bark in half a pint of boiling water, and straining.

Infusion of Fox-glove, infusion digitalis, is obtained by macerating for four hours, in a covered vessel, a dram of purple fox-glove leaves, dried and powdered, in half a pint of boiling water, and straining; then adding half a fluid-ounce of spirit of cinnamon. See Digitalis.

Infusion, Compound, of Gentian, infusion amaranth simplex, P. L. 1745, is procured by macerating in a covered vessel, gentian root sliced and orange-peel dried, of each a dram, two drams of fresh lemon-peel, in twelve ounces of boiling water, and straining.

Infusion, Compound, of Horsetail, infusion armoraciae compostium, is procured by macerating for two hours, in a covered vessel, fresh horse-raddish root sliced, and multhead feeds bruised, of each an ounce, in a pint of boiling water, and straining; then adding a fluid-ounce of compound spirit of horse-radish. An infusion for the belly may be made by infusing horse-radish root shaved, multhead feeds bruised, of each four ounces; and one ounce of the outer rind of orange-peel in two quarts of boiling water, in a close vessel for twenty-four hours. A tea-cupful of this warm stimulating medicine may be taken three or four times a day, in paralytic complaints. It excites the action of the fluids, acts diuretic, and, with warmth, promotes peroration. If two or three ounces of the dried leaves of marigold be used instead of the multhead, we shall have the antiscorbutic infusion.

Infusion of Laxative, infusion horis, is prepared by infusing two spoonfuls of linseed, or an ounce of linseed bruised, and half an ounce of liquorice root sliced, in two pints of boiling water by the fire for four hours, and then straining off the liquor. The pectoral infusion is made by adding to these ingredients an ounce of the leaves of coltsfoot.

These emollient liquors may be taken in difficulty of making water, and in coughs and other complaints of the breast.

Infusion of Quassia is obtained by macerating for two hours, in a covered vessel, a scruple of quassia-wood sliced, in half a pint of boiling water, and straining. See Quassia.

Infusion of Rhubarb, infusion rhoei, is procured by macerating for two hours, in a covered vessel, a dram of sliced rhubarb-root in half a pint of boiling water, and straining. See Rhubarb.

Infusion of Roses, infusion roae, tinctura rofarum, P. L. 1718, tinctura rofarum rubrarum, P. L. 1720, is made by infusing half an ounce of the petals of red roses, dried, in 2/3 pint of boiling water; afterwards pouring in three fluid-drams of dull sulphuric acid, and 1 1/2 ounce of double refined sugar. Pour the water upon the petals of the rose in a covered glass vessel; then add the acid, and macerate for half an hour. Lastly, strain the infusion, and add the sugar to it. A tea-cupful of this astringent infusion may be taken every three or four hours, in an excessive flux of the menses, vomiting of blood, and other hemorrages. It will likewise serve as a very good gargle.

Infusion of Seneca, infusion Senec, is prepared by macerating for an hour, in a covered vessel, 1/2 ounce of Seneca leaves, a dram of sliced ginger-root, in a pint of boiling water, and straining the liquor. An infusion of Seneca, named "infusion Senecia tartarzatum," may be had by adding extemporaneously to each pint of the infusion two drams of supertartrate of potash, in such proportions as circumstances may require.
IN

Infusion of Senna and Tamariads, is prepared by infusing for four or five hours one ounce of tamariads and senna, and the leaves of tartar, of each two drams, in a pint of boiling water; straining the liquor, and adding to it an ounce or two of the aromatic tincture. Persons who are easily purged, may leave out either the tamariads or the leaves of tartar. A tea-cupful of this agreeable cooling-purge may be taken every half hour till it operates.

Infusion of Simarouba is made by macerating for two hours, in a covered vessel, half a dram of Simarouba bark, bruised, in half a pint of boiling water, and straining. See Simarouba.

Infusion, Spanish, is made by infusing an ounce of Spanish juice cut into small pieces, and three drams of half of tartar in a quart of boiling water for a night; and adding to the strained liquor an ounce and a half of the syrup of poppies. In recent colds, coughs, and obstructions of the breath, a tea-cupful of this infusion may be taken with advantage three or four times a day. SeeLIQUORES.

Infusion of Tobacco, infusion tabaci, is made by macerating for an hour, in a covered vessel, a dram of tobacco leaves in a pint of boiling water, and straining. This infusion is intended to be used as a cathartic, to which purpose it is often directed.

Infusion is also used to signify the action of conveying liquor into the body by the veins. See INJECTION.

Some physicians have found out a new method of purging, by infusing a cathartic into the veins, which operates pretty much after the manner of a cathartic.

ING, in Agriculture, a provincial term, employed to signify a common pasture or meadow which lies low or wet, and which is chiefly employed as hay lands.

ING, in Botany. See MIMOSA.

INGANNO, Itali. a trick, a disappointment, a disappointed cadence, or clef, is, when, after preparing for a regular termination, some unexpected chord or modulation occurs to lengthen the movement and postpone the cadence. SeeCADENCE.

INGARD POINT, in Geography, a cape of Ireland, on the south coast of the county of Wexford, within which lies the small dry harbour of Fethard, which is only fit for small vessels.

INGARYD, a town of Sweden, in the province of Smalnd; five miles S. of Jonkiping.

INGASTONE, a small town in the hundred of Chelmsford and county of Essex, England, is situated 23 miles from London, on the high road to Colchester. It consists principally of one street, and contains, according to the late return to parliament, 120 houses and 645 inhabitants. In the church, which has a high embattled brick tower, are several elaborate monuments of the Petre family, whose burial place adjoins the chancel on the north side. A considerable market was formerly held here, but having greatly declined, it has been for several years wholly discontinued; but a very large fair for Scotch and Welsh cattle is still held on the first of December, annually. An alms-house, for seven women and three men, was founded, in the year 1557, by Sir William Petre, and endowed by him to the amount of 20l. 13s. 4d. per annum.

Near the town is Engastone-hall, a venerable, but irregular structure, which was the family residence of the lords Petre, previous to the building of a new mansion at WelThorndon. Beauties of England and Wales, vol. v.

INGATOP, a town of Sweden, in the province of Smalnd; 40 miles N. of Wexio.

INGELFINGEN, a town of Germany, in the principality of Hohenlohe, on the Kocher, six miles N. E. of Ohrenburg.

INGLEHEIM, Ober, a town of France, in the department of Mont Tonnerre, situated on the Saône; 12 miles W. of Montz. Lat. 49° 56'. Long. 8° 1'.

INGLEHEIM, Nieder, a town of France, in the department of Mont Tonnerre, one mile from Ingelheim Ober.

INGLELY, a town of Hindooftan, in Bengal, at the mouth of the Hoogly; 60 miles S. of Calcutta.

INGLEMUNSTER, a town of France, with a castle, in the department of the Lys, and chief place of a canton, in the district of Courtray; five miles N. of Courtray. The town contains 4873, and the canton 14,284 inhabitants, on a territory of 524 kilometres in four communes.

INGLESBURG, a town of Saxony, in the Vogtland; nine miles S.S. E. of Oelzinzt.

INGLESTAD, a town of Sweden, in the province of Smalnd; 10 miles S.E. of Wexio.

INGEMINATED FLOWERS, are those where one flower stands on, or naturally grows out of another; called also prolific flowers.

INGEN, in Geography, a small island in the North sea, near the coast of Lapland. Lat. 70° 56'.

INGENDRING. See ENGENDRING.

INGENERATE, in Natural History, is a term used to express the kind of petrifications produced by intumescence, or the introduction of the mineral particles into the internal texture of the original organized. Martin's "Outlines," p. 67.

INGENHOUZ, John, in Biography, an eminent physician and chemist, was born at Breda in the year 1737. Little is known of his early life; but in 1767 he came to England with a view of obtaining information on the Suttinian method of inoculation for the small-pox, and in the following year he went, on the recommendation of the late Sir John Pringle, to Vienna, to inoculate the archduchess Theresa-Elizabeth, only daughter of Joseph II., and the archduke Ferdinand and Maximilian, brothers of the emperor. For these services he obtained rewards and honours: he was made body-physician and counsellor of state to their imperial majesties, with a pension of 600l. per annum. In the following spring he went to Italy, and inoculated the grand duke of Tuscany; after this he returned to England, to which he was much attached, where he spent his time in scientific pursuits. He published a very valuable work, entitled "Experiments on Vegetables, discovering their great power of purifying the common air in sunshine, but injuring it in the shade and night." This work was first published in 1779, and has been frequently referred to by Dr. Priestley and others, who have carried their observations much farther. It was translated into the French and German languages, and highly esteemed by all the experimental philosophers of that period. He ascertained, that not only from the green matter found on flagrant waters, but likewise from the leaves of vegetables, from the green branches and shoots, even from the entire vegetable, when placed under water and exposed to the solar light, oxygen gas, in a state generally of great purity, is evolved; and as the result of his numerous experiments he adopted the conclusion, that oxygen is elaborated in the leaves and other organs of vegetables, by a vital action excited and sustained by the solar light. The doctor, through all the course of life, was fond of exhibiting among his friends, particularly young persons, experiments of this kind, which required hardly any apparatus, excepting a bell glass and a bell of fire, and with the oxygen gas which he obtained from cabbage leaves or other vegetables, he would exhibit the combustion of 20 l. wine, which is a 7.
flirting and very brilliant experiment. Dr. Ingenhousz was author of many papers inserted in the Transactions of the Royal Society, of which he was an active and useful member. Of these papers we may notice the following: Experiments on the torpedo:—Methods of measuring the diminution of bulk taking place on the mixture of nitrous with common air:—Experiments on the electrophorus:—New Methods of suspending magnetic needles:—Considerations on the influence of the vegetable kingdom on the animal creation. He died in the year 1798, highly esteemed for the simplicity of his manners, and for the discoveries which he had made in the several departments of experimental philosophy. Monthly and Gentleman's Magazine. Murray's Chemistry.

INGENITAE, is born, signifies any disease or habit which comes into the world with a person, nearly the same with hereditary.

INGENITAS REGNI, anciently signified the free-holders and commonalty of the kingdom: the title was also sometimes given to the barons and lords of the king's council.

INGENIUS, Ingenius, among the Romans, a title applicable to a person born free, or of free parents.

Idiote says, they are called ingenii, qui libertatem habent in genere non in fide; those who are born free, not those who acquire their freedom. A person was accounted ingenious, if only the mother were free, and the father a slave.

These could give their votes, and enjoy offices, from which the liberti, or freedmen, &c. were debarred.

Ingenious is sometimes also used to signify a native of a country in contradistinction to a foreigner.

INGRAM, in Geography, a small island in the straits of Malacca, near the coast of Salengore. N. lat. 3° 15'. E. long. 101° 26'.—Also, a town of Hindoostan, in the circar of Rajamundry; 30 miles S.E. of Rajamundry.

INGETORP, a town of Sweden, in the province of Schonen; 10 miles E. of Ystad.

INGINEER, or ENGINEER. See Engineer.

INGKALU, in Geography, a small island in the North sea, near the coast of Lapland. N. lat. 75° 50'.

INGLEBOROUGH, a mountain of England, in the N.W. part of the county of York, said to be 20 miles in circumference. The height is rated by Houfman to be 3987 feet; but by the barometrical measurement of Mr. Ewart 2277-12, and by trigonometrical measurement 2350.7 feet above the level of the sea.

INGLOTT, William, in Biography, an organist of the cathedral church of Norwich, who seems, by an inscription on his monument in that church honourable to his memory, to have been a man of no common abilities. We have never heard or seen any of his productions; but in all probability, Dr. Croft had; who, a hundred years after his decease, had his monument repaired. Inglott died in 1621.

INGLUVIES. See CRAW.

INGOLSTADT, in Geography, a town of Bavaria, situated on the Danube, and surrounded with a moras. It has an university, founded in the year 1473, which embraced the Reformation in 1743; 35 miles N. of Muschin. N. lat. 48° 43'. E. long. 11° 22'.

INGOT; a mass or lump of gold or silver, from the mines, melted down, and cast in a sort of mould, but not coined or wrought.

The word seems formed from the French lingot, which signifies the same.

Ingot is also a name given to the moulds or cavities, wherein they cast melted metals, or regulus of semimetals.

INGOULT, NICHOLAS LOUTH, in Biography, a French Jesuit, was born at Gifors, devoted himself to an ecclesiastical life, and became a very eloquent preacher. He published the eighth volume of the Memoirs of the Mission of the Society of Jesus in the Levant. He was author also of sermons which were highly applauded. He died in 1753.

INGOUVELLE, in Geography, a town of France, in the department of the Lower Seine, and chief place of a canton, in the district of Le Havre. The place contains 5500, and the canton 10,347 inhabitants, on a territory of 40 kilometres, in six communes.

INGRAFTING, or Engrafting. See Engrafting.

INGRAILED. See Engrailed.

INGRAM, ANDREW, in Biography, was born in Yorkshire, and educated at Beverley School, from whence he was sent to Corpus Christi college, Cambridge, of which he became fellow, and took there his degrees in arts. His first preceptor was the perpetual curacy of Bridlington, in Kent, after which he obtained successively the small vicarage of Orlrun, in Nottinghamshire, and the vicarages of Wormington and Dixted, in Essex. He died in 1804, leaving behind him a high character for simplicity of manners, great integrity, and genuine benevolence. He had a high sense of the dignity and importance of the clerical functions, and for 50 years of his life was indefatigable in his attention to professional duties. He was author of “A View of the great events of the seventh plague, or period, when the mystery of God shall be fulfilled.” “Accounts of the ten tribes of Irael being in America, originally published by Mansfield Ben Israel, &c.” “A complete and uniform explanation of the prophecy of the seven vials of wrath, or seven last plagues contained in the Revelations of St. John, &c.”

INGRASSIAS, JOHN PHILIP, was a native of Sicily. He studied medicine at Padua, where he took the degree of doctor in medicine in the year 1557, with singular reputation; insomuch that he soon received several invitations to professorships from different schools in Italy. He accepted the chair of medicine and anatomy at Naples, which he occupied for a number of years, lecturing to the most crowded audiences drawn by his fame from all parts of the country. He possessed peculiar qualifications for the office, having united a consummate knowledge of the writings of the ancient physicians with great practical skill and a sound judgment, which led him to estimate justly the merits and defects of those fathers of the art. A singular testimony of his talents and unremitting attention to the improvement of his pupils was given by the latter, who caufed his portrait to be placed in the schools of Naples with the following inscription: “Philippo Ingrassiae Siculino, qui veram medicinam artem et anatomiam, publice inuicino, Neapolitum, dedicavit memoriae cauab, P. F.” At length he quitted his situation at Naples in order to return to his native island, where he settled at Palermo. Here also he received many marks of public distinction. The rights of citizenship were conferred upon him; and in 1563, Philip II. king of Spain, appointed him first physician for Sicily and the adjacent isles. By virtue of the powers attached to this office he restored order in the medical constitution of the country, by preventing all persons, unqualified by their education and abilities, from practising there. His zeal for the credit of his profession rendered him rigid and severe in his examination of candidates; and he exercised his art himself in the most honourable manner. When the plague raged at Palermo in 1575, he adopted such excellent regulations, in quality
leaves of land, signifying a free entry into, a going out of and returning from some part of the premises leased to another; as to get in a crop of corn, &c. after the term expired.

INGRESSU, a writ of entry, whereby a person seeks entry into lands or tenements. It lies in various cases, and has various forms. It is also called precipit quod reddat.

INGRIA, or INGERMANLAND, in Geography, that part of Russia, which was wrested by Peter the Great from the Swedes, and confirmed to Russia at the peace of Nyildin in 1721. It is now called the "Government of St. Petersburg," which see.

INGRIN, or GRAIN, a town of Africa, in the country of the Foulahs; 30 miles S.W. of Cayor.

INGROSSATOR Magni Rotuli, is the same as clerk of the pipe.

INGROSSER, or ENGROSSER, in Common Law, is one who buys up corn growing, or any provisions by wholesale, before the market, to sell again. See FORESTALLING.

It also signifies a clerk, who writes records, or instruments of law, on skins of parchment. See ENGROSSING.

INGROSSING of a Fine, is the making the indentures by the scribe, for delivery of them to the party to whom the fine is levied.

INGROWITZ, in Geography, a town of Moravia, in the circle of Brunn; 30 miles N.N.W. of Brunn. N. lat. 49° 36'. E. long. 16° 2'.

INGSKAR, a small island in the gulf of Bothnia. N. lat. 61° 17'. E. long. 17° 24'.

INGUE-LOUKA, a town of Chinese Tartary. N. lat. 42° 16'. E. long. 124° 44'.

INGUEN, in Anatomy, the technical term for the groin.

INGUIMBERTI, DOMINIC-JOSEPH-MARY D., in Biography, a learned French prelate, was born at Charpentras in 1683. He devoted himself from a very early age to the ecclesiastical profession, became a member of the Dominicans, and afterwards joined the Cistercians, in order that he might submit to what he conceived the more perfect rules of monastic discipline. In this last order his merits raised him to the highest offices of honour and confidence. Being deputed to Rome on the business of his monastery, he so highly recommended himself to the see of pope Clement XII. that in the year 1733, he was raised to the rank of bishop of Charpentras, and other ecclesiastical preferment. He died in the year 1757, and is known in the republic of letters by several original works, and translations of others. As a bishop he obtained universal respect, and employed his wealth in serving the public and relieving the poor. He built a large and noble hospital, and he collected the most extensive and valuable library in Provence, which he gave for the use of the public.

INGUINAL GLANDS, in Surgery. See GLANDS.

INGUINAL Hernia, a rupture, or protrusion of the bowels at the abdominal ring; a bubocele. See HERNIA.

INGUINAL Ligament. This, which has been also called from its discoverer ligamentum Fallopian, is an aponeurotic, or ligamentary band, falcated by one end to the anterior and superior part of the os ilium, and by the other to the spine of the os pubis. The middle portion of it is very narrow, but it expands considerably towards both its extremities. It is closely joined to the muscles of the abdomen, and to the aponeurotic fascia of the thigh, but seems to be often wanting.

INGUINALIS, in Anatomy, an epiphete sometimes applied to the external iliac artery and vein.

INGUL,
INGUL, in Geography, a river of Russia, which runs into the Bug, near Matveevka.

INGULETZ, a river of Russia, which runs into the Dnieper; 12 miles N.E. of Chernov.

INGULPHUS, in Biography, a monastic historian, was the son of a courtier of Edward the Confessor, and was born at London about 1040. He pursued his maturer studies at Westminster and Oxford, and distinguished himself as a great adept in the Peripatetic philosophy. Scarcely had he attained the age of manhood when he was appointed secretary to duke William, by whose permission he visited the Holy Land and Constantinople in 1064, and upon his return, he entered into the order of the Benedictines at the abbey of Fontencelle, in Normandy, of which he became prior. When his patron, William, obtained the crown of England, Ingulphus was created abbot of the rich monastery of Croyland, which being in a dilapidated state, he rebuilt, and for which he obtained many privileges. He died in 1109, leaving behind him as evidences of his great learning, a work on the life and miracles of St. Guthlac, and a history of the monastery of Croyland. The last gives the author rank with the English historians. It was published at London, by Sir Henry Savile, among the quinque scriptores, in 1596, being almost five hundred years after the death of the author. It has been several times reprinted: the best edition is that of Oxford, in 1684.

INGULSK, in Geography, a town of Russia, in the government of Ekaterinoflav, on the Ingul; 28 miles S. of Elizavet.

INGURTY, a town of Hindooftan, in the province of Golconda; 22 miles S.E. of Warangole.

INGWEILER, a town of France, in the department of the Lower Rhine, on the Motter; 21 miles N.N.W. of Stralsburg.

INHALER, in Surgery, a machine lately invented by Mr. Mudge, and fo contrived, that the air drawn through a tube in respiration, paffes first through hot water, and thus comes to the lungs loaded with warm vapour. The same air, when expelled in expiration, paffes back through the tube, and thence through a valve, when by proper management it may be distributed over the surface of the body and thus act as a vapour-bath. The author's directions for the procfs are as follow:

In the evening, a little before bed-time, the patient, if of adult age, is to take three draus, or as many tea-spoonfuls of elixir paregoricum in a glafs of water; if the subject is younger, e.g. under five years old, one tea-spoonful, or within that and ten years, two. About three quarters of an hour after he fhould go to bed, and being covered warm, the inhaler, filled three parts with water nearly boiling, and wrapped up in a napkin, but fo that the valve in the cover is not obstructed by it, is to be placed at the arm-pit, and the bed-cloaths being drawn up, and over it close to the throat, the tube is to be applied to the mouth, and the patient fhould inpire and expire through it about twenty minutes or half an hour. This, he affures us, is an infallible and immediate cure for the cough conqulent on catching cold. Mudge's radical and expeditious Cure for a recent Catarrhous Cough, 1778.

INHALLOW, in Geography, one of the larger Orkney islands, between Pomona and Ronfa.

INHAMBANE, or INNANBAM, a kingdom of Africa, in the country of Mocaranga, bounded N. by Sabia, E. and S.E. by the Indian sea, S.W. by the river Manica, and N.W. by an unknown country.

INHAME, in Botany. See Dioscorea.

INHAMOIT, in Geography, a town and district of Africa, in the country of Mocaranga, situated about S. lat. 17° 20'. E. long. 21° 20'.

INHAMURO, a river of Africa, in the kingdom of Julambane, which runs into the Indian sea. S. lat. 24° 30'.

INHANBAO, a river of Africa, which runs into the Indian sea, S. lat. 23° 15'.

INHANGOMA, an island of Africa, in the river Zambeze. S. lat. 17° 43'. E. long. 32° 20'.

INHANZARA, a town of Nubia, in Sennar; 30 miles from Gieffen.

INHAQUEA, a town of Africa, in the kingdom of Sofala, possessed by the Portuguese, near the sea-coast; 20 miles S.W. of Sofala.

INHARMONICAL Relation, in Music. See Relation, inharmonical.

INHARMONICAL, or artificial or mechanical, is a species of an interval or chord that is impracticable in harmony, and, consequently, in melody. Notes out of tune are inharmonical.

INHARMONIOUS, or unnatural relations, according to Mr. John Holden (Effay, p. 331.) are such intervals or notes or intervals not contiguous in the scale, as a minor third to a major seventh, &c.

INHASSATO, in Geography, a small island in the Indian sea, near the coast of Africa. S. lat. 20° 35'.

INHERENCE, in Philosophy, is applied to the juncture or connection of an accident with its subsistence.

Thus quantity has a necessary inherence in a natural body.

INHERENT, in Natural History, is a term used by Mr. William Martin (Outlines, p. 186.) to express that class of organic remains or relics, which stick in the surface of the matrix or fossil. The extraneous fossils of veins are frequently found in this state.

INHERITABLE BLOOD, in Law. See Blood.

INHERITANCE, HEREDITAS, a property in lands and tenements to a man and his heirs. See Estate, in Law.

Inheritance is not only understood where a man hath inheritance of lands and tenements by descent or heritage; but every fee-simple or fee-tail, that a man hath by his purchase, may be said to be an inheritance, because his heirs may inherit it after him. (See Fee-simple and Fee tail.) The inheritances mentioned in our law are either corporeal or incorporeal; the corporeal relate to houses, lands, &c. that may be touched or handled; and the incorporeal are rights extending out of, annexed to, or exercised with corporeal inheritances; as advowsons, tithes, annuities, offices, commons, franchises, &c. (See Herediments.) There is like-wise another inheritance denominated several; that is, where two or more hold lands severally; as when two persons hold to them and the heirs of their two bodies, in which case these two have joint-estate during their lives, but their heirs have several inheritances. Goods and chattels cannot be turned into an inheritance. For the rules of inheritance, see Descent, collateral.

INHIBITION, a writ to inhibit or forbid a judge from further proceeding in a cause depending before him.

Sometimes prohibition and inhibition are put together, as of the same import; but inhibition is most commonly a writ issuing out of a higher court-christian to a lower; and prohibition out of the king's court to an inferior court.

INHIBITION, in Scott Law, is a pernicious prohibition, which paffes by letters under the signet, prohibiting the party prohibited to contract any debt, or do any deed, by which any part of his lands may be aliened or carried off in prejudice of the creditor inhibiting. It must be executed against the debtor, personally, or at his dwelling-house, as annuities, and afterwards published and registered in the same manner with interdictions. Inhibition may proceed either upon
INJ

Upon a liquid obligation, or even as an action commenced by a creditor for making good a claim not yet sustained by the judge; which last is called "inhibition upon a depending action." Although inhibitions, by their uniform style, disable the debtor from selling his moveable as well as his heritable estate, their effect has been long limited to heritage, from the interruption that such an embargo upon moveables must have given to commerce; so that debts, contracted after inhibition, may be the foundation of diligence against the debtor's person and moveable estate. An inhibition secures the inhibitor against the alienation, not only of lands that belonged to his debtor, when he was inhibited, but of those which he shall afterwards acquire; but no inhibition can extend to such after-purchases as lie in a jurisdiction where the inhibition was not registered; for it could not have extended to those though they had been made prior to the inhibition. An inhibition is simply prohibitory, so that the debt on which it proceeds, continues personal after the diligence. The heir of the person inhibited is not restrained from alienation by the diligence used against his ancestor, for the prohibition is personal, affecting only the debtor against whom the diligence is used. Inhibition do not of themselves make void the posterior debts or deeds of the person prohibited. When payment is made by the debtor to the inhibitor, the inhibition is said to be "purged."

INHOC, or INSHOE, in our Old Writers, is used for any corner or part of a common field ploughed up and sowed with oats, &c. and sometimes fenced in with a dry hedge in that year wherein the rest of the same field lies fallow and common. It is called in the North of England an intock, and in Oxfordshire a kitchen. And no such inshoe is now made without the joint consent of all the commoners, who in most places have their share by lot in the benefit of it, except in some manors where the lord has a special privilege in so doing. Kennet's Paroch. Antiq. 297, &c, and his Glossary.

The word is Saxon, compounded of in, within, and bote, a corner.

INHUMATION. See Burial and Interment.

Inhumation, in Chemistry, a method of digesting substances together, by burying the veil in which they are put in horse-dung, or in dry sandy earth exposed to the fun. See Digestion.

INIA, in Geography, a river of Russia, which runs into the Oby, 50 miles N.E. of Kolivan.—Alto, a river of Russia, which runs into the Lena, N. lat. 55° 20'. E. long. 116° 14'.

INJAMBI, or TIETS, a river of Brazil, which runs into the Parana, 180 miles N.W. of St. Paul, on the borders of Paraguay.

INIARA, a town of Russia, in the government of Penza, 48 miles W. of Penza.

INJECTION, in Anatomy, is the art of filling the blood-veins or other hollow organs of the dead body with various substances, for the purpose of investigating their structure, situation, &c. or for displaying any facts connected with these subjects by subsequent artificial preparation. See Preparations, Anatomical.

Injection, in Pharmacy, any liquid medicine made to be injected or thrown into the body, or any of its parts, by a syringe, clyster-pipe, or other instrument.

Injection, in Surgery, the throwing in of some liquor or medicine into a vein opened by incision. This practice, and that of transfusion, or the conveying the arterial blood of one man, or other animal, into another, were once greatly practised, but are now laid aside.

The method of injecting is this: a vein is to be opened in the arm with a lancet as if bleeding, and a small pipe of a syringe being introduced at the orifice, the liquor intended to be mixed with the blood, and contained in that purpose in the body of the syringe is to be forcibly injected, or thrown into the vein upwards, or toward the heart; which done, the orifice is to be secured with compresses and bandages as in bleeding.

Whether this practice of injecting proper medicines into the body may not be found of use in apoplexies, quinines, hydrophobia, &c. is worthy to be tried by repeated experiments. The method of injecting liquors into the blood of living animals, is said to be the invention of Sir Christopher Wren. His method was by making ligatures on the veins, and opening them on the side of the ligature towards the heart; then putting into them small syringes or quills fastened to bladders in the manner of clyster-pipes, containing the matter to be injected. Mr. Boyle soon made the experiment upon dogs, with infusions of opium and crocus metallosum; all which he circumstantially described, in his Observations of Experimental Philosophy, part ii. eff. 2. Phil. Trans. N. 7. p. 128.

The ingenious Dr. Hales made a variety of experiments of this kind on different animals. See his Statical Essay, vol. ii. paffim.

Many disorders of particular parts are no way curable, unless the parts affected are injected with a proper liquor by means of a syringe and proper tube. The method of performing this is too obvious to need any directions; but these general cautions are necessary in regard to it, that the syringe or tube be applied tenderly and carefully to the parts, especially in very sensitive or nervous parts, to avoid giving the patient any pain; and that the liquor to be injected be neither too hot nor too cold.

In ulcerations and inflammations of the uvula, tonsils, and fauces, injections are generally useful; but care must be taken to press down the tongue with a spatula, or with the flat end of a spoon, and having introduced the syringe two or three fingers breadth into the mouth, the injection is to be carefully and gently thrown in at several times. In gonorrhoea, injections are often necessary to allay the heat and foreheads of the urethra, and to wash out the matter. The faeet and bitt injections on this occasion are warm milk and barley-water, sweetened with sugar, honey, or syrup of marshmallows; and towards the end a little fæcharum furarii, dissolved in plantare water.

INJELLE, in Geography, a province of Bengal, on the right side of the Hoogly, near its mouth.

INO, a small island in the Baltic, near the coast of Finland, with a town. N. lat. 60° 26'. E. long. 21° 14'.

INIS, a word in the Irish language signifying island; and therefore used as a prefix to the names of many islands on the coast of Ireland, some of which are noticed in succeeding articles, but a much greater number passed by as too insignificant.

INISBEG, in Geography, the name of several small islands on the coast of Ireland, the name signifying little island. One of these is in a small bay of the county of Cork, near the town of Skibbereen; another is on the west coast of Kerry, near the Great Blasket island; and a third is on the north coast of the county of Donegal, about 6 miles N.E. of Bloody Foreland Point.

INIS-BOFFIN, or LANNISBOFFIN i.e. the island of the White Cow; an island near the west coast of Ireland, containing 1200 acres. It is about a mile and a half from the main land of the county of Galway, and is a parish in the diocese of Tuam. There was formerly an abbey here. There is an island of the same name on the coast of Donegal.
INISLE, an island in Newport or Clew bay, county of Mayo, Ireland, which gives name to one of the best fisheries for salted eels in that extensive bay. Mackenzie.

INISHMURR, INISMOOR, or Inis-moidhe, an island which lies off the coast of Sligo, Ireland, about three miles distant from the main land. It contains 130 acres, two wells of excellent water, and a fennel bog of remarkably good turf. The inhabitants are few, and live by fishing. There are the remains of some chapels within a stone wall ten feet high, and from five to seven and eight feet thick, without cement. Mr. Archdall says it is impossible to determine whether it is round or oval; and that more rude, inconstant workmanship was never seen. There are a few old foundations upon the ground, which receive their light through a hole at the top, others through a loop-hole in the side; they are dark and horrible dangerous. Gen. Vallancey infers from part of these ruins, that in Pagan times, the island was dedicated to the worship of Baoobs, and says that a monument in this island is an exact representation of the Mahody of the Gentious found in the island of Elephant, near Bombay, by captain Pyke. Many devotees still flock to this island to do penance in the cells, and many are brought from great distances to be buried in the churches. There is a ledge of rocks running from this island, which requires the attention of all who enter the bay of Sligo. Vallancey's Prospectus of a Dictionary; Carlile.

INISTIOGE, a small port-town of Ireland, in the county of Kilkenny, and province of Leinster. It is situated on the river Nore, which is navigable to it, and over which it has a bridge with ten arches.initioge is one of those places which before the Union sent to two members to the house of commons of Ireland. It is 63 miles S.W. from Dublin.

INISTUISKAR, an island off the west coast of the county of Kerry, Ireland, about four miles from Causa head, and north of the Biscuits. N. lat. 52° 34'; W. long. 10° 35'.

INISTURC, an island situated about seven miles from the west coast of Mayo, Ireland, not far from the Killaries. N. lat. 53° 42'; W. long. 10°.

INITIALIS et paula generalis, the beginning of a musical composition, and the cad. See TEMPO, PROLATION, and PAUSE.

INITIAM PUNCTUM. See PUNCTUM.

INITIATE, Tenant by forfeiture; in Law. See Tenant.

INITIATE, a term properly used in speaking of the rejection of the ancient heathens; where it signifies being admitted to the participation of the sacred mysteries. The word comes from the Latin initiatus, from initiare, which properly signifies to begin sacrificing, or to receive or admit a person to the beginning of the mysteries, or of ceremonies of least importance. The
INJUNCTION, in Law, a writ generally grounded upon an interlocutory order or decree out of the court of chancery or exchequer, sometimes to give possession to the plaintiff, for want of the defendant's appearance; sometimes to the king's ordinary court, and sometimes to the court-christian, to stop proceedings in a cause, upon suggestion made, that the rigour of the law, if it take place, is against equity and conscience in that cause, that the complainant is not able to make his defence in their courts for want of witnesses, &c. or that they act erroneously denying him some jut advantage. The writ of injunction is directed not only to the party himself, but to all and singular his counselors, attorneys, and solicitors; and if any attorney, after having been served with an injunction, proceeds afterward contrary to it, the court of chancery will commit the attorney to the fleet for contempt. But if an injunction be granted by the court of chancery in a criminal matter, the court of king's bench may break it, and protect any that proceed in contempt of it.

INJURY, INJURIA, in a general sense, signifies any thing contrary to justice and equity; that is, any wrong or damage done to a man's person, reputation, or goods.

The word is derived from the Latin preposition in, which here has a negative power; and jus, law, right: injuria, effectus omne good non furt. The ancient's made a godchild of injury, and called her Ate. Homer makes her the daughter of Jupiter, and says she did mischief to every body, even to her father; that she was very nimble and tender-footed, and walked altogether on men's heads without ever touching the ground.

Civilians define injury a private offence, committed designated, and with an evil intention to any man's prejudice, with regard to his person or his property. All civil injuries are of two kinds; the one without force or violence, as slander or breach of contract; the other joined with force and violence, as batteries and false imprisonment. The author of the Rhetorics to Herennius says, "Injuria est quod aut pululatione, aut convictio, aut turpitudine, corpus, aures, aut vitam aliquis violat."

By the Roman law, the action for an injury was annual; that is, no reparation could be required after the expiration of a year. By the law of the twelve tables, where the injury was the breaking of a limb, the injured person might demand talionem, that is, that he might break the same limb of the criminal.

For the breaking of a bone there were also considerable pecuniary punishments assigned: for other injuries only twenty asses were decreed, which the poverty of those times thought a sufficient penalty; but the pratores afterwards finding this too slender a satisfaction, in lieu thereof, appointed the injured person to set a rate on the injury, which they afterwards increased or lessened as they thought good.

Some of our lawyers make a distinction between a damage and an injury; and indeed there are many acts which may be done to the prejudice of a third person, which may be properly said to be damnum sine injuria.

As the absolute rights of individuals are those of personal security, personal liberty, and private property, the wrongs or injuries affecting them must consequent ly be of a corresponding nature. Injuries that affect the personal security of individuals are injuries against their lives, their limbs, their bodies, their health, or their reputation. For the first class of injuries, see HOMICIDE, MANSlaughter, and MURDER. The two next species of injury, afflicting the limbs or bodies of individuals, may be committed by threats, assault, battery, wounding, mayhem, which are respectively. For the four last injuries now enumerated, an indictment may be brought as well as a action; and frequently both are accordingly prosecuted, the one at the suit of the crown for the crime against the public; the other at the suit of the party injured, to make him a separate indem nities. Injuries affecting a man's health are those by which any wholesome practices of another cause not to fulfill any apparent danger in his vigor or constitution as by fellowing him bad provisions, as wine (1 Rob. Ab. 92.) by the exercise of a noisome trade, which affect the air in the neighborhood (9 Rep. 349. Fitt. 135. 140.) by the neglect or unskillful management of his physician, surgeon, or apothecary. (Lord Raym. 214.) For those injuries, unaccompanied by force, there is a remedy in damages by a special action of trespass upon the case. Injuring and asugging a man's reputation, or good name, are, first, by malicious, scandalous, and slanderous words, tending to his damage and derogation. (See Words and SCANDALUM MAGNITUDINIS; and Action upon the case.) A second way of affecting a man's reputation is by printed or written libels, pictures, signs, and the like; which fet him in an odious or ridiculous light, and thereby diminish his reputation. (2 Shaw. 314. 11 Mod. 99.) See Libel. A third way of destroying or injuring a man's reputation is by preferring malicious affidavits or accusations against him; which, under the mask of justice and public spirit, are sometimes made as engines of private spite or enmity. For this, however, the law has given a very adequate remedy in damages, either by an action of conspiracy (Finc. L. 565.), which cannot be brought but against two at the least; or, which is the more usual way, by a special action on the case for a false and malicious prosecution. (F. N. B. 118.) The violation of the right of personal liberty is effected by the injury of false imprisonment, for which the law has not only decreed a punishment, as a heinous public crime, but has also given a private reparation to the party, as well by removing the actual confinement for the present, as, after it is over, by subjoining the wrong doer to a civil action, on account of the damage sustained by the loss of time and liberty. (See IMPRISONMENT, and FALSE IMPRISONMENT.) The injuries that affect the rights of personal property, affect it either as an in possession or in action. (See PROPERTY.) The former kind of property is liable to two species of injuries, the alienation or deprivation of that possession, and the abuse or damage of the chattels, while the possession continues in the legal owner. The deprivation of possession comprehends the unjust and unlawful taking away, and the unjust detention, though the original taking might be lawful. The remedy which the law has provided for the wrongful taking of goods, is the restitution of them, with damages for the loss sustained by such unjust invasions, which is effectuated by action of "replevin," which fee. Other remedies for other unlawful taking of a man's goods consist only in recovering a satisfaction in damages, by an action of mischief or damage, or action of trespass et armis, or action of trover and conversion, which fees respectively. For unjust detention of another's goods, when the original taking was lawful, the remedy for the recovery of possession is by action of detinue; or action of trover, which see. The remedies given by the law to redress damages, which the thing's detainee may have suffered, are action of mischief et al armis, where the act is in itself immediately injurious to another's property, and accompanied with some degree of force; and special action on the case, where the act itself is indifferent, and the injury only consists.

Q 2, quod
quential, and therefore arising without any breach of the peace. As to injuries that regard things in action only, they pertain to such rights as are founded on, and arise from contracts, which may be either express or implied. The former are debts, covenants, and promises; see each term; the latter are such as reason and justice dictate, and which the law presumes that every man has contrived to perform. Thus it is that every person is bound, and hath virtually agreed to pay such particular sums of money as are charged upon him by the sentence, or assailed by the interpretation of the law. A debt is thus contrived, and the defendant is bound to pay it. The same reasoning will apply to all penal statutes, that is, such acts of parliament by which a forfeiture is inflicted for transgressing the provisions therein enacted. The party offending must pay the forfeiture incurred to such persons as the law requires. Another class of contracts includes those which arise from natural reason, or the just contract of the law. (See Assumpsit.) The last class of contracts, implied by reason and construction of law, arises from this supposition, that every one who undertakes any office or employment, trust or duty, contracts with those who employ or trust him, to perform it with integrity, diligence, and skill; and if for want of these qualities any injury accrues to individuals, they have their remedy in damages by a special action on the case.

Besides the special action on the case, there is also a peculiar remedy, entitled an action of deceit, (F. N. B. 95.) to give damages in some particular cases of fraud, and principally where one man does any thing in the name of another, by which he is deceived or injured.

As to those injuries that affect men with regard to their relative rights, they may be done to persons under the four following relations: husband and wife, parent and child, guardian and ward, master and servant; and they comprehend in the relation of a husband, addition, adhesion, and beating or otherwise abusing the wife. In the relation of a parent, the injury is addition, which is remedied by a writ of ratiification, or action of trespass vo et armis, de filio vel filâ, rapto vel adduction. (F. N. B. 95.) See the other terms above specified. Having briefly recited the principal injuries that may be done to persons or property, with their several remedies by suit or action, we shall next direct our attention to those injuries which affect that species of property which the laws of England have denominated real. Real injuries, or injuries affecting real rights, are principally the following: suyfer, trespass, sufusion, us, sawte, sabotage, and disturbance; which see respectively. Blackf. Com. b. iii.

INJURIES OF THE HEAD. Some subjects, connected with this highly interesting part of surgery, have already been treated of in the preceding volumes of this Cyclopedia. See Compression; Concussion; and Extravasation. Here it is incumbent upon us to consider certain other cases, which are the consequence of external violence applied to the head, as wounds and contusions of the scalp, inflammation of the dura mater, and suppuration under the cranium; fractures of the skull, &c.

Injuries of the Scalp.—Injuries done to the scalp by external violence are generally of a more ferosious nature than a similar degree of mischief done to any other part of the common integuments. Surgical authors have endeavored to account for this fact by advertizing to the prodigious quantity of nervous filaments distributed to the scalp, the many different parts which compose it, its structure, connections, &c. We are not, however, to suppoee every injury of the external coverings of the head dangerous. A mere cut with a sharp instrument usually heals as favorably in this situation as in any other, and often more so, perhaps, in consequence of the great vascularity of the skin of the head, and the very leedy manner in which the edges of the wound admit of being kept in contact, supported as they are upon the fixed surface of the cranium. But punctures, lacerated wounds, and contusions of the scalp, as every experienced surgeon well knows, are cases frequently followed by such symptoms as may terminate fatally.

We shall pass over incised wounds of the scalp, since they are attended with no peculiarity, and only require the same treatment as ordinary cuts upon any part of the surface of the body.

Lacerated wounds of the scalp are divided by Mr. Pott into two kinds; viz., those in which the scalp, though torn, or equally divided, still keeps its natural situation, and is not flipp'd nor separated from the cranium to any considerable distance beyond the breadth of the wound; and, in which it is considerably detached from the parts it ought to cover.

The first of these, if simple, and not combined with the symptoms, or appearances of any other mischief, do not require any particular or different treatment from what the same kind of wounds require upon all other parts; but the latter, or those in which the scalp is separated and detached from the parts it ought to cover, are not only, by the different methods in which they may be treated, frequently capable of being cured with a considerable deal more or less ease and expedition, but are also sometimes a matter of great consequence to the health and well-being of the patient.

Not many years ago surgeons were accustomed to treat this laft fort of case in a most objectionable way. Too hastily convinced of the impossibility of the separated and torn pieces of the scalp ever becoming united again, practitioners used, without hesitation, to cut them away, so as to occasion a large fore, requiring a long time to heal, and leaving considerable deformity. Far different is the practice of the most approved modern surgeons, with whom it is an invariable maxim, that the preservation of the scalp ought always to be attempted. The reasons for this line of conduct are plain and obvious. The detached portions of the scalp were formerly cut off, because it was supposed that they were in such a state as precluded all chance of their union. But the fact is, it can never be foreseen with certainty whether the detached torn edges of a lacerated wound will slough or not. Now, as no harm can arise from trying whether they will live and unite; as considerable benefit will result from the success of such an attempt; and, as the excision of the part is painful, and productive of no solid advantage, even when sloughing is unavoidable, the method is supported neither by reason nor experience. Whatever may be the course of the case, the proceeding is only calculated to cause unnecessary pain, lengthen the time required for the cure, and render deformity, which is uncertain, quite inevitable. The head having been shaken round the wound, the torn piece of the scalp is to be first freed from all dirt and extraneous substanccs, and then restored as quickly and as perfectly as possible to its natural situation. Strips of adhesive plaster fully suffice for bringing the parts together without the assistance of futures, which, unless absolutely necessary, ought never to be used. It has always appeared to us a very beneficial plan to maintain the pieces of the scalp closely applied to the cranium by means of small lint-compresses, bound on with adhesive plaster. Thus, no cavity will be left for the lodging of matter, and the parts will have the fairest opportunity of uniting. Sometimes the loosened scalp will unite with the parts from which it was torn and separated, and there will be no other care than what...
what arises from the impossibility of bringing the lips of the wound into smooth and immediate contact, the fear of which fore muff be small in proportion. Sometimes such perfect re-union is not to be obtained; in which case matter will be formed and collected in those places where the parts do not coalesce; but this will not hinder the preservation of the coverings of the head, the cure being only a little retarded by a few small abscesses, and the matter admitting of being let out by one or two small openings.

Occasionally, the whole separated piece will unite perfectly, especially in young and healthy persons. In certain instances the union will take place in some parts, and not in others; and, consequently, matter will be formed, and require to be discharged, perhaps, at several different points. In other particular cases, circumstances, and habits, there will be no union at all, the torn cellular membrane, or the naked aponeurosis will inflame and become floridly, a considerable quantity of matter will be collected, and, perhaps, the cranium will be denuded. But even in this case, if the surgeon takes proper measures, and refrains from being too much in a hurry to cut, things will be more prosperous than may be expected. Let him take care to keep the inflammation under by proper means; let him have patience till the matter is fairly and fully formed, and the sloughs perfectly separated; and when this is accomplished, let him make a proper number of dependent openings; and let him, by bandage and other proper management, keep the parts in constant contact with each other, and he will often find, that, although he was foiled in his first intention of procuring immediate union, yet he will frequently succeed in this his second; as he will still have the scalp, shorten the cure, and prevent the great deformity arising, particularly to women, not only from the fear, but from the total loss of hair.

Many persons have erroneously thought, that, when the pericranium is stripped off the cranium by external violence, or is afterwards cast off, the scalp cannot unite to the denuded cranium, which must of necessity exfoliate. However, these notions are now well known to be unfounded. The exposed part of the skull, unless much injured by contusion, or improperly irritated by stimulating applications, will generally live, throw out granulations, and become united to the separated scalp, without any exfoliation whatever.

Punctured wounds of the scalp are more apt than cuts to inflame and give trouble, and are indeed frequently the cause of fever and alarming symptoms.

According to Mr. Pott, if the wound affects the cellular membrane only, and has not reached the aponeurosis, or pericranium, the inflammation and tumour affect the whole head and face, the skin of which wears a yellowish cast, and is sometimes thick let with small blisters, containing the same colored serum; it receives the impression of the fingers, and becomes pale for a moment, but returns immediately to its inflamed colour; it is not very painful to the touch, and the eye-lids and ears are always contemplated in the tumefaction, the former of which are sometimes so dilated as to be closed; a feverish heat and thirst generally accompany it; the patient is restless, has a quick pulse, and most commonly a nausea and inclination to vomit.

Cafes are most disposed to assume this form in persons of bilious habit, the inflammation being in fact erysipelatous. The disorder is somewhat alarming to look at, but it is not often attended with danger. Mr. Pott remarks, that the wound does, indeed, neither look well, nor yield a kindly discharge, while the fever continues; but still it has none of that look which bespeaks internal mischief; the scalp continues to adhere firmly to the skull; nor does the patient suffer the tenue pain, and fatiguing reflex effects, which generally attend mischief underneath the skull.

Such erysipelatous inflammation commonly soon yields to phlebotomy, lenient purges, and febrifuge medicines, particularly those of the neutral kind. When the inflammation is gone off, it leaves on the skin a yellowish tint, and a dry scurf, which also, in time, disappear. Immediately the disorder subsides, the wound puts on a healthy aspect, and heals without trouble.

Surgeons must carefully distinguish from the foregoing another kind of erysipelatous swelling and inflammation to which the scalp is liable, as one of the effects of inflammation and suppuration of the dura mater. In this last important disorder the febrile symptoms are much higher, the pulse harder and more frequent, the anxiety and reflex effects extremely fatiguing, the pain in the head intense; and as, in these circumstances, the swelling of the scalp is most frequently the immediate precursor of matter forming between the skull and dura mater, it is generally attended with irregular fluorings, which are not followed by a critical sweat, nor afford any relief to the patient. When the inflammation is confined to the parts on the outside of the skull, the erysipelas generally appears within the first three or four days; but when the dura mater is affected, it seldom comes on till several days after the accident, when the symptomatic fever is got to some height. In the simple erysipelas, although the wound be crude and undigested, yet it has no other mark of mischief; the pericranium adheres firmly to the skull, and, upon the cessation of the fever, all appearances become immediately favourable. In that which accompanies an injury done to the parts underneath, the wound not only has a spongy, glairy, unhealthy aspect, but the pericranium in its neighbourhood separates spontaneously from the bone, and quits all cohesion with it. In short, says Mr. Pott, one is an accident proceeding from a bilious habit, and not indicating any mischief beyond itself; the other is a symptom, or a part of a disease, which is occasioned by injury done to the membranes of the brain; one portends little or no ill to the patient, and almost always ends well; the other implies great hazard, and most commonly ends fatally.

When the wound is small, and reaches to the aponeurosis and pericranium, disagreeable, and even alarming symptoms sometimes arise. In the case alluded to, the inflamed scalp does not rise into that degree of tumefaction as in the erysipelas; neither does it pit, or retain the impression of the fingers of an examiner. It is of a deep red colour, un mixed with the yellow tint of the erysipelas; it appears tense, and is extremely painful to the touch. The ears and eye-lids are seldom comprehended in the tumour, though they may partake of the general inflammation of the skin. It is generally attended with acute pain in the head, and such a degree of fever as prevents sleep, and sometimes brings on delirium. A patient, thus affected, may be more freely bled than one labouring under an erysipelas. Warm fomentations are proper in both cases; but emollient poultices, which are forbidden in erysipelatous diseases, may be employed in the present instance with much advantage.

In exceedingly urgent cases, Pott recommends making a division of the wounded part down to the bone, to the extent of half an inch, or an inch, as the best means of stopping the fever, and preventing the aponeurosis and pericranium from becoming flougy.

Mere contusions of the scalp, unattended by fracture, or injury of the parts within the cranium, are not of serious importance, considered abridged. It frequently happens, that when a severe bruise has been inflicted on the scalp, a large tumour, containing extravasated blood, quickly rul on
Upon the head, or blows on this part with stones, sticks, \\
but, notwithstanding the immense disfigurement attending \\
this sort of accident, if the skull and its contents be free \\
from injury, the case is not of a dangerous nature. The \\
effused blood generally admits of being removed by abso-

bution, provided the surgeon is careful to keep the patient's \\
bowels well open with saline purges, and apply to the tu-

mour itself linen wet with the faturine lotion, or with a \\
lotion composed of spirit of wine, vinegar, and the muriate \\
of ammonia. Many surgical authors countenance the plan \\
of discharging the collection of blood by a small puncture. \\
As far as our observations extend, this practice should be 

avoided in the generality of instances. When an opening 

is made, suppuration within the swelling becomes inevi-

table. On the contrary, abscesses may frequently be prevented 

altogether, by allowing the abscesses to do the office of 

taking away the effused blood, ascribed by the means already 

recommended. It is not to be denied, however, that matter 

will sometimes form, and then the method of making an 

opening for the discharge of the contents of the swelling 

is undoubtedly proper.

With regard to those tumours of the scalp, which are the 

consequence of blows, falls, &c. and which are filled with 

effused blood, J. L. Petit made a remark, which has been 

repeated by all subsequent writers, namely, the facility with 

which the centre of the swelling may be depressed, while 

the circumference seems hard and prominent, circumstances which 

may easily impede upon the inexperienced surgeon, and lead 

him to mistake the case for a fracture of the cranium with 

depression of the bone. If, upon such a supposition, he imme-

diately makes an incision into the tumid scalp, he may give 

the patient a great deal of unnecessary pain, and endanger 

his own reputation.

It is observed by Mr. Pott, that in this case the touch is 

so liable to deception, that recourse should always be had to 

other circumstances and symptoms, before an opinion is 

given. If a person, with such tumour occasioned by a 

blow, and attended with such appearances and feel, seems to 

labour under dangerous pressure upon the brain, a division 

of the scalp, in order to enquire into the state of the skull, 

is right and necessary; but if the patient is well, or not 

seriously affected with any symptoms of compression, the 

mere feel of some thing like a fracture, nay, we may add, 

even the actual existence of a fracture itself, will not autho-

rize or indite cutting the scalp.

For an account of the symptoms of pressure on the brain, 

see Compression and Extravasation.

Inflammation of the Dura Mater, and Suppuration under the 

Skull.—The symptoms attending an inflamed or bloody state 

of the membranes of the brain, in consequence of external 

violence, are all of the febrile kind, and never at first imply any 

immaterial pressure upon the brain. When, in these cases, the 

symptoms of pressure come on, it is not until the latter end 

of the disease, that is, until a considerable quantity of matter 

is formed, which matter must press like any other fluid.

The late eminent Mr. Pott has written a most able de-

scription of the inflammation and suppuration of the dura 

mater from external violence. The following observations 

are chiefly from his pen.

When there is neither fissure nor fracture of the skull, nor 

extravasation, nor commotion underneath it, and the scalp is 

neither considerably bruised nor wounded, the mischief is 

frequently discovered or attended to for some few days. The 

first attack is generally by pain in the part which received 

the blow. This pain is soon extended all over the head, and 

is attended with a languor or dejection of strength and 

spirits, which are soon followed by a nausia and inclination 

to vomit, a vertigo or giddiness, a quick and hard pulse, and 

an incapacity of sleeping. A day or two after this attack, 

if no means preventive of inflammation are used, the part 

becomes generally swelled, and becomes puffy and tender, but 

not painful. Neither does the tumour rise to any considerable 

height, nor spread to any great extent. If this tumid part of 

the scalp be now divided, the pericranium will be found of 

a darkish hue, and either quite detached, or very easily 

separable from the skull, between which and it will be found 
a small quantity of a dark-coloured ichor. If the diverder is 

so advanced, that the pericranium is quite separated from 
the skull, the latter will be found somewhat altered in colour 
from a healthy bone.

From this time the symptoms generally advance more 

quickly and more apparently; the fever increaseth, the skin 
becomes hotter, the pulse quicker and harder, the sleep more 

disturbed, the anxiety and readiness to fatigue; and to these, 
fays Mr. Pott, are generally added irregular rigours, 

which are not followed by any critical sweat, and which, 

instead of relieving the patient, add considerably to his suf-
ferings. If the scalp has not been divided, until the symp-
toms are thus far advanced, the alteration of the colour of 
the bone will be found to be more remarkable; it will be 
found to be whiter and more dry than a healthy one; or, 
as Fallopius has observed, it will appear rather like dead 

bone.

There will be more nausea or fluid under the pericranium, 

and this membrane will have a more livid aspect.

In this state of matters, if the dura mater be denuded, it 

will be found to be detached from the inside of the cranium, 
to have lost its bright silver hue, and to be smeared over 
with a kind of mucus or pus. Every hour after this period 
all the symptoms are exasperated; the head-ache and thirst 
become more intense, the strength decays, the rigours are 
more frequent, and, at last, convulsive motions, attended 
in some with delirium, in others with paralysis, or comatoze 

fupidity, finish the tragedy.

If the scalp is now divided, a very offensive discoloured 

fluid will be found lying on the bare and altered cranium. 
If, at this period, a perforation is made in the bone, matter 
will be found between it and the dura mater, generally in 
considerable quantity, but different in different cases and 
circumstances. Sometimes it will be in great abundance, 
and diffused over a very large part of the membrane; and 
sometimes the quantity will be less, and consequently the 
space which it occupies smaller. Sometimes it lies only on 
the exterior surface of the dura mater; and sometimes it is 
between it and the pia mater, or also on the surface, or in 
the substance of the brain.

The foregoing mischief is entirely the consequence of the 
diseases which the head has suffered. But it deserves 
attention, that as the inflammation and separation of 
the dura mater are not immediate consequences of the violence, 
so neither are the symptoms immediate, seldom coming on 
until some days have passed.

We have next to consider the case where the scalp has 
been wounded, either by the accidental violence, or by 
the surgeon making an incision immediately afterwards 
for the examination of the bone. Here the wound will, 
for some little time, have nothing particular about it; 
but after a few days, any favourable appearances which 
it may have put on will vanish; the fore will lose its florid 
complexion and granulated surface; will become pale, 
flabby, and flabby; instead of good matter, it will dis-
charge only a thin discoloured fluid; the lint with which 
it is dressed, instead of coming off easily, as in a kindly 
furring, fore, will stick to all parts of it; and the peri-
cranium
Injuries.

There will often be some difficulty in persuading a person, who has had what may be called only a knock on the part, to submit to such discipline, especially if he feels hims tolerably well; yet, in many instances, the timely use or the neglect of this single remedy, makes all the difference between safety and fatality. It is true, that by this method patients must sometimes be bled, who would escape inflammation of the dura mater without such evacuation; yet, let it be remembered, that the loss of blood, however necessary in these cases, never endangers life, while it is frequently the means of preferring it. In short, we must agree with Mr. Pott, that if every person who meets with a severe blow on the head were to be bled, as he undoubtedly ought to be, many a very valuable life would be preserved, which, for want of this kind of attendance, is lost. Acceleration, or hardiness of pulse, coldness, anxiety, and any degree of fever, after a heavy blow on the head, are always to be suspected and attended to. Immediate, plentiful, and repeated evacuations have, in many instances, removed these complaints in persons, to whom, Mr. Pott believes, very ten per cent would have happened had not such precaution been used. From these observations, however, let it not be concluded, that early bleeding will always prove a certain preservative; like all other human means it is liable; but, if it sometimes fails, it also succeeds to a greater extent than any other known plan.

When the inflammation of the dura mater has produced matter under the cranium, the fluid ought to be discharged through a perforation of the bone. This operation ought always to be done immediately when the above described symptoms manifest the nature of the case. The spontaneous separation of the dura mater, if attended with general disorder of the patient, with chilliness, inquietude, and fever, was invariably considered by Mr. Pott a sure indication of mischief underneath, and an urgent reason for perforating the bone without delay. In some cases one perforation will suffice; in others, more openings must be made. This variation will depend upon the space of detached dura mater, and the quantity of matter collected.

The repetition of blood-letting, of cooling laxative medicines, the use of antiphlogisitc remedies, and a most strict observance of a low diet and regimen, are as indispensably requisite after trepanning as before. The perforation obviates the dangerous effects of the confinement of matter; but it does nothing more: and the inflamed state of the parts under the skull still calls for our most earnest attention.

See Pott on Injuries of the Head.

Fractures of the Skull.—Whenever the head is struck with a certain degree of violence, the effect is not limited to a vehement concussion of this part of the body; or to the bruising and wounding of the scalp; the bone forming the cranium are also liable to be broken. When the weapon, or thing with which the blow is given, presents an angular or a projecting surface, the fracture generally happens where the violence is immediately applied; but it may occur at a different part of the head, when produced by a body of a certain width. The possibility of fractures happening in a situation more or less distant from that which received the blow, is explicable on the principle of the unequal resistance offered by the parietes of the cranium at different points of their extent. It is to such cases that the name of cougher's fracture is given.

In order to explain the manner in which counter-sutures are produced, let us suppose a blow to fall upon the os frontis, with a force equivalent to twenty, which bone, being in the situation of the forehead somewhat thick, makes a resistance equal to twenty-five. The solution of contu-
ity, therefore, cannot happen directly in the place struck; the force is transmitted to the orbital processes, a part which is thin, easily broken, and only capable of making a resistance expressed by twelve; consequently the violence, though weakened in its transmission, is still sufficient to fracture this last process. The foregoing reasoning coincides with experience. Many fractures of the orbital processes of the os frontis are met with in practice, while that part of the bone, which forms the forehead, remains free from injury. This first species of counter-fissure, though not exactly in the situation where the external violence was applied, happens on a part of the same bone which received the blow. There are other cases, where counter-fissures occur on some bone adjoining that which was struck, notwithstanding the check which the impulse must experience in crossing the futures. Thus, blows on the parietal bone frequently break the squamous portion of the os temporis.

Such counter-fissures as happen to a part of the skull, diametrically opposite the point which received the blow, notwithstanding the equal thickness of the bones in both places, admit of explanation by the imperfect spherical form of the cranium. Richerand, Nefog. Chir. tom. 2.

Fractures of the inner table of the skull, while the external is simply contused, are explicable by its great fragility, whence it has also been named by several authors vitrana.

Direct fractures, as well as counter-fissures, differ in point of situation, the extent of the solution of continuity, their particular shape, and the symptoms with which they are followed. Sometimes the crack is exceedingly fine and minute, which cause is often called a capillary fissure. Sometimes the edges of the breach are attended with a separation, more or less considerable. In some cases, the fracture runs in a straight line; in others it is flattered. In certain examples, the splinters of bone are beaten inwards, and compass the brain; these instances are usually named fractures with depression. On other occasions, the broken pieces keep their proper level. But even in the latter sort of cases, the brain may suffer a dangerous degree of pressure from an extravasation of blood under the bones, such pressure, indeed, as may urgently require the application of the trephine. Yet, it ought to be well understood, that this operation is not performed because the skull is broken, but because the brain is dangerously compressed by a quantity of extravasated blood, that lies confined under the bone, and was poured out of vessels, which were ruptured by the same violence as broke the bone itself.

Not only may fractures of the skull be complicated with extravasation, they may be conjoined with the effects of concussion. Depressed fractures are frequently accompanied with an actual laceration of the membranes and subflance of the brain. The recoveries which have been known to follow the most terrible wounds of this organ, as detailed in the Memoirs of the French Academy of Surgery, are both curious and surprising. But, generally speaking, the danger of all injuries of the head is in proportion to the mischief and violence done to the brain. A fracture of the skull, could it be occasioned, and exist without the least irritation and dis- turbance of the brain and membranes thereof, would be attended with no serious symptoms, and, of course, would require only simple treatment. In short, the breach of continuity would be repaired with calsus, just like a similar injury in any other bone. It is the earmarks of the brain, and the manner in which it is affected, either by the depression or inequality of the bone, or by the blow itself, which constitute at once the importance and danger of all fractures of the cranium. The ignorant and injudicious are apt to think, that because the skull is broken, the trepan must be employed, as a matter of course. Perhaps the doctrines of M. Quefnay, Pott, &c. might function the invariable use of the trephine; for, if the argument be allowed, that this operation is proper as a preventive of the bad symptoms to be apprehended in cases of fractured skulls, there cannot very well be any cases where the practice would not be justifiable. Let us not an opinion of such consequence, however, be taken up too hastily, and we shall pretentiously adduce convincing reasons against its validity.

We must first consider what are the symptoms by which the existence of a fracture of the skull may be known. It must be acknowledged, considerable obscurity prevails in the diagnosis of such accident, unless it so happen, that the nature of the case admits of being ascertained by the eye, or the touch. What are termed the residual symptoms are exceedingly fallacious. When a fracture of the skull occurs, attended with a wound of the scalp, and a denudation of the broken part of the bone, the surgeon may both see with his eyes, and feel with his fingers, what has happened. The existence of a fracture may likewise be ascertained by the touch, even when the soft parts are entire, if the solution of continuity in the bone is splintered, or accompanied with a considerable depression. When several of the fragments are entirely detached, a palpable crepitus will often render the nature of the accident still more clear.

Setting out of consideration such symptoms, there are none which can be regarded as characteristic of a fracture of the skull. Some writers direct us to inquire whether the patient was conscious, at the time of receiving the injury, of any noise, like that of a pot breaking. But how are we to gain information on this point from patients who are always stunned at first, and often remain senseless and speechless a long while afterwards? Other authors lay stress on the bleeding from the nose and ears, a circumstance entirely incidental, or, at most, indicative of nothing else, than that the head has sustained some kind of blow, or concussion, without at all informing us of the degree of violence that has been applied. Besides, every one knows what fright shocks will cause this kind of bleeding in particular persons, so that it cannot be received as a proof that the blow has been very powerful. Even did it prove that the blow has been violent, it would not justify the inference, that the skull is certainly broken. In short, we may assert, that a fracture of the cranium, without depression, without extravasation, and without concussion, is generally not only not productive itself of any alarming effects, but is also unmarked by any particular symptoms. Its existence can only be ascertained by the eye or the touch; and therefore its diagnosis is only easy, when the injury is exposed in consequence of a wound. However, a surgeon need not be licentious to find out an undeepressed fracture; for if symptoms demand the application of the trephine, he is to apply it to the bone, whether it is fractured or not; and if these symptoms are absent, the fracture itself cannot be a just reason for the operation.

We must not take our leave of the diagnosis of these cases, without cautioning surgeons not to be too hasty in pronouncing the skull to be fractured. Bloody tumours of the scalp often feel so much like fractures of the cranium with depression, as to make the most experienced men incapable of a positive decision. These cases have already been noticed in the present article. When the bone is bare, it is possible to mistake a future, or the furrow of a blood-vessel, for a fracture, and Hippocrates has gained considerable honour
honour by the candour with which he acknowledged his having fallen into an error of this kind.

We shall conclude this subject with a few observations on the treatment of fractures of the skull. For the relief of these cases, there cannot be a doubt that the usefulness of trepanning has been most unreasonably magnified. The necessity of only practising this operation when it is absolutely requisite, must be manifest to every one, who reflects, that cutting away a portion of the skull is a proceeding by no means free from the hazard of very dangerous consequences. We have also the testimony of several eminent surgical writers, that it is an operation, generally speaking, attended with remarkable ill success. It is not our intention, however, to endeavour to intimate, that the fatal terminations are not chiefly ascribable to the serious mischief which commonly exists when the operation is performed. Be this as it may, we cannot help looking upon trepanning as a thing, to which recourse should never be had without strong and urgent reason. Default, the most eminent of the modern French surgeons, entirely abandoned the operation in the latter years of his practice, as he found considerable successes arise from the employment of evacuations. "C'est une observation fort ancienne, que le peu de succés de l'opérations du trepan pratiqué à l'Hotel-Dieu de Paris ; fait, que l'air des falles, visé par le grand nombre d'individus, qui s'y trouvent rafemblés, ou par l'humidité dont le voisinage de la rivière le charge conflagment, exerce fur la place, que succède l'opération, ou fur les membranes du cerveau mises à nu, une influence délétère, fof que ce fait conçant dépend d'une autre cause ignoree," l'opération du trepan est presque toujours suivie de la mort des individus." Richerand, Nofographie Chirurgicale, tom. ii. p. 266. Edit. 2.

That the operation of trepanning is itself not exempt from serious danger we most firmly believe. We have seen it prove fatal, when performed with a view of relieving a violent invertebrate head-ache. We cannot bring our mind to believe, that Default was right in rejecting the operation altogether. There certainly are cases in which it may be the means of preservation as well as others, in which it may exasperate circumstances and render them fatal.

We have noticed that, in fractures of the skull, the operation of trepanning was advised by Pott, as a preventive of ill consequences. It gives us pleasure to state, that this practice is now never adopted by the most eminent surgeons in this country, great as their veneration is for so distinguished an authority. Many modern writers of the highest reputation have forcibly remarked against the method, as M. Default, of Paris; Mr. Deae, of Dublin; Mr. John Bell, of Edinburgh; and Mr. Abernethy, of London.

The reader cannot be surpried, that fractures without depression are not, abstraitely considered, a just cause for trepanning, when he is informed, that the skull is often broken and depressed, and yet the symptoms may not be such as to demand the operation, and the patient has the best chance of recovery when it is not performed. The more the present subject is studied, the greater will be the conviction, that there is only one genuine reason for trepanning, and that is, when symptoms of a dangerous degree of pressure on the brain exist, which symptoms are enumerated under the head of extravasation. When they prevail, the operation is to be done, whether the skull is broken or not; whether it be depressed or retain its proper level.

Mr. Abernethy has related several cases of fracture of the cranium with depression, which terminated favourably, although no operation was performed. This judicious fur-}

Jounal of the Royal College of Surgeons of Edinburgh, Vol. XIX.
officious in this way, when he can accomplish by it some
better object than the merely satisfying his own curiosity.
Now, since the removal of preffure off the surface of the
brain is the only admissible reason for ever perforating the
cranium, and since dividing the scalp cannot be useful, unless
preparatory to such operation, it is clear that neither the
one nor the other should ever be done, excepting such symp-
toms exist as unequivocally denote the prevalence of a dan-
gerous degree of preffure on the brain, caused either by
matter, extravasated blood, or depreffed portion of the
skull.

The true mode of presenting the bad effects frequently
following, but not arising from simple fractures of the skull,
(by which we mean cales unaccompanied by urgent symp-
toms of preffure,) is not to trepan, but to put in practice
all kinds of antiphlogistic means. For this purpose, let
the patient be repeatedly and copiously bleed, both in the
arm and temporal arteries; let him be properly purged;
give him antimonials; keep him on the lowest diet; let
him remain in the most quiet situation possible; and if, not
withstanding such steps, the symptoms of inflammation of the
brain continue to increase, let his head be flayed, and a
large blister be applied to it. When, in spite of all these
measures, matter forms under the cranium, attended with
symptoms of preffure, a puffy tumour of the injured part
of the scalp, or those changes of the wound (if there be
one), which Mr. Pott has so excellently described, and we
have already related; not a moment should be lost in de-
laying to perforate the bone with a trephine, so as to give
vent to the matter collected underneath.

Before concluding, we have one important caution to
offer, which is, in all cases of injuries of the head from
external violence, to continue an antiphlogistic regimen at
least a month after any serious accident of this description;
for it is by no means uncommon for inflammation of the
brain to follow injuries of the head a very considerable time
after the patients have had reason to fancy themselves in
perfect safety. Pott on Injuries of the Head; Difcale on
Wounds of the Head; Hill's Cales in Surgery; Abern-
thy on Injuries of the Head; Cooper's Dictionary of
Practical Surgery, &c.

will be found under the articles Compression, Concussion,
Extravasation, and Trephining.

INK, a liquor wherewith to write on paper or parch-
ment.

INK, Printing. See Printing.

INK, Writing, is commonly made of copperras and galls,
and gum arabic; but other astringent plants may serve the
same purpose; such as oak-bark, red roes, logwood, or
fumach. Mr. Boyle seems to doubt whether all astringent
vegetables will do the same.

Many are the preparations and methods of compounding
the materials for making of writing ink. For many years
the ink most generally used by European writers has been
the infusion of galls and other astringent vegetables, con-
taining gallic acid, rendered black by sulphate of iron, and
thickened by the addition of little gum or figar. This
composition, however, is liable to fade; but since the dis-
covery of the method of totally discharging the traces of
common ink by the application of the oxidized muriatic
acid, more serious confquences are to be apprehended from
the unferable use of the common amontaneous fluid, than
the decay of its colour from age; for it is well known that,
while the sulphate of iron remains on the paper, the colour
of the writing may be restored by washing the MS. with
fresh infusion of galls. We have several receipts in Nichol-
son's Philosophical Journal, vol. iv. p. 479, 480, for com-
posing ink capable of refilling the oxidized muriatic
acid.

Macquer, in the Chemical Dictionary, gives the follow-
ing receipt for making good ink. In four French pints of
common water or beer, let a pound of bruifed galls be in-
fused twenty-four hours without boiling; to this add fix
ounces of gum arabic; and when the gum is dissolved, fix
ounces of green viotril, which will soon give it the black
colour; the liquor is then to be strained through a hatt-
ieve.

The following method has been recommended by expe-
rience, and is easily and speedily practiced. To a gallon
of boiling water, put fix ounces of blue galls, grossly pounded,
and three ounces of copperras; flir the mixture well to-
gether, and then add fix ounces of gum arabic pounded.
After flirring the whole thoroughly, leave it to settle, and
the next day strain it off from the drags for use. See Its
lites palustris.

The following composition will make a very good black
writing ink. Take a gallon of soft water, and boil it in a
pound of chips of logwood for about half an hour; pour
the decoction boiling hot on a pound of the best Aleppo
galls powdered, and two ounces of pomegranate peels, put
into a proper vessel. After having flirred them well to-
ger with a wooden spatula, place them in the sun shine in
summer, or within the warmth of any fire in winter, for
three or four days, flirring the mixture occasionally; then
add half a pound of green viotril powdered, and let the
mixture remain four or five days more, occasionally flir-
ing it; and then add four ounces of gum arabic dissolved
in a quart of boiling water; and after the ink has settled,
strain it off through a coarse linen cloth, and keep it well
stopped for use.

Mr. Deval in his "Treatise on Colours," p. 37, in-
forms us, that with an infusion of galls and iron filings,
he had not only made an exceedingly black and durable ink,
but by means of it, without the addition of any acid, dyed
filk and woollen cloth of a good and failing black. But
this kind of ink, though the colour is far superior to that
of any other, may be easily discharged, either by the smallnest
quantity of any acid, or even by simple water; because it doth
not penetrate the paper in such a manner as is necessary to
preserve it from the infantaneous action of the acid or of
the water. During the action of the intution of galls upon the
iron in making this kind of ink, a very considerable effec-
tiveness takes place, and a quantity of air is discharged,
the nature of which has not yet been examined.

Many of the more volatile kinds of oil may be used in writing,
if reduced to a proper consistence by the addition of gum or
refin. Tolerable ink may be made by dissolving 30 grains of
common refin in 90 grains of oil of turpentine, and tem-
ppering the solution with 171 grains of lamp-black, and 24 of
indigo. In a dry flat, this composition refils the action of
water, but not of spirit. Copal is much superior to refin;
it will diffuse in only few liquids. It may be dissolved,
however, in oil of lavender. The only inconvenience at-
tending the use of copal in the composition of ink is, that it
is soluble at a low temperature. Ink may be composed of
oil of lavender, copal, and lamp-black in the manner fol-
lowing: Take oil of lavender 200 grains, copal, in powder,
23 grains, and lamp-black from 2 to 3 grains. With the
alliance of a gentle heat, diffuse the copal in the oil of
lavender in a small glass phial, and then mix the lamp-black
with the solution upon a marble slab, or other smooth sur-
face. Put the composition into the bottle, and keep it from
the air. After the repose of some hours, the ink must be
well
INK.

well shaken, and stirred with a piece of wine before it is used; if it be too thick, it must be diluted with a little oil of lavender, oil of turpentine, or alcohol. The facility of writing with this composition depends much on the quantity of the colouring matter. Nichollson's Journal, vol. ii. 8vo.

As the duration of records, and other valuable writings, depends much on the goodness of the ink employed, Dr. Lewis has thought this subject worthy of his attention. The chief imperfection of common inks is, that they decay in time, and at last the writing becomes invisible. From experiments made by that author, he infers, that the decay of inks is chiefly owing to a deficiency of galls; that the galls are the most perishable ingredient, the quantity of which, which gives the greatest blackness at first (which is about equal parts with the vitriol) being insufficient to maintain the colour; that for a durable ink, the quantity of galls cannot be much less than three times that of the vitriol; that it cannot be much greater without lefening the blackness of the ink; that by diminishing the quantity of water, the ink was rendered blacker and more durable; that distilled water, rain water, and hard spring-water, had the same effects; that white wine produced a deeper black colour than water; that the colour produced by vinegar was deeper than that by wine; that proof spirit extracted only a reddish-brown tinge, and rectified spirit a paler green; that the last mentioned tinctures funk into, and spread upon the paper; and hence the impropriety of adding spirit of wine to ink, as is frequently directed, to prevent mouldiness or freezing; that other astringents, as oak bark, billot, rose-bark, &c. were not so effectual as galls, nor gave so good a black, the colour produced by moll of thee, excepting oak-bark, being greenish; that the juice of sallows did not produce a black colour with martial vitriol; but that, nevertheless, the writing made with it became black, and was found to be more durable than common ink; that inks made with saturated solutions of iron in nitrous, marine, acetic, balsamic, tartar, or in lemon juice, were much inferior to the ink made with martial vitriol; that the colour of ink was depraved by adding quicklime, which was done with an intention of destroying any of the animal acid which might be supposed to be the cause of the loss of the colour of the ink; that the bell method of preventing the effects of this superabundant acid is probably by adding pieces of iron to engage it; and that this conjecture was confirmed by an instance the author had heard, of the great durability of the colour of an ink in which pieces of iron had been long immersed; and lastly, that a decoction of logwood used instead of water, feebly improved both the beauty and deepness of the black, without dispoothing it to fade. The same author observes, that the addition of gum arabic is not only useful, by keeping the colouring matter suspended in the fluid, but also by preventing the ink from spreading, by which means a greater quantity of it is collected on each stroke of the pen. Sugar, which is sometimes added to inks, was found to be much less effectual than gums, and to have the inconvenience of preventing the drying of the ink. The colour of ink is found to be greatly injured, by keeping the ink in vessels made of copper, or of lead, and probably of any other metal except iron, which the vitriolic acid can dissolve. The foregoing experiments point out for the bell proportions of the ingredients for ink; one part of green vitriol, one part of powdered logwood, and three parts of powdered Aleppo, or blue galls. The bell menstruum appears to be vinegar or white wine, though for common use water is sufficient. If the ink be required to be of a full colour, a quart, or at most three pints, of liquor may be allowed to three ounces of galls, and to one ounce of each of the other two ingredients. Half an ounce of gum may be added to each pint of the liquor; though the more gum we can employ, the more the vitriol and galls are rendered blacker. The ingredients may be all put together at once in a convenient vessel, and well shaken four or five times daily. In ten or twelve days the ink will be fit for use, though it will improve by remaining longer on the ingredients; or it may be made more expeditiously, by adding the gum and vitriol to a decoction of galls and logwood in the menstruum. To the ink, after it has been separated from the feculencies, a course powder of galls, from which the fine dust has been sifted, together with one or two pieces of iron, may be added, by which its durability will be secured.

It has been often remarked, says the same ingenious writer, that the inks used in former times were far more durable than those of later years; many modern records being more decayed than manuscripts of much greater antiquity, of which we have instances in the Letters of Camillo Pa- derni, published in the Philosophical Transactions for 1753 and 1754. Dr. Lewis made several experiments, in order to recover the composition of this durable ink. Instead of oil which is used in the printers' ink, he mixed both lamp-black and ivory-black with a solution of gum arabic; this liquor wrote of a fine black colour, but when dry, it rubbed off entirely by moisture. Concluding, therefore, that the colour could not be sufficiently fixed on paper without an oil cement, and as oils are made miscible with watery fluids by the intervention of gum, he mixed some of the fatter printers' varnish with about half its weight of a thick mucilage of gum arabic, working them well together in a mortar, and beat this mass with lamp-black, adding water by little and little, and continuing the rubbing, till the mixture became of a due consistence for writing. This produced characters of a dull brownish black colour, which could not be discharged by rubbing, nor washed off readily as the foregoing. Instead of the printers' varnish, or boiled oil, linseed-oil was mixed in the same manner with mucilage and lamp-black, and the mixture diluted with water; and the ink thus obtained was much the same as the other. To prevent the discharge by water, some of the more lasting kinds of paper, or common paper made damp as for printing, must be used, which will admit the ink to sink a little into its substance; and thus the characters will be as fixed as can be desired. Such Dr. Lewis found to be the ancient inks, that were so durable. Pliny and Vitruvius expressly mention the preparation of lamp-black, and the composition of writing ink from lamp-black and gum. Dioclesides sets down the proportion of three ounces of the foot to one of gum. This mixture was formed into cakes or rolls, and dried in the sun, which were occasionally tempered with water, as the Indian ink is with us for painting. The ancients were sensible that these inks were liable to be discharged by water, and endeavoured to obviate this imperfection, according to Pliny, by using vinegar, instead of water, for tempering the mixture of lamp black and gum, which promotes the sinking into the paper. After all, none of these inks can be discharged otherwise than by design; which is the case more with respect to the vitriolic inks, and those of printed books and copper-plates.

In the course of Dr. Lewis's experiments, a farther improvement occurred to him, which was that of using the common vitriolic ink, instead of water, for tempering the ancient mixture of gum and lamp-black. By this method the writing will have the durability of those of former times, with all the advantage that results from the vitriolic ink fixing itself in the paper. Common writing ink may, in many
INK.

many cafes, be improved by a small addition of the ancient composition, or of the common Indian ink. Lewis's Commerce of Arts, &c. § 16.

Mr. Affle, in his "Origin of Alphabetical Writing," indicates the necessity of making ink durable; and for this purpose suggests a comparison of the rolls and records that have been written from the 15th century to the end of the 17th, with the writings that remain from the 5th to the 12th centuries. These are in excellent preservation; but the former, though of more modern date, are defaced to such a degree that they are scarcely visible. Mr. Affle agrees with Dr. Lewis in the opinion, that the ancient inks were composed of foot or ivory ink instead of the galls, copperas, and gums, which form the composition of ours. Besides their black ink, the ancients used various other colours, as red, gold, and silver, &c. Green ink was frequently used in Latin MSS., especially in the latter ages: and it was frequently employed in signatures by the guardians of the Greek emperors till their wards were of age. Blue or yellow ink was seldom used except in MSS., but, according to Mr. Affle, the yellow has not been much in use for these 600 years. Some kinds of characters, particularly the metallic, were burnished. Wax was used by the Latins and Greeks as a varnish, especially by the former, and particularly in the 9th century. This continued a long time in vogue. Dr. (Sir Charles) Blagden, in the Phil. Trans. vol. Ixxvii. p. 451, &c. has proposed a new method of recovering the legibility of decayed writings. With this view he made some experiments on parchment and vellum MSS., with which he was furnished by Mr. Affle, employing those chemical re-agents which seemed best adapted to his purpose, viz. alkalis, both simple and phlogisticated, the mineral acids, and infusion of galls. The general result showed, that the ink anciently used, at least in these MSS., was of the same nature as the present; and the greater durability of the more ancient inks appeared to depend very much on a better preparation of the material upon which the writing was made, viz. the parchment or vellum. He suspected, however, that the ancient inks contained a rather higher proportion of iron than the more modern; and perhaps more gum was used then, or possibly they were washed over with some kind of varnish, though not such as gave any gloss. It occurred to our author, in the course of his experiments, that perhaps one of the best methods of restoring legibility to decayed writings might be to join phlogisticated alkali with the remaining cals of iron. In order to bring this idea to the test, he made several experiments, for which we refer to his paper, ubi supra. The method now commonly practised to restore old writings is the wetting of them with an infusion of galls in white wine. This has certainly a great effect: but, like the phlogisticated alkali, it is apt to stain the substance in which the writing was made. Sir Charles Blagden suggests, that a phlogisticated alkali, better adapted to this purpose than the common, might be prepared, by rendering it as free as possible from iron, diluting it to a certain degree, or substituting the volatile alkali for the fixed. This would serve to bring out a prodigious body of colour upon letters which were before so pale as to be almost invisible, and it would be preferable to the infusion of galls in this respect, that it produces its effect immediately, and may be confined to those letters only for which such affinities are wanted.

In the "Monthly Review" of the volume of Transactions above cited, the following method is proposed for preventing ink from decaying. It consists in washing over the paper on which the writing is to be made with the colouring matter of Prussian blue; and by writing upon it afterwards with common ink, a ground of Prussian blue is formed under every stroke; which will remain strong after the black has been decayed by the weather, or destroyed by acids. The ink will thus bear a larger proportion of vitriol at first, and will have the advantage of appearing blacker when first written.

INK Powder may be prepared, by infusing a pound of galls powdered, and three ounces of pomegranate-seeds, in a gallon of hot water for a week, in a gentle heat; and then draining off the fluid through a coarse linen cloth. Add to it eight ounces of vitriol dissolved in a quart of water, and let them remain for a day or two; preparing in the mean time a decoction of logwood, by boiling a pound of the chips in a gallon of water, till one-third be wasted, and then draining the remaining fluid while it is hot. Mix this decoction and the solution of galls and vitriol together, and add five ounces of gum arabic, and then evaporate the mixture over a common fire to about two quarts; when the remainder must be put into a vessel proper for that purpose, and reduced to dryness in balneis Mariae, i.e. by hanging the vessel in boiling water. The remaining mafs, after the fluid is wholly exhaled, must be well powdered; and when it is wanted for use, may be converted into ink by the addition of water.

A portable or extemporaneous ink may be made without galls or vitriol, by mixing half a pound of honey and the yolk of an egg, adding two drams of gum arabic finely levigated, and thickening the whole with lamp-black to the consistence of a stiff paste; which being put to a proper quantity of water, may be used as an ink.

INK, Indian, or Chinea, is an admirable composition, in vain attempted to be imitated in Europe. It is not fluid, like our writing inks, but solid, like our mineral colours, though much lighter. They make it of all figures, but the most useful is rectangular, about a quarter of an inch thick. Some of the flicks are gilt with figures of dragons, birds, flowers, &c. In order to do this, they have little wooden moulds, so curiously wrought, that we could hardly equal them in metals.

To use this ink, there must be a little hollow marble, or other stone, with water in it, on which the flick of ink must be ground, till the water becomes of a sufficient blackness. It makes a very black shining ink; and though it be apt to ink when the paper is thin, yet it never runs or spreads; so that the letters are always smooth, and evenly terminated, however ever so thick. It is of great use in designing, because it may be weakened or diminished to any degree; and there is abundance of things which cannot be represented to the life without it.

From an analysis of this ink, Dr. Lewis concludes that it contains an animal substance soluble in water, and consists of a black powder, mixed with some animal glue. He tried to imitate it, by mixing some lamp-black, prepared from linseed-oil, by hanging a large copper pan over the flame of a lamp to receive its smoke with as much melted glue as gave it sufficient tenacity for being formed into cakes. These cakes, when dry, answered as well as the genuine Indian ink, in regard both to the colour, and the freedom and smoothness of working. Ivory black, and other charcoal blacks, being very fine, had the same effect with the lamp-black. It appears from three receipts for the preparation of Indian ink, in Du Halde's History of China, that the colouring material is lamp-black, to which is added, in one of them, a quantity of horse-hoofs, burned till the smoke ceases. The conglutinating matter, in one of the prescriptions, is a thin slice of neat's leather; in another, a solution of gum tragacanth, and in the other, a mixture of size, with a decoction
coction of certain vegetables, unknown to us. Du Halde observes, that the Chinese have inks of different goodness and price; that the most efficient difference proceeds from the quality of the lamp-black, and that the bell is the foot of oil, burnt in lamps, in apartments fitted up for this purpose.

The Chinese have often attempted to use this in their porcelain, to give the colour of black to the figure traced on white vessels, but it has been a vain attempt; for however beautiful and strong the figures might appear when first laid on, and even when the vessels were dried, it all disappeared on the baking, and they came out quite white as they were put in. The colours for this use must be such as can penetrate the varnish, and endure the fire. Mineral colours are found to have these qualities, and these alone therefore are to be employed; such light ones as this black burning off from the surface, and wholly disappearing. Obf. sur les Coustumes de l'Afie, p. 329.

Ink is also an appellation given to any coloured liquor used in the same manner as black ink; as red, green, blue, yellow, &c. Inks. Red writing ink is prepared by infusing a quarter of a pound of the raspings of Brazil wood for two or three days in vinegar; boiling the infusion for an hour over a gentle fire, and afterwards filtering it, while hot, through paper laid in an earthen cylinder; then put it again over the fire, and diffuse in it, first, half an ounce of gum arabic, and afterwards alum, and white fugar, of each half an ounce. Red ink may be also made of vermilion, by heating together the gruel of four eggs, a tea-spoonful of white fugar, or fugar-candy, powdered, and as much spirit of wine, till they be of the consistence of oil; then adding such a proportion of vermilion as will produce a red colour of sufficient strength; the mixture should be kept in a small phial, or well-lost ink bottle, and well shook before it be used. Gum-water is often used instead of the gruel of eggs, but thin size made of singlafis, with a little honey, is much better for the purpose. Red ink may be made by tempering the solution of copal with red sulphuret of mercury, e.g. take of oil of lavender, 120 grains, copal, 3 grains, and red sulphuret of mercury, 60 grains, dissolve the copal in the oil, and then mix the sulphuret with the solution upon a smooth surface. This, and also the black ink made with copal, poises a permanent colour, and other essential properties of the ink used in printing. The oil of lavender being dissipated with a gentle heat, the colour is left on the paper surrounded with copal, a substance insoluble in water, in spirits, in acids, or in alkaline solutions.

For red printing ink, see PRINTING.

Green ink may be made, by putting an ounce of powdered verdigris to a quart of vinegar, and straining the fluid, after it has stood two or three days; or, instead of this, the crystals of verdigris dissolved in water will answer the purpose; then diffuse in a pint of either of these solutions, five drams of gum arabic, and two drams of white fugar.

Blue ink is made by grinding indigo with honey and the white of eggs, and making it fluid with water.

Yellow ink is made by an infusion of saffron in water, with a little alum and gum arabic; or, by boiling two ounces of Avignon, or French berries, in a quart of water, with half an ounce of alum, till one-third of the fluid be evaporated, and then dissolving in it two drams of gum arabic; and one dram of fugar, and afterwards a dram of powdered alum.

In general, inks of all colours may be made by using a strong decoction of the ingredients used for dying, mixed with a little alum and gum arabic. See the several colour Blues, Green, &c.

Inks, Sympathetic, or Secret. Every sort of liquor with which a person may write, so that the letters do not appear till there is some particular means used to give them a colour different from that of the paper, is called by the name of sympathetic ink; and of this there are a great many kinds described in the writings of Baptista Porta, L Secomy, and other authors.

All these inks may be regularly distributed into different classes, according to the different means which are to be used to make them appear; and these are in general the four following. 1. By giving a new liquor, or the vapour of new liquor, a place on the paper, on which the letters are written with the natural invisible ink. 2. By exposing the paper to the air, by which means the letters at first invisible will appear. 3. By puffing gently over the letters a matter of some remarkable colour reduced to fine powder. And 4. By exposing the paper to the fire.

This last is by much the best method, and is so general, that it may be prudently used to all papers suspected of containing any secret writing, as it seldom fails to discover it. All the common inks of this kind, however, when they have been once made to appear, either by fire or by any other method, can never be made to disappear again; but there is one kind described by Mr. Hellelt, in the Memoirs of the Academy of Sciences at Paris, and since tried many times with us, and elsewhere, which, though the letters it gives are in themselves invisible, and appear like those of some other of these inks, on their being held to the fire, yet they after that will fade and disappear on the paper again, and may be reproduced in this manner several times. This, therefore, is the first known ink of a fifth general class, of which future researches may discover perhaps more.

Of the first class of sympathetic inks, or those which do not appear till the paper on which they are written be made to imbibe another liquor, or the vapour of another liquid, are the following kinds.

To two or three parts of unflaked lime put one of yellow orpiment; powder and mix the two, adding fifteen or sixteen times as much water as there was orpiment; drop up the phial with a cork and bladder, and let it in warm embers; shake the phial now and then for five hours, and carefully decant the clear part, or rather filtrate it. In the room of this preparation may be used a saturated solution of common brimstone, made by boiling the brimstone either with quicklime, or in strong alkaline ley. In the mean time, burn a piece of cork thoroughly, and when well inflamed, quench it in common water, or rather in brandy. Being thus reduced into a friable coal, grind it with fair water, wherein gum arabic has been dissolved; and it will make a liquor as black as the common ink.

While these are doing, dissolve, in three times as much distilled or strong vinegar, over warm embers, a quantity of red lead, or of faccharum saturni, in thrice the quantity of water, for three or four hours, or till the liquor have a sweet taste. This liquor will be as clear as common water. Solutions of lead in aquafortis answer the same end, except that, when written with, they are apt to corrode the paper.

The liquors thus prepared, write any thing on paper with this lait fort, dry it, and nothing will appear. Over the place, write what you please with the second liquor: it will appear as if written with common ink: when dry, dip a small piece of rag or sponge, in the first liquor, rub it over the written place, and the black writing will vanish; and that wrote with the invisible ink will appear black and legible.
Again, take a book four or five inches thick, and on the first leaf write any thing with the half liquor; turn to the other end of the book, and rub there with a rag, dip in the half liquor, on that part, as near as you can guess, opposite to the writing, and leave also the rag there, clapping a paper over it; then nimbly shutting the book, strike four or five smart strokes thereon with your hand, and turning the other side uppermost, clap it into a press, or lay it under a good weight for a quarter of an hour, or even half that time; then will the writing done with the invisible ink be found legible there.

The above operation may be varied by writing the invisible characters with the solution of bismuth in nitrous acid, and exposing them to the vapours of liver of sulphur, or moistening them with a solution of liver of sulphur.

Dissolve white or green vitriol in water, and writing with the solution, nothing will appear. Boil gall in water, and dip a linen rag in the decoction, and with it rub the place before writ, and it will appear black and legible. Rub it over again with spirit of vitriol, or its oil, and the writing will disappear again; rub it over again with oil of tartar per dilution, the letters will appear again, but of a yellow colour. If the blackness of ordinary ink be destroyed by a sufficient quantity of nitrous acid, the writing made by it will remain invisible till it be moistened with liquid fixed alkali.

The golden sympathetic ink.—This is made by dissoloving in aqua regia as much gold as that menstruum can take up, and then adding to the liquor five or six times as much water; in another vessel there must be some tin dissolved in aqua regia; and when that menstruum has also taken up as much of the metal as it can, there is to be added to it an equal quantity of common water. The letters must be written on white paper with the solution of gold, and the writing being dried in the shade, the letters will not appear, at least not for seven or eight hours afterwards; dip a pencil in the solution of tin, and rub that over the solution of gold with which the letters were written, and they will appear of a beautiful purple. It might be supposed, that any other metals which were soluble in the same acid menstruum would equally produce this effect; but experiment shows, that this is not the case; and silver and copper, though both soluble in aqua regia, yet produce no change of colour by these precipitations made by mixing the solutions of them on paper; and this example of such an effect in the solutions of gold and tin, is an exception to the general rules in the solutions of metals, and their effects on one another.

The purple colour of these letters may be again effaced by rubbing some simple aqua regia over the paper, and may be made to appear again by rubbing over that the solution of tin. Kunkel, Caffius and Ofschal, with some other writers, made the first steps towards this discovery, by their attempt to give crystall, by means of gold, the colour of the oriental rubies. There are, beside these mineral preparations, some vegetable ones, which give the same phenomena, but these are the more certain.

Of the second kind of sympathetic inks, or those which appear on being exposed only to the air, is the golden ink made by adding to a solution of gold in aqua regia, so much water that the liquor shall not stain a white paper; letters written with this will not appear till the paper has been exposed some hours to the open air, and they will then begin to acquire a colour by degrees, till they at length become of a deep violet colour, tending to black. If, instead of exposing the paper to the air, it be kept in a box close shut up, or closely folded in another paper, it will remain invisible two or three months; but at the end of that time it will begin to appear, and will by degrees become of a deep violet colour. So long as the gold remains united to its dissolvent, it is yellow; but the acid that dissolves it being of a volatile nature, the greater part of it evaporates, and leaves no more than is just necessary to colour the calx of gold which remains upon the paper.

The second of these is the silver ink, made by a solution of silver in aquafortis, weakened by distilled water, till it will not stain the paper. Letters written with this will be invisible for three or four months, if stint up in a box; but if they be exposed to the sun, they become legible in about an hour, because by this means the evaporation of the acid is accelerated. The letters written with this ink are of a slate colour; and that from the fulphurous nature of the aquafortis, every thing that is fulphurous blackening ink. This black subsidiary colour, however, is not permanent; for the fulphurous part finally evaporating, the letters are left to their natural appearance, and are of a fine true silver colour, if the silver that was used was fine, and the place open.

In this class there may also be placed several metallic dissolutions; as that of lead in vinegar, and of copper in aquafortis, which give at length a brownish colour upon the paper; as also the solution of tin in aqua regia, of mercury in aquafortis, of iron in vinegar, of emery and several of the pyrites in spirit of salt. But all these, though they give letters which are after some time legible, on being exposed to the air, are also made to appear instantly on the paper, holding them to the fire. Each of these solutions gives its own particular colour; but they have all this disadvantage, that in time they eat away the paper, and the letters are seen in the shape of so many holes.

Of the third class of inks, or that which appears on rubbing over the paper with a brown or black powder, are almost all the glutinous expressed juices of plants, which are themselves of no remarkable colour, the milk of animals, or any other thick and viscous fluids. To use these, the letters must be written on a white paper, and when dry, there is to be thrown over them the fine powder of any coloured earth, or other such substance; and the writing will afterwards appear coloured, because its viscous quantity remains sufficiently in it for the entangling and retaining this fine powder, though it falls easily off from every other part of the paper.

Mem. Acad. Science, Par. 1757.

Among the methods which Ovid teaches young women to deceive their guardians, when they write to their lovers, he mentions that of writing with new milk, and of making the writing legible by coal-dust, or foot.

"Tuta quoque efl, fallitque oculos, e ludo recenti
Littera: carbonis pulvere tange: leges."

De Arte Amandi, L. iii. v. 619.

Aubonius proposes the same means to Paulinus, and he afterwards teaches other methods of secreting writing. Auct. Epist. xxvii. p. 21, &c. Eneas, in Puliscrotica, cap. 37, and Gallius, lib. xvii. cap. 9, mention the like. Pliny, lib. xxxvi. cap. 8. mentions the milky sap of certain plants for a similar purpose.

Of the fourth class, or those inks which become visible on holding them to the fire, there are a vast number; and indeed all infusions, the matter of which is readily burnt to a fort of charcoal by a little fire, will answer this purpose. The need of this kind is the salt ammoniacal ink, made by dissolving a scruple of salt ammoniac in two ounces of fair water. Letters written with this solution are invisible on the paper, till it is held before the fire, or has an iron
INK.

iron a little heated paffed over it. The rationale of this is, that the inflammable part of the sal ammoniac is burnt to charcoal by a heat which is not sufficient to scorch the paper; and this is the case with all the rest of these clafs. The letters written with this solution are, however, of no great duration; for the salt being apt to moisten in the air, the letters foon spread, and run together in a confusing manner.

Dr. Lewis says, that all the salts which he has tried produce this effeet in a greater or lefs degree; nitre, alum, tartar, very weakly; fea-falt more strongly; fixed alkaline salts still more so; but sal ammoniac the strongest of all. Metallic solutions, made in acids, and diluted fo as not to corrode the paper, act in the fame manner. The juice of lemons and milk have also been used as sympathetic inks, the writing with which appears upon the application of heat sufficient to decompose the oily and mucilaginous parts of these liquors.

The fifth clafs of sympathetic ink contains only one yet known kind.

This, though in itself invisible, becomes of a blue-feet green when held to the fire; and this colour disappears again as the paper cools, and is to be produced again on holding it again to the fire; and this for a long time, and a repeated series of trials. It may also, according to the different manner of treating it, be made to appear blue, green, yellow, red, and fome other colours. This property of the tingling matter of bismuth ore was published at full length by a German lady, in 1705.

A certain German chemifl fhowed the academy at Paris a falt of rof-water, which became blue on holding it to the fire, and at the fame time fowed the ore from which he procured the falt, which he called an ore of marfaife, a name given by many to the bismuth ore. He added, that this was the mineral from which the fine blue fmal of Sneebough was prepared, and that no other ore but this afforded it, and that he made the tingling from this mineral with aquafortis, which he fixed with sea-falt.

This was the substance of what the German declared, and from what Mr. Hellot, in 1736, took the hint for his discovery of this remarkable ink. The falt was, after many experiments, at length found to be produced from an arfenic ore; and it was found, that all the cobalts and ores of bismuth afford a tingling capable of these changes by fire.

The method of preparing it is this: pour upon two ounces of arfenic ore, grofsly powdered, a mixture of five ounces of aquafortis, and five ounces of common water. After the firft effusion is over, place the veftiil in a gentle band-heat, and let it stand there till no more air-bubbles be left; and after this increase the fire, so as to make the liquor boil for about a quarter of an hour; after this the liquor will become of a reddish colour, and when cold it is to be decanted clear off from this fediment into a phial; and after standing in that fame time, it is to be again decanted off from what is precipitated there; and so on for three or four times till it is quite clear; for it must not be filtered, left the acid fhou'd take fomething from the paper that might spoil the effects. When the liquor is clear, there must be added to it two ounces of white sea-falt; this mixture is to be evaporated over a gentle band-heat, till there remains only a dry fmal fubsfance. When the liquor is grown hot, it changes from its orange colour to a fair red; and when the a"eous humidity is evaporated, it becomes of a beautiful emerald colour, and from this, as it dries up, it changes by degrees to a dirty green, like that of verdigris in the cake. As it becomes nearly dry, it must be fiftred about with a glafs rod or peiltte, to keep it from uniting into a mass; and it must not be kept over the fire till perfectly dry, because by that means the colour is often loft, and the falt from green becomes of a dusky yellow; but if it be taken from the fire while it is green, it gradually becomes reddifl as it cools, and fnally is of a rofe-colour. The manner of using this sympathetic ink is this: write with it on a fine and smooth paper, or draw with a black-lead pencil the figure of a plant or tree on the paper; then trace over the fame lines with this liquor; let it dry in the open air, and then rub off the black lines with bread, and the paper will appear altogether fir. though the lines made by the ink are in reality fink deep into it. On holding this paper to the fire the lines will all appear, and the figure of the plant or the letters will be painted in a beautiful blue-feet green, which will continue fo long as the paper is warm; but when it is cold again, they will wholly disappear. The lines, therefore, disappear much sooner in winter than in summer; and in very hot weather it is often neceffary to lay the paper on a marble, or other very cold body, in order to produce this effeet. At any time, if the paper be fcorched in the experiment, the colour of the lines will not disappear again, even if ice be laid upon them. If the writing be exposed for three or four days to a humid air, the lines will appear of a fine pale red. If the impregnation of the ore of bismuth, instead of sea-falt, have alum added to it, and the whole proccs be continued as before defcribed; and if letters be written with the red liquor as it is taken out of the veftiil, the letters will not appear even on holding it to the fire; but if the paper be wetted over with a clear folution of marine falt, and then left to dry, and afterwards held to the fire, the letters will appear blue. The fame alfo will be the effeet, if the writing be exposed to the vapour of hot spirit of falt. When this preparation is thus made with alum, instead of common falt, the liquor never becomes green, but continues red, and never changes colour in the drying, or afterwards. The green colour seems to be wholly the effeet of the sea-falt; for not only this aluminous impregnation, but others in which other salts had been employed, were always found to be of a different colour.

Glauber's falt, used instead of common sea-falt, left the mafs red in the fame manner as alum did. Nitre added, instead of sea-falt, gave the precipitate or dried falt a beautiful purple colour, which became white on the infant that water was poured upon it, and a role-coloured tingling was drawn from it, which gave lines or letters on paper, which continued invisible as long as they were cold, but assumed a beautiful red on holding the paper to the fire; which colour they retained no longer than while the paper continued warm, disappearing afterwards in the fame manner with the green colours made by the sea-falt; and if a pale solution of sea-falt be rubbed over the paper, and suffered to dry, and the paper be afterwards heated, the lines appear blue. Borax has the fame effeet in this preparation with the nitr; All thefe experiments were made with the neutral fals; but in order to try what would be the effeets of alkalis in the mixture, Mr. Hellot added to three ounces of the impregnation of the ore in aquafortis, pure falt of tartar, till the effuilion ceafed; but the confequence of this was no great precipitation, but merely the forming of a small white fediment; this mixture being evaporated nearly to a dryness, the remaining falt, so long as it was warm, appeared of a beautiful purple; but this became papery as it dried, and turned white in an infant on pouring...
ing water upon it. This dissolved in water, in the manner of the others, gave lines on paper of a faint rose-colour, which appeared or disappeared in the manner of those made by the other solutions, according as the paper was hot or cold; and the wetting of the paper with a solution of sea-salt, had the same effects on this as on the others, making the lines appear blue on holding to the fire. Mem. Acad. Par. 1737. See Colours from Metals.

The ink may be easily made by digesting zaffre, commonly used by druggists, in aqua regia; and thus is obtained the soluble part of zaffre, which is the calx of cobalt. This solution is then to be diluted with a little common water. In expelling the paper written with this solution to the fire, care must be taken not to heat it too much; for in this case, the writing will not again disappear by exposure to cold. This ink, say: Macquer, the author of the Chemical Dictionary, may be applied to the drawing of landscapes, in which the earth and trees constitute of verdure, being drawn with common ink, give a prospect of winter; and which may be made to assume the appearance of spring, by exposure to a gentle heat, which covers the trees with leaves and the earth with grass, by rendering visible those parts of the landscapes which are drawn with this sympathetic ink; and, as the solution of regulus of cobalt or zaffre in spirit of nitre acquires a reddish colour by the application of heat, the red solution might be contrived to represent the fruits and flowers.

Inlagation, Inslagation, a reddening of one outlawed to the protection of the law and benefit of a subject.

The word comes from the Saxon inlagium, i.e. inlagare.

Terms of Law.

Inlach, Inslagatus, he that is of some frank-pledge, and not outlawed. It seems to be the contrary to unlagh.

Inland implies any thing situate in the main land, or heart of a country, far from the sea-coasts.

Hence inland bills, in traffic, are such bills as are payable in the same land, wherein they are drawn. See Bill.

Inland Navigation, is applied to the passage of boats, barges, and vessels on canals and navigable rivers, within a country, to distinguish it from navigation, properly so called, by means of ships on the open seas or the largest of the lakes. No country in the world can vie with the British islands at the present day, for the extent and importance of their artificial inland navigation or Canals, under which article we have given a connected view of these, and of the navigable rivers and railways, forming altogether a system of improved communication no where to be equalled; and yet nearly the whole of them originated and were completed by individuals without the assistance of the state. See also the names of the several canals, rivers, &c. for further information.

Inlaying. See Veneering, Mosaic, and Marquetry.

Inleased, in our Old Writers, signifies entangled or ensnared. It is used in the champion’s oath. 2 Inst. 247. Blount.

Inlets, Bay of, in Geography, a bay on the coast of New Holland, so called by Cook, in June 1770, lying between cape Palmerston and Cape Townshend.

INLI, a town of Corea; 45 miles W. of Hoang-tcheou.

Inlisting, in a Military Sense. See Listing.

INMATES, such persons as are admitted, for their money, to live in the fame house or cottage with another man, in different rooms, but going in at the same door; being usually fupposed to be poor, and not able to maintain a whole house themselves. These are inquirable in a court-leet.

No owner or occupier of a cottage shall suffer any inmates therein, or more families than one to inhabit thereon, on pain of forfeiting 10s. per month to the lord of the leet.

INN, in Geography, a river which rises in the country of the Grifons, about 13 miles S.W. of Zul, and runs into the Danube near Papal.—Alto, a river of Austria, which runs into the Danube near Efferding.

INN, a place appointed for the entertainment and relief of travellers.

Inns are licensed and regulated by justices of the peace, who oblige the landlord to enter into recognizances for keeping good order. See Allhouses.

If a person who keeps a common inn refuses to receive a traveller into his house as a guest, or to find him victuals and lodging, on his rendering him a reasonable price for them, he is liable to an action of damages, and may be indicted and fined at the king’s suit. (1 Vent. 333.) By the yearly acts against mutiny and desertion, the constable, and in his default a justice of the peace, may quarter soldiers in inns, livery-stables, ale-houses, and victualling-houses. The rates of all commodities sold by innkeepers, according to our ancient laws, may be allowed; and innkeepers not selling their hay, oats, beans, &c. and all manner of victuals, at reasonable prices, without taking any thing for litter, may be fined and imprisoned, &c. by 21 Jac. I. c. 21. Where an innkeeper harbours thieves, persons of infamous character, or such as juries in his house, or sets up a new inn where there is no need of one, to the hindrance of ancient well governed inns, he is indictable and finesable; and by statutes such inn may be suppressed. (1 Hawk. P. C. 335.) Action upon the case lies against any innkeeper, if a theft be committed upon his guest by a servant of the inn, or any other person not belonging to the guest; though it is otherwise when the guest is not a traveller, but one of the same town or village; for in that case the innkeeper is not chargeable; nor is the master of a private tavern answerable for a robbery committed on his guest. It is said that even though the travelling guest does not deliver his goods, &c. into the innkeeper’s possession, yet if they are stolen he is chargeable. An innkeeper is not chargeable for any thing out of his inn, but only for what is within it; yet where he of his own accord puts the guest’s horse to graze, and the horse is stolen, he is answerable; he not having the guest’s orders for putting such horse to graze. The innkeeper may justify Roping the horse, or other things of his guest, for his reckoning; and may detain the same until it be paid. Where a person brings his horse to an inn and leaves him in the stable, the innkeeper may detain him until such time as the owner pay for his keeping; and if the horse eats out as much as he is worth, after a reasonable appraisement made, he may fell the horse and pay himself. But when a guest brings several horses to an inn, and afterwards takes them all away, excepting one, this horse so left may not be sold for payment of the debt of others; for every horse is to be sold, only to make satisfaction for what is due for his own meat.

Any person found tippling in an inn, is adjudged within the statutes against drunkenness; and innkeepers, or ale-house-keepers, permitting tippling in their houses, are liable
INN

To the penalty of 10s. &c. by 1 Jac. cap. 9. 1 Car. cap. 4.

INNS. Our colleges of municipal or common law professors and students, are called inns: the old English word for houses of noblemen, bishops, and others of extraordinary note, being of the same signification with the French word boul.

INNS of Court are so called, as some think, because the students there are to serve and attend the courts of judicature; or else, because anciently these colleges received none but the sons of noblemen, and better sort of gentlemen, who were there to be qualified to serve the king in his court; as Fortescue affirms. And in his time he says there were about two thousand students in the inns of court and chancery, all of whom were filii nobilium, or gentlemen born. But this custom has gradually fallen into disuse; so that in the reign of queen Elizabeth, Sir Edward Coke does not reckon above a thousand students, and the number at present is very considerably less; for which judge Blackstone assigns the following reasons: 1. Because the inns of chancery being now almost totally filled by the inferior branches of the profession, are neither commodious nor proper for the rest of gentlemen of any rank or figure; so that there are very rarely any young students entered at the inns of chancery. 2. Because in the inns of court all sorts of regiment and academical superstintion, either with regard to morals or studies, are found impracticable, and therefore entirely neglected. Lastly, because persons of birth and fortune, after having finnished their usual courses at the universities, have seldom leisure or resolution sufficient to enter upon a new scheme of study at a new place of instruction; wherefore few gentlemen now resort to the inns of court, but such for whom the knowledge of practice is absolutely necessary in such as are intended for the profession. Comm. b. i. p. 23.

Our inns of court, justly famed for the production of men of learning in the law, are governed by masters, principals, benefactors, and other officers; and have public halls for exercises, readings, &c. which the students are obliged to attend, and perform for a certain number of years, before they can be admitted to plead at the bar. These societies have not, however, any judicial authority over their members; but instead of this they have certain orders among themselves, which have by custom the force of laws. For lighter offences persons are only excommunicated, or put out of commons; for greater, they lose their chambers, and are expelled the college; and when once expelled out of one society, they are never received by any of the others. The gentlemen in these societies may be divided into benefactors, clerks, barristers, and students.

The four principal inns of court are the Inner Temple, and Middle Temple, heretofore the dwelling of the Knights Templars, pur chased by some professors of the common law about three hundred years ago; Lincoln's Inn and Gray's Inn, anciently belonging to the earls of Lincoln and Gray. The other inns are the two Serjeants Inns.

INNS of Chancery were probably so called, because anciently inhabited by such clerks as chiefly studied the forming of writs which regularly belonged to the curitors, who are officers of chancery.

The first of these is Thaynes Inn, begun in the reign of Edward III, and since purchased by the society of Lincoln's Inn. Besides this we have New Inn, Symbold's Inn, Clement's Inn; Clifford's Inn, anciently the house of lord Clifford; Staple's Inn, belonging to the merchants of the staple; Lion's Inn, anciently a common inn with the sign of the lion; Furnival's Inn, and Bernard's Inn.

There were heretofore preparatory colleges for younger students; and many were entered here before they were admitted into the inn of court. Now they are mostly taken up by attorneys, solicitors, &c.

They all belong to some of the inns of court, who formerly used to send yearly some of their barristers to read at them.

INN or Inner, in the Middle, is applied differently, according as the horse works to the right or left upon the volcanic, or as he works along by a wall, a hedge, or the like. For along or by a wall, the leg that is on a side with, or next the wall, is the outer, and the other the in or inner leg. And if upon volutes, the horse works to the right, the right heel is the inner, and left the outer heel, and so of the other parts of the body, furniture, &c. The direct contrary of this will happen, if the horse works to the left.

INNATE AIR. See Air.
INNATE Force. See Vis fistung.
INNATE Heat. See Heat.
INNATE Ideas, or Principles, are certain primary notes or characters, by many supposed to be stamped on the mind of man when it first receives its being, and which it brings into the world with it.

But the doctrine of innate ideas is abundantly confuted by Mr. Locke. See Idea.

INNATE, in Natural History, particularly in that branch of it which treats of fossil remains or relics, is applied to such parts of the animal bodies as have been produced independently of any effort of the animal, and are either internal parts, as the bones, which often give the form to extraneous fossils, or external parts, as the scales and fins of fishes, the horny covering in some of the amphibia, and the integument which includes the whole of the body in insects, all of which are sometimes found in a fossil state, as Mr. William Martin observes in his "Outlines," p. 86. The genera of relics which do not depend on innate parts, but on fabricated parts of the animal parts, which are superadded to the body by some voluntary effort of the animal, are called concholithic and creniform.

INNER Barrister. See Barrister.
INNER Pulpit, is an additional piece of oak timber brought on to the forside of the main poll upon which the transoms are hung or fastened; it adds to the security of the planks as the main poll is seldom sufficient before the rabbit for that purpose, and greatly strengthens the form or main poll.
INNER Sea, in Geography, a river which rises about five miles N.W. of Guildford, and runs into the Leine, in the bishopric of Hildesheim.
INNER Sound, a strait of the North sea, between the isle of Skye, and the N.W. coast of Inverness, in Scotland.
INNERSHON, a small isle on the west side of the gulf of Bothnia. N. lat. 61° 34'. E. long. 17° 6'.
INNICHEN, a town of Germany, in the Tyrolese situation near the Drau; anciently called "Augsbirona;" 19 miles E. of Brixen. N. lat. 46° 41'. E. long. 11° 22'.
INNINGS, lands recovered from the sea, by draining and banking.
"INNITPOUR, in Geography, a town of Bengal; 48 miles N. of Dacca.
INNO. Ind. a hymn, or spiritual song.
INNOCENT I. pope, in Biography, was a native of Albano, and was unanimously elected to the popedom by the clergy and people, on the death of Anastasius in the year 492. He obtained from the emperor new and severe laws against the Donatists, in consequence of which they felt very cruel
cruelly persecuted, and those who refused to return to the bosom of the Catholic church were punished with fines, banishment, the confiscation of goods, and in some instances with death. He espoused the cause of Chrysoftom, and even refused to hold communion with the eastern churches, on account of their treatment of that eminent man. He was the first who persecuted the Novatians at Rome, by depriving them of their churches, and preventing their assembling in public, for religious worship; the Pelagians came likewise under his lash; he declared them not only unworthy of Christian communion, but of human society, and even of life. He died in the year 417, after having presided over the church about fifteen years. He was a person of great address, and a lively genius, and was well acquainted with the traditions of the church. He decrees sufficiently show his upbuilding and domineering spirit, and his wishes to make the Christian world submit to his infatuation. They have been frequently quoted by the advocates of the see of Rome, to demonstrate how early the popes claimed, as the successors of St. Peter, an universal authority and jurisdiction. Thirty-four letters, in the first volume of the "Letters of the Popes," have been attributed to this pontiff, but by many of the ablest critics the greater part of them has been regarded as forgeries.

Innocent I., pope, a descendant from a noble family at Rome, ascended the papal throne in the year 1150. He had already filled some respectable offices in the church, and it is said to have led a most exemplary life from his infancy, and to have been distinguished for eminent abilities and virtuous probity, while he was at the same time of a most humane and courteous disposition. He was promoted to the sacred college by the title of cardinal St. Angelo, and was employed by several of the popes in important negotiations at home and abroad. Upon the death of Honorius I. he was elected his successor by a part only of the conclave, the rest choosing Peter de Leon, the son of a Jew, who took the name of Anastasius II., and was acknowledged by the kings of Scotland and Sicily, while Innocent was received by the other princes of Europe. Being driven from Italy, he fled to France, where he held several councils, at one of which he thundered out a sentence of excommunication against Anastasius, and all his adherents. He crowned the emperor Lotharius with great solemnity, and for the support of his new dignity granted to him, to his daughter, and to his son-in-law, during their lives, all the estates of the countess Matilda. On the death of his rival, another pope was chosen by the same party, who took the name of Victor, but who, probably, feeling himself unequal to contend with the power of Innocent, threw himself at the feet of the pontiff, and thus put an end to the schism in the church. Innocent, having no enemy to disturb his peace, took up his residence at Rome, and summoned a general council to meet in the Lateran in the year 1150. This was the most numerous council that had ever been held, consisting of a thousand bishops, besides a crowd of abbots and other ecclesiastics, who, besides other businesses, declared the ordinances of Amaeleus null; excommunicated Roger, king of Sicily; and condemned the opinions of the famous Arnold of Brescia. Innocent, after this, was not contented with the pacific duties of his office, but actually marched in person, with his army, against the prince who seemed to set at his defiance the sentence of excommunication. Roger was too well skilled in military tactics to leave the event of the contest doubtful, he attacked the episcopal army, which he put to flight, and was so completely successful, as to take the holy pontiff prisoner, with several cardinals, and other persons of distinction. When Innocent was conducted into the king's camp, he found, what he little expected, that he had fallen into the hands of a generous enemy; the victorious king sent some of his principal officers to beg his holiness's pardon, and to assure him he was ready to enter into an accommodation upon the terms which he had formerly offered by his deputies. Innocent readily acceded: the terms were drawn up and executed, in consequence of which the pope absolved Roger from excommunication, and solemnly invited him with the kingdom of Sicily, the dukedom of Apulia, and the principality of Capua; while, on the other hand, the king acknowledged Innocent for lawful pope, and engaged to fulfil him wherever his aid should be required. Upon the recovery of his liberty Innocent returned to Rome, but the remainder of his life was one of much difficulty. The last two years of his life were wholly occupied in reducing several cities which attempted to shake off the yoke of the apostolical see, and to recover their ancient liberty. The Romans also refused to obey him as their prince, restored their fonts, and created their own magistrates. In the midst of these calamities the pope fell sick, and died in 1154, after a pontificate of nearly fourteen years. His life, in private, was most highly esteemed on account of the fineness of his manners, but from the severe revolts which took place while he was head of the church, it has been suspected that his administration of government was not conducted with prudence and wisdom, and that his zeal for exalting the papal pretensions was not behind that of any of his predecessors. Forty-three of his letters are inserted in the tenth volume of the Collect. Concil.

Innocent III., pope, originally called Lotharius, was a descendant from the illustrious house of the counts of Segni, and born at Anagni about the year 1161. After pursuing his studies at Rome, he went to the university of Paris, where he was admitted to the degree of doctor. From this period he was advanced very rapidly in the church; was ordained sub-deacon by Gregory VII., and preferred to the dignity of cardinal-deacon by Clement III., under the title of cardinal St. Sergius, and St. Bacchus. On the death of pope Celestine III. in the year 1198, Lotharius was elected his successor, being then only in his thirty-seventh year. Being at this period only in deacon's orders, he was first ordained priest, in order to his being able to undertake the high office of pope, when he assumed the name of Innocent III. From the moment of his exaltation, he seems to have felt before him, as objects for his imitation, the character and conduct of pope Gregory VII., and with equal intrepidity and address, purged his plans of ambition, till he arrived at a height of despotism, which the world beheld with wonder and astonishment, but to which the states of Europe submitted with a silence that was highly disgraceful to them. "Under this young and ambitious priest," says Gibbon, "the successors of St. Peter attained the full meridian of their greatness; and in a reign of eighteen years, he exercised a despotic command over the emperors and kings whom he raised and deposed; over the nations, whom an interdict of months or years deprived, for the offence of their rulers, of the exercise of Christian worship. In the council of the Lateran he acted as the ecclesiastical, almost as the temporal, sovereign of the East and West. It was at the feet of this legate that John of England surrendered his crown; and Innocent may boast of the two most signal triumphs over fene and humanity, the establishment of transubstantiation, and the origin of the inquisition. At his voice, two crusades, the fourth and the fifth, were undertaken; but except a king of Hungary, the princes of the second order were at the head of the pilgrims; the forces were inadequate to the design; nor did the effects correspond with the hopes and
and wills of the pope and the people." Innocent did not
conspire his efforts to the Holy Land, he promoted a crusade
against the Albigenses. He first attempted to convert
them by his missionaries, one of whom was murdered, which
was the signal for the display of all his wrath; he did not
even deign to institute an inquiry, but ordered the whole
race to be pursued with fire and sword, and to be treated
with more severity than the Saracens themselves. Immense
numbers of lives were sacrificed in his holy war, and bar-
barities practised, before unheard of; but the perpetrators
of them were applauded and rewarded by the cruel pontiff,
and the infernal spirit by which they had been actuated was
impiously called zeal in supporting the cause of God and of
the church. In 1219, the fourth general Lateran council
was held at Rome which was so managed by the all-controlling
power of the pontiff, that instead of exercising the functions
of a deliberative body, it was made use of as only as an
instrument to register canons and decrees which Innocent had
drawn up, and which he permitted to be read for their appro-

In this council a sentence, which had been pro-
nounced some time before, suspending Stephen Langton,
archbishop of Canterbury, was confirmed. The pope,
later, thundered out a sentence of excommunication
against the barons, which they treated with merited contempt,
and bravely perished in defending those privileges, the char-
ters of which they had lately compelled their monarch to
sign. In the year 1216, Innocent undertook a journey
to Pisa; but on his arrival at Perugia he was attacked with
a violent disorder, which put an end to his life in a few days.
According to Mr. Berlinton, "I nocent was learned, mag-
nificent, perseverant, wife. In the knowledge of laws and
politics he had no equal; he professed the art of govern-
ment; and was obeyed more from fear than love. Ambition
was his ruling passion, to gratify which, he overstepped the
bounds of decency and justice, playing as wantonly with the
solemn censures of the church as if they had been instituted
for the common purposes of wayward caprice or relentless
vengeance. To look into him for the amiable virtues of life,
or for those which should form the pastoral character,
would be lost of time. The prerogative of the holy fee,
built up by adulation and misjudging zeal, filled his mind;
its aggrandizement he fought sometimes, perhaps, from
motives which the cool reasoner may excuse; and the meteor
of universal empire gleaming on his fames, did not permit
the operation of a dispassionate and unbiased judgment. No
tears were shed when Innocent fell, but those which Religion
wept, too jufully pained by the inordinate exertions and
worldly views of her first minister." Innocent was the
author of a variety of works, which are enumerated by
Dupin, but the most valuable are his "Epistles," which
threw considerable light on the ecclesiastical history of his
time. His works have been collected in two volumes folio;
the best edition is that published at Paris in 1682.

Innocent IV., pope, was a native of Genoa, and being
distinguished for his learning and attainments, he was in early
life made canon of Parma, from which he was promoted to
the chancellorship of the Roman church. In 1227 he was
railed to the purple by Gregory IX., and in 1223 he was
elected to the papal throne, when he took the name of
Innocent IV. Previously to this he was on terms of strict
intimacy with the emperor Frederic II., who had been en-
gaged in a contest with the court of Rome, and that prince
no sooner received the news of his exaltation, than he sent a
splendid embassy to congratulate him upon his election, and
to assure him that nothing should be wanting to re estableish
harmony between the church and the empire. The pope,
however, began to assume a dignity inconsistent with friend-

ship, and he plainly declared that he was resolved to main-
tain the highest pretensions of the apostolic see. Legates
were dispatched to accommodate all differences, but it was
of no avail, and hopes of reconciliation being at an end,
Frederic prepared to reduce the pope to reason by the terror
of his arms. Innocent, unable to refit the power of the
emperor, fled for protection to his native city, where he was
received with every mark of distinction. Here he assembled
a council, consisting of about 130 prelates, some princes, and
the ambassadors of most of the crowned heads in Europe; he
laid before this august assembly the motives which induced
him to call them together, defending the emperor as a tyrant,
and deprived of the church, and as guilty of heresy, sacrilege,
and other grievous crimes. The council gave credit to the
pontiff, and functioned the sentence of excommunication
pronounced against him. This led to a most destructive war,
which was carried on in Germany and Italy till the death of
the emperor Frederic in 1250, who was succeeded by his
eldest son Conrad, who took up his father's cause with so
much zeal and intrepidity, as rendered Innocent fully sensible
of his inability to withstand that prince with his own forces
only. He accordingly made many unsuccessful attempts
for obtaining alliance, and his army was defeated, which is
affecting the pontiff, that he fell sick and died in the month
of December 1254, after he had presided over the church nearly
twelve years. He had high notions respecting the power
and authority of the papal see: he professed considerable
learning; was well acquainted with the divinity of the times,
and was regarded as the best civilian of his age. He was
author of a work entitled "Apparatus, Libris quinque
distinctus, in totem Libros Decretalium," first printed at
Venice in 1570; and of several other pieces, besides twenty
letters, which are inserted in the eleventh volume of the
Collect. Council. He was not only learned, but a great en-
courager of learning, and is said to have been the first who
 gave red hats to the cardinals.

Innocent V., pope, was born at a town on the Ifere, in
Burgundy. When very young he entered the Dominican
order of preaching friars, and pursued his studies in divinity
with so much success, that he was appointed to fill the theo-
logical chair in the university of that city, and was considered
as one of the most learned divines of the age. He obtained
considerable preferment in the church, and about 1271 was
nominated by pope Gregory X. archbishop of Lyons, and
soon afterwards was promoted to the sacred college by the
title of cardinal bishop of Ostia. On the death of Gregory
he was unanimously chosen his successor in the papal
dignity, and took the name of Innocent V. Besides reconciling
those states of Italy which were carrying on the most bloody
wars against each other under the opposite denominations
of Guelphs and Ghibelines, and bringing about a peace bet-
ween the republics of Lucca and Pisa, he projected the mission
of a splendid legation into the East, to obtain from the emperor,
Michael Paleologus, the confirmation of the articles of union,
but he died before he could carry his design into execution,
after a short pontificate of about five months. He wrote
"Commentaries" upon the Pentateuch, the Canticles, and the
Gospel; "Notes on the Epistles of St. Paul," and
other pieces, which have been published since his death.

Innocent VI., pope, formerly called Stephen Asbert,
was brought up to the study and practice of the law, and in
1335 he was professor of the civil law at Toulouse, and chief
judge of that city. In two years after we find him bishop
of Noyon, and in 1340 he was translated to the see of Cler-
mont. In 1342 he was raised by pope Clement VI. to the
dignity of cardinal bishop of Ostia, and at the same time ap-
pointed grand penitentiary of the Romish church. In 1349,
he was unani- mously chosen pope, and took the name of Innocent V. He made it his business to correct abuses, and also abolished the heavy impositions laid upon the clergy, when preferred to any new benefice or dignity. He re-

trenched all the unnecessary expenses of the papal court, con- 
tenting himself even with a small number of attendants: he ob- 
liged the cardinals to follow this example, urging them to bellow the superabundance of their wealth, in relieving the nee-dities of the poor. Innocent maintained the decrees of 
his predecessors against those Minorite friars who assumed the 
title of "Spiritual Brethren," and who contended against the 
right of the clergy in disposing any property. Two of 
this description were arraigned at Montpellier in the year 1354; 
the depositions were taken from them, from the error of their 
ways, but finding them obstinate, he gave them up to the 
impiators to be burnt alive. In the following year he sent 
a legate a latere to Rome to crown Charles, king of Ger-
many, and his queen Anne with the imperial crown, but not 
before that prince had subscribed to the most humiliating 
conditions. After this, nothing occurs during the remainder 
of Innocent's pontificate which requires to be noticed. He 
died at Avignon in 1362, after he had filled the papal chair 
forty years. He has been highly commended for his 
probity and the sanctity of his life: he was generous to the 
waits of the poor: an enemy to vice, the patron and pro- 
tector of virtue in every condition of life. He left behind him many epistles, some of which have been printed, and 
others are preferred in the Vatican.

Innocent VII., pope, was born at Salerno, in Abuzzio, 
about the year 1339, obtained a high reputation for his 
knowledge of the civil and canon law, was made clerk of the 
apotolic chamber by pope Urban VI., and was afterwards 
employed to collect the revenues of the apostolic see of 
England. As a reward for his services in those situations he 
received considerable church preferment, and was at 
length raised to the sacred college under the title of car- 
dinal prelate of Santa Croce. On the death of Boni-
face IX. he was chosen to the papedom, and took the name of 
Innocent VII. Searcely had he been consecrated, when a 
dreadful tempest broke out in Rome between the Gibel- 
lines and the Guelphs: this led to other disturbances, which 
paralleled during the pontificate of Innocent, who died in about 
two years after his elevation. He is represented as of a mild 
and pacific disposition; of a generous and benevolent temper; 
an enemy to all pomp and show; free from pride and ambish-
ion; and of great address in state affairs. He is much blamed 
for having been the occasion of elevating unworthy personages, 
to the highest-posts of dignity and trust. He is author of a 
discourse "On Church Union," and some "Letters."

Innocent VIII., pope, was born at Genoa in the year 
1432: at an early age he was sent to the court of Naples, 
where he lived several years during the reigns of Alphonso 
and his son Ferdinand, and received sublunial marks of 
favour from both princes. After this he removed to Rome, 
and obtained considerable church preferment, till at length 
he was raised to the purple by the title of cardinal of 
St. Balbina in the year 1473. Upon the death of Sixtus IV. in 
1484, he was elected his successor, and took the name of 
Innocent VIII., having been previously known by that of 
John Baptist Cibo. As soon as he was vested in his poma-
cerit, he attempted to procure another crusade, but 
without success. He therefore, however, contributed to bring 
much wealth into the apostolic treasury, part of which the 
pope appropriated to his own use; and the rest he expended 
on the repair of ancient works of art, or in support of a war 
in which he soon became involved with Ferdinand, king of 
Naples. Innocent spent the concluding years of his ponti-
cate in endeavouring to maintain order and good govern-
ment in the church, and in cultivating the arts of peace. He 
cleared the country of robbers and abusities, with which it was 
at that time much infested; adopted measures for the regular 
supply of Rome with provisions, and adorned it with many 
magnificent buildings. He died in the year 1492, aged 60, 
after he had filled the papal throne nearly eight years. He 
was possessed of a very moderate share of learning and talents, 
but secured the attachment of all ranks by the sweetness of 
his temper and the gentleness of his manner. His character, 
in a moral point of view, will not bear examination: he un-
blushingly acknowledged himself the father of a numerous 
progeny of natural children, and is said to have been the first 
of the popes who introduced that new and extraordinary 
proceeding of owning publicly his impious issue, heaping 
on them riches without measure. He left behind him 
some letters, and one to Henry VIII., king of England, 
against citing the clerical orders before secular tribunals.

Innocent IX., pope, known originally under the name of 
John-Anthony-Tacchini, was born at Bologna in the 
year 1519, where he received his education, and was 
admitted to the degree of doctor in 1544. He now became 
a domestic in the family of cardinal Farnese, who lent him in 
the capacity of vicar to Avignon, and again to Parma. In 
1556, he was sent by Pius V. as nuncio to Venice, where he 
had a principal concern in establishing the confederacy 
between the pope, the king of Spain, and the republic 
against the Turks. After this he created patriarch 
of Jerusalem, president of the inquisition, and cardinal. In 
1551, he was unanimously elected to the papedom, when he 
took the name of Innocent IX. He immediately projected 
grand plans of improvement, of an ecclesiastical and econo-
mical nature, none of which did he live to execute. He 
died in the second month of his pontificate, at the age of 
seventy-two.

Innocent X., pope, was born at Rome about the year 
1575, where he was educated and brought up to the pro-
fession of the civil law, of which he was admitted doctor 
when he was only in his twentieth year. He obtained many 
instances of preferment in the church, and, in 1627, a car- 
dinal's hat was presented to him by pope Urban VIII. He 
was most made prefect of the ecclesiastical immunities, su-
preme judge of the inquisition, and protector of the king-
dom of Poland. On the death of Urban he was elected 
pope; he had already carried on an illicit commerce with 
his brother's widow, Donna Olympia Malaberti, to whom 
he now abandoned himself, the administration of his tem-
poral affairs, and the government of the church. All be-
nefactors, all employments, whether ecclesiastical, civil, or 
military, were dispensed by her to the highest bidders, 
without any regard to merit or merit, or to the char-
acter of the purchaser. She induced the pope to forget 
all sense of right and wrong when it interfered with her 
will. In 1645, upon the application of the Dominicans, 
who were associated with the Jesuits in the mission to China, 
Innocent condemned the indulgence which the Jesuits 
had shown to the Chinese inscriptions. The most remark-
able transaction of his pontificate, was his condemning, by a 
bull, in the year 1653, the five propositions inflicted by the Jesuits 
from Janmaic's "Aspersionii." He died in 1655, about 
the age of eighty-one, having filled the papal throne little 
more than 17 years.

Innocent XI. was born at Como, in the duchy of 
Milan, in the year 1641. He was the son of a rich banker, 
and his first profession was that of a foother, in which he 
distinguished himself by his gallantry. Quitting the mil-
itary character he embraced the ecclesiastical profession, and 
went
went to study at Naples, where he was admitted to the degree of doctor. Having filled, with high reputation, several offices in the church, he was raised to the purple in 1645, and, in 1678, he was elected to the papedom. He began his high career with abolishing abuses, and suppressing many gross superstitions then prevailing in the church of Rome. He likewise attempted, by wise institutions and judicious regulations, to reform the manners of the clergy, and to stem the torrent of licentious morals among the laity. In 1677, he suppressed "the right of asylum," enjoyed by foreign ministers at Rome, extending much farther than their palaces, the immunities of which it was not designed to violate. Mott of the ambassadors from foreign courts readily acquiesced, but the minister from the court of France refused to hearken to it, and the pope, unwilling to enter into a contest with Lewis XIV., allowed his ambassador to enjoy his ancient privileges. He had now a contest with the French king, about the right of disposing of benefices and church lands claimed by that monarch, and confirmed to him by an assembly of the clergy, which nearly terminated in a separation of the Gallican church from the Roman communion. It was on this occasion that Lewis summoned the famous assembly of bishops, which met at Paris in the year 1682, and drew up the four celebrated propositions declaring the power of the pope to be merely spiritual, and inferior to that of a general council, and maintaining the inviolability of the rules, institutions, and observances of the Gallican church. Innocent died in 1689, having presided over the Roman see twelve years and a half. He was virtuous and pious, but without preteniions to learning. His zeal for the reformation of abuses, the improvement of morals, and the reformation of church discipline, has given him a rank among the bii of the popes.

INNOCENT XII., pope, originally named Anthony Pignatelli, was defended from an illustrious family at Naples, and born there in the year 1615, and succeeded to the popedom in 1691, as successor to Alexander the VIIIth. In imitation of the example of pope Innocent XI. he applied himself to the reformation of the church and court of Rome. He was unwearying in his endeavours to reform the corrupt manners of the clergy, which were not wholly unsuccessful, though he found that the entire accomplishment of the Hermeneutical work was a confirmation, which all his prudence and resolution were unable to effect. He was anxiously devoted to the interests of the poor, and the wealth which many of his predecessors had been accustomed to accumulate, or to bestow on worthless relations, he devoted to the public benefit, employing it in the erection of hospitals, and other useful institutions, and particularly in the improvement of the ports of Anzio and Nettuno. Innocent died in the year 1700, at the advanced age of eighty-five, after preying over the church about nine years. He had rendered himself universally respected by his talents, and beloved on account of his many virtues.

INNOCENT XIII., pope, formerly named Michael-Angelo Cesi, son of Charles Cesi, duke of Poli, was born at Rome in the year 1655. He rose successively to the highest offices in the church, till at length he was elected successor to Clement XI. in the papal dignity, in the year 1721. He died in 1734, leaving behind him a character for great wisdom, virtue, and learning. When a cardinal he distinguished himself above most of the members of the sacred college; but the infirmities to which he had been some years subject, prevented him from distinguishing his pontificate by any actions which are worthy of being recorded. As authorities for the foregoing articles, see Bower's Hist. of the Popes; Moreri, Gibbon, &c.

INNOCENTS DAY, the name of a festival celebrated on the twenty-eighth day of December, in commemoration of the infants murdered by Herod.

Herefore it was the custom to have dances in the churches on this day, where were persons, who represented bishops, by way of deference, as some had; and of the episcopal dignity; though others with more probability, suppose it done in honour of the innocence of childhood. See EPISTLES PASCHALIS.

By a canon of the council of Constance, held in 1265, these were expressly forbidden; but they were not wholly suppressed, at least in France, before the year 1444, when the doctor of the Sorbonne addressed a written letter on this subject to all the bishops of the kingdom.

INNOMINATA ARTERIA, in Anatomy, the first large trunk bent off from the arch of the aorta. See AORTA.

INNOMINATA glandula, the ischial gland. See EYE.

INNOMINATI, Gli Innocinati, Anonymous, persons who have no names, a title by which the academicians of Parma distinguish themselves.

Most cities in Italy have an academy, and each has its proper name. Thus those at Parma entitle themselves Gli innocinati, as if it was their characteristic to have no name at all.

INNOMINATUM, Os, in Anatomy, the large bone composing the chief part of the ribs of the pelvis, and receiving the articulation of the lower extremity. See EXTREMITIES.

INNOVATION, in Law. See NOVATION.

INNUENDO, of rumo, I not, or he, con, is a word frequently used in writs, declarations, and pleadings, to affect a person or thing which was named, but left doubtful, before: as, he (innuendo the plaintiff) did to and: mention being before made of another person. In common observation or writing, an innuendo denotes an oblique hint, or distant reference; in contradistinction to a direct and positive charge.

INNY, in Geography, the name of two rivers in Ireland: one which rises in the county of Wexford, and having passed through Loughs Dervaragh and Iron, forms a boundary between this county and Longford, for several miles, after which it crosses the southern part of the latter, and flows into Lough Kee, an expanse of the Shannon: the other is a mountain stream in the barony of Iveragh, Kerry, which empties itself into Ballin Skegh's bay.

Gen. Chi. Cals. Pani, of one leaf (capsulate, according to Thumberg) in two, roundish, nearly equal segments. Cor. of one petal, tubular; tube cylindrical, longer than the calyx; limb longer than the tube, divided into five, linear, acute, undulated, often reflexed segments. Stam. Filaments ten, very short, inserted into the tube; the lower ones alternate; anthers ovate, tunic, erect. Pet. Germ. oblong, hairy, superior; style none; stigma a hollow point. Peri. Drupa ovate, incurved, compressed, large, single-seeded. Saw. A nut composed of woody fibres; kernel oval, compressed.

1. L. edulis. Wild. Sp. Pl. v. 2. 624. (Gujianus; Rumph. Amburin. v. 1. 170. t. 65) A native of the Society, Friendly, and
and New Hebrides Islands, in the South seas, and also of Amboma. Forster describes this as a lofty tree, having a trunk as thick as a man's body, with a brown chinky bark. Branches woody, spreading, variously divided. Leaves ovate-oblong, finely cordate, netted with abundance of veins. Flowers dirty white, fiercely half an inch in length. From Cook's last voyage we learn, that the nuts of Inacarpus are called $E$--$i$.

The kernel of the seed, which is kidney-shaped, and about an inch in diameter, is eaten roasted by the natives. It is sweetish, but less pleasant than the chestnut, harder, and not so farinaceous. The bark is aromatic, and used in the dyefactory. In New Guinea, they smear their arrows with the expressed resinous juice.

INOCULATING, in Gardening, the art or practice of infecting the buds of trees of the same kind into their stocks or other parts. It is a sort of grafting which is often had recourse to in the summer season for raising different kinds of trees and plants, as it frequently succeeds better than that of the common method. It is usually executed in the manner described below. A sharp knife, with a flat haft for the purpose, and proper cuttings of the trees designed to be propagated being provided, a choice should be made of a smooth part of the stock which is to be inoculated; five or six inches from the ground, where intended to be dwarf, but when for a standard at the height of five and a half or six feet; and a horizontal cut made across the rind of the stock, as well as a slit, about two inches in length, downwards from the middle of that cut, taking care not to go deeper than the thickness of the bark, left the stock be wounded; then having the cutting in readiness, the leaf should be cut off from the bud, leaving the foot-flaik remaining, but taking off the bud lengthways some way longer than the slit in the stock, with part of the wood adhering to it; which being done, dip the wood from the bark with the knife by means of a sudden jerk, observing whether the eye of the bud be left or not, as such buds as lose their eyes in straining are quite useless; as soon as this has been done, the bark should be gently raised on each side of the slit in the stock with the handle of the knife, and the bud inserted into it, being careful to place it smooth between the rind and the woody part of the stock, cutting off that part of the rind of the bud which may happen to be too long for the slit; having thus exactly fitted the bud to the stock, they should be tied closely round with wetted strong bafs, taking care not to pass any ligature round the eye of the bud, which must always be left open and at liberty. In the course of three weeks, or a month, the buds will require to be loosen'd of the bandage, and which, if not executed in time, will be highly injurious to them; but they should not be wholly divel'd of the binding, it being proper to tie them again slightly, by which the bark of the stock will be prevented from becoming open, which sometimes takes place, and the bud is thereby greatly injured, if not wholly destroyed.

There is nothing further required until the following March, when the stock should be cut off about three inches above the place of inoculation, hoping it the contrary way to the bud. This length of stock left is beneficial in facilitating the stock which springs from the bud, and which might otherwise be blown out by strong winds; in the autumn following, however, it should be cut away quite close just above the bud, that the wounded part may be more readily become barked over. It may be noticed, that the mott proper season for this sort of work is, from the middle of June until the middle of August, according to the forwardness of the season, and the particular sorts of trees to be increased; but it may be easily known by trying whether the buds will come off well from the wood or not. The most general rule is, when the buds are found to be formed at the extremity of the same year's shoots, which is a sign of their having finished their vertical growth. The first sort commonly inoculated is the apricot, and the last that of the orange-tree, which should never be done until the middle of August.

In doing this sort of work, choice should be made of cloudy weather, as when done in the middle of the day, in very hot weather, the shoots perspire so fast as to leave the buds destitute of moisture; or should the cuttings be taken off from the trees long before they are used; but if fetched from some distance the leaves should be cut off, but all the foot-flaiks left, and then wrapped up in wet moss, and put in a tight box to exclude the action of the extant air upon them. But the practice of throwing cuttings into water is highly improper, as it saturates the buds with moisture, that they have no attractive force left to imbibe the sap of the stock, for want of which they very often miscarry, and disappoint the operator.

It has been remarked by Mr. Forfyth, that when the pear-trees which are grafterd in the spring have not taken, he would advise the cutting them off a little below the graft at a joint or bud. The tree then throws out a greater number of healthy shoots; all of which should be rubbed off, except so many as are sufficient to fill the wall; taking those up to prevent the wind from breaking them. About the latter end of July the shoots will be fit to inoculate, which should then be done, leaving a little of the wood on the inside of the bud when inoculated into the stock, and rubbing in some of the composition, tying on the bafs at the same time.

Having grafterd some summer bonchêtiens with the bergamot de Pafque (or Eather bergamot) and pear d'Anch in the spring, most of which failed, he cut them off below the grafts, and in July following they had produced shoots from five to six feet long, which he inoculated in the latter end of that month with the before-mentioned ports, which all took. About the beginning of September he ordered the bafsies to be slackened; which being left too loose, the barks began to separate. He then made them be tightened, letting them remain till the following spring. About the beginning of April, when he saw the buds begin to shoot, he cut the shoots near to the buds; but finding many where the bark had not united, and some of the eyes apparently dead, he took a sharp penknife and cut out all the decayed bark, rubbing in some of the composition in a liqoid flake, till the hollow parts were filled up; he then smoothed it off with the finger even with the bark of the stock. He also rubbed some of the composition over three eyes that were in the world flake, being quite black, but with very little hope of recovery. "To his great astonishment, many of those which seemed perfectly dead recovered, and by the middle of July had shoots from five to six feet long (many of the shoots which took well having fruit-buds formed for next year), and covered a space of wall larger than a young tree would have done in eight years; all the cavities where he cut out the dead bark and applied the composition were, in the course of the summer, filled up with sound wood, and the bark between the shoots and grafts perfectly united.

"Three years ago he inoculated some brown beurres and crafitanes with pear d'Anch, one of which now covers a wall sixteen feet high and fifteen feet, and has more fruit on it this year than a maiden tree would have produced twenty years after planting," But he "never recommends inoculating or grafting of old trees, except when bad forts, or more of any sort is wanted for a supply; in that case he would recommend to inoculate or graft with pear d'Anch, colmar, etc."
INOCULATION.

colmars, and winter bronchietias, which keep much longer
than beurreis, crafanes, &c.

But for standards that have been grafted in the spring and
have milled, he advises that they should be cut below the
graft, as when so treated, they throw out a great number
of shoots, which should by no means be too soon thinned,
as in that case they will be liable to be broken by the wind.
The weak/est shoots may be begun to be taken off about
the latter end of May or beginning of June. About the
middle of the latter month they will have acquired con-
siderable strength, then thin them, leaving as many strong
regular shoots, and of those nearest the top of the stem,
as will form a handsome head. If the stem be very strong,
will be necessary, perhaps, to leave more than are intended
to be inoculated on purpose to receive the fap, which will
flow in great abundance from a large trunk, and without
this precaution be apt to burst the shoots. He has often
seen shoots as large as his arm burst by a superabundance of
fap. When that is likely to happen, the best thing is to
scarify the shoots and rub a little of the composition into
the wound. See Bud, Budding, and Grafting.

INOCULATION, among Gardeners, signifies an op-
eration in the management of some sorts of fruit trees, which
is frequently denominated budding. See Budding, and
the preceding article.

Inoculation, in a surgical and medical sense, denotes the
practice of delicately communicating from one person
to another certain diseases, which is generally done by in-
roducing some of the infectious matter into a small wound,
or puncture, made with the point of a lancet. The com-
mon purpose of such operation is to diminish the severity
and peril of a distemper, which, taken in a casual way,
proves exceedingly destructive, and the hazard of catching
which, at some period of life or another, is very con-
siderable. A chief object of the plan is also, in general,
to render the patient incapable of being again affected by
the dreaded contagion. Hence inoculation is seldom per-
formed, but for a disease with which the human constitu-
tion can only be affected once, as the small-pox and cow-
pox. The latter, which is so mild as scarcely to defer
the name of a disease, being only communicable by con-
tact, and existing originally no where except upon the teats
and udders of cows, would never perhaps have troubled any
other persons than a few milkers, had it not been for the
discovery of the important fact, that persons who had
undergone the complaint were made completely insusceptible
of the small-pox contagion. The cow-pox inoculation has
now, therefore, been very generally substituted for that
with various matter, and the beneficial consequences of this
change are so truly important that the Jennerian dis-
covevry will ever be regarded as a most memorable event,
ot only in the annals of medicine and surgery, but in the
history of the world. See Cow-Pox and Vaccination.

Although it is our intention to devote this article to the
history of the small-pox inoculation, we may here remark,
that the measles have been propagated by inoculation. Dr.
Home, of Edinburgh, was the first who actually made the
experiment. Not being able to collect either matter, or a
sufficient quantity of broken cartilage at the time of disem-
nation, to produce the disease, he drew blood from a su-
pericial cutaneous vein, where the eruption was thickest.
Cotton was then dipped in this blood, and applied to a wound
made in each arm of the person about to be inoculated.
In this manner Dr. Home inoculated twelve persons. The
eruptive fever generally began six days after inoculation;
the symptoms were less severe; the cough was milder, or
entirely absent; and the inflammation of the eyes was trifling.

Notwithstanding Dr. Home's success, inoculation for the
measles is seldom or never practised, others, who have
made the experiment, not having given reports equally fa-
vourable.

Inoculation for the plague has likewise been tried, in or-
der to ascertain whether that distemper might not be ren-
scribed less fatal and less prevalent in particular parts of the
world. In Egypt, Dr. Whyte inoculated him with matter taken
from the buboes of an infected person. The experiment failed twice; and the third proved fatal in three
days after the commencement of the symptoms. See for R.
Wilson's Hist. of the Expedition to Egypt.

In the present state of our information, inoculation for
the plague appears unjustifiable. It was attempted in
Egypt, that many of the convulsed took the plague a sec-
tond time; nor, in all probability, does inoculation render
this distemper milder. Indeed, what M. Sommier observes,
seems to lead to a contrary conclusion; for he mentions, that
a Russian surgeon, who was a prisoner at Constantinople,
with a number of his countrymen, took it into his head to
inoculate these unfortunate men with the plague, under the
idea of rendering the contagion less destructive; but the
result was, that two hundred lost their lives, as well as the
surgeon, who had also inoculated himself. See Sommier's
Travels into Greece and Turkey. p. 497.

The idea of intentionally imparting any kind of disease to
the human body would appear, to persons unacquainted
with the reason of the thing, equally extraordinary and cruel.
But the design and utility of the inoculation for the small-
pox are now so fully known among all classes of society,
as fearcally to need explanation. When it is remembered,
that the small-pox contagion has, at various periods, nearly
depopulated extensive kingdoms, and occasioned greater de-
struction than the most destructive wars, any measure, cal-
culated to render milder so terrible a disease, must be looked
upon as a discovery of the very highest importance. It has
been estimated, that, upon an average, before the intro-
duction of inoculation, one out of every six persons affected
with the natural small-pox, or sometimes even a half, perished;
but that the proportion of deaths, among such as have
been inoculated in the most improved manner, does not
amount to more than one in several hundred. Besides this
circumstance, we have to mention, that before inoculation
became common, the small-pox frequently committed rav-
eges like the plague, and the fury of the distemper was
always dreadful whenever the contagion made its first visit to
a country. If, then, we are to hail the small-pox inocula-
tion as a general and momentous benefit to society, on the
principles just now specified, with what joy and admiration
must we behold the discovery of a complete security against
the small-pox infection, in the new and perfectly safe
kind of inoculation with vaccine lymph. The small-pox inocu-
lation materially alleviated the calamities arising from that
disease, by making the distemper milder, and lessening its
mortality. But, still, the distemper was not unfrequently
seen in a fever form; at least one out of every three or
four hundred inoculated died; and the countenance of
those who survived were often miserably pitted and dif-
figured. On the other hand, the vaccine inoculation hardly
ever produces any serious indisposition, and being followed
by no eruption, cannot deform the face. Its safety and
efficacy are daily receiving more and more confirmation
from all quarters of the world, and we have no doubt
that, after prejudices have had time to subside, the small-
pox inoculation will be universally superseded.

The original introduction of inoculation, however, will
always constitute a most memorable event in history, and is
a subject...
INOCULATION.

The small-pox, like the measles, and several other diseases, is produced by a matter fals genus, or, in other words, by a specific contagion, and it has originated from causes so perfectly incomprehensible, as to set at defiance all rational conjecture. From the silence of the ancient Greeks and Romans respecting a disease so very fatal, and of such peculiarity, as the small-pox, it is reasonable to conclude, that it is subsequent to their times, and, consequently, that the world existed several thousand years before it was visited by this dreadful pestilence.

Khazes, an Arabian physician, who practised at Bagdad in the beginning of the tenth century, is one of the oldest writers on the small-pox, whose works are still extant. On this subject, however, he quotes several of his predecessors, the most ancient of whom is Abnor, who was a priest and physician at Alexandria, when that city was belted by the Saracens. Abnor's book has, therefore, been deemed the first in which any notice is taken of the small-pox. The introduction of the disease, at that time, into Egypt, might have been by the armies of Abnor, which, in the caliphate of Omar, poured in thither from Arabia.

The celebrated Dr. Friend conceived, that the Arabsians might originally have derived the contagion from some of the more distant regions of the East, and Persia. A translation, a missionary's visit to Pekin, informs us, that, upon looking over some Chinese books, he found the small-pox mentioned in them as a disease known in very ancient times. See "Lettres edifiantes et curieuses," tom. 21. p. 52. ed. 1781.

Mr. Holwell, a Bengal surgeon, has likewise endeavoured to confirm the accuracy of Dr. Friend's opinion, observing, that, at the period in which the Aughtorrah Rhade scriptures of the Goocos were promulgated, (according to the Romans 3366 years ago,) this disease must then have been of some standing, as these scriptures instruct a form of divine worship, with prayers, or orations, to a female divinity, assisted by the common people Goote ka Tagooran, the Goddess of Spots, whose aid and patronage are invoked during the continuance of the small-pox season; also in the meads, and every cutaneous eruption that is in the smallest degree typhoidal. See "An Account of the Manner of inoculating the small-pox in the East Indies," p. 7.

On the other hand, Dr. Woodville is unwilling to admit, that the supposed antiquity of the small-pox in India is at all proved by what D'E treckles and Mr. Holwell have observed. He marks, that the former has added no direct fact, having said, that the disease was really described by the ancient Chinese physicians; while Mr. Holwell's reasonings are inadmissible, not only as founded on the authority of the Hindu chronology; but because the Goddes of Spots was not worshipped or prayed to in any particular eruption disease, but over all cutaneous eruptions that were epidemic. Besides, Dr. Woodville judiciously notices, that the small-pox existed in India more than 3366 years, it could not the small-pox have been transported in early times both to the Greeks and Romans, by the constant intercourse, which they indirectly maintained with the Indian nation.

Dr. John James, a French Jesuit, that, in an old Arabic MS. preserved in the public library at Leyden, he read, that, in the year of the death of Mahomet, the measles and small-pox made their first appearance in Arabia. Diff. inapr. Lugd. Bat. 1746. Now it appears also from some Arabic annals, procured by that adventurous traveller, Mr. Bruce, that the era of the first appearance of the small-pox in Arabia attaches to that of the siege of Mecca, and that the Abyssinian army, commanded by Abrahah, was the first victim of its fury. Mr. Gibbon states, that the siege of Mecca happened only two months before the birth of Mahomet; a fact, which Dr. Woodville points out as deserving particular notice; for if the year of the birth of Mahomet be ascertained to be also of that of the siege of Mecca, the Arabian MS. cited by Dr. Reiske, and that written by Hancely, the Arabian author mentioned by Mr. Bruce, perfectly coincide. According to Gibbon, Mahomet was born A.D. 569; which, on the above independent authorities, is to be considered as the period when the small-pox first made its appearance in Arabia.

From this era, to that of the conquest of Alexandria in 425, no traces of the existence of the small-pox are to be discovered; but the disease certainly spread into that city at the time it was invaded by the Saracens; and, as Dr. Woodville states, it may therefore be supposed to have been brought into Egypt by the Mahometan army, which, six years before, had invaded Persia and Syria, where this destrucutive pestilence probably had already made a considerable progress.

After this period, to the revival of literature in the 15th century, succeeded that general state of ignorance and barbarism, during which the present subject, in common with many others, is obscured in the darknes of the times as to elude the most diligent research.

It is manifest from the works of Rhazes, that many of the Arabian physicians had written on the small-pox before the 10th century; and notwithstanding the Saracens history is silent on the ravages which must have accompanied the general diffusion of the small-pox during the empire of the caliphs, the progress and prevalence of the distemper are to be inferred from collateral evidence. Thus, the caliph Yezid, who died in 693, is mentioned as being pitted with the small-pox; and the caliph Abul-Abbas Alaffah actually died, in 753, of this disease.

The time when the small-pox contagion first spread into Great Britain is involved in doubt. Most writers suppose that the distemper was imported into Europe by the crusaders, upon their return from the Holy Land in the 13th century. The improbability of this statement is inferred upon by Dr. Woodville, who adverts to the known activity of various nations, the long time it retains its infectious quality, and the unlikely circumstance of the small-pox prevailing six or seven centuries over various parts of Asia, having free intercourse with Europe, before it was conveyed to this kingdom. It is indeed surprising, that the dreadful effects which must have attended the first introduction of the small-pox into this as well as any other country, have escaped the notice of all our historians and medical writers. But, by examining some of the MSS. of the Harleian and Cottonian collections, preserved in the British Museum, and bearing indubitable evidence of having been written before the year 560. Dr. Woodville succeeded in tracing the existence of the small-pox in our island, and on the neighbouring continent, long before the crusades took place. In these curious records the word variola occurs several times in the same sense in which we now use it. We likewise learn from the MSS., that the people in those early times lived in continual dread of the small-pox, as several prayers, exorcisms, and incantations, to which they had recourse for preservation, are to be found. Dr. Woodville refers us to No. 585, of the Harleian Catal. vol. i. and Bibl. Cotton, Caligula A. 15. No. 30.
INOCULATION.

The first British medical writers of any note were those of the 15th century, and they, as well as all their successors, from John of Gaddesden to the immortal Sydenham, &c., have bestowed much attention on this important subject. History of Inoculation of the Small-pox.—The exact part of the world where inoculation was first adopted is quite unknown; nor do we possess any information of the circumstances which originally suggested the benefit that might result from the practice. From the Arabian physicians having been the first informed of the nature and treatment of the small-pox, it has been supposed that inoculation had its origin among them. (See Second Memoir sur l’Inoculation par M. de la Condamine.) Avicenna, who lived at Bokhara on the east coast of the Caspian sea, or his disciples, have in particular been suspected of being the authors of this valuable invention, in consequence of the countries between the Caspian and Euxine seas being the supposed centre from which inoculation spread to other places. Dr. Woodville, however, considers this conjecture as very ill-founded. He contends that we have no evidence that any of the people near the Caspian sea were the first practitioners of inoculation. Had the invention originated in this part of the world, the Tartars could hardly have been so ignorant of the practice, as, according to D’Entrecalles, they actually were in the year 1724. Nor is it probable that the method spread from west to east; for it has been observed, inoculation is more prevalent in the eastern parts of China than it is in the western provinces of that empire. Dr. Woodville remarks that inoculation was certainly first introduced in Constantinople from the Morea; but as the event did not take place till towards the end of the 15th century, we may conclude, that, had the art been practised for many ages, at so short a distance from that metropolis, it would have been known there sooner. Besides, in various countries, very remote from the Caspian sea, it is proved to have been an immemorial usage.

Inoculation was introduced into London as a foreign invention, and, from its success upon the younger branches of the royal family in 1723, became the subject of public conversation, when, to the great surprise of the learned, several communications proved that it was already a practice known in South Wales, where it had existed under the denomination of buying the small-pox as far back as tradition could be traced. The manner of inoculating, or buying the small-pox, here alluded to, was subject to variety. Some persons either rubbed the matter, taken from the pustules, when ripe, on several parts of the skin of the arms, &c., or pricked such parts with pins, or other pointed things, first infected with the same matter. Some scraped the skin with a knife, until the blood began to flow, before they applied the various pus. Others produced the di-temper by holding a certain number of dried pustules, for a considerable time, in the palm of the hand. (See the Letters of Dr. Williams, Mr. Owen, and Mr. Wright, in the Philosophical Transactions for 1722, and Dr Jurin’s account of the success of inoculation in 1723.) The inhabitants of the Highlands of Scotland have also for many ages performed a kind of inoculation by tying worldly threads, moistened with various matter, round the wrists of their children. (Monro on Inoculation in Scotland.) The same custom likewise prevailed in many other parts of Europe, Asia, and Africa; and, what is highly curious, the practice was, in several of these distant countries, termed during the small-pox, just as it was in South Wales; for it was superficially imagined that inoculation would not produce the proper effect, unless the person from whom the various matter was taken received a piece of money, or some other present, in exchange. The practice of buying the small-pox has been found to have prevailed from time immemorial, not only in South Wales, but also at Naples, Pavia, in Auvergne and Perigord, and among the peasants in many parts of Germany, Denmark, and Sweden. See Second Mem. sur l’Inoculation, par M. de la Condamine; Murray’s Historia Infectionis Variolaram in Svecia; Schultz’s Account of Inoculation, &c.

In Barbary and the Levant the various matter was also purchased, and infected in a small incision made in the fleshy part of the hand between the thumb and the fore-finger. (See Shaw’s Travels into Barbary and the Levant.) In Tripoli, Tunis, and Algiers, an incision was made on the back of the hand, between the thumb and fore-finger, and a little of the various matter put into the wound. According to Dr. P. Ruffel, inoculation is so ancient in those far kingdoms that nobody remembers its first rise; and it has been practised not only by the inhabitants of the towns, but also by the wild Arabs. (See Phil. Trans. vol. Ivi. p. 140.) It appears, moreover, from this gentleman’s account, that buying the various matter and inoculating have been ancient customs at Bagdad, Mosul, and Balfoza, in Armenia, at Damacus, and all along the coast of Syria and Palestine. The Arabs allured Dr. Ruffel that the puncture might be made indifferently in any fleshy part; but he morefully found that it must be made with a fine needle. Some of the Georgians had been inoculated in the same part, though most of them in the fore-arm. Some of the Armenians had been inoculated in both thighs; but the greater part, like the Arabs, bore the mark upon the hand.

D’Entrecalles, by obtaining access to several medical books at Pekin, discovered one in which an account was given of the introduction of inoculation into China. The author of the book here alluded to, lived in the latter part of the dynasty of Ming. Hence it has been concluded that inoculation has not yet been practised in China 200 years. But in Hindostan the custom can be traced much farther back. The methods of practising this art by the Chinefe and Hindoos are also far widely different, that they cannot have been derived from the same origin. The Chinefe take from two to four dried various pustules, or fakes (according to their size), between which they place a small portion of musk; the whole is then wrapped up in cotton, and introduced into the patient’s nostrils. The fakes before-mentioned are kept in a clofe jar for several years, and when the Chinefe are obliged to employ recent pustules, they think it necessary to correct the serosity of the matter, by expelling it to the flear of an infufion of the roots of scor-sonera and liquorice. They sometimes reduce the dried fakes into powder, and form them into a paffe for the pur-pose of inoculation.

Dr. Woodville very properly observes, that the application of various matter, wrapped in cotton, within the nostrils, must be an exceedingly precarious mode of communicating the small-pox, and may perhaps afford a reason why inoculation in China is less successful than in other countries; for if the matter acts in the way of inoculation, a troublesome inflammation of the Schnedierian membrane must ensue; and, should not this take place, the musk, or effuvious, by being inhaled into the lungs, will produce the natural small-pox.

In Hindooslan inoculation is performed by a particular tribe of Dravmns. They do not refuse to inoculate upon any part, but, in males, they prefer the outside of the arm, midway between the wrist and the elbow, and, in females, the shoulder. The operator first rubs the part with a dry cloth for eight or ten minutes, and then lightly pricks it
at many points. He next takes a small pledge of cotton, charged with the variolous matter, moistened or two or three drops of the Ganges water, apply it to the punctured part, fixes it there with a bandage, and orders it to be kept on for six hours. The bandage is then to be taken off, the pledge being left to fall off of itself. The matter in the cotton is always taken from pullules of the preceding year fresh matter, and such as is the product of the natural small-pox, being considered improper. See Hill's Account of the Manner of inoculating in the East Indies.

It was immediately from Constantinople that the English first derived a full knowledge of the advantages of inoculation. The beneficial consequences of the practice among the Turks, were detailed by Dr. Emanuel Timoni, communicated by Dr. Woodward to the Royal Society, and published in the Transactions of that body for the year 1714. The Byzantine mode was to take some fresh variolous matter in a glass vessel, and drop it on punctures or scratches made with a needle or lancet in any flothy part, but especially in the arm and forearm. The matter, which was dropped on the punctured place, was well blended with the drops of blood oozing from the wounds, by means of a blunt file or ear-picker. The part was then kept covered with a walnut shell for a few hours, in order to prevent the matter from being rubbed away.

Another account of the Byzantine mode of inoculation was afterwards published by Dr. Pylarini in the same volume of the Transactions of the Royal Society for 1716. But the year before this gentleman's observations appeared, surgeon Kennedy had printed an account of the new method of inoculating at Constantinople, in his "Essay on External Remedies," and he seems to be the first British author on the subject of inoculation. Soon afterwards, lady Mary Wortley Montagu, the wife of the English Ambassador at Constantinople, in her letters, confirmed the accounts of the remarkable manner in which the severity and mortality of the small-pox were diminished among the Turks by means of inoculation; and, in one of her epistles from Adrianople, she expressed her intention to try the experiment upon her own little son. See vol. ii. lett. 31.

The mode of performing the operation at Constantinople gradually became more and more simple. We learn from Pylarini, that, in 1701, incisions were made in the forehead, cheeks, chin, and also in the extremities, for the purpose of inoculation. Timoni likewise, twelve years afterwards, mentions, that the operator is to make several little wounds in one or more places of the skin, and these succeed each in the feathery parts of the arm. In the year 1717, the infliction of variolous matter, at a simple puncture in each arm, seems to have been the prevailing method of inoculation, as will appear by the following relation: Mr. Maitland, surgeon to the honourable Wortley Montagu in his diplomatic character at the Ottoman court, informs us, that the ambassador's lady, being conversed of the advantages of inoculation, determined that her only son, then six years of age, should undergo the operation. For this purpose, the desired Mr. Maitland to procure the variolous matter from a proper subject, which being done, an old Greek woman, many years in the constant habit of inoculating, was employed to infect it. 'But (said Mr. Maitland) the good woman went to work so awkwardly, and, by the shaking of her head, put the child to so much torture with her blunt and rusty needle, that I pitied her, and therefore inoculated the other arm with my own instrument, and with so little pain to him, that he did not in the least complain of it.' (Maitland's Account of Inoculating the Small-pox. p. 7.) The consequent difficulty was very mild, and, if the mode of buying the small-pox be excepted, this inoculation, which was done at Pers, near Constantinople, in March 1717, was the first ever practiced upon any English subject.

The inoculation of the small-pox was first regularly adopted in England in the month of April 1721. The practice, in all probability, would not have been so soon pursued by the faculty, had it not been for the enlightened and philosophical mind of lady Mary Wortley Montague. After this celebrated lady had witnessed the great effects of inoculation upon her son at Pers, she determined also to try it upon her daughter, then an infant three months old; but for certain domestic reasons, the operation was at that time deferred, so that this child was fortuitously reserved to be the first example of inoculation in England, which was done by Mr. Maitland, in April 1721. According to Dr. Woodville, writers have universally erred, in dating this event in April 1722, and making it subficiuent to the inoculation of the malefactors at Newgate. He notices that Mr. Maitland's pamphlet, in which all the circumstances are stated, was published in February 1722, as appears by the advertisement prefixed to the work. Therefore Mr. Maitland, in saying April last, could mean no other than that in the year 1721. Besides, Mr. Maitland expressly mentions, that this was the first example of inoculation in England.

After the successful result of this case, Mr. Maitland performed the second inoculation ever done in this country, in the month of May 1721, upon the son of Dr. Keith, and with the best effects. Notwithstanding these confirmations at home of the favourable accounts of the practice which had been already received from Constantinople, and notwithstanding the firm and powerful patronage which the Byzantine inoculation met with in lady Mary Wortley Montague, it is for a while but was the specious caution with which the method was received, that several months elapsed before a third trial of it was made in London. Indeed, the very next experiment that was undertaken strikingly evinces the dangerous light in which inoculation was still regarded; for it was determined that several culprits in Newgate, who had forfeited their lives to the laws of their country, should, on submitting to be inoculated, receive full pardon by the royal prerogative. Six condoned criminals were inoculated by Mr. Maitland, on the ninth day of August 1721, in the presence of several eminent physicians and surgeons. These malefactors all obtained a remission of their sentence on very easy terms. None of them had the disease severer, and one, who had already had the small-pox, was of course not affected a second time. A seventh criminal, a young woman, was next pardoned, on condition of having the Chinese method of inoculating tried upon her, at the wish of Dr. Mead. Consequently, some cotton, moistened with variolous matter, was introduced in her nostrils; the diftemper followed in a mild form; but the patient suffered violent pains in her head, from the commencement of the eruption to the maturation of the pustules.

After these public proofs of the safety and advantage of inoculation, objections and doubts were still adduced against the method. Some considered the cases too few, while others, in consequence of the small number and mildness of the pustules, thought it doubtful whether the genuine small-pox had been at all communicated. Hence, in the course of the following six months, Mr. Maitland inoculated only eight subjects, who all recovered, though two, it must be confessed, had the small-pox so severely, as to be for some time in danger. See Maitland's Account of Inoculating the Small-pox. p. 7.

Maitland's publication was immediately afterwards followed by a letter from Dr. Nettleton, who, in December
Inoculation.

3721, and the two subsequent months, had inoculated with success upwards of forty persons at Halifax, in Yorkshire. This relation influenced the public very considerably in favour of the new mode of communicating the small-pox.

Early in the spring of the year 1722, inoculation began to be adopted in various parts of England; and by order of her royal highness the princess of Wales, it was practiced first upon six, and afterwards upon five charity children, belonging to the parish of St. James's. The successes of these trials induced her royal highness to have the princesse Amelia and Caroline inoculated on the nineteenth of April 1723, by surgeon Amiard. Both these younger branches of the royal family passed through the small-pox, in a very favourable manner; and inoculation, in consequence of this illustrious example, was now making a rapid progress; when unfortunately the practice received a great check, by the death of the earl of Sunderland's son, and by that of lord Bathurtt's servant, after being inoculated. A Miss Rigby also died, about eight weeks after her inoculation, making the third death. Therefore, out of 182 inoculations, in 1721 and 1722, three died; or nearly one in sixty.

About the time when the first death happened in London, accounts were received in town, stating that the practice had been tried to a much greater extent in New England. It appears that, after an absence of nineteen years, the small-pox had broken out with a great mortality at Boston, in April 1721. This induced the Rev. Mr. Mather to publish the account of inoculation, as related in the Philosophical Transactions by Timont and Pylarini. This publication, which was distributed to all the medical practitioners at that place, was the means of inciting Dr. Boylton to commence the practice of inoculation upon his own child, and two negro servants, at the latter end of June 1721. In the course of six months, he inoculated in and about Boston 224 persons. Of this number 10 died.

The reports which came from New England, were employed with great exasperation by the opponents of inoculation, who seized with avidity every circumstance that might have the least tendency to retard the progress of the improvement.

During 1723, the practice of inoculation became much more general in England, the number of inoculated this year far exceeding the numbers in the two preceding years taken together. It amounted to 292, which, added to 182, makes the whole number of inoculations in the years 1721, 1722, and 1723, to be 474, of which number, according to Dr. Jurin, nine died.

It deserves notice, that several of these nine cases were not generally admitted as deaths altogether in consequence of inoculation. But even allowing that they were so, the chance of recovering from the inoculated small-pox must appear infinitely greater than from the casual. For it was proved, that at this time, out of 14,539 persons who had been affected with the natural small-pox, 2353 died; nearly one in six, or five out of thirty-one.

In 1724, there were only forty persons inoculated. Their royal highnesses prince Frederick and prince William, however, were in this small list. Dr. Jurin accounts for the seeming decline of inoculation this year, by the fact that people will not easily submit to a practice in which they apprehend risk, unless impelled by the dread of a greater danger. Now it appears that in 1724, the natural small-pox was much less fatal than in 1722 and 1723, and it is to this cause we are to refer the above small number of inoculations. That the practice had not fallen into disrepute is manifest; for Dr. Jurin informs us that in 1725 the natural small-pox was very mortal, and of course, people being frightened, referred to inoculation again in a larger number. Of the above-mentioned forty, one is recorded to have died.

In 1725 and 1726, 356 persons were inoculated, of which number four died.

In the years 1727, and 1728, the practice of inoculation did in reality begin to decline; for, though the small-pox was very prevalent and fatal, only 124 inoculations took place in these two years, and of these the cases proved fatal.

We find that up to 1729, 807 persons had been inoculated in England, of whom seventeen are reported to have died. But on the other hand, the records show, that of 18,329 persons, who had been afflicted with the natural small-pox, during the first eight years of inoculation, 3003 died under the disease; or about one in six; whereas, the deaths by inoculation, admitting the utmost number considered for, does not exceed one in fifty. The reason why more died of inoculation at this early period of the practice than had been the case of late years, is chiefly ascribable to the better manner lately adopted of treating inoculated patients. Besides, formerly it was common to inoculate adults, in whom the disease is more disposed to assume a severe form than in children.

Inoculation was not regularly practiced in Scotland till the year 1726, when Mr. Maitland performed this operation upon ten persons; but as one of these cases was unsuccessful, the practice was discontinued in that country for twenty years afterwards, and was not revived again without considerable difficulty. At Dunfermline, indeed, where the casual small-pox had committed great ravages, inoculation was had recourse to in 1753; but in most other parts of North Britain the method was not introduced till 1753.

In Ireland, inoculation was first performed at Dublin in 1723. Twenty-five persons were inoculated in that and the three following years. Of this small number, three cases terminated fatally.

Inoculation at Hanover was first performed in 1724, by Mr. Maitland, upon his royal highness prince Frederick, and afterwards upon eight children of the Baron de Schullenberg. The example and success of these cases had the effect of establishing the practice in that country.

After 1729, inoculation was seriously on the decline in England; but it made considerable progress in the transatlantic world. In South Carolina, about the year 1738, not less than 800, or 1000 persons were inoculated, of whom only eight died. The account of this success contributed materially to revive the practice in Great Britain. In Philadelphia, likewise, inoculation proved soon afterwards still more favourable; and in St. Christopher's 300 slaves were inoculated, without the loss of one.

Such facts in favour of the practice, and the great fatality of the natural small-pox in Britain, soon led people to adopt inoculation more extensively than ever, and from the year 1735, this beneficial method may be regarded as having been completely and generally established, though partial opposition prevailed long afterwards.

In the year 1746, the institution called the Inoculation Hospital had its rise, though it was not at first so considerable an establishment as at present. Here the successes of inoculation did not disappoint the hopes and zeal of its patrons; for out of 593 cases of persons successively inoculated, from the year 1731, only one proved unsuccessful.

In 1751, it was determined to inoculate the three royal children, who had not yet had the small-pox. In the mean time, his present majesty took the disease casually, so that only the prince Edward, and the princes Augusta, were inoculated.
inoculated. These great examples, and the public approbation of the practice declared by the College of Physicians, gained numerous advocates to the cause, which never afterwards lost ground, till the still safer and milder mode of inoculation with vaccine lymph was brought into notice by the immortal Jenner.

In France, Dr. Boyer is the first writer who has noticed inoculation, which he did in 1717. In 1723, the successful trials of inoculation in England were published at Paris by Dr. de la Cotte, and the confecution was a declaration by the physicians of that city, "that for the benefit of the public, it was lawful to make trials of inoculation." The practice was on the point of having a beginning in the hospitals, under the function of the duke of Orleans, the regent, when, unfortunately for the experiment, this nobody died, and soon afterwards Dr. Hequet published his "Raifons de dire que l'Inoculation." The sentiments contained in this publication, and in a thesis written at Paris in 1723, the reports of the ill successs of inoculation at Bolton, and the great mortality of the natural small-pox in London, in 1723, falsely ascribed to the new practice, soon brought the method into disrepute in France, and the design of trying it there was laid aside.

The French paid little attention to the subject again till 1752, when Dr. Bottini, of Montpelier, published at Paris his "Traité de la Petite Verole communiquée par l'Inoculation." Two years afterwards, M. de la Condamine read his excellent memoir upon the advantages of inoculation, before a public assembly of the Royal Academy of Sciences at Paris. But, according to Dr. Woodville, the practice was not introduced into France till the 1st of April 1755, when, at the desire of M. Turgot, a child, four years old, was inoculated at Paris. On the 14th of May, M. Chaffot, aged 21, voluntarily submitted to the operation. About this time, Dr. Holy, who had been attending the small-pox and inoculation hospitals in London, at the request of the French minister, published at Paris the following report:--"That out of 463 cases of persons lated inoculated in the hospital, only one had been unsuccessful; whereas, in the Small-pox hospital, it appeared by the registers, that nearly one in four had died of the natural small-pox."--"That Mr. Ranby, principal surgeon to his majesty, had inoculated 1600 persons; and that Mr. Bell, pupil to Dr. Morand, had inoculated 903, without the loss of one."--"That in order to form a just comparative view of the fatality of inoculation and of the natural small-pox, it is only requisite to visit the two hospitals in London, the difference of their reports being so remarkable, that it must convince the most incredulous of the advantages of inoculation." Laitly, "with respect to the inoculation of other diseases along with the small-pox, that no instance of the kind has ever been produced; and that pears have been inoculated with various matter, taken from a patient affected with the veneral diltemper, yet have thereby received the infection of the small-pox only."

This statement had immense effect in promoting the introduction of inoculation into France; and in the year 1756, the family of the Duke of Orleans, and great numbers of the first rank, were inoculated by Drs. Tronchin, Holy, and others. In 1758, the practice had diffused itself over various parts of France. The inoculated were not, however, very numerous, and one or two unsuccessful cases, joined with false reports, that some persons had taken the natural small-pox after undergoing inoculation, once more call difcredited upon the plan, and excited a violent controversy. The great fatality of the small-pox at Paris in 1763, being imputed to inoculation, the practice was forbidden by parlia-

ment. At length the faculty of physic, and that of theology, were called upon to decide, whether inoculation ought to be tolerated or prohibited. This measure served to increase the disputes; nor was it till a very late period that inoculation was extensively practiced in France.

In Holland, inoculation was begun at Amsterdam in 1748 by Dr. Tronchin, who, on finding one of his sons seized with the natural small-pox, immediately inoculated the other. This physician, after his return from Geneva, in 1754, inoculated a great many persons in Holland. Dr. Schwenke, at the Hague, likewise promoted the practice; and so did a society of physicians and surgeons at Rotterdam, who were associated for the purpoe in 1757. The method was not, however, very generally adopted by the Dutch, till after 1764, about which time Morand and others had practiced it at Amsterdam with striking successes.

Inoculation was first introduced into Denmark in September 1754, when the coutarchs of Bernsdorff undertook the process. In 1758, two inoculation houses were established at Copenhagen; and, in 1760, the prince royal was inoculated with successes.

In Sweden, the first trial of inoculation was made by Haartman in 1754. The rapid progress of the method in Sweden was owing to the encouragement afforded by the Swedish court. Dr. D. Schultz was deputed to enquire into the successes of the plan at the inoculation hospital in London, and the accounts which he gave upon his return to Stockholm in 1755, led to the establishment of inoculation houses in different parts of Sweden. In 1757, the benefits of inoculation were commemorated by a medal.

Inoculation was first introduced at Geneva in 1751, whence it passed into Switzerland in 1753. In the latter country, it was first performed at Lausanne by a lady on her own child.

Inoculation commenced in Italy during the great mortal ity occasioned in Tuscany and Rome by the small-pox in 1754. Dr. Beverini was the first inoculator, putting out of consideration the custom which had long prevailed in the interior of the country, of women sometimes artificially communicating the small-pox to their children. In 1755, M. de la Condamine was at Rome, where, by his writings and personal influence, he succeeded in reconciling many to the practice. Before 1765, inoculation was practiced with successes at Venice, Padua, Verona, Brescia, Mantua, Bologna, Milan, Parma, &c. In short, Naples was the only important place where the method had not been introduced.

Inoculation was begun at Hanover almost as soon as in England. The opposition of Dr. Hagen, however, kept back the improvement in most other parts of Germany. The Prussians and Austrians were the last to adopt it. At Vienna, inoculation did not make any progress till 1756. The younger branches of the imperial family were inoculated in 1768, and shortly afterwards the emperor established an inoculation hospital in the suburbs of Vienna.

Owing to some unfortunate events of the first inoculations at Berlin, the practice was soon discredited in Prussia, nor was it revived till 1774, when Dr. Baylies was invited from Dresden to superintend the method.

Although some persons had been inoculated in Livonia by Dr. Schulein at an earlier period, the practice was unknown at St. Petersburg till 1768, when it was established there under baron Dimidale. This event must have been to the Russian an immense blessing; since in that country, the natural small-pox used to rage with great severity, that it is said to have annually destroyed millions of subjects. On the 29th of July, 1768, baron Dimidale inoculated the em press and the grand duke, both of whom speedily recovered.

The
INOCULATION.

The practice made rapid progress; an inoculation hospital was established; and at length Dimdlafe returned to England loaded with wealth and honours.

In Spain, inoculation was not extensively adopted before 1771, though it had been introduced by a surgeon forty-two years before at Jadrique, a small town in that kingdom, and had not been discontinued in that particular place. Dr. Don Miguel Gorman visited London for the purpose of learning the Suttonian method of inoculation, and returned to Madrid in 1772, where he practised the art upon several of the nobility to the great satisfaction of the court.

Of the Objections which were urged against Inoculation.—Having related the rise and first progress of inoculation in several parts of the world, it seems proper, before recting the particular methods pursued by the Suttons and baron Dimdlafe, to notice the various objections and arguments which were adduced for the purpose of suppressing the practice of inoculation altogether. The clamour against the method, indeed, was for many years excessively violent; both physical and moral reasons were brought forward against the system, and men of different professions entered into the controversy.

1. To the objection that inoculation did not produce the genuine small-pox, and consequently could not secure any one from having the disease afterwards, the celebrated Dr. Mead made the following judicious reply. "Now I own I cannot understand how contagion, that is the very seed of the disease, should produce not its own proper distemper, but another of a different kind. Neither, certainly, does it matter by which way the infection is received, provided it brings forth manifest marks of the disease. And as to those, who, after having been inoculated with success, are, notwithstanding this, said to have suffered the small-pox, I must protest that, after the most diligent enquiry, I have not been able to find out one convincing proof of this kind. But to speak plainly, if such a thing happened once, why do we not see it come to pass oftener? Or, what can a single example, supposing it to be true and certain, avail, when innumerable have produced nothing like it?"

2. One formidable objection was, the supposed danger that inoculation might be the means of communicating other terrible and fatal diseases, when the matter was taken from unhealthy subjects. The various matter being a poison sui generis, it cannot by inoculation communicate any other distemper. The venereal disease is known to be as communicable as any, yet several persons have been inoculated from patients labouring under considerable degrees of the venereal disease, and no ill consequences were ever known to follow. Mr. Burges informs us that he knew of one instance where the matter was inadvertently taken by a surgeon from a young woman, who fell ill of the small-pox, after being admitted into St. Thomas's hospital to be fattivated. Three patients were inoculated from this matter, and had the small-pox in the most favoured manner. Nothing particular happened about the wounds, and the patients all grew up healthy subjects. See Burges's "Account of the Preparation and Management necessary to Inoculation, 1754."

Dr. Kirkpatrick also mentions in his "Analysis of Inoculation," that he was assured by a respectable surgeon, that a young lady was inoculated by an apothecary from a gentleman's servant, who had a venereal bubo together with the small-pox. The lady, notwithstanding, did very well, and never had the frighted symptom of venereal infection. The affront, then, that other diseases may be communicated by inoculation remains quite unproved. That other diseases may follow the small-pox no man of common sense will deny; for it is no security against them. Nay, the debility which it sometimes induces, may even promote the accession of severe, consumption, &c.; but since inoculation tends to materially to diminish the severity of the small-pox, it must also have a great effect in lessening and preventing any circumstances, which are to be regarded as consequences of such severity.

3. Perhaps the disease may never attack in the natural way. This objection, one would think, must give way to the bare statement, that, previous to the practice of inoculation, the fatal small-pox annually destroyed about two millions of lives in the Russian empire alone, and committed equal devastation in several other parts of the world. It has been observed by Dr. Jurin, in an ingenious paper inserted in the Philosophical Transactions, that it is difficult to ascertain the exact number who die without having the small-pox; but that of all the children that are born, there will, some time or another, die of the small-pox one in fourteen; and that of persons of all ages taken ill of the same distemper, two in eleven will fall victims to it.

From a table of burials it appears that in Edinburgh and St. Cuthbert's parish, during ten years, about one-tenth of the dead was killed by the small-pox.

It may likewise be noticed, that no individual is originally unprotectible from the small-pox, and though a proportion of mankind might possibly escape the contagion, still the number of victims to the disorder casually taken would be very considerable. During the controversies concerning the advantages and disadvantages of inoculation, enquiries were made from house to house, in several towns, in order to ascertain the number of people, who had had the small-pox in one twelvemonth, when it appeared that nearly one died in every five who had taken the disease; and that of eighty-two persons who were inoculated in these places in the same year, not one died.

Dr. Nettleton, Dr. Whitaker, and some others, made an attempt to find out how many persons had had the small-pox, and how many had died of it in the year 1722. The result was as follows:

This table will serve to depict the general event of the casual small-pox. The mortality was considerable; but it was much greater at some periods, and in particular parts of the world. On the other hand, inoculation has sometimes been purified with such remarkable successes, that out of a thousand persons inoculated one after the other, scarcely one has perished.

We shall not dwell this article with a detail of the numerous physical reasons urged against inoculation, the present state of knowledge renders such a talk unnecessary; and all the objections alluded to, have been so often and completely proved to be frivolous and unfounded, that of late years the practice has encountered no opposition, if we put out of present consideration the praiseworthy endeaour to substitute everywhere where the vaccine for the variolous inoculation.

4. The moral and religious objections which were adduced against the practice of inoculation, gave rise to as much dispute as the medical differences of opinion, and certainly operated till more perspicaciously prejudicing the minds of people.
INOCULATION.

people against the art. The plan of bringing diseas upon ourselves, was represented as a Circassian impiety, altogether irreconcilable to a Christian confidence. Those who adopted the practice were branded with the appellations of poisoners and murderers, and were faiid to be filtigated by atheifm, quackery, and arfcries. One anonymous writer implored the interference of parliament. He observes, "while this heathen principle has so much hold upon mankind, 'tis highly necessary that there should be no doors left open for the practice, at least none that can be shut; that there should be no room for the covering of such horrid things from the reach of the law. Physicians they have already too much latitude in practice, to make havoc of mankind for the satisfaction of their judgment in physic, and increase of their experience; but every quack now may be a hireling to the devil, and, like that bastard in Italy, be ready to do the drudgery of removing heirs, and other obstructing incum- bents of many kind, and to do this under the mask of a cure, inoculating death instead of a disease, and making use of an art never before practised, in a manner not foreseen, and by the laws not yet sufficiently guarded against." See a pamphlet entitled "The New Practice of Inoculation con- sidered, and an humble Application to the approaching Par- liament for the Regulation of that dangerous Experiment, 1722."

A sermon was preached on Sunday, July 8th, 1722, against inoculation, at St. Andrew's church, Holborn, by the Rev. Mr. Maffey. His text was "So went Satan forth from the presence of the Lord, and lamed Job with sore boils from the sole of his foot unto his crown," chap. ii. v. 78. In this discourse, the Devil was depicted as having first put inoculation in practice upon Job. Inoculation was filmgitized as a diabolic operation, and an anti-providential project, that infuits our religion, and banishes providence out of the world.

It is almost unnecessary for us to say, that Job's being afflicted with the small-pox was nothing more than an un- warrantable affectation, and a whimsical conceit of the Rev. Divine. The following epigram on the subject appeared in the Monthly Miscellany for March 1774:

We're told, by one of the black robes,
The Devil inoculated Job;
Suppose 'tis true, what lie does tell,
Pray neighbours, did not Job do well?

Dr. Wagstaffe had asserted, that it never came into men's heads to take the work out of nature's hands, and raise dilempers by art in the human body. (See "Letter shewing the Danger and Uncertainty of inoculating the Small- pox." ) To this Mr. Maitland replied in his Vindication, "that the practice of physic is founded upon the principle of curing natural by raising artificial disfeafe. What is bleeding, but an artificial hemorrhagy; purging, but raising an artificial diarrhea? Are not blisters, issues, and fots, artificial impollumations?"

The virulence and farceum by which the opposers of inoculation were actuated, are well exhibited in the rejoinder, made by another writer, to the foregoing very sensible ob- servation. "Very good, sir, but go on,—what is correction at the cart's tail, but the noble art of muscular phlebotomy? What is burning in the hand, but the art of applying a cautie? What is hanging but an artificial quinzy, which makes the patient feel for the ground, and chokes him? What is breaking on the wheel, but the art of making dis- locations and fractures, and differs from the wounds and am- putations of surgeons only by the manner and intention?"

-A Short and Plain Account of Inoculation, &c. by B. D. Maddox, bishop of Worcester, was an able and zealous friend to the cause of inoculation, and preached an excellent sermon in support of the practice. He observed, that it was needless to enter into a disquisition, which is the null proper method of designedly raising the small-pox in the human frame, by carrying the poison that is to receive it to the contagious creams, or effuvis, or bringing to him the infected matter. Religious difficulties (if any hill remain, concerning a practice that has preferred to many lives, and prevented the heaviest grief in so many families,) are exactly the same, in either method of voluntary communi- cation.

For it is no more invading the prerogative of heaven to occasion one easy and voluntary conveyance of the infection than another, by a flight and hardly feasible rasure upon the arm, than communicating the same dilemper, by invisible particles, to that tender organ the lungs, which are so frequently affected by the venom of this disease, when contracted by the breath, or receiving into the body infected particles in what is called the natural way.

Were this preventive method (continues the learned pre- late) universally successful, and never once to fail in any in- stance whatsoever, it is fearfully to be presumed that any ob- jection would be raised against a salutary expedient, to pre- serve from destruction so great a part of the human species as daily fall by this mortal enemy; when it attack men as it were in the dark, ignorant of, and unprepared for the af- fault.

This method of inoculation would then be no more liable to censure than the making a voluntary wound, by incision, to form a necessary drain; or administering any operative medicine, which, upon repeated trials, had proved an unfail- ing security against any other dangerous and prevailing pel- tence or contagion.

But, in order to excite and secure a dependence upon his divine providence, the great Governor of the world has ap- pointed that no human affairs, not even our necessary suffe- rence, should be attended with such absolute certainty: a very wise appointment, that vain man might not fancy him- self an independent being; but, among all the changes and chances of this mortal life, should still look up unto, be- cause he can only be defended by, God's most gracious and ready help.

Experience alone must determine the good or bad con- sequences of this artificial infection, as it ought to do in all other medical attempts, which, in many instances, are, in reality, little more than curing or alleviating one dilemper, by exciting or introducing another. And, in this view, the method now under consideration, of lessening the hazard of a very mortal disease, should be considered in the same light as every other antidote, or preventive attempt in physic or surgery, against any probable, almost certain malady, internal or external.

The philanthropic prelate forebore to derive any strength to the argument, from the great number of noble, venerable, and worthy persons, of every rank and profession, who were in his time the public advocates of this compassionate design: he wished to found upon its own proper evidence and founda- tion.

He remarked, that a safe passage through this dilemper, like the emancipating slaves, is a deliverance to vast numbers of people kept, as it were, in bondage; who, before they have undergone this abhorred disease, are excluded from many offices in life, and prevented from pursuing their ne- cessary buisnesses; and it gives tranquility and cheerfulnes
INOCULATION.

To persons of better condition, who, under apprehension of this loathsome and infectious disorder, were all their former days subject to great anxiety and constant fear.

The bishop commented with great ability upon the advantage that inoculation affords of communicating the small-pox at the most favourable time of life, viz., infancy, if the disease is most inclined to put on a mild form. He mentioned, authentically, that, out of 1500 persons inoculated by Mr. Sergeant Rankby, Mr. Sergeant Hawkins, and Mr. Middleton, only three died.

He flated to his congregation, that, from the annual account within the bills of mortality, (in which many places in and near the city were omitted,) it appeared that, in twenty years, viz. from the year 1731 to the year 1750, inclusive, no less than 39,115 persons died of this fatal distemper; which, including the cases not infected in the weekly bills, must have been considerably more than 30,000 every year, that fell in the two adjoining cities and parts adjacent. And, he noticed, that if only one in seven is supposed to die by the distemper taken in the natural way, then the whole number of persons who, in this period of twenty years, were thus infected, must have amounted to 280,000, of which number no less than 40,000 perished. But if one in every 200 should be supposed to die under inoculation, which is really more than four by that artificial infection, instead of 40,000, only 1400 would have died in one district in twenty years, had inoculation been universally adopted. Thus the difference in that short period, in one spot, would have been no less than 38,600 lives preserved, besides the numerous pities that might have been derived from them.

The learned divine inferred, that humanity, regard to our country, the dictates of reason, and the precepts of religion, are all in favour of the system of inoculation.

During the opposition to the introduction of inoculation, many affected to be actuated against it by religious scruples, and the practice was alleged to be unlawful.

In answer to this, the scriptures all, Is it lawful to save life, or to destroy it? Luke, vi. 9. We should also remember, that, as the fall of man brought the danger of diseases into the world, so to evade, oppose, or destroy it, is not only his right, but duty, if in his power. When danger surrounds us, no conduct is more proper than to inquire into, and pursue the means of escape. To neglect our safety is to sink below brutes, which are taught by instinct to run from the evil to which they are exposed. Inoculation is certainly in many instances a means of saving life, and of moderating the severity of affliction. And, in a moral point of view, wilfully neglecting the means of preferring life must appear almost as bad as the guilt of murder.

The bringing of a distemper on ourselves was likewise represented by bigoted individuals as usurping the sacred prerogative of God.

As to the first part of this objection, if by distempers are meant sickness and pain, the same thing is practised daily in other infirmities, in concurrence with the scriptural dictate, viz. of two or three choose the leaf. Inoculation is not done from a mere want of desire of importing any distemper, but is performed in order that the patient may go through an unavoidable distemper with the least difficulty, and the greatest chance of recovery. The natural small-pox being highly perilous, it must be a great disaster to avoid it, and inoculation enables us to do so, by destroying that disposition in the body, without which the disease cannot take place.

Respecting the offence given to God, a reliance on providence does not imply that we are not to prevent or oppose the evils which we foresee, and which we have in our power to guard against by prudent precautions. Would these objectors, in other instances, refuse the means of lessening the malignity and danger of disease, than which the practice of inoculation is no more? Let the objectors of the rights of God fury, whether, when God permits the discovery of preferring ourselves, he forbids our using it? If our Maker offers us a remedy, it is offending him to reject it.

It was moreover objected, that the decrees of God have fixed the comminution of every disease, and that our precaution cannot prevent what He has determined.

To this it was answered, that, however true it is, our days are determined, &c. yet is it God's revealed will, and not his secret purpuses, which we are to regard as the rule of duty. God has required of us to have a tender regard of our lives; and they who disobey him therein are guilty of a degree of self-murder, and will never be acquitted of that guilt by the secret determination of Heaven concerning them. Besides, God, who has ordained the end, has also determined the means leading to it. St. Paul, in his dangerous voyage, had a special revelation to assure him, that all who were with him should escape; and yet, when the seamen were getting out of the ship, he declares, that if they did not stay in it they could not be saved. Acts, xxvii. 31. God purposed to preserve them in the way whereby they were afterwards delivered.

It was likewise contended that we ought not to do evil, that good may come.

On the other hand, it was acknowledged, that if inoculation is, in its own nature, a moral evil, it certainly should be rejected, however great its advantages may seem to be. The prospect of relief from any calamity in life should not tempt us to offend God. But they who make the foregoing objection proceed upon a mistake. Their principle is true with regard to moral evil, but is not so when applied to physical. It is certainly lawful to pull down one house to save a great number from being burnt. This is a physical evil, which can hardly take place without some degree of moral evil; and many other instances may be pointed out, where, for a greater good, a lesser ill is submitted to.

It was further objected, that the patient might die, and then his last moments would be distressing, and the future reflections of his friends grievous.

This objection led many to decline the practice of inoculation, even while they allowed the theory of it to be reasonable. They entertained hopes of escaping the distemper in the natural way, and they had fears of dying in this, and thus they were prevented from undergoing the disorder. But they should have considered what grounds they laid for either their hopes or fears, and what was to be advanced to balance the account, in an examination of the different degrees of probability attendant on what they hoped for, and what they were afraid of, in the neglect or adoption of inoculation. Dying is an awful thing; but if inoculation was a probable and lawful means of preferring life in a time of danger, it was a duty to comply with it; and what reflection could be more peaceful than that of dying in the way of duty?

It was further objected by the religious opposers of the new practice, that fear was a dangerous passion in the small-pox, and that inoculation increased the causes of fear, by lessening our faith and trust in God.

When the small-pox was left to nature, such were its ravages, that, not to fear, would have been to sink beneath humanity: its consequences were too grievous to be viewed with indifference. Experience manifested the advantages and
and general safety of receiving the dissafe by inoculation, and
so far the practice was a remedy to that just alarm which en-
chanced the danger, when the distemper was left to itself.
As to faith in God, none was desirable, except that which
was agreeable to the scripture, and which could never have
the effect of creating a disregard to calamities and danger.
Inoculation was well proved to be a means of safety, and it
would have been as rational to conclude that our lives could
be preserved without eating and drinking, as that we should
be delivered from danger without a prudent care for our own
safety. We are to depend on the care of providence only in
the way of duty. To boast of courage and trust in God,
while we omit the means of escaping danger which surroun-
us, is not faith but presumption.

Thus, when inoculation became a probable means by
which life might be saved, the neglect of it, so far from
being truth, was preposterous.

We shall now take our leave of these theological disputes
and scruples, which have now been long removed by the in-
fluence of right reason and sound sense. When it was once
well ascertained and universally believed that inoculation was
realy a means of preserving life, the idea of its being crim-
nal to adopt the practice could not have much duration.
A very able discussion of most of the foregoing objections
was published in a pamphlet, entitled "Inoculation impar-
tially considered, and proved to be conformable with Reason
and Revelation," by the Rev. David Scone, edited by Dr.
Doddridge, 1759.

Of Inoculation, as practifed by the Suttons, Baron Dimfde,
&c. — The introduction of the Suttonian practice was re-
garded quite as a new era in the history of inoculation, from
the novelty of the method, and its unparalleled success.
Mr. Robert Sutton, the first of this name, who acquired
celebrity as an inoculator, resided at Debenham in Suffolk,
where he practised surgery and pharmacy. From the year
1757 to 1767, he inoculated 2514 persons.

Two of his sons, Robert and Daniel, followed the medical
profession, and after affixing to him the three first years
of his practice of inoculation, Robert established himself as
an inoculator at Bury St. Edmund's, where Daniel became
affiitant to Mr. Bullhead, a surgeon at Oxford. Daniel,
on his return to Debenham, in the year 1763, suggeffed to
his father a new plan of inoculation, in which he proposed to
shorten the time of preparation to a few days, and not to
confine the inoculated patients to the house, but to oblige
them to be in the open air as much as possible during the
whole progress of the distemper.

The father condemned this scheme as rash and dangerous.
Its advantages, however, soon becoming manifest to patients,
they evinced a desire of being fully under the management
of Mr. D. Sutton. The consequence was, that the father
and son separated about the end of the year 1763, when the
latter opened an inoculating-house near Ingatestone, in
Essex. Here, by public advertisements, he made known his
plan of inoculating in an improved way peculiar to himself.
The encouragement which he met with may be estimated
from his receiving, during the first year, 2000 guineas, and
above 6000 the second. His fame spread to the most distant
parts of the kingdom; and the numbers that referred to
him for inoculation, constantly filled the village of Ingate-
stone, so that accommodations could hardly be procured for
the purpose. His practice in Kent being also very exten-
sive, he was obliged to employ several medical affiitants. In
1765, Mr. D. Sutton removed to London, in hopes of reap-
ing still more emolument; but his receipts fall far short of his
expectation.

According to Mr. Houlton's statement, the number of
persons inoculated by Mr. Daniel Sutton in the year
1763 was 1629
1765
1766

13793

"To the above number," says he, "should be added
6000 that have been inoculated by Mr. Sutton's affiitants;
so that he may be said to have inoculated, within these three
years, 20,000 persons."

Of this number, not one was allowed to have fairly died
of inoculation. The vilen pen of the preceding writer cer-
tainly exaggerated every thing, and great boast was also
falsely made of the Suttons having a specific medicine for
preventing too many pustules. However, no doubt was
entertained that the Suttonian practice was incomparably
more successful than any other.

Medical practitioners, brisk with the advantages of the new
practice, let about the investigation of the caufes. Sir George
Baker published the following account of the manner in which
Mr. D. Sutton practiced inoculation. "All persons are obliged
to go through a strict preparatory regimen for a fortnight
before the operation is performed. During this course, ever-
ry kind of animal food, milk only excepted, and all fer-
mented liquors and spices are forbidden. Fruit of all sorts
is allowed, except only on those days when a purging medici-
ne is taken. In this fortnight of preparation, a dose of a
powder is ordered to be taken at bed-time, three several
times; and on the following morning a dose of purging falt.
To children, only three doses of the powder are given, with-
out any purging falt. The composition of this powder is
indultriously kept a secret. But, that it consists partly of a
mercurial preparation, is demonstrated by its having made
the gums of several people foare, and even salivated others.
The months of May, June, July, and August, are preferred as
the most favorable for inoculation. But healthy people
are inoculated at any season of the year indifferently. The
autumn is held to be the worst season; and an agrain habit
the least proper for this operation. No objection is made to
any one on account of what is vulgarly called a feborrhoeic
habit of body, or bad blood. The person who is to be inocu-
lated, on his arrival at the house used for this purpose, is car-
ried into a public room, where, very probably, he may meet a large
company assembled under the feveral fages of the small-pox.
The operator then opens a pufhule of one of the company,
chasing one where the matter is in a crude flate; and then
just raifes up the cuticle on the outer part of the arm, where
it is thickest, with his moist lancet. This done, he only preffes
down the raised cuticle with his finger, and applies neither
puffer nor bandage. What is extremely remarkable, he fre-
fquently inoculates people with the moisture taken from
the arm before the eruption of the small-pox, nay, within four
days after the operation has been performed. And," says Sir
G. Baker, "I am informed, at preffent he gives the preference
to this method. He has attempted to inoculate by means of
the blood; but without success. If the operator happeneth
not to be at home when the new patient arriva, this is
looked upon as no matter of no importance. And to far he
from any apprehension of accumulating infection, that it is
very common for persons, just inoculated, to lie in the fame
bed with a patient under any figafe of the disease, as it may
happen; nay, sometimes in a room where four or five people
are lice. On the night following the operation, the patient
takes a pill. This medicine is repeated every other night,
INOCULATION.

until the fever comes on. All this time, moderate exercise in the air is strongly recommended. In twenty-four hours after the inoculation, the operator can often distinguish whether or no the patient be infected. He every day examines the incision; and from hence seems to prognosticate, with some degree of certainty, concerning the degree of the future discharge. In three days after the operation (provided that it has succeeded), there appears on the incision a spot like a flea-bite, not as yet above the skin. This spot, by degrees, rises to a red pimple; and then becomes a bladder full of clear lymph. This advancement to maturation like the various pulsates, but is the last which falleth off. In proportion as the discolouration round the place of the incision is greater, the less quantity of eruption is expected. And, therefore, whenever only a small discoloured circle is observed, purging medicines, more than ordinary, and more frequently repeated, are held to be necessary.

"The preparatory diet is still continued. If the fever remains some hours without any tendency to perspiration, some acid drops are administer'd, the effect of which is to bring on a profuse sweat; but in some cases where the fever is very high, a powder or pill, still more powerful, is given. In general, during the burning heat of the fever, the inoculator gives cold water. But the perspiration beginning, he orders warm balm-tea or thin water-gruel. As soon as the sweat abates, the eruption having made its first appearance, he obliges every body to get up, to walk about the house, or into the garden. From this time, to the turn of the disease, he gives milk gruel. *ad Editionum.*

"On the day following the first appearance of the opaque spot on the pustules, to grown people he gives an ounce of Glæber's purging salt. To children he gives a dose of it proportioned to their age. Then, if the eruption be small, he allows them to eat a little boiled mutton, and toast and butter, and to drink small beer. But in case of a large eruption, he gives them, on the third day after their having taken the first dose, another dose of the false salt, and confines them to the diet ordered during the preparation."

Sir George, after representing this as the practice of Mr. D. Sutton, ascribes its superior success to the free use of cold air. Dr. Glaafs, of Exeter, in a publication which appeared shortly after that of the preceding gentleman, imparts the advantages of the Suttonian method to the patient being sweated; while another author, Mr. Chandler, differed from both the former writers, and referred the chief benefit of the plan to the infecting humour being taken in a crude state, 'before it has been ultimately varicoloured by the purging fever.' Baron Dimsdale likewise thought, that although the whole process might have some share in the production of the succeed, yet he believed the chief good was owing to the method of inoculating with recent fluid matter, and the management of the patients at the time of the eruption.

In November, 1766, baron Dimsdale published his well known work, entitled "The present Method of inoculating for the Small-pox." The instructions contained in this book have deservedly continued ever since, almost without exception, to regulate the practice of inoculation.

The baron, when the age is left to his choice, avoids inoculating children under two years of age. The subjects considered by him improper for the operation, are such as labour under any acute or critical discharges, or their effects; and also such as have evident marks of corrosive acrimonious humour, or manifest debility.

As for the most eligible season of the year, he thought, that persons generally had more pustules in the spring than any other time; and epidemic discharges (especially fluxes, intermittents, and ulcerated sore throats) being most frequent in the autumn, the baron did not look upon this as in general the most favourable season. But he was of opinion, that we might safely inoculate at all seasons, provided care were taken to screen the patients as much as possible from heat in summer, and to prevent them from keeping themselves too warm, and too much shut up from the weather in winter. He thought it prudent, however, to avoid inoculation while any peculiar epidemic discharges were prevalent. He recommended a preparatory regimen, so as to reduce the patient, if in high health, to a low and more secure state; to strengthen the constitution if too low, to correct what appears vitiated; and to clear the stomach and bowels as much as may be from all crudities and their effects. Young or middle aged persons, enjoying a good state of health, were strictly confined to a milk and vegetable diet for nine days previous to the operation, during which period they were ordered to take the following powder three times at bed-time, and a dose of Glaeb's salt each succeeding morning. The powder was composed of eight grains of calomel, the same quantity of compound powder of crabs' claws, and 5th of a grain of emetic tartar. For women or children the dose was lessened, according to their age and strength. For those who were of a tender delicate constitution, or valetudinarians, he preferred a milder medicine, and rather of the alternative than the purgative kind; indulging some with light animal food, and in case of lownesses, with a glass or two of wine. The baron preferred the following method of inoculating. The patient to be infected being in the same house, and if no objection is made to it, in the same room with one who has the disease, a little slighter matter is taken from the place of infection, if the subject is under inoculation, or a pustule, if in the natural way, on the point of a lancet, so that both sides of the point are moistened. With this lancet an incision is made in that part of the arm where issues are usually placed, deep enough to pass through the scarfl-skin, and just to touch the skin itself, and in length as short as possible, not more than one-eighth of an inch. The little wound being then fretched open between the finger and thumb of the operator, the incision is moistened with the matter by gently touching it with the flat side of the infected lancet. The baron generally performed the operation in both arms, and sometimes in two places in one arm, a little distance from each other. Neither plainer nor bandage is to be applied to the inoculated part. The baron preferred using such matter as was taken during the eruptive fever, it being then in his opinion endued with most activity. When the disease was to be communicated from an inoculated person, he took the matter, not from the secondary pustules, but from the place of inoculation. The second day after the operation, if the inoculated part is viewed with a lens, he says, there generally appears a kind of orange-coloured film about the incision, and the surrounding skin seems to contract. At this time the baron used to prescribe the following medicine to be taken at bed-time: calomel and compound powder of crabs' claws, of each three grains, emetic tartar 4th of a grain. On the fourth or fifth day a hardness is perceptible to the finger. The part itches and appears slightly inflamed. He remarks, that a little clear fluid may be seen under a kind of vesication, the part resembling a superficial burn. In general, about the sixth day some pain and lownesses are felt in the arm-pit. This was regarded as a very desirable symptom, as foreboding the near approach of the eruptive symptoms; and the favourable progress of the disease. Sometimes on the seventh, more often on the eighth day, the symptoms of the eruptive fever appear; such as flight

U
remitting pains in the head and back, succeeded by tran-
fient shiverings and alternate heats, which continue in a
greater or lefser degree till the eruption is perfected.

The inflammation in the arm at this time spreads fast, and
upon viewing the incision with a good glafs, it appears for
the most part surrounded with an infinite number of small
pufles, which increase in size and extent as the diffe-
rate advances. On the tenth or eleventh day a circular or oval
efflorescence is usually discovered surrounding the incision,
and extending sometimes nearly half round the arm, but
more frequently to about the size of aalling, and, being
under the cuticle, is smooth and not painful. This efflo-
rescence was also regarded as favourable; it accompanies
the eruption, every disagreeable symptom caesas, and the pain
and flufhes in the axilla go off.

When the eruptive symptoms came on with more severity,
baron Dimofdale used to direct a repetition of the last-men-
tioned powder, and on the following morning three or four
fows were procured by a laxitive draught.

The baron notices that sometimes the flate of the incision
is such for several days, that the effects of the inocula-
tion can barely be perceived, the colour about the wound
remaining pale instead of changing to red; the edges of the in-
cision spread but little, they remain flat, and are attended
neither with itching nor uneaffines of any kind. Nay, some-
times on the fifth, and even on the fifth day, the alteration
is fo little, as to make it doubtful whether the infection has
taken place. Dimofdale fets down fuch appearances as unfa-
vourable, and implying a late and more untoward diffe-
ance. To prevent this, he used to direct the powder or pill to be taken
each night, and in cafe it failed to operate by ftool, or
there was the leaff difpofition to coffivenes, an ounce of
Glauber's fauce, or a laxitive draught, was given in the
morning, once or twice, as the cafe might require. The ba-
ron believed that these measures forwarded the inflamation,
which he always wished to fee, as he had contandy ob-
erved, that an early progrefs on the arm, and an early com-
 mencement of the eruptive complaints, depended that the
diftemper would be mild and favourable; and on the con-
trary, that when both were late, the symptoms proved more
irregular and untoward. The patient, instead of being con-
fined to his bed or room, when the symptoms of the eru-
five fever came on, was directed, as foon as the purging
medicine had operated, to keep abroad in the open air, be
it ever fo cold, as much as he could bear, and to drink cold
water, ifthrifty, always taking care not to fland still while
abroad, but to walk about with moderation.

In certain cafes, notwithstanding, baron Dimofdale found
the eruptive symptoms extremely violent, and the patients
almost incapable of motion, and apprehensive of cold as the
greatest evil, yet he perfuaded them to rife out of bed and
go out of doors, often supported by affiliants, and he allowed
them to drink as much cold water as they choose. No fmi-1er
accident was the confequence, but, on the contrary, the pa-
ifton's spirits were revived, and every symptom feemed
benefited by the method.

When any uncommon languor happened, a basin of thin
broth, or a glass of wine, was allowed in the day, or fome
white-wine when at bed-time. Indeed, fuch things were
allowed at any time to tender, aged, or weakly persons.
After the eruption was completed, if occafion required,
they were indulged in a little well-boiled meat of the lighteft
kind, as chicken, veal, or mutton.

The practice of baron Dimofdale was certainly, in a great
measure, an imitation of the method purfued by Mr. D.
Sutton.

We shall conclude this article with a few necefsary in-
structions and references.
1. The age of the perfon to be inoculated for the small-
pox should be as little advanced as poiffible; but (if it can be
avoided) not lefs than four months.
2. The matter, when convenient, should be taken from a
young subject who has the small-pox in a favourable way,
and fresh matter should have the preference to fuch as is old.
It deferves particular attention, however, that it is chiefly
for the fake of avoiding unprofesfional blame that we choofe
matter from patients labouring under the diftemper mildly,
ifce experience rather provet, that the lenity or malignity
of the small-pox depends very little on whether the matter
is taken from one patient who has the diftemper favourably,
or from another who has it severely. Nor can we wonder
at this fact, fince the contagion can only be of one fort.
Therefore, were a patient much expofed to the caufal
small-pox, and no matter could be procured from any sub-
fect that had the diftemper mildly, the furgeon should recom-
med inoculation with fuch matter as it would be in his
power to obtain.
3. In inoculating, the operator is to make the lighteft
puncture, or {cratch, imaginarie in the arm orer the place
where the infection of the detdof muscle terminates. That
part of the lancet which is beatmeared with the matter, is
to be repeatedly rubbed over the wound, and left the matter
be wiped away, it is bell not to pull down the flirt-feeve
till the part is quite dry. Some operators prefer introducing
the lancet, armed with the matter, obliquely beneath the
cuticle. When this mode is followed, it is proper at the
time of withdrawing the lancet to press the wound with the
finger, fo that the parts in conlact with the matter may
wipe it off the lancet with more certainty.

The works on the inoculation for the small-pox are too
numerous to be even mentioned: we would, however, par-
ticularly refer to Friend's History of Medicine, D'Entro-
colle's Lettres Edifiantes et Cariennes. Avicenna Opera,
Memoires pour l'Inoculation par M. de la Candamine,
Philosophical Trantafions for 1722. Monro on Inocula-
tion in Scotland. Holwell's Account of the Manner of
inoculating in the East Indies. Maitland's Account of
inoculating the Small-pox. Mead de Variolis et Morbillis.

INOM BARLEY, in Agriculture, a term applied to fuch
barley as is from the fecond crop after the ground has been
fallowed, or cleaned from weeds.

INORDINATE PROPORTION, is where three magni-
itudes being in one rank and three others proportional to
them in another, you compare them in a different order.
E. gr. If there be in one rank thefe three numbers, 2, 3,
9; and in another rank, thefe other three, 8, 24, 36, which
are proportional to the precedent, in a different order; fo
that 2 be to 3 as 24 to 36, and 3 to 9 as 8 to 24; then call-
ing
ING AWAY THE MEAN TERMS IN EACH RANK, YOU CONCLUDE THE FIRST IN THE FIRST RANK TO BE TO THE LAST, 9; AS 8, THE FIRST OF THE OTHER RANK, TO THE LAST, 36.

INORGANIC, IN NATURAL HISTORY, OR UNORGANIZED BODIES, ARE MINERAL SUBSTANCES WHICH ARE NOT ORGANIZED OR CONSTRUCTED AS ANIMALS AND VEGETABLES CAPABLE OF LIFE; AND SUCH ARE ALSO CALLED NATIVE SOILS, TO DISTINGUISH THEM FROM ORGANIC REMAINS OR RELIQUIA. MARTIN’S "OUTLINES," P. 1.

INOSARCION, A NAME GIVEN BY THE OLD GREEK AND ROMAN AUTHORS TO A PECULIAR SPECIES OF EMERALD, CALLED ALSO BY SOME THE CHALCEDONIAN EMERALD. THE GREAT DISTINCTION OF THIS FROM ALL THE OTHER KINDS OF THIS GEM, WAS NOT BEING OF THE PURE, CLEAR, AND UNVARVING COLOURS OF THE OTHERS, BUT HAVING THICK VEINS IN IT, WHICH GAVE PECULIAR REFRACTIONS AND REFLECTIONS TO THE LIGHT; AND THOUGH THE STONE WAS IN ITSELF WHOLLY GREEN, YET WHEN VIEWED IN TRUE LIGHT, THESE VEINS GAVE ALL THOSE CHANGEABLE COLOURS THAT ORNAMENT THE FEATHERS OF A PEACOCK'S TAIL, OR THE MEAT OF A PIGEON.

INOSCALATION. SEE ANATOMY AND ARTERIES.

INOWLOCZ, IN GEOGRAPHY, A TOWN OF THE DUCHY OF WARSAW; 56 MILES S.E. OF LOMOZEC.

INOWLOCZAW, OR JUNGENLEESAW, A TOWN OF THE DUCHY OF WARSAW; 26 MILES W. OF WŁADOWN.

INOWSAL, A SMALL ISLAND NEAR THE NORTH COAST OF THE ISLAND OF BORNEO. N. LAT. 6° 45'. E. LONG. 117° 27'.

IN A PLACE, A LATIN TERM, USED AMONG MONKS, TO SIGNIFY A PRIEST, WHERE SUCH OF THEM ARE PUT UP AS HAVE COMMITTED ANY GROVON FALS.

FORMERLY THERE USED TO BE A GREAT DEAL OF CEREMONY IN PUTTING A RELIGIOUS IN PAUSE; BUT IT NOW IS NOT SO MUCH REGARDED. SUCH AS ARE PUT UP IN PERPETUAL IMPRISONMENT, ARE ALSO FAID TO BE IN PAUSE.

SOMETIMES, ALSO, THE WORDS "REQUEST IN PAUSE" ARE USED BY WAY OF ALLELUIA TO A CUSTOM IN THE ROMISH CHURCH, OR PRAYING THAT THE SOUL OF THE DECEASED MAY REST IN PEACE.

THE SAME WORDS ARE ALSO FREQUENTLY SEEN AT THE BOTTOM OF EPITAPHS, IN LIEU OF THOSE USED BY THE ANCIENT ROMANS, S. T. T. L FOR "SIT TIBI TERRA LEVIS, LIGHTLY THE EARTH;

OR, "SIT LURUS CINERI NON ONEROUX TUA.

IN PALE. SEE PALE.

INQUIRING, IN THE CIVIL AND CANNON LAW, A MANNER OF PROCEEDING FOR THE DISCOVERY OF SOME CRIME BY THE SOLE OFFICE OF THE JUDGE, IN THE WAY OF SEARCH OR EXAMINATION.

INQUIRING IS ALSO USED, IN COMMON LAW, FOR A LIKE PROCEED IN THE KING'S BEHALF, FOR DISCOVERY OF LANDS, PROFITS, AND THE LIKE. IN WHICH USE IT IS ALSO CONFUSED WITH OFFICE; WHICH SEE.

INQUIRING, OR THE HOLY OFFICE, DENOTES AN ECCLESIASTICAL JURISDICTION ESTABLISHED IN SPAIN, PORTUGAL, ITALY, &c. FOR THE TRIAL AND EXAMINATION OF SUCH PERSONS AS ARE SUSPECTED TO ENTERTAIN ANY RELIGIOUS OPINIONS CONTRARY TO THOSE PROFESSING IN THE CHURCH OF ROME.

IT IS CALLED INQUIRING, BECAUSE THE JUDGES BY THEIR OFFICE TAKE CONCERN FOR CRIMES ON COMMON REPORT, WITHOUT ANY LEGAL EVIDENCE, EXCEPT WHAT THEY THEMSELVES ARE ABLE TO EXPLORE.

SOME PEOPLE FANCY THEY SEE THE ORIGINAL OF THE INQUIRING, IN A CONSTITUTION MADE BY POPE LUCIUS, AT THE COUNCIL OF VERONA, IN 1184, WHERE HE ORDERS THE BISHOPS TO GET INFORMATION, EITHER BY THEMSELVES, OR BY THEIR COMMISSARIES, OF ALL SUCH PERSONS AS WERE SUSPECTED OF HERESY; AND Distinguishes THE SEVERAL DEGREES OF SUSPECTED, CONVICTED, PENITENT, RELAPSED, &c. HOWEVER THIS BE, IT IS GENERALLY ALLOWED, THAT POPE INNOCENT III. LAID THE FIRST FOUNDATION OF THE HOLY OFFICE; AND THAT THE VAUDIANS, AND ALBIGENCIANS WERE THE FIRST OBJECTS OF IT. THAT CONSTITUTE, IN THE BEGINNING OF THE THIRTEENTH CENTURY, FORT RABIER, A GENTIAN MONK, AND PIERRE DE CAILLON, ARCHDEACON OF MAGUELONE, TO THE COUNTRY OF THOULOUZE, OR NARBONNE GAUL, IN ORDER TO BLOW UP A SPIRIT OF ZEAL AND PEACOCK AGAINST THE PRELATES AND PRINCES. THESE MILLIONAIRES WERE FOON FOLLOWED BY OTHERS, AMONG WHOM WAS THE FAMOUS SPANiard, DOMINIC, FOUNDER OF THE ORDER OF PREACHERS, WHO RETURNING FROM ROME IN THE YEAR 1266, FELL IN WITH THESE DELEGATES, ENCOMPASSED IN THEIR CAUSE, AND LABOURED, BOTH BY THEIR EXHORTATIONS AND CONDUCT, IN THE EXTRAPOLATION OF HERESY. THESE SPIRITUAL CHAMPIONS WERE TO GIVE AN ACCOUNT TO THE POPE OF THE NUMBER OF HERETICS IN THOSE PARTS, AND OF THE BEHAVIOUR OF THE PRINCES AND PERSONS IN AUTHORITY TO THEM; AND THENCE THEY ACQUIRED THE NAME OF INQUISTORS; BUT THOSE ORIGINAL INQUISTORS HAD NOT ANY COURT, OR ANY AUTHORITY, THEY WERE ONLY A KIND OF SPIRITUAL SPIES, WHO WERE TO MAKE REPORT OF THEIR DISCOVERIES TO THE POPE, AND TO EXCITE THE CATHOLIC PRINCES AND PEOPLE TO EXTIRPATE HERESY.

THIS ACCOUNT IS CONTROLLED BY MOYNE, WHO MAINTAINS, THAT ST. DOMINIC WAS NOT APPOINTED BY THE ROMAN PONTIFF TO PROCEED JUDICIAL AGAINST HERETICS, AND SUCH AS WERE SUSPECTED OF HERESY, TO PRONOUNCE SENTENCE ACCORDING TO THEIR RESPECTIVE CAUSES, AND TO DELIVER OVER TO THE SECULAR ARM SUCH AS PERSECUTED OBVIOUSLY IN THEIR ERRORS, AND THEREFORE, IN THISSENCE, WAS NO INQUISTOR; THOUGH, ACCORDING TO THE ORIGINAL MEANING OF THE TERM, HE WAS INVOLVED WITH THE COMMISSION AND AUTHORITY OF THE ROMAN PONTIFF TO EXTIRPATE HERESY, AND OPPRESE ITS ABETTERS, BUT WITHOUT ANY JUDICIAL POWER: MAY, IT IS FARTHER URGED, THAT THE COURT OF INQUIRING WAS NOT ERECTED DURING THE LIFE OF ST. DOMINIC. THE HORRID WAR, WHICH WAS ERRECTED BY INNOCENT III. AGAINST THE ALBIGENCIANS IN NARBONNE GAUL, AND WHICH WAS CARRIED ON BY THE CROSS-BEARERS WITH THE UMTOLL CRUELTY FROM THE YEAR 1230 TO 1229, WHEN A TREATY OF PEACE TOOK PLACE BETWEEN RAYMOND VIII. OF THOULOUZE, AND LEWIS V. KING OF FRANCE, WHICH GAVE A MORTAL BLOW TO THE CAUSE OF HERESY, PREPARED THE WAY FOR THE FULL ESTABLISHMENT OF THE INQUIRING.

INQUISTORS OF THE FIRST KIND HAD, IN THE COURSE OF THIS TIME, BEEN PLACED IN ALMOST EVERY CITY, WHOSE INHABITANTS HAD THE MISFORTUNE TO BE SUSPECTED OF HERESY, NOTWITHSTANDING THE RESISTANCE WHICH THE PEOPLE MANIFESTED TO THIS NEW INSTITUTION, AND THE VIOLENCE WITH WHICH THEY FREQUENTLY EXPELLED AND
sometime maligned these bloody officers of the popish hierarchy. At length, the council held at Tholouse, in the year 1229, by Romanus, cardinal of St. Angelo, and pope's legate, went ill farther, and erected every city a council of inquisitors, confounding of one priest, and three laymen. This institution was, however, superceded in the year 1233, by Gregory IX, who entrapped the Dominicans, or Preaching Freres, with the important mission of discovering and bringing to judgment the heretics that were lurking in France; and in a formal epistle discharged the bishops of that painful office. Immediately after this, the bishop of Thas, who was the pope's legate in France, began to execute this new resolution, by appointing Pierre Cellan and Guillaume Arnaud, inquisitors of heretical pravity at Tholouse; and afterwards proceeded in every city where the Dominicans had a convent, to constitute officers of the same kind chosen from among the monks of that order. From this period we are to date the commencement of the dreadful tribunal of the inquisition, which in this and the following ages subdued such a prodigious multitude of heretics, part of whom were converted to the church by terror, and the rest committed to the flames without mercy. For the Dominicans erected a fire at Tholouse, and afterwards at Carcassone, and other places, a tremendous court, before which were summoned not only heretics, and persons suspected of herey; but likewise all who were accused of magic, forcery, Judaism, witchcraft, and other crimes of that kind. This tribunal, in process of time, was erected in the other countries of Europe, though not everywhere with the same success. The method of proceeding in this court of inquisition was at first simple, and almost in every respect similar to that which was observed in the ordinary courts of justice. But the Dominicans modelled it after that of the tribunal, called in the Roman church the tribunal of peace; and hence arose that strange system of inquisitorial law, which in many respects is so contrary to the common feelings of humanity, and the plain dicta of equity and justice. And that nothing might be wanting to render the spiritual court formidable and tremendous, the Roman pontiffs pernicious to the European princes, particularly the emperor Frederic II, and Lewis IX, king of France, not only to enact the most barbarous laws against heretics, and to commit to the flames those who were pronounced such by the inquisitors, but also to maintain the inquisitors in their office, and grant them their protection in the most open and solemn manner. The edicts issued to this purpose by Frederic II, are well known; edicts every way proper to excite horror, and which rendered the most illustrious piety and virtue incapable of saving from the most cruel death such as had the misfortune to be disagreeable to the inquisitors. The laws of Frederic, in relation to the inquisitors, may be seen in Limborch's History of the Inquisition, book I. chap. 12.

The edict of St. Lewis, in favour of these ghastly judges, issued out in the year 1239, is generally known under the title of Council. After the death of Frederic, who had long before repeated the power he had given the churchmen, as having seen some of the fruits of it, pope Innocent IV, erected a perpetual tribunal of inquisitors, and deprived the bishops and secular judges of the little power the emperor Frederic had left them. And this jurisdiction, which depended immediately upon himself, he took care to introduce into most of the states of Europe. In 1251 it was established in Italy; in 1255 Alexander IV appointed inquisitors in France, at the request of St. Lewis. But the inquisitors were so fiery hot, and made such horrible butchery among the reputed heretics, that they raised an universal detestation even in some Catholic countries themselves. Hence it was that their reign proved very short both in France and Germany; though they were occasionally exerting themselves, and their power was established in many parts of France and Germany about the time of the Reformation by Luther; but afterwards gradually declined. Nor was even Spain entirely subject to them till the time of Ferdinand and Isabella, when their power was increased, under pretence of clearing the country of Judaism and Mahometanism.

The inquisition was first introduced into Spain in the year 1478; but the first inquisitor-general, and the supreme council of the inquisition, were not fixed till the year 1483. This tribunal is arisen to such a height in Spain that the king of Castile before his coronation subjected himself and all his dominions, by a special oath, to the most holy tribunal of the inquisition. It was under the direction of an inquisitor-general, appointed by the king, and confirmed by the pope; and this inquisition has power to name particular inquisitors in every place there where there is any tribunal of the inquisition.

The inquisition was established in Portugal, at the pressing solicitation of king John III. about the year 1530; and both the Spaniards and Portuguese have established it in their territories in the western continent.

The power of the inquisition was very much limited in some countries, particularly at Venice, where it was introduced about the year 1289, and where it was received under such modifications, as proved a great check on its authority; the office confining of secular and ecclesiastical persons, though the latter had been long endeavouring to bring it into their own hands, but could not prevail with the Venetian senate to agree to it. Indeed at Venice it seemed rather a political than a religious contrivance; and served rather for the security of the state, than that of the church. There are appeals from the subaltern inquisitions in Italy, to the congregation of the holy office residing at Rome.

The congregation was first formed by Paul III. in 1542; and finally established by Sixtus V. in 1588. The members of it, called supreme inquisitors, assembled thrice in the week, and every Thursday in the presence of the pope, who presides in it.

The officers or ministers of the inquisition are the inquisitors, who derive their power from the pope, either by word of mouth, or by his apostolic letters, and can be removed only by him, or by authority conferred by him on those cardinals who are the inquisitors-general; vicars-general, who manage the affairs of the inquisition during the absence of the inquisitors; auditors and counselors, who give their advice in points of theology and law; the promoter fiscal, whose office it is to examine the depositions of the witnesses, to give information of criminals to the inquisitors, and to demand their apprehension and imprisonment, and, finally, when apprehended and condemned, to accuse them; notaries or registrars, who write down the injunctions, accusations, and all the pleadings of the causes; the judge and receiver of the confiscated effects; the executor and officials, who apprehend and keep in custody criminals; the attendants or familiars; the draftsmen and engravers; and the visitors, who visit all the provinces of the inquisitors, and report to the inquisitor-general and council whatever was proper to be amended. The civil magistracy is entirely excluded from the cognizance of herey; but the inquisitors require their assistance for the punishment of heretics, in consequence of the sentence which they pronounce: and they are severally threatened with the most grievous punishments, if they neglect their duty. The punishments inflicted by the inquisition on heretics are ecclaiastic.
Lical and civil; the ecclesiastical or canonical are excommunication, deprivation of ecclesiastical burial, dignities, benefices, and offices. The civil are condemnation of goods, which is inflicted on all who are convicted of hereby, or confides, whether they repent or perish in their hereby; because they are Catholic, they can never inherit the estates of their fathers who died in hereby; infamy, which excludes from all public offices, from bearing witnesses, making wills, &c. lots of all dominion, natural or civil, as power of parents over children, masters over servants, magistrates and princes over subjects; and the deprivation of all property in every thing they have; imprisonment; ban, which is a kind of sentence of excommunication, by which any person is cast out of the commonwealth, so that he cannot enjoy the public protection, or discharge any public offices, or receive any benefit of law; distillation, which declares heretics to be enemies of their own country and of the empire, so that any person, by his own private authority, may seize, plunder, and kill him, as an enemy and robber, even though he be a clergyman; nor is it lawful for any one to undertake their defence when apprehended; and the advocates who favour and plead for them, are pronounced infamous, and suspended from their office; and finally death, which is of being burnt alive, in some cases heightened by being gagged with an iron instrument, so that in the midst of their torments they can utter only an inarticulate sound.

It is the constant practice of the inquisition to affect, in all their procedures, to inspire as much terror and amazement as possible; every thing is done with the profoundest silence and secrecy, and with the greatest rigour and pretended impartiality. When a person is seized, all the world abandons him; not the nearest friend dares to speak a word in his defence; that alone would be enough to render them suspected of hereby, and would bring them within the claws of the inquisition; may, the nearest relations are bribed and constrained to accuse one another. The criminals are seized, examined, tried, tortured, and, unless they recant, are even condemned and executed, without ever fearing or knowing their accusers; whereas the revengeful have a fair occasion of wreaking their malice on their enemies. By the forms of the inquisition, a person defined only for hereby is obliged to make a canonical purgation, i.e. to purge himself with leon, more or less, compurgators, for that, if he falls in one, two, or more, he is accounted guilty: besides, every one, though excluded by other courts, is admitted as a witness, a mortal enemy only excepted. The names of the witnesses are not shown to the prisoner; nor is any circumstance discovered, by which he can obtain the knowledge of them. If two unexceptionable witnesses testify of different facts; yes, sometimes if there be only one, or a mere report, it is thought sufficient for ordering the torture; the evidence of two unexceptionable witnesses, who agree, is sufficient for the conviction and condemnation of any person. Those that are informed against are constrained to become their own accusers; and various arts are used to extort a confession from them. The advocate allowed them is under the direction of the inquisition, and employed chiefly in order to betray them; moreover, when the crimes cannot be proved against them, they are only absolved from profession, but their crimes and names are recorded against them. The use of torture for discovering secret crimes lying concealed in the mind, is a flagrant instance of injustice; and persons are put to the torture upon half full proof of the crime, i.e. flattering, defamation, one witness of his own knowledge, or when the tokens are vehement, or violent. These tortures are used under a pretence of discovering the truth, and they are varied and continued with the most wanton cruelty. After these, and many other shocking proceedings, when the inquisition has done with the criminals, and condemned them to death, they are turned over to the secular arm, with much prayer, and pious interreat, that their lives may not be touched.

Time is no manner of security in point of hereby; nor, does the grave itself shelter the accused from the pursuits of the inquisition; even the deceased have their trials, and they proceed in all their form and solemnity against the dead carcasses. The executions are always deferred till the number of the condemned is very great, that the multitude of sufferers may strike the deeper horror, and make the scene more terrible and shocking. See Act of Faith.

The inquisition is very severe in the Indies. It is true, there must be the oaths of seven witnesses to condemn a man; but the deposition of slaves or children are taken. The person is tortured till he condemns himself; for his accusers are never brought to confront him. Persons are accused for the flenderest expresion against the church; or even for a disrespectful word of the inquisition.

The standard of the inquisition in Spain is a piece of red damask, on which is painted a cross, with an olive-branch on one side, and a sword on the other; with these words of the psalm, Exsuge, Domine, & judica confirm meam.

The standard of the inquisition in Portugal hath their supposed founder Dominic's picture on one side, and on the other side the cross, between an olive-tree and a sword, with this motto, Judicium & misericordia.

See on the subject of this article Limborch's Hist. of the Inquisition, by Chandler, p. 113, &c. 8vo.

INQUIRORS, in Law, are sheriffs, coroners super visum corpus, or the like, who have authority to enquire into certain cases, &c. office.

IN QUO, Medium in quo. See Medium.

INROLLMENT, the registering, recording, or entering of any lawful act, or instrument, in the records of chancery; as a recognizance acknowledged, or a statute, or a fine levied.

Inrollments are also made in the rolls of the exchequer, king's bench; and common pleas; in the hulings at Guildhall, London; and by the clerk of the peace in any county. See Register.

Inrollments. Clerk of the. See Clerk.

INSAG, in Ornithology, a name given by the people of the Philippine islands to one of the several species of parrots, common in their woods. The infag is a very beautiful bird; its body is of a very bright green, and its head of a fine florid red.

INSANITY. See Mental Derangement, Mania, and Melancholy.

INSANUM PARLIAMENTUM. See Parliament.

INSCHI, or Inschi kno, in the Materia Medica, a name given by some authors to the common ginger.

INCONCED, in the Military Art, denotes that part of an army that have fortified themselves with a fence, or small fort, in order to defend some part, &c. See Scone.

INSCRIBED, in Geometry. A figure is said to be inscribed in another, when all the angles of the figure inscribed touch either the angles, sides, or planes of the other.

Inscribed Hyperbola, is such an one as lies entirely within the angle of its asymptotes; as the conical hyperbola doth. See Hyperbola and Circumcribing.
INSCRIPTION, a title, or writing affixed to any thing, to give some further knowledge thereof; or to transmit some important truth to posterity.

Antiquaries are very curious in examining ancient inscriptions found on stones, and other monuments of antiquity. Strachoniathon, contemporary, as it is said, with Gideon, drew most of the memoirs whereof his history is composed from inscriptions which he found in temples, and on columns, both among the heathens and the Hebrews.

It appears, indeed, that the ancients engraved upon pillars the principles of sciences, as well as the history of the world. Those mentioned by Herodotus shew, that this was the first way of instructing people, and of transmitting histories, and sciences, to posterity. This is confirmed by Plato in his Hippias, wherein he says, that Pisistratus engraved, on stone pillars, precepts useful for husbandmen. Pliny affirms us, that the first public monuments were made of plates of lead; and that the treaties of confederacy concluded between the Romans and the Jews were written upon plates of brass; that, says he, the Jews might have something to put them in mind of the peace and confederacy concluded with the Romans. The Greeks and Romans were much addicted to inscriptions, and were extremely fond of being mentioned in them; and hence it is that we find so many in those countries of ancient learning, that large volumes have been composed; as the collection of Gruter, &c.

Since Gruter's collection, Th. Reinecius has compiled another huge volume of inscriptions. M. Fabretty published another volume at Rome in 1669, wherein he has corrected the errors which had escaped Gruter, Reinecius, and other antiquaries, &c. and added a great number of inscriptions omitted by them. Since all these, Graevius has published a complete collection of inscriptions, in three volumes folio.

INSCRIPTION, Academy of. See Academy.

INSCRIPTIONS, Notes, or Abbreviations, used in. See Character.

INSCRUTABLE, Unsearchable, in Theology, is usually understood of the secrets of Providence, and the judgments of God, which cannot be found out, or into which human reason cannot penetrate.

INSE, in Geography, a town of Prussia; 22 miles W. of Tilsit.

INSECTS. See Entomology.

INSECTS, Anatomy of. Many parts of this subject have been already considered in the article Entomology, to which we refer the reader; our present object is to supply what has not been inferred there.

Organs of Motion. —A striking difference is observed in the position of the hard parts, which constitute the effential organs of motion, between this class and the mammalia, birds, &c. In the latter, the bones are placed in the centre of the limbs, and are surrounded by the muscles, which are covered externally by the skin; while in the former, the resisting matters, which are analogous to bones and perform their functions, are hollow, placed externally, supply the place of skin, and contain the moving powers in their cavities.

The structure and appearances of the external coverings vary considerably in the different orders of this class. In the crab, lobster, &c. a hard calcareous crust covers the whole body and limbs, serving for skin and skeleton. In the perfect insects the surface of the body is covered by horny substances of various degrees of hardness and resilence. The larvae have coverings of a softer kind, and approaching more nearly, as far as external characters go, to the skin of mammalia and of the neighbouring classes. Yet this is analogous in its functions to the calcareous and horny crusts; for it receives the infection of the muscles, and therefore constitutes the chief agent of locomotion.

The sensible characters of the calcareous crust of the crab and lobster (their carapce as it is commonly called) resemble those of the shells of tefaceous animals, and in some degree those of bone; but the chemical constitution is in some respects different. The very valuable researches of Mr. Hatchett have made us acquainted with the chief circumstances of the composition of these matters. After having detailed his experiments on shells and on the coverings of the echin, he proceeds: "It was now requisite to ascertain if phosphate of lime is a component part of the substance which covers the crustaceous marine or aquatic animals, such as the crab, lobster, prawn, and cray-fish. Pieces of this substance, taken from various parts of those animals, were at different times immered in acetic and diluted nitric acid; those which had been placed in the diluted nitric acid produced a moderate effervescence, and in a short time were found to be soft and challic, of a yellowish-white colour, and like a cartilage, which retained the original figure. The same effects were produced by acetic acid, but in a less degree; in the latter case also the colouring matter remained, and was soluble in alcohol. All the solutions, both acetic and nitric, afforded carbonate and phospate of lime, though the former in a larger proportion. There is reason to conclude, therefore, that phosphate of lime, mingled with the carbonate, is a chemical characteristic, which distinguishes the crustaceous from the tefaceous substances; and that the principal difference in the qualities of each, when complete, is caused by the proportion of the hardening substances, relative to the gluten, by which they are cemented; or by the abundance and constancy of the gelatinous, membraneous, or cartilaginous substance, in and on which the carbonate of lime, or the mixture of the carbonate and phospate, has been secreted and deposited. And as the presence of phosphate of lime, mingled with carbonate, appears to be a chemical character of crustaceous marine animals, there is every reason to conclude that Linnaeus did right not to place the echin among the tefaceous ones. The presence of phosphate of lime, in the substance which covers the crustaceous marine animals, appears to denote an approximation to the nature of bone, which, not only by the experiments of Mr. Gahn, but by the united testimony of all chemists, has been proved principally to consist, as far as the softening substance is concerned, of phosphate of lime."

Philol. Trans. 1799. In a recapitulation of these researches, in the Transactions for 1800, he says, "It was proved, that the crust which covers certain marine animals, such as crabs, lobsters, cray-fish, and prawns, consists of a strong cartilage, hardened by a mixture of carbonate and phospate of lime; and that thus these crustaceous bodies occupy a middle place between shell and bone, though they incline principally to the nature of shell." Similar refults to these were obtained by Merat-Guillot, who has described his investigation in the Annales de Chimie, t. 34. From 100 parts of lobster crust, he obtained 60 of carbonate of lime, 14 of phospate, and 26 of animal matter. In 100 parts of cray-fish crust there were 60 of carbonate, 12 of phospate, and 26 of animal matter. So far as the horny coverings of insects have been examined, they correspond in chemical properties to horn, hoof, scales of serpents, feathers, &c. and do not owe their firmness to calcareous matter, which seems not to be an effential part in their formation. See Horn.

An interesting enquiry arises here, concerning the mode
of formation of these coverings; but our data are hardly
sufficient to resolve it satisfactorily. "Some observations,"
says Cuvier, "seem to prove that there are telluric
animals, which lose their shells entirely at certain periods,
and are supplied with new ones. But this reproduction
might be effected by development like that of the an-
tler: and if it be also a development, which produces the
interior layers of those shells, which do not drop off, it
may be compared to that which forms the inner lamina of
the horns of cows, sheep, and other ruminating mammalia,
and also to the production of the epidermis in all animals:
that is to say, it is a degenaration, a kind of death of a mem-
brane, which appeared to have some sort of organization, as
long as it was protected from the contact of the external air,
or had not acquired completely its characteristic solidity.
All the hard parts which hold the place of bones in in-
vertebral animals seem to be developed in this manner. In
the crab and lobster, for example, that which serves at
the same time for integuments and skeleton, grows no more
when it has once attained its perfect hardness; yet the
soft parts still continue the progress of their development.
When they are too much confined by the hard covering,
that separates and is detached; but another is found under
it, which was in a state of formation while the former was
detaching itself, or, as we may say, dying. This new cov-
ering is at first soft, fleshy, and even vascular; but a
quantity of calcareous matter, previously collected in the
omach, is very soon conveyed to it, hardens it, obstructs
the pores and vesicles, and renders it, in short, perfectly simi-
lar to that of which it has supplied the place. Inflets do
not acquire their perfect hardness until they have taken
their fall form, and have no further change of skin to un-
dergo; but all the skins which they had cast off before, al-
though fleshy, were dead, and already replaced by others,
developed before they were discharged. Thus all the hard
external organs of white-blooded animals, whatever their con-
formity and chemical nature may be, should rather be com-
pared, in their mode of growth, to the epidermis, to hol-
low nails, and horns, than to true bones." Leçons d'Ana-
tomie comparée, t. i, p. 118.

Epidermis.—Crustacea and insects, whether in their larva
or perfect state, have a true epidermis; but, as this integ-
ment, when it has once become dry and hard, is no longer
susceptible of that extension which is necessary to accom-
modate the growth of the animal, it is separated at certain
periods, which are definite in each species, but influenced
considerably by the atmospheric temperature: the animal
quite its skin, passing out from it as from a sheath. This
proceeds as called moulting; the insect, in many cafes,
is several days preparing for it, and sometimes perishes.
Most of the larvae of the papilio and bombyx kinds change their
covering seven times before they pass into the state of chry-
saids. The bombyx caja has ten succedaneous coverings.
This most singular process is not analogous to the mere
separation of the cuticle in the human subject; for the parts
which are detached in insects, in many cafes afford attach-
ment to the muscles of the animal. Thus, in the crustacea
the whole skeleton is shed, and this takes place annually.
"The frequent moultings," says Lyonet, "of the cater-
pillar of the phalena collus is the more singular, insomuch
as the caterpillar does not simply change its skin, but casts
its whole external covering, in which we observe the head,
jaws, cornea, all the scaly parts composing the lips, the
cirri, the spinning hole, the antennae, and even the scales
excluded within the head, and affording attachment to several
muscles; also the flabella, the nails, scales, and hooks of
the feet, the hairs, the anus, in short all the visible external
surface of the animal. In disposing itself for this operation,
it passes some days without taking any nourishment; the
muscles, and other interior organs of the head, are detached
from the old cuticle, and withdrawn into the neck; they
form a new covering, similar to that which they have left,
but larger, and at first soft. When the new skin, and all the
other parts, which contribute to the covering of the cater-
pillar, are formed, the old one is opened, and the animal
withdraws from it by an operation so much the more difficult
in consequence of the weakness caused by the soft state of
the new organs, which will not allow it to act with vigour,
nor to take any nourishment for some days.

"The caterpillar, thus newly clothed, exhibits different pro-
portions from those which it had before moulting; the head,
legs, and all the horns are sensibly larger in comparison
with the rest of the body; these therefore do not increase after-
wards. The body and soft parts of the animal only grow,
until they become again too large for their covering, and a
new moulting is necessary." Lyonet, Traité Anatomique
de la Chéville, p. 7.

Rete Museutm.—The place of this organ is held in the
crustacea, by the calcareous shell, which immediately suc-
cedes the epidermis; its colour is commonly a dull green,
sometimes red, blue, white, or black. Alcohol, acids, and
particularly the application of heat, often produce remark-
able changes in these colours, as we may observe in the
lobsters brought to our tables. In larve a layer of mucous
substance is seen between the epidermis and the muscles;
and the colours of this vary infinitely in the different species.
It is particularly remarkable for its brilliancy in caterpillars,
and the larvae of some hymenoptera; it gives to their bodies
the purest and most lively tints, of which the shades and
symmetry are admirable. Red, purple, violet, blue, green,
yellow, scarlet, black, &c. are distributed in the most regular
and striking manner. Probably the brilliant colours of the
perfect insects are owing to the mucous body dried and
blended with the horny covering. For whilst the lepidoptera
are in their chrysalis state, the small coloured scales which
will afterwards adorn their wings, appear like the muci-
city which is under the skin of the caterpillars. The colours
of the spiders are also owing to this mucous matter, which
is found under their skin, and has the appearance of small
glandular points marked by different tints of colour. But
in the coleoptera, and in several other orders, the colours
seem to reside in the horny tunic, as those of the tellacta do
in their calcareous shells.

Nothing can be seen in this class, which can be compared
to the cutis; there is a pellicle under the shell of the crustacea,
but it is fine, transparent, and has very little consistence.
The layer which is separated from larvae in their moltings,
is of the same nature and thickness as that which is under
it and succeeds. The coverings of the contracted chrysalis,
such as those of the lepidoptera and diptera, cannot be
regarded as a true skin; it is rather a horny epidermis. Lastly,
in their perfect state, insects have nothing in their coverings
which can be compared to cutis. The hairs of insects seem
to be productions of their epidermis; for they are discharged
with that in moulting, and are supplied by new and longer
ones. The scales of the wings and body in the lepidoptera
and some other orders, are small horny plates, differently
coloured, implanted in the skin, and placed one over the other,
like tiles in the roof of a building. The plumes of some
insects are prolongations or shreds of the wings, furnished
with long hairs on their sides.

Joints.—The crustacea and the proper insects agree in the
kind of their articulations; the particular nature of which
arises from their hard parts being placed externally to the
muscles.
mucelle. The former being made like sheaths, and having their cavities filled by the mucelles, cannot be articulated by simple and plane surfaces; their joints therefore exhibit no specimens of arthrodia and enarthrodia. All their moveable articulations may be reduced to three kinds. Where the parts require a solid point of support, the ginglymus is employed; the horny coverings of the limbs, being tubular, must rest on each other in two points of their circumference at least, and this arrangement necessarily determines the ginglymoid form. Where a solid point of support is not required, the parts are merely suspended by ligaments, or are articulated by a kind of setting in. In the latter construction, one part enters and is received into the hollow of another. Thus the thighs of insects are set in the thorax, and the rings of the abdomen are set into each other. Since the part which receives, and that which is received, are segments of a spheroid, the latter may perform a twirling motion; it may be pushed more or less completely into the cavity, either equally in its whole circumference, or to a greater degree on one or the other side; but flexion properly so called cannot be performed. The parts which are connected by ginglymus, and which are chiefly the different portions of their legs, have deep notches on that side where the flexion is most extensive; the interval is filled with a plant membrane, and there is no other ligament. The articular tubercles and excavations are so arranged that they cannot be luxated without fracture.

**Mucelles.**—The muscular system of the crustacea is confined to the motions of the legs, tail, and false feet; there are no mucelles for moving the head on the thorax, since the two parts are consolidated into one piece in this order. The antennæ, the jaws, and the palpi, have particular mucelles, but we shall not consider them at present. The tail is a very principal part of the body in most crustacea. It consists of a very strong and moveable member, which they employ with great effect both in jumping and swimming. It is composed in several monoculi of long threads, which in the polyphemus (mulonica crab) are solid and moveable at their bases only. In the crabs it is short, flattened, and curved under the body in a depression placed between the legs. The cancer bernhardus (thermit crab) has a soft tail without scales, which it introduces into a small shell or hollow flones.

The tail defers a particular description in the lobster, where it is formed of six chief segments, and terminated by five plates. The former are not all of exactly the same figure; they are convex above, and cover one another like tiles; below they are narrower, and united by a loose membrane which allows them considerable mobility. In the latter situation, at the angle of union between their dorsal and lower portions, they have a kind of firm fins, bordered with ciliated processes, and formed of several articulations. These are called false or swimming legs (pedes natatori). These admit of being moved from before backwards, and a little from without inwards, by means of small mucelles contained in their interior, but not differing sufficiently from those of the true legs to merit a particular description.

The five plates, which terminate the tail, consist of two pairs and a single one; the latter is placed in the middle, and articulated directly to the last segment. The opening of the anus is found under it. In some species it is divided in its middle, so as to admit a flight motion. Each of the lateral pairs is supported by a common piece articulated to the last segment of the tail. The internal plate of each pair is simple, and ciliated, like the middle one, only at its extremity; but the external is in a manner articulated, or rather formed of two pieces; the first of these covers by its extremity, which is denticulated, the smaller which succeeds, and of which the edge is set with very close cilia. The mucelles which move this tail are so singular, as to merit a distinct description.

**The mucelles of the tail, in the lobster,** form two masses, separated from each other by the intestinal canal. In the dorsal mass, which is the thinnest, and leafy complicated, three kinds of fibres may be observed. The first consists of a muscle attached to the dorsal portion of the thorax towards its posterior fourth part. It is then directed obliquely backwards and outwards towards the sides of the first segment of the tail, in which it is inserted. The portion of one side acting separately, will carry the tail towards the right or left; when both act together, they will extend the tail, and maintain it in the extended state. The second and third series of muscular fibres are extended through the whole length of the tail in two parallel and contiguous lines. They arise from the upper and lateral portions of that septum of the thorax, on which the branchiae are applied, by several digitations. When it has arrived at the first ring of the tail, a small intersection is observed on the surface, and we observe that a small bundle of fibres turns off to be inserted into this first annular segment; and a similar insertion takes place in each of the succeeding rings. This disposition gives to the internal band the appearance of a twisted cord. The external portion of the dorsal mass is formed of distinct longitudinal fibres. These three orders of mucelles have much analogy to the straight dorsal mucules of caterpillars, as we shall see in the sequel.

The ventral mass of the mucelles of the tail is much thicker and more complicated than those of the back. In order to give a clear notion of its composition, we shall describe it as observed in three aspects. In the first place, from the back; the mucelles which we have described, as well as the intestinal canal, having been removed; secondly, from below, the scales which cover the under surface of the tail, and the nerves having been taken away; and thirdly, on the inner side, a longitudinal section having been carried through the mucelle in its middle line, in order to expose the internal structure.

The ventral mucelle of the tail, on its dorsal aspect, arises in the interior of the thorax, above the intricate bony texture, containing the mucelles of the legs. It is then divided into a right and left portion; each of which is formed of three broad digitations. Over the first segment of the abdomen, its longitudinal fibres dip under others, which turn round and embrace them. The rest of the mucelle, in the whole length of the tail, is thus formed of two series of convex fibres curved in parallel directions, placed laterally with regard to each other, and separated from right to left by a channel in which the intestinal canal is lodged.

On the under surface three very distinct orders of fibres may be seen. The first is produced from the interior surface of the digitations which arise from the bony frame-work of the thorax. The second consists of oblique fibres, which are a continuation of the former, extending from the middle line, in which the nervous cord is placed, to the sides of the rings at the angle of union between their dorsal and ventral portions. Each of these angles, from the first to the sixth, has two strong bundles. The third series is made up of transverse bundles describing arcs, of which the convexity is downwards. These muscular flattened loops correspond to the interjections of the rings, and seem to form derivative pulleys for the oblique fibres just mentioned.

Lastly, the ventral mucelle of the tail, divided longitudinally in its middle, resembles a rope with the strands rather obliquely disposed. The fibres belonging to the transverse bundles are distinct and narrower.

From this singular complication it results, that the mucelle, when
when inflated from all its adhesions, constitutes a very close twirl, the threads of which, instead of acting in the longitudinal direction, move obliquely in the canal which they occupy between the neighbouring fibres.

The legs of the crustacea vary in number and size. Their figures are very different in the monocyli; sometimes they hold the place of palpi, jaws, fins, branchis, &c. They differ considerably in form in the crabs, particularly the first pair. We shall describe the legs of the crab and lobster as an example of these organs. They are usually five in number on each side, and each has six articulations. The first pair is considerably the largest, and forms what we call the claws.

The hip, or branch, is attached to the chest, and moves only from before backwards. It supports one division of the branchis, as well as the second piece of the member, which corresponds to the thigh. The latter is flattened, short, nearly square, smooth, and a little curved. The plane of its articulation is parallel to the length of the piece; and as the two muscles which move it are inserted into the two most remote points, the thigh is situated horizontally. It has a hinge-like motion on the hip, combined of the two directions from before backwards and from within outwards. Its motion on the leg, which is very limited, takes place only from below upwards, and produces the approximation of the limb to the chest. The third portion corresponding to the leg is also rather flattened, particularly at its femoral extremity. It is slightly curved in the direction of the thigh, so as to correspond to the convexity of the thorax. Towards the tarsal end it becomes larger and rougher; its motion on the thigh is very limited. The fourth articulation is intermediate between the pincer and the leg, on which it moves in a very distinct angle. The pincer comprises the fifth, and by far the largest piece. It is terminated on the outside by a pointed and serrated projection; and it receives on the opposite side a movable pointed piece or pollux, capable of being opposed to it, which, with the other, constitutes the pincer. The motion of this on the fourth piece is from without inwards. The two following pairs of legs resemble the former on a smaller scale, with this difference, that the two pieces, composing the pincer, are of equal size. The two left pairs of legs differ from the three others in not being terminated by a pincer, but by a single nail. In every other respect they resemble the two preceding pairs.

Muscles of the Larva of Insects.—Each articulation has an extensor and a flexor muscle. The extensor of the hip is situated in the interior of the thorax, on the brown piece which supports the branchis, rather in front of the hip, which it draws forwards. The flexor arises from the same part farther back, and produces the contrary motion to the preceding.

The extensor of the thigh is stronger than the flexor; it is attached to the inner and front part of the hip, and to the superior eminence of the thigh. It depresses rather than bends. The flexor, or rather the elevator of the thigh, is shorter than the former; it occupies the posterior internal surface of the thigh, and is inserted into the inferior eminence.

The extensor of the leg is placed in the hollow of the thigh, of which it occupies the whole breadth; it is inserted into the external border of the leg. The flexor is less powerful, lies under the extensor, and is fixed to the inner edge.

The extensor of the first piece of the tarsus is attached to the whole upper edge of the leg, and is inserted into the highest eminence of the fourth piece. Its flexor arises from the lower edge of the leg, and is inserted into the lower eminence.

The extensor and flexor of the pincer occupy and divide the interior of the fourth piece: their functions are determined by their situation. The extensor of the movable piece or pollux is a very small muscle, occupying the upper part of the pincer; its flexor occupies all the rest of this part, is a very bulky muscle, and has a flattened oblong bony tendon in its middle. From this muscle arises the great power of the animal in seizing and holding objects.

Organs of Motion in the Larva of Insects.—As insects undergo considerable changes of form at certain epochs of their life, they exhibit remarkable differences in their organs of motion. Hence it becomes necessary to describe them in their various states. All the winged insects, which undergo a complete metamorphosis, differ very considerably in their first state from that which they have in the sequel; and the most striking of these differences regard the moving powers. At this time they are called larvae or caterpillars; and they prefer a form for a longer or shorter time after quitting the egg. They are covered with a bristly and soft skin, divided into segments or rings susceptible of motion on each other, by means of small muscular bands situated in the interior of the body. Frequently their motions are performed simply by crawling on these rings, after the manner of reptiles; or, by rolling successively each of the segments of the body on the plane which supports it. Such is the case with the larvae of the diptera, and of most of the hymenoptera. Sometimes the surface of these rings is furnished with spines, stiff bristles or hooks, in order to give them a firmer hold on bodies: this may be observed in some flies, cælifera, tipula, &c.

On the under surface of the body in some orders, there are six feet near the head, each of which is formed of three articulations: the first is horny and terminated in a hook. By opposing these to each other the insect can hold any object, hook itself to it, and then draw the rest of the body towards this fixed point. This formation is seen in the coleoptera, and many of the neuroptera. The six feet are very short, and hardly susceptible of any useful application in some other coleoptera, as, for instance, the cerambyces, rhinina (Fab.), &c. The latter move in the hollows which they excavate by means of their jaws, by which they attach themselves, and with the assistance of plates or tubercles, with which the hind feet are furnished on the back and belly; their mode of proceeding may be compared to that of sweepers in chimneys.

Lastly, the lepidoptera, and some hymenoptera have, besides the six horny articulated feet, a variable number of false feet, not articulated, terminated by hooks disposed in circles and half circles, and attached to the skin on retractile appendices or tubercles: they move by fixing themselves to bodies by means of these organs.

The larvae of such insects as undergo an incomplete metamorphosis, as the hemiptera, and of such as pass through none at all, as the aptera, except the flea, do not differ from the perfect insect in the feet.

After this general statement of the external organs of motions in the larva, we shall particularly describe the muscles of some. We shall first mention those of the proper caterpillars; then those of a scarabæus, which lives under ground; of a hydrophilus, which inhabits the water; and of a cerambyx, which is found in the hollows of wood.

1. Muscles of Caterpillar.—The deepest stratum of muscles in the caterpillar is formed of four principal rows; two corresponding to the back, and two to the belly: their direction is longitudinal. Those of the back are separated from each other.

Vol. XIX.
INSECTS.

other by the longitudinal vessels, and from those of the belly by the tracheae. They begin at the union of the first and second rings, by two fasciculi slightly separated from each other, which are inserted into a kind of tendinous line produced by the union of the second with the third ring. The same structure exists in the subseuent rings. On the third, the fibres of the two fasciculi, although still distinct, are much more considerable: on the fourth the internal fasciculus alone has its fibres separate. The muscle is continued, without any apparent interjection, over all the other rings. It diminishes in thickness towards the opposite end of the body, and forms again several fasciculi; at first three, then four, and, lastly, five or six. The body is shortened when these muscles act in conjunction with those of the belly; it is curved upwards when they act alone.

The longitudinal muscles of the belly are separated from each other by the medullary cord, and from those of the back by the tracheae. Their direction is precisely the same with that of the dorsal muscle. They commence at the union of the two first rings by several fasciculi, which are united into one mass over the third ring. Their fibres are separated again behind, higher or lower according to the species, and form four or five muscular cords, which terminate towards the last pair of false feet. These affit the dorsal muscles in shortening the body when both sets contract together; but they antagonize them, when they act separately, for they then invert the body downwards.

Between the long muscles of the back and the skin shorter ones are found, having an oblique direction. Some are extended from without inwards, towards the dorsal line, between the annular interjections. Others occupy the same interval, but have an opposite direction, passing from within outwards, so as to describe with the former the figure of the letter V. These two orders of oblique muscles have not everywhere the same quantity of fibres. In the first rings they are narrow and long; those of the fourth, fifth, and sixth are much shorter: further back they become much longer and more numerous in some species, while in others they still continue broad and short. These muscles act separately on each ring, which they shorten by their simultaneous contractions; but, as they do not extend over the whole length of the ring, the parts corresponding to the parts, over which the oblique muscles do not pass, are elongated, when, by the action of the latter, the diameter of the ring is diminished: thus progression is facilitated.

Under the long muscles of the belly is found another family, of which the fibres are oblique. These very much resemble the oblique muscles of the back; and may be distinguished, according to their direction, into two orders. Those of one set are found nearer to the middle ventral line, in which the knotted nervous cord is found; and ascend from within outwards, in the intervals of the rings. The others are not so oblique, with the exception of the three inferior pairs. These muscles, therefore, form, with the preceding, an angle, similar to that of A.

The oblique muscles which run from within outwardly, or the back internal, have many fibres. They usually consist of three or four distinct fasciculi. Those which extend from without inwards, or the most external, have fewer fibre; and never more than two or three fasciculi.

The action of these muscles appears to be similar to that of the oblique muscles of the back; but it is probable that they all extend immediately the skin of the feet on which they are situated.

Besides the longitudinal and oblique muscles of the back and the belly, caterpillars have some which are lateral; that is to say, muscles situated below and above the fligmates or apertures, which ought to be described separately. These muscles are of three kinds, the straight, the transverse, and the oblique.

The straight lateral muscles are situated between the annular segments, above the fligmates. They are all placed longitudinally one over the other. Their points of attachment are covered by the transverse muscles. They seem intended to bend the body towards the sides when they act separately; but when they contract, in concert with the long muscles of the back and abdomen, they shorten the body, and thereby assist its progression.

The transverse lateral muscles are of two kinds: the one, which are longer than the others, arise from the intervals unoccupied by the attachments of the straight lateral muscles, and are inserted at the termination of the oblique external muscles of the abdomen. Their fibres are disposed somewhat in the form of a fan. The others have the fasciculi formed of parallel fibres; they are shorter, and are extended in each of the rings between the straight, lateral, and oblique muscles of the abdomen. These muscles diminish the diameter of each ring, and consequently lengthen it in each of its folds. This mode of action is necessary for progression.

The oblique lateral muscles are situated on each side of the straight. They proceed in an oblique direction from below upward, under the insertion of the oblique lateral muscles, which they assist when they act together.

Such are the muscles of the body in general; but the true and false feet, and the head, have particular muscles, which must be described separately.

The muscles of the true or stumpy feet are situated within the three articulations of which these feet are formed. They may be distinguished into those which move the articulations, and those which act on the unguis, or claw, that terminates them.

The muscles of the first joint consist of five or six fasciculi, which arise from the superior margin of this articulation, and are inserted into the inferior margin of the next. The muscles of the second joint are nearly equal in number, and are inserted into the superior margin of the third.

The muscles of the unguis terminate by two tendons; but they are formed of several fasciculi, some of which arise from the second and third joints in two very distinct layers; others from a line which corresponds with the convexity of the unguis; and lastly, others from the line which answers to its concavity. These tendons are inserted into two tubercles at the superior extremity of the unguis, on the concave side, towards its point. They serve to bend the unguis, which probably recovers its position by the elasticity of its articulation.

There are two muscles to each of the membranous or false feet. Their direction, with respect to the body, is almost transverse. They extend from the centre of the foot, into which they are inserted towards the back, and beyond the fligmates, whence they arise by lateral bands more or less oblique. Their use is to draw the centre of the foot inwardly, and to retract the hooks with which the limb is armed. It is probable that the contractions of the oblique muscles of the abdomen produce the opposite effect.

With respect to the muscles of the head, we shall at present describe only those which produce its entire motion. We shall notice the others in treating of the different functions to which they are subservient. The muscles which act on the head, bend it upward, downward, and towards the sides. Those which bend it upward are very numerous. They arise from the second and first ring, and are inserted into different points of the cephalic; some near the middle line,
line, others more laterally. They form, in general, two fas-
ciculi. The most internal is the least bulky. The lateral flexors are very oblique. They arise from the inferior or abdominal part of the body, and extend to the lateral parts of the occiput. The inferior flexors, which bend it di-
2. Muscles of the Larva of a Scarabaeus.—The larva of the
scarabaeus have the body arched, and convex superiority, and
conceive the side next the feet. The back and the belly
are separated by a membranous border, which has folds, and
is situated under the elytra. These larvae have only five
articulated feet, none of which are membranous. On open-
ing these larvae longitudinally, either on the back or the
belly, we observe three layers of deep-feated muscles—
the lateral, the dorsal, and the ventral.

The dorsolayer is formed of two tolerably distinct series of
fibres. One series is external, and occupies the intervals of
the ten first rings; that is to say, those which are furnished
with the elytra. The muscles which compose this series are
narrow, and preserve a longitudinal direction. The
second series is produced by fibres, which are somewhat
oblique, and extended in the same space, but more towards
the middle line. These muscles are broader and stronger
towards the head, and more narrow and less fibrous towards
the tail. They terminate between the tenth and eleventh ring
by a very narrow fleshly band. These muscles seem intended
to shorten the dorsal portion of each of the rings: this action
diminishes the convexity of that part, and thereby serves to
assist progression.

Near the middle line, between the ninth and tenth ring,
there are two small muscles a little oblique; but between
the twelfth and the last ring we observe only one series of
small short muscles, which occupy all the convexity describ-
ed by the curvature. The action of these muscles is obviously
the same as that of the preceding, to which they are acces-
Bors. When the first layer of dorsal muscles is removed, we find
fibres precisely similar underneath, but running in the oppo-
site direction. Finally we observe, in the dorsal layer, lines
of very short muscular fibres above the inferior plane of
the ninth and tenth ring. The use of these little muscles is proba-
ably the same as that of all the preceding, though their
action is less apparent.

The ventral layer very much resembles that of the back.
These muscles, like the dorsal, form planes of opposite
directions; the most deep-seated proceeding from the in-
ternal side, while those which are nearest the skin ascend from
the external side. This produces a small but very regular
rhomboidal figure in the middle of each ring on the line
bisecting the belly. The action of these muscles is the op-
posite of that of the dorsal layer.

On the left segment, and towards the part that answers to
the anus, we observe a bundle of transverse fibres, which,
by their contraction, doublets serve the purpose of a
sphincter.

The lateral layer of muscles is composed of three kinds of
fibres, which are very distinct with respect to their course.
They represent a lace passed through the meshes of a net.
All these fibres are situated behind the elytra, and in-
serted into the folds which separate the belly from the back
on both sides.

The muscles of the first order are completely transverse.
They extend over the union of each ring with the succeeding in
the space included between the ventral and dorsal muscles. It
is obvious that they must diminish, by their contractions, the
diameter of the body, and consequently extend it longitudi-
nally. These muscles are in general very narrow.

The second set is formed by oblique fibres which ascend
from without inwardly towards the middle ventral line, from
the union of one inferior ring to the union of the preceding.
These muscles are broad and very strong, they serve to form
the folds of separation between the back and the belly.

The muscles of the third order are less oblique than the
preceding, to which they appear to be accessories. Each
of the muscles which compose this division arises from the
middle of a ring, and is inserted under the head, where the
preceding muscles are inserted, that is to say, on the ventral
side.

It should be remarked, that the two last rings have no
lateral muscles.

The muscles of the head are very strong, the flexors are
attached to the ventral muscles above the union of the fe-
cond ring with the third. They are formed of three prin-
cipal fasciculi, which approach each other, and are inserted
into the posterior and inferior part of the head, at the base
of that scaly piece called, by Latreille, ganache. The exten-
forors or elevators of the head consist also of these fasciculi,
but they are longer and stronger than the former. They
have their origin in the fide, and penetrate under the trans-
verse and oblique muscles; one is attached to the fifth
ring; another to the fifth, and another to the fourth.
They are inserted into the posterior lateral parts of the
head.

3. Muscles of the Larvae a Hydrophilus.—The larvae of the
hydrophilus are elongated. Their body is somewhat flat,
and all its rings are distinct. They not only walk very
quick, but they extend swim with great velocity, in con-
sequence of different inclinations suddenly and incessively
given to the body.

These larvae, when opened longitudinally, likewise ex-
hibit four different kinds or divisions of muscles: those of the
belly, those of the back, and those of both sides.

The ventral muscles very much resemble those of cater-
pillars; they are formed of two distinct layers. The deep,
or that which first appears on the belly, when examined through
an opening on the back, is composed of longitudinal fibres
with interjections which correspond to each ring; the second
layer, or that which is next the skin, is entirely covered by
the preceding; it is composed of oblique fibres, which cross
each other in the form of an X, and which are extended
longitudinally in each ring.

The dorso muscles are long, extending from the head
to the tail, and forming on each side two rows of fibres,
which appear twisted over each other like ropes. They are
broader towards the head. Their fibres are inserted partly
into the inferior border of an anterior ring, and partly into
the superior border of the next ring.

These long muscles cover those which are oblique, and
cross each other in the form of an X. They extend from
the middle part of one ring to the anterior edge of that
which precedes it.

The deep-seated lateral muscles, which are numerous,
have a transverse direction. Each ring has three or four,
and their course is such, that they resemble the letters N or
M lying on one side, thus N M.

Beneath the transverse there are some longitudinal
muscles that have a small degree of obliquity; they form a
pretty large surface, which is uninterrupted throughout its
whole length, and confused with the oblique muscles of
the belly. Their fibres determine the chief motions of
the
body, in the same manner as the long muscles of the back and belly.

The muscles of the feet are the same as in the perfect insect.

The head has no particular muscles. The long muscles of the back, being inserted into the occiput, become extensors. The first transverse lateral pair are inserted beneath the head, and produce the lateral flexion. The long oblique muscles, which terminate at the inferior part of the head, become real flexors.

4. **Muffles of the Larva of a Cerambyx.** — In the larva of the cerambyces we find the same muscles as in those of the scarabaëi; but, as the shape of the body differs considerably in these two kinds of larvae, there results some variation in the form and extent of the muscular organs.

A great part of the head of the larva of the cerambyces can be drawn within the skin whenever the animal pleases. Very strong muscles, similar to those we have described in the scarabaëi, are appropriated to this function. As the head, which is very large, enters into the body, the extremity which receives it is somewhat thicker than the fame part of the scarabaëi, and the muscles which move the rings are more extensive than theirs.

The flat flabby tubercles which we found continued along the back and belly, are a kind of feet, which this larva uses in progression. They move by the alternate contractions of the correspondent muscles; this larva, therefore, moves with equal facility on the back and on the belly.

5. **Of the Organs of Motion in Perfect Insects.** — The great variety of motions which insects are capable of performing, entitles them to hold the first rank among the animals that have no vertebrae. With this view, in these minute beings, all the requisites necessary to produce the voluntary actions, the execution of which affumines us in vertebral animals of far greater magnitude. They even unite several functions which are very seldom found combined in the other classes; for insects walk, run, leap, swim, and fly with as much facility as the mammals, birds, and fishes exercise one or more of these faculties.

Insects are probably indebted for this advantage to the numerous articulations of which their bodies are formed. We must therefore pay attention to their different articulations, before we proceed to examine the actions they permit or produce.

1. **Of the Head.** — For a description of the manner in which the head is articulated to the thorax, see Entomology, under the division Caput, or Head.

The muscles which move the head are situated within the thorax. We shall describe here only those most generally met with. The levators or extensors of the head are commonly situated in the superior part of the corselet, and the depressors inferiorly.

Immediately beneath the middle dorsal part of the corselet, we find a pair of muscles which arise from the anterior portion of the scutellum, when that part exits; or from the superior part of the pectus. These muscles are inserted into the posterior and superior part of the head, on the edge of the occipital hole; they draw the head back, and lift it up when it is depressed.

On the lateral parts of this first pair we find another which is more slender; the insertion of this pair likewise takes place at the occipital hole, but more outwardly. They arise obliquely from the lateral parts of the corselet. These muscles turn the head to one side when they act separately; they raise it, and bring the mouth into the middle line when they contract together. It will be easily conceived that

insects which have the head articulated like a knee, these rotatory muscles are much stronger and more conspicuous.

The flexors of the head are also four in number, two on each side. The first pair arises in the interior lateral part of the pectus, from a small horn or process, which, in the coleoptera is of a square form, and has the four angles terminated by solid branches. These muscles extend directly to the inferior part of the occipital hole. From their position they doubtless move the head directly backward. The second pair, which are much shorter, arise from the inferior lateral part of the corselet, and proceed to the side of the preceding, with which they concur in their effect when they act together; but when one of the two contracts separately it bends the head to the side.

2. **For the description of the thorax or corselet, of the pectus or breast, and of the abdomen or belly, see Entomology, under the respective divisions.**

3. **Of the Members.** — For an account of the number and structure of the feet, see Entomology under the division Members.

The motion of each joint is performed in a single place. It is provided with two muscles only, which are enveloped in the preceding joint. They are an extensor and a flexor.

In the coleoptera the coxae move by a kind of rotation on their longitudinal axis, which is situated transversely, and forms, with the middle line of the body, an angle more or less approaching 90°. As the femur is attached to the internal extremity of the coxa, the distance between the thighs is greatest in those insects in which the femur is most bent with respect to the coxa, to which it is articulated. It is obvious, therefore, that the position of the plane in which this flexion is made, depends upon the situation of the coxa; when it is turned forward, the plane is vertical; when turned backward the plane is always more oblique; and in the insects that swim, it is then horizontal. It appears, then, that the almost imperceptible motion of the coxa determines the most remarkable movements of the feet.

The muscles of each pair of coxae and femora are situated in the superior of the corselet or of the pectus. To obtain a proper view of them, it is necessary to cut the body of the insect in a vertical direction. Over the last pair in the pectus there is a socalled supposition, in the form of a Y. The stalk of this part affords an origin to a muscle which turns the coxa backward, and is inserted into its posterior edge. The muscle which turns it forward arises from the back, and is inserted by a thin tendon, into its anterior edge.

The muscle which extends one femur, while it is approximately towards the other, is very considerable. It arises from the whole branch of the piece in the form of a Y, and is inserted into the internal edge of the head of the femur. Its antagonist is situated within the body of the coxa.

The muscles which extend the two pairs of anterior femora, arise from the corresponding dorso-lateral parts, and not from particular internal suppositions; the flexors, however, are always situated within the body of the coxa.

The muscles which turn the coxae arise also from the posterior part of the corselet; viz., the muscle which moves it backward, from the dorso-lateral part, and that which moves it forward, from the lateral part. In the water beetles, which, as we have observed, have the posterior coxa consolidated and immovable, these muscles seem to extend to the femur, which is therefore furnished with four, two extensors and two flexors.

The
The other orders of insects have nearly the same conformation as the coleoptera.

The muscles of the tibia are situated within the femur. The extensor, which is short and slender, is attached to its external edge (the femur being supposed extended in the longitudinal direction of the body); the flexor is much stronger and longer. It is situated on the inner side, and in the whole of the inferior part.

There are likewise two muscles to each joint of the tarsus: one, which is small, and placed on the inferior or dorsal surface, acts as an extensor. The other, which is more conspicuous, and situated on the inferior side, acts as a flexor.

For the description of the wings, see Entomology.

The muscles that move the wings are not yet well ascertained. They appear to be two kinds. Some, which are small and short, are fitted to extend or fold the wings, at the same time that they move them to or from the body: the others, which are somewhat longer, are calculated to produce the motions of elevation and depression which the wings perform.

The dytra of the coleoptera, orthoptera, and hemiptera, do not appear to assist in the action of flying, at least they are not moved in the same manner by the muscles of the pectus.

**Organs of sensation.**—On comparing together all the nervous systems, we find only one common part, which is a single tubercle, situated at the anterior extremity of the system, and always producing two lateral transverse filaments or crura, which unite it to the root of the system. This part appears always to correspond to that named cerebellum in man. The cerebellum of animals that have red blood and vertebrae, is always preceded by several pairs of tubercles, forming usually a larger mass than the cerebellum itself, and united to the root of the system by two longitudinal filaments or crura, which are interwoven in crisscross with those of the cerebellum. This union takes place in such a manner that both are confused in the common mass which forms the root of the medulla oblongata, and medulla spinalis, and leaves no space between them. These tubercles make what we call the cerebrum.

In the white-blooded animals, or those that have no vertebrae, there are also tubercles corresponding to the cerebrum, but they are much smaller, removed from each other, and connected with the cerebellum only by separate nervous filaments. The crura of the cerebellum leave a large interval between them, which receives the affogamus as in a collar.

The two filaeuli, forming the medulla spinalis, are intimately united in vertebral animals, and no trace of their separation remains, except a longitudinal furrow before and behind. But, in the animals which have no vertebrae, when this production exists, it is formed below the affogamus by the union of the two crura of the cerebellum. These two filaeuli commonly remain distinct throughout the greater part of their length, and are only united at different spaces by knots from which the nerves proceed. This production, however, frequently does not exist. In some animals with white blood, which have no elongation of the medullary substance, as in the mollusca, the nervous trunks, which are derived from the crura of the cerebellum, enlarge and form ganglia, or two or three nerves unite with each other to produce a common ganglion; and in general it is only from their ganglia that the nerves which are distributed throughout the body take their origin.

In those white-blooded animals that have a knotted and double medullary production, that is to say, in the insects, crustacea, and certain worms, the nerves all arise from the knots or ganglia of the medulla, or from some of the anterior ganglia of the cerebellum. In the red-blooded animals the nerves of the spine arise from the medulla spinalis in two bundles of medullary filaments, which unite after the posterior bundle has formed a ganglion. They afterwards separate into two trunks, the anterior of which communicates with the great sympathetic nerve by one or two filaments, and a ganglion is always formed at the place where they unite.

The great sympathetic nerve, which is constantly found in all red-blooded animals, exils in none of those with white blood; unlefs we should regard as that nerve, the two nervous cords which unite all the ganglia, and which are commonly called medulla spinalis in the crustacea, insects and worms. Were this opinion adopted, a medulla spinalis would be no longer attributed to those animals, and the absence of that production would then be the common character of all the white-blooded classes.

Instead of having the parts, which represent the brain and medulla spinalis enclosed in bony cavities, the lower orders of animals have them included in the common cavities, with the other viscera.

**Brain and Nerves of the Crustacea.**—The crustacea, which, in their organs of motion, very much resemble the other insects, though those of circulation and respiration are exceedingly different, have also a similar nervous system, at least the essential parts.

In such of the genus Cancer as have long tails, the middle part of the system is a knotted cord, which extends from one extremity of the body to the other. The short-tailed kind, commonly called *crab*, have a medullary circle in the middle of the abdomen, whence the nerves of the body proceed like radii.

In these animals the brain is placed at the anterior extremity of the front, and consequently at a considerable distance from the mouth, which opens under the corselet. On this account the cords which make the collar of the affogamus are more elongated than in other animals.

**A Brain of the common Cray-Fish, (Achaeus Fluviatilis, Linn.)**—The brain of this animal forms a mass which is broader than long, and distinctly divided on the superior surface into four round lobes. Each of the middle lobes produces an optic nerve from its fore part. This nerve proceeds directly into the movable tubercle which sustains the eye, and is there dilated and divided into a multitude of filaments, which form a pencil, and unite to all the small tubercles of the eye.

Four other nerves arise from the inferior surface of the brain; these proceed to the four antennae, and detach some filaments to the surrounding parts. The cords which form the collar, arise from the posterior part of the brain. About the middle of its length, each detaches a large nerve, which extends to the mandibles and their muscles. These cords unite under the stomach in an oblong ganglion, which furnishes nerves to the different pairs of jaws. On leaving this part, the two cords remain near each other throughout the whole length of the corselet, where they form five successive ganglia, placed between the articulations of the five pairs of feet; each foot receives a nerve from its corresponding ganglion, which penetrates to the extremity of the foot; the nerve of the foreleg is the largest. The medullary cords extend into the tail, where they are so intimately united that it is not possible to distinguish them. They form its ganglia, the five fili of which produce each two pairs of nerves; the last produces four, which are distributed as radii to the fealy fins that terminate the tail.

The hermit crab, (*Pagurus, Fabr. Bernhardus, Linn.*)
the tail of which is not covered by articulated scales, appears to have much fewer ganglia than the cray-fish. We have observed only five.

In the *fugilla*, Fabr. there are ten ganglia, without reckoning the brain; that at the union of the two cords which form the collar, transmits nerves to the two forelegs, and to the three pair of feet which immediately succeed them, and which in these animals are ranged almost on the same transverse line; this ganglion is therefore the longest of all. Each of the three following pairs has a particular ganglion. There are afterwards six ganglia in the length of the tail, which distribute their filaments to the thick muscles of that part. The brain produces immediately four trunks on each side, viz. the optic, thole of the two antennae, and the cord which forms the collar. As the antennae are placed more posteriorly than the brain, their nerves are directed backward.

B. *In the Common Crab* (*Cancer Marat*, Linn.)—The brain of the crab resembles that of the cray-fish in its form and situation; it also furnishes analogous nerves, but they are directed more towards the sides, in consequence of the position of the eyes and the antennae. The medullary cords which form the collar, detach each a nerve to the mandibles, but the cords are prolonged much farther backward than in the cray-fish before they unite. They join only in the middle of the thorax, at which place there is produced a medullary mass of an oval ring-like figure, which is eight times the size of the brain. The nerves which proceed to the different parts arise from the circumference of this ring. It furnishes six nerves on each side to the jaws and the five feet, and there is a single nerve which arises from the posterior part, and proceeds to the tail. This medullary ring may be said to represent the usual knotted cord, but if it has any ganglia they are not visible.

C. *In the Onijsus Achlorus.*—The two cords which compose the middle part of the nervous system in this animal, do not perfectly join. We can distinguish them throughout the whole of their length. There are nine ganglia, exclusive of the brain; but the two first and the two last are so close together, that the number may be reduced to seven.

D. *In Monoculi.*—We know not the nervous system of the molucca crab (*limbus gigas*, Fab. *Monoculus polyphemus*, Linn.) In the monoculus apus of Linneus, however, the indistinct nature of that system, joined to some other peculiarities of organization, would almost induce us to class the animal with the inarticulated worms. The brain is a small globule, nearly transparent, situated under the interval of the eyes. The medullary cord is double, and has an enlargement at each of the numerous articulations of the body; but the whole is so thin and transparent, that the real nature of the cord can scarcely be ascertained.

**Brain and Nerves of the Larva of Insects.**

A. *Coleoptera.*

1. *Larva of the Scarceus Naeonis.*—We shall give a particular description of the nerves of this larva, because their distribution is essentially different from that which takes place in the other coleoptera.

The brain is situated under the great scale which covers the head immediately above the origin of the oesophagus; it consists of two approximated lobes, which are very distinct at the front and back part. Four nerves arise from the anterior part, two on each side, which are lost in the cirri and parietes of the mouth.

From the lateral and somewhat posterior parts of the brain, there arise a pair of nerves, which, embracing the oesophagus, proceeds inferiorly to form the nervous cord we shall presently describe.

Another pair departs from the inferior surface of the brain, or that part which rests upon the oesophagus; these are first directed forward; they afterwards turn inward, and proceed above the middle and superior part of the oesophagus, in order to approach each other. When they come in contact, they unite and form a small ganglion, which produces a single nerve; this nerve, continuing to proceed posteriorly, paffes below the brain, and accompanies the oesophagus to the stomach. It there enlarges again into a ganglion, which furnishes some small nerves that are sent to the stomach, and one more considerable, which is continued along the intermaxillary canal, and sends off, at regular distances, lateral filaments, which are lost in the coats of this tube. This nerve is analogous to that which Lyonet has described under the name of recurrent, in the caterpillar of the *cofus*.

The medulla spiralis, which, as we have seen, is formed by the posterior pair of nerves of the brain, is very thick at its origin; it forms a large funiform ganglion about 0.005 metre long, and half a millimetre broad. Four or five contractions appear on its anterior part, but they are so slight that they seem only transverse furrows. The posterior part of this ganglion is smooth.

From the lateral parts of this large ganglion, which extends very little beyond the third ring of the body, a great number of diverging nervous filaments are produced. Those which are nearest the head ascend a little; those which succeed them proceed almost transversely; and the latter are directed more and more posteriorly; the length of each is in proportion to its distance from the anterior part of the ganglion. The two most posterior filaments are therefore the longest.

2. *Larva of the Stag Beetle* (*Lucanus Cervus*).—The nerves of this larva differ greatly from those of the preceding, although the perfect insects are so nearly allied in genera.

The brain consists of two contiguous and almost spherical lobes; these produce four nerves anteriorly for the antennae and the parietes of the mouth; two inferiorly, which first proceed forward, then turn back, pass again under the brain, and form a nerve known under the name of recurrent. Lastly, two posteriorly, which form a collar round the oesophagus, and join underneath, to compose the nervous cord of the body. This cord is formed of eight ganglia, which extend to the ninth ring of the body. The distances between these ganglia are very unequal; they are joined by very fonder and closely approximated nervous filaments.

The first ganglion, from the head, is very large, and almost spherical; it is followed almost immediately by the second, which is one-half less, and which is distinguished from it only by a kind of contraction; the first produces four pairs of nerves on each side; one ascends to the head, the other three diverge and are lost in the muscles of the abdomen, and in those that move the head. The second ganglion, besides the two nerves that unite it to the third, produces two other nerves, which are also directed backward, and lost in the muscles of the fourth ring. The third ganglion, and those that follow as far as the eighth, are similar to the second; with this difference, that they are much more distant from each other, and that they produce longer filaments, in proportion as they are situated more internally. Lastly, the eighth and ninth ganglia are so close together, that they seem to form but one, with a slight contraction in the middle. This double ganglion produces three pairs of nerves,
insects.

ners, which are much elongated, and extend to the parts near the anus.

3. Larvae of the Cerambyces, Hydrophilus, Carabod, and Staphylinus.—The nerves of these larvae being very similar, it will be sufficient to describe them in one genus only. We shall take for our example the larva of the great diver (Hydrophilus picus).

The brain in this animal is situated in the head, above the origin of the oesophagus; it is formed of two lobes which lie very close together. From its anterior part it detaches some filaments to the palpi, the antennae, and the parietes of the mouth. Its lateral parts produce two cords which surround the oesophagus, and which are the origin of the nervous cord situated internally. It is probable that recurrent nerves also arise from this inferior part, but we have not yet been able to discover them. The chief nervous cord is composed of ten ganglia, each of which produce three pairs of nerves that are lost in the muscles of the abdomen, and without any distinct appearance of their being distributed to the intine. This induces us to believe that there is a recurrent nerve. The first ganglion is very large; it is prolonged posteriorly into two nervous filaments, considerably removed from each other; the second is almost similar, but the third is very near the fourth, which produces only a single filament posteriorly. All the others, as far as the tenth, present no peculiarity. The body is divided by a sensible contraction; from the first portion a single filament arises on each side, and from the second, three pairs of nerves are detached; thus four pairs of nerves arise from this ganglion. The fourth pair is directed to the rudiments of the parts of generation, which are very distinct in these larvae in the last period of their growth.

4. Larvae of the Water Beetle (Dyticus Marginata).—The brain of this larva is spherical, and consists of a single lobe, situated in the head above the origin of the oesophagus; its anterior part produces some filaments for the mouth; and its lateral parts the two optic nerves; the latter are composed of two parts which are very distinct, as the form. The first portion, or that which is next the brain, is of an oval figure, pointed at the extremity which joins the brain; the other extremity is rounded, and produces a slender nerve, which goes directly to the eye. It is nearly of the same thickness throughout the whole of its extent; but it is enlarged at its free extremity into a bulb, from which the nervous filaments of the eye arise.

The two cords which embrace the oesophagus are short and thick; they arise from the inferior surface of the brain, and immediately unite below the oesophagus, in a large square-shaped ganglion, which produces anteriorly the nerves of the mandibles, and posteriorly two cords, which pass from the head into the corselet. There is a greater distance between this first ganglion of the nervous medulla and the second, than between any of the others. It is more than double that which exists between the two next ganglia. The second ganglion is round; it produces two pair of nerves laterally; the anterior for the muscles which act upon the head, the posterior for those which move the anterior feet. There are two cords posteriorly, which are directed into the breast. The third ganglion is similar in every respect to the second; it furnishes nerves to the intermediate pair of feet. The fourth ganglion is also produced by the two cords which come from the preceding; it is situated on the union of the abdomen with the breast; it is more broad than long. Laterally it produces two pair of nerves, which run transversely parallel, and are lost in the muscles. The other eight ganglia are placed close behind each other; and the space between them is so small, that we can scarcely perceive the two nervous filaments which unite them; they also decrease in thickness, without diminishing in breadth, as they extend posteriorly. They all furnish laterally a pair of very long nerves, which float in the abdomen, and for the most part terminate in the muscles that move the wings. One pair, however, proceeds to the rudiments of the parts of generation.

B. Orthoptera and Hemiptera.—The nerves of the larvae of orthoptera and hemiptera present no sensible difference from those we observe in the perfect insects. It will be sufficient, therefore, to describe the nerves of the latter.

C. Hymenoptera.—In the larva of the saw-fly (Tenthredo, Linn.), which has a large head furnished with eyes, the brain is very broad and short; it seems to form four bulks of equal magnitude, and nearly spherical; the two external nerves serve as the base of the optic nerves, which are slender, and which enlarge a little at their other extremity. The first ganglion is produced by two very small nerves, which arise from the inferior surface of the brain, and which, after having embraced the oesophagus, unite under the first ring of the body; it furnishes filaments to the muscles of the feet, and terminates posteriorly in two other nerves, which, at the distance of one line, produce a second ganglion, and so on in succession; the nervous cord is in this manner formed of eleven ganglia, without reckoning the brain; the farther the ganglia are removed from the head, the more they diminish in thickness; they are all nearly of a round form.

D. Neuroptera.—In the larva of the lion-ant (Myrmecia formicarius), the nervous system has some relation to that of the larva of the dipterus insects which we shall afterwards describe. There is a brain situated in the head; it produces nerves analogous to those we have already pointed out in the other larva. The nervous medulla consists, in the first place, of two ganglia, which are composed of two lobes, situated close together; these two first ganglia are separate from the others, and contained in the part corresponding to the feet, or in the thorax. The remainder of the nervous medulla is enclosed in the abdomen; it consists of eight ganglia, placed in an exceedingly close series, and each formed of two lobes; the first is nearly double the size of the other seven. This succession of ganglia appears to the eye like the extremity of the tail of a rattle-skeake; the last is round; the others are much broad than long. All these ganglia furnish nerves to the muscles. It is probable that this disposition and approximation of the ganglia have a relation to the changes which take place in the insect at the moment of its metamorphosis, as its abdomen then occupies five times the space it does in the larva state.

In those larva of neuroptera, which are nearly as long as the perfect insect, we find that the ganglia are separated in the usual manner.

The larva of the ephemeræ has eleven ganglia, without including the brain, which furnishes two large optic nerves. There are three ganglia in the thorax, and seven in the abdomen; the first six, reckoning all the ganglia, furnish more nerves than the five last.

The larvae of the dragon-flies have a small two-jointed brain, which produces optic nerves, larger or smaller according to the species. The genus aëthinæ has them the largest. The rest of the nervous system forms a series of ganglia of different sizes. In the aëthina, the corselet contains six, the two last of which are the largest of all. There are seven small and equal ganglia in the abdomen.

E. Lepidoptera.—The nervous system of caterpillars con-
Insects.

Filts of a series of thirteen principal ganglia, which furnish filaments to all other parts of the body. The first of these thirteen ganglia is situated in the cavity of the head; it lies above the oesophagus, and supplies the place of the brain: it appears formed superficially by the union of two round tubercles, and is situated inferiorly concave, and corresponds to the convexity of the oesophagus. This ganglion communicates with the root of the nervous cord by two thick filaments, which embrace the oesophagus, and which are united below it to the anterior and lateral part of the next ganglion; it besides produces eight pairs of nerves.

The first partly unites with other filaments; produces four to the oesophagus, and forms several remarkable ganglia below the upper lip. The largest and most posterior, which Lyonet has named the first frontal ganglion, is prolonged posteriorly into a thick recurrent nerve, which is continued the whole length of the body, near the back; this recurrent nerve furnishes filaments to the oesophagus and its muscles; it penetrates into the dorsal vessel, and it afterwards re-appears, and guides along the oesophagus as far as the stomach. This nerve produces, at certain distances, very solid filaments, which keep the oesophagus attached to the skin of the back.

Besides the recurrent nerve we have just noticed, several filaments are furnished by the posterior frontal ganglion to the muscles of the oesophagus, and two to the second frontal ganglion; the latter also detaches several filaments to the oesophagus, and, in particular, a very remarkable one, which, by a sudden enlargement, constitutes the third frontal ganglion. This ganglion likewise affords several filaments to the oesophagus.

The second pair of the brain appears chiefly intended for the antenna, though it furnishes several filaments to the neighbouring parts. The third pair terminates particularly in the antenna, and the muscles which move them. The fourth pair is proper to the eye of each side; it accompanies the air-tube which goes to that part, and is divided into four branches, that penetrate into the eye, which, by their union, form that of the caterpillar. The fifth is directed a little backward, where it divides into two branches; one posterior for the adductor muscles of the jaw; the other anterior, which is lost in the membranes that cover the frontal scale. The sixth and seventh pair unite to form a ganglion from which several filaments are detached, to the oesophagus and its muscles. Finally, the last pair of the brain is entirely lost on an air-tube.

But besides these nerves produced by the first nervous ganglion, several others are detached from it, which we shall briefly notice. In the first place, we observe, that it furnishes several filaments to the dorsal canal; it afterwards gives origin to a pretty long filament, which terminates on the air-vessels, between the second and third ganglion. Lastly, it produces a nervous ring, which embraces the oesophagus inferiorly like a girdle, and supplies it with several filaments. The second ganglion is intimately united with the third, and is distinguished from it only by its contraction. The nerves which proceed from the anterior part appear to be produced by the second ganglion, and those which arise from the posterior part, seem to belong to the third.

Besides the two filaments which form the collar round the oesophagus, and which unite the first to the second ganglion, the latter has four pairs of very distinct nerves. The most anterior pair is sent forward to the mouth, but in its course it divides into two branches; one terminates in the tongue and the adjacent parts; the other branch proceeds to the lateral parts, where it sub-divides, to supply the mandible, the jaw, and upper lip, communicating, at the same time, with the first ganglion, and with the second frontal. The second pair proceeds to the jaw, but detaches a number of filaments to the muscles of the neighbouring parts. The third pair is defined for the spinning apparatus; in its course it gives filaments to the silk vesicles and muscles of the head. The fourth pair arises near the constrictor, which indicates the union of the two ganglia, between the head and the first ring; it is lost in the fat, in the skin of the neck, and in the muscles inserted into the head.

The third ganglion, which, as we have observed, is united to the second, produces only three pairs of nerves: the posterior is merely the continuation of the visceral trunk of the other two pairs; the anterior is entirely lost in the muscles and the skin; the intermediate pair supplies that part also; but it is distributed chiefly to the muscles, which move the articulations of the legs.

We have already stated, that each ganglion communicates with that which precedes, and that which follows it by two filaments that are distinct from their origin, and are the bifurcation of a single trunk. The middle of this bifurcation, from the third to the eleventh ganglion, produces a small nerve, which Lyonet has named the spinal frenulum; this single nerve is situated in the middle line; it presently divides into two branches, which follow the divisions of the air-tubes, and penetrate with some of them into the longitudinal vessel.

The fourth and fifth ganglia produce the same number of nerves, the distribution of which is also nearly similar; their anterior pair proceeds to the muscles, and into the skin of the rings to which it corresponds; the intermediate pair furnishes, more particularly, filaments to the muscles of the leg.

The sixth ganglion, which corresponds to the fourth ring of the body, also furnishes two pair of nerves, which are lost in the muscles and the skin.

The nerves of the five following ganglia are distributed nearly in the same manner.

The twelfth ganglion, which is the termination of the nervous cord, are very close to each other, though distinct. The distribution of the nerves, produced by the first, presents nothing remarkable. Those furnished by the second are very long, being sent to the last rings, in the skin and muscles of which the first pair is partly lost. The second pair is only subdivided when it has reached the first ring; if there produces a plexus, from which a number of filaments are detached to the giant interlacing. The trunk appears to end on the parietes of the rectum towards the anus.

F. Dippera.—The nerves of the larva of the firstyomis have some resemblance to those of the larva of the scarabaeus naucorae.

The brain is formed of two lobes, placed close together, and almost spherical; it is situated above the oesophagus, on a level with the second ring of the body. A number of small nervous filaments arise from its anterior part, and are distributed to the parietes of the mouth, to the mandibles, and to all the adjacent parts. These nerves are very distinct, particularly those which are removed from the middle line. The posterior part of these two lobes sends off two thick branches which embrace the oesophagus, and form the origin of the nervous medulla. This nervous cord is very short, and its diameter is one-half less than that of the brain; it consists of eleven ganglia placed very near each other, each of which produces one pair of nerves.

These nerves proceed directly backward. Swammerdam has erroneously represented this cord as twilled, like the tail of a scorpion, and producing nerves on the left side only.
only. It is true, that those which arise from the right side are parallel to the cord, while those of the left side remove farther from it. The ganglia, thus approximated, are eleven in number, and in a straight direction; they produce long nerves, which are lost in the muscles.

The nerves of the cheese-worm (Musca pratis, Linn.) are distributed in a very curious manner. The brain is situated immediately above the origin of the esophagus, behind the head; it is very large in proportion to the rest of the body; it is rounded posteriorly, and notched anteriorly, as if it were formed of two lobes.

A pair of nerves arise from the anterior part of the brain, proceed forward, and are distributed to the mouth, and even to the parietes of that cavity. It should be remarked, that these nerves experience a very conspicuous enlargement previously to their distribution.

Posteriorly the brain presents an aperture, which affords a passage for the esophagus; the nervous part, situated on its sides, may be regarded as the cords which produce the medulla, and all below the esophagus as the medulla itself.

Two pairs of nerves arise from the origin of the nervous medulla; these are directed forward, and principally distributed to the vicera, and to some of the muscles of the anterior rings. The third pair of nerves which this medulla produces is the most remarkable; it comes from the part which nearly corresponds to the third ganglion; we say nearly, because in this insect the ganglia are so close to one another, that the medulla seems to form only one piece on the surface of which we merely perceive twelve transverse wrinkles, which indicate the number of ganglia in this third pair extending almost transversely. At a certain distance from its separation it swells into a ganglion, and then divides into several filaments; these are the ganglia which Swammerdam supposed to be intended for the muscles of the wings, when they shall exist in the perfect insect.

Another pair of nerves, which go to the muscles of the body, arise from each of the other contractions; but they require no particular remark.

Brain and Nerves of Perfect Insects.

A. Coleoptera.

1. In the Stag-beetle (Lucanus cervus).—We find in this insect, as in its larva, a brain composed of two approximated spherical lobes, situated above the esophagus; its anterior part produces two pair of nerves, which terminate in the palpi and other parts of the mouth. There is probably a recurrent nerve, but our researches have not yet discovered it.

There are two ganglia on the lateral parts of the brain, which are almost as large as each of the lobes. In their form they resemble a pear, and rest upon the brain by their base; they are prolonged transversely into a large nerve on each, chiefly intended for the eye. Before the nerve arrives at that part, we observe it detach a slender filament, which enters into the great mandible; then, more externally, another filament which enters into the cavity of the antennae; lastly, the nerve itself, having reached the eye, swells again into a bulb, and produces a number of nerves, which we shall describe when we treat of the organ of vision.

Posteriorly the brain produces two very long and slender nerves which accompany the esophagus to the point where the head unite to the thorax, immediately above the articulation cordyli. The two nerves situated above the esophagus, then produce a ganglion of a long oval form, from which several nervous filaments are detached to the muscles that move the mandibles, and those that act on the head. This ganglion terminates posteriorly in two parallel nerves, which proceed to the middle of the thorax, above the origin of the two paires of feet, and there form a second ganglion of an hexagonal figure; this ganglion furnishes filaments to the muscles of the face, and likewise terminates posteriorly in two nerves, which extend above the union of the two palpi, with the pectus; they there unite and form a third ganglion, which is crescent-shaped, with the convexity posterior; two other nerves proceed from this convexity, which almost immediately produce another ganglion of the same form, but smaller. This ganglion gives origin to five nerves: two lateral, defined to the muscles of the intermediate feet, into the coxae of which we observe them enter: posteriorly two, which are flender, and distributed to the muscles of the hind feet and the wings. The fifth is situated in the middle line; it is also thicker, it swells almost immediately into an oval-shaped ganglion, which is divided posteriorly into two exceedingly slender filaments. These filaments, which pass into the abdomen, form a kind of bridge in the breed, in which they occupy the middle line, and leave between them the muscles of the feet and wings of either side.

2. In the Scarabaeus nasicornis.—With respect to the nerves, this insect differs in the perfect state from the description we have given of its larva. The optic nerves, which are very distinct and large, proceed to the eye, into which we observe them enter by a multitude of filaments when we make a horizontal section of that organ.

The nervous cord presents a very conspicuous difference. In the larva there is only a single ganglion; but the perfect insect has several, which are very distinct. The first is situated above the corflet; it proceeds from the posterior filaments of the brain, and is distributed to the muscles which move the head on the corflet. Its posterior part produces two filaments, which pass into the breast, where they unite towards the middle part, and form a triangular ganglion; from the sides of which three pairs of nerves arise, and are distributed to the muscles. Its posterior angle detaches two parallel nerves, which proceed into the breast, where they form a third and a fourth ganglion, situated very near each other, and apparently divided into two lobes by a longitudinal furrow. All the other nerves of the body depart from those two ganglia by an irradiation, precisely in the same manner as in the larva.

3. In the Water Beetles (Dytiscus) and the Ground Beetle (Carabus).—The nervous system is entirely similar in these insects. The brain is formed of two large hemispheres, separated from each other by a longitudinal furrow. The anterior part produces the nerves of the mouth, and the lateral parts those of the eyes and antennae. The nerves of the eyes are short, and differ greatly from those of the stag beetles; they are of a pyramidal form: their base corresponds to the eye, and their apex to the brain. We have not observed any recurrent nerves.

The two filaments which produce the nervous cord depart from the brain, not posteriorly, but inferiorly, on the side of the optic nerves: they are very short, as they pass immediately under the esophagus. They furnish some filaments to the muscles and the esophagus. The first ganglion they form lies under a kind of bridge, formed of horny substance, which is situated in the middle of the head, and which affords a point of attachment to the muscles of the jaws; it is of an elongated and quadrangular figure, and occupies almost the whole space that corresponds to the corflet above which it is placed. It is terminated posteriorly by two filaments which proceed in a parallel direction.
INSECTS.

direction, and form a second ganglion in the middle part of the corselet. This ganglion furnishes nerves to the muscles of the anterior feet. We observe them enter into the cavity of the coxæ. The third ganglion appears bilobed, or formed of two oval bulbs, the union of which is marked by a longitudinal furrow. This ganglion is situated longitudinally above the anterior inferior edge of the breadth. It sends filaments to the muscles of the intermediate feet. The fourth ganglion is very near the preceding; it is of a roundish form, and is distributed to the muscles of the posterior feet and the wings. The space between the fifth and sixth ganglion is very small; their form is round; and they furnish filaments to the muscles that move the abdomen on the breadth. The remainder of the medullary cord is formed by a series of five ganglia, situated so close to one another, that they appear to the naked eye to form only one; but with a glass they may be observed very distinctly. We even perceive the two filaments produced by each to form the succeeding ganglion. The fifth presents a transverse furrow, which seems to indicate the union of two ganglia. The end of the medulla appears to float in the abdominal cavity, but above the intestines.

4. In the Great Diver (Hydrophilus Piceus, Linn.)—The brain of this insect, which is situated in the head, and above the origin of the œsophagus, consists of two spherical bulbs closely united. The lateral parts give origin to the optic nerves which proceed towards the eyes without changing their diameter, but which terminate there by a triangular bulb that produces a vast number of filaments externally.

The anterior part of the brain detaches some filaments intended for the parietes of the mouth. We also remark, at the same place, a small spheroidal ganglion, which appears to belong to the recurrent nerve that accompanies the œsophagus.

Two filaments, which should produce the medullary cord, arise inferiorly: they embrace the œsophagus at their separation, unite immediately below it, and again, in the cavity of the head, to form a small ganglion, which furnishes nerves for the muscles of the mandibles and the palpi. Two nervous cords are detached from the posterior part of this first ganglion. Almost immediately after their origin, they pass under a horny arch, which is produced by the internal surface of the ganache. We observe that they re-appear posteriorly, and proceed into the corselet. They form a second ganglion exactly in the middle of the corselet; its figure is quadrangular. The anterior and posterior angles produce the nerves of the medulla, and the lateral those intended for the muscles of the anterior feet. The interval included between the second and third ganglion of the medulla is very great. The third ganglion corresponds to the inferior of the intermediate feet: it is large, and of a round form; it furnishes nerves to the wings, and to the intermediate pair of feet. Posteriorly it produces two cords, which, at the distance of about half a line, swell and form a fourth ganglion, almost as large as the preceding. This ganglion detaches, from its inferior part, a number of filaments for the muscles of the posterior feet, which are specially appropriated to swimming. Two other very short cords produced by the posterior part of this ganglion swell into a fifth, which is one-half less than the former, and which furnishes a single cord posteriorly. This cord passes into a kind of longitudinal groove, formed above the horny appendix, that furnishes attachments to the muscles of the coxæ. A sixth ganglion is situated at the posterior and wide part of this appendix: at a certain distance, and exactly above the union of the abdomen with the breast, a seventh appears. These two ganglia produce only one pair of nerves, which are distributed to the muscles.

There are only two ganglia in the abdomen; one corresponds to the middle part of the second ring; the other, which is the last and ninth, is situated above the union of the second segment with the third. The last ganglion but one is in every respect similar to the two preceding; but the ninth is one-half larger, and produces posteriorly four pair of nerves, which are distributed on both sides to the parts of generation.

B. Orthoptera.—In the Cockroach (Blatta Americana.)—The brain of this insect is composed of two lobes, separated by a very distinct notch anteriorly. The optic nerves arise on the sides, and its anterior part detaches some filaments to the parietes of the mouth, and to the infrarnets of mandulation.

The nervous cords which form the medulla arise from its inferior surface. They proceed directly downward, and closely embrace the œsophagus. They afterwards proceed in a parallel direction, but very distinctly from each other, towards the corselet. When they reach its middle, they form a very large ganglion, which produces three pairs of nerves laterally, and one posteriorly. The first lateral nerves ascend obliquely towards the head, and furnish filaments to the muscles that move it on the thorax, and which act on the antennæ and the parts of the mouth. The others are distributed to the muscles of the first pair of feet.

The posterior nerves proceed in a parallel direction backward. At the middle of the pectus they produce a still more considerable ganglion than the second, which furnishes laterally nerves to the intermediate and posterior feet, as well as to the muscles of the wings. It also sends off two cords posteriorly, which, by their union at the junction of the abdomen and the breast, form a fourth ganglion, situated on a projecting horny substance to which the muscles of the coxæ are attached.

After this fourth ganglion there is only a single nerve, which has, at certain spaces, small enlargements. Five of these swellings may be counted. Each produces a pair of nerves for the muscles of the rings of the abdomen: the first is the largest, and furnishes besides two nerves which ramify in the parts near the anus.

In the Great Green Grasshopper (Grillus Virdissimus, Linn.)—The brain is situated in the head above the œsophagus: it consists of two lobes, which have the form of pears, united at their base, and prolonged at the other extremity into an optic nerve for the eye of each side. The anterior part also produces two nerves of a pyramidal form, the base of which rests upon the brain. Some filaments arise from the apex of the pyramid, which are lost in the mandible, the jaw and its galea, as well as in the upper lip.

Between these two anterior nerves we observe a small ganglion, which is produced by the union of the two filaments of the inferior surface of the brain. This is the recurrent nerve which follows the intestinal canal. Posteriorly, and a little inferiorly, we observe the origin of the two cords which form the nervous medulla. They embrace the œsophagus, below which they are immediately directed, and form a ganglion. This first ganglion is protected and covered by a kind of horn yard bridge of a reddish colour. It furnishes nerves to the muscles of the mouth, and to those of the head within which it is included. Posteriorly it produces two long nervous cords, which penetrate into the corselet. These two cords unite about the middle of the thorax before the appendix, which gives attachment to the muscles of the coxæ and the anterior pair of feet. At this union they form a large
INSECTS.

A large bilobed ganglion, of an irregular quadrangular figure, the sides of which produce several filaments for the muscles of the anterior feet.

The posterior part of this second ganglion furnishes two filaments, which penetrate into the breast. The fold appendices of the coxa, which afford insertions for the muscles, pass between these two filaments. They form a third ganglion, which corresponds to the middle space included between the two intermediate feet. This ganglion sends nerves to the muscles of the wings and the feet.

The fourth ganglion is also contained in the breast. It is situated before and between the posterior pair of feet. It is produced by two nervous cords from the preceding ganglion; and furnishes two posteriorly, which are close to each other, that they appear to the naked eye to make only one cord. This nerve is received and contained in a kind of groove formed above the triangular piece, which affords an attachment for the muscles of the feet.

The other ganglia, which are all situated in the abdomen, are six in number. They are, the last excepted, of the same size and form, placed at equal distances, and produced by two similar and closely approximated cords. Each furnishes two pair of nerves for the muscles of the abdominal rings.

The last ganglion of the medulla is one-half larger than the fire preceding. It is situated below the parts of generation, to which it is distributed by four pair of filaments.

In the Mole-cricket (Acheta Gryllo talpa).—The brain of this insect is also composed of two rounded lobes, which are particularly distinct at the posterior part. We can clearly perceive the origin of the nerves of the palpi, of the antennae, of the smooth eyes, and of the eyes properly so called. In general the nerves of the principal medulla are similar to those we have described in the cock-roach. The two first ganglia are produced by two nerves. The first, which is in the corset, furnishes the muscles of the head, breast, and anterior feet. The second, which is larger, and in the breast, gives filaments to the muscles of the wings, and of the intermediate and posterior feet. It also sends two nerves posteriorly, which produce the abdominal ganglion. The cord then becomes single and flat, like a ribbon, and contains only four ganglia, occurring at different distances. Each produces two pairs of nerves, which are directed posteriorly and distributed to the muscles. The first corresponds to the middle part of the first abdominal ring; the second to the third, the third to the fifth, and the last to the ninth.

This last ganglion is the most remarkable of all. It is of an oval shape, and produces, from the whole of its circumference, nerves which are distributed to the neighbouring parts. Two, which are longer than the others, diverge as they proceed backward, and thus represent a bifurcation of the medullary cord. These branches furnishes filaments to the parts of generation.

C. Hemiptera.—In the Oval Water Scorpion (Nepa Cinerea, Linn.)—The nervous system of this insect consists of three ganglia. The first, which supplies the place of the brain, is situated in the head. It is formed of two approximated lobes. These lobes are pyriform, and touch each other at their base. Their funnits are directed obliquely forward towards the eyes, in which they terminate, and thus answer to the optic nerves by their anterior extremities. The middle and anterior part of these lobes also produce some filaments for the parts of the mouth. Posteriorly, the brain detaches two cords, which embrace the esophagus as they pass below it. They unite at the origin of the breast in a tetragonal ganglion: each of the angles of which produces or receives several nerves. The anterior receives the two cords which come from the brain; the posterior, the two which are the continuation of the medullary cord. Each lateral angle produces a fasciculus, composed of four nerves, which are directed to the muscles of the breast and anterior feet. We observe one of them enter into the cavity of the coxa.

The two nerves produced by the posterior angle of the second ganglion proceed in a parallel direction backward. Having arrived in the breast above the horny appendices, to which the muscles of the coxae of the intermediate and posterior feet are attached, they swell into a large round ganglion, considerably more voluminous than the brain. A vast number of nerves are detached from the edges of this ganglion, like folar rays. The two most remarkable filaments are exceedingly long and slender. They extend from the breast nearly as far as the anus, where we have observed them to terminate by three minute branches in the parts of generation of the male, furnishing, at the same time, some filaments to the adjacent parts. All the other filaments, which proceed from this third and last ganglion, are distributed to the muscles. We can very plainly distinguish those that belong to the middle and intermediate feet, as they are somewhat larger than the others.

D. Lepidoptera.—In the Zig-zag Moth (Phalaena Difsera, Linn.)—The brain in this species is almost spherical. We, however, perceive a longitudinal furrow on the middle line. Its anterior part produces some exceedingly slender nerves. There are two large optic nerves on the sides, which proceed into the concavity of the eye, where they terminate by a bulb, which produces a great number of filaments.

The esophagus palls immediately behind the brain, through a small triangular interval, the posterior sides of which are formed by the two cords of the medulla. These cords afterwards unite, and proceed in the form of a single trunk, on the middle part of which we perceive only a longitudinal furrow. Arrived in the corset, it forms a ganglion, the surface of which is reddish. This ganglion produces two nerves posteriorly, which leave between them an interval that affords a passage for the horny appendices to which the muscles of the coxae are attached. The two cords again unite behind these appendices in the same cavity of the breast, and produce a much larger ganglion, the lateral parts of which furnish nerves to the muscles of the wings and feet. It is prolonged posteriorly into a single cord, which again enlarges when it arrives above the articulation of the breast with the abdomen into a third ganglion.

It should be remarked, that this large ganglion, which has the form of a heart, is the only one, besides the brain, of a completely white colour. All the others exhibit darker shades, and we perceive them in their true form, when viewed by a glass, reddish points more or less elongated and sinuous, that resemble the blood-vessels of injected glands.

The third ganglion is prolonged into a single cord, which produces a fourth ganglion above the first ring of the abdomen. The latter, as well as those that succeed it, detach on each side a long slender nerve which passes under the muscular fibres, precisely in the same manner as the threads of the wool pass through the warp in cloth. Their direction is completely transverse. The fifth ganglion does not differ from the preceding. It is prolonged into a single cord, upon which we can clearly distinguish the longitudinal furrow. It is situated in the middle part of the third ring of the abdomen. The sixth ganglion is, in every respect, similar to the preceding; it is placed in the middle of the fourth ring. Finally, the seventh and last ganglion is much larger than those that precede it in the abdomen. It is of an oval
oval form, and situated upon the lunula that terminates the fifth abdominal ring posteriorly. Besides the nerves intended for the muscles of the fifth ring, which are detached from this ganglion in two distinct parts, it produces four other pairs posteriorly. These nerves appear to be distributed to the parts of generation, and to the muscles of the last abdominal rings, which, in the female, are elongated like a tail to assist in laying eggs.

E. Neuroptera.—The insects with naked wings, that is to say, the hymenoptera, neuroptera, and diptera, which have frequently very large eyes, have also the optic nerves of a proportional size. This is particularly observable in the dragon flies. Their brain is formed of two very small lobes; but their optic nerves are dilated into the form of two large plates, which have the figure of a kidney, and which is spread upon all the inner surface of the eye next the head. The remainder of their medullary cord is exceedingly slender, and furnished with twelve or thirteen small ganglia, the last of which is, as usual, connected with the parts of generation.

F. Hymenoptera.—The brain of the bee is small, and divided into four lobes. It produces immediately the nerves which are distributed to the different parts of the mouth, and the two large optic nerves which are dilated and applied behind each eye as in the dragon flies. There are afterwards seven ganglia, three of which are in the corselet, and four in the abdomen. The nerves of the last chiefly supply the parts of generation.

G. Diptera.—The apiform fly (Musca tenea; Linn.) has a small brain, formed of two lobes, which are situated very close together, but distinguished by a longitudinal furrow; the anterior part produces a large nerve, which is afterwards distributed to the antennæ and the proboscis.

The optic nerves are very thick, cylindrical, and equal in diameter to the length of the brain, on the lateral parts of which they rest; they terminate at their extremities in very large bulbs, which correspond to the breadth of the eyes.

The first ganglion of the medulla is produced by two cords, which come from the posterior part of the brain, and embrace the cephalus as a collar; it is very slender, and situated in the breast; it furnishes a pair of filaments to the muscles of the anterior feet.

The second and the following ganglia, in all three in number, are united to each other merely by a single cord. The last ganglion is one-half larger than that which precedes it. Posteriorly it produces eight or nine filaments, which are intended for the parts near the anus; the first of the third is situated in the breast, where it furnishes nerves for the muscles of the wings and the feet; the other two ganglia are in the abdomen; the last but one is placed above the union of the third ring with the fourth; and the last on the interior and interior edge of the fifth ring.

The hornet-fly (Asilus crostiformis) we also observe a single cord uniting the abdominal ganglia, which are fixed in number.

The brain is similar to that of the syrphus; but the bulbs, formed by the optic nerves, are still broader, in proportion to the extent of the eyes they have to invert.

H. Gnataptera.—In the great scolopendra (Scolopendra morifanta), the brain has a very singular form: it is, as usual, composed of two lobes, which are almost spherical; it produces laterally the optic nerves, which are very short, and may be observed to divide long before they reach the eye. The filaments are four in number; but two nerves arise anteriorly, which are very thick, that they appear a part of the brain, to which they are equal in diameter. These nerves are particularly intended for the antennæ, into which we observe them enter, and in which they may be followed on account of their magnitude.

The two cords which embrace the cephalus proceed directly downward, and form a large ganglion at the union of the first ring with the head. The first ganglion produces two nerves posteriorly, and several towards the sides. A ganglion, precisely of the same shape, is placed above each of the articulations: thus there are, in all, twenty-four very distinct ganglia; the last of all is smallest, nearest the preceding, and seems to float in the abdomen; each detaches three pairs of nerves; one which ascends towards the head, a second which runs transversely; both these are distributed to the muscles of the abdomen; the third descends, and then proceeds backwards and upwards; it furnishes filaments to the lateral muscles, and to those of the back.

Organs of Sense.—We have very little to observe on this subject, in addition to what will be found in the article ENTOLOGY, under the divisions, Organs of Taste, Palæ, Olfactory Organs, Eyes, Stomach, Organs of Hearing.

Few subjects in comparative anatomy and physiology have given rise to more various and contradictory opinions, than the organs of sense in some classes of animals. Much misunderstanding on this point has clearly arisen from the inconsiderate application to animals, of inferences drawn from the human subject. Thus, it has been supposed that those which possess a tongue, must have it for the purpose of tasting; and that the sense of smell must be wanting, where we are unable to ascertain the existence of a nose. Observation and reflection will soon convince us, that the tongue, in many cases (in the ant-eaters among mamalia, and almost universally in birds) cannot, from its substance and mechanism, be considered as an organ of taste; but must be subservient merely to the ingestion and deglutition of the food. Again, in several animals, particularly among insects, an acute sense of smell seems to exist, although no part can be pointed out in the head, which analogy would justify us in describing as a nose.

However universally animals may possess that feeling, which makes them sensible to the impressions of warmth and cold, very few possess, like the human subject, organs exclusively appropriated to the sense of touch, and expeditely constructed for the purpose of feeling, examining, and exploring the qualities of external objects. This sense appears, according to the present state of our knowledge, to exist only in three classes of the animal kingdom; viz. in most of the mammals, in a few birds, and probably in insects. All the observations and investigations of the structure of the antennæ, those peculiar organs which exist universally in the more perfect insects; and of the use which these animals generally apply them to; lead us inevitably to the conclusion, that they really are, what their German name implies (Fühlhorn); the literal translation of which is feeling horns) proper organs of touch; by which the animal examines and explores surrounding objects. Such organs are particularly necessary to insects, on account of the insensibility of their external coat, which is generally of a horny consistence; and also from their eyes being destitute in most instances of the power of motion.

We are not warranted in considering the tongue as an organ of taste in all animals, because it is subservient to that function in the human subject, and in some other instances. We have already observed, that this organ, in many cases, serves merely for taking in the food; and it is at least very doubtful whether it possesses the sense of taste in many others. Yet, on the contrary, we should not be warranted in denying the existence of the sense in these animals, nor even in such as are entirely destitute of a tongue; for this function may be
INSECTS.

Be exercised by other parts. The organ which is commonly considered as the tongue of insects, merely serves for taking in the food. But the accurate observations of professor Knoch, (in his Contributions to the Knowledge of Insects, in German,) renders it very probable, that the posterior pair of palpi, or feelers, pothilizes the power of taste in several of this clafs.

Numerous facts have long ago proved, that several insects can distinguish the odorous properties of bodies, even at considerable distances. But the organ in which this sense refides, has not hitherto been clearly pointed out. Since all red-blooded terrestrial animals smell only through the medium of the air which they take in in inspiration, several naturalists have supposed, that the olfame organs of insects are to be considered as organs of smelling. Others ascribe this office, and with some probability, to the anterior pair of palpi.

There is no doubt that several insects possess the sense of hearing, but the organ of this sense is very doubtful. In some of the larger animals of the genus cancer, a part can be distinguished which seems to be analogous to the veibulum of the former clafses. A small bove tube is found on each side at the root of the palpi; its external opening is closed by a finer membrane, and it contains a membranous lining, on which a nerve, arising from a common branch with that of the antennae, is expanded. The latter circumstance might favour an opinion, that the antennae themselves are organs of hearing; but this is refuted by considering the exquisite sense of hearing, which some insects possess, who have no true antennae, as the spiders; and by experiments on others, which shew that the sense of hearing is not weakened by removing the antennae.

The compound eyes and the illematæ have been described in the article Entomology. The former are found in different numbers in most of the apertæ, as also in the larvæ of many winged insects. When these undergo the laft or complete metamorphosis, and receive their wings, they gain at the fame time the large compound eyes. Several genera of winged insects, and apertæ (as the larger species of monaculæ) have illematæ besides their compound eyes. Further investigation is necessary to shew how these eyes enable the insect to see; and to determine the distinctions between two such very different organs. Blumenbach considers that the illematæ are designed for seeing near objects, and the polyedrotal eyes for distant ones; because butterflies have the latter only in their winged or perfect state, while in the eftablished state of the illematæ. But knowledge, however, that this opinion is very doubtful, becaufe some insects, which live completely underground, as the mole-cricket (gryllus grallotalpa, Linn.) have both kinds of organs.

On the organs of the senses in this clafs, the reader may consult Lehmann, de sentibus externis animalium exan- gium; commentatio primo regis ornata, Goetzing, 1793, 4to. F. J. Schelver verfuch einer naturgeschichte der finnes werkzeuge bey den Insecten und Wirmern; Eaff towards the Natural History of the Organs of Sense in Insects and Vermes; Goetzing, 1798, 8vo. Lehmann de annis infe- fiorum, 1799, 8vo. Knoch’s neue byträge zu der Infectionskunde; Contributions to the Knowledge of Insects.

Organs of the Digestive Functions.—For a general account of the parts about the mouth and their nomenclature, see Entomology.

Jaws of the Crustacea.—Most of the genus cancer have at their mouth five or fix pairs of organs, which must be regarded as jaws, since they move laterally in a horizontal plane; they are placed successively one over the other, and the most exterior has been called by some anatomists the lip, but wrongly; since it is not single, and the two parts which compose it have lateral motion like the others. All these jaws are articulated under the thorax, anteriorly with respect to the feet, of which they seem to continue the series in front; and each of them has, on the inner side of its root, a membranous plate, which, flipping under the lateral border of the thorax, between the anterior branches, serves to separate their lobes, and to compress them in the act of respiration. The feet have similar laminae for the posterior branchiae, but they are deficient in those species which have the branchiae under the tail, as the quilla. (Fab.)

These jaws, with the exception perhaps of the one or two most interior parts, are formed of two divisions; one, which properly belongs to the jaw, and another, which includes dorsal palus or feeler. The latter is more elongated, and terminates in an articulated and pointed thread: the other has at its end, but in the two right pairs only, a feeler which does not end in a pointed bristle like the other. This arrangement is common to the crab, lobster, cray-fish, hermit, and, in general, to all the crustacea decapoda of Latreille. In the first the outer jaw is flattened, and joined so well to the corresponding piece and to its feeler, that the four pieces together form a kind of thrust, which covers all the other jaws. But in the lobster and cray-fish the outer jaw is prismatic and strong; and the divisions of the feeler being nearly as large as the body of the jaw, the whole together resembles a foot, and has often been described as such by the ancient naturalists.

In the crustacea decapoda, the second jaw, reckoning from the outer one, resembles the first, whatever may be its form, except that it is smaller, and that its inner edge is extemated and ciliated, instead of being denticulated. The body of the third is divided into two lobes, the fourth into four, and the fifth into two; all these are thin and ciliated. The palpi of the two latter have generally a simple point instead of a thread. The fifth is merely a small, oval, membranous plate, without cilia or palpus. Some varieties are observed in the number and figure of the jaws in the crustacea. Thus, among the decapoda, the fcyllurus (Fab.) has no thread-like processes on the dorsal piece of the two first jaws; the third is undivided, and the fourth only divided into two without a dorsal piece in either. The fifth and laft is the usual small oval plate. Among the branchiopoda there are still more remarkable differences: in the quilla (Fab.) the two first jaws are extremely slender and elongated, have the form of feet, and are terminated by a dilated rounded articulation, and a movable hook. They really perform the office of feet, and not of jaws, and have no dorsal palpi. The third is a long plate, with three notches on its inner edge. The fourth is hyd; its inner lobe is ciliated; the external is pointed, and has on its dorsal surface a small oval palpus of a single articulation. The fifth and laft is a simple plate.

Notwithstanding all these varieties, it is still true that all the crustacea have many pairs of jaws, very different from each other in their functions; and that these organs must act on the food, and prepare it for the proper mastication in a peculiar manner. In fact, over all these organs are found the true mandibles, which are very strong in all the genera. The triturating part varies in form. In the lobster and crayfish there is on the inside a blunt and truly molar surface, and on the outside a cutting edge divided into three rounded denticulations. In the hermit crab the denticulations are pointed and separate. In the crab there is a continuous cutting edge. The fcyllurus (Fab.) has two separate denticulations; a pointed one in front, and a blunt one behind. The
The structure of the mandible is the most singular in the family. It is divided into two parts; an anterior one concaved under the lip, directed according to the axis of the body, pointed, and having two rows of small denticulations; a posterior transverse one, with the cutting edge directed from below upwards, and poising a row of stronger denticulations. All these mandibles have feelers; they are composed of three articulations, and dilated at the end in the lobsters, crabs, &c.; of three articulations, and pointed in the squilla; of a single piece in the scyllarus, &c. The entomotrichaceae vary still more than the ordinary crustacea. The molucca crab (monocus polyphemus, Linn.), has five pairs of maxille, short, compressed, and covered with small spines; each poising a very large palpus like a foot, with four articulations, terminated by a pincer like that of the fore-foots of the crab and lobster. The pincers of the first pair are very large in the male. Tho'of the la't are small, and accompanied by some scaly laminae. In front of these maxille is the upper lip, of a prismatic figure, having two palpi composed of two pieces, and terminated by pincers. The lower lip is behind the last pair of maxille, and is formed of two denticulated plates. The monocus apus has two strong and toothed mandibles, then two pairs of small maxille without palpi, and hastily twenty-six other pairs of broad plates resembling maxille by their bases, and branching in the rear of their extent, and of which the first has four palpi resembling articulated bristles: three of these are very long, and have been taken by some for antennae. These twenty-six pairs of plates occupy nearly the whole under surface of the body. The smaller entomotrichaceae have been very little examined in respect to the organs of the mouth. The family of the onifer resembles the crustacea in the multiplicity of their jaws, as by their four antennae; perhaps it ought even to be entirely ascribed to them. The first pair, which has also been called the lower lip, although it is clearly divided into two halves, is plane, and covers all the others; it has a very small feeler on its external angle. Next to this come two or three thin oblong pairs, of which the second is denticulated at its end; these have no palpi. The mandible is strong, denticulated, and has a small conical feeler. These organs are exceedingly diminished in the parasitic species, as in the cymothoe (Fab.), which have only two pairs of maxille, like small scales, small, conical, obtuse mandibles without teeth, and in the middle of the whole a small conical tongue. The pycnonomon ceti (Fab.) has no visible jaws, although we can still discern two articulated palpi. The proper place of these, as well as of the other pycnonomus, cannot at present be affixed. But some parasitic insects, which have been arranged among the entomotrichaceae, do not belong to that class, and have a feeler, like fleas. Such are the numerous calygi (Cuvier) found on the gills of fishes, &c.

Mandibles of the Jaws.—The mandible is moved on the cheeks by two muscles. One strong and long approximates its loose edge to that of the opposite side, and at the same time elevates it. It is moved by two distinct flabby portions to the membrane which covers the thorax immediately above and on the sides of the stomach. One of these pieces is anterior and smaller: it is composed of short radiated fibres, terminating in a slender bony tendon, articulated to the tendon of the first portion, of which it appears to be an angular production. The largest portion is left oblique; it is situated between the liver and stomach; its fibres, more numerous and also radiated, terminate at the extremity and front edge of the common bony tendon, which is itself fixed to the middle of the loose edge of the mandible, which it tends to elevate by drawing it towards that of the opposite side.

The other muscle is inserted in a particular eminence near the middle of the opposite or fixed edge. Its fibres are short and numerous. They pass downwards and backwards, and are fixed towards the middle line of the bony case of the head. Their contraction will produce a contrary effect to that of the preceding muscle; that is to say, it will draw the edge of the mandible away from that of the opposite side.

There appear to be two other muscles in the crab, having the same functions; but they are situated at the articulated extremity of the mandible. Each articulation of the feeler contains two muscles, a flexor and an extensor; of which the former is the largest. The flexor is placed in the broadest part of the concavity of the mandible; it is inserted in a small bony tendon situated at the anterior edge of the articulation. The extensor is more slender, and attached to the fixed edge of the mandible; it is attached by a long and slender tendon to the posterior edge of the articulation of the first piece. The muscles of the other two pieces of the feeler are arranged nearly in the same manner.

The maxille are moved from within outwards, and reciprocally, by muscles analogous to those which we have just described as belonging to the mandibles; and the pieces which compose them, when they confit of several articulations, contain in their interior two muscles, an extenor and a flexor, very similar to those of the legs.

Moreover, each of the maxille, and particularly of the lower ones, has, on the piece corresponding to the lip in the legs, one, two, and sometimes three laminae directed internally to the cavity of the branchiae; these will be considered in the account of respiration.

Jaws of Insects.—I. In the Gnatapodera (Cuvier).

This order obverses no common law, like all those which are founded on negative characters only; it must be divided into families, in order to obtain some general rules. The first, that of the milppedes, affords none; for the pilli have only small mandibles, under which is a conical piece composed apparently of the lower lip and the maxille confoled together, without any feeler. The eclopendre have small mandibles, larger maxille without palpi, a pair of palpi under them, and a large lower lip, of which the articulated and pointed palpi form together a strong pincer. The second family, or the arachnida, has strong mandibles which cannot cut, but are armed at their extremity with a moveable hook, often forming a pincer, with a prominence of the body perforated for sucking. The maxille are fearfully visible, and only serve to support palpi, which are always very long, and in the form of feet, and sometimes enormous, as in the scorpions, where they resemble the claws of crabs. In the phrynes, where they furnish the animal with a formidable weapon, there is neither lower lip nor palpal palpi. We might contest the propriety of calling these organs mandibles, since they serve for sucking and not for mastication; but their position, and the analogy of other insects, forbid us to refuse them this name. Fabricius has adorned the character of his class of ungarata on the small movable hook which terminates them.

The third family, that of the riciin, or legs of birds, has only mandibles, between which is a small retractor, and appears to have neither maxille nor lips. Tho' of the lepisma and podura have not been sufficiently examined.

2dly. In the Neuroptera.—This order is not much more conffent than the preceding in the forms of the mouths of the insects belonging to it. We meet first with the beautiful family of the agnathea, insects defined to live fearlessly a few infants in the perfect state, and possessing merely what is necessary for copulation and laying. They have no occasion...
INSECTS.

affix them but little in procuring their food, but serve them merely as armour, and as instruments for working. What they might chew would arrive with difficulty at the under surface of the tongue to be swallowed; but the latter organ imbibes nutritious matter in the liquid form, or in a state of minute division, as the pollen of plants, &c. These genera with short tongues present very interesting differences in the form of the organ. It is sometimes simple and conical, as in the evani, or formed like an oval spoon, as in the firex, the mantilla, and the hornet, or dilated and grooved, as in the leucopis, or divided into three pieces, as in the tenthredo, or into three conical and villous bristles, as in the seolia, or more or less equally and deeply divided into three or four lobes, as in the vespa, and most of the genera separate from that of sphex, &c. These different configurations determine the kind of food which the animal employs, and the situations in which it procures it. The differences of the maxilla are less important; it forms in front merely a feaky piece, covering the tongue above, and having its length proportioned to that of the tongue.

The palpi vary more in their absolute and relative length, in the form and number of their articulations. The bee has exceedingly small maxillary palpi. The same may be said of the firex, but the labial palpi are here large and club-shaped. Most others have them illiform or fetcceous, and with several joints. The upper lips sometimes affume a peculiar form for a particular office. In the leaf-cutting bees, for example, it forms a feaky shield, protecting the trunk, upon which it is folded back; that it may not be injured by the edge of the leaf which the mandibles cut.

3dly. In the Hymenoptera.—This natural family, the most interesting of the insect tribe, by the numerous and varied species, with which the different species are endowed, has, in the structure of its mouth, a character of which the first appearance has but been indicated in the panpora. Part of the basis of the maxilla, and the horny portion of the lower lip (the gnache), are there united by a membrane, and are always moved together. The portion of the jaw beyond the feeder covers the tongue more or less, and serves it for a sheath, which is sometimes very complete.

The hymenoptera, which suck the nectar of flowers, may be recognized by the prolongation of their maxilla and lower lip, which are often much longer than the head, but admit of being folded up so as to be withdrawn under the production of the mandibles. This kind of organ is sometimes placed on a pedicle, which admits of being moved backwards and forwards. This may be seen in the bee and the neighbouring genera. In these elongated trunks the tongue forms the external part, the true sucking tube; but it is always only folded up so as to form a half tube, and opens longitudinally below.

In the bee, of the articulations of the labial palpi is prolonged, and forms the first sheath of the tongue; the outer portion of the jaw is prolonged in a similar way to form a second sheath; Fabricius calls this structure linguina quinquedida. In the Eugera (Fabr.) two scales of the basis of the tongue, which are clearly seen in the bee, where they are very small, are prolonged as much as the tongue, and the organ is therefore a linguina septemnifida. In other genera the labial palpi do not serve for sheaths, and the trunk is therefore trid, as in the sphex arenaria, &c. Even when the tongue is not prolonged into a trunk, it is always opened below; and this is a character peculiar to the hymenoptera, whence it results that their mandibles

6
INSECTS.

meloIonthae, Fabr.) others have them simply ciliated (the exotane), or in the form of a pencil (the lucani).

The fame variations take place in the lips and palpi, and are not merely observed between the different genera. For, although great pains have been taken to subdivide this family into numerous genera, none of these arrangements are founded on a perfectly similar conformation of the mouth. Nothing can prove more clearly the impracticability of the project, fo reluctantly perfilled in for thirty years by M. Fabricius, of establishing a method of inéology on the conformation of the mouth only.

A third natural family of the coleoptera, that of the rofirecricia, is characterized by having its mouth at the end of a long frout. Such of the others as are well determined, for example, the herbivora, the lignivora, &c. have no flirking character common to all the genera, although there is a certain resemblance.

The different configurations of the palpi, of the horny and membraneous portions of the tongue, of the maxil- ke, &c. have been carefully described by naturalists; but their labours have not hitherto furnished any general remarks which suit our present purpose.

6thly. In the Orthoptera.—This order is very uniform in the structure of the mouth; it poifefles always strong mandibles and maxilke, under which is the lower lip. A moveable upper lip covers the mandibles more or less completely. The maxilke are strongly denticulated, and have always an articulated feeder, and another not articulated, which sometimes grows so broad as to cover and protect the maxillae, whence it has been called galea; but often it is as slender as a thread. The lower lip has always two articulated palpi, between which is a more or less divided tongue. The pharynx opens upon the tongue, as in the coleoptera, not under, as in the hymenoptera; so that these insects are true naticators: the principal differences of the genera are founded on the division of the part called the tonguc, and on the equality or inequality of the portions. Thus, in the mantis there are four, pointed and equal; in the phasma the two middle ones are much the shortest. The acher, loculte, and acridia of Fabricius, have the two outer ones broad and rounded; and the intermediate one short and pointed. The blattce and the forficulae have two oblong ones; the truxilile (Fabr.) the grviol, and the pneunome, have only two rounded ones, &c.

6thly. In the Larvae of Insects.—These organs are not distributed in the larvae, as in the perfect insects: many larvae with jaws produce perfect insects, which have none, such are all those of the papilias, and several of the diptera. Different larvae have often similar jaws when the insects produced from them have very different ones; as in the whole family of the lamellicornia.

The larvae of insects which go through an incomplete metamorphosis, have the same kind of mouth as the perfect insects, with the exception of some modifications in the proportions of parts; thus the mouth of all the orthoptera is the same in the three states. The change of proportions just mentioned produces the most sensible effects in the nepoptera odonata or the libellule. Their mandibles and maxilke are the same in the larva as in the perfect state.

Their lower lip presents also the same division, but it is placed on a very long pedicle, with an angular turn or elbow in its middle, so that it remains commonly in its natural position under the maxilke, but the animal can, by straightening the curved pedicle, carry it suddenly considerably forwards; and, as the notches which terminate it will serve the purpose of pincers, they are employed for seizing the small insects which come within reach. When the libellule has its wings, it no longer needs such an artifice: its lip is shortened, and confined to the ordinary functions.

The larvae of the hymenoptera have very simple organs of mastication, consisting principally of small, short, and strong mandibles. The mouth of the larvae of the coleoptera has the same parts as that of the insects; but they are differently shaped. Thus the lucani, which in the perfect state have such enormous mandibles, and such peculiar pencil-shaped maxilke, have, while larve, a nearly orbicular upper lip, immediately articulated with the front; short, strong, thick, pointed mandibles, slightly arched externally and on the inner side; towards their loofe extremities they have three denticulations on one plane, and towards their bases a serrated and plane molar surface: it is plain that these are in their mouth instruments for cutting and chewing wood. The maxilke are terminated by two small hooks, of which one is moveable, a very singular structure, and support a feeler of four articulations. The lower lip is broad, and in a manner truncated, and has two palpi; each composed of two pieces.

The scarabaei differ remarkably from the lucani in their mouth; but the two genera agree almost entirely in the mouths of the larvae; the same observation may be made of the melolonthae and cetonie, which are also very different from each other.

This small moveable hook may be considered as a second maxillary feeler; these larvae would then have six, while their perfect insects have only four. We must observe also, that the larve, both of the lucani and of the scarabaei, have two strong teeth on the upper surface of the lower lip near the pharynx.

The priom (Fabr.) which have elongated mandibles like the lucani, have nothing of this kind in the larva state. There is a very large upper lip, lobated, rounded, villous, supported by a membraneous lamina, then two strong, curved, cutting mandibles, furnished at their bases with two conical palpi, of which the rings enter one into the other, like the tubes of a telescope, and which are probably the rudiments of antenna. A soft mass, consisting of three lobes placed behind the mandibles, reprefents, by its middle lobe, the lower lip with two very short rudiments of labial palpi, and, by each of the lateral lobes, the maxilke properly fo called with its proper palpi, composed of four conical articulations, of which the last is the smallest.

On the contrary, the dytisci, which have very slightly prominent mandibles, have them very long in the larva state. They represent two sharp hooks, perforated at the extremities, which serve for sucking. There are no visible maxilke, but merely two long filiform palpi of five pieces; while the perfect insect has four maxillary palpi. This is exactly the reverse of what we have just seen in the lamellicornia.

Instead of the lower lip there are two tubercles, each of which supports a feeler of two pieces. The larva of the hydrophius also wants the maxilke, but has four palpi; the mandibles are short, cutting, and not perforated.

Of all larvae, those of the lepidoptera differ the most widely from the perfect insects in respect to the mouth; and, what is very singular, their mouth is constructed on the plan of that in insects with jaws, although it poifefles no trace of these parts in the butterflies. Under a semi-orbicular upper lip, and under two strong, cutting, denticulated maxilke, are three tubercles representing the lower lip and the maxilke; the latter seem composed of pieces, which enter more or less one into the other, and terminate by two small tubercules, of which the internal, armed with two
Afif bristles or teeth, is the maxilla properly so called; the other is the feeler. The lower lip has two very small palp, and a hollow point in the middle: this is the spinning hole, through which the silk comes out, employed by the caterpillar for forming its cocoon.

The Muscles.—When the upper lip is movable, it is drawn backwards by two bundles of feeby fibres situated within the cranium, and which are themselves divided into two planes. The motions of the mandibles are analogous to those of the hives in insects. At the base, on the side corresponding to their convexity, there is a kind of condyle, or convex rounded eminence, received into a small cotylid cavity, excavated in the temporal scale in front of, or below, the eye. On the side corresponding to the cutting edge of the mandible, there is commonly observed, at least in large insects, such as the scarabaeus monoceros, the priamos, the capricorne (cerambyx), the lucanus cursor, the locusta, a kind of solid tendinous plate, which is apparently prolonged into the interior of the solid parietes, and affords attachment to muscular fibres implanted in it laterally, as the barbs of a feather are on the common shaft. Thse muscles approximate the jaws to each other, or shut the mouth. Those which separate the mandibles and open the mouth are much shorter, and not one-tenth of the size of the preceding. They are invested in a small apophysis, corresponding to the convex external line of the mandible, on the outside of the condyle. Lyonet has described and figured these muscles in the larva of the phalaena cooix. He calls them adductors and abductors; but he has regarded as so many distinct organs, the fasciculi of fibres inserted into the common tendon; so that he has distinguished nearly eleven muscles or bundles defined to close the mouth, and three principal planes for the purpose of opening it. Thse fibrous planes are found in all other insects; but very great varieties are observed in their number and relative disposition. Thse differences depend evidently in the first place on the very different insertions of the tendinous plates, which are to be considered as prolongations of the muscles; they seem also to be modified by the length and size of these plates. The latter always have a relation to the form and extent which the inner parietes of the mandible and of the cranium afford for their infection.

Salivary Organs.—No express organ, for the purpose of supplying a salivary secretion, has been hitherto discovered in the crista cea; but the place of salivary fluids is supplied in the following manner. The branchiæ, placed at the fides of the body, under the edges of the corfelet, are comminced and agitated by the cartilagineous plates connected to the jaws and feet; at this time, the water in contact with the branchiæ flows along these plates, and comes out at the two sides of the mouth; hence, when a crab or lobster is taken out of the water, much froth is observed to ilue from that part. This water, although foreign to the body, may serve to moisten the food, when the animal eats out of water. At other times no saliva can be needed, as in the cetaeæ and fishes.

Many insects furnish, during mastication, more or less fluid, which is often acrid, and of a penetrating odour, and supplies the place of saliva. In the carabæ it is black and foetid, very corrosive in some gryllæ; and capable, in the larva of the coxæs, of softening and dissolving the wood of the willow, on which the animal feeds.

The sources of these fluids are not yet known in all species; probably, however, they are produced by organs analogous to each other, and those of one species may serve as an example of the rest. The larva of the coxæ has two long spongy vessels, like all the secretory organs of insects, very much convoluted, and opening into a large reservoir, which communicates with the mouth by a small canal. This organ seems to produce a liquor, necessary to the animal for the purpose of acting on the wood by which it is nourished. It is deficient, or very small in moft other caterpillars.

Organs of Deglutition.—I. In insects with jaws. The membranous extremity of the lower lip, in the coleoptera, and the orthoptera, which has been called a tongue, scarcely deserves that name. But in the second of these families there is a real feeby tongue, loose only at its point, and analogous in figure to that of quadrupeds. The odonata, among the neuroptera, have a structure somewhat similar; but the tongue of the hymenoptera is only a membranous tube, often open below, and forming the extremity of the lower lip. In the waifs, and in all the hymenoptera, which have no trunk, it has an arched form, being open and concave below, and more or less divided into pieces. The bees, and all the hymenoptera which have a long trunk, possess a complete tube with annular fibres; suction is performed by the successive contraction of these fibres.

2dly. In insects without jaws. Since deglutition is the first act of nutrition in these insects, the form of the organ employed in suction determines the species of juice which the animal can imbibe, and consequently influences very considerably its way of life. The relations of the natural families of these animals to their organs of suction, are much more constant than they are to the instruments of mastication in the other half of the class. There are four orders of insects without jaws, viz., hemiptera, lepidoptera, diptera, apsera; and there are three kinds of suction particularly belonging to the three first of these. The hemiptera have a stiff proboscis enveloped in a sheath; the lepidoptera a membranous trunk spirally convoluted; the diptera a trunk terminated by two feeby lips. Hence the names of rhynota, glosata, and antillata applied by Fabricius to these three orders; which he has preferred the same as in the Linnæan arrangement, and which many others had adopted before.

The greatest varieties are observed in the diptera. In this order the organs consists essentially of a fleety trunk, divided below into two lips more or less prolonged, and capable of being applied to the object which is to be sucked: two tentacula are detached to the root of this trunk. Between the latter is a pointed scale, sometimes employed to cut the vesicles from which the fluid is to be sucked, but often serving only to cover other pieces, which are much sharper and more appropriate to this function. In the fratyomyias, and the common flies, there is merely a single short point under the scale. The syphii and rhingii have in addition a stiff bristle under each palpus. In the rhagio there are three bristles under the scale, and the middle of them is the strongest. The tabani have four, all pointed and sharp like the blades of lancets; hence these insects have the power of inflicting the severest wounds on the skin. All the parts are much elongated in the genera empsi and bombylius; the trunk is more particularly extended than the bristles in the latter, which indeed have only one bristle under the scale. In the empsi all the parts are equally prolonged, and there are four bristles.

In the myopa (conops, Linn.) the trunk is elongated into a slender tube with an angle at its middle; there is a short scale without any bristle. In the asilis and flomoxys (conops, Linn.) the trunk is hardened, and assumes a horny texture, so that it is capable of cutting. There is a single bristle within it in the flomoxys, and three in the asilis. The trunk is reduced almost to nothing in the hippoboeas; and the single bristle is long and flexible.
All these genera have palpi of a single piece. The tipule and culicæ have them articulated, and often very long; the trunk of the tipule is short, with large lips, and no bristle; that of the culicæ is long, slender, and contains a fine bristle.

In the cephalic part of the head, so as to expose externally only three rather prominent points.

The hemiptera (Glyptota, Fabr.) are more uniform in the structure of these parts than the diptera; in general they have a tube composed of some articulated pieces, and open above in its whole length. This tube contains five fine bristles nearly as long as itself; it exhibits scarcely any other varieties except in its position and inflexions.

The lepidoptera (glossata, Fabr.) are equally uniform in the structure of these parts: their tongue is formed of two membranous plates, curved transversely in their whole length, so as to form a tube, and, when the insect does not employ it, convoluted spirally, and lodged between two flat villous palpi, composed commonly of three pieces. The differences depend on the variable length of this organ, which is sometimes very inconsiderably, and on the figure of the palpi: they are not of importance in connection with our present subject.

Among the aptera, the louse has only a simple and short fopner, inclosed in a small prominence: the flea has one with two bristles, inclosed in a sheath of three pieces, opened longitudinally above.

Intestinal Canal.—It is straight in the crustaceæ, and uniform in its size, with the exception of the thorax. The latter is very different in the crustaceæ decapoda, and in the branchiopoda, it possesses, in the former, a singularity of structure, which is remarkable as the only example of the kind in the whole animal kingdom; that is, it is supported by a bony apparatus, a species of skeleton, and consequently does not collapse when empty. The definition of this apparatus is not left extraordinary than its existence; it serves to support five hard and moveable teeth, which perform in the cavity of the thorax a true mastication. They are placed before the pylorus, and allow no substances to pass through that opening until they are perfectly triturated.

The thorax is found in the thorax above the mouth, and the esophagus communicates with it by a large aperture. The anterior portion is more spacious than the posterior, and the teeth are placed where the cavity begins to grow narrower. On the superior surface, or that which is opposed to the mouth, there is a thin transverse plate occupying the middle of the thorax. This supports the first tooth or foon oblong plate, conjoined to the superior surface of the thorax, directed towards the pylorus, and terminating behind in a tubercle.

On this posterior extremity is articulated a second plate, directed backwards, bifurcated like the letter Y; and on each of its lateral divisions another is articulated, which turns forwards and outwards, and reaches the lateral extremity of the first transverse plate. The two arcte teeth are fixed on these two lateral pieces. They are oblong, have flat crowns, which are grooved transversely, and the grooves and inequalities vary in the different species. In the cancer of the lower part of the crown is finely fluted, has large tubercules at its lower edge, and a prominent part in front which is not fritated. In the lobster there are nine transverse ribs, of which the three front are much the larger.

Point of union of the transverse portion with the lateral of each side, another lateral piece is continued, proceeding lower than the first, and having at its extremity a lateral tooth smaller than the preceding, placed rather before and below its anterior extremity, and having three and sometimes even five small, sharp, and bent points. The two small teeth with curved points limit the nourishment which comes from the mouth; they convey it to the two teeth with flat crowns, which bristle it between each other and against the first single plate.

When it has undergone this operation, the aliment passes through the narrow part of the stomach, where its course is filled interrupted, first by a fleshy oval prominence corresponding to the interval of the two large lateral teeth, and afterwards by a sharp crest, which divides the pylorus into two half canals.

There are muscular fibres in this stomach, which approximate the bony pieces, and the teeth which they support: there are exterior muscles which separate the teeth from each other, and are attached to the neighbouring, and particularly the lower parts of the thorax. These muscles must be subject to the will, which is another remarkable singularity belonging to these stomachs.

These teeth are discharged from the stomach when the old shell is shed; and are supplied by new ones.

After this large stomach, which is always dilated, comes a very flender intestine, which takes a straight course to its termination at the end of the tail. Towards its middle a thick ring is observed, on the inside of which there is a strong valve, and the commencement of a very long caecum.

These circumstances have been ascertained in all classes which have long tails, as the cray-fish and the lobster, also in the parasitical species (the hermit crab), and in the crabs, as the cancer, the eater, and the masse: the stomach may therefore be considered as common to all the echinacea decapoda. The branchiopoda possess a small membranous stomach, shaped like a triangular prism, furnished on each side of its posterior extremity with a row of small pointed teeth, and followed by a very thin intestinal canal, continued from one end of the body to the other, and nearly uniform in size throughout.

In this case the front of the canal is a little swollen compared to the continuation.

In the rest of the classes of insects we find as many varieties in the structure of the alimentary canal, as in all the classes of vertebræ. There are not only differences between the classes and species, but very considerable ones between the larva and perfect states of the same insect; and all these varieties bear a very accurate relation, which in many cases can be very clearly appreciated to the animal's kind of life, whether of shorter or longer duration. Thus the various larvae of the scarabæi and butterflies have intestines ten times as large as the winged and other insects, if we may be allowed to use that term, to which they give birth.

There are the same general relations in the natural families of insects, as in the rest of the animal kingdom; thus all the coleoptra lamellicornia, all the carnivora have similar intestines in each of their flutes, &c. Here, as in the other classes, the length and complication of the intestinal canal indicate a vegetable nourishment; shortness and thickefs, on the contrary, show that the animal is carnivorous, &c.

1. In the Coleoptra.—We shall select for description some very natural families, which are remarkable for any peculiarities of their own, and shall notice together the intestinal canal of the larva and of the perfected insect, in order to exhibit in the clearest view the very striking difference between these two states.

1. In the coleoptra lamellicornia. The last mentioned point
point is very clearly exemplified this family. The larve of the cerambicæ have large and short alimentary canal, divided into the following parts. 1. A short and weak oesophagus. 2. A straight cylindrical stomach, surrounded by three circles of small ceca, placed, one at the commencement, one at the middle, and the third at the end of the cylinder. The ceca are numerous, weak, and thin: the last circle of the third circle is ramified in the larve of the scarabæi, properly so called (by Geoffroy of Latreille). In the melolonthæ the ceca of the first circle have small lateral denticulations, which may be regarded as so many smaller ceca. The upper and lower circle in the hind parts are composed of a small number of large ceca, while the middle is made up of very numerous smaller ones. Probably they all secrete and pour into the stomach some digesting fluid. 3. A short intestine of much thinner sides, and rather shorter in length than the stomach. Its origin, which is rather expanded, receives above the hepatic vessels; it terminates at the posterior extremity of the body of the larve. 4. An enormous colon, or large intestine, three times as large as the stomach, and filling all the posterior third of the body. It possesses two smooth bands, between which are transverse folds, producing a cellular appearance like that of the human colon. Its course is in a direction contrary to that of the small intestine; that is, it returns from behind forwards, and lies upon that intestine. 5. A rectum running from before backwards upon the colon, in order to terminate at the anus. It is slender and straight, without any inequality.

We should have expected that the perfect insect would retain some trace of such strongly marked peculiarity: yet there is really no vestige of them discernible. All these insects, locustæ, scarabæi, melolonthæ, cetonies, have a long slender canal, four or five times longer than the body, very much convoluted, and possessed hardly any dilatation. Sometimes the anterior portion is merely a little larger and folded transversely.

2. In the coleoptera carnivora. As the habits of these animals are very different from those of the preceding, their alimentary canal is different in both sexes. In the perfect state it consists of, on the right side, a long and very dilate oesophagus. 2. A firm stomach, nearly spherical in its shape, with muscular paries and transverse wrinkles. 3. A second stomach, membranous, elongated, and villous; not on the intide, as these of certain vertebral animals are, but on the outside. The villi are vesicles which draw from the surrounding mucous fluid, the gallic juice which pour into the stomach, according to the laws of secretion in insects; considered as animals which have no circulatory organs. 4. An intestine of moderate length, between once and twice the length of the body, small and uniform in its diameter throughout. 5. A conical and rather long cecum, filled with the amnun of the anus. The margin of the anus is furnished with two scales, which secrete the acid fluid almost constantly voided by these animals when they are feasted.

Such is the structure of the gener species separated from the carabæi, the cetonies, and the dytiscæ; their larvae have no dilatation like a stomach; their canal is small, all of one size from the mouth to the anus, and about one-half longer than the body. A cecum, however, may be observed near the anus in the larve of the dytiscæ.

3. In the coleoptera chinchonæ. The hydrophilus pieces, in its perfect state, has very long cylindrical intestines (four or five times longer than the body), uniform in size throughout, and forming large convolutions in the abdomen. The larve, which is much more carnivorous, has short intestines (half as long again as the body), of which nearly two-thirds form an elongated stomach, villous externally; the rest is smooth, and divided by a contraction into two parts. The pharynx, on the contrary, have in their perfect state such a stomach, followed by a small intestine twice as long as the body.

4. In the coleoptera lignivora. The larve of the prionæ and cerambycæ have very large intestines, with their sides nearly uniform throughout, and forming four folds, each of which is as long as the body. The commencement, which alone can be compared to a stomach, is rather corrugated transversely as a colon. The perfect insect has first a membranous and round stomach, then an oval one, which is inflexibly contracted into a cylindrical canal, suddenly growing foatter at the termination of the hepatic vessels, and continuing to the anus. The whole canal is at most twice as long as the body.

The larve of the lamia, Fab, has first a very distinct stomach, then a knotted small intestine, which is suddenly changed into a large intestine longer than itself.

5. In the coleoptera silvicornæ, of the family of the vesicatoriæ, the meles poises an enormous oval stomach, filling nearly all the abdomen. The front is covered with strong circular fibres; and a cylindrical valve, analogous to the valvula coli, man, is observed at the cordis.

In the family of the locustæ, the tenebrionæ has a cylindrical elongated stomach, a first intestine, which is rather slender, and another somewhat larger. The whole canal is about three times the length of the body. The tubes have a muscular cylindrical stomach, another equally large but membranous, separated from the former by a slight contraction, and a small intestine which is a little enlarged towards the anus. The proportionate length of the whole is about the same as in the last instance.

6. The brachelytra, or thryphuliæ, resemble the carnivora in the villosity of the stomach, as they do in their habits.

11. In the Orthoptera.—These, in the class of insects, seem analogous to the ruminants among the quadrupeds, at least in respect to the complication of the stomach, and some suppose that their aliment may be seen brought back into the mouth for the purpose of a second mastication. As they undergo an imperfect metamorphosis, their alimentary canal is the same in the larve as in the perfect state. It consists in general of the following parts. 1. An oesophagus of the usual kind. 2. A firm membranous stomach. In most genera this is a simple dilatation of the oesophagus, which is the internal membrane is smooth and folded longitudinally. In the locustæ it is rather, and in the blatta considerably larger than in the other genera. In the acheta it is a oval bag, having quite a lateral position, connected to the side of the oesophagus like a cecum, with one opening for the reception and discharge of its contents. 3. A second stomach or gizzard, firm, nearly round, possessed a very thick muscular coat, and armed internally with scales or teeth. In the locustæ and acheta there are longitudinal rows of fine and numerous scales, placed one over the other like the tiles of a roof, and directed backwards. In the blatta there is a single row of six or eight large curved teeth, dentilicated like the bills of birds of prey, and directed backwards. 4. The ceca or third stomaches are immediately round the posterior orifice of the gizzard, and vary in number. The locustæ and blatta have two large ones, and this has given rise to the remark that the grilli have four stomaches like the ruminating mammalia. The internal membrane is much folded, and its extremity receives many small secretory vessels, which pour out gallic juice. There are five or six ceca in the grilli, and eight or ten in the blatta. 5. The intestinal canal varying in length and diameter.
The earwig is said to be very different from the other orthoptera in having only a simple elongated stomach, a very short intestine, and a dilatation with longitudinal folds near the anus.

III. In the Hymenoptera.—The bees have a first stomach, which is membranous and transparent, pointed in front, large and divided into two portions behind. In this organ the nectar of the flowers is converted into honey; it is the reservoir of this matter, which they deposit in their hives by the act of vomiting. The second stomach proceeds from the interval of the two divisions; it is elongated and swollen laterally towards the middle. The hepatic vessels are inflected immediately after the pylorus. The first intestine is small, and scarcely equal in length to the second stomach; the rectum is large but still shorter.

The first stomach of the wasp is smaller; the second longer, and particularly much more muscular. The larve of both genera have an immense cylindrical muscular stomach, filling nearly the whole abdomen, and followed by a very short intestine.

In the sphex the structure resembles that of the bee; the parts are only larger in proportion to their length.

IV. In the Neuroptera.—The family of the odonate, which is truly carnivorous, has very short intestines in its three states; they do not exceed the length of the body. In the libellula grandis, Lin., a short oesophagus is succeeded by a small oval muscular stomach, dilated longitudinally; then comes a straight large intestine or second stomach, with a constricting place far back at the entrance of the hepatic vessels. The interval between this part and the anus is very short, and folded longitudinally. In its larva, the oesophagus has a circular dilatation; the constricting of the cordis produces a kind of valve. From this point the canal has a bright yellow colour, as far as the secretion of the hepatic vessels; its last portion is white and much thicker; and contains the singular respiratory apparatus, which we shall describe afterwards.

In the family of the anagnatha, the ephemera, during its larval state, has merely a straight uniform canal, without any convolution, which becomes extremely thin in the perfect insect.

V. In the Hemiptera.—These poiffs in general a simple, oval, and muscular stomach, of considerable size, followed by a small intestine of moderate length, near the end of which is a small caecum. Such at least is the case in the nepa, notocerus, &c.  

VI. In the Lepidoptera.—The caterpillars have a large, short, straight, intestinal canal, without any considerable inequalities. The oesophagus is the slenderest portion, the stomach is elongated and contracted at the pylorus. After the pylorus the intestine is larger than in the rest of its length; it is contracted towards the anus. At the latter part it has the strongest circular fibres; on its parietes other fibres are found, variously decussated and ending in two white lines, which extend over its whole length, one above, and the other below. The diameter varies in different situations, according as the contents are accumulated. Sometimes the division between the stomach and intestine can scarcely be observed.

This canal is obviously calculated for solid and abundant food. The butterfly, which fulfills entirely on the juices of vegetables, has a very different digestive apparatus. Among the diurnal insects of this order, the atlanta has a slender oesophagus, with a membranous dilatation on its side, like a carp, more or less rounded in its figure, and often full of air. Then comes a second elliptical membranous stomach, the sides of which present many hemispherical cellular pro-

minences; and afterwards a third, cylindrical, and rather muscular, followed by a small intestine of moderate length, terminated by a rather larger rectum.

VII. In the Diptera.—In general their intestinal canal is tolerably long in both sexes. It is five times the length of the body in the larva of the stratiomy, and consists of a short oesophagus as slender as a thread, a very small oval stomach, and an intestine, of which the first half is wrinkled transversely, which becomes afterwards larger and smoother to the intestine of the hepatic canals, below which it is suddenly constricted and remains narrow. The differences between this and the larva of the flyrus are very slight; and the distinctions between both and their perfect insects are not more obvious. However, Swammerdam represents four small caeca, after the stomach, in the larva of a fly which inhabits cheese; Cuvier has not found them in the diptera deflected by himself.

VIII. In the Gnatopera.—The scolopendra have a long canal contracted behind; the juli have an equally long and cylindrical one. We have already mentioned that of the oniscus.

IX. In the Apera without Jaw.—The loose has two small swellings at the origin of the stomach, which is elongated; the intestine is not longer than the stomach; it is small, and terminated in front of the anus by a muscular enlargement.

Hepatic Vessels.—Although the cruralca have a heart and blood-vessels, most of them have not a liver, properly so called. The organ which produces bile in them consists of a considerable number of small tubes ending in cul-de-sacs.

The structure is analogous to that of the pancreas of fishes, which consists, as we suppose, of the multitude of caeca opening at the origin of the intestine.

The appearance of the hepatic caeca in the cruralca disclosing their nature and office; they are yellow, have spongy stiles, produce a brown and bitter liquor, which gives its peculiar taint to the substanee in the body of the lobster; for the hepatic caeca, with the stomach, fill nearly the whole thorax of these animals; and, in the hermit crab, they fill also a great part of the tail.

The liquida, Fab. is an exception to this rule; these animals have a liver of a firm texture, very much resembling a conglomerate gland, consisting of lobes arranged on each side of the alimentary canal in its whole length.

In the insects, properly so called, there is still less appearance of liver than in the common cruralca. Since they can have no glads on account of the absence of blood-vessels, the bile, like all the other secretions, is produced in them by fine vessels with spongy stiles, floating in the fluid, which bathes all the parts, and deriving from it, by the organization of their tissue, the elements proper for the formation of this liquor.

These vessels exit equally in the larva and in the perfect insect: the fluid, which they form and contain, tinges them with its own colour. They are usually yellow, sometimes, as in the scorbazi and cerambyces, of an opaque white; and in other instances, as in the dytics, of a deep brown. Their bitter taint arises from this fluid, which would probably be found to poiss many of the qualities of bile, if it could be procured in sufficient quantity for analysis.

The number of these vessels is variable; when it is large, they are short, so that the extent of surface is nearly the same. Sometimes they all end in a common extraneous tube, which terminates in the intestine. This is the case with the gryll-talpa. They are commonly inflected after the stomach, but sometimes not till near the middle of the intestinal canal, as in the gryllis; or even towards its end, as in the libellula. The onicci alone have them inflected near the oesophagus; in these
these insects they are only four in number, large, undulated, as long as the body, and of an orange colour.

Among the neuroptera, the libelulae have a considerable number of short ones, surrounding the intestine at a small distance from the anus, where it becomes large. The same structure exists in the common griffins. In the grillo-talpa there is a large packet of these vessels, terminating by a common canal in the middle of the large intestine. The larvae and the perfect insects have the same structure in the ye species. This resemblance means moreover to exist, with respect to the hepatic organs, in even orders where the metamorphosis is the most complete in all other parts; the number at least is not changed. It is considerable in the hymenoptera, but generally amounts only to two in the coleoptera. In the latter they are generally found parallel to the intestinal canal, and make numerous windings. Their infection is immediately after the flomach in the larve of the Scarabae the dytici, the carabí, &c.

The caterpillars and the perfect insects produced from these have two, each of which is subdivided into three, placed in the former, at the sides of the posterior half of the canal, and forming their principal folds completely in the back of the body. Among the hemiptera, they have seem to have only two. The larve of the frattomyis and lyrrhyis, of the order diptera, have four, which end in the intestine by a common trunk.

Covering and Supports of the Alimentary Canal.—We have mentioned already that the flomach of the crustacea is supported in its situation by its muscles; the remainder of the canal is maintained only by vessels, and by the compession of the surrounding parts.

In the proper insects, the intestinal canal is retained in its place by the trachee only; there is neither mesentery vessel nor cellular subsistence; consequently when an insect is opened and placed in water, all the folds of its canal rise, and are developed from the specific tightness derived from the air in the trachee.

The fine membrane lining the abdomen, and enveloped by the rings of the skin and their muscles, may be called peritoneum.

But the most remarkable circumstance belonging to insects in their larve state, and existing in them exclusively, among all invertebrate animals, is the portions of cellular texture filled with fat, which may be compared to oments, and may have the same functions. They seem particularly designed to supply the materials of nutrition to the animal, during all that time, in which, as a chrysalis, it eats nothing, as the fat of the omenta supports life in those quadrupeds, which pass the winter in a leathery sleep. When the animal changes its coverings and its form, and becomes a perfect insect, these fatty organs probably furnish the prodigious quantity of materials, which the sudden development of so many parts must require; consequently they are not found in the latter state.

The forms, colour, and confidence of thece muscles very in the caterpillars they are oblong, flatter, full of a white fat like cream. In the larve of the scfnsbali they are large semi-transparent membranes, with many opaque and white grains; in those of the flies and frttomyis they have a flapped appearance, like narrow ribbands irregularly joined. They are inconsiderable, and do not exist at all, in the larve of insects, which undergo an incomplete metamorphosis, which eat during their whole existence, and never pass into the chrysalis state. In all the orders they receive numerous air-pores.

Absorption in Insects.—The nutritive fluid prepared in the alimentary canal is taken up by a particular order of vessels, called aborbsents, in the four flrst classes of the animal kingdom; these convey it into the blood-vessels, in which it passes to all the organs of the body. The application of the new matter furnished by digestion to the parts of the fylem is performed in some other way in insects, as they seem to have neither absorbing nor blood-vessels (excepting the crucifaceous insects).

Cuvier is of opinion that the nutritive process is performed in this class by imbibition. We arrive, says he, at this conclusion by proofs of different kinds; some are direct, but negative; others supply only inductions: their union will probably suffice to produce conviction. In the first place, he continues, no vessels are found in digesting insects; I have found for them with the greatest attention, and by the aid of the microscope, in those organs, which in other classes contain them in the greatest abundance, as the choroid coat of the eye, and the membranes of the intestinal canal; I have never found any thing like them, although the trachee and the nerves are very easily discovered, and the innumerable ramifications of the former may be traced with the naked eye. Lyonet, who has described and represented in the larve of the coccus parts a thousand times smaller than the principal blood-vessels would be, could never discover any thing of that kind.

There is indeed in insects an organ, to which many anatomists have given the name of heart; it is a membranous tube, continued through the whole length of the back, both in the larva and in the perfect state, exhibiting alternate contractions and dilatations, which seem to pass successively from one extremity to the other; but, notwithstanding this circumstance, which seems to indicate an organ of circulation, this tube produces no branches, and we can neither attribute to it the functions of a heart, nor discover any other purpose to which it is subservient. Lastly, those naturalists who have observed with the microscope the transparent parts of insects, have discerned only a fluid at rest, bathing them on all sides.

Such are the negative arguments on this subject; those drawn from induction refer principally to two points; viz. the mode of respiration in insects, and the form of the secretory organs.

In animals which have a circulation, it is continually collected in a central reservoir, whence it is forcibly expelled to all parts; it always arrives at the organs from the heart, and it is always sent to the heart before it comes back again. It may then be modified from its source by the action of the air; and, in fact, before it is brought by the aorta and its ramifications to the parts which are to be nourished by it, it circulates through the lungs or gills. If this arrangement is not found in insects, the reason probably is that their nutritive fluid is not contained in vessels, but this does not come from a common source, and consequently that it could not undergo any modification in a separate organ before arriving at the parts. It continually and quietly bathes all the parts, which are to draw from it substances suited to their wants; the action of the air should therefore reach it everywhere, and this point is very completely secured by the diffusion of the trachee, as there is no point of the body to which the ramifications of these vessels do not penetrate, and where the air does not immediately exercise its chemical action; in a word, as the blood cannot go in search of the air, the air is everywhere where brought in contact with the blood.

The secretions of insects are never performed by compound glands; their organs are simple, in all cases, as we have just seen in the example of the liver, of lung and hinder tubes, floating in the cavity of the body, without being connected.
nested together, or fixed in any way except by the tracheæ. This appears clearly to be a necessary consequence, and therefore a very probable indication of the absence of blood-vessels. When the powerful agents of circulation exit, they convey with facility the nutritive fluid to the most remote points of the organs; the intertexture of the blood-vessels forms a thick and close tissue, in which the peculiar vessels of the gland are placed. When, on the contrary, there is neither heart nor blood-vessels, nor any force to impel the fluid towards the digestive organs, the latter require a more powerful attractive force; and as this can be exerted only by means of the tissue compelling their sides, it becomes necessary that they should be unattached, loose, long, and slender, in order to augment their surface.

Organ of Circulation in the Gryllacea.—The heart of the crulacea decapoda is very differently formed from that of the branchiopoda. In the former it is oval, circumferenced, and placed nearly in the middle of the thorax; in the others it is elongated, and extends from one end of the body to the other, so as to form apparently a connecting link between the heart of the decapoda and the dorsal vessel of the other insects. In this point of view it has led some naturalists into error; we shall, however, find a structure which is more analogous to it in the red-blooded worms.

The decapoda (the crabs, lobster, cray-fish, hermit crab, &c.) have an aortic heart, like that of the mollusca. It receives the blood from the branchiæ by a large vessel, which lies longitudinally in the chest, to which this blood is conveyed by blood-vessels. Cuvier states that this is the case in the hermit crab; but he thinks that in the lobster the branchial vessels form two trunks, which go directly to the two sides of the heart. When one of the veins of the branchiæ is injected, the fluid arrives at the heart by the route just indicated. From the same posterior part of the heart arises an arterial vessel, which goes directly backwards, and supplies the organs of generation and the muscles of the tail. The anterior portion produces other arteries, varying in number according to the species.

Each pedicle of the branchiæ contains two principal vessels; an artery and a vein. The venous trunks all go to the heart; and, as we have already stated, by a single trunk in the decapoda; but, in the branchiopoda, where the heart is elongated, they all terminate in it directly, so that a pair of veins enters at each ring of the body. The branchial arteries do not come from the heart. When the latter organ is injected, the fluid does not enter the branchiæ, although it will pass easily from the latter to the heart. In the fiala falcata, Fabr., Cuvier observed a large longitudinal vein, extending from one end of the body to the other, under the integument, and consequently on the opposite surface to that occupied by the heart. Its tissit is much thinner than that of the heart, and transparent, and it produces as many pairs of branchial vessels as the heart receives from those organs. This anatomist has very little doubt that the same vessel will be found in the decapoda, but he had not examined them for this purpose since he first saw it in the other division.

The circulation of the crulacea is then the same with that of the gastropoda mollusca; viz. a double circulation, of which the aortic system only supplies a ventricle; and each the ventricle does not receive the name in the branchiopoda, it so much resembles in them a vessel by its elongated form. Under this point of view the circulating system of the animals resembles that of red-blooded worms.

The heart of the crulacea, even in the decapoda, has no aorta, and vessels have not hitherto been observed in it.

It is hardly necessary to state, that the blood blown by

the heart into the arteries, passes through the veins into the vena cava.

The motions of the heart may be seen in the small mollusca of this country, but their extreme smallness prevents us from following the distribution of the vessels. The anatomy of the mollusca crab is not yet known.

Circulation of Insects.—All insects have in their back a longitudinal vessel, filled with a transparent fluid, and for a long time regarded as the heart, after the statement of Malpighi, who described it in the pill-worm, and represents it as a knotted canal, that is divided at intervals by constrictions. He conceived that each dilatation was a particular heart, and that these different organs transmitted the blood to each other: but he remarked at the same time that the succession of the pulsations was not regular, and that the fluid sometimes took a retrograde course. Lyonet has given a better account of this dorsal vessel. It is an uniform canal, proceeding from the head to the opposite extremity, and enlarging a little in its course, but closed at the two ends. It poises on each side a certain number of transverse muscular fæceculi, somewhat in the form of wings, which are fixed by their opposite ends to the general covering. Its dilatations and contractions are produced by these, which are exterior muscles, and not by its own tissit. Lyonet assures us, that he has not been able to discover any vessel produced from this and proceeding into the body, although he has described tracheæ and nerves a thousand times smaller than these vessels must be if they exist. Cuvier has tried all known methods of injection, without any greater success. Swammerdam indeed mentions that he injected small vessels from it in the gryllæ; but we cannot help entertaining doubts on this subject, until the experiment shall have been repeated with success.

The dorsal vessel of insects cannot then in any manner perform the functions, nor deserve the name of a heart. Perhaps, like all other parts of this kind in insects, it is a sècretoir vessel: but we are at present quite unable to determine what liquor it secretes, and for what use. Its contents are transparent, light yellow, viscous, mifcible with water, easily dried, and then becoming hard and cracking like gum. Besides the analogy of its contractions, its situation might favour the idea of its being a heart. The latter organ is placed near the back in almost all the mollusca, and in all the crulacea; and this is the position of an organ, which can hardly be regarded in any other light than as a heart, in the arachnides insects (araneæ, phalangia, and scorpions). In the present state of knowledge, the organs of circulation might be regarded as the same, and tend to show that, in insects, the idea of a heart in the anterior end of the body, may be observed very easily in the spiders; and may be seen beating through the integuments of the abdomen in the species which have smooth bodies. On removing the integuments we expose a hollow oblong organ, pointed at its two ends, and advancing as far as the thorax by its front end: two or three pairs of vessels very manifestly pafs off from its sides. If we add to this account, the fact, that the spiders have no tracheæ, but that theirpiration is circumferenced within a small number of vessels, and that they appear to have glands, we shall be induced to believe that their circulation is more complete, and more analogous to our's than that of other insects.

Respiratory Organs.—The class of insects exhibits two different arrangements of the organs belonging to this function: the crulacea have gills, resembling those of fishes and many mollusca; other insects have air-vessels distributed to all parts of their bodies. The branchiæ of the former extract air from the water in which they live, in the same way as the gills of fishes act. The respiration of insects produces in the air the same effects as that of the warm-blooded animals. Experiments show us that oxygen is con-
furred in this case, and that the residue of the air is rendered impure by the admixture of carbonic acid gas.

An important result of respiration seems to be the maintaining the irritability of the moving powers: hence the definitive result of this process, with respect to the fibre, is power in executing the motions which it has to perform. Thus the energy of the motive force will be in proportion to the quantity of respiration. The organization of insects corresponds to this theory: they are the only classes among the lower ranks of animated existence, which possess the faculty of flying, and we consequntly find the trachea carrying air over the whole body, so that respiration is carried on at all points. In these insects which do not fly, the force of the muscles may be attained by the rapidity of their other motions. The running of the millepede and the jumping of the flea, shew that they belong to a very irritable class of animals; the bee is analogous to that of the ostrich and cassowary, which run with great celerity, although they are birds without wings.

Respiration of the Crustacea.—Their branchiae are larger in proportion than those of most of the mollusca. In the decapoda they are attached to the base of the feet, under the lateral and descending edge of the thorax, which confines them within a narrow space. The branchiopoda have no gills in this situation, but under the tail, between the fans, and floating loosely in the water.

In the crabs the structure is in some respects peculiar. Each gill represents a triangular elongated pyramid, attached by its basal side only, and having the point directed upwards. The middle of the pyramid is divided by a plane, proceeding from the apex to the basis, and composed of a double membrane; and the body of the pyramid is formed by a large number of plates placed one over the other, perpendicular to the vertical plane just mentioned, and confining merely of doublings of the double membrane. A large vessel runs along each of the two longitudinal edges of this plane, and penetrates at its basis into the thorax of the animal; one of these is arterial, and the other venous. If we inflate them, immediately all the small laminae which compose the pyramids are distended with air. In the same way the blood is expanded over all the surfaces, and is thus favourably disposed for the action of the water.

There are seven of these pyramids on each side. As the edge of the thorax, which embraces and confines them, is inelastic, a particular mechanism becomes necessary for renewing the water which washes the surface of the organs. This effect is secured by two plates of a substance resembling parchment, articulated on the chelae near the maxillae, very elongated, and paving obliquely, the one within, between the branchiae and the body, the other without, between them and the edge of the chelae. By compressing the branchiae, these plates squeeze the water from the intervals of the laminae, and when the pressure is remitted, they allow the introduction of a new portion of fluid.

The branchial pyramids, although placed in a similar situation, are more numerous and complicated in the decapoda with long tails, as the lobster, cray-fish, and palinurus, Fabr. They have rows of cylindrical filaments, instead of laminae, piled on each other in the fives of the vertical plane, so that their surfaces resemble the flag of velvet. There are several thousands of these filaments in a pyramid; each of them is formed of an artery and a vein united; each pyramid has two, its large artery and large vein ending in the body.

These pyramidal forms are arranged in groups, between vertical laminae, of which one ascends behind each group. These laminae are attached to the first articulations of the feet, which cannot move without moving them, and without either compressing or filling free the branchiae. The lobster and cray-fish have five groups of four pyramids each, and a solitary one before and behind, of which the anterior is very small. This will make twenty-two gills on each side. The first group is attached to the most exterior pair of maxillae; and the solitary pyramid in front to the pair concealed by the former. The second group is connected to the claws, and the others to the following feet, except the last, which has only a solitary pyramid. In each group the exterior pyramid is attached to the pedicle of the parchment-like plate, and moves with it; the three others adhere to the body of the animal, and have no separate motion. The first solitary pyramid is also attached to its plate; but the latter is fixed to the body, and has only a rudiment of a plate behind it. Moreover, two other plates are attached to two maxillae, anterior to those of which we have already spoken, and support no gills; yet they are placed obliquely against these organs, and contribute to their compression and relaxation. The action of all these plates occasions the expulsion at the two sides of the mouth of all the water in contact with the branchiae.

The tail of the branchiopoda, particularly of the squilla, bears on its under surface five pairs of fins, forming broad membranous and ciliated oars, divided into two large lobes, an exterior, which is rather anterior; and an interior, which is a little posterior. The gill is attached to the root of the first at its inner edge. It consists at first of a conical pedicle composed of the two large vessels; from this proceeds a row of cylindrical tubes, gradually diminished in size from the basis towards the apex: each of these is curved, and forms a long conical and flexible tail, which also supports a very numerous row of long and loose filaments. Each gill contains a very considerable number of these, and resembling, on the first view, a large brush: it is only by separating the filaments that the regularity of their infection and succession can be perceived. It is almost unnecessary to add that each filament contains two vessels: and that each tail and each tube has the same vascular arrangement, just as in the general pedicle. The branchiae float in the water, are moved like the fins, and are even agitated between the two lobes of the latter: consequently no mechanism is required for renewing the water in contact with them.

Trachea and Respiration of Insects.—Some remarks on this subject will be found in the article Entomology, under the division Siphonata. We shall enter here more minutely into the anatomical details.

We have already stated that the surrounding element, the air, distributed by means of an infinite number of tubes, exerts its action on all points of the interior of the body. These canals have been called trachea, on account of their analogy to the trachea or large vessel which conveys air into the lungs of such animals as poach these organs. Their structure is remarkable: they are composed of three membranes, an internal and an external one of the common structure; and a middle one composed of an elastic thread, polishing a fine metallic fibrous, rolled spirally, or in a double spiral course round the canal, from one extremity of the tube to the other, and admitting of being unravelled with a little assistance. By this the fides of the tube are constantly maintained circular, so that the passage of the air is always free. Yet all the tracheae are not provided with this part in their whole length: some, which Cuvier calls vascular, are dilated at certain intervals, fo as to form merely membranous pouches, not provided with this elastic support.

The tracheae communicate externally by small lateral holes pierced on each side of the body, and called siphonata; or
fometime by one or two tubes opening into the anus. The
latter structure belongs to the true aquatic insect; some of
which, as the larva and chrysalides of the libellulae, have in
the rectum a particular apparatus for this purpose, which
we shall describe.

The trachee of the larve do not resemble those of the
perfect insects any more than the other organs; indeed
the differences in this respect are often still more surprising.

We shall describe the organs successively in the most
remarkable families.

Theos of the caterpillars are the best known, through the
admirable description given by Lyconet of that insect. A
nearly cylindrical tube, receiving air by ten stigmata, ex-
tends on each side of the body. Its branches go off in a
radiating manner, from points exactly corresponding to the
stigmata; those at the beginning, which go to the head, are
larger than the succeeding ones. We observe here, once for
all, that no part is unprovided with these air-vessels, and
that the very membranes of their trunks even receive
small branches. In the caterpillar they are strong, opaque,
and of a fine silvery colour, which, however, depends in part
on the contained air; for the brilliancy is lost, both here
and in other families, when they are macerated and filled with
water or spirits of wine. The air-vessels of the butterflies,
produced from these caterpillars, have a very different ap-
appearance; they are thicker, finer, rounder, and prove almost
throughout small yellow or white elliptical bodies of
a fatty nature: such at least is their appearance in the atalanta
and the phakena pavonia.

A much more considerable change is observed in the cole-
optera lamellicornia; the larva has faciculi of cylindrical,
silvery, and very fine trachee, distributed from each stigna
over the surrounding parts. In the perfect insect they are
of a dead white, swelled every where into small oval or irre-
gularly-figured vessels, with very thin sides; they resemble
trees much loaded with leaves. Examples of this arrange-
ment may be seen in the melolonthia, the fecarabaei, the
copridae, the lucani, &c.: and it occurs in no other families.

The hymenoptera and the dippers have two large vessels
at the sides of the abdomen, and some small ones; but the
number is always inconsiderable.

The hydrophilus piceus has four large ones at the sides
of the abdomen; and, as this is a strictly aquatic insect, they
may assist the animal, as the swimming-bladder of fishes does,
in raising or depressing itself in the water.

The principal air opening in the aquatic larvae is generally
near the anus, that they may the more readily reach the air:
in this case the two lateral trunks of the trachea are of great
size, apparently for the purpose of holding a larger supply
of the fluid; and the branches go off in the form of slender
cylindrical threads. This arrangement is found in the larvae
of two very different families, the hydrophilus and lepsy-
omy. The latter, as all the aquatic larvae of the dippers,
can elongate its tail considerably in search of air without
raising the body; the anus is surrounded by small trachee in
the form of radii. These insects suspend themselves at
the surface of the water by means of their tails.

The larva of the libellulae exhibit the most singular dis-
position of the respiratory apparatus. The orifices, which
abord the air, are found in the rectum, under the form of
very small tubes, ranged in little groups in ten rows, which
represent so many long pinimated leaves. A number of
small trachee, equal to that of the tubes within, pass from
the rectum into the body; and these terminate in four
trunks extended through the whole length of the body.
Two of these are of vast size, and appear to serve as refer-
voirs; for they send the air which they contain by tranverse
branches into the other two smaller trunks, which proceed
as usual along the sides of the body, and supply all parts
with air-vessels. Each of them produces a recurrent branch,
which, after having crossed the corresponding one, proceeds
along the intestinal canal, and gives it an infinite number of
small ramifications. Cuvier thinks that the air contained
in these different trunks follows a determinate course, relative
to the occasions of the parts to which it is distributed. The
four trunks and the two recurrent branches are found in the
perfect libellula; but they no longer derive their air from
the anus. As the animal lives in the atmosphere, its trachee:
are supplied from stigmata, near each of which is a vein-
cel, serving probably as a refertoir. There is also a single row
of larger vessels along the back.

The trachea appear to be deficient in some insects, that is,
in the arachnida, where we have stated that something like
a heart is perceptible. There is however a single stigna at the
basis of the abdomen in the spider; but it leads only into
a vein, from which no air-vessels have been traced. Can
this be the lung? and are there blood-vessels distributed on
its sides?

Organs of the Voice.—By the voice we understand the
sound produced by animals in expelling air from their lungs,
through the glottis; in this sense it can be produced by those
animals only which have lungs, as the mammals, birds, and
reptiles. Several insects produce sounds, and often very
confiderable ones, by the motions of various parts of their
body; but there are no express organs for this purpose. By
these sounds they invite each other, and express their wants
or their passions.

Organs of Generation.—Many very striking peculiarities
are observed in the propagation of insects. The two sexes
of one and the same species are often so extremely unlike each
other, that they would rather be taken for completely dif-
ferent species, than for animals that could pair together.
Among the bees and other neighbouring species, the greatest
number of individuals have no sex; they are conceived
and born without being defined, as in the ordinary course,
to conceive or produce impregnation. Their copulation is
performed in a very extraordinary manner in many in-
fiances. The act is performed on the wing, and some are winged
during the short season of copulation. Several copulate
only once, and the act is very soon followed by death: the
life of the animal may be prolonged by deferring the copu-
lation.

In several, as the cochineal insect (coccus cacti), and
the chigger (pulux penetrans), the pregnant female increases
to an enormous size. The abdomen of the white ant (termes
fata is), when ready for laying, is calculated to be two thou-
sand times larger than it was before impregnation.

Organs of Generation in the Cystus.—These among
the invertebrata are what reptiles and lizards are among the
vertebrata animals; their exterior organs are double; but, which
is peculiar to themselves, their internal organs, both tend-
cles and ovaries, are sometimes united into one.

The decapoda in general have two penes and two vulva:
the openings of the latter are found at the basins of the third	pair of feet. The two penes are quite at the back of the
thorax, behind the fifth pair of feet; in this situation there
is, on each side, a horny, pointed, tubular piece, opened
longitudinally, which may be introduced into the vulva, and
conducts the penis which passes through this tube. We see
in the male, on the inside, two very tortuous va dea deferentia,
each of which is continued to the root of the penis of its
own side. In the lobster and cray-fish the two canals proceed
from a telence divided into two lobes, situated under the heart,
behind the stomach, and between the two masses of hepatic
vessels.
veffels. The testis is whitish, and has a glandular appearance. In the crabs the two canals are very large near the penis, become afterwards slender, and are so convoluted as to form the appearance of a gland on each side. These glands are not united.

In the common lobster the two ovaria are joined, so as to form a single one to all appearance. The two oviducts are short, straight, and go directly to the vulva: the latter are simple holes' pierced in the substance of the cocoon, near the third pair of feet in the crab, and in the very basis of this third pair in the lobster and hermit crab.

The female crustacea attach their eggs, after laying them, to the filaments of the fin under the tail, and carry them in that situation until they are hatched.

**Organs of Generation in the proper Insects.**—The external parts are simple, and placed at the posterior extremity of the body in most insects. To this rule there are some exceptions, both in number and position. In the spiders they are double; and the male organs are placed on the maxillary palpi; the phalangia have a simple male organ, coming out from the root of the abdomen.

The libellule have the male organ at the basis, and not at the point of the abdomen; and hence arises their very singular attitude in copulation. The male seizes the neck of the female with the hooks at the extremity of his abdomen, until the female bends herself back, and brings the extremity of her own abdomen to the basis of that of the male.

The generative organs of the naii are about the middle of the body.

1. **Male Organs.**—These consist in general of a penis with its coverings, of a common spermatheca canal, and of two pairs of organs, which may be regarded as testicles and vesicles feminales. Each of these pairs may be more or less subdivided; they vary in figure and in size.

1. **In the Coleoptera.**

a. **In the Lamellibranchia.**—The genera separated from the fearabahi of Linnaeus, as the melolonthae, cetoniea, trichiae, scarabaei, &c. have numerous globular testicles and vesicles in the form of tubes, as slender as threads, and exceedingly long. In the fcarabaeus macinonis, for example, the two vesicles feminales are more than twenty times the length of the body, and are convoluted into a packet or masts, which it is not very difficult to unravel. Their tube is a little enlarged before it joins the common canal. On each side there are six testicles of a small size, and producing each an excretory tube mere slender than a hair; these six small tubes are united into one canal, which is joined to that of the opposite side precifically at the point where the vesicle feminales are united. The common canal, resulting from these four tubes, becomes large and mufcular, and then goes into a hornv sheath, terminated by a kind of piners, between the lamina of which the penis is placed. The latter is merely a small cylindrical tube. It appears that the two branches of the piners are introduced into the vulva, and then separated so as to facilitate the entrance of the penis. Swammerdamp has given a very accurate figure of these parts.

The melolonthae resembles the Scarabaeus. The organs are more complicated in the cetoniea: there are twelve testicles on each side, and, besides the filiform vesicle, which are probably thirty times as long as the body, there are two other short and thick pairs; the flotlof the latter has its extremity forked. The canals of the three pairs of vesicles, as well as the canals of the two groups of testicles, join together at the same point to constitute the common spermatheca tube, which goes to the penis.

The trichiae resemble the cetoniea. The coprudes, or dung beetles, and the Lucani, or flag beetles, do not follow the same type: they have only one testicle on each side, and this is a globular and compact mass made up of the convolutions of a single tube. Their vesicles feminales are also filiform, but not so long in proportion as those of the scarabeii.

b. **In the Carnivora.**—The organs are very simple in the dytics; there are two large vesicles of moderate length, very little convoluted; two globular testicles covered by a yellowish matter, which may be removed; they are easily unravellable into a single, filiform, slender and long vesicle. The vas deferens is merely the continuation of this; it enters the vesicle a little before that joins the opposite tube to form the common spermatheca canal.

c. **In the Lepidoptera.**—The structure of the hydrrophila is more complicated than that of the dyticus; it has two oval testicles, each of which is formed by the convolutions of a single vesicle. The vas deferens, which is as fine as a hair, swells into a small oval vesicle where it ends in the common canal. The principal vesicle feminales are large, with strong sides, spirally convoluted, and terminating suddenly in a small vesicle folded in zig-zag, and forming the appearance of another smaller vesicle. There are, moreover, two accesorv vesicles, with thin sides, each divided into three branches, and into some small blind appendices. The common spermatheca canal has a muscular enlargement towards its middle, and becomes again suddenly small to enter the penis. These parts are figured by Swammerdam, but rather rudely.

The filupha atrata has two large oval testicles, formed of an infinite number of small foort vesicles, resembling the brushes of which the hairs project in every direction. The vas deferens is short and short. There are two pairs of vesicles, both cylindrical and tolerably large; one of them is folded in a serpentine manner round the intestine, and may be four or five times the length of the body; the other is much shorter. The common spermatheca canal is cylindrical and short. The penis is also cylindrical, covered with hornv pieces, but has no piners. An oval bladder, of which the use is unknown, but which resembles in its position and figure the urinary bladder of the mammals, is found at its internal bails.

d. **In the Filicorina.**—The common spermatheca canal is eight or ten times the length of the body in the haemostigma; four organs resembling vesicles are connected to it at its origin. Two of these first make some very regular spiral turns, growing at the same time smaller; and then enlarge again and are irregularly folded. The two others have a zig-zag course, and are much shorter.

2. **In the Orthoptera.**—The Gryllci have two considerable oval vesicles attached to the back; they are covered by a yellow mucosity, in which the tracheae may be seen beautifully distributed. They are composed of small short vesicles, which make up a kind of brush. The vas deferens is folded in the form of an epididymis: a little before joining the opposite one, to form the common canal, it is enlarged, because it receives two groups of vesicles. One of these contains more than sixty, and the other above two hundred much smaller than the former. The four bundles fill nearly half the abdomen. Two small oval vesicles are found at the very point of union of the two vasa deferentia.

3. **In the Hemiptera.**—The water scorpion (nepa copeia) has two small, short, and cylindrical vesicles, two large vasa deferentia convoluted like the epididymis, and divided at their origin, each into four small testicles, each of which is again prolonged into a very long filiform vesicle. These eight vesicles are convoluted into a mass.
4. In the Lepidoptera.—There are two different forms in this order: the bombyx pavonia will serve as an example of one, and the same has been imperfectly exhibited by Swammerdam and Malpighi in the silk worm moth (bombyx mori). The common spermatic canal is divided into two female parts; at first it is little enlarged, and then prolonged in the form of tubes. They continue united to each other in half their length. The ova deferentia enter in a very slender form into the dwellings of the vesicula. They gradually enlarge, and terminate on each side in a mass, which may be regarded as a telesphic. Malpighi has represented the vesicles broken a little above the insertion of the ova deferentia; and Swammerdam a little beyond this point. The telesphic are smaller in the pavonia than in the bombyx mori.

The second form may be exemplified in the sphinx euphorbias, and it is just the same as Swammerdam represents in the papilio urticae. The common canal, much longer, is divided into two long and slender vesicles, each of which is joined by a vesica deferentia: but the two half, instead of having separate telesphic, are united into a single rounded mass.

The preceding are the species of insects, in which Cuvier has hitherto observed the male organs; there are three others in Swammerdam, which agree with these in the principal points.

The bee, among the hymenoptera, has two large oval vesicles, two rounded telesphic, with long filiform vesica deferentia. There are two short and small accessory vesiculae: the common canal is enlarged before it enters the penis.

In the order diptera the stratomy is has two oval telesphic, formed, like those of the fylpi and gryllus, of small vesicles; two vesica deferentia, and two simple filiform vesiculae. The common canal is of a middling size. In the fly, which lays in cheese, on the contrary, there is a very long common canal, very short vesica deferentia, and large vesicle divided into two lobes.

11. Female Organs.—These are much more uniform than the male in the whole class. They consist, in general, of a common oviduct, opening at the vulva, and divided at its origin into two branches, each of which is again divided into a certain number of conical tubes of various length. The ova are so arranged in the interior of these tubes, that the largest are the rear end of the oviduct, and that the others gradually decrease in size to the point of the tube, where they are imperceptible. When the ova have been discharged, the tubes remain empty. They may be already differentiated in the chrysalis, a little before the metamorphosis. Secretory vesicles of various forms end in the oviduct, and deposit in fluids for covering the eggs or for forming a shell.

The scarabaeus napiformis has six oviducts on each side, each containing five or six eggs: an oval vesicle and a small but rather long vesiculae end in the oviduct.

The carabi have ten or twelve tubes, and the dyticei twenty or fifteen; the oviduct has a simple and small bladder, which is prolonged further in the carabus.

In the filha atrata there are seven or eight tubes, and each contains four eggs. The latter do not become large until they arrive in the branches of the oviduct, which are of considerable size.

The tubes are very numerous in the hydrophilus, and form two large branches; round the base of each of these five are long and large secretory vesicles containing a green liquor.

The butterflies have on each side four very long tubes, filled with a large number of eggs, and forming, particularly in the fruitful species, rows like strings of beads, four or five times longer than the body. The common oviduct is so short as to be scarcely perceptible; it receives one or two vesicles, and two long vesicles.

The grylli have on each side about thirty tubes, each of which does not contain more than three or four visible eggs: they are united by the tracheae, and by a mucous substance, into two oval males. The common oviduct receives a vesicle and a long vesiculae.

The bees have the two half mentioned parts: their rows of eggs are numerous on each side. Cuvier thinks that he can perceive very small ones in the neuter bees, which would confirm the notion of their being imperfectly developed females.

In the filha there are five, and in the notonecta six rows on each side.

The libellulae have two very long branches; their tubes are short, small, and almost innumerabil.

The various boring instruments which certain genera, as the gryllen, Ichneumon, tenthradae, and cynips, employ for depositing their ova in suitable situations, may be arranged with the organs of the female sex. But, as these parts are completely external, and have been well described by naturalists, we shall not lay any thing more on the subject.

Spinning Instrument of the Caterpillars.—Almost all the caterpillars spin themselves a covering, or at least an attachment of some kind, before their metamorphosis. The caterpillar of the bombyx mori is the most celebrated in this respect, since the thread composing its covering being abundant, flexible, brilliant, and easily wound, forms the material from which our most splendid hisks are formed. Other caterpillars, as that of the bombyx pavonia, form as large a quantity of silk, but it is hard, liable to break, and cannot be wound off.

The secreting organs producing the silk are the same in all caterpillars, excepting varieties in size, which is proportionate to the quantity of silk produced. These, like all the other secreting organs of insects, are two long tubes, commencing in a very slender and convoluted form; then growing larger to form a kind of retorium, and terminating in an excretory canal so small that it can hardly be seen. The two canals terminate under the lower lip: and the animal draws out and elongates the vultrile matter by moving its head from side to side.

Organs for producing Light.—Several animals of this class have the power of producing light; and the substance in which this property resides is sometimes diffused through the animal’s body, sometimes collected into a particular organ. The luminous matter must be regarded as an animal secretion produced like any other animal substance. A very full and interesting account of this subject is contained in a paper by Mr. Macartney, in the Philosophical Transactions for 1810, from which the following passages are extracted.

“Tha power of emitting light has been observed in two animals of the crullaceous order, and seems to reside in the whole body. One of these, observed by Sir Joseph Banks, in the passage from Madeira to Rio Janeiro, resembled the common shrimp, but was less: it is named by Mr. Macartney cancer fulgens. The other was found in the Red sea by captain Horsham, appeared to be a monoculus, and to belong to the genus limnus of Müller. Mr. Macartney calls it limbus noctilucus. A third crullaceous animal of the genus lymenes of Müller, possessing luminous properties, has been seen off the coast of Malabar. Of other insects some species yield light in the following genera; viz. elater, limpris, fulgus, paufus, scolopen-
dra. The only animals which appear to possess a distinct organization for the production of light are the four first of the last mentioned genera.

The light of the lampyrides (glow-worm) is known to proceed from some of the last rings of the abdomen, which, when not illuminated, are of a pale yellow color. Upon the internal surface of these rings there is spread a layer of a peculiar soft yellow subfusible, which has been compared to paste, but by examination with a lens I found it organized like the common interstitial subfusible of the insect's body, except that it is of a closer texture, and a paler yellow color. This subfusible does not entirely cover the inner surface of the rings, being more or less deficient along their edges, where it presents an irregular waving outline. I have observed in the glow-worm, that it is absorbed, and its place supplied by common interstitial subfusible, after the seafon for giving light is passed. The segments of the abdomen, behind which this subfusible is situated, are thin and transparent, in order to expose the internal illumination. The number of luminous rings varies in different species of lampyris, and as it would seem at different periods in the same individual. Besides the luminous subfusible above described, I have discovered in the common glow-worm, on the inner side of the last abdominal ring, two bodies, which to the naked eye appear more minute than the head of the smallest pin. They are lodged in two flight depressions, formed in the shell of the ring, which is at these points particularly transparent. On examining these bodies under the microscope, I found that they were faces containing a soft yellow subfusible, of a more clore and homogeneous texture than that which lines the inner surface of the rings. The membrane forming the faces appeared to be of two layers, each of which is composed of a transparent silvery fibre, in the same manner as the internal membrane of the respiratory tubes of insects, except that in this case the fibre passes in a spiral instead of a circular direction. This membrane, although so delicately constructed, is so elastic as to preserve its form, after the face is ruptured, and the contents discharged.

The light that proceeds from these faces is less under the control of the insect, than that of the luminous subfusible spread upon the rings; it is rarely ever extinguished in the seafon that the glow-worm gives light, even during the day; and when all the other rings are dark, these faces often shine brightly.

The organs for the production of light in the genus elater are situated in the corflet; these likewise consist of a peculiar yellow subfusible, placed behind transparent parts of the shell, which suffer the natural color of this subfusible to be seen through them in the day, and when illuminated give passage to the light. On dissecting the organs of light in the elater noctilus, I found that there is a soft yellow subfusible of an oval figure lodged in the concavity of the yellow spots of the corflet, which parts are particularly thin and transparent in this species. This subfusible is so remarkably close in its texture, that, at first view, it appears like an inorganic mass, but with a lens it is readily perceived to be composed of a great number of very minute parts or lobules closely pressed together. Around these oval maffes the interstitial subfusible of the corflet is arranged in a radiated manner, and the portion of the shell, that immediately covers the irradiated subfusible, is, in a certain degree, transparent, but less so than that which lies over the oval maffes; it is therefore probable that the interstitial subfusible in this situation may be endowed with the property of luming. In the elater ignitus the maffes of luminous subfusible are extremely irregular in their figure; they are situated nearly at the posterior angles of the corflet, and are more loose in their texture than the oval maffes of the noctilus, resembling rather in composition the interstitial subfusible which surrounds these maffes in that species. The shell of the corflet is somewhat thinner, and more transparent along both sides of the margin, than at other places, but it is not so the noctilus, elevated, and peculiarly clear and thin immediately over the seat of the luminous organ; consequently the light emitted by the elater ignitus cannot be very brilliant.

In the fulgora candelaria and lanterna, Mr. Macartney has found the hollow organ, from which the light proceeds, to communicate freely with the external air, by means of a chink or narrow aperture, placed on each side of the head of the proboscis. This organ is lined by a membrane, between which and the horny part or shell there appears to be interposed a pale reddish soft subfusible, arranged in lines or stripes in the candelaria. It could not be determined whether this furnishes the light, or is the pigment, upon which the colour of the proboscis depends.

The globes of the antennae constitute the organs of light in the paufusipherocerus.

"It is worthy of remark," says Mr. Macartney, "that in all the diffusions I have made of luminous insects, I did not find that the organs of light were better or differently supplied with either nerves or air-tubes, than the other parts of the body. The power of emitting light likewise exists in many creatures, which want nerves, a circumstance strongly marking the difference between animal light and animal electricity." Swammerdan's Book of Nature, or History of Insects, Lyneart Traité Anatomique de la Chenille, qui rouge le bois de faune; Cuvier Leçons d'Anatomie comparée.

Insects infesting the human body. The parasitic animals, which are most commonly found inhabiting, and deriving their nutriment from, the internal cavities of the human body, are the three species of worms, which are denominated, by naturalists, ascarias, lumbricus, and tenia; that is, the maw-worm, or thread-worm, round-worm, and tapeworm; to which may be added the tricharis, which is occasionally seen. (See these words.) The external parts of the body, again, afford a nidus and suffittance to one or two of the infect tribes, especially the pedicul of the head and of the pedes; the former of which are sometimes bred in great numbers, and infest other parts of the surface, producing a loathsome and very obblate disease, the morbus pediculutaris, or lousy disease. (See Pithiehmas and Prurigo.) It is not our object, however, to treat of these under the present article; but merely to notice briefly the exceptional existence of various species of the swopt insects, in the different cavities of the human body, especially in their first state, that of larva, caterpillar, or grub; and to point out the manner in which they are probably introduced.

The medical writers of the sixteenth and early part of the seventeenth century have recorded instances of various reptiles and other animals, which were dislodged from their abode in different parts of the body, such as frogs, lizards, serpents, &c.; which may be found on consulting the collections of Borsili, Marcellus Donatus, Scheneck, and others. But their credulity was at least equal to their learning and industry, and subsequent observation has not confirmed their statements, which probably originated from gross ignorance of the economy of these creatures, or from wilful deception on the part of those from whom they were said to have been dislodged. On the other hand, the microscopic philosophers not only peopled every organ of the body with worms and vermiles; but believed that all contagion
Insects.

It must be acknowledged, however, that the bladder is the least probable nidus for the larvae of insects, and we cannot readily conceive how they should find their way into that cavity; while, on the other hand, mistakes may be made upon such a subject with the greatest facility, as Valdivieri long ago remarked. These larvae might have crept or fallen into the uteri, or the ova might have been deposited there, and the larvae afterwards observed in the urine. An instance of this kind of mistake was related to the writer by an eminent surgeon. A body was in great alarm, from the belief that the frequently passed from the bowels several little red worms, extremely lively in their motions, which were found in the excretions. But it was strongly suggested, that these worms must be inhabitants of the water-closet; and upon accurate examination, theagination was confirmed; they proved to be the larvae of the common nain, which are well known to be aquatic in their mode of life. In all cases, therefore, it is necessary to be cautious in examining all the circumstances, before it be concluded, that insects, found in the excrements, are discharged, actually passed from the human body.

There is another species of insect, which, in its state of larva, or caterpillar, appears to be not unfrequently an inhabitant of the cavities of the human body, though not so commonly as the different species of fly; we mean the common black beetle, the tenetio molitor of Linnaeus. The grub of this insect is a sort of caterpillar, about an inch and a quarter in length, and equal to a large crow-quill in circumference, with its feet near the head, but distilute of feet at the other extremity: its body is divided into thirteen sections. The introduction of this larva into the human body, or of the ova from which it is hatched, will be readily understood, when we mention that it lives principally in flour or meal; whence from the time of our oldest writer on insects, Moiset, it has been known by the appellation of the meal-worm. This writer has given a rude figure of the grub. (See his Historiwm Thraemum, Lond. 1664, lib. ii. cap. 20, p. 254.) Two cafes, in which this meal-worm was discharged from the human body, have come to the knowledge of the writer of this article. (See Edin. Med. and Surg. Journal, above quoted.) Another is mentioned and figured by Dr. Kellis, of Leith, in the fame Journal.

And Tulpius has given a figure of the same larva, two of which, he says, were passed from the bladder of a woman of fifty years of age, and a similar one from the navel of another woman, who had previously suffered severe headache. (See his Observ. Med. lib. ii. cap. 51, tab. 7, fig. 3; and lib. iv. cap. 22.) The discharge of two from the bladder was probably inferred, by mistake, from the grubs being found in the uterine which received the urine: but the escape of the one from the navel is probably correctly stated; for in this way the larva passed in one of the cafes, to which we have just alluded, and the navel, or the adjoining cavities, are common receptacles for the ova of larvae of other species of insects, as we shall presently shew. Forcibus has recorded some cafes, in which the grubs were mott probably of the same nature. He mentions the circumstance, which he witnessed, of a girl who rejected from the stomach two beetles, one at the interval of two days after the other, and likewise a living worm or grub, which was, in all probability, the grub of the beetle. He also mentions the rejection of a species of caterpillar, "vernum ecruem simile," by vomiting, after which a feverish pain of the stomach of considerable duration was removed. Forelli Opera, lib. xxxi. ob. 25.

Several of the insects above-mentioned were discharged from the navel, in which cavity, in brute animals, the excremen
INSECTS.

The entrance of larvae is very common, and the cases appear to be actually deposited there by the parent insect. Mr. Brady Clark questions the existence of human botas (Olf. domitiae); but that insects of this species sometimes find a nidus in the nasal passages of the human subject, is proved by a case, related by Dr. Heyham, of Carlisle, in which three botas were discharged from the antum of Highmore, or sinus of the cheek of a woman, after that cavity had been perforated by a razor. An intolerable hemiastia was occasioned by their presence, and ultimately proved fatal. (See Medical Communications, vol. i. art. xxx. and plate t. figs. 2 and 3.) An example of an emplaced lodging in the frontal sinus is recorded in the Edin. Med. Essays, vol. i. p. 291. In the tropical climate, one learns from Dr. Leyden, that the maggot or larva of the large blue fly, which are continually buzzing about the sick, are generated in the nose, mouth, and gums, in the last stages of fever, when the patients sleep or doze with their mouths open, the nurks finding great difficulty in preventing the deposition of the case in those parts. This author mentions one instance, in the lady of an officer, who had escaped from the attack of fever, but in whom "these maggots were produced, which burrowed and found their way by the nose through the orifices, into the cavity of the cranium, and afterwards into the brain itself, to which she owed her death." Lempiere, Obf. on the Dif. of the Army in Jamaica, vol. ii. p. 182.

It is probable that those cases on record, in which worms were laid to be coughed up the lungs, were in reality incursions of the larvae of insects, bred in the posterior cavities of the nose, and removed by the agitation of coughing into the throat, and thence expelled. See a case of this sort, related by the late Dr. Percival, in his Med. Essays, vol. iii. p. 272, in which two mites of grumous blood were brought up by coughing, as large as a nutmeg, one of which, when opened, "was found to contain a considerable number of worms, like maggots, in a very lively state."

Besides the larvae of figs, of the black beetle, and of the aldrus, above-mentioned, fearfully any other insects are described upon good authority, as being nurtured in the human body, if we except the millepedes, which are mentioned by some authors. It is impossible to say much on the subject of destroying these larvae by medicine; since their existence cannot be ascertained before they are actually discharged and seen. The symptoms produced by the irritation which they excite, confine only of severe pains in the parts where they happen to be, which of course cannot be distinguished from pain occasioned by other causes. If the existence of the worms was known, or could be formed, perhaps the internal exhibition of the oil of turpentine might be referred to with success; for it appears that this liquor is poisonous to all the insect tribes, as well as to worms. Experience has now decidedly proved its efficiency in the destruction of the tapeworm. See Edin. Med. and Surg. Journal, for April and July, 1810. It has been used with success in the way of glycer in the case of ascarides; and Dr. Lempiere found it serviceable when injected into the passages infested by maggots.

INSECTS. Anatomical Use of. The insect-world affords us numerous uses, and these many of them such as no one would at first thought imagine, and which no other operations or operations could so well effect. In the minute of anatomy, where knives cannot be introduced, the maggot or the ant may be employed with great success. Skeleton of the foot has been prepared by burying them in an ant-hill, and that in so accurate and perfect a manner, that all who have seen them, have admired by what means they could be so nicely finished; and the secret of the great Ruyfch, by which be cleared away the parenchymatous substance from his vascular preparations, was of this kind. After injecting the vessels of any part with wax, all that remained to the completing of these preparations, was the taking off the parenchymatous or fleshy matter from between and among them. Other anatomists of his time did this by the knife, or by maceration in water and other liquors; but it appeared a sort of magic to them, that his were always not only much sooner executed, but to a greater nicety and perfection than their's ever possibly could be. His method was only to put a number of the common flesh-eating maggots to the substance; and these regularly eat away all the flesh, their heads getting into crevices which no instrument could reach, and the whole substance of the injection remained unhurt, as their soft bodies could glide between its nicest parts without injuring them; and the wax being no food for them, was in no danger of being eroded, even in its smallest pieces. The several sizes of the worms or maggots bred from the eggs of different flies were of great use in the perfecting of the preparations; for while the larger sort eat the more fleshy parts, where the vessels are large and but few in number, the middle-sized maggots got into the interstices of the more vascular parts, and the minute parts of all, which are usually the most numerous, kept about the surface, and eat away between and among the capillary vessels.

The maggots produced from flies are not the only animals fit for this kind of business. There are several species of beetles of the smaller kinds, whose eggs hatch into a six-legged worm, which eats as much and as nicely as the fly-maggots. All these may be employed very successfully in the preparations of the parts of animals.

These nice anatomists are not confined to animal substances; they often exert their power also on vegetables. Many of them feed on the leaves and fruits of plants; and some species of these work so nicely, that they eat away all the outer membrane and internal parenchymatous substance of the leaves, so as only to leave the net-like plexus of vessels standing. Yet these being unhurt flew the true figure of the leaf, and are a sort of vegetable skeletons, but very poorly imitated by art in the common way, by long macerations in water; this method usually destroys and wailing away many of the smaller vessels, which the tender mouths of these creatures spare. If they exert their skill often upon leaves in this manner, they do it also sometimes with equal, if not greater, success upon fruits. As in the leaves, those which have the tenderest parenchyma and the firmest ribs succeed best; if also it is in fruits. The leaves of the rucus or butcher's broom are often found thus beautifully anatomised; and of all fruits, none succeds so well as that of the framboise, or thorn-apple. Wherever this plant grows in any plenty, the fruit towards autumn, while it is yet full of juice, is attacked by a small worm, which eats away all the parenchyma, and leaves every vessel standing in its place; and this not only in the outer coat of the fruit, but in the very inner cells of the seeds. These vessels remain exactly in the shape of the fruit, and, growing white with the air, exhibit the most elegant and beautiful skeletons imaginable, while yet standing on the plant. The animal which effects this, is a hexapode worm produced from the egg of a small beetle; and differs very little from some of those which so elegantly eat away the fleshy parts from the injected anatomised preparations. These are gregarious animals like some species of the smaller caterpillars, and numbers of them are always at work together on the same leaf or fruit, so that the skeleton is soon made. They begin by piercing a number of little holes into
INSECTS.

into the substance of the leaf, and thence burrow under the integument till they meet one another; and this being done all over the leaf, they leave it, and go to work upon another.

Insects. Vegetable Diseases of. All such vegetable affections or diseases as are produced by different sorts of animals of the insect kind, are very numerous according to their nature and those of the plants; but the chief infefts that affect plants of the fruit-tree kinds, are those of the aphis, acarus, ant, chermees, cicada, coccus, carwigs, papilio, phalaena, and thrips tribes.

And of the first fort there are a vast number of species, each tree being said to be infested by a different distinct speeies. Hence the author of the "Systena Vegetabilium" has denominated them from the trees on which they are found; as the cherry aphis, the currant aphis, the plum aphis, &c. The males are few in comparison with the females, and have wings, while the latter are numerous and without them. See Pucerons, and Vine-burret.

The second is a highly destructive insect in houset where forcing is practised. It is not furnished with wings, but the female is oviparous. The species, as in the former case, are very numerous. It often commits great mischief on vines, peaches, neclaines, cherries, forced kidney-beans, melons, &c. See Red Spider.

And the third, or ant, is highly injurious to fruits, especially those of the peach kind, as they become in a state of maturity. They run all over the trees, and the beet fruit is occasionally filled with them. It has been supposod by some that they are of use by devouring the aphides on the trees; but Mr. Forfyth is of a different opinion, and we have seen fruit much spoiled by them in various inaccidents.

The beet method of destroying them, according to the above author, is, by making holes in the ground along the side of the wall where the fruit-trees are, by an iron crow, so that the inside surface may be quite smooth. These infefts, from being disturbed, soon come to the holes, and fall into them; when, being prevented from getting up by the smoothness of the sides, they may be readily destroyed by pouring water upon them. But more effective methods are, either by mixing quick-lime with foot, and placing it on their tracks, or putting it in their nests, and then pouring water, or urine and soap-fuds, upon it, so as to slake it, confining the heat by a turf or some earth. The heat thus produced soon destroys them. The powder of flavefaces, laid round the stems of the trees, is said to prevent their running upon them and thereby becoming injurious.

The fourth, or chermees, belongs to the order hemiptera; and there are several speeies. Their specific names are taken from the different plants on which they are generally met with: as the chermees graminis, or grass bug; chermees fucus, or shrub tree bug, &c. The last is one of the largest of the genus, being brown above and greenish beneath, and has four long wings, placed in the form of an acute roof. The larea is of an oblong form, and has six feet, but its motion is slow. When attempted to be caught, the chermees makes its escape rather by leaping than flying, by means of its hinder legs, which play like springs. Several of the speeies are provided at the extremity of their bodies with small sharp-pointed implements, but which lie concealed; and these they draw out in order to deposit their eggs, by making punctures in the plants that fuit them. It is in this way that the first-tree chermees produces that enormous scaly protruberance, which is sometimes found at the summit of the branches, and which is formed by the extravafation of the juices occasioned by the punctures. The young larve shelter themselves in cells contained in the tumour. These insects are capable of being destroyed in the same manner as the coccus tribe.

The fifth, or cicada, belongs to the same order as above, and the larvae of many of this tribe void large quantities of frothy matter upon the leaves and branches of the plants and trees, in the midst of which they are always concealed, probably for protection, and to be hidden from the same influence. These infefts should be destroyed, as the froth is unpleasant, and the leaves of the trees are often devoured, by rubbing off the larvae with the hand, and afterwards watering the trees well with soft water, such as that of ponds or other exposed situations.

The sixth, or coccus, also belongs to the same order, and the males have wings, but the females none. It may be noticed, that the forts most commonly met with when full grown, have somewhat the form of a boat with the keel uppermost, being apparently without feet, eyes, &c. while in this state resembing some forts of galls or excrences of the bark of trees or other plants.

It has been observed by Mr. Forfyth, that a "thin film," of a white cotton-like substance, is interposed between the flat part of the body and the tree. This is common, in a greater or lesser quantity, to all the species, and appears at first all round the edge as a kind of cement, to join it to the tree. The males are very few in proportion to the females, and not nearly one-fourth of their size; they are beautiful little flies, which, after a short but active life, terminate their existence without having tasted food, being provided with no fорт of organs for that purpose.

It is likewise remarked, that the peach, neclaine, and pear-tree, are very much infested with these insects: they frequently cut through the bark, and the trees then appear as if they had been scratched by cats. He has "seen forms with this appearance all over them."

It is advised, that, "when these insects first appear on the bark, they should be scraped off with a wooden knife, and the stem and branches of the tree well washed with soap-fuds and urine, applied with a still painter's brush. This should be done in February before the buds begin to come out. But if the outer bark is perforated, it must be cut or scraped off with a long knife; and if you find any brown spots in the inner bark, they must be carefully cut out. This disease is, it is supposod, one great cause of the canker, and of the death of the tree."

And it is added, that "when this disease has made its way through both barks, as is often the cafe, the branches on each side of the tree may be cut close to the stem, if it has an upright one; but if the tree be trained fan-fashion, the belt way is to head it near to the place where it was grafted." He states, that he has "headed old pear-trees which were so dead, except a small strip of live bark on one side, that you might rub the bark off them as easily as off a bundle of faggot-llicks that had been cut upwards of a year; yet these trees have shot out fresh branches to the length of seventeen feet in two years, and produced fine fruit the second year." It is advised to apply the composition immediately after heading or cutting, or paring off the diseased bark. See Composition.

It is further remarked, that "a very destructive species of the coccus tribe has done incredible damage to the apple-trees in the nurseries and gardens in the neighbourhood of London. Some nurserymen have lost several thousand apple-trees in one year. These insects attach themselves to their bark by their suckers, and by feeding on the juices of the tree, rob it of its nourishment. Such trees as are infested with them have a tickly appearance. These insects generally make their cells where branches have been cut off, or in hollow
hollow places, where the canker has eaten holes in the trees. Their first appearance is like a white down; on touching or rubbing them they tinge the fingers of a crimson colour, like cochineal. If suffered to remain long on the trees, they take wing, like aphides.

It is flayed, by the same author, that the method that has been followed for these ten years to destroy them, is to "rub the places where their nects are with an old brush, such as painters use; till they are all cleaned off; and if the part be canker-eaten, to cut it clean out with a knife or chisell; he then takes of soap-fuds and urine equal parts, and with this he washes the wound and the bark all round it; and with a brush applies the composition, mixed with wood-ashes and the powder of burnt bones, covering the wound all over with it. Afterwards he makes some of the powder of wood-ashes and burnt bones, mixed with an eighth part of unaltered lime finely powdered and sifted over the hollows, or where knots have been cut off."

And it is advised, that "at the same time that the trees are cleared of the coécu, the caterpillars should be picked off."

The writer remarks, that "the first time that he observed the new coécu which has done so much mischief to the apple-trees about London, was in a garden of his own near Chelsea, about the year 1782, or 1783, and as far as he can learn, the trees were imported among some apple-trees, by the late Mr. Swinton of Stane-street. Mr. Swinton afterwards removed his nursery to the King's Road near Chelsea college, which now goes by the name of the Foreign Nursery." By force, train oil has been tried, laid on with a painter's brush; but without effect.

The seventh, or earwig, is often very destructive to fruit, particularly that of the peach kind. The method recommended by Mr. Forsyth is to destroy them, and which he has long pursued with success, is to "take old bean-flaks, and cut them about nine inches long, tying them up in small bundles with some pack-thread, or with small yellow willos, and hanging them on nails against the wall, at different parts of the trees. The first thing in the morning, being provided with a board about eighteen inches square, and a small wooden trowel, take down the bundles of bean-flaks one by one, strike them against the board, and with your trowel kill the earwigs as they fall out of the flaks. If you follow this up every morning, (or every other morning,) you will be able to keep them under," without much difficulty.

It is suggested, that this method answers for any Fort of trees infested with earwigs. In some years the writer has "seen a great part of the fruits, especially the smooth-skinned forts, destroyed by these insects, and a small green caterpillar; and in a scarce year of fruit, the leaves of peaches are frequently destroyed by them." It is advised, that "the thredds taken from trees that have been unnailed in autumn, should be soaked in boiling hot soap-fuds for three or four days previous to their being used again; as this will kill the eggs of earwigs and other insects that may be deposited on them."

The eighth, the papilio or butterfly fort, belongs to the order lepidoptera.

There are a great many species of this genus, mostly distinguished by the colour of their wings. The more common forts, with their caterpillars, are well known; and Mr. Forsyth advises, that the caterpillars and chrysalides should be carefully picked off, and the trees well watered with clear lime-water and tobacco-water mixed well together. The ninth, the phalena or moth kind, are extremely numerous, their caterpillars differing much in size, shape, and colour. After casting their flough several times, all of them spin their cod, in which they are transformed to chrysalides. In this state they are often found rolled up in the leaves of fruit trees, especially those of the pear, plum, and cherry kinds. See PHALENA.

And of the sphinx, or hawk moth kind, there are a vast number of species. Their caterpillars apply the hinder parts of their bodies to the branches of the trees, holding the reed erect; hence the name. But in general they spin their cod under ground. They appear early in the morning, or after fun set, flying heavily, and making a fort of noice. Several of the caterpillars are green, and some brown, yellow, spotted, or banded.

The phalena multris, or hackey moth, deposits its eggs in rings or circles round the branches of fruit trees, having the appearance of a necklace. See PHALENA.

The tenth fort, or thrrips, belongs to the order hemiptera, and there are several species. It is extremely small, so scarcely to be discovered. This insect produces great mischief on fruit trees, devouring the fruit as well as the leaves. It is capable of being destroyed in a similar manner to that of the coécu.

But the nature of the various effects of these different insects, and the means of removing them, will be more fully considered and explained, in describing the several vegetable diseases that are produced by the attacks of different sorts of animals of this kind. See VEGETABLE DISEASES.

INSECTS. Petrified, in Natural History. The works of the earlier writers on extraneous foils, contain accounts of various insects said to be found in the earth. Mr. William Martin, a late and correct writer on this subject, seems, however, to doubt, whether the remains of any of the winged tribe of insects have been found enveloped in the ffra; although such insects in a perfect and natural state of preservation are very common in pieces of amber. The limestone of Oening is said by M. Werner to produce specimens of the larvae of the libellula or dragon-fly, and of the napa or water-scorpion. Insects without wings, of the cancer, monoculus, and oniscus genera, are not uncommon in some ffrata. In his "Petritracata Derbenha", Mr. Martin describes and figures (tab. 45.) an insect found in the shale limestone of Affford and Lakewell Moor, which he calls the Derbyshire oniscite, and expresses an opinion, which seems pretty well founded, that it differs essentially from the oniscite of the Dudley and Coalbrookdale lime quarries. He also figures and describes a limated monoculus, said to be found in iron-stone, near Mansfield, in Nottinghamshire, but this probably is a mistake, particularly if others of the same kind were found near Chatterfield in Derbyshire. The late ingenious Dr. Woodward had perused himself, that all the many flies and insects preferred in amber, were of the vernal tribes, and concurred with other foil subjects in proving, that the Mosaic deluge happened in the spring feion of the year; but more correct observations seem, however, to prove, that all the organic remains of the ffrata, and even mould of those of the alluvia, cannot have relation to that event, since they differ essentially from the recent insects, animals, &c., to which they have a resemblance, and all such seem rather to have been created and lived, during the incalculable creation and deposition of the mineral substances, composing the ffrata in which they are imbedded, and long prior to the creation of the present race of animals and vegetable tables, of whose original Moses has given us so succinct and satisfactory an account, as according to the present appearances of nature.

INSERTED COLUMN. See COLUMN.

INSERTION, a term frequently used, in Anatomy, to signify the implication of one part within another.
The infiltration of the bones, muscles, and nerves in the members of an animal, is exceeding artful: the venae cavae has its infection in the right ventricle of the heart.

Insertion is also used, in Agriculture, for the inclining a graft within the cleft of a tree. See Grafting.

INSESSUS, or Insectio, in Medicine, a kind of half-bath or leeching, usually prepared with a decoction of several herbs proper for the lower parts, wherein the patient sits down to the navel.

It has several uses; as the easing of pain, softening the parts, dispelling a flautulent matter, and frequently promoting the menses.

INSIDIARIA, in Geography, a town of Africa, near the E. coast of Tunis; 136 miles S. of Tunis.

INSIDE GUARD, in Poetical, a guard with the broadsword, to secure the face and front of the body from a cut made at the inside of the position, above the wrist. See Guard.

INSINUATION denotes a cunning, and covert way of creeping into any person's favour.

Insinuation of a will, among Civilians, is the first production of it, or the leaving it with the registril, in order to its probate. See Will.

INSIPID, Tasteless, that which has nothing in it pungent enough to affect the palate, tongue, &c. and to occasion that fermentation we call tasting.

INSIENTATION, INZITIO, in Botany, denotes the fame with engraving; viz. the act of inferting and uniting a cion, bud, or the like, in the substance of the stock.

INSOKO, in Geography, a town of Africa, on the Gold Coast; 120 miles from the sea.

INSULATION, in Medicine, from in and sol, the sun, a term used by some writers to express the disease, occasioned by the direct action of the sun's rays upon the human body, which has been called, in the Latin and French languages, isus felis, and coup de soleil. See an account of this disorder under the head Heat, in Medicine.

Insolation, in Pharmacy, a method of preparing certain fruits, drugs, &c. by exposing them to the heat of the sun's rays; either to dry, to maturate, or to sharpen them, as is done in vinegar, figs, &c.

The word comes from the Latin verb insolare, which is used by Pliny and Columella; and signifies to expose to the sun.

INSOLVENCY, Act of, in Law, an occasional act, frequently passed by the legislature, whereby all persons whatsoever, who are either in too low a way of dealing to become bankrupts, or not being in a mercantile state of life are not included within the laws of bankruptcy, are discharged from all suits and imprisonments, upon delivering up all their estate and effects to their creditors on oath, at the feisions or assizes; in which case their perjury or fraud is usually, as in case of bankrupts, punished with death.

INSOLVENT, a term applied to such persons as have not wherewithal to pay their just debts.

A person dying, and not leaving estate sufficient to discharge thee, is said to be insolvent.

INSPECTING field-officer of a District, in Military Language, denotes an officer, selected from the line, and nominated by the War-office, to superintend and to vouch for the faithful distribution of monies which are issued to officers acting on detachment, or on recruiting parties, within the limits of his station.

All district paymasters are strictly enjoined by the last general regulations to get their muster-rolls and pay-lists duly authenticated, not only before a justice of the peace, but to have them witnessed by the inspecting field officer. All the recruiting officers, &c. within the limits of the district are accountable and subordinate to the inspecting field officer. It is the duty of the latter to be particularly minute in his examination of every thing which appertains to the recruiting service. They have the command of all recruiting parties of regiments of cavalry and infantry in their districts; they are authorized to give an immediate approval of the receipts whom they judge fit for service, except in cases where regiments are to quartered, as to render it, in point of diliance, equally convenient for the recruits to be sent to their own head quarters.

The senior officer in each quarter is ordered to report to the field officer of the district. No officer is to leave his station even for one day, without reporting to the field officer who has the command of the recruiting parties in the district, or to be absent from it for more than one day, without the previous permission of the field officer. The field officers in their districts, are to be responsible for the credit, regularity, and good conduct of the officers, non-commissioned officers and private men of the several recruiting parties under their command. They are constantly to wear their uniforms, whilst in their districts, and they are to see, that his majesty's orders respecting the due observance of discipline, regularity, and uniformity of appearance among the officers, non-commissioned officers and privates, be strictly and unequivocally adhered to.

Field officers of districts may order detachment courts martial, to be composed of the recruiting officers in their districts, in the usual number and ranks, and they are to approve of every such court martial, and to direct the punishment awarded thereby to be executed, mitigated or remitted, as they shall think expedient. They are to receive orders from the inspector-general of the recruiting service, respecting the nature of their returns; and all returns and reports are to be come to the inspector-general through them.

Each district field officer has an allowance of ten shillings a day, in addition to the full pay of his respective regimental rank, and he is to be reimbursed for the actual expense he incurs for stationery and postage of letters; which charge must be accompanied by a certificate upon honour.

Each district field officer is allowed to appoint a subaltern officer (not employed upon the recruiting service) to act as adjutant in the district. The pay or allowance of such subaltern is three shillings a day in addition to his full regimental pay; he is also authorized to nominate two serjeants, with the additional pay of fixpence each, one to act as serjeant major, and the other as clerk to the district.

Each field officer may moreover give directions to the hospital mate, who is placed under his orders, to examine the recruits when brought for inspection, and to give such medical assistance as may be in his power, to the several recruiting parties in the district he belongs to.

When colonies of regiments take upon themselves the whole direction of the recruiting service for their own corps, they must conform to the regulations which require returns to be made to the inspector-general of the recruiting service; and they must instruct their officers to send weekly returns to the regulating field officer, in whose district they are stationed, of all the casualties that have occurred. See pages 105, 106, 107, and 118 of the General Regulations.

INSPECTION denotes examination, survey, and superintendence of general, regimental, and company duties. A general inspection is made annually by the reviewing generals of districts. Every regiment, on this occasion, is minutely looked into, and a faithful account must be delivered by each commanding officer of the actual state of his regiment, together with all the casualties that have occurred during the current
current year. The inferior economy of the corps is not
only investigated to the bottom, but the discipline of the
men is likewise examined. For a more particular explana-
tion of the latter, see Review.

Inspection, Regimental, is made once a month by the
commanding officer. The clothing, the necessaries, arms,
and accoutrements belonging to the different companies are
examined by the lieutenant-colonel or major of the corps.

Specific returns are made by the officers commanding troops
or companies, by whom the debts and credits of the men,
which have been made up and accounted for on the 24th day
in each month, in infantry regiments, and on the 24th day
in each second month in cavalry corps, are exhibited for ex-
amination at head quarters. This forms the ground-work
or basis of the general inspection, at which the troop or com-
pany book should always be produced.

Inspection, Private, of Companies, is the first step towards
the other two, and ought to be made every Monday morn-
ing, by each officer commanding a troop or company, or by
his tabernum.

Inspection of Necessaries is an examination of the different
articles which every soldier is directed to have in good repair.
The regular or established proportion of necessaries that
each soldier of cavalry and infantry is to be in possession of
on the 24th day of each month, to entitle him to receive the
balance that may be due to him, consists of the follow-
ing articles.

Cavalry.—3 shirts, 2 pair of shoes, 3 pair of stockings,
1 pair of gaiters, 1 forage cap, 1 faddle-bag, 1 pair of can-
vas, or woollen over-hose, 1 canvas, or woollen frock or
jacket, 1 stock, 1 black-ball, 2 brushes, 1 curry-comb and
brush, 1 mane comb and sponge, and 1 horse-picker.

Infantry.—3 shirts, 2 pair of shoes, 2 pair of stockings,
or 2 pair of socks, 1 pair of long gaiters, 1 forage cap, 1
pack, 1 stock, 1 black-ball, and 2 brushes.

Inspection, or Examination, Trial by. See Examina-
tion.

Inspector-General of Cavalry, a general officer,
whose particular duty is to inspect all cavalry regiments,
to report the state of the horses, and to receive specific accounts
from the different corps of their actual state; he communicates
with the commander-in-chief, and whenever a cavalry
regiment is ordered to be disbanded, it must be looked at by
the inspector-general before it is finally broken.

Inspector-General of the Recruiting Service, an officer of
rank, to whom the field officers of districts, and colonels
of regiments (when they personally manage the recruiting
service of their own corps) transmit their returns to the
adjutant-general's office. All recruiting parties which are
sent to the great manufacturing towns in England and
Wales, as also to Scotland and Ireland, must be previously
authorized to be done by the inspector-general.

Two field officers have been lately appointed as permanent
inspectors of clothing. These inspectors, or the inspectors for
the time being, are directed to view and compare with the
sewed patterns, the clothing of the several regiments of cavalry
and infantry, as soon as the same shall have been prepared by
the respective clothes; and if the said clothing appear to be
conformable to the sewed patterns, they are authorized to grant
two certificates of their view and approval thereof; one of
which certificates is to be delivered to the clother, to be
sent with the clothing to the head quarters of the corps, and
the other to be lodged with the general clothing board, as the
necessary voucher for paying the allowance of the allowance
for the said clothing.

All clothing must be viewed, and certificates be signed by

both inspectors, except in cases where the absence of one of
them shall be unavoidable; in all such cases the cause of such
absence is to be stated by the other inspector, in his certifi-
cate of the view of the clothing.

Inspectors of clothing are to follow all instructions which
may be transmitted to them from the commander-in-chief,
the secretary at war, or the clothing board.

Inspector of Hospitals, the next on the staff to the surgeon
general. Inspector, a person to whom the care and conduct
of any work is committed.

Inspectors, in the Roman Law, were such persons as
examined the quality and value of lands and effects, in order
to the adjusting or proportioning taxes and impositions to
every man's estate.

The Jews also have an officer, in their synagogue, whom
they call inspector, or, haansen. His business consists
principally in inspecting, or over-looking the prayers and lections,
in preparing and showing them to the reader, and in standing
by him to see he reads right; and, if he makes mistakes,
he is to correct him.

INSPICIENDO VENTRE. See VENTRE.

INSPIRATION, in Physiog, the act of drawing the
atmospheric air into the lungs. See LUNG.

Inspiration, among Divins, &c. implies the convey-
ing of certain extraordinary and supernatural notices, or
motion, into the soul: or, it denotes any supernatural
influence of God upon the mind of a rational creature,
whereby he is formed to any degree of intellectual improve-
ments, to which he could not, or would not, in fact, have
attained in his present circumstances, in a natural way.

If a man were instantaneous enabled to speak a language
which he had never learned, how possible forever it might
have been for him to have obtained an equal readiness in it
by degrees, few would scruple to say, that he owed his ac-
quaintance with it to divine inspiration. Or, if he gave a
true and exact account of what was doing at a distance, if
he published a particular relation of what he neither saw
nor heard, as some of the prophets did, all the world would
own (if the affair were too complex, and the account too
circuitous to be the refult of a lucky guess), that he
must be inspired with the knowledge of it; though another
account, equally exact, given by a person on the spot,
would be ascribed to no inspiration at all.

Thus the prophets are said to have spoken by divine
inspiration.

Some authors reduce the inspiration of the sacred writers
to a particular care of Providence, which prevented any
thing they had failed from failing, or coming to nought;
maintaining, that they never were really inspired, either with
knowledge, or explication.

According to M. Simon, inspiration is no more than a
direction of the Holy Spirit, which never permitted
the sacred writers to be mistaken.

It is a common opinion, that the inspiration of the Holy
Spirit regards only the matter, not the style, or words; and
this seems to fall in with M. Simon's doctrine of direction.

Theological writers have enumerated several kinds of inspi-
ration: such as an inspiration of superintendence, in which
God does influence and direct the mind of any person, as to
keep him more secure from error in some various and complex
difficulties, than he would have been merely by the use of his
natural faculties; plenary superintendence inspiration, which ex-
cludes any mixture of error at all from the performance of
superintended; inspiration of direction, where the facul-
ties act in a regular, and, as it seems, in a common manner,
yet are raised to an extraordinary degree, so that the com-
poser shall, upon the whole, have more of the true sublime,
or pathetic, than natural genius could have given; and in-
spiration of 
fugge toIon when the use of the faculties is 
superficial, and God does, as it were, speak directly to the
mind, making such discoveries to it as it could not otherwise
have obtained, and dictating the very words in which such
discoveries are to be communicated, if they are designed as a
message to others. It is generally allowed that the New
Testament was written by a superintendant inspiration;
for without this the discourses and doctrines of Christ
could not have been faithfully recorded by the evan-
gelists and apostles; nor could they have assumed the
authority of speaking the words of Christ, and evinced
this authority by the actual exercise of miraculous
powers; and besides, the faced writings bear many obvious
internal marks of their divine original, in the excellence of
their doctrines, the spirituality and elevation of their design,
the majesty and simplicity of their style, the agreement of
their various parts, and their efficacy on mankind; to which
may be added, that there has been in the Christian church,
from its earliest ages, a constant tradition, that the faced
books were written by the extraordinary affiliation of the
spirit, which must at least amount to superintendant inspira-
But it has been controverted whether this inspiration
extended to every minute circumstance in their writings,
so to be in the most absolute sense plenary. Jerom,
Grotius, Eразinus, Episcopus, and many others, maintain
that it was not; whilst others contend, that the emphatical
manner in which our Lord speaks of the agency of the
spirit upon them, and in which they themselves speak of
their own writings, will justify our believing that their in-
spiration was plenary, unless there be very convincing evi-
dence brought on the other side to prove that it was not:
and if we allow, it is said, that there were some errors in the
New Testament, as it came from the hands of the apostles,
there may be great danger of subverting the main purpose
and design of it; since there will be endless room to debate
the importance both of facts and doctrines.

What has been above denominated superintendant inspiration
in the language of Dr. Doddridge, Mr. Whitby ex-
presses it by inspiration of direction: and he thus distinguishes
it from the inspiration by 
fugge toIion. 1. Where there is no
antecedent idea or knowledge of the things written for the
good of others, to be obtained from reason or a former reve-
lution, an inspiration of fugge toIon must be vouchsafed to the
apostles, in order to enable them to make such things known
to the world. But where there is such an antecedent know-
ledge of the things to be indited, it can only be necessary
that God should immediately, or by some special occasions,
excite them to indite those things, and should so carefully
preclude over and direct their minds, whilst writing, as to fug-
gell or to bring into their memories such things as his wisdom
thought fit to be written, and should not suffer them to err
in the delivery of what was thus written in his name, or as
apostles of God the Father and our Lord Jesus Christ.
2. In all their revelations of 
fyeries, or things which could
not otherwise be made known to them, either by natural reason
or antecedent revelation, they must be acknowledged to have
had them by an immediate fugge toIon of the holy spirit.
3. As for those things which they did know already, either
by natural reason, education, or antecedent revelation, they
needed only such an affiliation or direction in them, as would
secure them from error in their reasonings, or in the con-
firmation of their doctrines by passages contained in the
Old Testament; and therefore a continual fugge toIon must
be necessary in this case. 4. In writing the historical parts
of the Old Testament, or matters of fact relating to them-
selves and others, it is only necessary, that that which is there
delivered as matter of fact should be truly performed, as it
is said to have been done; but it is not necessary that they
should be related in that order of time in which they were
performed, unless also that be affirmed of them; for this
must be sufficient to assure us of the truth of what they thus
delivered. Moreover, in writing the discourses contained in
these books, it is not necessary that the very words should
be fugge toIon or recorded, in which they were first spoken,
but only that the true intent and meaning of them should be
related, though in diversity of words; though the promise
made to the apostles by our Lord, that the holy spirit should
bring to their remembrance all things which he had told
unto them, doth fairly plead for this exactness in what they
have delivered of our Saviour's sermons; it being fearlessly
imaginable their memory, without divine affiliation, should
exactly give us all that was spoken in such long discourses.
Lastly, it appears, says Dr. Whitby, that I contend only
for such an inspiration, or divine affiliation, of the faced
writers of the New Testament, as will assure us of the truth
of what they write, either by inspiration of fugge toIon or
direction only, but not for such an inspiration as implies,
that even their words were dictated, or their phrases fugge to
Ion to them by the Holy Ghost. Dr. Whitby cannot allow,
1. For any slips of memory in the compilers of the faced
books of the New Testament; for though these are allowed
by some in matters of small conseqnece, as they are pleased
to style them, yet it is of great conseqnece that we do not
believe them; for, if you grant they have slipped at all, by what
rules can we affirm that they have not slipped above an
hundred times, or even in most of their historical relations?
2. He cannot grant, that the apostles determined any matters
of practice merely from rules of human prudence, without
the guidance and direction of the holy spirit. 3. Dr. Whitby
does not allow that St. Paul doth not always use the best
arguments, but such as are best fitted to the capacities and
notions of those to whom he writes: if so, by what rules
shall we be able to distinguish betwixt his arguments, on
which we may safely rely, as being absolutely true, and those
which are only accommodated to the notions of those with
whom he had to do?

Dr. Whitby next proceeds to lay down the arguments
which prove, that the apostles were affihted and preferred
from error by the spirit of God, and were enabled to deliver
to us an unerring rule of faith. These arguments are the
following: 1. Their affirmations concerning their own writ-
ings, and what they say respecting the declarations made
in the doctrines delivered, and the directions given in them.
2. The things which God spake to his servants the proph-
ets are styled the things which I command by my spirit.
(Zech. i. 6.) 3. The apostles were thus affihted. Peter
says they preached the gospel by the Holy Ghost sent down
from heaven; they spake as they were moved by the Holy
Ghost; they spake themselves prophets and apostles; they
challenge a like illumination with the ancient prophets:
they pretend to teach others in words taught them by
the Holy Ghost. In all these sayings they must have been guilty
of a false testimony concerning God, and must impugn upon
the church of Christ, if no such affiliation of the holy spirit
was imparted to them. 3. The infallible affiliation granted
to the apostles is inferred from our Saviour's promise to
them, repeated on different occasions. 4. The faced
records were to be a standing rule of faith through all ages;
and therefore in all things propounded in them to our faith,
they
Inspiration.

They must contain a divine testimony, or a revelation of the will of God. 5. That the apostles and writers of the New Testament were inspired both in their preaching and writing by the spirit of God, is attested by Christians of all ages from the beginning.

Dr. Benson, in his "Dissertation on Inspiration," published in his "Commentary on the Epistles," and included in bishop Watton's "Collection of Tracts," observes, that many of the difficulties and objections that have been raised concerning inspiration have been very much owing to the mislaid accounts given by some of the friends to revelation. What he takes to be the genuine account, appears, at first view, easy and natural, and also, upon examination, the most unexceptionable. It is this: as Moses retained in his mind the perfect and entire idea of the pattern shewn him in the mount, according to which model he was to make all things; so the apostles, and they alone, had in their minds the full and complete scheme of whatever they were to preach or write concerning the Christian doctrine. And according to that model they were to found and erect the Christian church. Not that they had the whole scheme of the Christian revelation in its utmost extent fully communicated to them at once, the contrary of this is evident; for on the day of pentecost, the twelve apostles of the circumcision do not appear to have received any more than the revelation of that gospel, which they were to preach to Jews only. It was some years after that they had the particular revelation concerning their going to the devout Gentiles, and concerning the gospel which they were to preach to them; and it was a long time before the particular revelation was communicated to the apostles of the uncircumcision, concerning their going among the idolatrous Gentiles, or what gospel they were to preach to them. And finally, different apostles of both classes had, besides the general scheme, different revelations communicated to them. What is meant is this, that they had by immediate revelation the whole scheme of what they were to preach to the Jews, before they addressed themselves to the Jews; and the whole scheme of what they were to preach to the devout or idolatrous Gentiles, before they addressed themselves to devout or idolatrous Gentiles; and that they retained in their minds coextensively the complete idea of the whole scheme, after it was communicated to them. From this coextensive fund of knowledge, they were enabled clearly to determine (as far as any case required) what was, or was not, the Christian doctrine. This revelation of the whole scheme of the religion of Jesus is, as Dr. Benson apprehends, what St. Paul understood by the word of wisdom, which stands first in the order of spiritual gifts; 1 Cor. xii. 8. Though the evangelists and prophets had some of the inferior gifts of the spirit, yet it was what they had received from the apostles, that they were to teach and to commit to faithful men, who were to teach others. The Old Testament prophets were not under a coextensive divine inspiration, unless we except Moses during the time in which he was exciting all things, according to the pattern shewn him in the mount: but the apostles had this fund of illumination coextensively residing within them, from the time of its being communicated to the end of their lives. Christian prophets, being of an order inferior to the apostles, were neither under coextensive inspiration, nor had they at any time any more than particular revelations, relating to particular causes. Dr. Benson supposes, that the books of the New Testament derive their infallibility from their being written, taught, reviewed, or approved of by some of the apostles, who alone had this fund of knowledge coextensively residing in them. Whenever, therefore, they spoke or wrote concerning Christianity, this fund of revelation kept them right. But they were reasonable creatures as well as inspired apostles, and therefore could speak or write about common affairs, as men that have the use of their reason, without any inspiration, can easily do; infinences of which frequently occur. Upon this system, such things only are ascribed to inspiration, as (all circumstances considered) required inspiration; and such things to human reason, as human reason alone was capable of.

It appears by citations from the writings of the primitive fathers, Clemens Romanus, Polycarph, Justin Martyr, Clemens Alexandrinus, Origen, Tertullian, &c., that most of them maintained the plenary inspiration of the sacred writers, and particularly of the apostles. This kind of inspiration some have conceived necessary to indicate the credibility of the doctrines and the authority of the precepts which they delivered under a divine commission. Others, however, have objected to this plenary inspiration; and allege mislakes and contradictions which occur in the history of their conduct and in their writings, see Matt. xix. 19, 23; Mark, xiii. 11; compared with Acts, xxii. 6-9.

It has been said that the apostles did not seem to apprehend each other to be inspired, and appears by their debates with each other in the council at Jerusalem (Acts, xv.), and by Paul's blaming Peter (Gal. ii. 14); and it is farther urged, that the Christians in those early days did not apprehend them to be infallible, since their conduct was in some instances questioned and arraigned. (Acts, xii. 2, 3. xxi. 20-24.)

It has been also said, that Paul, who affords himself to have been inferior to none of the rest of the apostles (2 Cor. xi. 5. xii. 11.) speaks of himself in such a manner, as plainly to shew that he did not apprehend himself under such a plenary inspiration (1 Cor. vii. 10. 25. 40. 2 Cor. xi. 17.) nor do we find that any of the apostles introduce their disputes with such phrases as the prophets used, to declare that they spoke as the oracles of God. To this objection, however, it has been replied, that their distinguishing in the cases here referred to seems strongly to imply, that their decisions in other points of doctrine and duty were by "immediate revelation from Christ." It has been also pleaded, against the plenary inspiration above stated, that it is inconsistent with that diversity of diction or style which occurs among the sacred penmen. Is not the style, it is said, of all inspired writers the same, as being the style of the same spirit by which they were alike directed? It is argued on the other hand, that in some sense the style of all those writers is the style of the holy spirit, who spoke by them, and was the same in them all; but that the holy spirit should always employ the same style in conveying celestial truths to men, is no more necessary than that he should always use the same language. We have no reason to doubt that the sacred writers were permitted to employ the style and idiom most familiar to them, in delivering the truths with which they were inspired. So far only were they over-ruled in point of expression, by the divine spirit, that nothing could be introduced tending in any way to obstruct the intention of the whole. And sometimes, especially in the prediction of future events, such terms would be figured as would, even beyond the prophet's apprehension, conduct to further that end. But this doctrine, it may be said, is liable to an objection from the gift of tongues conferred on the apostles and others for the promulgation of the gospel. In the languages with which those primitive minimiers were miraculously furnished, it may be objected they could have no style of their own, as a style is purely the effect of habit, and of inflexible imitation. This objection, however, is easily obviated: 11. as they received by inspiration these tongues only of which they had previously no knowledge, it is not probable, at least it is not certain, that this gift had any place in the writings of the New Testament.
In the first place, we must not give a wrong notion of inspiration, as Christ himself has done in saying, "Ye also shall bear witness, because ye have been with me from the beginning." (John, xvi, 27.) And no one that attempts to convince an unbeliever of the truth of Chrillianity, would begin his demonstration by pre-supposing a doctrine which has adversary does, but would ground his arguments on the credibility of the evangelists as human historians for the truth of the miracles, the death and the resurrection of Christ. Even those who examine the grounds of their faith for their own conviction, must treat the evangelists as human evidence, since it would be arguing in a circle to conclude that the facts recorded in the gospels are true, because they are inspired, when we conclude the scriptures to be inspired in consequence of their contents. In these cases, then, we are obliged to consider the evangelists as human evidence, and it would be no detriment to the Christian cause to consider them at all times as such in matters of historical fact. We find it nowhere expressly recorded that the public transactions which the apostles knew by their own experience, and of which St. Luke informed himself by diligent inquiry, should be particular objects of divine inspiration. We should even be considerable gainer, in adjusting the harmony of the gospels, if we were permitted to suppose that some one of the evangelists had committed an immaterial error, and that St. John has rectified some trifling mistake in the preceding gospels. The most dangerous objections that can be made to the truth of our religion, and such as are most difficult to answer, are those drawn from the different relations of the four evangelists. Mr. Kiddle, in the beginning of the second section of his "Essay on Inspiration," entertains sentiments similar to those of Michaelis; now, if we advert to the sentiments of Grotonius, already recited, and which gave rise to the famous theological disputes between the Dominicans and the Jesuits, will the distinction between the inspiration of the historical books, and that of the epistles, appear to be new? As to the writings of those that were apostles, Michaelis maintains that their inspiration depends on their authenticity. If they are written by the apostles, to whom they are ascribed, we consider them as divinely inspired: if not written by apostles, they can make no pretension to inspiration. But it may be asked, on what argument the position is grounded, that the writings of the apostles are inspired, if genuine? It is answered, on the testimony of Christ and his apostles, which is credible and facer, because they have confirmed their doctrines by numberless miracles. But, where is this evidence recorded? It is certain, in the first place, that the apostles must be regarded not only as prophets, but as greater than prophets. (Mark, xix, 11.) Again, we consider whether the more immediate promises of inspiration to the apostles, we shall find that he has given them, in the most proper sense of the word, at three several periods: 1st, when he sent the apostles to preach the gospel (Matt. x, 19, 20); 2dly, in holding a public discourse relating to the gospel, at which was present a considerable multitude (Luke, xii. 11, 12.); 3dly, in his prophecy of the destruction of Jerusalaem. (Mark, xiii, 2. Luke, xxi, 14, 15.) It is true, that when we argue from their inspiration on these occasions to the inspiration of their writings, we draw a conclusion "a minore ad majus," but it is a conclusion to which no rational objection can be made; for if were to expect inspiration for those speeches and answers, which were only temporary, and in which they appeared rather as advocates than teachers, how much more reason had they to expect inspiration in these writings which were to serve as a standard of faith to posterity? Michaelis conceives, that Christ alluded to the future writings of the apostles, when he said to Peter, "Thou art Peter" (i.e. a rock), &c. Another promise, first given to Peter, and afterwards extended to all the apostles,
the knights of the Garter are placed in their rank, in the chapel of St. George, at Windsor; and on many other like occasions.

INSTANT, such a part of duration, wherein we perceive no succession; or it is that which takes up the time of only one idea in our minds.

The schoolmen distinguish three kinds of instants; a temporary, a natural, and a rational instant.

INSTANT, Temporary, is a part of time immediately preceding another; thus, the last instant of a day precedes immediately and really the first instant of the following day.

INSTANT, Natural, is what we otherwise call a priority of nature, which obtains in things that are subordinated in acting; as, first and second causes; or causes and their effects for the nature of things requires, that if there be a second cause, there must be a first; and that there must be a cause, if there be an effect.

INSTANT, Rational, is not any real instant, but a point which the understanding conceives to have been before some other instant, founded on the nature of the things which occasions it to be conceived. For instance, as God has made several things voluntarily, which he could otherwise have not alone; there is a reasonable foundation to conceive God, such as he is in himself, before he had made any of those voluntary determinations; but as there was no real instant when God had not formed any determination, this instant is called a rational instant, by way of opposition to an instant of time.

INSTANTANEOUS Action. See Action.

INSTANTER, Trial, in Law. See Receipt.

INSTAURATION, the re-establishment, or reformation, of a religion, a church, or the like, to its former state.

The word is by some derived from the old Latin instaurum, which signifies the flock of things necessary for the tilling and managing of grounds; as cattle, tools, harnesses, &c. The word instauratio is only of the middle age; but instauratio is of much greater antiquity, and by some is derived from instar, like; as importing a thing's being brought to its former likeness or appearance.

INSTEP, in the Mango, is that part of the hinder leg of a horse which corresponds to the flank in the fore-leg, extending from the ham to the pattern joint.

INSTEBURG, in Geography, a town of Prussia, Lithuania, containing two churches, about 3500 houses, and 3000 inhabitants. The principal articles of its trade are corn and beer; 44 miles of Konigberg. N. lat. 54° 55'; E. long. 22° 21'.'

INSTINCT, a natural disposition, or fagacity, whereby animals are enabled; and by virtue whereof they are enabled to provide for themselves, and know what is good for them, and are determined to preserve and propagate their species.

The term instinct, however, has been variously explained and defined. Instinct, according to Dr. Reid, is a natural blind impulse to certain actions, without having any end in view, without deliberation, and very often without any conception of what we do; and he considers instinct as one species of the mechanical principles of action, the other being habits. An ingenious writer, of whose observations we avail ourselves in the compilation of this article, defines instinct to be a tendency implanted in the minds of animals, when under the influence of certain feelings or sensations, to perform spontaneously, unerringly, independently of all teaching and experience, and without any determinate view to
to consequences, certain actions necessary for the preservation of the individual and the continuation of the kind.

Instinct in brutes bears some analogy to reason in men. There have been many systems adopted to explain the principles which produce and direct the spontaneous actions of brute animals.

Many of the ancient philosophers ascribed to brutes an understanding differing only in degree from that of man, and attributed their inferiority to the want of proper and sufficient bodily organs. This system has been very strenuously supported by M. Helvetius, de L'Epreu, tom. i. p. 2 &c. Among the moderns the learned Cadworth endeavoured to explain the instinct of animals, by means of a certain plastic nature. Des Cartes thought that all the actions of brute animals might be explained by the simple laws of mechanism, and considers them as machines totally devoid of life and sentience, but so curiously constructed by the Creator, that the mere impressions of light, sound, and other external agents, on their organs, produced a series of motions in them, and caused them to execute those various operations which had before been ascribed to an intellectual principle of life and spontaneity. But the actions and manners of animals, which are totally incompatible with the mere principles and laws of mechanism, evince the absurdity of this opinion. The dogma of Des Cartes is said to have been first introduced by Perercedes, the master of Pythagoras; and though Des Cartes had the merit of developing and applying this hypothesis, the doctrine was before published by the Spaniard Pereira. M. Buffon adopts the opinion of Des Cartes in part, but grants brute animals life, and the faculty of distinguishing between pleasure and pain, together with a strong inclination to the former and aversion from the latter. By these inclinations and aversions he undertakes to account for all, even the most striking operations of animals; affirming, that, in consequence of impressions made on the brain, by means of the sensitive organs, and by the re-action of the brain and nerves on the muscles, these machines acquire a motion conformable to the nature of the animal, and of the impressions of the different objects which act upon their organs, and excite desire or aversion. See BRUTES.

The pre-established harmony of Leibnitz has also been applied to explain the actions of brute animals. Others have considered the actions of animals as produced by the constant and immediate influence of the divine energy, directing all their inclinations and motions: such appears to have been the opinion of Mr. Addison, in the second volume of the Spectator. The late ingenious Hermann Samuel Reimair, professor of philosophy at Hamburg, has enumerated and expounded these and other opinions, with regard to the instinct of animals, in his Observations Physiques, &c. published in two vols. 12mo. at Amsterdam and Paris, 1772: and, defining instinct, in the most comprehensive sense of the word, to be every natural inclination, accompanied with a power, in animals, to perform certain actions, divides instincts into three heads. The first, which he calls mechanical instincts, belong to the body considered as an organized substance, and are exercised blindly and independently of the will of the animal. Such are those which produce the motion of the heart and lungs, the contraction and dilation of the pupil, digestion, &c. The second class of instincts is ascribed in common both by men and brutes, and in some measure even by vegetables. The second class comprehends those which he terms representative instincts, which consist partly in the power of perceiving external objects by their present impression on the senses, and partly in the faculty of rendering the ideas of these objects present to the mind by the powers of imagination, or of memory, in a lax sense of the word. There are common to men and other animals, excepting that brutes possess only the faculty of imagination in common with us, and not that of memory, in the strict and proper sense of the word. Indeed this author endeavours to prove, that the knowledge of brutes does not merely differ in degree from that of man, but that it is of a kind entirely different from it; and that they are incapable both of memory and reasoning; the faculty of imagination serving to give them a confused idea of events that are past, by the view, or other impressions of objects that are present. The third and principal class of instincts is that which comprehends all those which M. Reimair calls spontaneous. This species of instinct is not attended with any power of reflection, determining the animal to decide freely between two different modes of action, present to his imagination; nor is it merely corporeal or mechanical. It is put into action by the natural and primitive principle of welfare, implanted in all animated beings; or by a love of pleasure and aversion to pain, producing a voluntary inclination to perform certain actions which tend to their well-being and preservation. To the performance of these actions they are particularly prompted by their present sensations, by imagination supplying the place of memory, and by other canes. The wonderful effects produced by these instinctive appetites, are farther to be attributed to the exquisite mechanism in their bodily conformation, particularly in the structure of the various organs with which they execute their operations, and to the superior perfection and acuteness of their external senses, by which they are quickly and distinctly informed of those qualities of objects which most materially concern them. In order to account for the more curious and surprising operations of brute animals, M. Reimair adds two other principles, viz. 1st, an internal instinctive perception of the precise power and proper use of their various bodily organs, together with the infant knowledge of the qualities of those objects around them in which they are interested; and, 2dly, certain innate and determinate powers and inclinations, impressed by the Author of nature, à priori, on the soul itself; by which they are arbitrarily, and without their own knowledge or consciousness, directed and irresistibly impelled to the performance of these various operations which they execute with such unerring industry and art. These determinate forces, which constitute the principal part of M. Reimair's system, are no where so visible and distinguishable as in that numerous set of instincts which he classes under the title of the indiffusive instincts of animals. For a farther account of this system we must refer to the work itself, or to an abstract of it, with several of the author's illustrations, in the Monthly Review, vol. xiv. p. 535, &c.

The majority of philosophers, even in Des Cartes's time, maintained, that the actions of the brutes were merely instinctive, and not mechanical. This prevailing sentiment was altered a little by a wrong application of the principles of Locke. But the balance was soon afterwards restored to its former preponderance in behalf of instinctive principles, by the writings of lord Shaftesbury and Dr. Hutcheon; and still more particularly by those of Dr. Reid. Some authors, who, with Locke, reject innate notions and innate principles, both speculative and practical, allow that the mind acts sometimes instinctively; others, who reject Locke's ideal theory altogether, detail a great number of instinctive ideas of the mind; whilst a third class of writers will have the actions, that have been generally denominated instinctive, to be either habitual, associated, or mechanical. Nor does the matter rest here: for some authors of a very modern date go so far even
as to maintain that the word instinct is unphilosophical; since all that has been referred to this principle, whether in man or in the brutes, may be the result of experience, or of imitation.

Some writers confound the actions that have been generally deemed instinctive with those that spring from reason; some with those that spring from mechanism; and others with such as spring from habit and association. But it is easy, we think, to distinguish them from each and all of these, by pointing out actions which differ from such as are called rational, habitual, or mechanical. An action is called rational when it is performed under the influence of a motive; that is, with a view to consequences: Thus, to worship the Deity for having created us, for his goodness towards us, and that he may reward us hereafter, is a rational action. Some are of opinion that the motive, or the end we have in view in our rational actions, is the cause of these actions; but for our part, as we think that the human mind can act not only in opposition to the strongest external motives, but again all external motives whatever, properly so called, we cannot help thinking it more correct to call them simply inducements, and to consider the mind itself solely and properly as the cause. Mechanical actions also have a cause: as well as those that are rational; namely, mechanism or organization. But this cause is not an end proposed, or a motive; neither is it an inward feeling, disposition, or sensation: Thus a clock goes through its course of hours, minutes, and seconds, without a view to consequences, without spontaneity, and even without being able to check its own action. To this class belong the actions of the heart and arteries, the vermicular action of the intestines, and those of secretion and respiration in animals. In instinctive actions may be traced to a cause as well as both the preceding; but this cannot be referred to the clas of motives, as they are not performed with a view to consequences; neither can the cause be said to be mechanical, as they are accompanied with spontaneity. The proper cause, however, is the internal feeling, sensation, or disposition, that leads to the performance of them, without design or intelligence, on the part of the animal. Thus an infant, in a few minutes after birth, seems the breast without any knowledge whatever of its necessity for its preservation; and a pair of young birds, without teaching or experience, build their nests with as much skill and exactness as the oldest of their tribe could do; and that, too, of the customary materials of their species, and in the situations best calculated for depositing and hatching their eggs. Ininstinct and mechanism have been oftener confounded with each other, particularly of late, than any other of those principles of action which we are considering; and yet we cannot help thinking that the distinction between habit and instinct will not appear so palpable as thefe we have already made, particularly as some habits are formed at so early an age that it is very difficult to al certify whether the actions that spring from them are from habit or from nature. But supposing each a principle as instinct, such as we have described it, the actions that spring from it must differ from such as are habitual in this, "that the former must be from nature, and the latter acquired." Habit has been defined to be a facility of doing, and not only a facility, but also a proneness to do certain things from having done them frequently before. This definition, however, is manifestly not applicable to habits of art, but only to such as can be properly called principles of action. (See HABIT.) Instinctive actions agree with habitual ones of the latter kind in this, that they are both performed without intelligence, will, or design; and this has accordingly induced Dr. Reid to confound them, and to class them, very improperly we think, under the head of mechanical actions.

Their agreeing in a few particulars could not warrant him in reducing them to the same class, particularly when he tells us himself, that the origin of one is natural, of the other acquired." But, besides this, the habitual actions of man seem to want altogether that spontaneity which we observe in the instinctive actions of the other animals; such as building, for instance, and the operations of bees, described in a subsequent part of this article, or the migrations of birds of passage through the pathless air without chart or compass." One infatnce of an action confoundedly habitual will illustrate this more fully. Let us take that motion of the eye-lids which occurs almost every instant. This action cannot be the necessary result of mechanism, as we see that children do not, for some days after birth, close their eye-lids on the approach of external objects. But as soon as some object (suppose too much light) has made them feel inconvenience or pain, and thus produced a voluntary or mechanical motion of the eye-lids, this effect becomes gradually so intimately associated with its cause, that even the appearance of the candle will produce the effect. And, finally, habit gives us so great a proneness to this action, that we perform it constantly, amidst all our occupations, without consciousness, will, or spontaneity; and even without perceiving that, in every waking minute of our lives, we are several moments totally in the dark. And so far is this motion from being a voluntary act, that it requires a strong exertion of will and attention to check it, even for a short time; but do what we will, we can never check it altogether. To avoid being misunderstood, it will be necessary to illustrate more fully the distinction between habits of art, in which we acquire a facility only from frequent practice, such as playing expertly on the violin or harpsichord, and those habits, which, besides a facility, induce also a proneness to act; for instance, in that motion of the eye-lids just described, and many other awkward motions and habits learned from bad example and bad company. This is the more necessary, as it has not been illustrated sufficiently by any author with whom we are acquainted; and forcibly calls on us to collect the words of a French writer, who remarks: "Tout ce tient dans un certain ordre de spéculations: Voulez vous développer une vertu? Il faut en éclaircir un autre, qui l'avoit enfermé, ont, dont la lumière vient, pour ains dire, l'éclairer par réflexion." Habits of the latter kind may be properly called principles of action; habits of art cannot. These require thought, attention, and will in the performance of their operations; whilst the others require no small exertion of thought, attention, and will to check them. Nor can they, even thus, be completely overcome, until, by repeated exertions, a counter habit is established, which is the best way to obviate their effects. It was this that made Dr. Reid say, "I conceive it to be a part of our constitution, that what we have been accustomed to do we acquire not only a facility, but a proneness to do on like occasions: such that it requires a particular will or effort to forbear it, but to do it, requires, very often, no will at all. We are carried by habit, as by a stream in swimming, if we make no resistance." Dr. Reid distinguishes these two species of habits as we do; but in some passages he seems to confound them, for he classifies them and instills under the head of mechanical principles. Thus, he says, "Habit differs from instinct, not in its nature but in its origin; the latter being natural, the former acquired. Both operate without will or intention, without thought, and therefore may be called mechanical principles." (See HABIT.) From both these passages it would seem that he meant habit in general; for the allusions are not qualified in any shape. If such was his opinion, his doctrine agrees exactly with that of Dr. Hartley, whose language affords
no opportunity for being in doubt about his meaning. But, for our part, we cannot help thinking it more philosophical to admit any possibly conceivable rapidity in our intellectual operations, than to suppose, that any action performed with so much correctness, and with such rapidity, as violin and harpsichord playing in some instances, can be merely habitual, or automatic; that is, in every one of its minute sub-divisions altogether disconnected with the exertions of the will. In habits of art, then, we deem it more correct to admit the interference of the will; but in the other cases, which only, because they give not merely a facility, but also a proneness to act, ought to be called principles of action, we see no reason for admitting its interference in any respect. A different opinion seems to be maintained in a late elegant treatise, for whose author we have a high respect. Upon this we shall offer a few remarks; but we have not as yet done with Dr. Reid. After having attentively examined what he has written on this subject, we do not think that he intended to include habits of art in the passages cited above. Surely to confect an observer of nature could not think, that in habits of art, such as playing the violin and playing the piano, we acquire, from frequent doing, "not merely a facility, but also a proneness to do the same thing on like occasions." In all habits of art we acquire more or less of facility, but surely no proneness, as Dr. Reid affords of the habits he had in view in one of the passages cited above: for who can affect with any truth, that a violin-player feels a particular proneness, or inward impulse, to play upon that favourite instrument, as often as it is presented to him? And yet he has acquired a facility in playing, from having often played before. The truth seems to be, that Dr. Reid, after laying the distinction of habits already mentioned, threw the habits of art into the back ground altogether. This, indeed, is strongly confirmed by the circumstance, that in the essay and chapters to which we allude, he treats only of what can be called principles of action, which he defines to be "every thing that incites us to act;" and particularly when he tells us that habits of art, since they give only a facility, cannot with propriety be called principles of action. "Habit," he says, "is commonly defined a facility of doing a thing, acquired by having done it frequently. This definition is sufficient for habits of art; but the habits which may, with propriety, be called principles of action, must give more than a facility, they must give an inclination, or impulse, to do the action; and that, in many cases, habits have this force, cannot be doubted." It deserves to be remarked, that in this passage he does not say, that habits give a proneness (in his own words, an inclination or impulse) to act in every case, which he should have done, if he meant to bring habits of art under the observation. He only says, "that habits give an inclination or impulse in many cases," which seems to prove, that he meant only "those habits, which may, with propriety, be called principles of action." This opinion is fully further strengthened by the following extract: "Aristotle makes wisdom, prudence, good sense, science and art, as well as the moral virtues and vices, to be habits. If he meant no more, by giving this name to all those intellectual and moral qualities, than that they are all strengthened and confirmed by repeated acts, this is undoubtedly true. I take the word in a less extensive sense, when I consider habits as principles of action. I conceive it, &c." (as quoted above.) In this extract he tells us, that he takes the word habit in a confined sense, meaning only such habits as he calls principles of action. And he has already told us, that habits of art do not come under that denomination. If the latter part only of the paragraph be attended to, it seems to shew that Dr. Reid held the same opinion on this point with Hartley; but if the whole be taken together, and interpreted with fairness, and considered in connection with our remarks on the subject, we think it will appear more probable, that Dr. Reid meant only a particular species of habits, those which he calls principles of action, and that he did not intend to characterize such habitual actions as violin and harpsichord-playing, as involuntary and mechanical. It must not be concealed, that professor Stewart of Edinburgh seems to think otherwise of Dr. Reid's meaning; and that he has proved, partly in consequence of that opinion, that some of our habitual actions are under the guidance of the will. From the preceding remarks it will appear, that our opinion differs not from the learned professor's, if he means only habits of art: but if he means to bring the other classes of habits under the influence of the will, (as it is probable he does, for he talks of habitual actions in general, and does not even hint at a distinction,) we cannot help thinking, as even analogy itself affords no support to this opinion, that he was swayed too much by an over-ardent zeal for premature generalization. It deserves to be remarked, as an additional proof of the fairness with which we have interpreted Dr. Reid's opinion, that he says nothing of habits of art in his chapter on habit, except mentioning one solitary instance, merely to shew "the power of habits and their utility:" whereas he expressly mentions, as beloning to that species which he calls principles of action, many "awkward habits in address, motion, looks, gesture, and pronunciation, acquired by frequenting bad company; to forbear which, when fully formed, a general resolution (he says) is not sufficient." He even affirms, that particular attention is necessary, on every occasion, to reftir their impulse, until they be undone by the habit of opposing them; 

"those habits operate without intention." It is remarked by professor Stewart, on the subject of habitual actions, "that the circumstance of our inability to recollect our volitions does not authorize us to dispute their possibility." To this observation we have no objection; but when he further contends "that it does not add any force to the objection, to urge, that there are instances in which we find it difficult, or perhaps impossible, to check our habitual actions by a contrary volition;" we must remark, that this very circumstance, since it has not been obviated, renders the objection inapplicable, and the doctrine against which it militates, so far as that relates to the species of habits which we have called principles of action, altogether inconclusive. Let any one try, by the most firm and persevering efforts, to check for a short time the most common of all habits, that of coughing the eyelids, and he will find, though he may succeed for a few moments, that he cannot do so altogether. Nor is it an answer to this fact to say "that the contrary volition does not remain with us steadily, during the whole operation; but is merely a general intention, or resolution, which is banished from the mind as soon as the occasion presents itself, with which the habitual train of our thoughts and volitions is associated." For the time requisite for trying this experiment, and being defeated in it, is so very short, that the contrary volition may be easily kept in view, all the while, without its dwindling away into a general intention or resolution; and besides, if the person who tries the experiment, thinks that he is unable to keep up the counter-volition steadily himself, he can easily have an affiant or two, to fit near him, and remind him to keep his thoughts and attention fixed upon the object in view. Some may perhaps urge that this motion of the eyelids is infallible; but by the learned professor himself it is allowed to be habitual. We may besides remark, that there is a wide difference between our being unable to recollect the volitions, which in this theory are supposed to precede all our habitual actions,
and that rate of mind in which we are not only not conscious of any such volitions, but fully aware that the habitual actions occur, even when we are conscious of having exerted the strongest efforts of volition to prevent them. But to conclude this preliminary, but necessary, discussion, we may, by way of recapitulation, observe, if the exhibition we have been giving be correct, that the difference between the four species of actions under one consideration converges nearly in the following circumstances. That *rational* actions are done with intelligence, will, and design on the part of the agent; *intuitive* actions spontaneously, but with no proper intelligence or design in the doer; *mechanical* actions without will, spontaneity, design or intelligence; and *intellectual* actions, like mechanical ones, (we mean the habits that may be properly called principles of action,) without spontaneity, design, or intelligence; but differing in this, that they are accidental in their origin, and in many instances capable of being checked and even removed by contrary habits; whereas *mechanical* actions, properly so called, are in a manner necessary in their origin (for instance circulation, secretion and respiration in animals), and can never be removed or supplanted altogether, without the destruction of the animal, by any voluntary effort of ours.

As we are of opinion, that the origin at least of some of the actions of man cannot be explained, unless we admit the existence of such a principle as instinct, it becomes necessary to consider some of those actions of the lower animals, which are generally allowed to be instinctive. This step is the more necessary, as the existence of instinct, even in the lower animals, seems of late to have been wholly denied, since it has been asserted, in a "New System of the Natural History of Animals," published in Edinburgh, in 3 vols. 1777, by Mr. Hill; and "that the laws of analogical reasoning do not justify the opinion, that the brutes act, on any occasion, absolutely without design." While, on the other hand, it has been maintained by Mr. Smellie, in his "Philosophy of Natural History," "that between reason and instinct there is no difference, and that the reasoning faculty is itself the necessary result of instinct." Nothing can be more directly opposite than both these opinions; and like most extremes, nothing can be more easily shown to be false. To prove that some of the natural operations of the lower animals are not performed with design, or with a view to consequences, in opposition to the former, many examples will not be necessary; and first, let us attend to the operations of the winged tribe. The young of pair of birds, it is known, without instruction or experience, build their first nests of the materials commonly used by their species; in situations, whose privacy, &c. render them fit to afford them security, and convenient for incubation and the rearing of their young. It is also certain, that they flew equal skill with the oldest and most practiced of their tribe, in the neatest, accuracy, and symmetry of their work. It is further known, whenever the climate or situation, or any change of circumstances renders a change in the structure of nests necessary, that this change is made by all the individuals (young and old) of the same species equally, and that only when such a change is necessary. Thus, "in countries infested with moths, many birds, which, in other climates, build in bushes and crevices of trees, suspend their nests upon slender twigs, and, by this ingenious device, elude the rapacity of their enemies." It is moreover certain, that no improvement has been made, within the memory of man, in the art of nest-building, by any tribes, or by any of its individuals. Now the nature of all the arts with which we are acquainted is such, and their history shews us, that they were first invented by some person, and then improved in the course of time, either by the inventor or by others, and finally brought to some degree of perfection. History and experience also shew, that human arts are both known and practiced with most skill and dexterity in general, by those only to whom they have been taught; and that in different ages and countries they all undergo considerable variations. But in the arts of animals we observe no such variations; nor can any individual be pointed out as the inventor, the improver, or the perfector of any of them; for instance, of nest-building. Each of them is perfectly skilled in the workmanship of its tribe; we do not say that they know the nature and the rules of the different arts which they practice; but that they are acquainted with the mode of working in them to perfection. How many very simple arts do we daily see practiced by our species, without being able to practice them, or learn them ourselves. What a long apprenticeship is generally necessary before we can practice even some of the most common and necessary. A peasant spends months and years under his simple roof, and yet is not able often to build such a hut as he inhabits. Birds require no such teaching or experience: they served no apprenticeships; and yet a pair of young birds kept solitary and unfettered from their infancy, build exactly such another nest as that in which they themselves had been brought into life. But what is the inference to be drawn from these facts? If the natural actions of the lower animals, for instance this of nest-building, be all under the influence of motives, in other words, *rational,* we must conclude, since they are so variable, either that their workmanship is perfect beyond the reach of improvement, or so imperfect as not to be capable of degenerating. The former of these conclusions cannot be supported, unlefs it be contended at the same time, that the lower animals have made more early and greater discoveries and advances in the arts and sciences than we have. Nor will the latter be maintained by any man, who considers the structure of a honey-comb, or who reflects, that all the skill of man has never yet excelled the workmanship even of a worm in the structure of such a nest as he builds. However, if the supposition be admitted, the former seems the better inference. But, if this doctrine be true, we must say, that birds are good judges of climate and circumstances; that they know the dangers and advantages resulting from them, and the best methods for obviating the former and securing the latter. We must say, that reasoning shews them the necessity of equality in the structure of their nests; or when, after having been absent for some time, they turn their eggs so as to heat them properly, and at all times equally, we must think, that they know heat, and even an equal distribution of it, to be necessary for incubation. But as none of these can, we think, be affirmed with the smallest appearance of truth, and hence those actions of birds are, without teaching, habit, or experience as perfectly performed by the young as by the old, and always as variable, we must conclude, that in these instances we recover not the reasoning of animals, pointing to consequences and devising means, but the unerring reason and wisdom of Him who made them, and implanted such principles in their constitutions as guide them unceasingly in the performance of their various natural operations, the complete purpoase and utility of which He only knows. Our reasoning is confirmed by that of Addisom—"What," says he, "can we call the principle which directs every different kind of bird to observe a particular plan in the structure of its nest, and directs all of the same species to work after the same model? I cannot be imitation; for though you hatch a crow under a hen, and never let it feed any of the works of its own kind, the net it makes shall be the same, to the

Vol. XIX.
laying of a flock, with all the other nefs of the fame 
species. It cannot be reason; for were animals enured with 
it to as great a degree as man, their buildings would be as 
different as our’s, according to the different conveniences 
that they would propofe to themſelves.” Some birds dis- 
dplay a wonderful flare of fagacity in the procefs of ince- 
bation and in rearing their young. Without attentive and 
cautious obervation, one would be almoft poifive, that in 
every step they are guided by reaion. But it is easy to 
feew that this is not the cafe. Let us take a very familiar 
infantine: a hen feeks a filent and an unfrequented place for 
her neif; when she has laid her eggs and began to cover 
them, she takes care to turn them frequently, that the vital 
warmth may be communicated to all parts of them. When 
she is oblige’d to leave them, in order to procure food, she 
is ture to return before they have time to cool, which would 
render them incapable of producing chickens. In fummer 
she will often fly away for two hours; but in winter, 
when the cold would destroy the principle of life, the flies away 
a much shorter time. When the birth approaches, with 
how much nicety and attention does she help the little ones 
to break their prifon. When brought forth, how cautio- 
usly does she cover them from the injuries of the weather, 
provide them proper nourifhment, and teach them to help 
themselves. It delveres alfo to be remarked, that she forlakes 
the neif if, after the ufual time of reckoning, the young do 
not begin to make their appearance. Can any thing have a 
greater appearance of reaion and fagacity than all this. 
“ But, at the fame time, the hen that has all this feeming 
ingenuity (which is indeed absolutely necefsary for the 
propagation of the fpecies), confidered in other refpects has 
not the leaft glimmering of thought or common fenfe. She 
miffakes a piece of chalk for an egg; and fets upon it 
in the fame manner; she is inconfible of any increase or di- 
inution in the number of thofe she lays; she does not 
diftinguish between her own and thofe of another fpecies; 
and when the birth appears of ever fo different a bird will 
cheriſh it for her own. In all these circumstances, which do 
not carry an immediate regard to the fubftance of herfelf 
or her fpecies, she is a very idiot.” None of these inaines 
justifies the doctrine, “ that animals, in all their natural op- 
erations, act with a view to confequences.” To confirm our 
reaoning and opinion still farther, out of the numberlefs 
examples afcribed to us by Natural History, we shall confent 
othlings with one, which, if we miffake not very much, is 
decife of this quifition. This we take from the operations 
of the bee, as it feems to act with a view to confequences, and 
to be, as was faid of the ant, “ haud ignara et non incuata 
futuri.” Let us attend a little to the ftruture of a honey- 
comb. The cells of the bees are equal and fimilar; and of 
the three poifible ways in which this can be efeeted, they have 
chofen the beft for holding their hone and rearing their 
young. The cells are built on both sides: they may then 
be placed exactly oppofite one another, fo that two would 
reif upon the fame bottom; or they may be fo placed, that 
the bottom of one will reif upon the point where the par- 
titions meet on the oppofite side. This latter mode gives 
them more strength, and they are accordingly built thus. 
Further, the bottoms of the cells are not planes perpendi- 
cular to the fides, but confit of three planes meeting in a 
fold angle in the centre, exactly where the partitions on 
the oppofite side eufs one another. And it has been demo- 
grated, that this makes the cells fimilar without lofs of room, 
and confiderably fpares both labour and materials. Thus, 
then, it is faen, that bees build their cells fo as to lofe no 
room; to have no ufelefs partitions; in the strongest pos- 
sible manner; and with the leaft poifible expece of labour 
and materials. All this, as far as geometry and mathemati- 
cs can fhow it, has been rigorously demonftrated by Mr. 
Maclaurin, and proves them, on the fuppoftion that they act 
with a view to confequences in this infantine, more skilled in 
both the fe infainces than the moft philosophical and learned 
men; and that too from the earlieft ages. But as this is a 
docline too improvable to be infalft upon, we muft rather 
conclude, that the bees, although they act geometrical- 
y, underfand neither the rules nor the principles of the 
arts which they praftice with fuch accuracy; but that the 
geometry in this infantine is in the Maker of the bee, 
“ that Great Geometer, who made all things in number, 
weight, and meafeure.” (Reid’s Active Powers of Man, 
and the London Philofophical Transafions.) Were a man to 
contruct fo nice a piece of workmanship as a honey- 
comb, we fhoold immediately conclude, that he worked 
according to rule, and underfood the principles upon which 
he proceedes. Is it neceffary to remark, that we have no 
reaion whatever for thinking that bees underfand one or the 
other? In the moft complicated works of human con- 
trivance, a man of equal knowledge and skill will compre- 
hend the principles and general defign of the artifl: but 
to underfood the rules and principles, which are fo rigor- 
ously adhered to in the constructing of a honeycomb, is, 
and will always be, beyond the comprehension of the far 
greatet part of mankind. The few infaines of animal 
infinite operations, which we have now briefly detailed, 
will, we hope, be fufficient for the precent: they corre- 
pond fully with our notion and explanation of infaince, 
and ferv our purpofe, as well as a million of infainces crowded 
together. But it is objected, that this infaince, which we 
call a fimple, original principle, accommodes itfelf to cir- 
cumftances; that it is improved by experience and imitation; 
that no fuch accommodation to circumstances can 
take place without reaoning, or a comparifon of ideas; 
and, therefore, that this principle of the conftitution of the 
lower animals is not infallt, but reaion. The infainces to 
prove that infaince accommodates itfelf to circumstances are 
numerous. Birds fly away from their eggs longer in warm 
than cold weather. The offrich in Senegal, where the heat is 
great, neglects her eggs during the day, but fits on them 
during the night: but at the Cape of Good Hope, where 
the heat is lefs, the fits on them both night and day. In 
countries infelted with monfies, birds, which in other cli- 
mates build in bushes and clefts of trees, fuppend their neifs 
on slender twigs, and thus elude their enemies. The fame 
species of birds build their neifs differently, when cli- 
mate and circumstances require it. We have numberlefs 
inflainces of this accommodation to circumstances in the 
paring infainces of animals. None, it has been oberved, 
ever pair, except those whose young require the nurfing 
care of both the parents. The extent and conftance of the 
pARENTIAL care are in the proportion of the wants and help- 
leefs of the young. When the wants of the young 
cafe, the mother withholds her fonducts, and leaves them 
to provide for themfelves; but the love of the parent 
may be lengthened out beyond its ufual time, as we fee in birds, 
which continue to feed their young, if they are tied to the 
neif, or confined within a cage, or by any other means 
appear to be out of a condition of fuplying their own 
neefs. This infaince, whilft it verily exemplifies an 
commodating infaince, affords the happiest proof of 
the guardian care of a kind and parental Providence. In 
answer to the objection which these facts contain, it may be 
first obferved, that taking infaince, as it is generally de- 
fined, to be a principle in the conftitution of animals, given 
them by their Maker, for the purpofe of preferring the 
individuals
Individuals and continuing the kind, in other words, a predisposition to perform certain actions necessary for these ends, when incited by certain feelings or sensations, that its accommodating itself to circumstances and situations is no argument against its existence, nor a good proof, that it is the result of reasoning; since He, who made it a part of the constitution of his creatures, knows, that the same ends must be often sought by different means, particularly when times, places, and circumstances are altered; and only manifests his wisdom and goodness the more, by constituting this principle of such a nature, as to vary when requisite, and to change only when such a change is necessary. Let us add to this, that did He not impart this accommodating property to instinct, it would not produce the effects for which it seems intended; as we know it to be impossible, that similar means should produce similar effects, when circumstances, climates, and situations, are different. Indeed this accommodating peculiarity, so far from being a good argument against it, is a necessary consequence of instinct. The abettors of this principle do not maintain, that the accommodating variations will take place on every occasion. They will occur only where the disadvantages exist, against which the instinct is intended to provide. Instinctive actions take place when certain feelings exist, and when these do not exist, we cannot wonder that the actions do not occur. In the following remarks we follow the learned author of "Ancient Metaphysics," a work, in which we find a just view of the subject of instinct. Before we positively conclude, that no accommodation to circumstances can take place without reasoning, or a comparison of ideas, it may not be irrelevant to consider some of the appearances which the vegetable and inanimate worlds exhibit. If, before the operations of some animals are fo artificial, and because they sometimes adopt, and sometimes reject their actions to circumstances, we must say, that they reason and compare ideas, we must contend, that vegetables and inanimate bodies do fo likewise: we know, that a vegetable reared in a dark cellar, if some light be admitted, will bend itself towards the light: or, if made to grow in a flower-pot with its head downwards, that it will turn its head upwards, according to the natural position of a plant. Can it be maintained, that the plant in either case does what it does from any judgment or opinion, that it is bent, and not from a necessary determination of its nature? The facts taken from the inanimate world are equally in point. How shall we account for the phenomena of elective attractions? when one body unites with another, and then, if a third is presented to it, quits the first and unites itself with the other, shall we say that this is the effect of reasoning and of a comparison of ideas, and suppose, that this preference of the one to the other proceeds from any predilection or opinion, that it is better to cleave to one than to the other? What shall we say of the crystallizations and configurations of faults exhibited to us by the microscope, so various and yet so constant and regular? Mutil we say, that their minute particles reason and compare ideas, because their operations are so various, and, at the same time, so regular and constant? Or, if nobody affirms this, why should we think, that the actions of animals, not more various and furprising, not more constant or regular, than these motions of the faults, should be the effect of reasoning and of a deduction of inferences? Should we not rather affirm, as those inanimate substances arrange themselves fo regularly, and yet so various, upon different occasions, in consequence of an original law of nature, that the benevolent Author of all such laws, intending to display his providence and wisdom still more conspicuously in his animal kingdom, bestowed upon his creatures this accommodating instinct, without which (supposing that they act instinctively on any occasion) the great purporses of their propagation and preservation could never be attained? This objection, upon which we have been commenting, is contained in the "System of Natural History" already mentioned in this article. The compilers of that work have been carried much too far in their zeal to do away Mr. Smellie's very unphilosophical notions concerning instinct: and, although we have read over their opinions with much attention, we are still at a loss in some parts to comprehend their meaning. Their diuertation on the subject is but short, and yet, we think, they often contradict themselves. One time you would suppose, that they admit such a principle as instinct in the lower animals; at another they seem to reject it altogether. This latter, indeed, seems to be the fairest account of their opinions. What they have, in view, when they called instinct a mechanical principle, we know not. It could not be the exploded doctrine of Des Cartes, nor the equally unphilosophical theory of Buffon, which has been fo fully and foolishly refuted by Condillac. Perhaps they referred to Dr. Reid's, who, as we have already observed, calls instinct a mechanical principle. We are equally at a loss for their allusions, when they call brutes infensible instruments under the influence of instinct, which they denominate a "mysterious influence." None of the advocates for instinct, so far as we know, have ever held this absurd opinion. On the contrary, they all allow them not only infusibility, but even spontaneity, in their instinctive operations. And, when they are allowed to poefs these, we cannot deny them consciousness, by which they must mean that they are acting. The supporters of instinct assert no more than this, since some of the natural operations of animals are to complicated, and yet so perfect and invariable, that it is irrational, with such evidence as we poefs, to suppose them acquainted with the rules of the arts which they practise, or the ends for which they operate. These, however, are known to Him, and perhaps to Him only, who implanted such principles in their constitutions, as direct them unerringly in all their ways. Besides those now mentioned, there are some other mistakes and errors in this work on the subject under discussion. These, however, with one exception, we shall pass unnoticed. The error we mean, and which, indeed, is not peculiar to these writers, is their supposing, that the advocates of instinct deny reason altogether to the brutes. But this opinion is wholly groundless. That some animals display wonderful facacity and docility, that they even reason on several occasions, is, we think, clear from the most satisfactory evidence. We shall mention a few facts in support of this opinion. On the northern coast of Ireland a friend of Dr. Darwin's saw above a hundred crows at once preying upon muscles: each crow took a muscle up into the air twenty or forty yards high, and let it fall upon the stones, and thus, by breaking the shell, got possession of the animal. A few years ago there was flown at Exeter Change, London, an old monkey, who having lost his teeth, used, when nuts were presented to him, to take a stone in his hand, and crack them with it one by one; thus, using means, like the crows in the preceding instance, to accomplish its purposes as well as we do. We are told by Linnæus, that the martin dwells on the outside of houses in Europe under the eaves; and that, when it has built its nest, the sparrow frequently takes possession of it. The martin, unable to dislodge his intruding enemy, convokes his companions, some of whom guard the captive, while others bring clay, completely close up the entrance of the nest, and then fly away, leaving the sparrow to be suffo-
INSTINCT.

cited, as the punishment due to his injustice and temerity. This fact is mentioned in the "Amusement Philosopbique, &c." of Father Boucicaut. There is also an instance of it in the "Gentleman's Magazine," in which we find also some interesting particulars concerning a raven kept some years ago, at the Red Lion at Hungerford. The account is, however, too long to be transcribed, although very much to our present purpose. We recollect seeing a few years ago, a very sensible cat, which, when out at night, would tap regularly at the windows, if the doors and shutters were closed; knowing by experience, that she was often let in at the windows by day. And what is still a better proof of her reasoning and sagacity, she would always tap at the bed-room windows, when disapponted at the others, or when the night was far advanced. A lady whom we were acquainted, had a tame bird, which was in the habit of letting out of its cage about her room every day. One morning as it was picking up some crumbs of bread off the carpet, her cat, who always before showed great kindness for the bird, seized it on a sudden, and, with eagerness, put it in her mouth, upon a table. The lady, much to the joy of her favourite, on turning about, observed that the door had been left open, and that a strange cat had just come into the room. After turning it out, her own cat came down from her place of safety, and dropped the bird, without injury, if we may so express it, a hair of its head. Cowper's beautiful little poem on the dog and the water fowl, gives an amiable instance of the reasoning of the lower animals, which has been so sweetly, and yet with such elegant simplicity, told in verse, that we cannot think of melting it down into the languid drolleries of prose. When we see brutes thus using means to obtain their ends, as well as ourselves, must we not conclude that they reason? When the cat watches for hours in silent expectation of her prey; when the hound traverses a wide extent of country in the chase; when the meekest insect that we tread on, drags its wounded frame to a safe retreat; they shew as much perceiving volunta]y as man can boast. No animal manipulates its food, or laps its drink, from the mere pleasure of the motions. It uses them as means for an end; and if hunger and thirst were not felt, they would be considered as labours, and would not be performed. "Animals (says professor Stewart, nearly in the words of Mr. Hume,) are left to make some small acquisitions, by experience, as sufficiently appears in certain tribes, from the sagacity of the old, when contradicted with the ignorance of the young; and from the effects which may be produced on many of them, by discipline and education."—"It seems as evident to me," says Mr. Locke, "that some animals do, in certain instances, reason, as that they have fenes; but it is only in particular ideas; just as they receive them from the fenes. They are the belt of them tied up within those narrow bounds, and have not, as I think, the faculty to enlarge them, by any kind of abstraction." The observations which Mr. Locke makes in this part of his work on the faculties of the brutes, as compared with ours, are in general very just and worthy of perusal. But there are several facts, which our sires do not allow us to state, from which it is evident, that brutes on some occasions exhibit proofs of the power of abstraction. That an animal can be capable of gratitude and affection for its master, without reasoning, can, we think, hardly be maintained. From the master's protection and kindness, it infers that it is under obligations to him, which it owes not to another. Before concluding our remarks on the reasoning of animals, we may quote one instance of the affection of a dog, which we think has never been surpassed. And we do it the more readily, as the circumstance has been very poetically described by an author, who, with all his great merit, seldom writes better than upon this occasion. The inconstancy which we allude is very interesting, from the incident to which it relates, the death of an unfortunate young gentleman of promising talents, who perished, by losing his way, in the spring of 1805, on the mountain Helvellyn. His remains were found three months afterwards, guarded by a terrier bitch, that had long been the companion of his solitary rambles. This last circumstance in particular, is very finely alluded to by Mr. Scott, in his little piece on the subject, to which he has given the name of Helvellyn. As the few instances now related are sufficient, and speak fully for themselves, we shall not add to the number, nor step to make any comments upon them. But it has been asked, if we allow reason to the lower animals, in what does the difference between them and man consist? Do their faculties and ours differ in degree, or in kind? To this question we have not the vanity of thinking that we are able to give a satisfactory answer; we may, however, offer a few remarks. We see that animals learn much from experience and observation as well as ourselves. It is thus they learn the nature, or the properties, of the objects that surround them, such as heights, depths, distances, &c. "A horse that has been accustomed to the field, becomes acquainted with the proper height which he can leap, and will never attempt what exceeds his force and abilities. An old greyhound will thrust the more fatiguing part of the chase to the younger, and will place himself to us to meet the hare in her doyles; nor are the conjectures which he forms on this occasion, founded in any thing but his observation and experience." By training and education we can teach our domestic animals much more than they would ever learn, if left to themselves and their own observation. If we put them in new situations, we see that their acquired knowledge is much increased and improved, and that by a proper and strict discipline we can train them up to a mode of acting directly contrary to their instincts, or natural propensities. If these observations be just, (and we cannot see how they can be questioned,) it follows, that in the lower animals instinct is susceptible of very great and striking modifications. To produce these, however, strict culture and discipline are necessary; without which, we do not think that their own experience and observation would ever teach them to deviate much from the line of acting chalked out to them by their instincts, or original propensities. And accordingly we agree with a remark of Mr. Hume's, that though animals learn many parts of their knowledge from observation, there are also many parts of it which they derive from the original hand of nature, which much exceed the share of capacity they possess on ordinary occasions, and in which they improve little or nothing, by the longest practice and experience." Yet, notwithstanding this susceptibility of improvement by culture and education in the lower animals, we can never observe in them any thing approaching to the knowledge and sagacity of man. They do not, like him, leap observation upon observation, they do not improve by the experience of the past, nor manifest any indications of a regard to futurity; their manufactures are always stationary, and all their acquisitions of knowledge perish with the individual. They never learn the arts of man; for instinct, though often as fond of artificial heat as we are, not one of them has been ever known to lay a piece of coal or of wood upon the fire to keep it from going out. All this may be owing to their want of language; but it seems strange, that they possess not this art, as some of them seem to have organs of articulation, as perfect as ours. They use means, it is true, for obtaining their ends sometimes; but these in general are very simple and obvious. They reason...
on too on some occasions; but the want of language, or of
general signs, puts it out of their power to reason, but on
particular facts. The powers of classifying objects, of ab-
tract reasoning, of using artificial signs as instruments of
thought and of mutual communication, form to be almost
altogether peculiar to man. From these confederations, and
several others, relating both to the intellectual and moral fa-
culties of man, as contrasted with those of the lower animals,
has been inferred, that the regular chain of being every
where else observable, on our globe, holds entirely here, and
that their faculties differ from our's, not in degree, but in
kind.

Thus then we see, that animals perform certain operations
that are neither rational, habitual, nor mechanical; and although
it cannot be doubted but some of them reason in several in-
fractions, still, even from the short details now given, we can-
not allow, that their natural operations are performed with a
view to consequences. Nor ought the effects of instinct,
(the labours of birds and bees for instance) appear extra-
tordinary to us, when we consider what astonishing effects
habit, which has been happily called "a second nature,"
enables us to produce. For instance, we need go no farther
than reading, writing, and playing upon musical instru-
ments, all of which we learn by great attention, pains, and
study; and most of all, perhaps, correct and quick extem-
orary eloquence. And surely, when the effects of an ac-
quired principle are so very uncommon, it cannot be deemed
strange, that an original principle of the constitution of ani-
mals should perform works still greater or more astonishing.

INSTITUTA, a word used by the chirurgical writers, for a
filler or other bandage of that kind; and by medicinal
writers, for that sort of flat worms bred in the intestines
called by many the tape-worm, or flat worm.

INSTITUTE, National, of France, was newly
organized in pursuance of a decree of the French government,
with the advice of the council of state, as follows: I. It
is now divided into four classes, viz. 1. Class of phylical
and mathematical sciences. 2. Class of French language
and literature. 3. Class of history and foreign literature.
4. Class of the fine arts.
The members and foreign associates of the institute,
shall be divided into these four classes.
A committee of five members of the institute, named by
the First Council, shall adjust this division, which shall be
subordinated to the approbation of government.

II. The first class shall be formed of the ten sections which
at present compose the first class of the institute, with a new
section of geography and navigation, and eight foreign associ-
te.
The sections shall be composed and called as follows:

Mathematical Sciences.
- Geometry - - - - - - 6 members.
- Mechanics - - - - - - 6 ditto.

Physical Sciences.
- Geography and Navigation - - 3 ditto.
- General Physics - - - - 6 ditto.
- Chemistry - - - - - - 6 members.
- Mineralogy - - - - - - 6 ditto.
- Botany - - - - - - 6 ditto.
- Art - - - - - - 6 ditto.
- Anatomy and Zoology - - - - - - 6 ditto.
- Medicine and Surgery - - - - - - 6 ditto.

The first class shall appoint, with the approbation of the
First Council, two perpetual secretaries, one for the mathem-
atical sciences, the other for the physical sciences. The per-
petual secretaries shall be members of the class, but shall not
form a part of any section.
The first class may elect six of its members from the other
classes of the institute.

The second class shall be composed of forty mem-
bers.
It is particularly charged with the composition of the
dictionary of the French language. It shall examine, with
respect to language, the important works of literature, history,
and the sciences. The collection of its critical observations
shall be published at least, four times in a year.
It shall name from its own body, and with the approbation
of the First Council, a perpetual secretary, who shall continue
to be of the number of the forty members which compose it.
It may elect twelve of its members from the other classes of the
institute.

IV. The third class shall be composed of forty members,
and eight foreign associates.
The object of its researches and labours shall be learned
languages; antiquities and monuments; history, and all the
moral and political sciences connected with history. It shall
particularly apply itself to the enriching of French literature
with the works of Greek, Latin, and Oriental authors, which
have not yet been translated.
It shall employ itself in the continuation of diplomatic
collections.
It shall name from its own body, under the approbation
of the First Council, a perpetual secretary, who shall be of
the number of the forty members which compose the class.
It may elect nine of its members from the other classes of
the institute.

V. The fourth class shall be composed of twenty-eight
members and eight foreign associates.
They shall be divided into sections, described and formed as
follows:

- Painting - - - - - - 10 members.
- Architecture - - - - - 6 ditto.
- Engraving - - - - - - 3 ditto.
- Music (composition) - - - 3 ditto.

It shall appoint, with the approbation of the First Council,
three perpetual secretaries, who shall be a member of the class,
but shall not be a part of a section.
It may elect six of its members from the other classes of
the institute.

It may name thirty-six correspondents, national or for-

VI. The foreign associated members shall have a deliberative
voice only on subjects of science, literature, and the arts;
they shall not form part of any section, nor interfere in any
way.

VII. The present actual national associates of the institute
shall form part of the one hundred and ninety-six correspond-
teurs, attached to the classes of the sciences, belles lettres, and
fine arts.
Correspondents may not assume the title of members of
the institute.
They shall lose that of correspondent when they shall be
domiciliated at Paris.

VIII. Nominations to vacant places shall be made by each
class in which the vacancy happens; the persons elected shall
be confirmed by the First Council.
IX. The members of the four classes shall enjoy a recipro-
conversion.
The institutes, in a general sense, the act of ordaining, founding, or establishing anything.

Thus we say, Moses instituted the ceremonies of the old law; Jesus Christ instituted the sacraments of the new.

Institution, in the Canon and Common Laws, is the act of the bishop, or of one commissioned by him, whereby a clerk, after the patron's presentation has been admitted, is invested with the spiritualities of a rectory, or vicarage: for by institution the care of the souls of the parish is committed to his charge. See Presentation.

The clerk kneels down before the bishop, whilst he pronounces these words of institution (instituo te) reorem ecclesiae de A.B. cum cura animarum, & accipe curam tuam & manum); and the clerk holds the written instrument, with the episcopal seal annexed, in his hand, during the ceremony.

Before the clerk is instituted, he must subscribe the thirty-nine articles of religion, in the presence of the ordinary, or his substitute; and this subscription must be without reserve, exception, or qualification; else his institution is, ipso facto, void and null, and the church is still vacant. 13 Eliz. c. 12.

At the same time the ordinary requires the clerk to subscribe the other two articles mentioned in the 36th canon about the king's supremacy, and the lawfulness and use of the liturgy: the clerk must also, before institution, subscribe to that part of the declaration enjoined by the act of uniformity, 15 Car. II. c. 24, viz. "I will conform to the Liturgy of England, as by law established."—Before institution, he must also take the oaths mentioned in the first statute of William and Mary, c. 8. instead of the former oaths of allegiance and supremacy, required by flat. 1 Eliz. and then he must take the oath against simony, enjoined by the 4th canon, and the oath of canonical obediency; and if it is a vicarage, the oath of personal residence; and he is to have certificates given him of his subscribing the declaration contained in the act of uniformity, in English, in a distinct instrument, under the hand and seal of the bishop; and of his other subscriptions and oaths, in Latin.

The clerk ought by all means to have witnesses of his institution, his taking the oaths, making subscriptions, &c. and therefore he should make some present to write their names on the back of his instrument, and make memorandums who they are, and where they live.

The church, by institution, is full against all persons but the king, but it is not full against the king, till induction; and the clerk by it may enter upon the patronage house and glebe, and take the tithes; but he cannot let or grant them, nor live for them, if they be refused to be paid till he be inducted.

After institution, the clerk is to receive a written mandate from the ordinary to the archdeacon, or other proper person, in order to his induction; without which he has not a full right to his temporalities, unless the benefice be a donation. See Induction.

Institution, African, a society formed by the friends of the Abolition of the Slave-trade assembled on the 14th of April 1807, and established on the subsequeut 15th of July. The resolutions adopted by the conjunct meeting, as the basis of the association, are as follow: 1. That this meeting is deeply impressed with a sense of the enormous wrongs which the natives of Africa have suffered in their intercourse with Europe; and from a desire to repair those wrongs, as well as from general feelings of benevolence, is anxious to adopt such measures as are best calculated to promote their civilization and happiness. 2. That the approaching cessation of the slave-trade, hitherto carried on by Great Britain, America, and Denmark, will, in a considerable degree,
grees, the barrier which has so long obstructed the natural course of social improvement in Africa; and that the way will thereby be opened for introducing the comforts and arts of a more civilized state of society. 3. That the happiest effects may be reasonably anticipated from diffusing useful knowledge, and exciting industry among the inhabitants of Africa, and from obtaining and circulating throughout this country more ample and authentic information concerning the agricultural and commercial faculties of that vast continent; and that through the judicious prosecution of these benevolent endeavours, we may ultimately look forward to the establishment, in the room of that traffic, by which Africa has been so long degraded, of a legitimate and far more extended commerce, beneficial alike to the natives of Africa, and to the manufacturers of Great Britain and Ireland. 4. That the present period is eminently fitted for prosecuting these benevolent designs; since the suspension, during the war, of that large share of the Slave-trade, which has commonly been carried on by France, Spain, and Holland, will, when united with the effect of the Abolition laws of Great Britain, America, and Denmark, produce nearly the entire cessation of that traffic along a line of coast extending between two and three thousand miles in length, and thereby afford a peculiarly favourable opportunity for giving a new direction to the industry and commerce of Africa. 5. That, for these purposes, a society be immediately formed, to be called the "African Institution." See the first report of the society, which proceeds to obviate the difficulties which may appear to lie in the way of the attainment of these interesting objects; and particularly to remove the most conspicuous objection to the design, viz. despair of its success. The means by which this laudable association purposed to accomplish its noble and captivating objects are as follows: First, of all, this institution, wife by the example of the Sierra Leone company, disclaims in the outset all projects of a colonial or commercial nature. It endeavors itself with no concern of government—no mercantile speculations—no factories or forts—not even with the possession of a single ship, or an acre of ground. This clears the way for exertion, not only by removing every suspicion of unworthy or doubtful motives, but by throwing off a thousand clogs which must have hampered an establishment of a different character. For obvious reasons the society also disclaims all schemes of religious mission; and avowing, upon that important subject, not certainly any kind of indifference, but a wife and necessary neutrality, it leaves in other hands the task of propagating the gospel among the Africans, and confines its own exertions to the introduction of that civilization, which is the best preparative for the truths of Christianity. Not to mention other reasons for this salutary caution, it has—one most important and beneficial effect. It opens wide the doors of the institution to all sects and denominations of Christians,—whom it thus invites to co-operate for purposes equally subservient to every form of worship, and every modification of religious belief. The means which it is proposed by this society to employ for the purpose of promoting civilization and improvement in Africa, are of the following kind: 1. To collect and diffuse throughout this country accurate information respecting the natural productions of Africa, and, in general, reflecting the agricultural and commercial capacities of the African continent, and the intellectual, moral, and political condition of its inhabitants. 2. To promote the instruction of the Africans in letters and useful knowledge, and to cultivate a friendly connection with the natives of that continent. 3. To endeavour to enlighten the minds of the Africans with respect to their true interests; and to diffuse information amongst them respecting the means whereby they may improve the present opportunity of substituting a beneficial commerce in place of the slave-trade. 4. To introduce amongst them such of the improvements and useful arts of Europe, as are fitted to their condition. 5. To promote the cultivation of the African soil, not only by exciting and directing the industry of the natives, but by furnishing, where it may appear advantageous to do so, useful seeds and plants, and implements of husbandry. 6. To introduce amongst the inhabitants beneficial medical discoveries. 7. To obtain a knowledge of the principal languages of Africa, and, as has already been found to be practicable, to reduce them to writing, with a view to facilitate the diffusion of information among the natives of that country. 8. To employ suitable agents, and to establish correspondences, as shall appear advisable; and to encourage and reward individual enterprises and exertion in promoting any of the purposes of the institution."—First Report. Besides, the society has adopted from the beginning, and since speedily pursued, the resolution of watching over the strict execution of the abolition laws—of procuring all information respecting the evasion or breach of those laws, which daring speculators may attempt; of keeping the attention of the government alive, and quickening the exertions of the crown-officers on those points.—of suggesting, from time to time, such improvements in those laws as a practical experience of their imperfections, or the change of circumstances, may point out; and, finally, of promoting, as far as possible, by communicating information, and other appropriate methods, the abolition of the African Slave-trade in foreign countries. This latter service is quite essential to the improvement of Africa; and it is such as a body, like the African institution, is well adapted to perform. The president of the African Institution is the Duke of Gloucester; and of the directors, who chiefly carried on its ordinary business along with this distinguished prince, we shall only mention the names of Mr. Wilberforce, Thornton, Van Reit, W. Smith, Brougham, Clarkson, G. Sharp, Allen, Stephen, and Macaulay, who, much to the advantage of the society, undertook the laborious and difficult office of secretary, until it could be filled by a permanent arrangement. A respectable subscription of about 3000l. was immediately raised. At the end of 1808, this had increased to 4374l., of which 531l. arose from annual subscriptions. Since that time the funds have been augmented by many donations, and the list of annual contributors soon increased. For a further account of this institution, we refer to its annual reports, and to the Edinburgh Review, No. 30.

Institutions, in Literary Matters, denote a system of the elements, or rules, of any art or science. Such are institutions of medicine, institutions of rhetoric, &c.

Institutional Botany, thirtiy letters of authors in this science who have laid down certain settled rules, axioms, and in litutions in it.

Instructive Colloquy. See Column.

Institute of Sacrifice, in the Antique Architecture, are ornaments.
Instruments, as vases, patere, candletsicks, knives, &c. where-with the victims were killed, &c. instances of which we see in a Christian frieze in the remains of a temple behind the Capitol at Rome, &c.

Instruments is also used, in Law, to signify some public act, or authentic deed, by means whereof any truth is made apparent, or any right or title established, in a court of justice.

Instrument, primarily denoting writing, charter, or record, is sometimes used by Latin writers for the Old and New Testament. It occurs several times in Tertullian, reckoned the most ancient Latin writer of the church now remaining. He calls the Gospels, or the New Testament in general, the Evangelic Instrument, and says, "how large claims Marcion has made in the epistle to the Romans, by leaving out what he pleases, may appear from one entire Instrument," or one unaltered copy of the New Testament, particularly of that epistle. Speaking of the shepherds of Hermas, he says, it was not reckoned a part of the Divine Instrument; thereby meaning, as it seems, the New Testament. He calls the law and the prophets the Jewish instruments, that is, writings or scriptures. He speaks of the antiquity of the Jewish instruments, or scriptures. He feems in one place (Apol. cap. 18.) to use the word instrument as equivalent to scriptures, containing the doctrine of revelation, or the revealed will of God. Lardner.

Instrument, in Musè, is a general term, under which all artificial bodies, capable of producing and varying musical sounds in imitation of the voice, are comprehended. Every body capable of agitating the air by some shock, and exciting by its vibrations in this agitated state undulations sufficiently frequent, may produce sound; and all bodies capable of accelerating or retarding these undulations may vary their sounds. See Sounds.

There are three ways of producing sound found by instruments: by the vibration of strings, by the vibration of elastic bodies, and by the collision of air inclosed in pipes. The invention of these instruments will be considered at the word Music.

Instruments are generally classed under the three following heads: stringed-instruments, wind-instruments, and instruments of percussion. The stringed-instruments of the ancients were very numerous. Those most known were the following: the lira, psalterium, trigonon, lambaca, citirra, pectis, magadis, barbiton, tectudo, epigonium, tympanum, &c. All these instruments were touched with the fingers or played with a plectrum.

Their principal wind-instruments were the tibia, sibil, tabla, cornu, linius, hydraulicon, &c.

Their instruments of percussion were the tympanum, cymbalum, cymbalina, timbalinum, crotalum, &c; but many of these are monotonous, and only render one sound.

Of most of these ancient instruments representations on plates have been given (Hill. Mus. vol. i.) from drawings made at Rome under our own eye, and under the guidance of Piranesi, and Meiffis, Jenkins, Morrizon and Byers, the bell antiquaries at Rome in 1770; with a description and authority for their local situation at the time.

The bell books on the subject of ancient musical instruments, and the most worthy of being consulted, are Blanchini de Tribus Generibus Instrumentorum Veterum Organica; Gabicletto Armonica, del Bonami; Bartellinus de Tribus Vetricum; and Effais for la Musique par M. Laborde; who has given representations very neatly engraved of the musical instruments during the middle and lower ages, from illuminations in ancient MSS. of the Bibl. Royale at Paris in 1780; which, if the wish to render their delineation picturique had not a little injured their fidelity, would be invaluable.

Instruments, Physical, of the Abyssinians, from Mr. Bruce, the authenticity of whose account seems to be no longer doubted, we shall give from his letter inserted in Burney's General History of Music, vol. i.

There are six musical instruments known in Abyssinia; the flute, the trumpet, the kettle-drum, the tambourine, the fifrem, and the lyre.

"The four first are used in war, and are by much the most common; the fifth is dedicated to the service of the church; and the sixth is peculiarly an attendant on fealty and rejoicing.

"There are two principal languages in Abyssinia, the Ethiopic, which is the literal, or dead language; and the Amharic, or language of Amhara, spoken by the court. The flute, in the Ethiopic, is called Kere, a word difficult to be written or founded in English; in the Amharic, it is called Agada: it is about the shape and size of the German flute; but played upon longer ways, with a mouthpiece resembling that of the clarinet; its tone is not loud, but accompanied with a kind of jar, like a broken hautbois; not owing to any accidental defect, but to construction and design, as it would not be esteemed without it.

"The kettle-drum is called in both languages Nagaret, because all proclamations are made by the sound of this drum (these are called Nagar), if made by governors, they have the force of laws in their provinces; but if made by the king, they are for all Abyssinia. The kettle-drum is a mark of sovereign power: whenever the king promulgates a subject to be governor, or his lieutenant-general in a province, he gives him a kettle-drum, and standard as his insignia. The king has forty-five of these drums always beating before him when he marches. They are in shape and size like our's, only they are braced very disadvantageously; for the skin is strained over the outer rim, or lip of the drum, and brought a third down its outside, which damps it exceedingly, and deprives it of that clear, metallic sound which our's has. Each man has but a single drum, upon the left side of his mule, and beats it with a crooked stick, about three feet long. Upon the whole, its sound is not disagreeable, and I have heard it at an incredible distance.

"The third instrument is the small drum, called Kabaro, in Ethiopic and Amhara; though in some parts of Amhara it is also called Hatamo. It is about half the diameter, and twice the length of our common drum; it is just the tambourine of Provence, only rounded to a point at the lower end. This is beaten always with the hand, and carried sometimes on foot, sometimes on horseback, when any inferior officer (not having a Nagaret) marches.

"The trumpet is called Meleketa, or Melek; and Keram in Amharic, but Keram in Ethiopic (or horn); which shews of what materials it was anciently formed. It is now made of a cane that has less than half an inch aperture, and about five feet four inches in length. To this long flûk is fixed at the end a round piece of the neck of a gourd, which has just the form of the round end of our trumpet; and is on the outside ornamented with small white shells; it is all covered over with parchment, and is a very neat instrument. This trumpet sounds only one note, E, in a loud, hoarse, and terrible tone. It is played when on a march, or before an enemy appears in sight; but afterwards it is repeated very quick, and with great violence, and has the effect upon the Abyssinian soldiers of transporting them absolutely to fury and madness, and of making them so regardless of life, as to throw themselves in the middle of the enemy, which they do with great gallantry. I have often in time of peace tried what effect this charge would
would have upon them, and found that none who heard it could continue seated, but that all rose up and continued the whole time in motion.

The fifth instrument is the cithara; it is used in the quick measure, or in allegros, in singing psalms of thanksgiving. Each priest has a cithara which he shakes in a very threatening manner at his neighbour, dancing, leaping, and turning round with such an indecent violence, that he resembles rather a priest of paganism, whence this instrument was derived, than a Christian. I have forgot the name of the cithara in Ethiopic, but on looking into my notes I shall find it.

The sixth and last instrument is the lyre, which is never played solo, but always in accompanying the voice, with which it plays conjunctly in unison; nor did I ever hear music in parts, in any nation, savage or polisied, out of Europe: this is the last refinement music received, after it was in perfection of complete instruments, and it received it probably in Italy.

The lyre has sometimes five, sometimes six, but most frequently seven strings, made of the thongs of raw sheep or goat skins; cut extremely fine, and twisted; they rot soon, and are very subject to break in dry weather, and have fearce any found in wet. From the idea, however, of this instrument being to accompany and sustain a voice, one would think that it was better mounted formerly.

The Abyssinians have a tradition, that the cithara, lyre, and tambourine were brought from Egypt into Ethiopia, by Thoth, in the very first ages of the world. The flute, kettledrum, and trumpet, they say, were brought from Palatine with Menelak, the son of their Queen of Sabba, by Solomon, who was their first Jewish king.

The lyre in Amharic is called bég (the sheep); in Ethiopic, it is called mčänk; the verb fingo signifies to strike strings with the fingers: no pletrum is ever used in Abyssinia, so that męfikö being literally interpreted, will signify "the stringed instrument played upon with the fingers." This would seem as if anciently there was no other stringed instrument in Abyssinia, nor is there any other till. See THÉBAN HARP, with Mr. Bruce's drawing and account of it, in the same volume.

Modern musical instruments will be described under their several heads as they occur.

In modern times, since harmony has sustained its importance in music, musical instruments have been divided into perfect and imperfect, the first of these being such as are capable of executing or sounding as many notes of different pitches within a given compass, as within an octave for instance, as the harmony of the music performed upon it may require, without being forced to introduce notes, which make false or tempered intervals, or Voxvus with the other notes of the piece, found at the same time; as in the second class necessarily happens, in very numerous inscriptions, where the notes are previously fixed and tuned, as it is called, to some certain scale or system of 12 notes within the octave, and which notes the performer of any one part in a piece of music has not the power of altering and adjusting to the true harmonic relation with the simultaneous notes of the bass, or other principal part: imperfect instruments are not, however, confined to those with 12 strings, pipes, &c., in an octave, but the term applies, though in a less degree, to instruments with 14, 16, or 17 strings, as shown in our article HAWKE'S temperament of the musical scale, where his 17 notes in the octave are proved to be incapable of banishing wolves, or false intervals, even from tempered systems, and which

Dr. Smith's harpichords with 21 notes in the octave were alike unable to effect, in the numerous passages of modern music where double sharps or double flats occur: but on the improved organs and piano fortos of D. Loechmann, whose scale is extended to 24 notes, all such notes as usually occur can be truly given, according to an affigned system of temperament. The violin, viola, bass-viol or violincello, and double babs, have held a distinguished rank in modern refined concertos as perfect instruments, and were, indeed, the only instruments that should be admitted to accompany the human voice, which exceeds, in the perfection of its scale, any instrument whatever, since a vocal performer, with a good ear and intonation, can infantly strike a perfect interval to a note whatever, without the least beating or degree of temperament or perfection in the tuning, and this he does, by attempting the leaps or intervals of the melody (see MELODY, Temperaments of): it being absolutely and demonstrably impossible to avoid temperament, or the use of imperfect intervals, either in the harmony or in the melody, (but they need not be used in both,) on perfect instruments, as on imperfect instruments they necessarily must, as is shown in our article HARMONY, Temperaments of: the late Mr. Maxwell, in the year 1781, in his "Essay on Tune," sketched out the principles of an organ capable, by means of 44 pipes in each octaves, of entirely banishing temperaments from the harmony, in 24 keys, 12 major and 12 minor: but we never heard until very lately, that any one had constructed such an instrument. It appears, however, that on the 3d of July 1810 the Rev. Henry Liffon took a patent for his instrument, called the ENHARMONIC ORGAN, and in the autumn of the year issued proposals for publishing, by subscription, "An Essay on Perfect Intonation," and for exhibiting one of these patent organs in London, which had been completed in Scotland, and tuned, says his prospectus, "perfectly true throughout, without any temperament whatever, and performs every chord, in every key absolutely perfect, nor is there any combination which it is not capable of performing."—The decided superiority of the harmony has been acknowledged by the best judges, and the performers have found no serious difficulty in the most sudden and extraneous modulation, or in the widest range of keys; such were the pretensions of this instrument, and which no musical persons that we conversed or corresponded with seemed disposed to expect would be realized: however, in the beginning of this month (April 1811), Mr. Liffon arrived in London with his organ, and had it put up at Flight and Robson's, organ builders in St. Martin's lane, and tuned it, and on the 16th politely gave us the opportunity to be the first that heard it performed on in London, and of hearing the effect of some glee sung to it; which proved delightful indeed, and rather exceeded our expectations than otherwise, though they had, as above hinted, been raised above those of most musical persons. The Rev. Mr. Liffon also favoured us with the perusal of the manuscript of the first part of his intended work, in which we were delighted to observe, that a good knowledge and a correct application of mathematics is combined with a thorough knowledge of composition, and of the wants of the practical musician: the defect of one of which essential qualifications we have so often had to deplore, and even to reprobate, in our numerous quotations and references to modern writings on temperament, and on the nature and magnitude of musical intervals, in the different articles of our work. Mr. Liffon's work will describe an instrument with 24 pipes in each octave, and to each of which two valves or flackers, of different sizes, are adapted, affixed to radii from rolls or axles, that can be turned
turned by means of pedals, so that each of these pipes can
be made to sound one major comma or two major commas
flatter than the pitch of the pipe, making in all 72 sounds
in each octave, which, by the 12 usual finger keys and
the use of twelve pedals, enables the performer to give 33 per-
fected keys, without any tempered harmonies. The instru-
ment, although as above, has not b F, but contains 20 pipes,
and gives 60 different sounds within the octave. See the
Philosophical Magazine, vol. xxxvii. p. 273, and our article
Liston's Scales of Musical Intervals.

INSTRUMENT, Wind. See Wind.

INSTRUMENTAL Arithmetic. See Arithmetic.

INSTRUMENTAL Cause. See Cause.

INSTRUMENTUM Synodale. See Synodale.

INSUFFLATIO, a term used by some writers in medic-
ine, to express the blowing into any part, in order to con-
vey the fumes of medicine into it.

INSULATE, or Insulated, a term applied to a co-

dum or other edifice, which stands alone, or free and detached
from any contiguous wall, &c. like an island in the sea;
whence the denomination is apparently derived.

Insulated, in Electricity, is a term applied to bodies that
are supported by electrics or non-conductors; so that their
communication with the earth, by conducting fubfiances, is
interrupted.

INSULT; in Law. See Assault.

Insult, a military term used for the attack of any poff
with open force: without the apparatus of trenches, faps,
or any regular approaches. See Assault.

INSULTUS, a word used by the writers in medicine to
signify the access of the paroxysm in intermittent difeases, or
sometimes the firft invasion of a difeafe.

INSUMA, in Geography, a town of Arabia, in the pro-

vince of Hedjas; 10 miles S.W. of Mecca.

INSUPER, a word used by the auditors of the Ex-

chequer. In their acquaints they say, so much remains in-
jurer to such an accomplicant; that is, so much remains due
on his accomplish.

INSURANCE, or Assurance, in Law and Commerce,
a contract or agreement whereby one party, in considera-
tion of a flipulated sum, undertakes to indemnify the other
against certain perils or risks to which he is exposed, or
against the happening of some event. The party, who takes
upon himself the risk, is called the "Insurer," sometimes
the "Underwriter," from his fubferibing his name at the foot
of the policy; the party protected by the insurance is
called the "insured;" the sum paid to the insurer, as the
price of the risk, is called the "premium;" and the written
instrument, in which the contract is fet forth and reduced to
form, is called a "policy of insurance, or assurance." See
Policy.

The risks against which insurances are made are in-

finitely various, and many frauds have been practiced on
the ignorant and credulous, under pretence of insurance, which
the legislature has found it neccessary, from time to time, to
repress. In the reign of queen Anne, severall offices were
opened for making insurances on marriages, births, chriften-

ing, service, &c. and fraudulent practices prevailed to such
a degree, that by Stat. 4 Ann. c. 6. § 37, a penalty of 500l.
is imposed on every perfon setting up such office, and 100l.
on every perfon making such assurances in any office already
set up. Fraudulent insurances have also occurred among
dealers in lottery tickets, the shares and the chances of them,
which, besides the restraints to which they are subject in
the annual lottery acts, have occasioned the Stat. 27 Geo. III.
c. 1, made expressly with a view to this evil, and by which
they have been considerably diminished. See Lottery.

Insurances of the greatest public utility a.re, "Marine
Insurances," including bottomry and respondentia, which are
a species of marine insurance (see each of these articles) —
"Insurance upon Lives" (see Assurance); and "In-

surance against Loffes by Fire.

INSURANCES, Marine, are made for the protection of per-
sons having an interest in ships, or goods on board, from the
loss or damage that may happen to them from the perils of
the sea, during a certain voyage, or a fixed period of time.
By "peril" is here meant, not danger or hazard, according
to the common acceptation of the term; but it signifies the
"happening;" of the event or the misfortune of which danger
was apprehended. The utility of this contract consists in
the protection it affords to maritime commerce, by dividing
lofes, when they happen, between many, so as to make them
fall less heavily on individuals, who are thus enabled to
embark their whole capitals in hazardous enterprises. (See the
preamble to the Stat. 4 Eliz. c. 12.) As the Turks are
unacquainted with insurance, they require for the loan of
money 15 or 20 per cent.; and when they lend money
to merchants who trade by sea, they charge 30 per cent.
Some have ascribed the invention of insurance to the ancient
Romans. Accordingly Puffendorf, Barbeyrac, Lococins,
Kulpis, and others, refer to a passage in Livy (l. xiii c. 44.),
who says, that when the Roman army in Spain was diftricled
for provisions, clothing, and other necessaries, a company
engaged to convey to them every thing of which they stood
in need, under this stipulation, that the flate should make
good their losfs, in cafe their veffels should be shipwrecked by
storms, or taken by the enemy. This was undoubtedly a
promise of indemnification, but by no means an insurance,
in which it is always necessary to give a premium. Kulpis,
Anderfon, Malyne, and others, rely on the authority of
Suetonsius (l. v. c. 18.) who tells us, that the emperor Clau-
dius promised to indemnify merchants for their losfs, if their
ships should perih by storms at sea; but neither this passage
nor another that has been referred to in Valerius Maximus
(l. vi. c. 5.), contains any thing that can be applied to in-

surance in the modern fense of the term. A passage has
also been quoted by Groton from Cicero's epiftles (Epit.
ad Fam. ii. ep. 7.), as a proof that the Romans were ac-
quainted with this contract. But Cicero's words, duly in-
terpreted, seem to bear a much stronger allusion to the prac-
tice of remitting money by means of bills of exchange, than
to that of insuring against the perils of the sea. In the Pan-
dects we have an observation of Ulpian, which affords greater
reason for supposing that the contract of insurance was not
altogether unknown to the Romans, than any of the passages
already cited. He says (Dig. l. xlv. de verb. oblig.), "illa
flipulatio, decem millia falva fore promittis? valet." This
passage, however, shews, as ferves Marshall has observed,
that the contract alluded to, whatever it might have been,
was very little known at the time when Ulpian wrote, since
he thought it neccessary to remark, that "it was not illegal."
Malyne, Anderfon, &c. affirm, that insurance is mentioned
in the marine laws of the isle of Oleron, on the coast of
France, which was much celebrated in the 11th, 12th, and
following centuries, on account of its trade. But in these
laws there is no trace of insurance, as the learned editor,
Clearac, acknowledges. The celebrated maritime laws of
the city of Wipby, in the ifland of Gotlhland, are equally
silent with regard to insurance. Insurance was, undoubtedly,
not known in 1507, when the ordinances of the Hanseatic League were framed, nor in 1614, when several new regulations were added; because, though the contract of bottomry is mentioned in these regulations, there is not a word on the subject of insurance, nor does any thing certain occur in the collection of maritime laws, intitled "Il Confolato del Mare," written in the Catalan dialect, partly framed in the 11th, but for the most part in the 13th century; and published at Leyden in 1504. (See Marine Law.) Some have said, without sufficient authority, that the practice of insurance was introduced by the Jews in 1182; and others have sought its origin about the year 1560, in the great woolen commerce that subsisted between England and the Netherlands. But as the maritime commerce of the Italian states appears to have been carried on to a very considerable extent about the end of the 15th century, it is very probable that insurance came into use in Italy about that time. From thence it was transplanted into all the countries where the Lombards had established their trading companies. One of these companies settled in London, and from thence Lombard-street in that capital took its name. According to Malyne insurance was introduced into England by the Lombards somewhat earlier than into the neighbouring countries on the continent; and in proof of this, he says, that even Antwerp, in its meridian glory, borrowed insurance from England; and that, down to the time in which he wrote (1622), there was, in every policy made at Antwerp, and other places in the Low Countries, a clause inserted, that it should be in all things the same as policies made in Lombard-street, in the city of London; the place where the Lombards are known to have first settled, and carried on their commerce in England, and where the merchants of London used to hold their meetings before the Royal Exchange was built. Anderson (Hist. of Commerce) says, that the early commerce carried on about the middle of the 16th century, between England and the Netherlands, introduced the practice of insuring from losses by sea, by a joint contribution. But the preamble to the statute 43 Eliz. c. 12, already cited, which statute was passed in 1601, distinctly states, that it had been an "immemorial usance" among merchants, both English and foreign, when they made any great adventure, to procure insurance to be made on their ships or goods adventures. From this it may be reasonably supposed, that insurance must have been in use in England long before the middle of the preceding century. The law of insurance, says Mr. Marshall (ubi infra), is considered as a branch of marine law; and it is also a branch of the law of merchants (see Law); and it may be collected from these two sources in the ordinances of different commercial states, in the treaties of learned authors on the subject of insurance, and in judicial decisions of this country, and also of others professing to follow the general marine law and the law of merchants. The earliest ordinance now extant on the subject of insurances is that of Barcelona, supposed to have been published about the year 1455. The next ordinance on this subject was published at Florence in the beginning of the year 1523. The emperor Charles V. in 1551 published several regulations concerning maritime commerce, called the "Caroline" code, to which his son Philip II. added a number of new ordinances in 1563 and 1565. Magens, in his "Treatise on Insurance, Average, and Bottomry," published at Hamburg in 1753, has collected many of these ordinances; but the most complete system of positive law for the regulation of insurances, that has yet appeared in any country, may be found in the celebrated ordinance of the marne of Louis XIV., published in 1681.

The statutes pertaining to this subject, which have been enacted in England, have not been numerous; and, therefore, the practice among us has been found most conformable to the general usage of trade. As to treaties on insurance, the earliest now extant is that entitled "Le Guideron de la Mer," which is found in the collection of marine institutions, published at Rouen in 1671 by Cleirac, under the title of "Les Us et Coutumes de la Mer." This is supposed to have been written about the 15th century. In France, Valin, Potheo, and Emerigon, have written on this subject. The treatise of the latter is, in the judgment of ferjeant Marshall, the most useful to an English lawyer of all the foreign publications on this subject. Roeceus, Cafaregis, Locennius, Bynkerhock, and Santerna, have also published treatises on this subject. We have also in England detached observations on insurance in the treaties of Malyne, Molloy, Beaves, Postlethwaite, and some others of less note. Mr. Magens, a merchant, in 1737, republished in two volumes his "Essay on Insurance," which he had before published in German at Hamburgh. Mr. Millar, a learned advocate at the Scots bar, published at Edinburgh, in 1787, the "Elements of the Law relating to Insurances;" Mr. Park has also given to the world his excellent "System of the Law of Insurances;" and in 1802 the public was favoured by Samuel Marshall, ferjeant at law, with his "Treatise on the Law of Assurance," in 4 books, containing an ample account of everything that is essentially necessary to be known on this subject. As to judicial decisions, none of these are considered as binding authorities in our superior courts, except such as have been there determined; and even these may be re-considered and over-ruled. Before the passing of the act of queen Elizabeth, above cited, almost all disputes, arising upon contracts of insurance, were settled by arbitration, and without recurring to any legal proceedings. And there seem to have been a particular tribunal for such arbitrations, established in London, composed of persons annually appointed by the lord mayor. From Malyne we learn that there was an "office of assurances," on the west side of the Royal Exchange, where insurances were made; and to this office belonged certain commissioners, who were annually appointed. The authority of these commissioners was confirmed by act of parliament, in the latter period of the reign of queen Elizabeth. (See Court of Policies of Assurance.) This court gradually sunk into disrepute, and all suits on policies of insurance were preferred in the courts of common law. After some of the decisions of the courts of Wiltmin- ster, on questions of insurance, came to be generally known, the confidence which the justice, impartiality, and ability of those courts inspired throughout Europe, soon induced the merchants of all countries to prefer English insurances to those of any other country.

The parties to the contract of insurance are the insured and the insurers. In this country, all persons, whether British subjects or aliens, may, in general, be insured. The principle of insurance, not the exception only to this rule, is the case of an alien enemy. The insurance of the ships and merchandise of France, during a war with that country, is prohibited by 21 Geo. II. c. 4; and by 33 Geo. III. c. 27. § 4, which latter statute not only declares such insurances to be void, but also subjects the parties concerned in them to three months' imprisonment. The policy of this prohibition was however disputed in 1741, by Sir John Barnard, and in 1748 by Sir Dudley Rider and Mr. Murray, then attorney and solicitor-general. But their objections were over-ruled. Nevertheless, it appears that a neutral, though residing in the enemy's country, and carrying on trade-
trade there, and even in partnership with an alien enemy, may injure his interest in the joint property.

Those who are insurers, or underwriters, should be persons of great prudence and circumspection; and cafes may occur, which will require more than ordinary sagacity, penetration, and experience. At common law, any man, or company of men, might be insurers; and individuals, upon their own separate account, have still the same right. But about the beginning of the last century it was thought expedient, partly with a view to counteracting the evil arising from insurance by insufficient persons, and perhaps, principally for enabling government to raise a sum of money by the sale of a monopoly, to erect two companies for making marine insurances, with such funds to answer all demands on their policies as might give confidence to venturers and traders, who were unwilling to depend on individual underwriters; still, however, leaving to merchants the option of insuring with such underwriters whom they thought proper.

To this end the 6 Geo. I. c. 18, authorized the king to grant charters to two distinct companies or corporations, for the insurance of ships, goods, and merchandise, at sea, or going to sea, and for lending money on bottomry. In pursuance of the powers given by this act, the two proposed companies, the one called the "Royal Exchange Assurance," and the other the "London Assurance," were established by royal charter, bearing date June 23, 1720. The most important privilege granted to these companies was the exclusive right of making marine insurances, and lending money on bottomry, as a "Company" or "Partnership," on a "joint capital."

Insurance is said to be "a contract of indemnity from loss or damage, arising upon an uncertain event." So that the object of insurance is to avoid a possible loss. Hence it appears, that there cannot be an indemnity without a loss, nor a loss without an interest. A policy, therefore, without interest, is not an insurance, but a mere wager. It is not easy to define and ascertain insurable interest. The interests of commerce, and the various rights which different persons may have in the same thing, require that not only those who have an "absolute" property in ships and goods, but those, also, who have a "qualified" property in them, may be at liberty to insure them; and this principle has been so extended, that if a servant abroad, in order to secure the payment of a debt due to his correspondent in England, mortgage to him his interest in certain goods and freight; the correspondent, after the mortgage becomes absolute, may insure the "legal" interest on his own account, or the "equitable" interest on account of the mortgagee. A reasonable expectation of "profit," or a well-founded expectation of a future interest in the thing insured, is an insurable interest. But a mere hope or expectation of future gain, however well founded, is not an insurable interest, unless accompanied by possession of the subject-matter of the insurance. Of this nature is the interest which the captor acquires in a prize regularly taken in war. It also appears, that persons in the character of "trustees," for the disposal of ships and goods according to such instructions as they might receive from third persons, may insure such ships and goods for the benefit of the persons who may eventually be entitled to the produce of them. Accordingly, commissioners, entitled "The Honourable Commissioners for the Sale of Dutch Property," were appointed by 3 Geo. III. c. 80. § 21, to take into their care all Dutch ships, &c. detained in British ports, and to dispose of them in pursuance of directions from the privy council; and they were authorized to insure, in their own names, such ships, after seizure at sea, and while they were on their passage to England. At common law, an insurance might have been made without interest; nor is it necessary to aver interest in any case not prohibited by 19 Geo. II. c. 37.

An insurable interest can only be founded on a legal or equitable title; but a mere claim, which the law cannot admit to be either legal or equitable, is not an insurable interest. As freight can only be due to the legal owner of a ship, he can only insure it; and no person can have either a legal or equitable title to a ship, unless he be named in the regisier. Although "respondentia" and "bottomry" are of themselves a species of insurance, yet the lender has an insurable interest in his securities, and therefore may protect himself from the sea-risk by insuring them. However, a policy on bottomry or respondentia cannot be subinscribed by the borrower of the money; for if he were to become an insurer, this would be no longer a loan upon bottomry, but a cloak for usury. See Hagar's Policy, and the sequel of this article.

Insurances are of various kinds, as on ships or parts of ships, on merchandise and goods jointly, on freight, and bottomry loans; and these are again branched out in time for the sum stipulated for, to one single part, or out and homewards, with liberty to touch at the different places mentioned in the policy.

It is laid down as a general rule, that no insurance can be legally made upon any voyage undertaken contrary to the laws of this kingdom, or to those of its dependencies, or to the law of nations. Nor is it of any importance whether the insurer was or was not informed that the voyage was illegal. Consequently, an insurance upon a voyage undertaken contrary to the navigation laws would be void. The case is the same with regard to a voyage prohibited by the laws made for the protection of the monopoly of the East India company. Under the treaty allowing the Americans to trade in the British colonies in India, concluded in 1755 and confirmed by 37 Geo. III. c. 97, it is not necessary that this trade should be carried on from America to the British settlements in the East Indies "direct," but it may be carried on "circumstantly" by the way of Europe. With respect to the ricks or perils against which insurances are usually made, they are expressed in the words of the policy, which are as follows: "Touching the adventures and perils which we the affurers are contented to bear, and do take upon us in this voyage, they are of the seas, men of war, fire, enemies, pirates, rovers, thieves, jettisons, letters of mar and counter-mar, furprifals, takings at sea, arrefts, restraints and detainments of all kings, princes, and people, of what nation, condition, or quality whatsoever; barry of the matter and mariners; and of all other perils, losses, and misfortunes, that have or shall come to the hurt, detriment, or damage of the said goods and merchandise, and ships, &c., or any part thereof, without prejudice to this insurance." But by the agreement of the parties, the general words of the policy may be altered or qualified, and any of the ricks may be wholly or in part excluded; and the insurance may be made only against some particular ricks, or as to, or beyond certain degrees, or upon particular articles. In the policies of most countries it is stipulated that the insurer shall not be liable for any partial loss under a given rate per cent. A clause to this purpose, which was first introduced in 1749, is inserted at the bottom of all English policies. Nevertheless, the insurer is liable for losses, however small, called "general average," and losses occasioned by the "flandering of the ship." In the policies of private underwriters the memorandum is as follows: "corn, comprehending every sort of grain, and also peas and beans," fish, salt (not including salt-petre), fruit, flour and seed, are warranted free from average.
average, unless general (denoting losses arising from any cause affecting the general safety of the ship and cargo), or the ship be stranded; sugar, tobacco, hemp, flax, hides and skins are warranted free from age, under 5 per cent., and all other goods, also the ship and freight, are warranted free from age, under 3 per cent. unless general, or the ship be stranded."

In 1753, the two companies, viz. those of the London and Royal Exchange, assured left out the words, "or the ship be stranded," but private underwriters have continued them. If any loss or damage happen to the goods, from any fault or defect of the ship, the owner has his remedy against the proprietors of the ship, and the insurer is not liable: because, in every contract of insurance, there is an implied warranty, that the ship is seaworthy; if otherwise, the contract is void. In many cases the master also is liable. The marine law, with which agrees the common law of England, considers the owners, as well as the master, as common carriers, and answerable for all losses, except such as arise from the act of God, the king's enemies, or the perils of the sea. In order to charge the insurer, the loss must happen in the course of the voyage, and during the continuance of the risk. In our policies the words usually employed to express the commencement and end of the risks on goods are these: "Beginning the adventure upon the said goods and merchandize from the loading thereof aboard the said ship, and so shall continue and endure until the said ship with the said goods shall be arrived at ______ (her port of delivery), and until the same be discharged and safely landed." This rule, however, admits of some exceptions, which our limits will not allow us to enumerate. The duration of the risk on the ship varies with us in almost every case. In outward-bound voyages it is generally made to commence from her beginning to load at her port of departure. Ships engaged in the coasting-trade, or in short voyages, are insured for a limited period of time; and in such cases, the risk commences and ends with the term, wherever the ship may then happen to be. If a ship be insured from the port of London to any other port, and before she breaks ground, an accident happen to her, the insurers are not answerable; for the risk does not commence till the facts fail on her departure from the port of London: but if the insurance be "at and from" the port of London, the insurers are liable for any accident that may happen to her, "from the time of subscribing the policy." When a ship, in homeward voyages, expected to arrive at a certain place abroad, is insured "at and from" that place, or from her arrival there, the risk begins from the first moment of her arrival at the place specified; and the words "first arrival" are implied, and always understood in policies so worded. As to the termination of the risk on English policies, it is usually made to continue only "until the ship hath moored at anchor 24 hours in good safety." The risk on the furniture, the rigging and tackle, and provisions of the ship, may continue even when put on shore. With insurers, a liberty to touch and lay at any ports and places, means ports and places in the usual course of the voyage. This liberty to touch and lay at any ports or places, does not authorize the insured to break bulk and trade. Although a ship, through necessity, change the order of the places at which she is to touch, yet if she do not abandon the original voyage, the risk continues. In an insurance upon freight, the risk generally begins from the time the goods are put on board. If an accident happen to the ship before any goods are put on board, which prevents her from sailing, the insured cannot recover for the loss of freight, which the ship might have earned if the accident had not happened. But if part of the cargo be put on board, and the rest be ready to be shipped, the insured may recover for the whole freight, upon a valued policy. (See Policy.) If a ship be lost in her way to her port of loading, the insurer is liable for the whole freight. If, after the insurance is effected, any thing be done by the insured to alter the nature of the risk, this must be done with the consent of the insurer, otherwise it will void the contract.

Insurances may likewise be made on goods sent by land, or by horse, &c. on rivers; and this is frequently done, more especially on jewels, and other things of great value. They may likewise be made on ships and goods, lost or not lost, which is commonly done when a ship has been long missing; and those words being inserted in the policy, oblige the underwriters to pay, though the ship was lost at the time of making such insurance, except the assured had then certain knowledge of the ship's being wrecked; in which case the subscription shall not oblige, as this is accounted a mere fraud. So likewise if a person get more insured than the ship is worth, with a villainous design to delay her, this fraudulent act will not oblige the insurers, but expose the proprietors to suffer death for their knavery. An insurance made on prohibited goods is illegal and void, unless they were not prohibited till after the insurance was made. The insurance of men's wages is prohibited in all maritime countries; and by the law of England such insurance is unquestionably illegal. But they may insure goods purchased abroad with their wages; and the captain is allowed to insure goods which he has on board, or his share in the ship, if he be a part-owner. By the law of France, the insurance of freight, not actually earned, is prohibited; but in England the freight, as well as the ship, may be legally insured. To entitle the owner, however, to recover for a loss on a policy for freight, it must appear, that, before the loss, the owner's right to freight had commenced; that is, that the ship had actually begun to earn freight. For till that time the risk on freight does not commence. Although it is not unusual in England to insure profit, the question whether this be a proper subject of insurance has never yet come under solemn discussion. Where the policy expressly mentions that the ship is to depart with convoy, it is intended that she shall, if possible, keep with the convoy during the voyage, and if she depart wilfully from the convoy, it is a fraud; but if having departed with the convoy, she by force of weather loses the convoy, and is taken, the insurers are liable. (See Warranty.) If there be thieves on board among themselves, the master of the ship is to answer for that, and not the insurers; for though the words of the policy insure against losses by thieves, yet assailing or external thieves are only here intended, and for external theft the insurer as well as the owner of the ship is liable; but the proprietor of the goods, or the insurers in his name, may recover against the owners. An insurance made in a foreign country, may be sued in England by the common law, if the insurers come here. Where the policy is against restraint of princes, that does not extend to a navigation carried on against the laws of nations, or where there shall be a seizure for not paying of customs or the like. If goods be insured as the goods of an ally, when they are the goods of an enemy, it is a fraud, and the insurance not good. If a man pays money on a policy of insurance, supposing a loss where there was none, this shall be money received for the use of the insurer, for which he may maintain an action. A suppression of the truth, or a false allegation, is sufficient to discharge the policy; for it is a general rule, that the insured ought to
INSURANCE.

inform the insurer of all material Circumstances that were come to his knowledge at the time of making the policy, in order that the contract may be fairly adjusted; which being a contract upon chance, cannot be done, if one party knows more than the other; for equality in contracts, by the law-merchant, is essential; but a proof of an intention to make a deviation, will not avoid the policy before the deviation is actually made. See REPRESENTATION.

By an act made in 19 Geo. II. c. 37, it is determined, that after the first day of August, 1746, no insurance shall be made on ships or lading, "interfet or no interest," or "without further proof of interest than the policy," or by way of gaming or wagering, or without benefit of salv- age to the insurer, and that every such insurance shall be void: that it shall not be lawful to make re-insurance, unless the insurer shall become insolvent, become a bankrupt, or die: in which cases such insurer, or his executors, &c. may make re-insurance to the amount of the sum before insured, provided it be expressed in the policy to be a re-in- surance (see REINSURANCE): that all sums of money lent on bottomry or respondentia, upon any ships belonging to his majesty's subjects, bound to or from the East Indies, shall be lent only on the ship or merchandise, laden, or to be laden, on board such ship, and shall be so expressed in the condition of the bond; and the benefit of salvage shall be allowed to the lender, his agent or affiants, who alone shall have a right to make insurance on the money so lent; and no borrower of money on bottomry, &c. shall recover more on any insurance, than the value of his interest in the ship or merchandise, exclusively of the money so borrowed; and in case it shall appear, that the value of his share in the ship and merchandise does not amount to the full sum bor- rowed, such borrower shall be responsible to the lender for so much of the money borrowed, as he hath not laid out on the ship or merchandise, with lawful interest for the time, together with the insurance and all other charges, to the proportion which the money not laid out shall bear to the whole money lent, notwithstanding the ship and merchandise be totally lost. And, in all actions brought by the injured, the plaintiff, or his attorney or agent, shall, within 15 days after he shall be required so to do, in writing, by the defendant, or his attorney or agent, declare in writing what sum or sums he hath insured or caufed to be insured in the whole, and what sums he hath borrowed, at respondentia or bottomry, for the voyage, or any part of the voyage in question.

Whenever advice is received of the loss of a ship or goods insured, application is to be made to the insurers, and the vouchers produced; and if they are satisfied, they will pay the money: but if they have cause to scruple the doing it, the insured must lay till the insurer can obtain a more satisfactory account; but if nothing be heard of the ship in any reasonable time, the insurers will be obliged to pay the money agreed upon.

In adjusting a loss, the quantity of damage for which the underwriters are responsible is first to be ascertained; and the next point to be settled is by what rule this shall be appreciated. The adjustment is usually indorsed on the policy and signed by the underwriters. When the loss is admitted to be total, and the policy is a valued one, the insured is entitled to receive the whole sum insured, subject to such deductions as may have been agreed by the policy to be made in case of loss. It is merely in respect of total losses that any difference falls between an open and a valued policy. Upon the latter the value is admitted, and the insured has only to prove, if the insurance was on goods, that the goods valued were on board. Upon an open policy, it is necessary to prove, not only that the goods were on board, but also the value of them, which the insurers, provided it does not exceed the sum insured, are bound to pay. But in the case of a partial loss, the amount of the loss should be ascertained in both kinds of policy. When a part of the goods insured is saved, and this exceeds the amount of the freight, the practice is to deduct the freight from the salvage, and to estimate the loss by the difference; but when the freight exceeds the salvage, then it is a total loss. If the goods insured are damaged in the whole, or in part, it will be necessary to ascertain the quantity of such damage, which is done by taking the value of the goods, in their damaged state, from the prime cost, and the remainder will be the amount of the losses. If several articles be in- sured for one entire sum, but with a distinct valuation to each, and only one be lost in riks, and if that one be lost, the insured shall recover such a proportion of the sum in- sured as the value of that article bore to the value of the whole. If the policy has a clause, to be free of average from a particular risk, under so much per cent. and a loss occasioned by that risk takes place, the proportion which the losfs bears to the cargo must be calculated upon the cargo which was on board when the loss happened, not upon that which was on board at any other time. With respect to the valuation of goods insured, there has been a difference of opinion; some contending for the prime cost, others for the current price at the time of loss; some again insisting on the price at the time and place of shipping the goods, others on the price at the port of discharge. In England, if the policy be an open one, it is an irreparable rule to estimate a total losf, not by any supposed price which the goods might have been deemed worth at the time of the losfs, or for which they might have been sold, if they had reached the market for which they were defined; but according to the prime cost, that is, the invoice price, and all duties and expenses till they are put on board, together with the premium of insurance. The value is never affected by the rife or fall of the market, nor by the course of exchange. A ship is valued at the sum she is worth at the time when she fails on the voyage insured, including the expense of repairs, the value of her furniture, provisions and stores, the money advanced to the sailors, and, in general, every expense of the out-fit, to which is added the premium of insurance. A partial losf upon either ship or goods is that proportion of the prime cost, which is equal to the diminution in value occasioned by the damage. An adjuftment, being indorsed on the policy and signed by the underwriters, with a promise to pay in a given time, is prima facie evidence against them, and amounts to an admission of all the facts necessarily to be proved by the insured to entitle him to recover in an action on the policy. It is like a note of hand, and being proved, the insured has no occasion for further proof. An ad- justment, however, may be impeached by shewing that the underwriter was induced to sign it by some fraud or con- ceit, or by some misconception of the law or fact; but this must be done by evidence, and not by doubts or surmises after the time for payment is come.

If it be insured, under what circumstances the insured shall be entitled to demand a return of premium, the particular cases are as follow. In general, the premium ought to be returned, when the contract is void ab initio; that is, when no intention of interest in the insured, or because the insur- ance is illegal, or on account of fraud on the one side or the other. However, upon a wager-policy the insured can-
not recover back the premium, at least after the risk is run. 19 Geo. II. c. 37. But before the risk is run, and while the contract is executory, the insured may recover back the premium. If the contract be void, as being a re-insurance, within the above cited statute, the insured shall not be intitled to a return of premium. If, under any circumstances, the insurer might, at any time, have been called upon to pay the whole sum insured, the premium is earned, and he shall not be obliged to return any part of it. Although an insur ance to protect trading with the enemy is void, yet the insured shall not recover back the premium. In the case of fraud likewise on the part of the insurers, the premium shall be returned. However it has been doubted, whether the insurer be bound to return the premium, in a case where fraud has been committed by the insured. The court of chancery, in two instances, ordered a return of premium where the policies were declared void for fraud committed by the insured. The courts now hold a contrary doctrine. As to the commencement of the risk, the rule in England is, that where the risk has not been begun, whether this be owing to the fault, pleasure, or will of the insured; or to any other cause, the premium shall be returned. But if the insurances be upon a voyage, divisible into several distinct risks, or, which amounts to the same, into several distinct voyages, the premium may be apportioned, according to these several risks; and if one or more of these risks should not have been commenced, the proportion of premium applicable to those parts shall be returned. But if the risk be entire and be once commenced, there shall be no return. If part of the premium is to be returned upon the performance of some stipulation agreed upon between the parties, this shall be returned, though the insurer be obliged to pay a partial loss. As the insurer can never, by his own act, discharge himself from the contract, it seems reasonable, that, where the insured thinks proper to put a stop to the adventure, and prevent the risk from ever commencing, he should make some compensation to the insurer for his trouble and disappointment; it is therefore the general custom in all the maritime countries of Europe, to allow him to retain one-half per cent.

With regard to actions on policies of insurance, the sole jurisdiction belongs to the courts of common law; and the proper form of action against private underwriters, is special "Affirmpt," which fee. The two insurance companies, being corporations, can do no act but by deed under their common seals. Their policies of insurance, being under seal, no action of "Affirmpt" will be upon them, but only debt of covenant. See St. 6 Geo. I. c. 18, and 8 Geo. I. c. 30. The evidence generally adduced on the part of the plaintiff is reducible to the following heads, viz. proof of the contract, payment of the premium, interest of the insured, performance of warranties and loss. For a further detail of these and other particulars, relating to matters of insurance, and the determinations of judges and courts of law in illustration and confirmation of them, see "A Treatise on the Law of Assurance," by Samuel Marshall, serjeant at Law, in 2 vols. Lond. 1802. On this subject, see farther under BARTRAY, Assurance, Brokers, Deivation, Policy, Salvage, Underwriters, and Warranty. See also BOTTOMY and RESPONDENTIA.

INSURANCE upon Lives, is a contract by which the insurer, in consideration of a certain premium, either in a gross sum or by annual payments, undertakes to pay the person, for whose benefit the insurance is made, a stipulated sum of money, or an equivalent annuity, upon the death of the person whose life is insured, whenever this shall happen, if the insurance be for the whole life, or in case this shall happen within a certain period, if the insurance be for a limited time. For the principles on which this kind of insurance is made, and other particulars relating to it, see the article Assurance. It is generally a condition or warranty, in insurances upon lives, either inserted in the policy, or contained in a declaration or agreement signed by the insured, that the person whose life is insured has not any disorder which tends to the shortening of life; that he has, or has not, had the small-pox; and that his age does not exceed so many years; that this declaration shall be the basis of the contract between the insurers and the insured; and that if any untrue averment be contained therein, the contract shall be void, and all money paid on account of the insurance forfeited. As this declaration is to be taken as part of the written contract, amounting to a warranty, it becomes every person who makes an insurance upon a life, to be very circumspect in ascertaining the truth of the allegations which it contains; because upon that the validity of the contract must depend. When there is no warranty, the insurer takes the risk upon himself, whatever may be the state of health of the person whose life is insured, unless there be some fraudulent misrepresentation or concealment.

In order to check the spirit of gaming, which is ready to avail itself of insurance upon lives, it is enacted by Stat. 14 Geo. III. c. 48, § 1, that no insurance shall be made by any person or persons, bodies politic or corporate, on the life or lives of any person or persons, or on any other event or events whatever, wherein the person or persons, for whose use or benefit, or on whose account, such policy or policies shall be made, shall have no interest, or by way of gaming or wagering; and that every insurance made contrary to the true intent and meaning of this act, shall be null and void to all intents and purposes whatsoever; and that it shall not be lawful to make any policy or policies on the life or lives of any person or persons, or other event or events, without inserting in such policy or policies the name or names of the person or persons interested therein, or for what use or benefit, or on whose account, such policy is to be made or written; and that in all cases where the insured hath an interest in such life or lives, event or events, no greater sum shall be recovered, or received from the insurer or insurers, than the amount or value of the interest of the insured in such life or lives, or other event or events. This act extends to every species of insurance except marine insurances, which are expressly excepted. The different insurance companies annex to the contract certain conditions or exceptions. For those of the "Royal Exchange Assurance" (see Assurance.) The same exceptions are adopted by the "Wellsminster Society," the "Equitable Assurance," and the "Pelican Life-insurance," adopt the same exceptions, only omitting the word "duelling," even where the party insures his own life. Other societies for insurance on lives, such as the "Rock Insurers Society," &c. have been more recently established, and insurances of this kind are made by some of those societies, which will be noticed in the next article.

The societies which restrict themselves to insurance on lives are the following; viz. the "Amicable Society," incorporated by royal charter of queen Anne in 1706, functioned by the grant of two subsequent charters in 1730 and in 1790, and further improved under the powers conferred by a new charter in 1807. By virtue of this charter, persons are admitted to insure their own lives, or the lives of others, in which they may have an interest, on the following payments:

</table>

The whole of the annual contributions for every share granted previous to the last charter, and seven eighths of the contributions on shares subsequently granted, are to be divided every year amongst the claimants by deaths which happen in that year; a principle of division, which is calculated, in the general course of things, to raise each claim considerably above 18s. which sum at least the corporation engages each share to pay to the claimant. See Assurance.

The "Society for Equitable Assurances on Lives and Survivorships" was established by deed, inrolled in his majesty's court of king's bench, Westminster. For an account of this society, which has acquired high reputation, under the conduct of its present actuary, William Morgan, esq., see Assurance. The "Westminster Life Insurance Office" was established in 1792. The "Pelican Office" for insurance of lives, granting annuities and endowment of children, was established in the year 1797. The "Rock Life Assurance Company" was instituted in 1806, on a principle different from that of any society hitherto established for the assurance of a sum to the representatives of a person affurred. The company consists of a number of proprietors, possessing a capital stock of one million; and each proprietor is under the necessity of affuring a sum on his own life, if accepted by the directors; or on that of an approved nominee, to the amount of one quarter of the stock in his name. Thus by affuring each other's lives, the proprietors have a mutual interest in the support of the society, and are engaged to each other to take care that no improper life, with their knowledge, be admitted into it. By the mode of affuring property in this society, the representatives of the affurred receive a certain sum at his decease, and whatever addition may have been affixed to that sum by the previous resolution of the society, agreeably to its deed of settlement. The persons who affure in this office are not all partners; they are not all responsible for the payment of the sum affured to each individual. The affurred are either proprietors or non-proprietors. The proprietors are answerable each to a certain amount; they lay down a certain sum, and form a determinate capital to answer all contingencies, and by thus forming a capital, they are enabled to make a due allowance of the sum to be added at different periods to various policies of assurance. The affurred non-proprietors have no share in the risk: they pay down definite premiums, which affure to the representatives the sum affured, and who partake equally with proprietors in the addition which may be made at different periods to each policy. The security for the payment of that sum is the capital stock of the company and the amount of all the premiums, with the interest upon them. Such a security, it is said, may be deemed as a "rock." And that we apprehend the company derives its appellation; for the transfer of shares will produce a continual renovation of policies, which, with the capital of the company, and the amount of annual payments from assurances, will form an increasing fund, adequate to every purpose of profit and security. The character of William Frend, esq. the actuary of this society, as a mathematician, is well known. The "Provident Life Ininitation" was established in 1806. In the same year was also established the "Philanthropic Annuity Institution;" the object of which is to enable those, who wish to raise an immediate sum of money by the grant of annuities, or to invest money for the purpose of accumulation, to do it on the most advantageous terms suited to the various circumstances and contingencies of life; and also to provide endowments for children, &c. The investment of money in this institution may be made in three different ways: 1st, by paying a certain sum of money down, to receive an annuity, to commence immediately; 2dly, by paying down a certain sum of money, to receive an annuity, to commence at a future time; and, 3dly, by paying a sum of money at particular periods, to receive back a sum, or an annuity when the investor requires it. The "London Life Assurance" for the assurance of lives, consists of persons affuring their respective lives for the whole term of life; and the members become, to the amount of their policies, mutual assurees to one another. The society also undertakes every description of assurance on the lives of persons, not members; and it is part of its plan to make endowments, and to grant and purchase annuities, by virtue of an act of parliament of the 47th Geo. III. c. 32. The distinguishing principle of this society is, that the benefits resulting from its transactions shall be enjoyed by the members, during life, so as to render life assurance as easy to the affurred, as due regard to security, will allow admit. The "Royal Exchange Assurance Annuity Company" has been already mentioned under the article Assurance; but it May 1803, the following table of rates was formed:

### N.B.

The foregoing annuities are receivable in quarterly Payments.

---

Insurance against Fire, are founded on a contract, by which the insurer, in consideration of a certain premium, received by him, either in a gross sum, or by annual payments, undertakes to indemnify the insured against all losses or damages which he may sustain in his houses or other buildings, goods, and merchandize, by fire, during a limited period of time. Although the precise time of the introduction of this kind of insurance into England cannot be ascertained, it has certainly been in use here considerably more than a century. Of late years, notwithstanding a very heavy, and we may add impolitic, stamp-duty imposed on these insurances, they have very generally, not to say universally, prevailed in this country: particularly in London, and other cities and large towns. In other countries they have been less general, and more recently introduced. The fire-office at Paris is said to have been established in 1745.

In Holland, though insurance against fire is not altogether unknown, yet few people seek its protection; because they rely on their own caution, and do not chuse to incur the expense of any greater security. It has, indeed, been confidently asserted, by persons well acquainted with the cities both of London and Amsterdam, that after making all fair allowances, there is, upon an average, more property destroyed by fire in the former in one year than in the latter in seven years. Some persons have charged many of the fires that occur in London and its vicinity on insurance; but though negligence and fraud may in some instances derive encouragement from this establishment, the benefits must be allowed far to overbalance the mischief of which it is, directly or indirectly, productive. In London and other
parts of the kingdom, companies or societies for insurances against fire have been very numerous; and their number has possibly been augmented by the emoluments that accrue to those who establish and conduct them. Some of these are called "Contribution Societies," in which every person injured becomes a member or proprietor, participating in profit and loss. Such are the "Hand in Hand," and the "Wellminster" fire-offices, for the insurance of houses and other buildings; and the "Union" fire-office, for insurance of goods. The other companies insure both houses and goods at their own risk. Of these, the principal are the "London" and "Royal-Exchange" Assurance Corporations, the "Sun," the "Phoenix," and the "British" fire-offices.

As to the duties to which this contract is liable, the flat 37 Geo. III. c. 90, § 23, repeals all the former stamp-duty imposts on policies of insurance against fire; and (by § 24) imposes on every policy, in lieu thereof, a new duty of three shillings, where the sum insured is under 100l., and of six shillings where the sum insured amounts to 100l. or upwards. And by the flat 44 Geo. III. a duty of two shillings and threepence per cent. per annum is to be levied on property insured against fire. It is much to be regretted, that insurances against fire are often made to a large amount upon property of very small value; this can only be done with a fraudulent view, and a premeditated fire must be the necessary consequences. Such practices require caution in the insurers, ought to be restrained, and when they occur severely punished. If there be several insurances on the same property in different offices, each office should have notice, that the same may be allowed by indorsement on the policy; in order that each office may bear its proportion of any loss that may happen. But unless such notice be given to the office where another insurance is made on the same effects, the insurance made without such notice will be void. In general, the risk commences from the signing of the policy, unless some other time be specified; and it will of course end with the term for which it is made. Insurances against fire are, in general, either annual or for a term of seven years, at an annual premium; and the offices, as an inducement to the insured, generally allow fifteen days from the expiration of each year for the payment of the premium for the next succeeding year. But the insurers have always been concerned as being under the protection of the policy till the expiration of the period of days, provided the premium was paid within that time. Several offices now hold themselves liable for any loss during the fifteen days that are allowed for the payment of the renewed premium upon annual policies, and others for a longer period, but every policy for a shorter period than a year ceases at six o'clock in the evening of the day that is mentioned in it. A policy of insurance, being a chose in action, is, in strictness, not assignable at law; but it may be assigned in equity. However, the mere assignment of the policy would be of little avail without an assignment of the subject-matter of the insurance also. In the printed proposals of all the offices, it is declared, that, upon the death of an insured, his interest in the policy shall be continued to his representatives to whom the property insured belongs, provided that such representative, before any new payment be made, procure his right to be indorsed on the policy at the office. The policies of the Contribution Societies, viz., the "Hand in Hand," "Union," and "Wellminster," may be assigned, without any express permission from the respective offices for that purpose; and it is sufficient if the assignment be brought to the respective offices to be entered. But the other offices give notice, generally upon the policy, that it shall be of no force if assigned, unless such assignment be allowed by an entry in the books of the office, or indorsed on the policy; and hence it seems to be a settled rule in all the offices, not to allow any transfer of any policy without the consent of the managers. If an assignee of the property insured undertakes to get the policy transferred to the assignee, he will be liable to an action for neglecting to do it; even though his undertaking was merely gratuitous. For the proof and recovering of loss, the following article is found in the proposals of several of the offices, importing, "that persons injured fulfilling any loss or damage by fire, are forthwith to give notice thereof at the office, and, as soon as possible afterwards, deliver in as particular an account of their loss and damage as the nature of the case will admit of; and make proof of the same by their oath or affirmation, according to the form practised in the said office; and by their books of accounts, or other proper vouchers, shall be reasonably required; and procure a certificate under the hands of the minister and churchwardens, together with some other reputable inhabitants of the parish not concerned in such loss, importing, that they are well acquainted with the character and circumstances of the person or persons injured, and do know, or verily believe, that he, she, or they, really and by misfortune, without any fraud or evil practice, have sustained by such fire the loss and damage, as his, her, or their loss, to the value therein mentioned. But till such affidavit or certificate of such injured's loss shall be made and produced, the loss-money shall not be payable. And if there appears any fraud or fault, having a like effect, all such sufferers shall be excluded all benefit by their policies." In the policies of these offices the insurers undertake to pay the loss, not exceeding the sum insured, "according to the exact tenor of their printed proposals," describing their proposals by their respective dates.

Insurances against fire are described in the plans and proposals of the different societies, with little variation, as common, hazardous, and doubly hazardous; and they comprehend buildings and goods. Buildings subject to common insurances are those of brick or flax, standing alone, or separated by partition walls, and covered with slate, tile, copper, lead, or iron, with brick chimneys; in which no hazardous trades are carried on, or hazardous goods deposited. Goods are household goods, in private dwellings, not hazards to brick, not hazardous to brick or flax buildings as above described, and in which no hazardous trades are carried on, nor hazardous goods deposited. Hazardous insurances comprehend buildings of timber or plater, brick and timber, or brick and flax, not having party walls of brick or flax, wherein no hazardous trades are carried on, or hazardous goods deposited, brick or flax buildings in which hazardous trades are carried on, or hazardous goods deposited; also thatched barns and out-houses (having no chimneys, or adjoining to any building having a chimney), containing farmer's stock or implements of husbandry: likewise all flours and warehouses which have German or metal bowls with pipes. Goods subject to the same kind of insurance are the stock and goods of bakers, brewers, vinegar and sweet-makers, printers, hot-pokers and calenders, carpenters, chemists, coach-makers, colour-men, cooperers, hemp and flax-drovers, inholders, malthoues, oil leather-drovers, flax, and tallow-chandlers, flax-creapers, pawn-brokers, hemp, flax, pitch, tar, turpentine, rosin, tallow, hay, straw, and all manner of fodder, and corn unthreshed, apothecaries' stock; also, oil and spirituous liquors, as merchandise and the stock in timberyards. Doubly hazardous insurances comprehend buildings which
which are thatched, also timber or plaster buildings, in
which hazardous goods are deposited, or hazardous trades
carried on; and goods or stock in thatched dwellings; also
salt-petre, working-perfumers, tallow-melters, wax-chand-
lers, spermaceti candle-makers, and rope-makers in brick
and tiled buildings, boat-builders, china, glas, or earthen
wares.

The "Hand in Hand Fire-office" was instituted in the
year 1696; and its terms are, for common insurances, 300l.
or under, 2s. per cent. per annum; for hazardous insurances,
300l. or under, 3s. per cent. per annum: for doubly hazard-
ous insurances, 300l. or under, 5s. per cent. per annum. If
insurances are desired for any larger sums than are spe-
cified in the table of premiums, a special agreement may be
made for the same, and also for particular buildings, goods,
&c. not included in the second and third articles above
enumerated. Persons insuring in this office are allowed
one year's premium and duty, and must pay the requisite
premiums and deposit according to the nature of the
risk. They become joint proprietors and members of
the society, and are entitled to a proportionate share of the
profits.

The "Union Fire-office" was instituted in 1714, for in-
suring houses and buildings, goods, merchandise, and ships
in harbour, in dock, or while building, from loss or damage
by fire. The septennial insurances are allowed one year's
premium and duty, and become proprietors, partaking of
the profits of the society. The annual or short period in-
surers are completely protected from any loss or damage by
fire, or from any call or contribution towards any loss or
damage happening to others, by a very ample fund which
has been raised for that purpose.

No charge is made for policies of 300l. and upwards. Farming stock may be insured at 2s. per cent. The "Royal
Exchange Assurance," of which we have given an account, as far as it is a life-insurance office, under ASSURANCE, insures
also from loss or damage by fire.

Perfons affuring for seven years, will be allowed one year’s premium, and duty; for six years, 10 per cent. on the premium; for five years, 8 per cent.; for four years, 6 per cent.; for three years, 4 per cent.; for two years, 2 per cent.

Five per cent. discount allowed on premium. The premium on goods, hazardous or not hazardous, in any of the warehouses or sheds, or on the open wharfs, or in any part of the port of London, within five miles of the Royal Exchange (the West India docks excepted), with the average clause, 5s. per cent.; on goods not hazardous, similarly situation, 3s. per cent. The average clause, so often referred to, is as follows: It is agreed, that if the goods assured shall be of greater value than the sum assured, and the same shall not be totally consumed, the insurer shall only be liable to pay such a proportion of the loss as the sum assured shall bear to the whole value of the goods at the time of the breaking out of any fire. On sums of 300l. and upward, the policy and mark are allowed gratis.

The “Sun Fire-office” was established in the year 1710, and insures against loss or damage by fire, upon the following terms.

Sums above may be injured by Special Agreement.

Farming Stock, on any Part of the Farm, insured under General Policies, without the Average-Clause, at 2s. per Cent.

N. B. Any barn, or other out-building, and the farming flock therein, may be insured under one sum:—premium 3s.
rates. Policies are allowed in all cases where the annual premium amounts to 6s. Insurances for seven years are charged only five years premiums; and a considerable reduction is made on country insurances. The insurances on lives and on survivorship are made at the rates of other offices; nor does the company require entrance money, or admission fees, from persons effecting life insurances. The capital of the company is stated to be one million sterling, the whole of which has been invested in government or real securities, and it is stipulated that no members of the company shall be liable to pay any sum beyond the amount of his subscription or share in the said capital of one million.

The "Imperial Fire-office" was established in 1803. Its capital, of one million two hundred thousand pounds sterling, has been subscribed in shares of 500l. each; and no member is a subscriber for more than 5000l. Each member has deposited 12l. per cent. on the amount of his subscription, amounting in the whole to 120,000l. which sum is invested, and to accumulate for five years, without dividends to the members of the company. In case the current premiums on insurances, with the deposit of 120,000l. and all its accumulations, shall prove inadequate to satisfy the losses which may arise, the members of the company are, from time to time, to be called upon for further sums, in proportion to their subscriptions, and even to their full extent, if necessary. If the current premiums shall be more than sufficient to answer losses, and the expenses of management, the surplus is, from time to time, to be invested; but such profits are in no event to be divided, but are to be applied for augmentation of the capital stock; and the dividends and interest of the profits only are to be divided, after the expiration of five years. The premium in common insurances is 2s. per cent. per annum for 3000l. and under; in hazardous insurances, 3s. per cent. per annum, for 1000l. or under; and in double hazardous insurances, 5s. per cent. per annum, for 1000l. or under. Persons enlisting to insure for seven years will be charged for five years only; and for any number of years, less than seven, will be allowed a reasonable discount, both on the premium and duty.

The "Albion Fire and Life Insurance Company" was instituted in the year 1805; and is rated to pollers a capital of one million sterling. Its insurance against losses or damage by fire is in the first class of common insurances 2s. per cent. per annum to the amount of 5000l.; in the second class of hazardous insurances, 3s. per cent. per annum; and in the third class of doubly hazardous insurances, 5s. per cent. per annum to the same amount. Insurances are taken to a larger amount than that above stated; and policies are granted at suitable premiums for less than 12 months. On insurances for seven years, or for any greater or less term, exceeding one year, a considerable allowance is made, both on the premium and duty. The following abatements are made on the premiums of fire insurances of the first class, out of London: viz. 25 per cent. per annum on policies for single years; 30 per cent. on policies for three years; 35 per cent. on policies for five years; 40 per cent. on policies for seven years; and in the like proportion for policies for other periods. Insurances on lives are conducted on the same terms with those of other offices of a similar kind. No admission is charged on life insurance.

The "British Fire Office" insures houses and goods in the three classes above specified at 2s., 3s., and 5s. per cent. per annum respectively.

The "Hope Fire and Life Insurance Company" was instituted in 1807. Its annual rates of insurance on the three classes above named are, 2s. per cent., 3s. per cent., and 5s. per cent. on sums not exceeding 10,000l., 6000l., and 3000l., respectively. Farming stock is insured at 2s. per cent. on a sum not exceeding 10,000l. Special risks may be insured on terms corresponding to them. The following abatements are made upon country insurances, viz. 10 per cent. on policies for a single year; 15 for three years; 20 for five years; and 25 for seven years. Every person not being a proprietor of a share or shares in the company, and who shall insure or procure to be insured, property to the amount of 1000l., shall, upon the payment of 5l. beyond the premium of insurance, be entitled, out of the profits (arising from fire insurance only) to such interest or dividend as may arise, and become payable on one 50l. share in the capital stock of the company; and to a like manner for every additional 1000l. so insured; and such interest or dividend shall continue to be paid to such person or persons, or to his or their legal representatives or representatives, during such period as such insurances shall continue to be effected, and in the event of the same being discontinued, all dividends and interest, which may be then due or payable, together with the sum of 5l. to be paid for every 1000l. so insured as aforesaid, shall be forfeited and become the property of the company. Life insurances are effected by this company on the same terms with those of other offices. Persons not being proprietors, who insure, or procure to be insured, 500l. upon their own lives, or lives of others, will, upon the payment of ten shillings per cent. (on the admission of the party) beyond the premium paid for the insurance, be entitled, out of the profits of the life fund, to such interest or dividend as may be paid on a 50l. share to the several proprietors thereof, and to a like manner for every 500l. so insured; but in no case whatever are they to be responsible for any claims which the life fund may be called upon to pay, the capital of the company being of a sufficient magnitude for that purpose.

The "Eagle Insurance Company" was instituted in 1807, for fire and life insurance, and for granting annuities. Its capital is rated at two millions sterling. The annual rates of insurance against fire are as follows:

The building and stock of sugar refiners, sugar grinders, tea-biscuit bakers, distillers, musical instrument makers, cotton-spinners, calico printers, flax dressers, and other extraordinary risks, may be insured by special agreement.

Policies for short periods, or less than a year, may be effected at considerably reduced premiums, and will pay only a proportionate part of the duty. The insurance on lives is conducted as in other offices.

The "County Fire Office" was established in 1805, for the express benefit of country residents. The distinguishing principles
principles of this institution are, that its business consists of
the protection of the best risks; that the persons injured become
members; that all the members share the profits equally,
according to the sums which they respectively contribute
during seven years (whether their policies be taken out ori-
ginally for seven years, or be renewed annually), and with
the important advantage of not being liable to make good
the losses of others, as a surplus capital of £400,000 has been
provided to meet any excess of losses that may occur. In
common insurances of £500 and under, in one risk, the an-
nual premium is 2½ per cent.; in hazardous insurances, of
3000l. and under, in one risk, 3½ per cent., above 3000l.
and under 5000l., 4 per cent.; in doubles hazardous ins-
urnces, 5000l. and under, in one risk, 5½ per cent., above
3000l. and under 5000l., 7½ per cent. Larger insurances,
according to the above description of risks, may be made by
special agreement; and other insurances against more hazard-
ous risks may be settled in the same manner. Hay, corn,
and other agricultural stock, of whatever description, on any
part of a farm, may be insured in one general sum, at the
reduced rate of 2½ per cent. without the average clause.
Persons insuring for seven years will be charged only for ½x;
and for any number of years more or less than seven, dis-
count will be allowed both on the premium and duty. All
the offices insure against fire by lightning. It will be re-
membered, that a duty of 2½ 6d. per cent. on sums, on all prop-
erty insured from fire, is payable to government, under an
act of the 44th of George III.

The "Atlas Assurance Company" was established in
1888, and undertakes to assure the proprietors of buildings,
merchantize, furniture, farming stock, goods and effects,
and also of craft and shipping upon canals and in harbour,
against loss by fire; and also grant assurance upon lives. The
capital is fixed at one million two hundred thousand pounds,
of which the sum of £500,000, invested in government or real
securities, will be applicable to the immediate purpo-
ses of the institution; and the remainder guaranteed under a
deed of settlement by a numerous and respectable pro-
netary.

Terms as moderate as the nature of them will permit.

N. B. An additional premium of Sixpence per cent. will be required on buildings or goods within the
Water-Side District, for extra risk.

No charge is made for policies or indorsements on them;
and for the encouragement of persons making assurance for
seven years by one payment, a deduction of one-seventh part
of the premium and duty will be made; and if at the end
of that period a further assurance of seven years be effected
on the same property, a deduction of one-fifth part of the
premium, and so on for succeeding years. The terms of
life-assurances are much the same as those of other offices.

INTACTE,
INTACTÆ, right lines to which curves do continually approach, and yet can never meet with them; more usually called asymptotes.

INTAGLIOs, precious stones, having the heads of great men, inscriptions, and the like, engraved on them; such as we frequently see set in rings, seals, &c.

INTAKER, a name anciently given to certain banditti, or free-booters, who inhabited part of the North of England, and made frequent incursions into the very middle of Scotland; plundering the inhabitants wherever they came.

Those who made the expeditions, were called out-parters; and those who were left behind to receive the booty, inter-takers, q Hen. V. c. 7.

INTAVOLARE, Ital. to write music for the lute and guitar in tablature, instead of musical characters. See Table and Time-Table.

INTAWA, in Geography, a town of Hindoostan, in Bundelcund; 15 miles E. of Pannah.

INTEGERS, in Arithmetic, denote whole numbers; in contradistinction to fractions.

Integers may be defined to be, numbers which refer to unity, as a whole to a part.

INTEGRAL, or INTEGRANT, is applied by the schoolmen to those parts which are necessary to the integrity of a whole. In which sense they stand contradistinguished from essential parts.

Thus the arms, legs, &c. are integral parts; body and soul, essential parts of a man.

INTEGRAL Calculus, in the New Analysis, is the counter part to the differential calculus.

This latin has been completely explained by the marquis de l'Hôpital; but the other still remains imperfect, having been yet but little cultivated.

The integral calculus of Leibnitz, and other foreigners, answers to what the English call inverse method of fluxions. See Fluxions, and Calculus.

INTEGRANT PARTS, in Philosophy, the similar parts of a body, or parts of the same nature with the whole; as filings of iron are the integral parts of iron, and have the same nature and properties with the bar they were filed off from. The chemists distinguish in their resolutions of bodies, between the dividing and resolving them into integral parts like those, and what they call constituent parts; that is, distinguishable, or the principles of the bodies they work upon. Thus when crude mercury is dissolved in aquafortis, though held imperceptibly in the meniscus; yet when that meniscus is diluted with water, and a copper-plate is suspended in it, the meniscus leaves the mercury, to work upon the copper, and the mercury subides united and in its own natural form; the mercury, therefore, in this operation, was only divided into its integral parts, or small parcels of the same nature and properties of the whole; but when artificial cinnabar is resolved or divided into crude mercury and sulphur, neither of these are of the same nature and properties with the cinnabar, and are not its integral but its constituent parts. This therefore is the dividing a body into its constituent parts or principles.

INTEGRITY of the Action. See Action.

INTEGRUM Folium, among Botanists. See Leaf.

INTEGRUM, in Restitution. See Restitution.

INTEGUMENTS, in Anatomy, the coverings of the body; the word is generally employed with the epithet common, as they are of the same nature and number in all parts of the frame. They consist of the cuticle or epidermis, with its appendages the nails, of the rete mucosum, and of the true skin, cutis, or dermis. The hair in its nature seems to resemble the cuticle; but it grows from the cutis. To these three layers a fourth is sometimes added, under the name of the adnus membrana. In truth, the skin is always connected to the subjacent organs by cellular tissue, the interfaces of which in most cases contain fat, but not invariably so. This connecting stratum belongs entirely to the cellular organ. See Cellular Substance.

To the technical explication of common integuments, the word skin corresponds in common language; but this term is often used by anatomists to denote the cutis, in opposition to the cuticula.

The three parts composing the integuments of the body are so different in their organization and functions, that we cannot approve the common arrangement, by which they are all considered together as forming one organ system. We prefer the method of Bichat, who describes the cutis, with the mucous layer on its surface, under the name of the dermoid system; the cuticle with the nails under that of epidermoid system; and the hairs under that of hairy system (futître pileux). We shall employ this division, and derive our account of the subject chiefly from the Anatomy General of that writer.

Dermoid System. The surface of the body is covered in all animals by a more or less dense membrane, generally proportioned in its thickness to the volume of the body, and serving the purpose of protecting the subjacent organs, of separating a considerable portion of the residue of nutrition and digestion, and establishing the relations between us and surrounding objects. In man it is the sensitive limit of his frame, placed at the extremity of his sentient powers, incalculably exposed to external impulses, thus giving rise to the relations of his animal life, and connecting his existence to that of external objects. This covering is the skin or cutis.

Being every where proportioned to the external parts over which it is applied, it follows their chief inequalities, rendering the large projections very sensible, but concealing a great number of the smaller; hence the different appearances of the body in its entire and confined states. It is continuous throughout, and reflected at the different openings into the interior of the body, giving origin to the mucous system. The limits of the two systems are constantly marked by a reddish line, the mucous being within, and the dermoid on the outside of that boundary. The demarcation, however, is not so decided in the organization as in the colour; they appear to be insensibly blended. The dermoid system becomes thinner in the neighbourhood of these openings, particularly about the face. At their commencement the mucous organ borrows more or less of the characters of the dermoid.

The external surface of the dermoid system is every where contiguous to the epidermis, and is remarkable on account of the hairs implanted in it, of the oily matter which habitually covers it, of the sweat which is deposited on it, and of the sense of touch residing in it. We shall disregard these points at present, and confine ourselves to the consideration of the external forms of the system.

Various kinds of folds are seen on the external surface.

1. Some depend on certain superficial muscles, which, adhering closely to the dermis, and almost consolidated to its substance, throw it into wrinkles when they contract. Such are the wrinkles of the forehead produced by the cranium; the radiated folds round the eyelids formed by the orbicularis; the of the cheeks by the zygomatic and levator anguli oris; those round the mouth when the lips are contracted by the orbicularis oris, &c. These folds arise from the circumstance that the skin cannot contract...
as the muscles do; and they are of the same nature with what we observe in mucous surfaces, particularly in the
 stomach, when the contiguous muscular plane is contracted.
 Hence their direction is always perpendicular to that of the
 subjacent muscles, whose fibres they cut at right angles.
 As the motions of these parts in the human countenance
 are much influenced by the passions, the wrinkles and irreg-
 ularities in the face are highly important in a physiognomical
 point of view. The repeated actions of particular muscles,
 under the habitual impression of particular passions, pro-
 duce permanent lines, which give the character of the in-
 dividual.
 2. Other wrinkles arise from the motions of parts, but not
 from those of the subjacent muscles; such are those of the
 palm and sole. Here there is no sub-cutaneous muscule ad-
 hering to the skin, except the palmaris brevis, which has no
 share in producing the folds, where the skin is habitually
 modified by the flexion of the organ. To this clafs belong
 the impreffions at the articulations of the phalanges.
 In the palm there are three principal ones: at the base of the
 thumb, produced by the motion of opposition of that or-
 gan, at the front of the palm, by the flexion of the fingers,
 and in the middle of the palm. The cuts forms folds in
 these depressed lines when the palm is rendered hollow.
 Numerous other small folds, corresponding to less marked
 and frequent motions, cut the former at various angles.
 In the back of the foot and hand we observe numerous
 wrinkles at each articulation of the phalanges, when they
 are extended; they disapper on flexion, and arise from the
 skin being looser and more copious in those parts to ac-
 commodate the motions. There are analogous folds at all of
 the articulations, but they are less strongly marked, be-
 cause the skin is less adherent to the neighbouring organs.
 Over the whole trunk, on the arm and fore-arm, the leg
 and thigh, no depressions are observed except those produced
 by muscular prominences.
 3. A third kind of wrinkles, or rather of cutaneous im-
 preffions, which are very inconsiderable, occurs particularly
 in the sole and palm, where they are easily distinguished
 from the foregoing. They indicate the rows of papilla:
 and nothing of the kind occurs on the surface of the trunk.
 4. Lastly, there are the wrinkles of old age, the nature
 of which is quite different. When the sub-cutaneous fat has
 begun to disapper, the skin is too large for the parts which
 it covers: it loses its contractility by age, and cannot there-
 fore accommodate itself to the altered bulk of parts. Thus,
 where there was molt fat, as in the face, the wrinkles are
 molt strongly marked. When young perfon are suddenly
 emaciated, the skin contracts, and no wrinkles ensue.
 The internal surface of the skin corresponds every where
 to the cellular tifufe, which is loose on the trunk, the thigfs,
 arms, &c. and more dense on the cranium, hand, &c.
 In molt animals, a muscular plane, named pancreaticus carno-
 nus, and analogous in its form to that which is everywhere
 connected to the muscles membranes in man, separates the
 skin from the other organs, and imparts to it various motions.
 Traces of such a structure occur in a few instances in man,
 as in the latifimus collis, the epicranis, and the muscles of
 the face.

The cellular tifufe connects the cutis to muscles almost
 universally in the trunk; but it has nothing to do with the
 motions of these muscles, and receives from them no sen-
 sible influence. It is separated from the muscles in the
 limbs by aponeuroses. Many vessels pursue their course
 under it: large veins may be observed through its substance;
 numerous arterial ramifications are distributed on its sur-
 face; and nerves are found among these.

Organization of the Dermoid System.

1. Proper Tifufe of this System.—This comprehends,
 1. The corion; 2. the rete mucosum; and, 3. the
  papilip or vili. The corion is the essential part, which
determines the thickness and form of the skin: the rete mu-
 cosum is not very distinct from it; and the papilles mani-
 festly grow out of it.

The corion is always white in the human subject. its
 thickness varies considerably. In the head it poilifies op-
 posite characters on the cranium and the face; in the former
 it is very thick and dense in its texture, in consequence of
 the numerous hairs which traverse it; in the latter it is every
 where thin and delicate, but more particularly in the eyelids
 and lips. On the posterior part of the trunk, and espe-
sially along the back, its thickness is nearly double that
 which it has in front, where it is nearly uniform in the
 neck, cheeL and abdomen. We must except, however, the
 penis, scrotum, labia, and breasts, where its texture is much
 thinner. The corion is nearly of equal thickness in the
 shoulder, arm, and fore-arm; in the hand its thickness is
 rather increased, and more so in the palm than on the back.
 It is generally much thicker on the thigh and leg, where there
 are more bulky muscles than in the arm and fore-arm. It
 grows thicker in the foot, but less so in the dorcal than in
 the plantar region, which is the thickeft part of the cutifum.
 The relation of its functions to the various degrees of
 thickness observed in the hand, foot, and cranium, may be
 easily understood; but in other parts we do not clearly see
 the reason of these differences.

It is generally thinner in women than in men, so as to
 prevent a sensible difference when the two are contrasted in
 any region of the body.

In order to examine the interior structure of the corion,
 it should be carefully separated from the cellular and adipo-
 us tifufe, to which the inner surface adheres more or less closely:
 we shall then find that surface differently disposed in the dif-
 ferent regions.

1. In the sole and palm we see an infinite number of
 whitifh tifules, shining like those of an aponeurotic nature,
detached from the inner surface of the skin, decussating each
 other in every direction, leaving, particularly towards the
 hand, numerous arcades of different sizes filled with fat, and
 gradually lost in the sub-cutaneous tifufe. Hence there is
 not the fame mobility of the skin over the covered parts,
on these surfaces, as in molt other situations; an arrange-
 ment well suited to the functions of prehension and support
 belonging to these parts.

2. The cutis of other parts of the body has thefe tifules
 much less distinct, not interwoven with the cellular tifufe,
 and separated by smaller arcades; hence it is much looser,
 and more easily deflected from the subjacent parts. The
 arcades represent a vast number of openings placed irre-
 gularly by the side of each other, and lodging small ma-
 fles of fat: when these are carefully removed very sensible
 vacuities are left. The tifules, which form them, are suffi-
 ciently close to give the appearance of an uniform structure
 perforated by numerous apertures. These arcades are very
 favourable to the action of the tanning principle, which is
 introduced through them to the corion much more effec-
tually than it can penetrate on the opposite side. Bichat
 acertained this point by a direct experiment on the human
 skin. Chaptal has observed that the epidermis is a real ob-
 stacle to the action of tanning, and that its removal, with
 that of the hair, is an effential preliminary for this reafon:
 but that the hide, even when thus prepared, is affected much
 more caufily on the inner than on the outer side.

3. On
3. On the back of the head and foot, as well as on the forehead, the corion does not exhibit these numerous openings on its inner surface; it is smooth and whitish, particularly after being macerated a little: the fame observation may be made concerning that of the cerottum, prepaire, and labia. Its tiffue is more compact, and exhibits no intervals; so that although it is thinner than on the limbs and trunk, it contains nearly as much substance. In that, which corresponds to the hair and beard, we observe only the openings necessary for the transmission of those parts.

The three great modifications in the organization of the skin, which we have just described, are merely differences of form, and not in the essential nature of the organ. The areolae may be seen in all parts, where they exist at all, by means of maceration, which is a very good method of examining the structure of the skin. Immersion in water softens the skin by separating the fibres of its corion, and rendering their intervals more distinct: we then find that the areolae are not confined to the internal surface, but are prolonged into its substance, which is penetrated by them in its whole thickness. These areolae do not terminate in cul-de-sacs towards the external surface, but they open on that surface by numerous holes very apparent in skin, which has been macerated for a month or two. The epidermis must be removed in order to render them sensible: they penetrate the skin obliquely, and admit in some parts and some subjects the introduction of a pin's head. They are simple communications from the interior to the exterior for the passage of hairs, exhalants, and absorbents, as they come to the surface: thus the subjacent areolae are merely cells containing the blood-vessels, and the tiffue of the skin altogether is a true cellular net-work, of which the interstices are very distinct on the surface, but less obvious externally. Thus the corion constitutes the bafis or skeleton of the cutaneous organ, lodging in its areolae all the other parts of the organ, and giving to them their proper form.

Bichat considers that the areolar tiffue, which composes the corion of the skin, has much analogy with that of the fibrous sylfem. Its density and resileance are nearly the fame in the heel: it becomes yellowish and transparent by boiling; it refists maceration for a long time; and it receives in some situations the insertion of muscular fibres. Yet the sensibility and the diseases of the two sylfems differ altogether.

The acute sensibility of this organ does not reside in the areolar tiffue of its inner surface, but in the part containing the papillae. And we find that the fame part is the seat of most cutaneous eruptions. The external surface only is coloured by the blood in capillaries; and hence light pressure, by driving this fluid into the deeper vessels, removes the red colour. In measles, scarlet-fever, &c. the redness is superficial. Injections occasion much greater redness of the external than of the internal surface; as the arterial trunks are found in the latter, and the numerous exhalants in the former. These considerations prove clearly that the cellular tiffue of the skin has much less vital activity than its outer surface; that this tiffue is foreign to almost all the great phenomena occurring in the skin, particularly those of fation and circulation, which take place in the papille and the reticular body. Its functions, like those of the fibrous sylfem, suppose it almost always in a passive state, as they confine merely in shielding the body, and protecting it against external agents. Its properties are well suited to this office of a general protecting medium. Very large weights are supported by slender strips of skin, and dragging in any direction tears them with great difficulty. Yet this resileance is still much less than when the corion has been submitted to the action of the shaving principle. After such preparation it offers the strongest connecting medium which we have in the arts: no other tiffue in the animal economy, except the fibrous, unites in so remarkable a degree pliability and resileance.

Haller, who regarded cellular substance as the principal component part of most organs of the human body, and particularly as forming the bafis of membranes, describes the cutis as being made up of this tiffue in a condensed form. "Its structure," says he, "is on the whole the same as that of membranes; it is made of soft, intricate, and closely-adhering threads and laminae. Its external surface is dense; the internal is gradually resolved into the cellular texture, so that there are no accurate limits between the two parts. Under maceration it swells and becomes loosened, and separates into its component laminae and fibres, both in man and animals." Elements Physiologie t. v. p. 3.

The reticulum membrane, or reticular body of the skin, is so called from its supposed perforations by the papillae and the hairs, and because it appears of a soft mucous nature. It was first noticed by Malpighi, after whom it is sometimes named reticulum. The colour of the surface of the body seems to reside entirely in this membrane: Riolan said that the cause of the black colour in the negro is in the epidermis, and does not go so deep as the true skin. Malpighi, by showing the dilatation between the cuticle and reticulum, demonstrated the true seat of the colour of the body. "Ex quo," says he, "deducro non incongruum parte nigredinis Argothii, corium cutanum: certum enim eft qui ad docrin cutaneum effe fictum et cuticulam, unde taeta nigro futuro mixico et recticulare sponda cutaneum." The reticulum membrane in the negro is a thin black layer, about as thick as the cuticle itself. Putrefaction easily detaches it with the cuticle from the cutis; but it can hardly be separated from the former. It dissolves in water, and communicates a turbid cloud to it, like that produced by the pigmentum nigrum. Mr. Cruikshank describes it as being "double, and consisting of a grey transparent membrane, and of a black web, very much resembling the nigrum pigmentum of the eye." The demonstration of this reticular body is much less easy in the white races than in the negro; and indeed very little seems to be known concerning its anatomy in the former. "Moll authors," says Bichat, "represent the reticulum membrane as a mucous stratam interposed between the cutis and epidermis, and pierced by a large number of openings for the passage of papillae: but I do not understand how this can be demonstrated on the cuticle, if it be fluid according to the usual description. I have employed, for discovering it, several means, none of which has succeeded. So closely does the cuticle adhere to the cutis, that they cannot be separated without injuring one or the other in the recent state. Yet, if we succeed in an attempt of this kind, there is no appearance of mucous upon the corion. After a longitudinal friction, particularly in the foot, where the epidermis is very thick, the line of division between it and the corion is very manifest: but nothing escapes from between them. When the cuticle has been removed, after boiling the skin, nothing remains on either of the surfaces. Maceration and putrefaction, but particularly the latter, produce a kind of viscid covering on the skin, very obvious when the epidermis is detached: but this is produced by decomposition, and nothing of the kind is seen under ordinary circumstances. I believe, from all these considerations, that there is no substance deposited by the vessels on the surface of the cutis, and forming an external covering in the fave in which Malpighi has represented the Th.
INTEGUMENTS.

to the cuticle, the trunks of which, already very minute, after passing through the numerous perforations of the corion, are ramified on its surface, and contain different kinds of fluids. The existence of this vascular net-work is placed out of all doubt by minute injections, which entirely change the colour of the skin on the outside, without altering it much internally. This is the principal seat of the various eruptive disorders, most of which are altogether foreign to the corion.

"We may then conceive the cuticular body as a general capillary system, surrounding the cutaneous organ, and forming, with the papilla, a stratum intermediate to the corion and epidermis. In the white part of the human race this system contains only white fluids; in the negro they are black, and of various tints in the other varieties of our species. The enumeration of the different shades of this organ, and the consideration of the causes of these varieties, belong to the natural history of man. Hitherto we have very few data concerning this substance; it does not seem to circulate in the part. We see that the negro's skin is black, and we know very little more. The rete sometimes adheres to the cutis, but generally to the cuticle, when they are separated after maceration. It is manifestly foreign to both, since they have the same colour in the dark as the white races."

It seems really to be a matter of doubt, whether in the white races there be any colouring-matter in the exterior capillary system analogous to the black substance of the negro, or whether the colour of their surface arise merely from that of the cutis and cuticle. That there is some colouring-matter is rendered probable by the singular anomaly exhibited in the albinos which we see. Can we demonstrate in that case the absence of the pigmentum nigrum of the eye, and we see clearly the deficiency of colour in the hair. The peculiar dead white of the skin is referred, by analogy, to the want of the colouring principle in that organ. There is generally a connection between the colour of the skin, hair, and eyes, which is remarkably evinced in this instance. A dark complexion is accompanied with black hair and dark eyes; and the light irides, as the blue and grey, occur in individuals with red, flaxen, or other light shades of the hair and light skin. All these circumstances lead us to conclude that the skin, hair, and eyes have their colour dependent on some peculiar matter, the tint of which follows a general law in all these parts.

Even in the white races certain portions of the skin sometimes exhibit a dark colour. The arcula round the nipple becomes black or dark brown in women who are somewhat advanced in pregnancy, and affords a very fine mark that they are pregnant. Haller says that he saw the skin of the pubes in a woman approaching nearly to that of the negro in blackness; and Albinus mentions a similar circumstance in a man.

The colour of the skin is transmitted to the offspring, and is surprisingly altered by intermarrriages of the different races. Where a black and a white individual copulate, the offspring has the middle tint between those of its parents. If the child of a black man should intermarry with a white person, and their child with another white individual, and so on, the offspring will be white in the fourth generation; or vice versa. But the detailed consideration of this subject belongs, more properly, to natural history.

The colour of the cutaneous organ in the white races of the human species is much modified by accidental circumstances. Exposure to the sun's rays produces various shades of a reddish-brown colour, which effect is commonly called tanning: this alteration is very rapidly produced by going much on the water, in consequence of the reflection of the light from its surface. That this is the consequence of the cause just assigned, and that the effect is not produced by heat, is rendered obvious by the difference of colour in the face and hands, and on those parts of the body which are habitually covered: also by the brown tint of the face produced by asummer's fun, which offers a remarkable contrast to that of the forehead, where it is protected by the hat. Our clothes do not prevent the action of heat upon the skin, but will intercept the luminous rays. The pale and fawoof tints of the inhabitants of large towns, compared to the florid countenances of country people, arise from the same cause. Men are blanched like plants when shut out from the influence of the sun. Tanning takes place much quicker in individuals of light complexion, than in those of an opposite character. The effect in all cases is temporary, and goes off when the cause no longer acts. It is produced in a greater and more permanent degree in white individuals who move into warm climates; but neither here nor in any other instance is it transmitted to the offspring. Physiologists have chosen to represent this as a change occurring in the rete mucousum; on what authority we do not know. The light brown spots, called freckles, which occur about the head and neck when exposed to sun and air, seem to be of the same nature with the tanning. The colours impressed on the skin in the operation of tattowing, reside in the cutis, and conseqently remain when the cuticle and rete mucousum have been destroyed by maceration. These colours are permanent: they remain through life, and the marks can only be destroyed by removing the skin which contains them; a circumstance which is hardly reconcileable to our notions of the confiant changes of decomposition and composition in all parts of the frame.

Mr. Cruikshank describes a vascular membrane as existing between the rete mucousum and cutis; and apparently it is the same as the vascular net-work of Bichat. He injected this in the skin of persons who had died of small-pox; and was led to investigate the matter from a conversation with a gentleman who conceived that he had injected vessels in the rete mucousum. He macerated in putrid water, during the summer, portions of small-pox skin, which had been kept for some time in spirits. "CUTICLE and rete mucousum were already turned down; and upon the eighth or ninth day I found I could now separate a vascular membrane from the cutis, in which were also situated the injected small-pox pustules. These bore confluent of circles of long-floating villi at the circumference, but of a white uninjected subsurface in the centre. This central part Mr. Hunter had previously said was a rough formed by the irritation of the various matter. The surface of the skin, from whence this membrane was separated, was elegantly porous. The pores now appeared exceedingly more numerous, and this surface of the skin was still tough and thinning. I macerated the same skin for four or five days more, and separated another membrane, more delicate than the former, but also vascular. The former I easily preferred; the latter, attracted by the instrument that separated it, or unable to bear the agitation of the water or spirits in which it was separated, constantly broke down. But the corresponding surface of the skin was still tough and thinning: the pores were now much larger and more distinct than before, and convinced me that the appearance was natural, and that the skin had sustained no real injury in the process." Experiments on the infenible Peripilation of the Human Body, &c. p. 38.

It has generally been stated that the rete mucousum is not regenerated when it has been destroyed in ulcers; and con-
INTEGUMENTS.

ently that the cicatrices of blacks are always white. We believe that this point is not clearly proved.

Whatever opinion we may form concerning the different striae decribed above, as intervening between the cuticle and cutis, whether we regard them as distinct membranes, or as portions detached by art from the cutis, they are of importance, as containing an extensive distribution of capillary vessels. Independently of the colouring matter, these vessels seem ordinarily to be filled with white fluids: the exuding pores, which furnish the matter of perspiration, arise from them, and the same vascular net-work is the seat of erythros, and of all the cutaneous eruptions which do not affect the corion.

"The blood," says Bichat, "does not penetrate this capillary sytem in the ordinary state; but numerous causes will lead to its being suddenly diffused. Rub the skin a little roughly, and it is instantly reddened. Irritate it mechanically or chemically, its sensibility is immediately awakened, it becomes filled with blood, which could not enter before, and is diffused in a surface proportioned to the extent of the irritation. The cheeks exhibit an analogous phenomenon in blushing and flushing, or any sensation by which the great tendency of the superficial capillary sytem to admit, under circumstances of excitation, that blood which it rejects in its natural state. Bladders, and fire, applied to a degree short of destroying the surface, act in the same way: they cause a sudden species of erythros, which is followed by an abundant serous exhalation under the cuticle.

"Irritation of the skin is not the only cause which determines an influx of blood into the exterior capillary sytem. Whenever the action of the heart is accelerated, and the motion of the blood consequentlly precipitated, there is a tendency to this passage, as we see clearly after violent exercise, or on the access of the hot flag in fever.

"The capillary sytem of the face is more subject to this sudden influx of blood than that of any other part. This is seen in the two cafes just mentioned, of exercise and fever, where the action of the heart is accelerated. In various diseases of internal organs the facial capillaries are sympathetically affected, and produce redness or paleness of the countenance; and their dilatation always gives to the face in aphryxia a livid tint, which is confined to that part. In deaths resembling apoplexy, where the circulation becomes embarrassd in the lungs, and in apoplexy, the head is equally remarkable for its lividity. Three circumstances may be noticed, in explanation of this great susceptibility of the facial capillary sytem for the admission of blood: 1st, the ordinary redness of the checks shews that blood is habitually contained in these capillaries in a certain quantity, which is not the case in other parts; 2dly, anatomical injections shew us that the arteries communicate here more freely with the capillaries; fine injections colour the face much more deeply than other parts; and, 3dly, there is a more acute sensibility in the face: a slight blow will bring the blood into the checks in an infant, although it would produce no redness in the arm.

"The blood quits the capillaries of the face as quickly as it enters them; the pallors produce here, at least, in infantaneous fecedation, the lively red of a febrile attack, the deadly pallor of syncope, or any intermediate shades. Thus the face becomes well adapted to serve as a kind of scene, painted successively by the pallors with numerous shades, which are effaced, return, and undergo a thousand modifications according to the state of the mind.

Let me observe further on this subject, that the pallors have a threefold mode of expression in the countenance; 1st, by the capillaries which, being altogether involuntary, often betray what we should be inclined to conceal; 2dly, the muscular motions, which contract or expand the features to express the fear or the joyful affections, and thus produce the wrinkles already noticed; and, 3dly, the eye, which, as Buffon observes, not only receives sensitive impressions, but also expresses mental emotion. The two latter are in some degree voluntary; we can feign them, although we cannot deceive with the first.

"The tendency of the facial capillaries to become diffused with blood, diffuses them to numerous morbid affections. Erythros frequently attacks this part; varicous pulules are particularly active here; and several eruptions occur more frequently in the face than in other situations.

"We must therefore distinguish two parts in the capillary sytem external to the corion. One contains habitually the colouring matter of the skin, which is at rest, or experiences at least no other motion, than the flow and almost insensible one of compolation and decomposition, and which therefore never exhibits such sudden changes as we have just described. Though the other fluids are habitually circulated, and are constantly causing the transpiration, their passage is often through the blood. We must say of no communication between these; they appear to be absolutely independent. Some white fluids remain in the latter part at the time of death, as the following experiment will prove. Immerse a piece of skin in boiling water for a short time, and the epidermis will be elevated into numerous small vesicles containing a serous fluid.''

The papille of the skin are small eminences of its external surface, supposed to perforate the reticular body, and consequently to be contiguous by their extremities to the epidermis; they differ in form in various situations, and are called villi where they are small and fine. Malpighi first observed in animals, and particularly in the foot of the pig, that the external surface of the skin is not level, but elevated into certain prominences under the cuticle. This structure does not belong to the whole surface of the cutaneous organ, which, although rather unequal in consequence of small ridings about the hairs, has no regularly arranged parts deserving to be called papille. Thus Ruyfch could find nothing of this kind on the back of the foot, and acknowledges that they are obscure in other parts, and only to be seen after injections; and other anatomists have experienced considerable difficulty in detecting these parts, even with the assistance of glases.

"Neither," says Bichat, "are we to mistake for papille the numerous and very sensible tuberces, which make the skin of certain subjects very rough. These conflict of small cellular and vascular faciculi, or of sebaceous glands found at the openings of the corion under the epidermis, through which the hairs are transmitted; elevate the external surface, and thus cause projections. Maceration for two or three months converts these bodies, which always contain a little fat, into the firm, whitish, unctuous and fpermacoti-like substance always produced from adipous matter by maceration; the skin at the same time becomes soft and peppe, and is loofened round these tuberces, which are clearly seen to be continuous with the subjacent fat. These prominences are more frequent on the limbs and back than on the face; on the front of the trunk, and they are more numerous in the former, on the aspect of extension than of flexion. The absence of these ridges, and a consequent smoothnes of the outer surface of the corion, belong to our notion of a beautiful skin; and this character belongs much more to the cutaneous organ of women than of men. The epidermis covering these prominences is often detached in scales, particularly by any rather strong rubbing; and this contributes still more to the
integuments.

the proper papillæ of the skin are very visible in the hands and feet, and may be seen when the cuticle has been carefully removed after simple maceration for a sufficient time; but still more plainly when the cutis has been minutely injected previous to the macerating process. We observe narrow, longitudinal, and slightly prominent lines in the cutis, distributed spirally at the ends of the fingers and toes. From these ridges arise very small conical processes like fine threads or hairs, slightly inclined towards the nail, shorter and more imperfect in the smaller toes and fingers; they give a rough villous appearance to the surface, which is represented in the seventh figure of Mr. Cruikshank's work on the insensible perspiration. They are very distinct in the red part of the skin, where they are numerous and long, and produce a villous appearance; Ruyfch has figured them in his eighth Thesaurus. The soft and spongy skin of the glans penis is remarkable for a similar structure, which is well represented by Albinus in the Annot. Acad. lib. iii. tab. 4. They are more obtuse in the female mammae. The minute nes of these organs renders it difficult to ascertain their internal structure satisfactorily. They receive numerous blood-vessels, so as to become much more deeply tinged by coloured injections than the surrounding skin. They receive numerous nerves, and have generally been regarded by anatomists in a particular manner as organs of a nervous structure. That a considerable supply of nerves is bestowed on those parts of the skin which have these papillæ is very clear; but, that the minute filaments can be traced into the very prominences, and that they lay aside their coverings, so that the nervous pulp is bare in them, must be regarded as inferences from analogy rather than from direct observation. The density of the corium, and the extreme thinness of the nervous threads, are almost insuperable obstacles to our tracing the nerves into the papillæ.

We can scarcely doubt, says Haller, that these bodies are the organs of touch, when we observe them larger, more distinctly, and receiving a greater supply of nerves where this febex exists in the most acute degree, hardly discernable in other situations; and particularly calculated by their prominence to be impressed by external objects. Perhaps their existence in the sole of the foot, where they are covered by so thick a cuticle, is hardly reconcileable with this opinion.

That the vessels, which they contain, contribute to the separation of the matter of perspiration, is so conformable to general analogy, that we can easily admit it. Mr. Cruikshank was disposed to regard them as the organs of cutaneous absorption from their resemblance to the intestinal villi, on which he discovered the orifices of the lacteals.

Effect of various Agents on the Dermoid Tissues.—We have noticed already, under the head of the rete mucosum, the action of light upon the living skin.

The action of calorie on the living integuments presents different phenomena, according to the degree in which it is applied. A warm atmosphere relaxes its tissis, increases its action, and promotes the evacuation by the exhalants of the residual fluid of nutrition and digestion. It is contracted and corrugated by cold, and refuses to admit these fluids, which then go off chiefly by urine. The gradual change from one to the other of these states does not produce any unpleasant effect; but sudden vicissitudes are not to be feared. The cold produced by the evaporation of the cutaneous exhalation, enables the human subject to preserve his ordinary temperature in air, heated above the degree of boiling water. See the very curious facts on this subject detailed in the article Heat. Animal. The interruption of the cutaneous discharge on the corrugation produced by cold suspends this evaporation, and thereby prevents the temperature from being lowered beyond the natural standard.

When more considerable heat is applied to the skin, it produces first a feeble redness, which is followed by vesi.

Qusifications. If it be increased in degree, the texture of the organ is destroyed; it is hardened and curked up, like any other animal tissus when burnt; beyond this point it is blackened and converted into a coal. The first operation is on the vital powers of the organ, and consequently can take place only during life: the latter effects are produced on the tissus, and may be exhibited in dead skin. The latter, when heated, contracts, and then swells, exalas a fetid odour, and leaves a dense charcoal-like incrustation. On distillation it yields the same products as urine. Intense cold produces in the first place a redness of the organ, as in the nose, ears, fingers, &c. of individuals exposed in a very cold climate: inflammatory action and mortification ensue. The latter occurs immediately on the application of high temperature, but after some interval in the opposite case.

The air evaporates and contains habitually the mate.

ters secreted from the skin: and when this effect is not produced, they are accumulated on the surface, and render it moist. This evaporation is a physical phenomenon entirely distinct from the vital action of transpiration. The latter takes place in a warm bath, as well as in the air; but in the former case the fluid is dissolved by the water. Does free exposure of the skin to air increase or diminish the amount of its exhalation? The common opinion seems to be that the latter effect is produced; the exhaling pores are supposed to be obstructed by the impregnation of cold on the skin. Dr. Stark, however, proved by direct experiment in his own person, that the body lost more weight in a given time when naked, than when covered by the ordinary clothing.

Moisture of the skin may be produced in two perfectly distinct ways; 1st, by increased evaporation, which may arise from accelerated action of the heart, as in violent exercise or fever; from relaxation of the organ by the warmth of the air, or by baths; or from sympathy, as in consumption, fear, &c. Under all these circumstances the increased evaporation will keep the skin moist. 2dly, The same effect will be produced by insufficient diffusion of the perspiration when it is produced, as in bed, or in damp weather.

When the air has access to dead skin on all sides, it is dried, and becomes transparent, unless it should contain blood; it is then firm, but admits of being bent. In this state it yields very little to external agents, does not readily absorb moisture, and has no disagreeable smell. Hence skins simply dried are of great use in the arts, and afford serviceable and pleasant coverings; hence, too, probably the great durability of the mummies.

If the skin be left on the body, or exposed in moist air, it utrieth, assuming successively a brown, a greenish, and lastly somewhat black colour. It exhalas a mellow odour, and becomes swollen by the liberation of gas. A fluid meucus appears on its surface, from which the epidermis is then separated. When all the fluids are evaporated, a blackish fibrofat remains.

Water removes from the living skin those parts of the perspired matter which are not dissolved by the air; and the use of bathing, which is much neglected in these days, must be regarded as an efficacious means of preserving the surface free from acid and irritating matters, and consequently in a state of health. We cannot state precisely what action baths have on the living skin; we are told indeed that they relax and
and often, or constrict and brace; but no precise meaning is attached to these vague expressions. They seem to affect the vital powers of the part, to augment or diminish them, but we know of no influence on the tissue.

After macerating the skin for some hours in water, with agitation and pressure, evaporation of the fluid yields a little gelatine. When macerated longer it becomes softened, and tenaciously whitish, swells a little, and remains for a long time without undergoing any other alteration than a degree of putrefaction, much less than what occurs in the mucous glandular, and other tissues. This putrefaction is more marked on the surface in contact with the cuticle, but at the end of two months the skin has lost but little of its consistence; it begins to reduce into a fetid pulp at the end of three or four months. According to Fourcroy, spontaneous decomposition in water or moist earth converts it into a fatty matter, and into ammonia, which compose a kind of soap. It produces very little froth when boiled. Just before ebullition commences, so as always to be convex on the side covered by the epidermis, and concave on the opposite; the fibres are contracted and condensed at this time, and the contraction is greater on the inner surface, where the intervals are the largest. At the same period, small evi- dences are observed. This corrosion of the skin renders it dense, hard, and elastic, but reduces its dimensions. It soon acquires a semi-transparency and yellowish colour, like that of the fibrous organs when boiled. The hardness which it had acquired at the instant of corrosion is now gradually lost; the skin is softened, yields much gelatine to the water in which it is boiled, but instead of diminishing, is rather increased in thickness. All appearance of fibres is lost in this stage; a semi-transparent, gelatious, and homogenoeous mass remains; still it does not lose its elasticity; probably the large quantity of gelatine, which it contains, occasions it to retain this property. The flightly motion excites in it a general vibration as in the different animal jellies. By a continuance of the boiling nearly the whole gelatine is dissolved, constituting a viscid liquor, which by proper evaporation is converted into glue; and a small membranous residue only, which is dissolved with great difficulty, remains; a long time is required to reduce the skin to this state. From this solubility in water, the cutis of animals is mostly employed in the manufacture of glue.

Sulphuric, nitric, and muriatic acids act on the skin, as on any other animal substances, but in much more slowly, particularly in the fatty part covered by the epidermis. The first reduces it quickly to a blackish pulp; the second, even in a concentrated state, brings it readily into a pulp; the oxymuriatic acid produces very little effect on it. Nitric acid converts it into a salty acid and fat, while, at the same time, the atomic gas and prussic acid are emitted. Acids do not act in this way during life; they never produce this pulp state of the organ. A piece of caustic, enveloped in a portion of skin, is reduced to a yellowish-red thick fluid in the course of a day; the skin is crisped and contracted, but not penetrated; its tissue does not even appear injured on the surface. Alkalies have different effects, according to circumstances, in the living state; they destroy some granulations much more readily than others. An aqueous limityum, applied to the surface of the body, causes an uncertain and slippery feel, as its combination with the mucous matter produces a soap. Concentrated alkalies dissolve the dead skin, converting it into oil and ammonia.

"The cutis," says Dr. Thomson, "appears to be a peculiar modification of gelatine enabled to fulfill the action of water, partly by the compactness of its texture, and partly by the viscosity of the gelatine, of which it is formed; for those skins which dissolve the most readily in boiling water, afford the word glue. Mr. Hatchett has observed that the viscosity of the gelatine obtained from skins is nearly interfered with by its flexibility, the supplest hides always yielding the weakest glue; but this glue is very soon obtained from them by hot water." Syst. of Chem., v. 5. p. 575.

The production of leather, by the action of the tannin principle of vegetables upon the skin, is a subject of such importance, that it would be useless for us to enter on it here; it will be considered separately in the articles of the dictionary relating to tanning: further information on the chemical properties of the skin may also be derived under the heads Gelatin, Glue, &c.

Very little is known of the chemical constitution of the retic mucocutum. Oxymuriatic acid deprives it of the black colour, and renders it yellow in the negro. Beddoes states that immersion for some time in water, impregnated with that acid, will discolour the colour in the living subject. (On Facititious Ailurs, p. 45.) Fourcroy mentions that the foot of a negro, after a similar exposure, nearly lost its colour, but that the original black hue returned in a few days. Syll des Connoiss Chimiques, t ix. p. 259.

Common Parts belonging to the Tissue of the Dermoid System.—The skin contains a large proportion of cellular substance. Numerous prolongations of the subcutaneous cellular stratum penetrate the contiguous arcc of the corion, then pass into the more exterior ones, and end at the numerous pores which transmit the vessels, nerves, and hairs. Thus, if the cellular tissue could be completely separated, the cutaneous organ would represent a piece of sponge, being perforated in every direction. According to Bichat, boils perform this dissection, destroy the cellular organ, and leave the skin in this cribiform state. He adds, that the corion itself is not the seat of any acute affection; that all diseases of this nature either affect its surface, or the cellular tissue of its arcore. But it may be altered by chronic diseases; and is manifestly disorganized in elephantiasis.

In anasarca of long continuance the subcutaneous cellular stratum gradually penetrates the cellular substance of the dermoid arcore, separates its fibres, and sometimes arrives even at the epidermis, which it buries; through these openings it escapes.

Probably, says Bichat, the cellular tissue does not extend so far as the external surface, under the epidermis: for when that covering is removed, no granulations are formed, although they are always produced whenever cellular tissue is exposed.

The arteries, running in the subcutaneous cellular substance, furnish an infinite number of small branches, which enter the arcc of the skin with the cellular prolongations, Anastomose at every point in the arcc of the organ, and penetrate at last through the pores of the external surface to produce the capillary net-work already described, which, in the ordinary state, contains very little red blood. In this passage, through the arcc of the skin, very few branches seem to terminate on the fibres of the corion itself.

After penetrating the skin in the opposite direction, the veins open into the large subcutaneous trunks, which in many parts may be so clearly seen through the integuments. The venous ramifications of the arcc are nearly insensible in the natural state, but are considerably dilated over cancerous tumours, so that the skin is marked by numerous blueish retinaculous lines. All gradual extensions of the cutaneous organ, as in aneurisms, pregnancy, dropsy, &c. are attended with the same phenomenon, which is never exhibited in acute cases.

Numerous and considerable branches of nerves form a kind
of cutaneous nervous system, producing the filaments which enter the skin. They communicate with each other in traversing the areoles of the organ, and probably terminate on the papille. In the hand, where these prominences are very numerous and clearly marked, there are more cutaneous nerves, in proportion to the surface, than in any other part.

A great number of absorbing vessels is found under the skin; inso much, indeed, that this is the most favourable situation for investigating them. The veins are surrounded by them, and several fasciculi are observed in the intervals of these vessels; so that we may represent the skin and appendages as being separated, in the limbs, by a continuous formation of these vessels. We must refer the origin of many of them to the corrosion, from the areoles of which they carry into the blood the fat and cellular lymph, as well as the nutritive matter of its fibres. But is there, moreover, a particular order of branches opening on the epidermis, for the purpose of absorbing substances from the surface of the body under certain circumstances? Anatomical investigations do not enable us to decide this question directly: the absorbing pores cannot be demonstrated; we must therefore inquire whether the phenomena of the cutaneous functions indicate their existence. We may observe, previously, that the superficial absorbers are very numerous, and seem to be in greater number than would be required for absorbing the contents of the cellular substance.

It had long been received as an established truth, that the skin is an inhaling or absorbing, as well as an exhaling organ; that though the lofts by perfpiration commonly greatly exceeds what the system gains by absorption, yet sometimes, according to the varying circumstances of external relations and conditions of the body itself, the inhalation balanced, and even surpassed the exhalation. Of late this doctrine of inhalation has been called in question, and, in the opinion of many, has been completely overthrown.

The most direct argument in favour of absorption from the skin, is the action of various substances upon the body, when applied to this organ. This is shown in a particularly clear view in the instances of opium and mercury. Dr. Currie (Medical Reports, chap. 19.) considers, that in all such cases the article absorbed is forced through the epidermis by mechanical pressure; or that the epidermis has been previously destroyed by injury or disease; or if found, that the article applied to it is of an acid nature, which irritates and erodes this tegument; and then coming into contact with the mouths of the lymphatics under it, is of course absorbed. This explanation is quite unsatisfactory. The firm adhesion of the cuticle and cutis is well known; on the supposition just mentioned they ought to be separated, which is not the fact, we ought to see the ointment under the cuticle, which is equally untrue, and the ointment should penetrate equally in the dead subject, which is not the case. However, the action of mercurial fumigations, where no friction is employed, affords a case of absorption from the surface of the found cuticle, which cannot be denied. In the same fide of the question, it has been ascertained, that water is taken up by the skin in various cases. Many instances have been known of persons at sea, with no fresh water, having their thirst much allayed by wetting their cloths with the salt water. Haller affirms, too, on the authority of Deaquit, that the body acquires an increase of weight in the warm bath: "ducit evapores aquae calidae in manum reforbertur, et homini in balneo confititum cutis tumet et rubet, corpus conditum, et ossia seduntur, et omnino se duntur aequo reforberte et sanguini admirate." t. v. p. 82. Experiments have since been made with every necessary care, which seem to contradict this position, and to prove that the body acquires no additional weight in the warm bath. Seguin, from a great many experiments of this description, concludes that there is no inhalation, because the body, so far from gaining, always lost some part of its weight during immersion, although much less than in the air in equal times. Thus, in a bath heated from 10° to 12° of Reaumur, the loss of weight was to that sustained during the same time in air as 6.5 to 17; at the temperatures from 15° to 18°, as 7.5 to 21.7; and from 20° to 25°, as 13 to 25. La Medecine éclairée par les Sciences Physiques, tom. iii.

In other experiments, again, as in those of Drs. Gerard and Currie, there was no increase of weight; but neither was the body in general observed to have suffered any loss during immersion in the warm bath. "When I was at Buxton," says Dr. Currie, "in 1768, I made an experiment on the effects of bathing on the weight of my body, and after half an hour's immersion, I found it rather diminished than increased. This experiment had, I believe, been made before by Dr. Pearson with the same result; it has since been repeated with great care, and it is ascertained, as a fact, that no increase in the weight of the body is produced by immersion in water at the temperature of 82°. In the year 1799, I had a patient in diabetes, whose cuticle is as usual in that diseased, was in a morbid state; and being desirous of trying how far the inordinate action of the kidneys might be affected by a gentle stimulus applied to the skin, I immerged him in a bath of the temperature of 96°, weighing him before and after immersion. There was no sensible variation in the weight. This experiment has since been made by Dr. Gerard in another case of diabetes, an account of which is given in the publication of Dr. Rollo; and as it was repeated a great number of times with the utmost care and accuracy, it may be considered as established, that immersion in the warm bath in diabetes produces no increase in weight. I have made five different experiments of the same kind on myself, varying the heat of the bath from 87° to 95°, but never in any instance found my weight augmented." (Medical Reports, vol. i. p. 302.)

The doctor then details a case of strictured oesophagus, where the patient gradually wasted, and ultimately died of inanition, although he was immered daily in a tepid milk and water bath.

We may observe, concerning the facts just quoted, that they by no means warrant a decisive negative inference. We have every reason to suppose that the action of the skin goes not uninterrupted in the bath, and that the pulmonary exhalation proceeds as usual. Yet the weight either continued unchanged, or, if any loss was observed, this was of constant less, much less, than is experienced during the same interval in air: hence we may argue, that there must have been absorption. Dr. Currie's case of strictured oesophagus merits further consideration; no experiment could be more unfavourable for an opponent of cutaneous absorption. The patient, it is true, gained no weight while in the warm bath, but the losses continually going on in the air, was, as in other trials, suspended during the immersion. "It is worthy of observation, that there was neither increase nor decrease of weight in the bath; yet Mr. M. was at this time weighing twenty ounces in 24 hours, and consequently, if there was no absorption in the bath, it might be supposed that he would have lost five-sixths of an ounce during the hour of immersion. It is the more remarkable that there was no decrease, because in the bath the skin always softened, and the forehead became covered with a gentle moisture." Besides, "he always expressed great comfort from the bath, with abatement of thirst;"
INTEGUMENTS.

"Thirk," and "subsequent to the daily use of it, the urine flowed more plentifully, and became less pungent." An observation precisely similar is made by Mr. Cruikshank: "A patient of mine, with a stricture of the esophagus, received nothing, either solid or liquid, into the stomach for two months; he was exceedingly thirsty, and complained of making no water. I ordered him the warm bath for an hour, evening and morning, for a month; his thirst vanished, and he made water in the same manner as when he used to drink by the mouth." Anatomy of the Absorbing Vessels, p. 101.

Dr. Currie states further, concerning his patient, that the discharge by urine alone exceeded much in weight the waife of his whole body; and it cannot be doubted, he adds, that the discharge by sweat and perspiration exceeded the weight of the clysters. Thus it appears that the egesta exceeded the ingesta in a proportion much greater than the weight of the body will explain." That cutaneous absorption affords the only adequate solution of this phenomenon is an irresistible conclusion. Still, however, this is denied. When forced to confine that there are cases where the egesta exceed the ingesta, and which can only be accounted for by absorption, the opponents of the cutaneous inhalation deny this function to the skin, and below it malt gruitiously on the hogs.

Many other examples might be cited, in which the body evidently acquired weight from some other quarter than by the food or drink. Haller has many such instances. Rye and Linings gained several ounces by exposure in a moist atmosphere; and Fontana experienced a similar occurrence.

Some facts, which oppose the notion of inhalation by the surface of the skin, have been observed in the applications of medicated stimuluses to the body. Seguin made numerous experiments of this kind, with solutions of muriate of mercury on syphilitic patients; we are informed, that in cafes where the epidemicus was perfectly found, neither the known effects of mercury on the body, nor any amelioration of the venereal symptoms, was ever observed. He also immersed his own arm in a solution of two drachms of the mercurial muriate in ten pounds of water. At the temperature of 10° and 28° of Reaumur, no part of the salt was melting at the end of the experiment; but when the bath was at 18° of the same scale, there was a loss of one or two grains of the muriate in the hour, though the quantity of fluid was not diminished. It appears to us that the experiments on the whole shew that the muriate of mercury was not absorbed; we can hardly admit that two grams were taken up as stated in this account. The entrance of so large a quantity of this very active preparation into the system, must have been attended with very unpleasant effects on the subject of the experiment, which do not seem to have occurred.

The effects produced on the odorous properties of the urine, by exposure of the body to oil of turpentine, are well known. By inhaling the vapour of this fluid, the violet smell is imparted to the urine very piously: even a single full inspiration is sufficient to produce the effect. Walking in a room where it has been spilled will operate in the same way. It has been proved by experiment that the lungs are the organs by which the absorption takes place, and that the fluid is not taken up by the skin. Dr. Routheau, of Philadelphia, exposed his body freely to the turpentine vapour, breathing through a pipe, which communicated with the external air, and had no connection with the air of the room. No effect was produced on the urine. He immersed his arm in spirit of turpentine for two hours, lathering the vessel containing it to the arm, so that no vapour could escape; no change was perceptible in the properties of the urine. He smeared his body all over several times with the spirits of turpentine, guarding against the inhalation of the vapour of the lungs, by breathing the external air through a tube. He continued this for some time, until the surface was irritated, and the pulse quickened; the result was the same. The experiments were frequently repeated, and with the same result, whether the spirit of turpentine was employed, or camphor, garlic, or mukil. Currie's Med. Rep. v. 1. chap. 19.

The exhalent vessels of the skin arise in the exterior capillary pith, which surrounds the corium, and which affords the middle of termination of the cutaneous arteries. They draw from this source the fluid which they pour over the epidermis. We are entirely ignorant of their form, length, course and direction; but the phenomena of the cutaneous discharge, and of injections prove their existence. They do not seem to be equally abundant in all parts: in the face and chest they are numerous, so that we sweat easily in these parts; the number is smaller in the back and limbs. Sweat is very seldom observed in the palms and soles; but there is great variety in these respects in different individuals.

It appears from experiments, that a considerable discharge takes place from the skin habitually, although not in a form cognizable by our senses. This is called insensible perpiration, or tranpiration. Under particular circumstances, the cutaneous discharge consists of fluids possessing very sensible properties: this is called sweat. The epithet insensible is applied to the former, to distinguish it from the sweat, but under certain circumstances it may be rendered obvious to the senses. It has been often ascertained that a vapour may be observed to arise from the body, and may be recognized by its shadow against a white wall in the summer. This is observed more readily in a dense atmosphere. Haller saw a kind of cloud or smoke arising from the face, hands, and indeed every part of the naked body in the subterranean excavations of Cautrihal and Rammelberg. A still more obvious demonstration of the tranpiration is yielded by holding a finely polished metallic surface near the skin; the watery vapour is condensed by the metal, and clouds it. Under ordinary circumstances, the whole discharge is evaporated as it is produced, and passes off in this invisible form. As all bodies absorb heat in changing from a fluid to a gaseous form, this evaporation must have a very powerful effect in regulating the temperature of the animal frame. When the nature of our clothing confines the perpiration, and prevents its evaporation, an unpleasant feeling of heat is produced; this is particularly observed when the body is covered with oiled silk. On the other hand, exposure of the skin in a naked state, particularly in the wind, has a very rapid and powerful cooling effect. The importance of this function in regulating our heat did not escape the notice of that sagacious observer Benj. Franklin: "During the hot Sunday at Philadelphia, says he, in June 1750, when the thermometer was up at 10° in the shade, I sat in my chamber without exercise, only reading and writing, with no other clothes on than a shirt, and pair of long linen drawers, the windows all open, and a brisk wind blowing through the rooms. The sweat ran off the backs of my hands, and my shirt was often so wet as to induce me to call for dry ones to put on. My body, however, never grew so hot as the air, or as the immediate bodies immersed in the air." (Letters and Papers, p. 365.) It does not appear that Franklin actually regulated his heat; but he makes the inference of his comparative coolness remembering that all the bodies about him, even the shirt out of his drawer, felt warm to the touch; and he concludes that he was kept cool by the continued sweating, and by the evaporation of that sweat.

Probably sweat is only an increased quantity of the same kind.
kind of fluid with that of the transpiration: very small particles of fluid are observed on the skin, and they unite into larger and larger drops. Heat is the most common cause of sweating, as it is a very powerful means of exciting the action of the heart, on which this phenomenon depends in many cases: hence warm air and the warm bath are powerful causes. Strong bodily exertion, and warm food, by stimulating the vascular system, produce the same effect. Fear, and other affections of the mind, fainting, and various morbid states of the frame, also produce sweating. We cannot name any particular degree of heat at which sweating is certainly produced; and the pulse is often very greatly accelerated in disease without this consequence. Sometimes a particular part of the body only sweats: sometimes one side, as Haller has noticed in his own person. Dichter enquires whether the nerves have any influence on the cutaneous discharge. He observes, that in puffed patients sweat takes place on the diseased as well as on the sound side. "I lately," says he, "attended at the Hôtel Dieu a patient, in whom the left side of the body was rendered perfectly paralytic, in consequence of an apoplectic attack: yet he sweated only on this side. Examples of the opposite phenomenon are adduced; but they cannot invalidate the common observation that the discharge is equal on both sides. Is it not well known, that when the nervous action is entirely annihilated in a paralytic limb, blisters affect it in the usual manner? Do convulsions, in which the nervous action is increased, augment the cutaneous exhalation? Have the states of acute sensibility, where there is in the cutaneous nerves so great a susceptibility of impressions, any known influence on perspiration? Let us then consider, that in cutaneous respiration, as well as in secretion, we are entirely ignorant of the nature of the nervous influence, if any such exist."

The discharges by the skin and the kidney seem to be regarded by physiologists as the principal means by which the refusible matter of nutrition and digestion is expelled from the body: and they have attempted to shew the ratio which these bear to each other, to the pulmonary exhalation, and to the feces. We have not derived much information from these labours, which merely prove, in a general manner, that the discharge is effected through the internal organs in cold climates and feasons, and through the skin under opposite circumstances. In this respect, the kidney and the skin sare always in opposite states in relation to each other: the urine, in winter, the urine is much lighter, the blood impure, and in summer the perspiration has a faint taint and other peculiar characters, arising from matters which it does not contain in the former season. Every individual must have observed in his own person that while he sweats freely, no urine is collected in the bladder; and, that, when the cutaneous discharge is interrupted, the secretion of the kidney goes on very actively.

We do not know much about the pulmonary exhalation either as to its quantity, its nature, or its relations to the cutaneous discharge: but that the two organs very powerfully influence each other, is rendered very obvious by the phenomena of disease. The effect of exposure to cold and moisture in exciting pulmonary affections, and the disposition to such disorders in winter, when the cutaneous exhalants are less active, are well known.

We often have occasion to observe a manifest connection between the perspiration and the alvine discharges.

When the extent of the exhalating organ, the innumerable tubes by which it is penetrated, the quickness with which we can see the perspiration produced, are regarded, we shall expect to find that the quantity of the discharge is very considerable. Although it was known to the ancients, who had noticed its influence on the health, and introduced it into their pathology, we find little detailed information concerning this function before the seventeenth century, about the beginning of which it became the subject of the most patient research, and of the most extensive experiments perhaps ever undertaken. Sanctorius, a Venetian physician, dedicated thirty years to his experiments, which could chiefly in weighing whatever he ate and drank, as well as what he discharged by urine and stool. From him the infeetable perspiration has sometimes received the epithet of Sanctorian. His example was followed by several perfons in different countries; by Dodart in France; by Keel, Robinson, RyE, and Home in this country; and by Lynings, in South Carolina. The gray monarch, Charles II., amused himself with some experiments on this subject. Something must be taken from the numbers expressing the quantity of perspiration, on account of the pulmonary exhalation, the mucus of the air passages and nose, and spitting. For, in the experiments now alluded to, all the difference between the ingesta and the egesta is set down as loss by inelastic inspiration.

In the experiments of Home, in Scotland, the food amounted to 4 lb. 3 oz.; the feces to 7 1/8 oz.; the urine to 2 lb., or 3 lb.; the perspiration, in the course of an hour, varied from two-thirds of an ounce to 4 oz., and even fixed under exposure in the sun. In the twelve hours of night, the perspiration varied from 12 to 18 oz.; and in 23 hours the discharge amounted to 3 lb. 3 1/4 oz.; and on another occasion, to 2 lb. 6 oz.

Rye, who lived at Cork, in Ireland, found the urine in the winter season to amount in one day to 42 7/8 oz.; the perspiration to 52 oz. in spring, the urine was 40 oz.; the perspiration 60; in summer the numbers were 37 and 63. The average daily quantity of urine, therefore, was rather less than 40 oz., and that of the perspiration 56 1/2 oz. The average daily amount of the feces was 4 1/4 oz.; that of the food 96 oz. The large quantity of perspiration in the winter is chiefly made up of what is produced during the night.

Keil found the medium quantity of perspiration to be 31 oz.; of urine 38; of feces 5; food 78.

Robinson allows that the urine is diminished, and the perspiration increased in a very feensible manner in the summer, so that the average number of ounces of the former is in summer 27, in winter above 30. In the summer months the perspiration and urine are as 5 and 3, in the winter as 2 and 3; in April, May, October, November, and December, they are nearly equal. In a young person he estimates the ratio of the perspiration to the urine as 13 40 to 1000; in an old one as 907 to 1000. He makes the average quantity of food 86 oz., and 58 when he was old; the urine 35 and 28; the perspiration 46 and 27 1/2; the feces 53 and 31 1/4. Thus the food and all the excretions are diminished as age advances.

Hartman, in Germany, found the food to be 8 oz.; the urine 28; feces 6 or 7; and perspiration 45 or 46.

Dodart, in France, found that the perspiration was to the feces as 7 to 1. He estimates the discharge in summer at 40 oz. 3 1/2 oz. 26 gr.; in winter at 26 oz. 46 gr. Sanctorius in the warm and humid air of Venice, took 8 lb. of food; the perspiration amounted to 5 lb.; the feces to 4 oz.; and the urine in the night to 16 oz.; in the twenty-four hours to 44 oz.

Lynings has given us very accurate accounts of his experiments, which were performed in South Carolina. From his labours, as well as from those of Robinson, in Ireland, it appears that the perspiration is most abundant in the warm months.
months, and the urine in the cold: the former was in greater quantity during five months, and the latter during seven. The largest proportion of urine was 143 oz., which occurred in the month of December; and of the perspiration 130 oz. in November. The average daily amount of the food, on a mean of experiments continued for a year, was 27,18 oz.; of the drink 102,17; of the urine 64,83; of the perspiration 69,10; of the feces 4,35. The ingesta were to the urine, throughout the whole year, as 2,03 to 1; but at many particular times they were as 3 to 1; their ratio to the perspiration as 2,18 to 1; to the fecal discharge as 30,15 to 1; and the perspiration to the whole year to the urine as 1 to 1,48. These experiments differ from those of Sanctorius and of Rye, in showing that the urine exceeds the perspiration even in a hot climate.

It appears doubtful, says Haller, on comparing together the results of the trials made by individuals of different ages in various climates and seasons, whether the discharge by the skin exceeds that by the mouth. On such a comparison we must set down the cutaneous exhalation much below the quantity affirmed by Sanctorius, as it did not exceed 60 oz. in a very hot climate, and in colder countries was 56, 45, or even 32 oz.

It will be readily perceived, as we have already observed, that these calculations do not give the measure of the perspiration alone, but of the cutaneous and pulmonary discharges together. To separate these, and to determine the quantity of each, still remained an important problem, the solution of which has been attempted only of late years.

Mr. Cruikshank introduced his hand into a glass jar, and tied a bladder, fixed to the mouth of the jar, round his writ. In less than a minute the inside of the bottle was rendered dim, as if it had been heated over the flame of warm water: small drops appeared in less than ten minutes, and a teaspoonful of transparent and perfectly insipid fluid, weighing 30 gr., was collected in an hour. Assuming that the hand is to the whole body as 1 to 60, and that the whole surface perpises equally, the evaporation at this rate would be 7 lb. 6 oz. in 24 hours. When the experiment was repeated after taking exercise, 45 gr. were collected in an hour, which is at the rate of 12 lb. in 24 hours. By breathing into a bottle for an hour, this gentleman collected 124 gr. of insipid transparent fluid: the produce in 24 hours at this rate would be 6 oz. 1 dr. 36 gr. If this be added to the former statement of the cutaneous exhalation, the sum will be 8 lb. 1 dr. 36 gr.; and the evaporation from the lungs will be little more than 4th of the whole. Bichat says that he collected 2 oz. of fluid by breathing for an hour into a vessel.

Mr. Abernethy collected from his hand and wrists, inclosed in a glass jar for six hours, about 3 dr. of fluid. He estimated the surface from which this was collected at 4,8th of the whole body; hence, if the perspiration be equal at all times and in all parts, the produce in one day would be about 2 lb. This result is so different from that of Mr. Cruikshank, that there must be some signal error in the data on one side or the other.

The method adopted by Lavoisier and Seguin seems calculated to afford results more worthy of our confidence. The whole body was inclosed in a silk bag, varnished with elastic gum, impenetrable by air or moisture, having a small opening carefully cemented round the mouth through which the person might breathe; so that whatever came from the lungs escaped, while the whole of the cutaneous discharge was confined within the bag. By weighing the body, therefore, before putting on this dress, and immediately after leaving it, the total loss by the pulmonary and cutaneous discharges was ascertained. The amount of the loss by the hand was known by weighing the subject of experiment just before he put on the dress, and again immediately before he removed it. When the latter quantity was subtracted from the total loss, the remainder gave the value of the cutaneous discharge. From repeated trials performed in this manner, Seguin and Lavoisier found that, by the cutaneous and pulmonary exhalation, to be thirty 14 oz. in the minute, or 4 lb. 1 oz. in 24 hours. The cutaneous discharge amounted to 1 oz. to 8 lb. from the skin. That the quantity perspired is increased by drink, but not by solid food. Perspiration is at its minimum during meal hours and immediately after; it reaches its maximum during digestion.

Our next object of inquiry is into the composition and properties of the cutaneous exhalation. As it escapes from the surface indefinitely, there is a difficulty in collecting it in sufficient quantity for examination; hence its nature and composition are very imperfectly known. Lavoisier collected it by placing his hand in a glass, found it to be water with a faint and insipid smell.

The fluid collected by Mr. Cruikshank appeared pellucid all the properties of pure water. When Mr. Abernethy had procured 3 dr. of fluid, he evaporated one half; there remained on the glass a small residuum, which had a very slight taste of salt. The other half was suffered to stand many days, in which time no change appeared. It did not alter the colour of vegetable blue; no coagulation or precipitation of animal matter was produced by muriatic acid, neither was any change caused by the addition of pure alkali. It appeared, therefore, to Mr. Abernethy, that the water of perspiration contains little of anything, except a very small portion of salt.

We cannot reasonably doubt that the greater part of the matter of perspiration is water; but it certainly contains other matters, of which the nature is not well ascertained. Its sensible properties are often very perceptible: it causes the peculiar odour of the body, which is very remarkable in particular individuals, and poisons peculiar characters in whole races of mankind. Its fine is often four; and it is said, under such circumstances, to change the vegetable blue colours to red. Berthollet thought he detected the presence of the phosphoric acid; he observed that a blue paper, applied to a part labouring under a gouty paroxysm, became red; but Fourcroy remarks, that if this acid were constantly exhaled, it must accumulate on the skin, as it is too fixed to be volatilized with the aqueous vapour of perspiration.

From the strong odour of the perspiration when profuse, and from the tinge which it communicates to linen, there is reason to suppose that it contains a particular animal matter. In the perspiration of the horf, an animal substance of the nature of ura has been detected by Fourcroy and Vaque- lin, who have also discovered that the phosphatite of lime is left in considerable quantity by the evaporation of the perspired matter on the skin of the same animal. It seems to crystallize on the surface, and forms the branny matter detached by friction of the surface. The above-mentioned chemists observe that the urine of this animal contains no calculous phosphate.

Vol. XIX.
Mr. Cruikshank's experiments prove clearly that there is an oily matter secreted by the skin; indeed the familiar appearance of the repulsion of water, so as to cause it to run into globules, sufficiently evinces the fact. Mr. Cruikshank were the same vault of flaccy hollow night and day during the hottest part of the summer. At the end of this time he always found an oily substance accumulated in considerable masses on the top of the inner surface of the vault, in the form of black tears. When rubbed or paper, it makes it transparent, and harder on it like glass. It burns with a white flame, leaving behind a charred residuum.

Besides the condensable vapour which is exhaled from the skin, it has been ascertained that gaseous fluids are also separated. Many philosophers have laboured on this subject, but the results of their experiments are so contradictory, that we cannot deduce from them any very satisfactory conclusion.

The count de Millly seems to have been the first who called the attention of philosophers to this subject. He had often remarked the accumulation of small air-bubbles on the surface of his body, when immersed in the warm bath. At length, by means of a funnel and inverted glass jar he collected, in a few hours, half a French pint of the gas, which was examined by Lavater. It was incapable of supporting combustion, produced a precipitation in lime water, and suffered no change from the admixture of nitrous gas. Acad. Roy. des Sciences de Berlin, 1777.

Mr. Cruikshank found that a lighted taper, introduced into a bottle in which his hand or foot had been confined for some time, burned dimly; and lime water agitated in it was rendered turbid.

Ingenhouz could not procure the air from the skin in the warm bath in such quantity as the Count de Millly did. What he collected seemed to be azotic gas. Experiences sur les Vegetaux, t. 1.

Priestley denies that any gas is perspired by the skin. He repeated the experiments of Ingenhouz, and never could observe the appearance of gas arising from the body when he employed boiled rain water, from which the air had been completely expelled, and detached the adhering bubbles from his arm. He observes that the air obtained by Ingenhouz "was just that mixture of fixed air and partially phlogisticated air, that pump water, which he recommends for the purpose, generally abounds with." Experiments and Observations, vol. v. p. 103.

Fontana arrived at the same conclusion from his researches.

Such also was the result of Mr. Jurine's experience, who, after remaining in the bath at different temperatures from 18° to 30° of Réaumur for hours together, never could procure a single bubble of air from his skin. He obtained the same result from observations on several individuals in water of various temperatures. Histoire de la Société Royale de Médecine, tom. 10.

Mr. Cruikshank's experiments seemed to prove that air, which has been confined for some time in contact with the skin, becomes changed; though Dr. Priestley maintained that the perspirable matter has no such effect on the air, but leaves it as wholesome as ever.

A very extensive set of experiments performed by Mr. Jurine, of Geneva, and published in the volume already quoted of the Memoirs of the Royal Society, of Medicine, seems to confirm the observation of Mr. Cruikshank. Although Mr. Jurine could not collect any air from his skin, when immersed in the warm bath, he always found the air confined about the skin much vitiated. He fixed well-dried bottles under his arm-pits, and round his waist, and having left them there for an hour, accurately corked and removed them, that the contained air might be examined by the usual tests. In these experiments he always employed the mercurial trough. This air was found, on different occasions, to contain .7o, .74, .69, .41 of carbonic acid gas. He next inclined his arm in a glass cylinder containing 68 cubic inches of air. One extremity of this vessel closely embraced his arm, round which it was cemented. To the other extremity was fixed a bent tube, which, during the experiment, was plunged under water in the pneumatic trough. After two hours, the air of the cylinder was found to contain .8 of carbonic acid gas. In another experiment the same quantity was obtained after one hour; but the proportion of carbonic acid gas was not greater at the end of two, three, or four hours. Being thus satisfied that carbonic acid gas is formed by the skin when in contact with the air of the atmosphere, he concluded, that he should find the same gas under the bed clothes which confine the air round the body during sleep; and in experiments on different individuals he found that this air contained .49, .6, .7, .8 of carbonic acid gas.

In the same volume are some experiments by Gattoni, which do not lead to the same conclusions with those of Jurine; for they do not seem to have been very accurately performed, and the tell of lime water was not employed.

We come in the next place to the researches of Mr. Abernethy. From the hand, introduced into a glass jar filled with mercury and inverted, he collected, in the space of fourteen hours, one half-oounce measure of air, which had escaped in small bubbles from every part of the surface of the immersed hand. Two-thirds of this gas were absorbed by lime water; and the remainder suffered no diminution from the admixture of nitrous gas. When the experiment was repeated under water, a small quantity of azotic gas only was obtained, the carbonic acid having been, in the opinion of Mr. Abernethy, absorbed by the water. The hand was exposed five hours, in a jar containing seven ounces of atmospheric air, which was diminished about half an ounce. One ounce of the remainder was absorbed by lime water, with precipitation of the lime. By the left of nitrous gas the air was found to contain nearly 4th of oxygenous gas than it did before the experiment. When a similar experiment was performed with seven ounces of azotic gas, rather more than one ounce measure of carbonic acid gas was produced in two hours. The trials were repeated with hydrogenous, nitrous, and oxygenous gases, and in every instance nearly the same quantity of carbonic acid gas was obtained.

In the 45th vol. of the Annales de Chimie, there is a short paper by Dr. Troufct, who had noticed, like Millry, the appearance of bubbles on the skin in the warm bath. He seems to have been only in two individuals, and found the air to be perfectly pure nitrogen. In his own person, and in many others, he could observe nothing of the kind.

Spallanzani is the last experimental philosopher who has paid particular attention to this subject. The detail of his experiments has not been published, but the results are preferred in a letter to Senebur, introductory to the Memoirs on Respiration. He appears to have been completely satisfied that air in contact with the skin is changed exactly in the same manner as by respiration. When atmospheric air was employed, oxygen diffused into, and carbonic acid gas was produced; he was of opinion, that the oxygen of the
the atmosphere had no share in the production of the
bic acid gas, because it was equally great when the
animal was confined in cages containing no oxygen; and
be therefore concludes, that the carbonic acid gas was exhaled,
and the oxygen absorbed.
On a review of these very contradictory evidences we do
neat to be warranted in believing that any gas is fepa-
rated from the skin; but perhaps we may conclude that the
air in contact with the organ undergoes a peculiar modifica-
tion.
Saccous Glands of the Skin.—This organ is habitually co-
verted with a oily substantiae which occasions water to run
into globules on the surface of the body, which imparts a
greatiy to linen, when it is worn for a long time, and
which occasions dust, &c. to adhere to the skin. This
action of balance is more abundant in some parts of the
body than in others. About the face it is observed in con-
siderable quantities, and on the bony head. Hence, when
d看重 cleanliness is not sufficiently attend, the hair
becomes quite greasy and flamin. It is abundant in situa-
tions exposed to fricdon, as the axilla, perineum, &c.;
and when confined in such parts causes a very disagreeable
odour. It is found in very small quantity, so that it can
hardly be observed, in the palms and soles. Certain races
of mankind, as the negroes, have it in great abundance.
Probably the favable qualities of the cutaneous discharge
depend in great measure on this matter, the particular na-
mure of which is but little understood. It does not seem
to undergo those changes of augmentation and diminution
which are observable in the perspiration. Its obvious utility
seems to be that of protecting the skin from the agency of
external causes, and keeping it in a state of softness.
Is this matter simply an exhalation from the cutaneous
veins, or is it produced by glandular apparatus? In some
parts of the skin, as about the nose, and in other situations of
the face, the external ear, &c. there are very manifest
small roundish bodies, with a simple aperture, from which a
feaceous matter may be sometimes expressed like a fine
thread. Morgagni also admits their existence in the neck,
back, perineum, buttocks, &c. Haller does not conceive
that they are proved to exist in all parts, and we certainly do
not find them; yet this oily matter is formed over the whole
body. The examples of the fat of the cellular interlacies
and of the medullary fluid of bones show us that the exhaus-
tants can produce matters of this kind.
Properties of the Dermoid System.

1. Properties resulting from Organization.—These are found
to exist in all the skin in a very striking degree: the changes of
size, in which different parts, particularly the limbs, swell
twice or three times their natural bulk, and then recover
their former state, prove these properties; and the various
tumours, external aneurisms, sudden dilatations from great
bruises, collections of fluid in the abdomen, pregnancy, en-
largements of the tuchicle, &c. afford additional proofs.
In all these cases the skin is first expanded, and then
reflores when the distending cause ceases to act. A square
inch of integument has been found able to sustain a weight
of 200 lb.
The contractility of the skin occasions the retraction of
its edges when it is cut; and this occurs in the dead sub-
ject; but it seems to be heightened by the vital powers as it
occurs to a much greater degree during life.
The extensibility of the skin is less in many cases than it
would appear to be on first sight, as the neighbouring in-
eteguments are drawn over a tumour. Thus in large swell-
ings in the scrotum, the skin of the penis covers part of the
 tumour, &c.; in extensive ulcers the skin of the sur-
rounding parts is drawn towards the centre of the ulcer.
In moist extusions the thickness of the dermal tissue is
diminished. When it is dilated by the inflamation of water
in its interstices, as in annularis, its thickness increases, while
the dextity is diminished. It seems to lose the power of ex-
tension, so as to burst under the action of a distending
cause, from chronic inflammation. Most of the chronic
affections, which alter the tissue of this organ, destroy its
contractile power.

Vital Properties.

2. Properties of the Animal Life.—Animal sensibility exists
in this organ in a very high degree; it precludes over the
general sense of feeling, which is more acute in this than
in other tilffes, and also that of touch, which is very dis-
tinct from the former. The general sensc, called by the
French tact, is the power of perceiving the impressions of
surrounding objects; in this signification it seems to mean
the same as the English word feeling, which is the office of
a nerve in general; as those organs only are so affected by ex-
ternal bodies as to produce some change by which the mind is
rendered conscious that the bodily organ has been modified.
Thus heat and cold, roughness and smoothness, hardness
and softness, moisture and dryness; pressure causing pain;
acid qualities; titillation producing itching, &c. are all
perceived by the nerves. This kind of tact belongs to the
whole body; and does not suppose any peculiar arrange-
ment of the organ; it is merely the animal sensibility con-
sidered in a state of exercise. Thus, when the particular
modifications of this sensibility belonging to the other senses
have been destroyed, when the eye is insensible to light, the
to touch, &c., the organs still retain the power of per-
ceiving the presence of bodies and their general attributes.
The tact of touch is the power belonging to the skin alone,
of examining more minutely and accurately those
properties of bodies, which have just named. For this
purpose we employ chiefly the ends of the fingers; those of
the toes seem to be organized exactly in the same way, but
are incapable of being turned to this use by the hardness of
their coverings. These parts are conspicuous for the size of
their nerves, and for the number and prominence of the pa-
pille. This organization gives to them a more exquisite sen-
sibility of the same kind with that belonging to the skin in
genral. The form of the organ in the human subject, where it is
composed of several moveable parts, adapts it particularly to
serve as an instrument of touch, by facilitating its application
to external objects; and this advantage may be more particu-
larly seen in bodies of a rounded figure. We rub the fingers
gently against the object, so as to apply the papillae suc-
cessively to the different points of its surface. Whether any
physical change takes place in the organ, whether the papillae
for example are erected or not, is entirely unknown.
The distinction of colours by blind persons, if such a
power has really existed in any instances, must have arisen
from modifications in the surface produced by the colouring
matter. We know that the touch in all cases of blindness
acquires great acuteness, as it must be much more ex-
ercised and depended on, than in individuals who can see.
The temperature of bodies is estimated by a comparison;
those are called cold, which are of a lower temperature than
what we had felt immediately before; and vice versa. Or
we refer to the state of our own surface, and call the objects,
from which heat passes to us, warm, and those of the op-
and warm to the other, if we have previously immersed one in a warmer, and the other in a colder medium.

It has been conceived that the sense of touch is of great use to us in correcting the errors of the other senses, and particularly of the sight. This peculiarity belongs to it certainly, that the organ is modified by the very body whose properties we are examining, while, in the case of vision for example, the eye is affected not by the object itself, but by the light of light. Perhaps we are less deceived by the other senses, and by that of sight itself, than has been commonly imagined. Without any alliance from the sense of touch, for which his organization entirely disqualifies him, the horse measures the hedge or ditch with his eye most accurately, and draws the distance with great exactness. Newly born animals seem to commit no errors in seeking their food or their parents, &c. On the other hand, the touch is not free from error. The experiment of rolling a round body under two fingers decussated, which gives us the sensation of two bodies, foars this. Moreover, the touch no more informs us of the real nature of things, than any other sense; we acquire a knowledge of their properties through certain interpolated idea, and alterations in them very much modify the perception. When the epidermis is removed, external bodies cause pain, and do not excite the impressions, which inform us of tangible properties; again, when the cuticle is preternaturally thick, as in the hands of labouring men, no sensation takes place.

This sense is also subject to various morbid conditions. In hypochondrias there is sometimes a feeling as of cold air; and the slightest contact of air is intolerable. Ann of Austria found the finest linen manufactures unpleasantly rough; and some have not been able to endure the touch of silk, or of the down of a peach.

Habit, too, has a powerful influence in modifying the impressions which we receive from the touch. The heat of a glass-house, which is sustained without any unpleasant feeling by the workmen for several hours, is intolerable to a person unaccustomed to it.

The touch differs from the other senses in not requiring a peculiar mode of sensibility for its exercise; the hand is rather more sensible than the rest of the skin, but we can touch with other parts of our surface. In the other senses there are peculiar kinds of sensibility differing the organs to be acted on by particular objects, and rendering them insufficient of other impressions. The exercise of the touch is determined by volition, and is generally consequent on the employment of the other senses.

Most of the other senses require an express organic arrangement, as well as a peculiar sensibility in the organ; the touch, on the contrary, requires only a particular form in its organs. If they have the animal sensibility, and can embrace objects by several points, they can dilate with the tangible properties. The touch will be imperfect, if the organ is in contact with the body only in one or two points; yet it will take place. Thus we can touch with the hollow of the axilla, at the bend of the elbow, or the knee. But the sense is exerted more advantageously when the points of contact are multiplied. The fatness of the human hand is particularly well contrived in this point of view; it shows that man is calculated, much more than the quadrupeds, for communion with surrounding objects; that the domain of his animal life is therefore much more extensive; that his sensations are more precise, as the points are additional means of perfection; that his intellect and faculties are capable of filling an infinitely greater sphere, because they are grounded on the exertion of a much more perfect organ.

The sensibility of the skin seems to reside essentially in the papillæ, which is the part of the integuments truly belonging to the animal life, as the vascular plexus, containing the reticular body, is connected with the organic functions. Its acute sensibility requires a protection from too strong impressions; and this is afforded by the epidermis. When that is removed, even the impression of the air is painful, and causes a sensation, which we call smarting, which belongs perhaps exclusively to the dermoid system. It is felt in burns, blisters, erythemas, and in all the inflammations affecting the reticular body of the skin. Itching is another mode of sensation peculiar to this system.

Besides the impressions, which teach us the properties of bodies, the exercise of this organ produces feelings of pleasure and pain. So far as the sense of touch is concerned, pleasure may be considered as that condition of the body, which we should wish to have continued. The more exquisite feelings of this kind are produced by friction of the papille. Without referring to general sensations, we may mention a practice of the Chinese, of introducing a small pencil into the ear and moving it round so as to excite a very acute pleasurable feeling.Tickling must be something of this kind; it is peculiar to the skin, and in many individuals excites sensations which are almost intolerable. Great differences in this respect are observed in different persons. Pain is the very reverse of pleasure; and, in the skin, is the most acute, when the naked organ, where it possesses many papillæ, is irritated.

The animal sensibility of the skin, like that of the mucous surfaces, is under the powerful influence of habit, which transforms successively into indifference, and into pleasure what was at first painful. The air in the casement of the feaons, heat in the various states of the atmosphere, water in the bath, or in the humid vapours with which it loads the medium in which we live, our clothes, of which the woollen are at first very unpleasant, in short, every thing which acts on the skin by simple contact, produces sensations which are incessantly modified by habit. Observe the varieties of dress in different countries; sometimes the upper limbs are uncovered, sometimes the lower; in some instances more or less of the trunk is exposed to the air; often the favage is entirely naked. The parts which are left naked in each people, support the contact of the air without any painful sensation. Expose, on the contrary, the parts which are habitually covered, particularly if the atmosphere be cool, a painful sensation will be produced at first, but, as the parts become gradually habituated to the contact, they are at last insensible to it.

But habit has no power over that heightened state of the cutaneous sensibility, which results from an organic affection, as inflammation for example. The slightest contact of a foreign body is extremely painful in this case; and consequently the skin can no longer exert its function of touch. Even the tact, or the power of distinguishing general sensations, is destroyed. The impression of all bodies is uniform; it is that of pain.

The animal sensibility of the skin may be diminished or destroyed, as in paralytics; but the whole organ is never affected; and in this respect there is very seldom even hemiplegia. These cases afford a further proof that the cutaneous exhalation and capillary circulation are not influenced by the nerves, since both go on very well as they do in the paralysis of the moving organs.

Properties of the Organic Life.—The organic sensibility and the insensible contractions exist in the skin in a very high degree, and reside particularly in the exterior capillary system, which forms
INTEGUMENTS.

forms the reticular body. On these properties depend immediately, 1. the capillary circulation; 2. the cutaneous exhalation; 3. the absorption; 4. the nutrition of the dermal system; and 5. the secretion of the cutaneous oil, where sebaceous glands exist. Besides these numerous functions, we must reflect that the skin is similarly exposed to the action of external causes, which keep it in a state of habitual excitation, as the contents of mucous surfaces act on those surfaces.

The skin does not seem to possess the sensible organic contrariety; irritating applications act only on the capillaries, and therefore produce an effect, which is not obvious to the eye. Yet the corroboration of the integuments under the strong action of cold, resembles in some respects the sensible organic contrariety; this, which takes place in the corium, seems to hold the middle between the two kinds of organic contrariety.

Positive Sympathies.—The animal sensibility is often brought into action sympathetically in the skin, by the affections of other systems. There are various examples of itching, &c. without any derangement of the part, to which the sensation is referable.

Very often the feeling of heat or cold occurs in the skin, when there is no cause affecting the organ to produce such sensations; there seems to be an erroneous reference of the unpleasant feeling to its source, as in the case of pains felt in amputated limbs. The skin is sensitive to the action of cold and heat, and the sweat which accompanies a species of sympathetic cold is often referred to the skin at the commencement of digestion.

The feeling of heat often occurs sympathetically in the skin. The flushings, which occur so often and irregularly in different fevers, are well known, and are not attended with any disengagement of caloric. These feelings of heat and cold are produced without any alteration of temperature, as sympathetic pains occur without the action of those obvious causes, which give rise to them under other circumstances. In fact, the sympathies of the animal sensibility call into action, in each system, the feeling which is habitual to it. The same cause which produces the sensation of heat or cold in the skin, would have given rise to that of latitude in the muscles, &c.

The organic properties of the skin are frequently called into action by sympathies; thus cold drinks (prepares perspiration. Augmented cutaneous exhalation follows almost immediately the introduction of warm fluids into the flow. The effect of cold, and that of collection are of the same nature. Diseased exhibit to us innumerable varieties of dryness and moisture of the organ, phenomena which are generally sympathetic.

Active Sympathies.—The irritation of the skin in tickling, in very sensitive individuals, excites various organs sympathetically; as the heart, producing fainting; the stomach, vomiting; and the brain, convulsions. Affects of the cutaneous exhalation, or of the capillary system, from which they arise, act sympathetically on various organs. Thus the warm bath disturbs the process of digestion; while its influence in many cases always disorders of the stomach. The action of cold on the surface, particularly during sweating, produces several sympathetic effects. We express what occurs inaccurately, when we refer it to the translation or rejection of the sensory matter. The organic sensibility of the pleura is sympathetically affected by the application of cold to the skin; just as an external or internal hemorrhage may be stopped. The suppuration of transpiration is an accessory circumstance completely foreign to the internal inflammation. If there were no perspiration at the time that the cold is applied, the inflammation would still come on.

The shaking of the muscles, and the concentration of the pulse, produced by the weakened action of the heart, are phenomena caused entirely by the action of cold on the skin.

The numerous phenomena occasioned by the sudden disappearance of cutaneous eruptions should be referred to modifications of the vital properties of the organs, and not to any morbid matter expelled from the skin. The serous surfaces and the cellular substance on one side, and the skin on the other, are often in opposition in diseases. Patients never sweat during the formation of dropsies; and this dryness of the skin is often more remarkable than the small quantity of urine.

Character of the vital Properties.—1. They vary in the different regions of the body. The palms and soles are the most distinguished for their animal sensibility: the hypochondria are so sensible in some individuals, that tickling will produce convulsions: the anterior and lateral parts of the trunk are more sensible than the back. The organic properties do not differ less, of which the great susceptibility of the face to the influx of blood is a proof. Particularly parts are subject to particular cutaneous diseases, &c.

2. Intermittency of action in one respect, uninterrupted in another. The former character belongs to this system, as to all the senses, in its animal sensibility. Immediately before sleep comes on, external objects produce but an obscure sensation, which is entirely lost in that state, in which animals seem to part with half their existence. Yet the touch seems to be exerted occasionally while the other senses are in repose: pinch the limb of a person sleeping, and he will move it without waking, or retaining any recollection of the occurrence. In its organic sensibility the life of the cutaneous layer is uninterrupted; consequently the functions, over which this property prevails, have an opposite character to the preceding. The inelastic transpiration goes on continually, although it is more active at some times than others.

3. Influence of sex. The animal sensibility is more acute in women, in whom every thing belonging to the senses is more developed, while the power of the muscles predominates in man. No very sensible difference can be remarked in the organic properties.

4. Influence of temperament. The colour and other sensible properties of the skin vary in individuals, and these variations are in constant characters of the different temperaments. When we see these differences of temperament, can we be surprised at finding that the sensibility of touch is acute in some, dull in others; that some persons are very susceptible of tickling, and others almost insensible to it? That the organic sensibility admits a great quantity of blood into the capillaries of the face in some, and restricts it in others; that some have a moist and others a dry skin? That there are dispositions in individuals to particular emotions affections, chronic or acute? &c. &c.

Development of the cutaneous Syn.-The skin in the early times of conception appears as a vivid coat, which gradually condenses into a transparent layer, torn by a slight violence, and showing the subjacent organs.
particularly the blood-veils, to be easily seen through it. Its confidence increases until it acquires the appearance exhibited to the time of birth. In its mucous state cellular substance and veils compose it entirely: when the fibres of the corium are added, it becomes firmer. The external surface exhibits but few of the wrinkles described above; they are prevented from appearing by the large quantity of subjacent fat. The inner surface acquires but slightly to the cellular layer under it. It contains more blood than at any other period of life. The animal sensibility is not yet called into exercise; there are no causes to excite it. Is the organic sensibility in action at this time? It must be so in a certain degree to produce the unctuous secretion, by which the surface is covered.

This system undergoes a sudden resolution at the instant of birth. Hitherto it has received only black blood, and is consequently more or less lives at birth. This colour gives place to red, produced by the arterial blood now full formed: and the state of the skin in this respect may be considered as an index of what is passing in the lungs. All parts of the organ are penetrated uniformly by the red colour. A sudden excitation is thus communicated to the organ, exciting its vital properties, and rendering it more susceptible of the impressions of surrounding objects. The surrounding temperature, the air, clothes, the water used in washing it, communicate to the skin an excitation, which is the more sensible in proportion to its novelty. The sympathes connecting the skin to the other organs now become necessary: thus the internal organs quickly feel the excitation applied externally.

The organic sensibility is augmented at the same time; transpiration is established; various substances are separated by it; others perhaps absorbed; and various diseased affections flow themselves.

The organ still continues soft for some time after birth; and melts entirely into jelly very easily by chilblains. Its density increases gradually, but has not arrived at its greatest state till towards the thirtieth year. As this augmentation proceeds, the fibrous substance is increased in proportion to the gelatinous. At the same time the adhesion of the internal surface to the cellular substance becomes stronger, and the wrinkles of the face are gradually formed. No remarkable change is produced in this organ at puberty: sweats are more abundant after this time; in children the refuse of nutrition passes off by the kidneys rather than by the skin.

The organ still retains a great activity after the age of growth, and very easily influences other parts of the frame: hence the periphrenonies, pleurisies, &c. produced by the action of cold.

The increase of the fibrous substance renders it more firm: le$s blood seems to be lent into its veils, and it is less subject to those eruptions so common in infancy and youth.

In declining age the dermoid sytem becomes more and more dense: it rises chilblain for a long time, but yields a firmer and more consistent, though less abundant, jelly. It is stronger but less plant. The blood penetrates it in smaller and plentiful quantity; the redness of the cheeks disappears. The adhesion to the cellular substance is much more close. All the wrinkles are more strongly marked, and several are now perceptible for the first time.

The vital powers of the skin are more weakened than those of other systems in the old man: because it has been more excited by external objects during life: the habit of feeling has blunted its sensibility. The touch is now exercised but rarely; as this sense is employed in a great measure in subervience to those of sight, hearing, &c. to rectify or confirm our other sensations. The old man, being acquainted with what furrounds him, has no motive for the use of his organ of touch. Contrast, in this point of view, the two extremes of life. The infant, to whom every impression on the sight, hearing, &c. is new, wishes to touch, to seize every thing: his hands are in constant motion. Touching is a great pleasure to him, because all new sensations are agreeable. If an old man were placed in the midst of objects, which he has never before impregne his senses, he would exercise his touch more frequently; but, among the things to which he is accustomed, there is nothing to excite him.

Hence old age is as long as the time of enjoyment. Almost all our pleasures are relative: as habit renders these le$s lively, they cease in consequence of having existed; thus the advance of years, by leaving us less new sensations, diminishes the forces of our happiness.

For the contrary reason the happiest age is that of infancy; because the whole domain of sensation lies before us unexplored; at every stroke of this advancement man leaves behind him a source of enjoyment. His career ends in indiference, a state very suitable to that period, as it diminishes the interval between life and death.

The foli wing phenomena shew that the organic, as well as the animal sensibility, is remarkably diminished in the old man. Contagions are less easily aborbed. The sweat is le$s abundant, and hardly ever exhibits those augmentations which are so frequent in the adult. The grey covering is le$s copious, and hence the surface is drier. The various morbid affections, such as erythelas, and the various eruptions, are less common and much flower. The power of refilling cold is sensibly diminished.

Epidermoid or cuticular System.—The slightest examination is sufficient to shew very striking differences between this and the preceding system, although physioloists have generally described this merely as a dependance of the former. The organization, properties, functions, mode of growth, in short, every circumstance is different in the two cases.

Under this head we consider the exterior epidermis, that which covers a part of the mucous system; and the nails.

Many characters approximate the latter to the epidermis, although the external appearance is very different.

The exterior epidermis is a transparent layer, differing in thickness in different parts, everywhere covering the skin, and immediately exposed to the excitation of external bodies.

It has the same inequalities as the cutis, since they are everywhere exactly contiguous. Various pores penetrate it, and terminate on its surface: the more copious ones transmit the hairs; others give passage to exhalants. The latter are not easily seen; but if, when the skin is dry, we suddenly begin to sweat, we can distinguish them by the small points of moisture then exhalated over the whole cutaneous surface. We cannot actually see the pores in the cuticle, even with the assistance of the microscope; and the fluid under a blister does not escape through them: but the phenomena exhibited during life leave no doubt of their existence. The internal surface adheres most closely to the outer surface of the cutis. We conceive the union to be by means of the exuding and absorbing veils and the hairs.

Dr. Hunter thought that the veins could be demonstrated. On separating the cuticle after long maceration, particularly in the fold of the foot, a vast number of extremely fine and soft threads are seen passing between it and the cutis: they break after being extended to about one
one-eighth of an inch. These may be vesicles; but it is only a conjecture. On examining the surface of the sepa-
rated cuticle, numerous prolongations of various lengths are observed, appearing like small ends of fine threads, or as more inequtities, and dilated ophically. These may be absorbents and exhalants. Whenever the medium of connection may be, the adhesion of the parts to each other is very strong.

Various causes destroy this adhesion of the epithemis, and occasion its separation. Accidental inflammations, as cutaneous, phlyngitis, phimosis, &c., are followed by its detachment; and various eruptions, not of an inflammatory nature, cause its detachment, as a dry seal, which has given rise to the notion that it is laid up of scales in its natural state. When the skin is unstriped on the surface, friction detaches it in small scales, which give a very rough appearance to the part. Pervers are not so frequent, but are followed by desquamation of skin.

The action of volatilizers is familiarly known. In the dead subject, putrefaction, maceration, and distillation are the most effectual means of accomplishing the separation.

The thickening of the epidermis is in a general very uniform: it does not seem to follow those varieties which we observe in the cuts of the trunk, limbs, &c. It is only in the palms and soles, and on the corresponding surfaces of the fingers and toes, that its thickening is increased; and here the augmentation is so considerable, that there is no proportion between these and other parts of the body.

There seem to be in this part several additional lacing, and the inner surface, after separation, does not exhibit those processes already spoken of. This excessive thickens prevents the action of blisters. In repeated trials Bichat found that they produced no effect. The transparence of the epidermis is destroyed by this thickens: it is here whitish, and even opaque. Hence, in the negro, it conceals the black colour of the reticular body; which, however, is, at the same time, less black here than in other parts. The epidermis in these situations is manifestly composed of successive laminae, adhering with such force, as to be very difficultly separator in all other parts we can see in only a simple layer. No fluid can be noticed in this tissue; when cut in various directions, either in the living or dead subject, nothing exudes. Its scales are always perfectly dry; the absorbents and exhalants merely traverse it. No blood in the living state, nor injection after death, enter it in any case. It never participates in the diseases of the subjacent organs, except by being elevated when that is so, and then detached. Nerves and cellular tissue are completely foreign to it. Thus we see that none of the general fyllums, common to all organs, enter into the composition of the epidermis; it has not the common basis of all organized parts, and in this point of view may be regarded as inorganic. It seems to contain no fibre in its composition; it noiseflies very little power of resilience, breaking under a slight dilatation, except in the soles and palms, &c. where it is so thick.

The action of air produces hardly any effect on it. When a large piece is exposed, it becomes rather harder, and more contractile; and is torn more difficultly. Next to the hair and nails, it is the tissue least changed by desiccation. It is rendered a little more transparent, but immersion in water renders it to its former state. When the skin, pales into a plate of pate,

1fracture, the cuticle is not at all changed. It is separated from the cutis, but not rendered at all purpl: if it be thoroughly washed, it has no bad odour. When preserved in moist air, it is not changed; and it may be regarded as the most incorruptible of animal substances, after the hair and nails.

Moisture applied for a long time whitens the living cuti-

In teguments.

This effect is observed in the application of poultices, and seems to arise from the tissue becoming pressed with the fluid; it takes place to the greatest degree in the feet and hands, and is often hardly sensible in other parts. The sensibility of the skin is rendered more of this by this change in the cuticle. The water imbied by the part, there are evaporated, the wrinkles disappear, and the satin recovers its former state. When separated from the body, and immersed in water, it whitens: it undergoes no naphth. In certain, but is covered by a whitish pellicle formed of separate particles. At the end of two or three months it is swollen, and may be taken very easily, but does not swell: it is never used to a false analogy to that on other organs when immersed. Flaming or produces epilation or cornification of the cuticle. A prolonged chilblain renders it left deficient, so that it may be torn very easily, but never reduces it to its native, nor gives it any yellow colour. The lamine which compose it in the hand and foot are easily separated after long boiling. The tanning principles have no action on it; nor has alcohol.

When well dried in the air, and exposed to the flame of a candle, it undergoes no epilation, as a piece of skin does when treated in the same way: it exhibits a field under analo-
gous to that of burnt horn. It burns with great facility, so that it is not lighted at one end; it will often be quickly consumed. A blackish fluid is observed in the flame, like that of burnt feathers. This is clearly of an organic nature, keeps up the combustion by its great abundance, does not burn in large a quantity only in the hand and feet; this produces a disagreeable smell. A blackish coal remains after combustion. Light does not seem to affect the epidermis, which is not changed when exposure to the sun has altered the appearance of the skin.

Nitric acid turns it yellow, but dissolves it with great diffi-
culty. Sulphuric, on the contrary, when not much diluted, acts very powerfully on it, rending it very thin and transparent, or dissolving it entirely by long immersion. Alkaline fluids dissolve it, but with difficulty: pure chloride acts on it rapidly; as also does lime, according to Chapelier.

If, says Dr. Thomson, the cuticle be rubbed with nitric acid, the application of ammonia to it is well known to give it tumultuously a deep orange colour. Now, as Hatchett has shewn that this change is also produced on ragulated albumen in the same circumstances, as the epidermis resem-

bles that substance in all the properties above detailed, it can scarcely be doubted that it is any thing else than a pecu-

nlar modification of coagulated albumen. Syll. of Chem.,

52, P. 574.

Properties.—It has very little extensibility, as the smallest

cutaneous tumour causes it to crack, and be detached in

scales. Yet it is not entirely deliquent of this property, as its elevation in blisters proves. It has no contractility: when no longer distended, the portion elevated in a blister collapses in wrinkles, and does not regain its original size. It has no animal sensibility in any part: it may be, recked, cut, torn, or injured in all parts without exciting any irrita-
tion. It differs from other organs, as cartilages, tendons, &c. which also have a natural sensibility, in being altogether un-
susceptible of that property, which they often acquire under
certain kinds of excitement. The epidermis is equally def-
itive of the organic sensibility, and organic inextensible con-
tractility: it polishes no circulation, and is insusceptible of any

disorder, which depend on the organic properties. We have no

proof, in short, that it enjoys any vital powers at all; so that we may consider the whole superficial very composition of
dead matter. "Its life," says Bichat, "is extremely ob-

}
fears; I even doubt whether it can be said to possess life. I am inclined to regard it as a semi-organized, or rather inorganic body, placed by nature at the point of communication between external dead matter and the living skin, and serving as a gradation between them.”

The action of external bodies wears it away, and it is constantly reproduced. Scrape the surface with the blade of a knife, and an abundant greyish dust will be detached. This matter accumulates in greater quantity, when the skin is not frequently washed; under such circumstances there is often a considerable layer.

It is reproduced very completely after being removed; and differs in that circumstance from most other tissues. How this is effected has been a point greatly disputed by physiologicals; but the explanations have been entirely mechanical and unsatisfactory. That it is deposited by the vessels of the skin cannot be doubted; and we shall probably understand how the process is effected, when we understand how the vessels make figure, muscles, nerves, &c. This reproduction only takes place on the skin: the thin pellicle covering the cavities of other tissues has a completely different texture. The different supererences affecting the cuticle, as corns, &c., result from the exercise of this reproductive power. They are all insensible, have no vessels nor nerves, and possess the same consistence and colour as the epidermis. External pressure seems to promote their formation very powerfully; tight shoes produce corns; and much handling of heavy instruments in hard work produces the thick cuticular covering of the hand in blacksmiths and other mechanics.

The cuticle of the palms and soles is however originally thicker than that of other parts; this may be seen in the fetus.

In the dead body the cuticle has a remarkable effect in preventing the evaporation of the fluids; none of which are dissipated so long as this covering remains entire. If the body be exposed in a high temperature, as of 100 or 120°, it does not seem to become dried; and where the limbs are distended in anasarca, if it has not cracked, none of the fluid escapes. Remove the cuticle, and the cutsis quickly becomes dry, transparent, and horny, and the subjacent parts are subfequently affected in the same way.

The epidermis is seen very clearly in the fetus, where its development is greater in proportion than that of other systems. It may be recognized when the skin leaves that pulpy state which we have spoken of. At the end of the fifth month it is thicker in the palms and soles than in other parts. It appears to undergo no change at birth; but grows rather thicker afterwards as age advances. In the old subject it differs from that of the adult only in being subject to scale and crack, and thereby appearing dry and rough.

Internal Epidermis.—Most authors have admitted an epidermis on the mucous surfaces; and they have generally represented that this is the only part of the integuments that lines the mucous cavities. But a little examination will show us that this expansion forms only a superficial stratum, and that if it be detached by hot water from the tongue, palate, &c., an organ analogous to the corium is left behind.

1. Epidermis at the Origin of the Mucous Surface.—It is very different at all the origins of the mucous system, at the glans, urethra, anus, nasal cavities, mouth, &c. It may be demonstrated in these situations by the excoriations which sometimes affect them, by detaching it with a fine lancet, by the action of hot water, by maceration, &c. It is much more delicate in these situations than where it covers skin, and becomes more and more so as it penetrates deeper. In these parts it is easily reproduced. It is defitute, like the exterior epidermis, of vital properties; and its nature seems to be in all respects the same; it yields the same results, when exposed to the same agents.

2. Epidermis of the more deeply seated mucous Surfaces.—As we advance further into these organs, the epidermis becomes gradually thinner, and soon is no longer perceptible. The most delicate instruments and methods do not enable us to demonstrate it in the stomach, intestines, urinary and gall-bladders, vesicles, females, and the various excretory passages. No epidermis is elevated on the surface of these organs by boiling or maceration; nor by blisters; nor is there any thing like a separation of such a covering in any diseases. We shall be disposed to conclude, from these considerations, that there is no cuticle on the deeply seated mucous surfaces, and that the large quantity of mucous fluids poured out in their situations supplies its place by protecting the corium from the impressions of noxious matters.

The only circumstance that could induce us to hesitate, is the occasional separation of subslates like membranes, which might be regarded as exfoliations of an epidermis. Numerous examples occur in medical writers of such matters being voided from the bladder, stomach, and intestines. On this subject we posit no very precise data.

The Nails.—We connect the history of these organs with that of the epidermis, as they adhere to it very strongly, and come away with it in maceration. Their form in the human subject differs very much from that which they have in animals: they are generally thick and conical in the latter, thin and flattened in the former. They consist of hard, transparent, and elastic plates, of a substance resembling that of the hooves of animals, covering the extremities of the fingers and toes on the aspect of extension. Thus they are not adapted to purposes of offence, but are better suited to the support of the broad ends of these members, which confer on the human subject a more perfect power of touch.

Their length is limited by the universal practice of cutting them to a level with the end of the finger or toe: if left to themselves, they are prolonged, and at the same time bent so as to cover the ends of those parts. The natural limit of their growth seems to be that period at which they acquire a sharp cutting edge: for they are then gradually worn away at the margin.

Three parts may be very easily distinguished in the nail: a pollerion portion, covered on both sides by integuments; a middle part, which is the most considerable, adhering by its concave, and unattached on its convex surface; and an anterior, free from adhesion in both respects.

The posterior division is about one-sixth of the whole: it ends behind in a very thin ferrated edge, by which the nail seems to grow out of the skin. This part is soft and flexible, and of a white colour: it is bounded by a straight line, which, with the two margins, gives to the organ a square figure. The convex surface adheres intimately to the epidermis, which covers it in the following manner. The cutis terminates over the root of the nail in a semilunar edge, in front of which is a small cavity adapted to, and filled by, the white part of the nail. Along the concavity of this cleft the cuticle forms a small and distinct fold, which may be cut without any feeling of pain, and which is reproduced. It adheres closely to the root of the nail, and is produced anteriorly for some length on its surface, unless it be cut away. Many describe it as being continued over the whole convex surface. Behind it appears to be left in the soft and thin posterior margin. Without the adhesion, which connects the semilunar border of skin to
to the nail, there would be a species of cul-de-sac between these parts. Some have conceived that the extensor tendon reaches to the posterior edge; but its termination at the tubercle of the last phalanx is very distinct; and there is a space of two or three lines between this and the nail. The concave surface of this posterior division adheres in the same way as that of the middle part.

The convex unconnected surface of the middle division is smooth, whitish behind for a small space terminated by a semicircular edge, and red in the rest of its extent in consequence of the colour of the subjacent parts. On the sides it is covered with a little by the skin, which is continuous with the follicular projection already described. The fold of the cuticle is also continued, and adheres to the margin of the nail. The concave surface of this part is laminated longitudinally, and the plates end in very thin and membrane-like edges; but this laminated texture does not extend to the white part. The organization may be well seen in the hoof of an animal, as the horse; where the plates are of considerable breadth and number.

The edge of this concave adhering portion is fixed in front by the epidermis, which, after covering the extremity of the finger, is attached to the surface of the nail at the front end of its laminated portion, in a curved line; here again it seems to be conformed with the substance of the nail.

The loose anterior portion, the length of which is limited by cutting, is manifestly thicker than the middle and posterior parts. Indeed the thickened, hardened, and resistive of the organ increase gradually from behind forwards.

At the attachment of the nail, the skin is marked by a deep parabolic groove, in which the former is received: the fold, which bounds this groove behind, overlaps the white part of the nail, covers a considerable portion of it, and adheres firmly to the posterior thin edge. From this hollow the cutis is produced over the posterior surface of the last phalanx to the end of the finger, between the nail and the bone, and adheres closely to the periosteum. At the sides and in front it is continuous with the common skin. The cutis, in short, in function it has a peculiar organization; it becomes softer and redder, has more numerous vessels, and is distributed in longitudinal laminae, corresponding to, and received between, those of the nail. But the portion of skin corresponding to the white part of the nail, is also different in its colour, and not laminated on its surface. From this part numerous fine and long papillae or villi arise, and are received into corresponding hollows of the nail: the same structure exists more or less over the whole surface covered by the nail. It appears that the organ grows principally from the white part; at least, if a mark be made towards the root, it gradually advances to the loose edge, coming more and more forwards until it entirely disappears. The papillae of this part give to the organ a very exquisite sensibility: hence the acute pain of paronychia, and that barbarous practice of tearing off the nails.

Organisation and Properties of the Nails.—These can be most advantageously observed in the larger ones, as those of the thumb or great toe. A single lamina occupies the whole convex surface; this exists alone at the posterior edge, and hence the thinnest of that part. New plates are successively added on the concave surface towards the front, so that the organ becomes successively thicker and thicker: they may be easily removed in separate layers, and are shorter and shorter as they are placed more and more towards the front.

Vol. XIX.

These laminae, composing the nails, seem to be in their nature nearly identical with the epidermis. The most superficial is manifestly continuous with that organ by its edges. The nails may be detached and are regenerated exactly as the cuticle is. Their vitality is as obscure as that of the cuticle: they exhibit no trace of animal sensibility, nor of any organic property. When burnt they cause a disagreeable odour like that of the epidermis, and exhibit altogether the same phenomena. Mr. Hatchett conceives that they confit, like the cuticle, of coagulated albumen. They contain a little phosphi of lime. Maceration and cohesion do not, however, produce in these organs the same want of consistence or kind of brittle line that they do in the epidermis, on account of their greater solidity. The action of acids presents nearly the same phenomena. Thus, on the whole, the composition, organization, and properties of the nails and epidermis seem to be perfectly analogous: they make up together a perfect inpenetrable covering to the cutis, a structure void of vital properties, and therefore exercising no vital functions. The only differences between them seem to be modifications of form and arrangement arising from the uses of the parts which they cover. Physiologists affix to the nails the office of supporting the soft ends of the fingers by which the sense of touch is exercised, affording to the papillae a point of resistance, and protecting them from external violence. They are also supposed to enable us to grasp objects more firmly, and to take up minute bodies more conveniently.

Development of the Nails.—While the skin is still pulpy in the fetus, the nails possessed considerable thickness, but are very thin. Their length at the time of birth is not proportionate to what they acquire afterwards; they do not exceed, and frequently do not reach the ends of the fingers. At this time their transparence enables us to observe the vivid colour of the venous blood circulating before respiration, and to observe how it is succeeded by the redder arterial fluid. After birth they increase as the epidermis does; and they become extremely thick in old persons.

Of the Hair, (Système Pléth. of Bichat.)—The human frame possesses much less of this covering than that of animals: the contact of external bodies with the skin being in great measure intercepted in the latter, the animal sensibility of the cutaneous organ must have much fewer external relations in them, and consequently perform a much less important part. In animals the reproductive and digestive functions seem to be the principal sources of pleasure.

1. Hair of the Head.—The system predominates in this part, covering the cranium nearly as the bodies of animals are covered. For this reason, as well as on account of its convex form, which allows it to come in contact with bodies by a small surface only, it is very little capable of acting as an organ of touch. The face is less generally covered, excepting one part in the male sex. This portion of the body, in which most of our means of communication with external objects, as the organs of sight, smell, and taste are assembled, is not favourable in its form to the exercise of touch. The elongated snout of most quadrupeds enables them to touch external objects, to turn and move them in various directions, as well as to seize them for food; in man the former functions are exercised by the hands.

The boundary of the hair towards the front is very variable in different individuals: and these varieties influence the breadth and apparent height of the forehead; the direction of this part is dependent entirely on the bony structure. Hence the hair influences but slightly the expression
of the figure: we attach the ideas of majesty and grandeur
lefs to the breadth of the forehead, than to its perpendicular
direction. The number of the hairs in a given surface is
singularly variable: they may be so close as to touch in every
point, or may leave intervals in which the skin of the cra-
nium is visible. We hardly know the natural extent of
their growth. They will sometimes become so long as to
touch the thighs or even legs; and this circumstance, like a
crowd of others, tends to prove the destitution of the hu-
man subject to the erect attitude. It has been questioned
whether the practice of cutting them produces any phy-
siological effect; whether the confluent growth, rendered
necessary by this practice, be performed at the expense of
any other parts or functions.

The strength of the hair is very considerable in propor-
to its slender bulk: no part in the animal economy, not
even the fibrous system, will support such considerable
weights. Ropes made of hair would therefore be very use-
ful, if they could be procured of sufficient length.

Smooth and straight hair grows to the greatest length;
in proportion as it is curly it is shorter, of which the woolly
kind in the negro is a remarkable example. The colour
varies in the different races of mankind, and thus becomes
a characteristic attribute in the natural history of the species.
But it varies no less in the different individuals of the same
species; and these varieties follow the same general rule
with that which regulates the colour of the skin and eyes.
Hence these differences are to be considered in enumerating
the characters of the different temperaments.

The eyebrows and eyelashes are described under the ar-
ticle EyE. The hair composing the beard, which we have
alluded to in the article GENERATION, as one of the sexual
distinctions of the male, is shorter than the covering of
the head, and longer than any other hairs in the body; it is
always more or less disposed to curl, is stronger and less
greasy than the hairs of the head. It generally follows
their colour; but very often deviates into the red tint. Its
quantity varies singularly in different individuals; common
opinion associates the idea of strength to its abundance, par-
icularly if it be black. For some remarks on the effects of
cutting it, see Hair.

2. Hairs of the Trunk.—Their quantity is exposed to
very great variations; some being almost covered, while
others have the surface perfectly smooth. They are much
more numerous in front than behind; and in the former
situation abound chiefly on the chest, and in the course of
the linea alba in men. There are none on the thorax in
women, who have altogether but few on the trunk. A
considerable collection, resembling the beard in its nature,
is found about the generative organs in both sexes. These
are very seldom light in colour, frequently approaching to
red, and very commonly black. This increase of the hairy
system is almost peculiar to the human subject. Its quan-
tity varies very greatly.

3. Hairs of the Extremities.—These organs are for the
most part covered; the number of their hairs is nearly uni-
form in most individuals, but the length differs greatly.
In the hollow of the axilla, a small collection occurs resembling
the arch of the genital organs; but there is nothing like this
in the lower limbs. The inner surface of the arm and fore-
arm has none of this covering in most men; but the lower
limbs are more uniformly covered; the back of the foot
and hand are constantly covered, but the palms and soles,
and corresponding surfaces of the fingers and toes, are al-
ways perfectly smooth. The latter circumstance seems to
contribute to the perfection of the organ of touch.

On the organization and mode of growth of the hair, the
reader is referred to that article.

Properties of the Hair.—It experiences but a slight cor-
rugation from the action of heat, but it is twisted or curled
in various directions: moisture makes it straight again. It
hardly possesses any extensibility or contractility. Whether
they have any vital properties is a subject of dispute; at all
events they are exceedingly obscure. We are disposed to
deny their existence in this system, as well as in the epider-
nium and nails. Bichat, who, for some of the reasons
explained in the article Hair, conceives that they are the
seat of vital processes, adds, “we cannot however deny, that
in the natural state these organs come next to the epidermis
and nails in poising the least active life, and having the
fewest relations to other organs. While all other systems are
deranged by disease, this is generally unaffected; the
hair grows as usual, and seems not to experience the slightest
disturbance; its mode of existence is, therefore, quite dif-
ferent from that of other structures.”

Mr. Hatchett concludes, from his experiments, that hair
contains gelatine, and owes its suppleness and toughness
to that matter. This may be separated by boiling it in
water, after which it is much more brittle. If the proc-
eds be continued for a long time, the hair crumbles in pieces
between the fingers. The portion insoluble in water pos-
sesses the properties of compressed albumen. Vauquela
obtained a solution of human hair in water, by raising the
temperature of the fluid in Papin’s digester. When the heat
was too great, it was decomposed, and ammonia, carbonyc,
acid, and an empyreumatic oil formed. Sulphuretted hy-
rogen is always evolved, and its quantity increases with the
heat. The solution of hair effected in this way contains a
kind of bituminous oil, which is deposited very slowly. The
colour of this oil corresponds with that of the hair. Fil-
tration allows a colourless fluid, in which copious precipi-
tates are formed by infusion of gall and oxymuriatic acid,
to pass through. Silver is blackened by it, and acetate of
lead precipitated brown. Though very much concentrated
by evaporation, it does not concretize into a jelly. Water,
containing four per cent. of potash, dissolves hair with an
exhibition of hydro sulphuret of ammonia. A thick oil, dif-
fering in colour according to that of the hair, with some
sulphur and iron, remains undissolved. Sulphur, muriatic,
and nitric acids dissolve it: with the latter an oil is sepa-
rated. Oxymuriatic whitens, and then reduces it to a sub-
stance of the confidence of turpentine. Alcohol, digested
on hair, extracts from it two kinds of oil: the first is white,
and subfides in white shining flakes as the liquor cools; the
second varies according to the hair employed: it is greyish-
green when black hair is used, and as red as blood when red
is employed. When incinerated it yields iron and manga-
nese, phosphate, sulphate and carbonate of lime, muriate of
fuchsia, and a considerable portion of ashes. The ashes of red
hair contain fafer iron and manganese; those of white hair fluf
ashes, but they contain magnesia. The ashes do not exceed
0.015 of the hair. According to the above experiments,
performed by Vauquelin, black hair is composed of the nine
following substances: 1, an animal matter, which constitutes
the greater part; 2, a white solid oil, in small quantity;
3, a greyish-green oil in greater abundance; 4, iron in an
unknown state; 5, oxyd of manganese; 6, phosphate of
lime; 7, carbonate of lime, in very small quantity; 8, silica;
chap. 2, sect. 7.

Development of the Hair.—In the first months none can
be perceived. When the fibrous part of the cutis begins

19
to be perceptible, we see a slight down on the head, concealed, in great measure, by the white unctuous matter. The colourless down begins to assume something of the tint which the hair will have after birth, but it is in all cases pale till birth, when it may be half an inch long on the head, although it is only in the state of down in any other part. It grows much more rapidly after birth than before; but is always comparatively lighter in colour in proportion as the subject is younger. The age of puberty witnesses a remarkable change in this system in the development of the beard, of the hair about the organs of generation, and in the axilla. It undergoes very little change in the following years; but is said to grow more rapidly in summer than in winter. Towards the end of life the hairs feel that general obliteration which affects all the exterior vessels: it ceases to receive colouring matter, and becomes grey. On the subject of this change, see HAIR. After remaining grey for some time they fall off, and the bulbs shrink and disappear.

Bichat found no traces of the latter parts in the integuments of perfectly bald old men: but they were entire in the case of a man who had lost his hair from a putrid fever.

It has been very generally supposed that the hair, nails, and epidermis continue to grow after death: but we have no very accurate observations on this subject. Bichat saw the fact in a closely shaven head macerated for eight days: and there is no greater difficulty in admitting this than in allowing that the absorbing vessels can continue their action at the same time. The growth of the hair does not seem to go on at a rate proportioned to the degree of living power; it is as rapid in cases of prostration as in those where these forces are augmented.

INTEGUMENT is also extended to the particular membranes which invest certain parts of the body; as the coats or tunics of the eye.

INTELLECT, a term used among philosophers, to signify that faculty of the soul usually called the understanding.

The Peripatetics make two kinds of intellect: active and passive. See Idea.

INTELLECTUAL EDUCATION, is that branch of education which respects the understanding, considered in distinction from the affections and dispositions. By intellectual education we understand that series of means by which the various powers, which may be called the intellectual powers, are cultivated; by which those habitual qualities of mind are produced, which immediately respect the acquisition of knowledge, or are essentially auxiliary to it; and by which the mind is stored with those ideas which are subservient to scientific acquirements, or to the arts and pursuits of life.

The full consideration of these objects would lead to three primary divisions of this branch of education: first, the cultivation of the several intellectual powers and qualities; secondly, the value and mode of cultivation of the different branches of knowledge; and thirdly, the peculiar culture of mind and intellectual acquisitions requisite for the different sexes, classes, and professions. In a field so wide, it is necessary to make selection. In our present article we shall chiefly confine ourselves to a brief consideration of the culture of the leading intellectual powers and qualities. The last of the three divisions (which will include some remarks alluding under the second), would in some measure lead us to anticipate what more properly comes under the head of Moral Education; and we shall therefore leave the consideration of it to that article, for which also we shall, for the same reason, defer a comparative view of the advantages of public and private education.

Though it is not our business, in this department, to enter into the subject of mental philosophy, yet, as in a work so extensive as the present, the same arrangement, views, and employment of terms cannot be expected throughout, we shall find it at least expedient to lay more respecting the several powers of the mind than might be in any way requisite, if we were preoccupied of what will be brought forwards in a more direct form, under its appropriate head: independently of which consideration, we should be induced to give such general views of the intellectual powers as are necessary, in order to understand the principles of education, by the hope that thus we might be the means of exciting the attention of some of our readers to a branch of knowledge which is of peculiar importance, not only in the education of others, but in the cultivation of our own minds.

The first of the intellectual powers in the order of development is of course sensation (or less ambiguously the sensitive power) by which is meant that power or capacity of the mind, by whose operation it receives sensations from things which affect the organs of sense. Proceeding in the same order, we next find the retentive power, without which sensations would be of no avail: this is the power or capacity of the mind, by which it retains relics of sensations or ideas. Next succeeds the affective power, which is that power or capacity of the mind by which it connects and composes ideas. This last principle, if not the sole cause of all our mental phenomena (except the origin of sensations, and the retention of the simple uncompounded relics of them), has some effect in the origin and modification of all of them. It is owing to this important principle that sensations become the signs of thoughts and feelings, by which means man becomes a social being: that the whole mental furniture of perceptions, notions, affections, passions, sentiments, emotions, &c. is formed from the simple relics of sensation; that man, from mere sensation, rises to intellect. In short, whatever mental operation we attend to, except at the very earliest period of mental culture, we find association the cause of its productions, or intimately concerned in it.

These three powers may be considered as the elementary powers of the mind, to the operation of which all intellectual phenomena may be referred; but as it is under peculiar modifications and combinations that we find them act, this summary division would be insufficient for our purpose. We shall therefore follow in the order which we find most convenient, a somewhat more minute division of our intellectual principles, according to the combinations, or peculiar modes of operation, of the simple powers; viz. sensation, perception, observation, attention, abstraction, considered both as a habit and as a power, memory, understanding, and imagination.

1. Sensations are the rudiments or elements of all our ideas, that is, of all our thoughts and feelings. When an infant enters into the world, there is no appearance whatever which can authorize any one to expect that there are ideas in its mind; and no one can reasonably doubt, if a human being could be deprived of all his organs of sensation, before any sensations had been received, that he would never have ideas. In the earliest exercise of the capacity of sensation, sensations are simple, uncompounded with the relics of former corresponding sensations; but the sensations very soon become perceptions, that is, they instantaneously recall the relics of other corresponding sensations. That fact...
INTELLECTUAL EDUCATION.

1. By the law of association, many ideas, received directly from sensible objects, through the medium of different senses, become connected, and at last blended together, so as to form one very complex, though apparently unconnected, idea; and this complex idea is often recalled to the mind by a corresponding sensation; and by association it becomes so connected with that sensation, that the complex idea itself is often mistaken for a part of the sensation. For instance, the sensation produced by the impression made by a globe on the sense of sight, is, as can be proved, nothing more than that produced by a circle, with certain variations of light and shade; yet, immediately on the sensation being received, the idea of the solidity of the object, of its hardness, of its magnitude, and of its being something external to oneself, (all of which have been derived from the sense of touch, in connection with this object, or others in some respect similar,) immediately rise up in the mind in one blended form; by their complete coincidence they appear to be one, and by their immediate and constant connection with the sensation, they appear to the mind as a part of the sensation. The sensation thus connected with the complex idea is the sensation; and by the faculty of perception we understand that compound power (or rather combination of powers) by which perceptions are received from external objects. The accuracy and vividness of the sensation depend upon the sensitive power and its organs: the accuracy and vividness of the perception depend partly upon the accuracy and vividness of the component sensations, and partly upon the activity of the retentive and associative powers. Supposing the powers of sensation to be in a sound and vigorous state, yet it is obvious that the perceptions will vary greatly in different individuals, and in the same individual, at different periods. The perception is in fact the sum total of all the notions with which the individual has of the object. How much the perceptions of the same object vary in different individuals, may be understood from a simple instance. Suppose a watch to be subjected to the observation of three persons, whose organs of sense are alike healthy and vigorous, the one a very ignorant person, totally unacquainted with its purposes and movements; the second a well-informed person, not however possessed of any acquaintance with the particular mechanism; the third an artist, minutely and completely acquainted with it: the sensation may be precisely the same in all instances; the picture upon the retina may convey to the mind an equally impressive notion of the object; but how different the perception! The first sees a number of minute objects, which attract his attention perhaps by their beauty and regularity; but nothing more: he has no idea of their subordination to each other or of their general use; there is little more in his case than sensation, indeed we may say, nothing more than sensation besides those associated perceptions which so soon become connected with every impression from external objects, and to which we have already referred. The second, from his general knowledge of mechanism, has some ideas excited by the sensation of use and connection, but he cannot discern the specific kind of connection, nor how each part tends to answer the end of the whole. If he sets about to study the mechanism, he subjects each part to minute examination in its structure and connections; and by degrees may acquire an acquaintance with the whole, which, on a subsequent inspection, would give him an immediate, distinct perception of the parts and purposes. What he thus acquires by laborious and patient examination, the third at once. His perceptions have long been cultivated by daily attention to the movements and their dependencies, by studying their defects and excellencies, by the actual formation of various parts, and the construction of the whole: and a great number of the ideas produced by such observations and operations, become so intimately united with the sensation, that at last this at once excites them, and thus he sees (or, more correctly, perceives) what lies totally out of the reach of the observation of others.

From this brief account of the perceptive power, we may readily derive the most essential conclusions as to its cultivation. To render the sensations efficacious in forming distinct ideas, and to connect these ideas already derived from any object with the new impressions, depends principally upon the degree of attention (or fixed direction of the mind) which the sensations receive. Hence those who have the care of infants and young children, should give them every opportunity to keep their attention directed to the objects of their senses; and every means should be employed to lead them to such attention. An infant, intently gazing upon an object, or examining it with its little hands and lips, is as usefully employed in the cultivation of intellect as the fondest parent can wish. In the early periods of mental culture there is, however, more to be done in this connection by allowing a child full scope for its own efforts, than by any direct exertions which can be made by others. When its attention is fixed upon any object, let it remain so; if possible let the objects of sense be brought into view under different aspects, and exposed to the examination of different senses. Before words become to a child the signs of volunta
INTELLECTUAL EDUCATION.

Illuminary action, all that can be done is to expose it to sensations, and to allow them to fix the attention; but afterwards more direct efforts may be made, and the attention may be fixed by various other means beside the mere action of the sensations themselves.

Children of quick sensations, for the proper cultivation of the perception, require to be frequently induced to observe minutely the objects of perception. We do not venture to go so far as to assert, that it is of no consequence what they observe; provided that they do carefully observe it; but there can be no hesitation in saying, that when the sensations are constitutionally vivid, every instance of close observation given to objects which are within the scope of the comprehension, is cultivating the perception, and contributing to the flock of materials on which the highest efforts of the understanding are to be exercised; and however trifling, in common estimation, those objects may be, yet the mind is receiving a useful employment, and every thing is going on as effectually as could be wished. It is a most erroneous idea in education, that nothing is done except when children are engaged in the usual rudiments of instruction. A child watching the motions of objects around, observing their figures and forms, examining their structure, is employed in a work which it should be our aim as much as possible to aid and encourage, and from which we may expect very valuable results both on the faculties and furniture of the mind.

The leading point with respect to those whose physical sensibilities are lively, is to engage them in steady observation of the objects of perception; with respect to those whose sensations are by their constitution dull, our efforts must be directed to the awakening of the perception power. Whatever is found to stimulate the mind to the exercise of the power, must there be employed. It does not much signify in this case whether, in the first instance, we succeed in producing ideas which will be permanently useful; if the perception is exercised, it will become more vigorous, and by degrees the original dulness of sensation may be in some measure remedied, by the influence of associated feelings. But, in general, dulness of perception does not arise from dulness, and still less from deficiency, in sensation; but from the inefficient employment of the organs of sense. Many lively children are found to be dull in their perceptions; and on the other hand, children whose physical sensitiveness are far from vivid, see what their companions see not, and hear what they hear not: the former glance over, and see at a glance, the most impressive objects, or features of an object, but the more minute parts, or the less prominent, and brilliant objects, they do not lay to notice, and though they affect the organs of sense, they make no impression on the mind; the latter more readily dwell on the objects of their sensations, which allows the various parts to call up associated ideas, and in other ways to affect the mind, and thus to make their sensations efficacious.

The habit of accurate observation depends, in a great degree for its foundation, upon the manner in which the perception power has been early cultivated, while at the same time it vivifies the perceptions; indeed, in some points of view, it may be regarded simply as the employment of the perception power. This habit depends also, especially for its utility, upon the cultivation of the judgment, and upon the associations which are formed of the objects of sense. A child observant in the first instance, because the notice of the mind is excited by the pleasure or pain accompanying the sensation; afterwards also, through the influence of external motives, that is, of the pleasures or pains. When the understanding has so far developed as to perceive the utility of different objects, this again increases the motives to observation, and makes it subservient to much valuable cultivation of the intellect.

Every fact which is intelligible and interesting to a child respecting the objects of perception, excites the notice of the mind to those objects, at the same time that the communication, reception of it in the mind, and repetition of the ideas, increases the flock of knowledge and exercises the memory and judgment, and often the reasoning powers.

Yet here, as in every branch of education, by aiming to do too much, we may make our best directed exertions ineffective. To observe with effect, requires patient and frequently repeated attention. To observe is not merely to see, but to see as to perceive that, whatever it be, of which the ever active principle of association has made the visual sensation the symbol or index; and the more the observation is well employed, the more will be brought into the view of the mind by those sensations which to another would not lead on one link in the chain of thought. To force the observation is therefore impossible. We may make our children parrots, by giving them words; but the growth of ideas must be gradual. The objects and ideas must be employed upon directly sensible qualities alone; the more they are noticed, and the ideas of them associated together, (in other words, the clearer the perceptions,) the better foundation is laid for future knowledge. By degrees, and as it is perceived that the mind will bear it, those circumstances and qualities which imply some of the simplest exercites of the understanding, should be brought into view; and from these the helpful instructor (or rather instuctor, for we presume that in general the early intellectual education is chiefly conducted, as it will be best conducted, by the female sex,) will proceed to others which are still more remote from mere sensation. It will usually be found that children who have been educated in the country, or have had continual opportunities of being in fields and gardens, (other things being equal,) acquire much more completely the habit of observation than those who have been bred up in large towns. In the works of nature there is much more than in the works of art to excite the observation of children, much more in general than can be made the subjects of pleasing instruction; but the judicious parent will not be at a loss to find numerous objects within doors to excite the observation and exercise the perceptive powers; and provided that the observation is actively employed, and correct perceptions are acquired, the mental culture in this essential point is successfully going on.

The habit of observation depends in part upon the general culture of the mind, especially upon the associated thoughts and feelings connected with external objects. The poor plough-boy, with all the advantages that his rustic employment affords him for the excitement of his observation, will often be found extremely deficient in that habit; his perceptions are dull, and his mind is scarcely awakened. Sensations often repeated, without any associations being formed with them, cease to excite the notice of the mind; and where the work of instruction has been totally neglected, unhappily; it often is among the poor in country situations, the noblest powers of the mind lie dormant; there is nothing to rouse its capabilities separate from the narrow round of the daily employments; these soon becomes mechanical and cede to excite its exertions; and as far as intellect are concerned, the situation is far from favourable than that of the untamed savage, whose inanity and observation are limited by the necessities of life. — As the mind, therefore, is capable of receiving them, such ideas should be communicated in con-
INTERL preocupation with the objects of sensation as are calculated to keep up the interest which the mere sensations at first excite, and thus to continue that attention to them which may gradually render the observation habitual.

It will not be supposed that we would with the observation to be cultivated, to the exclusion of reflection; the two habits of mind are not in any respect in opposition, in the early periods of education; but, on the contrary, the one materially aids the other. The reflection may be well and successfully exercised upon the ideas which have been left by the absent objects of sense; and indeed it is only upon these that, at first, it can be properly exercised. If this be done, the interest by which the observation is stimulated will be kept up; and, what is not less important, the employment of the observation will be rendered effectual, and will afford materials for after-reflection. The exercise of thought respecting the occurrences of the day, reflecting those things which have been the subject of direct observation, in short respecting any object of sensation, is in various points of view of great value; and the more this is employed, the more the mind is prepared for further observation.

Nevertheless, the period of childhood is more the period of observation than of reflection (or steady attention to our own thoughts and feelings); and it is the former that, in the preparatory parts of education, we should make the primary object. It is of essential value in every branch of education, and in every department of life. The successful acquisition of every science depending upon experiment; indeed the acquisition of knowledge of every kind which depends upon the exercise of the perceptive power, the cultivation of the taste, the common concerns of life, the intercourses of civility, and the efforts of benevolence, require the constant exercise of the habit of observation; and to long as the observation of a child does not rest merely with the immediate objects of perception, but continues to connect with them that information which the instructor communicates, or which has been derived from past observation, it is very usefully employed. Whatever method is found to invigorate and correct the observation, should be frequently made use of; till the understanding has made considerable progress, this should be a leading object in the intellectual culture; and in every period of it, the habit should be frequently brought into exercise. By a proper cultivation of it, the memory and judgment are directly cultivated; and while it strengthens and rouses the energy of the mind, it furnishes it with some of the most serviceable materials for the understanding and imagination.

Those who have been at all engaged in the business of education, well know in what different degrees accuracy and quickness of observation are found, and how important it is for the progressive intellectual acquirements, and often for the moral culture, that the habit should be early and steadily cultivated: and we here wish to express our decided opinion, that the character of the intellect and affections, however much it may be modified by future cultivation, receives its stamp from the employment of the first few years of life; that the education of the nursery is of almost incalculable moment in the mental and moral culture; that, by the neglect of it, years of labour may be rendered requisite to compensate in some degree for it; and that by a proper attention to it, a foundation is laid for a clear and vigorous understanding, and lively and pure affections.

IV. Attention is an essential constituent part of the habit of observation, and is necessary to every observation of the mind in its first stage. Many corporeal, and even mental operations may, when become thoroughly habitual, go on without exciting the attention of the mind; and this we have no hesitation in saying, notwithstanding the great authority of Dugald Stewart to the contrary: but this is not the place for the discussion of this point; and what more immediately concerns our purpose is, that before any operation of mind is become habitual, the exercise of it requires the direct notice of the mind, that attention is requisite to render sensations efficacious, that every exercise of the understanding requires it, and that the habitual power of employing it in the direction which the judgment points out, may be regarded as what is most necessary for the attainment of the highest degrees of intellectual culture. In this perfect state it is very rarely to be met with; but in a considerable degree it is frequently acquired; and some good portion of it is to important in every stage of the mental progress, that the formation of the habit cannot be begun too early, nor the cultivation of it made too heedly an object.

Attention is now not unfrequently spoken of as a distinct faculty of the mind; and the philosopher to whom we refer in the preceding paragraph has greatly contributed to this change of nomenclature, if he did not begin it. It may perhaps be regarded as a mere verbal distinction if we deny it the appellation; but, in fact, it appears to be, in its simplest state, merely the notice of the mind, which in various instances is involuntary, but which by degrees may be connected with volition, and directed by habitual tendency, or direct motives, even in opposition to the strongest imperatives from external objects. We may very correctly speak of the power of the mind over its attention, and, by abbreviation, of the power of attention; but the true point of view in which the attention is to be regarded, both when it can be fixed by stimuli of different kinds without the direct intervention of volition, and when it is capable of being produced by direct volition, is as a state or habit, which we would in the one case speak of simply as a state or habit of attention, in the other as the habit of voluntary attention. In very young children the attention is entirely involuntary; the sensible excitements of various kinds which we employ attract the notice of the mind; and the attention is directed to the most impressive excitement. This is very much the case in every stage of education; but under judicious management the state of mind which we call attention may be early produced by the influence of motives without sensible stimuli; and the foundation is then begun for the habit of voluntary attention.

The attention produced by sensible stimuli begins even with the very first sensation which is received. It is a beautiful provision of Providence, that sensations which give pain, while they are the most impressive, are of rare occurrence; and that those which are of most frequent occurrence, or which it is important to the mind to seek for, are attended with pleasure. It is probable that no sensation is at first indifferent; and therefore in the commencement of the growth of intellect, every sensation will excite all the attention which is requisite to give it the degree of efficacy which is necessary for the period. All we need then to do, is to allow the attention to remain where the sensation calls for it. "It is unfortunately in the power of a foolish nurse," says Miss Hamilton, (vol. ii. p. 47.) "to retard the natural progress of the mind, by perpetually interrupting its attention. A child that is much dandied about, and much talked to, by a very lively nurse, has more many ideas than one that is kept by a silent and indolent person. A nurse should be able to talk nonsense in abundance; but then she should be able to know when to stop." And the same very respectable writer adds
INTELLECTUAL EDUCATION.

adds in a note, from the observation of a judicious friend, that nothing more effectually tends to retard the progress of the infant faculties than a cumbrous prevalent with nurseries, of keeping the child in a continual trot upon the knees; and this especially in cafes where its attention is most closely, and therefore most usefully engaged.

But it will not be long before the impressions which have often been received early, by the diminution of their vividness, to produce the same effect on the mind. When a child has had some cultivation of memory and application, the repetition of a former impression is oftentimes more pleasurable than the first reception is so new and novel; if the impression itself is left lively, and in itself considered less pleasant, the associated circumstances often communicate a still more interesting pleasure; the child remembers the pleasure before derived from it; the repetition of it lets his little faculties to work in connection with his former sensation, and the ideas to which it led, and the moderate exercise of the faculties is generally pleasant; and there is often a positive pleasure in the mere repetition of past impressions, even when the disposition of a child is very active, arising from the increased power of fully comprehending the objects causing the impressions. But before the affectionate power has been much exercised, new sensations are generally more attractive than old ones; and here begins that restless desire of novelty, which, while it operates as a most powerful stimulus to the pursuit of knowledge, requires to be carefully watched in every period of education, lest the attention should be completely dissipated, and no knowledge acquired; for there is no principle in education more certain, than that knowledge (clear, correct ideas respecting the objects of sense and intellect) cannot be gained by wandering, haphazardly.

At this point the efforts of the parent should be given to lead the little mind to the examination and re-examination of the objects of sensation; not indeed so much by direct influence, as by those little contrivances which a judicious method soon learns by experience, and to aid her in which she may consult Miss Edgeworth's excellent observations on the subject, which, though they more immediately refer to a later period of education, furnish many important hints respecting the best methods to be pursued here.

Though we perceive that we shall swell this division of our article beyond what may be thought its due proportion, yet the subject of attention is so important, that we shall select some of Miss Edgeworth's leading observations on the cultivation of the habit, and subjoin our own remarks in addition. In doing this we wish to lead our readers, if they have not already engaged in it, to the study of a work, the value of which we rank higher in proportion to our own experience and observation, and by no means to prevent it. Though in several of her positions we cannot agree, though we think her work essentially deficient, and are by no means satisfied as to the probable result of her plans on the whole, and though to follow them in detail to any considerable extent requires a degree of mental cultivation, and a combination of circumstances, which are very rare in those walks of life where the subject is likely to receive the most attention, yet we cannot hesitate in strongly recommending her work, as containing a fund of very important observations, the result of varied and long-continued experience, guided by sound judgment and good sense, and generally correct moral views, as exhibiting a number of very important phenomena and principles subservient to mental philosophy, and as furnishing to the "practical" parent very valuable aids, even where her plans cannot be minutely followed. Her elementary works ("Early Lessons," "Parents' Aid," &c) are incomparable; and if their striking and much-to-be-launched deficiency in every thing like religious principle were suitably supplied, they would leave scarcely a with ungratified. If any female writer should hereafter come forward to the public, polishing the clearness, simplicity, correctness, and well-tow to an understanding of an Edgeworth, the brilliant yet chaste imagination and "devotional taste" of a Barbauld, and the energy and high-toned moral principle of a More, divested of bigotry, and founded upon genuine Christian theology, in the scale of utility she will probably stand unrivalled among her contemporaries, however eminent her age may be in every thing great and good. But to return to sober realities.

The three principles which are laid down by Miss Edgeworth in her concluding Summary, as of universal application, are, that the attention of young people should at first be exercised for very short periods; that they should never be urged to the point of fatigue; and that pleasure, especially the pleasure of success, should be associated with the exertions of children. With respect to the first of these points we shall extract the following remarks from her chapter on Attention: "Besides distinctness and accuracy in the language which we use, besides care to produce but few ideas or terms that are new in our first lessons, we must exercise attention but during very short periods. In the beginning of every science pupils have much laborious work, we should therefore allow them time; we should repress our own impatience when they appear to be slow in comprehending reasons, or in furnishing analogies. We often expect that those whom we are teaching should know some things intuitively, because they may have been so long known to us that we forget how we learned them."—A reasonable precept will not be excepted from his pupil two efforts of attention at the same time; he will not require them at once to learn terms by heart, and to compare the objects which those terms represent; he will repeat his terms till they are thoroughly fixed in the memory; he will repeat his reasoning till the chain of ideas is completely formed. Repetition makes all operations easy; even the fatigue of thinking diminishes by habit. That we should not increase the labor of the mind unfavourably, we should watch for the moment when habit has made one lesson easy, and then we may go forwards a new step.

Referring to the third point, Miss Edgeworth urges, that the stimulus which we employ to excite attention should be proportioned in degree and duration to the mental character of the individual, and the circumstances of the case. It is not prudent early to use violent or continual stimulus, either of a painful or a pleasurable nature, to excite children to application, because we should, by an intemperate use of these, weaken the mind, and because we may with a very little patience obtain all we wish without these expedients." Besides which, violent motives frequently disturb and dilate the very attention which they attempt to fix. Regularly recurring motives, which interrelate, but do not distract the mind, are evidently the best. In proportion as the attention becomes habitual, the excitations producing it should be withdrawn. Success is a great pleasure, and when children have sometimes failed it, they will exert their attention merely with the hope of succeeding. Instead of increasing excitement to produce attention, we may vary them, which will have just the same effect. When sympathy fails try curiosity; when curiosity fails, try praise; when praise begins to lose its effect, try blame; and when you go back again to sympathy, you will find that after this interval it will have recovered its original power." At the conclusion of her remarks on this head, Miss E. judiciously urges the cultivation of the affections of children as a most important means of acquiring.
Intellectual Education.

inquiring power over their minds, and exciting them to the noblest exertions. "When once this generous desire of affection and esteem is raised in the mind, their exertions seem to be universal and spontaneous; children are then no longer like machines, which require to be wound up regularly to perform certain revolutions; they are animated with a living principle, which directs all that it inspires."

"With timid tempers we should begin with expecting but little from each effort, but whatever is attempted should be certainly within their attainment; success will encourage the most timid humility. It should be carefully pointed out to different children, that attentive patience can do as much as quickness of intellect; if they perceive that time makes all the difference between the quick and the slow, they will be induced to persevere."

"It is more difficult to manage with those who have sluggish, than with those who have timid attention; and with respect to that class of the indolent "who saunter at play and every thing," Miss Edgeworth does not appear to have discovered any remedy. If a child's mind is capable of active exertion in any thing there is hope; the object is to gain the direction of that exertion to the acquisition of knowledge, but in the other case the feems to consider as high as Locke's proposal of presenting them (among other stimuluses) with fine clothes, eating, &c. she regards as inadequate, but does not suggest any plan by which the love of knowledge may be produced. We doubt whether instances are at all common of such complete want of physical sensibility as the feems to attribute to the sluggish; but "the pain of attention," if it be not excited to something which is beyond the powers of the mind, cannot be so great as to render it preferable to undergo flame and punishment, if judiciously administered. It is probable that a moderate degree of exertion of the faculties is always attended with some pleasure. There are employments which engage the attention, without requiring great effort of mind. The simple operations of arithmetic, the copying of passages from a printed book, &c. are of this kind. If the performance of some of these is readily made necessary; if temporary abstinence, for instance, or the loss of every thing which is not necessary in diet, be made the regular consequence of determined sluggishness, and the reminiscences of attention be constantly followed with the trouble of rectifying errors, &c.; in short, if the pain of attention be constantly rewarded by the avoidance of some greater pain, and the comfort of indolence be constantly followed by that greater pain, it cannot be but that in process of time the attention will be left irksome, the mind awakened, and the idea of mental employment accompanied even with satisfaction. If once this state is reached, nothing more is wanting, than to make the attention habitual, to employ it gradually on more difficult objects, and as uniformly as possible to make reminiscences the source of inconvenience naturally following from it; and to reward exertion by whatever suitable consequence of it is found to gratify the now awakened mind. The most difficult case is, where indolence is united with that quiet amblenves of disposition, and that tolerable degree of good sense, which, united, make those who do not know how to appreciate the ill effects of the baneful quality, yield their affection and approbation, and give the appearance of injustice and hardhearted to every mesure of pain or privation which is employed to excite to exertion.

"Vivacious children are peculiarly susceptible of blame and praise; we have therefore great power over their attachment, if we manage these excitaments properly. These children should not be praised for their happy hits; their first glances should not be extolled; on the contrary, they should be rewarded with universal approbation when they give proofs of patient industry, when they bring any thing to perfection." "To win the attention of vivacious children, we must sometimes follow them in their zig-zag course, and even press to them the end of their train of thought. They will be content when they have obtained a full hearing; then they will have leisure to discover that what they were in such haste to utter was not so well worth saying as they imagined; that their bright ideas often, when readily examined, fade into abstractions." With respect to children of this character, we think Miss Edgeworth's remarks peculiarly happy; and from many which we might with advantage select, we will transcribe the following: "We should not humour the attention of young people, by teaching them always in the mode which we know suits their temper bell. Vivacious pupils should from time to time be accustomd to an exact enumeration of particulars; and we should take opportunities to convince them, that an orderly connection of proofs, and a minute observance of apparent trifles, are requisite to produce the lively figurations, great discoveries, and happy inventions, which pupils of this disposition are ever prone to admire with enthuiliasm. They will learn not to pass over old things, when they perceive that these may lead to something new; and they will even submit to Homer attention, when they feel that this is necessary to the rapidity of genius."

Judicious and useful as these observations are, we are of opinion that Miss Edgeworth has, in her system of education, too much left out of view the actual condition of human nature, that, in every department of life, circumstances are continually occurring in which it is necessary that the attention should be given to objects not in themselves pleasant, from their sublimity to others which are of importance, and that exertions, in like manner, must often be made, to which nothing but a sense of duty would prompt. With respect to the observations which we have extracted, they have all their value, and may be applied, with modifications, not only to the earliest periods of education, but to every succeeding stage; yet her plans strike us as deficient. They are principally calculated for those cases in which, from early example and cultivation, there is a desire of knowledge excited, in which it is imbibed without direct effort on the part of the parent or early instructor, in which, from the habits and pursuits of those around, its advantages are at once felt, and the acquisition of it regarded as of the first importance. In the hands of such teachers as Miss Edgeworth, so well fitted to the task by enlightened judgment, ready perseverance, and the ready command of much varied knowledge, with children whose early habits they have themselves formed, whole understandings they have cultivated and furnished with ideas, the processes which she has pointed out may be all which are sufficient; but we doubt whether the ends proposed can, in general, be answered by such means alone; and still more, whether they are, in general, calculated to produce that strength and energy of mind which, with a view to an object fixed upon as important, can readily purse a course of arduous exertion.

The habit of attention must be gained in order to make any progress in intellectual culture; that is of course a point decided. It cannot be acquired too early, because thus the utmost efficacy will be given to all the other operations of the mind, and especially to the acquisition of clear, imprefive, and serviceable perceptions; that is also a point indispensable. It must, too, be associated with volition as early as possible, and then the foundation is laid for every degree of mental culture to which circumstances may direct.

We
intellectual education.

we are of opinion that after this point Miss Edgworth's plans are defective. Her pupils are to be allured on too much. The path of knowledge is often a difficult one, and sometimes requires painful efforts; so also the path of duty; and the culture to which her system is chiefly confined, is scarcely calculated to produce that hardy vigour of mind, which, whether the polisher is called to engage in the highest pursuits of science, or in the narrower sphere of social employment and duties, cannot be otherwise than valuable. When the power of voluntary attention is acquired, then the various motives of confidence in the judgment of the teacher, of habitual submission to authority, of affection, and perhaps occasionally of fear, should be employed as circumstances direct, in order to give it strength and activity, to excite the pupil to such employment of it as may make it a hardy vigorous principle, capable of employment, even where the employment may have no intrinsic attraction, and may even be at first positively painful.

If a pursuit can be made attractive to a pupil at the outset, it is well; but if he has acquired that hardness of attention in which we speak, which will enable him to struggle through first difficulties, and perhaps by degrees to take some delight in them, he is then fitted for the acquisition of any branch of knowledge to which his objects in life, or the bent of his own inclination and cultivation of his understanding, may induce his instructor to direct him. If he has not acquired that strength or activity of attention, difficulties which will meet him in the higher departments of literature and science, will often be found to flog him; and however judiciously his attention may have been early cultivated, if it have not acquired this firmness, the attractions of less arduous pursuits, which will still gratify his taste for knowledge, will effectually check all progress.

There are few points in which the cultivation of the intellectual powers is concerned, in which we do not find the importance of the moral habits, particularly of diffidence, of submission, and the desire of doing what is right; where these are suitably produced in the mind by previous education, the culture of the attention very greatly depends upon the instructor. The attention may be reftless; but it may be flogging; but the more fuitable efforts are made to render it voluntary, the more it comes under the command. These efforts will be made, if the dispositions are right; and when the attention is once become to a considerable degree voluntary, the direction of it may be obtained (by the influence of those views and motives, which the above-mentioned moral habits put in the power of the instructor,) to whatever object it is thought right to direct it. Thus influenced and directed the way will be comparatively clear. Where the attention is fairly given, the mere employment of the mind becomes itself pleafant. Difculties will then be overcome, and the pleafure of successes will aid every other motive. By degrees the utility of the object begins to be distinctly seen, and the purposes of the different steps which are taken to gain it are also difcerned, and then if the habit of patient industry have been formed, or the continued direction of the attention be kept up by the influence of the moral habits, the judgment will aid and encourage every exertion, and at the same time the foundation of a moft valuable habit will be laid, of pursuing definite important ends, by the leedy use of fitiable means.

The habit of attention, or at least the direction of the attention to any object, must sometimes be produced by compulsion, wholly or in part. What kind of compulsion should be employed, and especially whether or not corporal pain is in any instance expedient for this purpose, and in other departments of education, will be considered under the head of moral education; but we here have only to flate the fact, that unless every impression could be regulated by a judicious parent, from the very birth, compulsion must sometimes be employed, even in the most painful symptoms of education, that education in which compulsion has not been employed, might probably produce amiable characters, but seldom such as will be great in intellectual or moral worth. That as early education has long been, and it is to be feared long will be, too generally conducted without any leedy cultivation of the habits of industry and attention, and of ready submission to authority, the instructor to whom children are committed, whether at home or at school, will commonly find some degree of compulsion necessary, in order to produce that degree of attention which is requisite for any valuable improvement. With respect to this period, and the cases of much neglected mental and moral culture, the chief points appear to be, to proportion the exertion required, as much as possible to the degree, not of actual capacity, but of habits possessed; to abstract as much as possible all causes of inattention, and to generate the impression that the effort must be made. By whatever means the habit of attention is produced and rendered voluntary, and the more frequently and regularly it is produced by volition, the more it becomes at the command of the will, the easier, and consequently the more pleasant it becomes, and the more therefore it can be excited when the motives are sufficiently strong to produce it. It is not, then, “the attention of circumstances,” but the attention of volition; and will then be subject in a great measure to the judgment, guided by a sense of the importance of the object either in itself or to the individual, or to those strong motives which arise from the pleasures of activity, from the gratification of curiosity, the influence of prevailing fabinions, the desire of obtaining the approbation of those we love, &c.

When the early training of the mind has made its perceptions distinct and efficacious, and has given it the habit of steady attention, the grand points in intellectual culture are secured; and the rest will proceed, with tolerable ease, in the direction which found views may dictate.

v. When the attention is directed to some particular object of thought, so as to prevent its being diverted to any other object of thought, or to any external impression, it is denominated abstraction. This state of mind has been termed dignified with the name of abstraction, except when directed to objects out of the common sphere of thought; but Miss Edgworth has shewn, by her usual happy method of illustration, that it is the same habit or exercise of mind, whether it be devoted to the highest flights of philosophic pursuit, or to the usual concerns of life. “Perfons of ordinary abilities,” she truly remarks, “trade men and shop-keepers, in the midst of the tumult of a public city, in the noise of rumbling carts and rattling carriages, amidst the voice of a multitude of people talking upon various subjects, amidst the provoking interruptions of continual questions and answers, and in the broad glare of a hot sun, can command and abstract their attention, so far as to calculate yards, ells, and nails, to cast up long fums in addition right to a farthing, and to make multifarious bills with quick and unerring precision.”

The habit of abstraction is dependent upon various caufes; but every person to whom the attainment of it is necessary, finds it susceptible of culture. It much depends upon the familiarity of the impressions which are otherwise most likely to affect the mind: novel impressions from external objects, by their novelty attract the notice of the mind and tend to distract the attention: sensations which have been long
INTELLECTUAL EDUCATION.

long and closely connected with trains of thought or feeling, are calculated to divert the attention; objects to which we have been accustomed to attend, in like manner solicit the notice of the mind from those to which we may otherwise wish to attend. In situations, therefore, where we receive novel sensations, unless there is a proportionate devotion of the mind to the object of its attention, there will at first distract the attention; and so on in the other cases. Abstraction depends, too, in part, upon the physical state of the system. If the nervous system is in a strong degree of excitement, external impressions proportionally affect the mind, and, of course, tend the more to distract the attention. Abstraction is likewise seriously impaired by a general tendency to dwell upon the directly selfish feelings, whether pleasurable or painful; because as these are constantly present to the mind, and constitute the most powerful agents, in their immediate effects, upon the mental system, the habitual tendency to give attention to them, puts an almost total stop to any valuable degree of abstraction in favour of those objects, which are not immediately connected with self; and this, by the way, furnishes us with another instance of the influence of moral upon intellectual education. This habit also depends for its vigour, upon the degree in which the interest of the mind can be excited towards an object. With minds of ardour and activity, if the mind be engaged, it is abstracted from every impression and thought, not immediately connected with the object; and if the interest of the mind is strongly excited from any other cause, the same effect will happen. The vigour of abstraction also, depends, in part, upon the degree in which the habit of observation is poiffessed; indeed they are so much in opposition to each other, that to any considerable degree they are seldom found united in the same individual. The habit of observation implies habitual attention to the objects of sense; the habit of abstraction to the objects of intellect. The habit of abstraction is not therefore to be expected, and indeed ought not to be directly cultivated in the earlies periods of intellectual education. Nevertheless, both qualities depending upon the general habit of close attention, the cultivation of the observation is indirectly laying a good foundation for the subsequent cultivation of the abstraction.

As two objects cannot engrave the attention of the mind at the same time, abstraction may be cultivated by rendering the mind habitually attentive to those objects which are not to occupy it, or by making it habitually attentive to those which are from any cause the objects of preference. The former plan should be adopted, if at all, with great caution. It may generally be left to the efficiency of habit in lessening the efficiency of impressions; and the habitual neglect of any commonly occurring objects of observation or reflection, is inconsistent with the pursuits of life. The second plan is in every point of view preferable; and every influence in which the attention is fixed, whether through direct volition, or by means of excitement without the exercise of volition, is essentially contributing to the cultivation of abstraction; still more so, every influence in which the attention is engaged upon the objects of thought, in situations in which there are frequent impressions from external objects which, if the attention were not so engaged, would then excite the observation. Hence it is desirable to accustom the young to mental exertion where there are scenes tending to distract their attention, provided however that from their novelty or their power they are not calculated to force it. Whatever tends to make the objects of the mind interesting, and to give ardour in the pursuit of them, also tends to cultivate the habit of abstraction; for that which deeply interests the mind, fixes the attention, and of course prevents every other object from sharing the notice of the mind.

The power of directing the mind to objects which afford no impression upon the senses, and even opposition to such as do, is of extreme importance in the later periods of mental culture, and at the same time, with the assistance of previous culture, is much easier than would, with any cultivation, be possible at an early period. In childhood and youth, abstraction more affects the mind, than the sensations themselves can do as we advance farther in life; and though associated thoughts and feelings assist to keep up the influence of the sensations themselves, yet if the mind have been accustomed early to think of what are not the direct objects of sensation, the power of its own thoughts and feelings easily overbalances the effect of at least customary sensations. Carried to an undue extent, the habit of abstraction is unsuitable to our situation as social beings; but there is scarcely any plan of life in which it is not in some measure requisite; and in the pursuits of science, whether physical or mental, it is continually required, and continually strengthened by exercise. It is even very important in the events of life. The power of directing the attention to some specific objects of thought, to the exclusion of others, and to the exclusion of external impressions, constitutes (as Miss Edgeworth well observes) the leading feature of that quality which we call preference of mind, and which is so often of signal service to our welfare, and even to the preservation of our lives. And this habit is essentially requisite in our moral and religious culture; the acquisition of religious knowledge constantly implies the employment of abstraction; in the exercise of religious affections it is absolutely necessary; and in the discharge of duty, in opposition to powerful associations, the power of fixing the attention upon those views and principles which ought to guide us, is of the utmost importance.

The habit of abstraction is in general to be cultivated rather indirecly than directly, in the earlier periods of education; and it is one advantage of the pursuit of knowledge, that it frequently requires fixed attention upon the objects of thought, without aid from the sensations. Perhaps it would be beneficial to extend the occasions for this, in literary and scientific education. An easy demonstration carried on without a figure, an operation in arithmetic suited to the progres of the pupil performed without the aid of the pen or pencil, the description of some former object of observation, the continuing or paring of sentences from the classics without book, and similar exercises of mind, are all calculated to cultivate this habit; and wherever the point can be gained, it greatly increases the power of the mind over its attention. These mental operations may usually be begun early; a child of three or four years of age, can easily be brought to make a little addition in his head; and while he does so, his mind must necessarily be occupied to the exclusion of other thoughts and of sensations. If he thinks closely of what he has seen, for the time he is exercising his abstraction. If he is led to think of some of the simple truths of religion, he is exercising his abstraction; indeed these constitute some of the earliest and most powerful exercises of abstraction. It is very important that these and similar mental operations should not be made too frequent, nor continued too long. They should not be continued too long, lest the fatigue of mind experienced should lessen the will to think, and in reality check the power over the attention; they should not be made too frequent, because, as we have already observed, childhood is the period of observation rather than of abstraction. If the young mind is too much accustomed to think about its own thoughts, the imagination will gain too much power, and that habit of attention to external
ternal impressions will be formed, which, in most cases, is always injurious, and which in the early period of life is sufficient to stop its progress in mental improvement. In this, however, as in every branch of education, our efforts should often be regulated by the prevailing mental habits of the individual. A child of lively conceptions should be directed as much as practicable to accurate observation; where the conceptions are dull, abstraction should be encouraged; and it is encouraged by every instance in which it is exercised with pleasure, by every instance in which the mind is pleasantly engaged upon the objects of thought without the aid of sensation, and especially if in opposition to sensations. The intelligent parent has greatly at her command an account of a walk requiring the recollection of little circumstances and objects which occurred during it, the retracing of ideas on any interesting subject, and various other exercises of a similar kind, contribute to cultivate the abstraction. But after all, it is rather by indirect means, than directly, that we are in the early periods of intellectual culture, to aim to produce and exercise this habit. By early giving a decided bias for intellectual pursuits, and exciting a lively interest in them, and by forming the habit of steady attention to the objects of knowledge as they are presented to the mind, we do in reality prepare it for the cultivation of the habit of abstraction, whenever it may be called for by the higher pursuits of knowledge.

Ablence of mind sometimes arises from the mind's being fully occupied with its own trains of thought, but is should not be confounded with abstraction. The latter implies, at least in the commencement of the particular exercise of it, a voluntary direction of the mind; the former, even where it is really caused by mental operations, commonly supposes a want of power over the attention; but it very often arises from a more flagrant inattention to external impressions. Absence of mind, proceeding from this last cause, should be steadily and constantly checked; not so much, however, directly, as by rousing the attention to the objects of sensation, by making the neglect of them unpleasing, &c: and it should by every means be discouraged in the early periods of education, because it will by degrees induce a tendency to reverie which must almost inevitably give the imagination undue power, and which is more than any quality of mind calculated to destroy all the valuable effects of the habit of well regulated abstraction. In the external appearances, absence of mind proceeding from reverie, differs little, if at all, from the fixed intentional devotion of the mind to some object of thought; but those who have experienced both, and who have watched their characteristics in the young, know that the difference is very important, and defeating of the careful attention of the early instructor. In fact, the habit of reverie is the most baneful possible to the influence of the mind over its trains of thought; and totally destroys, if too much indulged, all power of steadily directing the attention to specific objects of mental pursuit.

VI. We have hitherto spoken of the habit of abstraction, by which we understand (agreeably, we believe, to the common acceptation of the term) the devotion of the attention to some objects of thought, the exclusion of others, and also of impressions from external objects; but it is well known, that the word is also used by some writers on logic and mental philosophy, to denote the power which the understanding has (rather, is supposed to have) of separating the combinations which are presented by it. We introduce the qualifying clause, 'is supposed to have,' because in many cases the understanding has no such power; it is impossible, for instance, to form a conception of extension, without some idea of colour, or of length without breadth; but in reality, the abstractive power is, after all, nothing more or less, than the power of separate attention, the power of attending to one idea distinct from the combination in which it occurs,—of attending to one part of a conception distinct from the rest, and perhaps, by degrees, forming a conception of that part detached from the rest, of attending to one quality or circumstance separate from other qualities or circumstances with which it is really connected, or connected in the mind.

The habit of abstraction, or fixed attention to the objects of thought, is essential to any high degree of mental progress, and is requisite in various circumstances in life; the power of abstraction, or of separate attention to some object of the mind distinct from the combinations in which it is presented, is necessary in almost every process of reasoning, and is the foundation of an accurate, discriminating judgment. The power of abstraction, in this sense, may obviously be cultivated without the exercise of the habit of abstraction; except, indeed, where the object is purely mental. A child attending to one part of a prospect, to one part of a flower, to one of the sensations which an object presents, (to the colour of a fulness, for instance, instead of its shape, or size or weight, or to any one of these without attending to the colours,) is exercising the power of abstraction; and in these very useful exercise of the power of abstraction, the habit of abstraction is not called for; all that is wanting is that of observation. On the other hand, the habit of abstraction may have been cultivated even to excess, without the individual posessing the power of attending to one of a combination of objects, or to a part of a conception, so as not to allow the rest to influence his reasonings and judgment.

The involuntary exercise of the power of abstraction, is very often produced by the mere influence of the associative power, without any effort on the part of the individual, and sometimes by the influence of the sensations themselves. Inflances of the latter continually occur. That impression from any object which is the most vivid, attracts the notice of a child; and while the attention is directed to this, the other impressions from it remain unnoticed. But the exercise of the abstractive power is often, in a great measure, voluntary; and though that degree of this power which shall completely separate at once the combinations which are presented to it, is probably altogether unmeaning, yet it is in our power to acquire it to such a degree that the parts which we wish to exclude from the attention shall not affect our reasonings, and but little even our feelings. We do not mean that in all cases we have such power; but the more the mind is trained to it, the more it is to be acquired. And here again we perceive the advantage of the pursuits of literature and still more of science. The abstractive power is continually brought into exercise in most of the leading objects of mental occupation. The young are thereby continually led to leave out of view some circumstance or quality, and to direct their attention to the essential parts.

Every definition that is underfoot and made the foundation of reasoning, every exercise of classification of words or natural objects according to some system, brings into play this important faculty. It is necessary, in every correct judgment, and at the same time the cultivation of the judgment serves as its guide and brings it into exercise.

The abstractive power should be early exercised, but most commonly upon the objects of sensation. Still however not without caution; because, though separate, detached attention is of great consequence in the later periods of education, yet in the earlier periods, the first point is correct and extensive observation in order to lay up a fund of ideas for the future operations of the understanding.
With respect to the operations of the abstractive power, as necessary in the processes of the imagination, they may be very much left to themselves. We have no wish that the imagination should be sacrificed; for it is of great importance in the conduct of life, in the pursuits of science, and in spiritualizing the mind; but where there is that cast of mind which will lead to form new combinations from its conceptions; all that is necessary is, to give the observation frequent opportunities of exercise, in various situations, upon the objects of sensation, that they may be seen under different aspects, and in different combinations. It is in our own power, at any time, to see only parts of an object; and by dwelling upon these parts, we can form conceptions of them detached from others with which they are connected. Hence, the visual conceptions are very effectually subjected to the abstractive power; and as to the objects of hearing and smell, they have no necessary connection with the objects of sight, the sensations can be received, and the conceptions reproduced, so completely independent of visual impressions or conceptions, that there is still less difficulty in exercising the abstractive power upon them. Where, therefore, the imagination has any considerable strength and activity, the abstractive power may be expected to be sufficiently at its command without direct cultivation. Where, however, the imagination is weak or sluggish, it may be advisable, by leading the attention to separate sensations, and to points of objects distinct from the whole, and by directing the observation to the same objects under different points of view, to cultivate the abstractive power with specific reference to the conceptions as materials of the imagination. And this should occasionally be done with a still higher aim, to accustom the mind to separate the combinations presented to it, in order that those hastily, casual, and erroneous combinations may be weakened, which so often completely mislead the judgment, and which, where they do not directly and obviously affect it, imperceptibly warp it, and materially increase the difficulties which obstruct the reception of truth.

VII. By the Memory we understand that power which retains ideas, and which can bring them back again to the view of the mind. The latter act is generally known by the name of recollection; the former, as Mr. Stewart has observed, has not yet received any appropriate appellation. It might be called retention; but it appears decidedly preferable to appropriate this appellation to that capacity, or power of the mind, by which recollections are retained, by which, in fact, sensations produce ideas.

It is totally unnecessary that we should dwell upon the importance of this power of the mind. Were it not for the capacity of retaining ideas from sensations, man would be a being of mere sensation. But without going to this extent, if the retaining power of the memory were greatly impaired, past impressions, past reasonings, past conclusions, past experience, would be of no service to the mind in the conduct of life, or in the pursuits of science; and without the power of recalling them to the view of the mind when required by circumstances, they would in a great measure lose their efficacy and advantage. To make the memory, however, duly subservient to the usual objects of life, and to the acquisition of knowledge, it must be placed under the regulation of the judgment; and an accurately retentive memory, united with facility of recollection, accompanied with, and guided by, a sound judgment, may be considered as the summit of excellence in this branch of the mental faculties.

To enter into the proper discipline of the memory, when the individual is so far advanced in the cultivation of the understanding, as to be able to regulate the culture of his own mind, is not our province; and if it were, we should be able to add little to those very excellent and important remarks which our readers will find in Dugald Stewart's elegant and scientific section on the culture of the memory. The question which we have to consider is, what cultivation of the memory is most fitted to those periods which are usually devoted to education.

We cultivate the memory indirectly by every influence in which the attention is directed to the objects of sensation; for the vigour and correctness of the memory, so far as it respects external objects, must greatly depend upon the accuracy of the perception. In some points of view it may be considered as the only object at which we need aim with respect to the memory in the earliest periods of education; for where the sensations are duly made the objects of attention, the structure of every mind probably is such, that ideas will be received from them; and the first point is, to gain ideas, which may become the rudiments of perceptions, conceptions, notions, and feelings.

The mere formation of ideas from sensation, is, however, seldom referred to the memory; and though this is a most important object, and serves as a basis for every future operation of the mind, it is so closely connected with the act of sensation, that it can scarcely be distinguished from it. In all probability every impression and every thought which has the notice of the mind, have some effect in modifying or strengthening the corresponding ideas which were previously formed, if they do not form new ideas; and often without our observing the process; but we do not usually speak of such retention as an act of memory, confining the operation of this power to cases in which we can bring again into the view of the mind the objects of observation and reflection. If the ideas produced by observation or reflection have been so much impressed upon the mind, that by active or passive recollection they can be brought again into its view as they were at first produced, the retention and recollection of them are considered as operations of the memory.

As the mere retention of ideas without the power of recalling them, would be of little consequence, and as the recollection of ideas serves greatly to strengthen the retention of them, it appears that one leading object of our aim in the early culture of the memory, should be, to produce the habit of ready, distinct, and accurate recollection. This habit, of course, in the commencement of intellectual culture, be employed merely upon the objects of sensation, of which the first will be words. When a comparatively small number of words have been acquired, the recollection should occasionally be exercised respecting past sensations; chiefly those of sight, which are in the first instance most easily retained and recalled. By degrees, those which have been received by the sense of hearing, should also be made the subject of recollection; partly with a view to increase the power of recollection, but still more the habit of observation, and of attention to those directions which in the early periods of childhood are so essential to well-being, and sometimes even to existence. For several years from birth, it appears to us scarcely desirable to exercise the memory much upon a connected series of words; the power of recollecting words is of great importance in a later period of the mental progress, but in the earlier, the first object is ideas; and young children should seldom (if ever) be required to repeat words without having a clear idea of the meaning of them. Such ideas must necessarily be deficient, but they should be correct as far as they go, and at any rate should be such as the little mind can grasp. If the habit of re-
membering words, and of recollecting them, without understand-ing them, is once begun, there is afterwards a very great difficulty in cultivating the understanding, and in making the memory, what it ought always to be, however important it is, a subervient faculty.

In the early exercises of the recollection, we are to be fully satisfied with correctness, however deficient it may be in fulness. Correctness (we of course do not mean in the repetition of words, but in the recollection of ideas) should always be aimed at. The imagination will not lose by this; for the correct recollection of conceptions and notions tends to fix them more upon the mind; and these are the materials upon which the imagination is to be employed. Most certainly the understanding will be a gainer; for the object of the understanding is truth; and truth cannot be found by that mind which has been trained up to falsehood by early habit of inaccuracy. We have no objection for the little imagination early to work upon the conceptions which have already been treasured up in the mind, under those limits which continual attention will necessarily set upon the operations of the imagination; only let a child be habituated, in detailing its inventions, to detail them as such; and when recollecting the past objects of observation, to give a faithful outline of them, however imperfect it may necessarily be. We have known an instance in which a child not above four or five years of age, whose imagination was lively, and whose recollection (and perhaps observation also) had unhappily not been trained to accuracy, frequently told his friends circumstances which had no existence except in his own mind, with the regularity, and much of the conformity of real facts, and, probably, by degrees did not know whether he was speaking of the creations of his fancy, or of things which he had actually seen and heard. Such cases must excite our regret for the past, and our apprehension for the future.

Great difficulty often exists, especially in the minds of persons whose conceptions are vigorous, and who have not been habitually careful to cultivate accuracy of perception and correctness in the relation of recollections, to know whether the trains of ideas presented by the associative power are to be referred to the memory or to the imagination. Such persons, feizing only the outline of a fact or series of occurrences, owing to habitual inattention to their sensations, are, from readiness of association, able to fill up the transcript, so as to make it appear plausible to themselves; and by once or twice detailing it without minute regard to accuracy, except in those leading features, they give a degree of vigour to the ideas, and of eloquence to the association of them, which at last leads to the full conviction that the whole is recollected. Cases of this sort are very frequent; and they often leave upon the minds of others, the belief that such persons intentionally depart from truth; whereas the fact sometimes is, that part of their error arises from a desire to give the whole truth which they have materials for only a portion of it in their minds. However, the fault is one which should be carefully guarded against, particularly in the early part of life, by making young persons of lively imagination habitually attentive to the minute as well as to the leading parts of their impressions.

Recollection should often be exercised directly: but the main object, after all, is, to acquire the power of bringing forward our ideas when they are wanting; and it should therefore be often exercised indirectly, by leading to it for those various purposes of life, in which the young are sometimes capable of being useful, and still more, by encouraging the statement of past ideas as they are called up by pre-fect objects, especially when the connection is natural and of a kind likely to be serviceable. This species of recollection obviously depends upon the manner in which the associative power is exercised; and in fact it is itself an exercise of that power, to which the young should be led in every practicable way; in the period of childhood by free communication with their friends on their various pursuits and occupations, and afterwards, in addition to those means, by composition. Continual opportunities occur in almost every department of instruction, for the advantageous recollection of related ideas which have been before received; and it is only by their being brought into employment, and associated with other ideas and trains of thought, that they can be expected to be permanently retained in the mind, or, if retained, to be at its command.

The recollection of ideas is greatly aided by the connection of words both with them, and with the original impressions; for words being, from the confiant use of language, familiar to persons of moderate mental culture, even in various combinations, they are easily retained, and most materially affit in producing the recurrence of the corresponding ideas. And thus, when a person is relating a past fact, the ideas in some cases suggest the words, and in others the words suggest the ideas. Hence illiterate persons, other things being equal, do not remember nearly so well as others. Hence also the importance of teaching the young to remember words as well as things; for in most cases, as words serve as the bond of ideas, ideas will be loose and floating in the mind unless connected with words.

After what we have said respecting the memory, we shall not be misunderstood when we say, that the cultivation of it should constitute a very essential object in the early periods of intellectual education. Without a doubt there are original diversities in the capabilities of the mind; and it should be one grand object in mental culture, to excite those which are weak, and to curb and regulate those which are excessive. With respect to the memory, some young persons appear to retain words, and even ideas, with a degree of facility which astonishes and perhaps delights the partial friend, while at the same time it furnishes some ground for alarm, lest that which ought always to be made subervient should have the ascendancy, and prevent due attention to the cultivation of the judgment and reasoning powers. Others are slow in acquiring, but retain for a long time. Others again are distinguished by the readines with which they recollect, and the ease and aptitude with which they bring forwards what their memory has stored up; and if the memory has been judiciously employed, and the principles of association have been such as are advantageous to the judgment, this is all which can be wished for. With respect to those who possess great facility of retention, it should be the aim of the instructor to encourage, as much as possible, the found exerci-se of the judgment, and the long retention and suitable recollection of ideas, rather than the easy acquisition of words, even if properly understood. Durability of retention depends in a great measure upon the manner in which ideas are associated in the mind, and upon the use of the ideas which have already been received and retained; but this facility of retention, though depending in part upon exercise, seems to arise in a small degree from corporeal organization. It is valuable only as made the foundation of a good memory: it often leads to neglect those features of the understanding, to which it should only be auxiliary, because they are more difficult; and the consequent, in innumerable instances, has been, that while apparently the mental pro-gress is going on very rapidly, the judgment, and the reasoning powers, are almost dormant, and the whole of the mental force of the individual confines in the words, or at most the
the ideas of others, without any real acquisitions of thought, and even without that new-modeling and arranging of them, which would give a degree of appropriation to the possession. We have known an individual arrived almost at the age of manhood, who found it so much easier to learn Euclid's Elements by rote, than to understand them, that he actually went through several of the early propositions without anyulpinion being excited that he had not fully mastered them; till on an accidental change in the lettering of the figure, or in the construction itself, it was discovered that memory, not understanding, had been exercised throughout. Where, however, facility in retention is not poiffessed, though it is by no means the most important feature of the memory, yet it shou'd be cultivated, directly by actual exercise, but still more by well flowing the mind with those really valuable ideas which will serve as connecting bonds for new ones. That kind or degree of retention which arises from affiliation, not from original organization, is of the greatest value; and this may be improved to almost any valuable extent, where there is good fene to work upon.

Where the pursuits are directed to the acquisition of literature and science, there is no danger of a want of objects on which to exercise the memory in all its usual qualities. Indeed the danger principally is, of doing too much; and still more, of cultivating the memory almost exclusively. The apprehension of this has led many ingenious persons who have been concerned in education, to do too little. They consider it unnecessary to exercise the memory more than they think will be probably useful in life, or to burden it with things which, if they should be useful, may be easily acquired when they are wanting. They see the memory often made almost the only object of education, facts stored up without any judicious link of connection, and words, in themselves considered almost unintelligible, and which at any rate convey no ideas to the mind of the learner, committed to memory without explanation; and they go into the opposite extreme, and suppose that the cultivation of the judgment is all which they need attend to. Truth, as in many other inferences, lies between the extremes. The cultivation of the memory ought, most assuredly, never to supersede that of the judgment; but, on the contrary, should be kept in subordination to it, and be regulated by it: but when it is considered how many of the purposes of life require accuracy and facility of recollection, how necessary the memory is to the pursuits of science and literature, and even to the cultivation and exercise of the moral fene, can we doubt that as a subfervient faculty, and, with a view to its subferviency, we can fearfully cultivate it too much.

Without a doubt, the recollection of ideas is the object of the greatf confquence; but as we have already stated, the memory should often be exercised on words, both as an aid to the remembrance of ideas, and on account of the great importance of an accurate recollection of words in the usual, as well as in the more peculiar concerns of life. We shall never forget, that, in all probability, the reputed murderers of Steele 'lost their lives by the definite article being introduced,' we doubt not unintentionally, by the reporter of their words; if they said, "We must have had gin there," (not as we believed was flated in evidence, "We must have had the gin there," their words, so far from being a strong, indeed preponderating argument against them, were plainly confient, and indeed most confident, with their reiterated affervations: they were confifting the testimony of the king's evidence; and what they probably said, was designed to account to one another for his representations. We are often led to repeat the statements of others; and it very frequently happens that it is not sufficient to give what we think their ideas.

If we can give their words, every one may judge for himself as to the import of them; if we give merely our own ideas of their import, we preclude all correction of mistake, if from our peculiar prepossession, or any other circumstances, we have erred. We have ourselves known instances, and probably our readers can at once recollect others for themselves, where very serious confquences have followed from persons detailing their own apprehensions of the meaning of others, instead of what they actually said: and from a regard to truth, and from the consideration of such painful occurrences, we feel persuaded that the habit of the correct recollection of words should be early made an object, and should not be lost fight of in any part of education.

But besides the directly material effect of the correct recollection of words, and the importance of it in the concerns of life, we do not perceive how the necessity of it can be doubted in the various employments of a literary and scientific education. We have no wish that the memory should be burdened with a number of rules and facts which are of no direct subserviency to the objects of rational instruction; nor that it should be called upon to affume the principles of grammar, and flill less of philosophy, without the continual exercise of the understanding; but though the judgment will afford material aid to the memory, even in the rudiments of the languages, and of indispensible utility to its exercise in every department of science, yet the ready and accurate recollection of fundamental rules, of the flexions of words, of elementary principles, definitions, &c. is of such signal, and almost essential, advantage, in the progress of education, that we cannot but suppose, either that those who object so much to the frequent exercise of the memory on words, would not wish to be underflood to the full extent of their own representations, or otherwise, that they labour under a mortal material error, arising from ignorance as to what exercise of memory even a rational education requires, or from forgetfulness of those processes by which they have themselves made acquisitions which could not have been made without them.

The exertions of the memory may be claffed in three divisions, (as respects our present considerations,) those in which it merely supplies materials for the judgment; those in which it furnishes the reft on of previous exercises of the understanding, (or at least what have before been the objects of the understanding,) and in which the understanding should still be concerned; and those in which the processes of the memory are become habitual from constant employment, and go on "without our thinking about it." The last class is probably much more extensive than is generally supposed; facility in arithmetic, and in the subordinate exercises in the languages, continually require such an exertion of the memory, and where the memory has not been trained to it, the difficulties in thefe elementary acquisitions are constantly felt. All the power which we with the judgment to exercise in each cafe, is a controlling power; to suggest errors and omifions, but not to direct what is right; and if the readiness and accuracy of memory have not been early cultivated, fay before the age of twelve or thirteen, it will often prove up-hill work to acquire facility in those branches of knowledge which, from being of practical value, are of very frequent occurrence. One cafe has occurred to our own observation, in which the exceflive fear of making the memory paramount instead of subordinate, led to such a degree of flowerness in every operation in which the judgment is not principally concerned, that the individual found ten-fold difficulties, where the memory of much younger companions (without blindfolding the judgment) suggested at once every thing that the circumstances might require, and will doubtless enable
ble them to succeed both in the usual employments of life. Of course we should prefer the cultivated judgment, with great hesitation of memory, to the most fluent memory without judgment: but fluency in memory may be acquired without sacrificing the judgment; and who would then deprive it? One leading object of the work of instruction, in the middle period of life, (perhaps from the age of eight to twelve or farther,) is to give by practice that facility of recollection which, if not acquired before the understanding is become somewhat mature, will seldom be acquired at all; and which, though always to be regarded as a subliterate faculty, is of almost indispensable utility in the concerns of life, and even in the employments and researches of science.

The remarks in the last paragraph were suggested by what we are advancing on the memory of words, and chiefly refer to it. Words continually hand for many thoughts; and short combinations of them frequently imply trains of reasoning: but it is often sufficient, for the purposes of education, and indeed all that is desirable, that the memory should suggest such combinations, and afford the impression of their accuracy, without the exercise of the understanding to weigh the truth of them. Two instances will illustrate our meaning. The common rule of algebraic multiplication, "Like signs give plus, and unlike signs give minus," is in itself considered almost without meaning, and understood literally involves an absurdity; and we would never teach it to a boy, without first shewing him that it is a convenient abridgment of a number of operations in algebraic multiplication, all of which are well-founded: but when he has once seen the universality of its application, we would then lead him to employ it without hesitation, and even without thought as to its meaning: of course, however, recommending that he should never reason from it, but refer to the facts themselves as the foundation of inferences respecting the nature and combinations of algebraic quantities. But to take a more familiar instance: in common multiplication, where the multiplier consists of several digits, we are directed to place the first figure of each product under the digit by which we multiply. Nothing can be easier, when the effect of multiplication by 10, 100, &c., and the nature of our numeration are well understood, than to understand the reason and meaning of the direction; but we should not wish that the pupil should continually revert to this explanation; it is sufficient if he remember the fact distinctly, and at the time when it is wanted; and it would only serve to embarrass, if the rationale were to be constantly brought into view.

Leaving out of consideration all the intercourses of life, in which the ready recollection of words is often the source of so much interest and delight, there is still another point of view in which we feel the importance of the habit of recollecting words readily and accurately. Ideas fade from the memory much sooner when they are not connected with words. In sickness, and often in old age, the recollecting powers become languid; and the vigour of the mind, which would supply a succession of interesting thoughts, is lost under the prevalence of disease or gradual decay. In such circumstances the mind dwells upon the present impressions of pain, or weakness, and can scarcely raise itself above them; but if the memory have been well stored in the early part of life, with useful and interesting combinations of words, they will often recur, at such periods, without an effort, and without fatigue, and furnish objects of thoughts which will soothe and even cheer. Those who are subject to any degree of mental depression, disabling them from active efforts, to point out a channel for their thoughts, often find such sug-

gestions of the memory an important relief to them. And we need not say to those of our readers who have a religious turn of mind, that these remarks are peculiarly applicable to those devotional compositions and expressions, which, where they have been early and deeply impressed on the mind, occur at the call of affection to support, to strengthen, and to comfort; and which, thus suggeted by the memory, have in innumerable instances alloyed the emotions of passion and desire, or poured balm into the wounded heart.

Whether the memory should ever be exercised on words which convey no idea to the mind, we do not venture to determine; but as far as our own experience goes, we should be led to conclude that such a cultivation of the memory can be of little service in a rational use of life, and at least observed, that where a boy has possest great facility in committing to memory passages from the classics, without finding it necessary fully to understand them, (for that the recital of them went on with little if any aid from the understanding, but was effected by the mere dint of verbal recollection,) he has usually found it much more difficult to remember passages from English writers, in which the meaning is obvious, though the modes of expression are out of the common round. It appears to us, therefore, that exercises of the memory, in which the memory alone is employed, should seldom be resorted to, since it does not tend to produce that recollection of words which is subfervent to, and indeed accompanied with a recollection of notions and feelings. The first stage of recollection should be accompanied with the direct exercise of the understanding: the formula of words may, by habit, cause explicitly to excite the ideas which on reflection it would convey; but it should not be attended with a feeling of unmeaningness or unintelligibility.

The only case (separate indeed from the rudiments of language) in which it appears particularly expedient to exercise the memory upon words alone, is, where, though they have no usual connection with certain facts or truths, they serve, by an artificial connection, to bring those facts or truths to recollection; and even here there is the feeling in the mind, that they are merely abbreviated representations of a more full combination of words, which is itself at once intelligible. We refer principally to such contrivances as those in Grey's Memoria Technica. Of course we would be no means recommend the employment of his method to any thing like the extent which he proposes; but if it be of importance (as we are persuaded it is) in the reading of history, that a few leading dates should be well fixed in the mind, his method will be found of great utility by furnishing an additional aid to the memory; and the mere translation of his technical words, affixes materially in the permanency of the recollection. Cases may occur, though not very frequently, in which it will be very serviceable to bear in mind with minute exactness the latitude and longitude of places; and here also, the Memoria Technica may be found of considerable service. For the general purposes of geographical knowledge, there can be no doubt that much more benefit will be derived from forming in the mind a clear idea of the relative situation of places, by means of a familiar acquaintance with the globe, or even with maps. Little advantage can be expected from the extension of this method to astronomy, and other branches of physical science; but if any circumstances render it desirable to retain with accuracy the size of the planets, their distances from the sun, &c. or the specific gravity of different bodies, Grey's contrivance will be found a useful aid, though we can never recommend the employment of it in science, without a full previous acquaintance with the facts to which it relates, and a frequent explicit reference to them: in short it should always be employed merely to aid
INTELLECTUAL EDUCATION.

the remembrance of knowledge, not to enable the young to
prave about objects of which they are really ignorant. It
is well known to our mathematical readers that there are for-
mulae of eminent utility, in the remembrance of which the
judgment can have little share, and in which readines and ac-
ccuracy of recollection are the chief objects; for instance,
Napier's celebrated canons for the solution of right-angled
spherical triangles. Here the short sentence, "the rectangle
of the radius and the sine of the middle part, is equal to
the rectangle of the tangents of the extremes conjunct, or,
if the coines of the extremes disjunct," enables the calcu-
lator to solve with the greatest ease every case of right-angled
spherical trigonometry; but in the recollection of this com-
prehensive canon, the understanding affords little, if any
assistance; it is a technical formula, in which there is no op-
opportunity of exercising the perception of truth, except by ob-
erving the truth of every clause of proportions which may be
derived from the application of it, when the truth of the can-
non has been demonstrated, all we have to do is to remember the
canon. In this and many other instances in the mathematical sciences, a
ready and accurate recollection of signs of ideas is of great ser-
svice; and we cannot have hesitation in maintaining, even
from such cases alone, that it is desirable to train the memory,
among other objects, to the recollection of words, always
indeed as signs of ideas, or abbreviated signs of those which are
immediately signs of ideas, and, as much as circumstances will
allow, with an explicit exercise of the understanding, but
still so as to make the exercise of the memory in these in-
fances the primary consideration. The occasional utility of the
recollection of such abbreviations we have already suffi-
ciently adverted to; and we will only add one specimen of
the advantage even of the abbreviated statement of these ab-
abbreviations. The formula of Napier is readily suggest-
ted to the mind by the memorial words Tan con, Csc-Div; and
when these are well fixed in the memory, and connected
with the more expanded statement of the canon, it is almost im-
possible that the mind should ever be at any loss in the re-
collection of the canon itself, or at least of the import of it.

In cases where verbal recollection is found to be an ob-
ject of importance, the simplest and most correct modes of
expression should be employed; and, when they are re-
peated, it should constantly be done without variation in
the order or selection of words. If we can refer to the
understanding to check or suggest the words, this is not
of so much consequence; but wherever the ready recol-
collection of words is desirable, for purposes of dispatch and
accuracy, this precaution will be found of great moment.

We do not mean to charge the later writers on education
with being the sole cause of that neglect of the exercise
of verbal recollection, which, a few years ago, was prevalent
and fashionable at least in domestic education, and which
made its way into schools beyond what experience has shown
it to be useful; but the uncivilized language which has been
used by persons of intellectual eminence, aimed, perhaps
in some cases exclusively, against burdening the memory
with sounds unmeaning to the learner, and almost useless if
they were understood, has in many instances been extended
to all cases of exact verbal recollection, and has caused great
difficulties in the subsequent periods of education as well
as in the pursuits of life. We think that Miss Edgeworth
stands chargable with contributing to and supporting this
error, not perhaps directly, but by the low estimation in
which she teaches us to hold the memory, and by the too
unqualified manner of her generally excellent observations
on the culture of it, and the subjection of it to the judg-
ment; and we will deny that we have been led much
further than we otherwise intended, by our opinion as to
the impression which many have derived from her chapter
on the subject. Her own writings showed that she herself
possessed a judicious memory; but without more attention
to the cultivation of the recollection of words than the er-
courages, we feel persuaded that few will obtain one so ser-
cviceable. There is in that chapter a great deficiency in
precision and clearness; and it has consequently been the
source of much error, or at least countenanced it; and the
principle is often obvious, that exertion should be exacted
only by being made interesting. Her conclusion, "that
memory is chiefly useful as it furnishes materials for inven-
tion," is one of those extraordinary positions which can
only mislead persons who can implicitly bow to authority,
and who prefer quiet acquiescence to the trouble of think-
ing. It has not unfrequently occurred to us, that it is happy
for mankind that the human intellect is not generally to be
moulded by theorists; and we have no doubt that in the
common walks of life great numbers, not absolutely illi-
terate, may be found, who, though they poiffes a tolerable
share of good sense and judgment, never have had the mer-
it of forming one new combination of ideas for themselves,
and who, by the aid of memory, guided, we allow, by the
understanding, contrive to pass through life with credit
and utility. Viewing Miss Edgeworth's position as limited
to science and literature, the subfervency of the memory
to invention is only one, and that not the most important
department of its exertions; taken as we find it, without
any restriction or explanation, the position is as unfounded
as it is injudicious.

It is difficult, in education, to lay down any generally
applicable rules, especially if they require the specification
of ages; but we should be inclined to divide the course of
intellectual education into three periods, the first extending
to about seven or eight; the second to about twelve or
thirteen; and the third to the time when direct instruction
ceases. In the first, the exercises of the memory should be
constantly and directly subservient to the culture of the
understanding; and should not be employed but where they
can be made intelligible. In this period the chief object is
to produce ideas, and to connect them with words, to
cultivate the observation and the judgment, and to flour
the memory with ideas without much regard to philo-
osophical principles of arrangement. Some notion of caution,
however, begins very early in children; and where it can
be brought into exercise judiciously, there appears no reason
why it should be neglected; but the common bond of union
will be connection in time and place, and it is by these links of
association principally that recollection will be first pro-
duced. In the second period, though the exercise and cul-
ture of the judgment should go on as ever, and even be-
come a more prominent object of attention, the memory
of words should now be particularly cultivated. In the
third period, the exercise of verbal recollection should, we
imagine, constitute a very subordinate object. The primary
aim must then be, to strengthen the judgment, to exercise
the operations of reasoning, to cultivate habits of correct
generalization and classification; and, as the mind expands,
to lay the foundation of that judicious selection and ar-
angement of the objects of the memory, which will make
this faculty of the utmost utility in every valuable employ-
ment of the understanding, and indeed make every operation
of the memory itself an important exercise of the judg-
ment.

VIII. We now proceed to a few remarks on the culti-
vation of the Understanding. We employ this general term
(though in reality it may truly be said to comprehend all the
the preceding intellectual habits or faculties, principally with a view to those operations, which are usually referred to the heads of judgment and reasoning, and to those operations of the associative power by which ideas are combined and associated with words.

The foundation of an accurate, discriminating judgment, can only be laid in the acquisition of clear perceptions. During the period of infancy (that is, before the use of words is understood), this is almost the sole object of intellectual education; and whereas this is properly attended to, unless in very unfavourable circumstances, the development of the understanding will afterwards go on with success. Where this has been neglected, the injurious effects are seldom completely remedied. The acquisition of clear perceptions does not, however, necessarily introduce the operations of comparison, discrimination, and judgment; but when these are exercised, the perception is thereby rendered more acute and active. The perceptive powers are necessarily improved in proportion to the attention of the mind to the objects of perception; and whatever excites the operations of the mind, is productive of that pleasure which attends every natural and gentle exercise of the mental faculties, more or less, in every period of life, but particularly in those to which education is chiefly directed. Every such exercise of the mental faculties in connection with the objects of perception, tends to excite the attention to those objects, and consequently to improve the perception. And thus it is, as in every period of the intellectual culture, that the proper exercise of one faculty tends to the general improvement of the mind. But to compare, to discriminate, and to judge, does not necessarily follow from the exercise of the perception. In the more complicated perceptions, numerous judgments are often included; but for the formation of those simple ones which are the first exercise of the mind, nothing more is requisite than retention of ideas, and that elementary exercise of the associative power by which two or more ideas, derived from the same or similar objects, are connected with the appearance, &c. of the object, so as to be at once recalled by it, and by degrees combined with it: nevertheless, where the mind is active, and suitable opportunities are given, it very early begins to employ those faculties of the mind on the notions presented by the senses. We have observed, even at the age of twelve months, infancies of the most decided nature, proving the attentive examination and accurate discrimination of the objects of sensation. Among others, we recall to mind a little circumstance which we observed with great satisfaction, which parental partiality was not concerned. A boy, of a line intelligent cast of countenance, but not at all able to speak, had a strawberry with its stalk on, and a red garden daisy not fully opened, and which very much resembled the strawberry, placed before him. He had several times before eaten strawberries, and of course had an infantine motive for discrimination. He looked at one, and then at the other; at last he took up the daisy, but without putting it to his nose or mouth, he continued observing it, and after some time he put it down and took up the strawberry, which he immediately ate. Hence it might be supposed, on the one hand, that there was an operation of reasoning; and, on the other, that it was simply a judgment, formed by comparison of the sensations.

The truth appears to lie between the two suppositions. As far as we can form an idea of the operation of the infant mind, the case was this. There certainly was considerable resemblance between the two objects, or the child (whose discriminative powers were obviously clear) would have at once chosen the right one; but having taken up the daily, it did not, on minute observation, present those appearances which excited the connected pleasurable feelings, already associated with the conception and name of the strawberry, and consequently did not excite the disposition to eat it. The judgment was not a direct intentional one, and consequently differed from those which we employ by the use of words; but the process was the same with that which continually takes place in our own minds. The rejection of the daisy was in consequence of the perception of differences, or at least the perception of complete similarity, between the sensation and the conception which had been produced by the frequent sight of the fruit. In this instance we have no doubt that words were employed to fix the comparison in motion. Children often understand many words before they can at all utter articulate sounds. The child was probably told that one was a strawberry and the other a daisy, and that he might eat the strawberry.

Such comparisons should often be produced, but at first the objects should, as much as possible, be such, that the comparison may be suggested by the wants of the cafe; and it should, consequently, be always employed on objects which are completely within the grasp of the mind, at least in the view which we wish to have taken of them. It would be absurd, for instance, to lead a child to compare any of the qualities of a guinea and a shilling, but those which are obvious to the sight or the touch. Inferences will be continually occurring (where proper room is given for the exercise of the faculties), in which comparison will take place without any effort on the part of the parent; but it will usually be found expedient sometimes to bring about the employment of the judgment directly; and provided we take care never to make it painful, by displeasure at inaccuracy, or by too much solicitude as to the result, it may be done with great advantage. We never can be without objects to exercise comparison, when children understand the meaning of common words, even if they cannot themselves properly employ them. The size of things, their colour, shape, smoothness, weight, &c. (according to the degree in which the understanding is developed, and the meaning of words understood), furnish convenient means for leading to observe resemblances and differences in their various combinations; and the perception of these constitutes discrimination.

These things would doubtless appear trifling to many of our readers; but in all probability those who may consult this article will view things in a different light. Discrimination of judgment is a quality than which no one is more essential in the pursuit of truth; the ready perception of resemblances among diversities, and still more the quick and accurate perception of diversity in the midst of resemblances, constitute some of the most important operations of the understanding. And such discrimination will usually be produced, where the mind is awakened by having sufficient scope and exercise of its faculties. We may often leave it to its own silent progress; and if we encourage accurate and attentive observation, and the correct use of words, discrimination will, in all probability, be found to follow as a natural concomitance. But it must also be our endeavour, to awaken and exercise the mind by direct attention on our part; and provided we measure our efforts by the degree in which the understanding is developed, and do not attempt to force it, but only to guide and employ it, we may reasonably indulge the confidence that the work of education is going on successfully, and that we are beginning a progress of intellect, from which the most satisfactory results may be expected.

This quality of accurate discrimination should be kept in view and exercised in every part of education. It is, indeed,
INTELLECTUAL EDUCATION.

the foundation of clear ideas; and the acquisition of whatever can be truly called knowledge depends most materially on the possession of clear ideas. It is secured by various objects of instruction; and in fact it often is this exercise which gives those objects their leading value. Now, if we wish our children to think clearly, and to reason accurately, the works of thought and reasoning must be attended to early. Those who learn to think and reason comparatively late in life, have difficulties to overcome which can scarcely be appreciated by those whose intellectual qualities have been early cultivated. And no sensible parent need despair on this point. The object to which we would urge, is not to communicate extensive information; that will be gained, and beneficially gained, if the desire of knowledge has been produced, and the qualities of mind, on which the acquisition of knowledge depends, have been properly trained; we only wish that on those objects which properly fall within the sphere of capacity, during the early part of childhood, the observation should be so exercised, that the power of discrimination should be acquired. A few simple play-things, which a child has the opportunity of observing in every situation, the natural objects which surround us, and which usually strike the attention of a child, if he be allowed to observe, pictures of different kinds of animals, the letters of the alphabet, the dissected map, &c. furnish abundant opportunities for that discrimination, the cultivation of which we strongly recommend, as lying at the foundation of every thing which is valuable in the most serviceable exercises of the judgment. All that is requisite is, that we should ourselves be capable of discrimination; that we watch the opportunity, when the mind is alive, to encourage the observation, and to produce distinct and accurate perceptions. Our business is not to be continually making direct efforts, as in the later period of education, but to employ those occasions which do often present themselves to the attentive parent, to lead to the exercise of those qualities of mind which he knows to be of high importance. It scarcely matters what it is on which we do thus exercise them; provided always that we attend to the actual state of the mental progress; circumstances which, to uninterested spectators, appear of the slightest possible moment, often to the judicious parent indicate the operation of some useful quality, and enable him to discover, more than by any specific directions can do, what will enable him to promote those qualities of mind which he wishes to see professed. The grand point to be kept in view is, that we do not aim, on any occasion, to force the faculties, but to employ them as they advance in strength and accuracy suitably to their progress, and to furnish them with appropriate objects of exercise: and we may feel assured, that so long as those qualities are exercised, the business of education is going on much better than if we were endeavouring to store the memory with words to which indistinct ideas, or no ideas at all, are attached, or even to store it with facts, however in themselves considered useful and interesting. We ought never to think the work of education going on, unless the operations of the understanding are in some way or other brought into exercise; and when they are, we may feel fully satisfied. If the development of the intellectual faculties is properly begun, it will go on by the mere influence of external impressions. Our business is to regulate and employ those external impressions, so that their influence may be fitted to the state of the mind, and really productive of a suitable exercise of the understanding.

We should aim not only to produce discrimination, but to lead to the habit of observing the grounds of discrimination, the particular qualities or circumstances in which objects resemble one another, and those in which they differ. This is by no means a necessary effect of the perception of resemblance or difference; and it is often but partially acquired; yet it is certainly essential to correct reasoning, and may be properly included under the head of discrimination. Children very early acquire the power of finding out the grounds of difference and agreement; and the questions, In what are these two things alike? In what are they unlike? often serve, at the age of three or four years, to bring into exercise some of the most useful operations of the understanding. Every thing, in fact, which lets children to think upon the objects of their sensations, and upon their ideas, is a most serviceable employment; and the more they are early led to think correctly, the more ready in the later periods of education will correct thought become.

It would often serve as an important guide, if parents would themselves consider what qualities, or faculties of mind, are brought into exercise by the different circumstances which occur, by their own words to their children, and the modes of expression which they encourage them to use. We should always wish that intellectual education should be made supplemental to moral education; but attention to the one would in no way interfere with attention to the other. A sound, comprehensive, vigorous, discriminating judgment, is surely of the first importance, both in a moral and in an intellectual point of view. There can be no doubt that much might be done towards the acquisition of it, if parents kept it in sight as the chief mental object, and regulated their direct efforts, and as much as might be controlled accidental impressions, with a view to the cultivation of it, using their own good sense and patient observation as the best guides to the probable effect of each upon the mind.

IX. Reasoning, or the drawing of inferences, is a process which may be expected to go on successfully where the judgment has been cultivated. It begins very early; indeed the mental process is often independent of words. The direct exercise of it does not appear to be desirable, till the mind has acquired some vigour; more especially till the judgment has been tolerably cultivated, and a considerable acquaintance with words acquired: and this is the less necessary, because in every part of early education, circumstances of constant occurrence will continually bring the reasoning faculty into exercise, and give it a right direction, if we avail ourselves of the opportunities which they present. "Scarcely a day passes," says Mr. Edgeworth, "in which children do not make some attempt to reason about the little events which intercede them, and upon these occasions a mother who joins in conversation with her children may instruct them in the art of reasoning without the parade of logical disquisitions."

As the mind expands, the objects of the reasoning faculty, of course, increase in number and frequency of occurrence. And the judicious parent, without making it a formidable object, may exercise it efficiently. Two points, which are of universal application, should, however, be always kept in view; that the premises should be thoroughly understood, and this previously to the employment of them in the act of reasoning; and that the allusion of a child to the conclusion should never be exacted, when there is any hesitation. It is too much to expect from a child, that the conclusion should be admitted, if the understanding is to be exercised upon the premises also; and as we cannot force the reasoning powers, and cannot compel a child to see the justice of our reasonings, we shall either lead him to fall into the same errors as the parent, or to assert upon our authority and not upon the effect of the premises; or, we shall
INTELLECTUAL EDUCATION.

shall confute his understanding, and really prevent that effect which would otherwise have readily followed.

Single acts only of reasoning should be exercised in the early periods of education. We do not mean that one inference should never be made to support another, after the understanding had previously acquired some strength and clearness; but that, if ever a train of reasoning be employed, it should, in fact, be made to consist of single unconnected inferences in the first place. The links should be all comprehended separately before they are fastened together. When a child is so far advanced as to be able to pursue a train of premises and conclusions, there can be no loss for subjects on which to exercise the reasoning faculty: the fields of mathematical science will by that time be opening, and they will exercise it, and, at the same time, guide it.

It appears that, in general, the true method of teaching to reason accurately, is to accustom children to accurate reasoning. Long before they can form inferences for themselves, they can understand the inferences of others; and the grand point is, that the inferences which we employ to them shall be fully intelligible and thoroughly just. If we are sophistical with them, it is too much to expect that they will grow up in habits of clear and correct reasoning. If we make a point of going no farther in our conclusion than our premises will warrant, they will gradually acquire a kind of test, which may be considered as forming a part of good sense, which will effectually prevent them from feeling satisfied with false reasoning, even though they could not detect the grounds of the sophistry.

Parents must often require the affent of their children on the score of authority. They will naturally believe implicitly, if the truth is always spoken to them; and it is sometimes impossible to give them any reason which would be intelligible and satisfactory to themselves in reply to their question, Why? or, Why not? We prefer that children should be troublesome sometimes with these inquiries, rather than that they should not themselves be accustomed to think; and if a parent has, by judicious management, acquired the confidence of his children, it will generally be sufficient for him to say, "It is not always necessary that I should tell you the reason of what I desire you to do; I wish you to do it!" and in some cases, indeed, not unfrequently, it may be expedient to state what is often the matter of fact, "You are not old enough to understand the reason, if I were to tell it to you: when you have more knowledge and understanding, I shall be able to tell you the reasons of those things better than I can now." But after all, if assent, or obedience, be required on the ground of authority and confidence, let the ground of reasoning be kept out of view. If we once make any thing depend upon our reasoning being understood, let it be kept to that point. We may often assent to the conclusion as an intuited truth; but we never can assent to it as an inference, unless the reasoning is properly understood.

It may be doubted whether it is desirable to give specimens of sophistry to children, before they are really capable of entering into the ground of the sophistry. But if ever we find them drawing false conclusions, then is the time to shew them, if possible, how and why they are false. And it is highly desirable that we should accustom them to caution in their inferences. It is better that they should sometimes reason very erroneously, and draw very erroneous conclusions, than that they should never reason at all; and it is by no means to be expected, or even wished, that their inferences should be always accurate; it is not to be wished, be cause we should then have reason to apprehend, that the inference was an act of memory rather than of the understanding; and it cannot reasonably be expected, because the power of reasoning justly depends upon the degree in which the terms of the premises are clearly and fully understood, and also requires, for the acquisition of it, a long course of exercise. Nevertheless, the habit should be early produced of caution in receiving or in drawing inferences. We would never have children suspect the accuracy of their parents; but we should shew them in what they hear (if it can be done with prudence), and still more in their own little reasonings, those defects which their minds are sufficiently cultivated to perceive. And without giving rise to a habit of suspicion, (which sometimes is as injurious as a habit of presumption,) we should aim to lead them to take as many circumstances as possible into account, and not to be too decided with respect to inferences which may be drawn from them. If a child once feels that he has inferred too much, it will effectually keep him, for a time at least, from presumption, especially in opposition to the inferences of others.

In order to acquire that freedom from the influence of authority which is often necessary to success in the pursuit of truth, it is requisite that children be accustomed, and encouraged, to state their difficulties and objections against any reasoning or allusion which they hear or meet with in books. We have no wish to see the habit of objecting for the sake of objecting; but those are the most likely to acquire it, who have been accustomed to think but little when young, and to take every thing upon trust. Having believed every thing upon authority, when their minds acquire some degree of independence and activity, they usually find, or think they find, that many of those things which they have believed are inconsistent with truth, and they feel a kind of general suspicion, with respect to all which they have been accustomcd to believe; and the confusions often are highly injurious both with respect to the understanding and the conduct. Though we wish to see an unbounded confidence in parental declarations, and unlimited submission to parental authority, yet a parent should employ each only for the good of his children. It will not excite suspicion, if he sometimes lead them to perceive, that he is not equally sure of every thing that he tells them; that when they grow older they will perhaps understand some things better than himself; and that at any time they must learn to think for themselves, since he shall not always be at hand to instruct and guide them. He will always point out, or, what is better, lead them to find out, errors in reasoning, &c. in the books which they read, especially though the writers were men of great eminence. He will accustom them to think for themselves; but at the same time he will make them understand that they are not to reject every thing because they see that some things are erroneous. If the mind have been rightly trained, while its education is principally conducted by others, things will go on well when the individual has, as it were, to educate himself. If by early discipline, followed up by the well regulated pursuit of useful knowledge, he has been brought into that invaluable state of mind, in which freedom of thought is united with caution, and a tendency to suspect one's own conclusions, at least as much as those of others, it may reasonably be expected that the acquisition of truth will be an easy task, and that the judgment will have that clearness, activity, and correctness, which will enable the possessor to choose important objects, and to pursue them by suitable and judicious means.

X. After all, perhaps, the most important object in early intellectual education, next to the cultivation of the pr
INTELLECTUAL EDUCATION.

ception, is that which respects *Words*: at least, this is of
effential importance. A clear and correct understanding
of the force of words, is of the utmost consequence in
every period of the intellectual progress. On the care which
is early taken in furthering this object, depend, in a great
measure, the future development of the understanding and
the acquisition of knowledge. A well-educated child will
always hesitate to use words which he does not so far un-
derstand as to be able to feel their force in the particular
connection; and in many instances this is all which can be
understood by a child. The names of external objects, are,
of course, the first words which are acquired and under-
stood; and here all is plain. Either the things themselves
can be shewn, and the words connected with them; or pic-
tures can be employed to represent to the mind what cannot
be directly made the subject of perception. In like man-
ner, names denoting the actions of animated objects, and
the changes which take place among inanimate objects, the
sensible qualities of the different substances around, and, in
short, any thing which can be made the subject of direct
sentiment, or can be represented to the sight, are calculated
for the early exercize of the affective power. And it is in
the application of these, that the earliest efforts of clas-
nification are employed. The same name is unavoidably given
to a variety of things or animals agreeing in some parti-
cular; and indeed this circumstance is of the utmost con-
sequence to the progress of intellect. It may be truly said,
that without general terms little knowledge could be ac-
quired, that there would be almost a total stop to every pro-
cess of mind not immediately depending upon sentiment.
In the first periods of language the business of classifica-
tion, and the application of general terms, went on to-
gether; the processes of classification are now, however, in
innumerable instances, directed by the customary mode of
applying the terms. Still the application of them is ac-
 companied with classification; and when the mind is, in
some instances, a little familiarized with the operation, it
acquires, with great ease, the mode of applying general
terms in others. This is an excellent and important exer-
cise of the judgment; and it leads to notice circumstances
of agreement and circumstances of difference, which is in
itself a highly useful employment of the understanding. In
some instances children cannot but be puzzled, either by
the unavoidable irregularities of language, or by the ap-
plication of terms depending upon little niceties which can-
not be expected to lie within the sphere of their observation;
but wherever the grounds of the application can be shewn,
it will always furnish a useful exercize of the mind to be led
to observe them as such.

We have already referred to the great importance of the
mathematical sciences in training the mind to habits of correct
reasoning; indeed it is by the various acquisitions of knowl-
dge, that the different mental faculties are developed and
cultivated; and we fully expect the concurrence of our
readers when we say, that an early and accurate acquaint-
ance with our arithmetical notation and numeration, is pecu-
larly calculated to lay the foundation of habits of preci-
ion, of arrangement and classification. Our notation took its rise
in the necessities of circumstances, operating upon those
powers and qualities of mind which are possessed by every
human being; but it is an object worthy of the attentive
examination of the philosopher, while, at the same time,
from its distinctness and simplicity, it serves as a most im-
portant exercize to the juvenile understanding. A child,
early made familiar with the simple operations of arithmetic,
(taught, not technically, but by a constant reference to
the principles on which they are founded, and particularly to
those of the notation, on which in short the whole depends,) can
scarcely fail to form some precise ideas, and to acquire
a tendency to arrangement and method, which will almost
invariably lead on to a similar employment of the understand-
ing in other circumstances. It may not perhaps be known
to all our readers, that there is an excellent philosophical work
of Condorcet, which will furnish some highly valuable in-
formation to the intelligent parent, on the best means of
communicating an acquaintance with the first principles of
arithmetic. It is entitled, "Moyens d'apprendre un com-
ptement sans et avec facilite." If it were more the object of early
culture to cultivate the faculties of the mind, rather than
to store the memory with words, or with ideas, which are of
little importance enough, so far as they are made an exercize
of the understanding, this little tract would not have been
so long left inaccessible to the mere English reader. The
French editor judiciously remarks, that the first thing which
distinguishes these elements of arithmetic, is, that they are at
the same time the elements of the art of reasoning. The
usual formulæ of arithmetic are founded upon principles and
processes which can generally be made intelligible to those
who are capable of employing them; but the formulæ do
not of themselves sufficiently exercize the understanding:
they are a species of machinery with which we operate almost
mechanically. But in so far as those principles and processes
are made intelligible and familiar, the judgment is cultivated,
the reasoning powers are exercized, distinct ideas are gained,
and the commencement made of those intellectual operations
and habits, which are subordinated to the highest pursuits
of knowledge, and to the best conduct of life.

While we thus recommend the early employment of
the understanding upon numbers, we ought not in justice to our-
seftes to omit mentioning, that natural history furnishes
ample scope for the exercize of the intellect on things, on
words, and in classification; and in some respects it is a more
useful object of early mental culture; it brings into exercize
the habit of observation, while it equally requires and more
rewards the attention; it gives more room for the exercize of the
memory, and is more calculated to set the mind at work,
and supplies more numerous and interesting subjects for its
operations. "The art of forming a found and active under-
standing," says Miss Edgeworth, "consists in a due mixture
of facts and reflection." Dr. Reid has, in his Essay on the
Intelllectual Powers of Man, p. 297, pointed out, with great
ingeniousness, the admirable economy of nature in limiting the
powers of reasoning during the first years of infancy. This
is the season for cultivating the senses, and whoever, at this
early age, endeavours to force the tender shoots of reason,
will repent of his rashness. We have not yet been able to
meet with the passage to which Miss Edgeworth refers in our
8vo. edition of Reid; but we are fully convinced that
he cannot go the whole lengths of that philosopher, respect-
ing the degree in which the reasoning faculty is naturally
developed, or rather lies undeveloped: during the *childhood* as
we have already remarked, children reason much more than
is usually supposed; and provided we are cautious in giving
due vigour to the observation and judgment, we may some-
times directly employ the reasoning faculty, under the
restrictions which we have already pointed out. In hands, how-
ever, it is better to be satisfied with those processes of
reasoning, where, where the mind is healthy, will almost
invariably follow the exercizes of the observation and recollec-
tion, and make no direct effort to cultivate the reasoning
faculty, than to aim to bring it forwards prematurely; and
it was with a view to this principle, that we have thought it
defirable to subjoin the foregoing remarks to what we have
said on attention to numbers.
INTELLECTUAL EDUCATION.

In many cases the force of words can only be learnt gradually, by their use in various connections; to attempt to explain connectives, for instance, by aligning their abstract force, would be utterly useless to a child; the force of them must be shown in particular cases, and from these the mode of applying them, and the force of them will be learnt in others. Similar remarks may be made with respect to all abstract terms: and provided we are careful ourselves to employ them properly, and to take every opportunity of showing the force of them when level to the capacity or progres of the individual, we do all which is necessary, and probably do better than by attempting to do more.

Though we fully calculate on our readers going along with us, respecting the absolute necessity of early accustomed-the mind to seek for, and to acquire, clear ideas in connection with the signs of ideas, the following remarks of Mr. Locke may serve to corroborate their opinions; and, together with what we shall also quote from Miss More, may lead them to make it an object of daily, indeed constant, aim in the business of education, not merely as of great moment in intellectual cultures, and to smooth the way for intellectual acquisitions, but as incumbent on every one who has in view the moral welfare of his child. "Persons having been accustomed from their cradles," says our great philosopher, "to learn words before they knew the ideas for which they stand, usually continue to do so all their lives, never taking the pains to settle in their minds the determined ideas which belong to them. This want of a precise significations in their words, when they come to reason, especially in moral matters, is the cause of very obscure and uncertain notions. They use these undefined words confusely, without much troubling their heads about a certain fixed meaning, whereby, besides the ease of it, they obtain this advantage, that as in such discourse they are seldom in the right, so they are as seldom to be convinced that they are in the wrong, it being just the same to go about to draw those perons out of their mistakes, who have no settled notions, as to disposses a vagrant of his habituation who has no settled abode. The chief end of language being to be understood, words serve not for that end when they do not excite in the hearer the same idea which they stand for in the mind of the speaker."

"I have chosen," adds Miss More, after making the foregoing extract, "to shelter myself under the broad foundation of the great author here quoted, with a view to apply this rule in philology to a moral purpose; for it applies to the variety of conversation as much as to its correctness; and strongly recommends unqualified and simple truth, as accurate and just explication. Scarcely any one perhaps has an adequate conception, how much clear and correct expression favours the elucidation of truth; and the side of truth is obviously the side of morals; it is in fact one and the same cause; and it is of course the same cause with that of true religion also.

"It is therefore no worthless part of education, even in a religious view, to study the precise meaning of words, and the appropriate significations of language. 'To this end, I know no better method than to accustom young persons very early to a habit of defining common words and things; for, as definition seems to lie at the root of correctness, to be accustomed to define English words in English, would improve the understanding more than barely to know what those words are called in French, Italian, or Latin. Or rather, one use of learning other languages is, because definition is often involved in etymology, that is, since many English words take their derivation from foreign or ancient languages, they cannot be so accurately understood without some knowledge of those languages; but precision of any kind, either moral or philological, too seldom finds its way into the education of women."

If any of our readers with for an exemplification of the method of teaching to define, we refer them, with complete satisfaction, to the excellent little work called "Evenings at Home;" the attentive perusal of which must furnish to the judicious parent, many useful reflections and hints calculated to facilitate his views in intellectual education. We may mention in passing, that we cannot but consider it as a duty which the respectable author owes to the public, to make those alterations in the chemical articles which may adapt it more to the present state of the science; and we are persuaded that he could not render a more useful service to the rising generation, than by some supplementary volumes on other points of natural history and physiology, and natural philosophy, calculated, as those preceding eminently are, to convey clear ideas, and to exercise the understanding. We need scarcely add, that the mathematical sciences furnish most important lessons in the art of defining, and some of the finest and most useful specimens of it.

With respect, however, to the plan of definitions, we must again observe, that in a great variety of instances we must rest satisfied with perceiving that the force of a word is clearly understood in the particular case; and we must sometimes require even less than this. Words which are the most forcible to our minds, in consequence of numerous affected thoughts and feelings, often can scarcely affect the mind of a child. The force of these which represent very complex ideas (as most general terms do), must generally be acquired slowly, by the impressions derived from the manner of their employment, and the infinences of their application. But wherever the force of a word can be explained, so as to be made intelligible, this should be done; and there can be no doubt that the habit should be formed as early as possible, of never resting satisfied without some ideas connected with the words which occur in books on conversation. We have ourselves had an opportunity of observing the great value and force of this habit. A young person, who, in the course of his reading aloud with his early instructor, had uniformly been called upon to try to explain the meanings of words, and in case of failure had as uniformly been sent to search for a suitable explanation in a good dictionary which was always at hand, by degrees became so much accustomed to this exercise of the understanding, that, when arrived at years of maturity, he felt a kind of internal compulsion to refer to the same means of information, when he could not otherwise ascertain to his satisfaction the force of a word in a given situation, which feeling generally overcame the reluctance of indolence, and even the exasperation which so often urges on the ardent mind towards that which is yet unexplored. The effect of such discipline upon the habit of discrimination and clearness of intellect need not be pointed out. It can scarcely fail to bring the mind into the right frame for the search after truth; and even if only defective ideas are thus acquired, yet if correct as far as they go, the grand point is gained. After such habitual culture of the mind, the want of something upon which the understanding may rest with satisfaction is constantly felt; and if the whole truth is not grasped, the acquisitions actually made will usually be on the side of truth.

It appears highly inexpedient to attempt, in the early periods of the mental progress, to give the most comprehensive meanings of words. The first business in the early acquisition of knowledge, is to begin with individuals, and after a suitable acquaintance has been gained with them, to
go on to general facts and statements. In like manner with respect to words, it is sufficient if we can give a clear idea of the signification of a word as it occurs; it will afterwards be an excellent employment of the understanding to combine these meanings together, so as to generalize the term; and where the mind has been well cultivated, this will be done almost without our direct efforts. But it should not unfrequently constitute a direct exercise in the more advanced periods of education, to trace out that common signification which a word has throughout all its varieties of signification; and previously to this, it is desirable to accustom the young to expect that the particular force of a word which they have acquired is by no means the only one, and to be ready to receive the change of meaning which the circumstances of the connection may require, or which the writer may, by his definitions, endeavour to communicate to his readers.

The wrong application of words is one of the chief obstacles in the acquisition of knowledge, and constitutes the cause of some of our earliest and strongly prejudices. By the magic power of association, not only do the connections of ideas suggest combinations of words, but combinations of words, in innumerable instances, produce combinations of ideas. And this ought to furnish to the early instructor, a powerful motive to caution in the employment of words; so that, in his communications with his pupils, he may avoid, not only those modes of expression which are in themselves calculated to convey wrong ideas, but those also which may convey wrong ideas in consequence of the partial knowledge possessed by those who bear them. It should be a leading object, in every department of education, since it is totally impossible to give full and complete ideas, to render those which we can communicate clear and correct. Where this object is steadily pursued, the understanding may be expected for itself to seek, and will, in all probability, acquire all which is necessary beyond.

But notwithstanding all the care and self-culture of parents and instructors, numerous erroneous associations will be formed or imbibed, which will warp the judgment from the perception of truth, and sometimes obscure it. A large proportion of them operate through the medium of the affections; and some attention will be paid to these under the head of Moral Education; but still many remain which arise from the ambiguities of language, from partial observation, from accidental combinations of external objects, &c. These will often give way to the gradual development of the mental faculties, and the acquisition of knowledge; but sometimes these irregular associations will continue for a long period to perplex and muddle the understanding. It is highly desirable, therefore, to watch for them, and, when they are discovered, to take suitable means for destroying them. When we perceive a want of readiness to admit obvious truths which are level to the progress of the intellect, we may usually conclude that some incorrect idea has been connected with the words employed. Sometimes the immediate end may be gained by a change of words; but it is, perhaps, generally preferable to endeavour to enter into the little mind and trace its errors and their fountains. We remember often discovering that a child had formed the preposterous idea, that the dui which flies about in the road is in part composed of the particles of the human body; an idea derived (by some process of reasoning, which we do not now recollect, aided no doubt, by an effort of the imagination,) from impressions received from the words in the burial service, “dust to dust.” Here, and in similar cases, to discover the link and to separate it, are almost the same thing. It is one great advantage of domestic education, that it enables the parent or instructor to watch over the early associations, and to prevent the formation, or effect the diffusion, of many which are injurious to the acquisition of knowledge, and what is still more important, unfriendly to the moral judgment, and to the happiness of the individual. To have the power of averting themselves from this advantage, however, parents must accustom their children to view them as friends, to open their little minds to them with the utmost confidence; they must treat their erroneous judgments with mildness, and be habitually careful in their own modes of expression in their presence, and especially in their direct communications with them.

Before quitting the subject of words we would add, that it is very desirable to accustom children to the peculiar terms of science and art, as soon as they can understand their meaning. In very many instances this can be done with ease, not as a formal object, but in the course of conversation, or while explaining what is met with in books. When the terms are become familiar, and are pretty well understood, the difficulties attending the acquisition of many science are greatly lessened. Even familiarity with the mere words employed, is of some service when we begin a new branch of knowledge; but in many cases even clear ideas may be early obtained in connection with scientific language, which will efficiently prepare the way for future progress. Supposing for instance, the leading terms of geometry are early explained, by means of figures or models, not only will the understanding receive some exercise by the acquisition of distinct ideas in connection with words, but it will be ready whenever the reasoning powers are sufficiently matured to be directed to geometry, to enter upon the field without the perplexity which is so often produced by the multitude of new words as well of new ideas. The utmost care should, however, be taken to make our explanations correct as far they go. If possible, children should have nothing to unlearn; and though we cannot effect this completely, yet more depends than is usually supposed upon those who have to guide the early associations and mould the habit; and the least error enters the mind, the more readily will truth find admittance.

XI. “It is more likely,” says Miss Edgeworth, “that evil should be engraven upon judgment, than that judgment should be engraven upon wit.” Numerous excellent observations may be found in her Practical Education respecting the cultivation of the understanding; we shall conclude what we have advanced on the subject, by quoting her very judicious remarks on the subject of the early cultivation of wit.

“We have advised, that the judgment of children should be exercised upon the objects of their senses. It is scarcely possible that they should reason upon the subjects which are sometimes proposed to them; with respect to manners and society, they may have had no experience, consequently they can form no judgment. By imprudently endeavouring to turn the attention of children to conversation that is unfitted to them, people may give the appearance of early intelligence, and a certain readiness of repartee and fluency of expression; but these are transient advantages. Smart, witty children amuse the circle for a few hours, and are forgotten; and we may observe, that almost all children who are praised and admired for sprightliness and wit, reason absurdly, and continue ignorant. Wit and judgment depend upon different and opposite habits of mind. Wit searches for remote resemblances between objects or thoughts apparently dissimilar: Judgment compares the objects placed before it, in order to find out their differences rather than their resem- blances.
INTELLECTUAL EDUCATION.

writer, “any object of compassion;—a man, for example, reduced by misfortune from early circumstances to indigence. The one feels merely in proportion to what he perceives by his senses. The other follows, in imagination, the unfortunate man to his dwelling, and partakes with him and his family in their domestic distresses. He listens to their conversation while they recall to remembrance the flattering prospects they once indulged; the circle of friends they had been forced to leave; the liberal plans of education which were begun and interrupted; and pictures out to himself all the various resources which delicacy and pride suggest, to conceal poverty from the world. As he proceeds in the painting, his sensibility increases, and he weeps, not for what he sees, but for what he imagines. It will be laid, that it was his sensibility which originally roused his imagination; and the observation is undoubtedly true; but it is equally evident, on the other hand, that the warmth of his imagination increases and prolongs his sensibility.

The foregoing observations may account, in part, for the effect which exhibitions of fictitious distresses produce on persons who do not discover much sensibility to the distresses of real life. In a novel or a tragedy, the picture is completely finished in all its parts; and we are made acquainted, not only with every circumstance on which the distress turns, but with the sentiments and feelings of every character with respect to his situation. In real life we see, in general, only detached scenes of the tragedy; and the impression is light, unless imagination supplies the characters, and supplies the incidents that are wanting.

It is not only to scenes of distress that imagination increases our sensibility. It gives a double share in the property of others, and enables us to partake, with a more lively interest, in every fortunate incident that occurs either to individuals or to communities. Even from the productions of the earth, and the vicissitudes of the year, it carries forward our thoughts to the enjoyments they bring to the sentient creation, and by interregling our benevolent affections in the scenes we behold, lends a new charm to the beauties of nature.

I have often been inclined to think, that the apparent coldness and selfishness of mankind may be traced, in a great measure, to a want of attention and a want of imagination. In the case of misfortunes which happen to ourselves, or to our near connexions, neither of these powers is necessary to make us acquainted with our situation; so that we feel, of necessity, the correspondent emotions. But without an uncommon degree of both it is impossible for any man to comprehend completely the situation of his neighbour, or to have an idea of a great part of the distresses which exist in the world. If we feel therefore more for ourselves than for others, the difference is to be ascribed, at least partly, to this, that, in the former case, the facts, which are the foundation of our feelings, are more fully before us than they possibly can be in the latter.

The power of forming vivid and accurate conceptions is an important acquisition; but the true foundation of it is only to be laid in clear distinct perceptions; and if the imagination early gain such influence as to call off the mind from observation, the most injurious effects may be expected to follow. The exercise of the imagination, (including, as is generally done, what Mr. Stewart denominates the conception,) is necessary to enable us to enter into the reasonings of the Philosopher, where these respect individuals, as well as into the pictures of the poet, and the details of history. In reference to this last head, we may be allowed here to mention, that the conception aids the cause even of religious truth: for he who is not able, or who does not take the trouble,
trouble, to picture to the mind's eye the statements of the gospel historians, will not have his judgment suitably affected with the reality of the facts which they record, nor will his affections be warmed as they ought to be by the contemplation of the character, which, with the most artless simplicity, they pour out.

Like the memory, though in a different way, the imagination should be made a subervient faculty; and the early cultivation of it must depend upon the tendency which we perceive to the exercise of it, and the degree in which it is likely to gain ground among the intellectual faculties. If the conceptions are very lively, and we perceive a tendency to dwell upon them instead of the objects of perception, our aim must be to invigorate the observation, to cultivate the judgment, and, as much as possible, to turn the efforts of the imagination into the channel of philosophical invention. If, on the other hand, as is sometimes the case, either from early neglect of the observation, or a want of what may perhaps be properly called physical feebility, the conceptions are very dull, and the mind seems unable to enter into anything which cannot be made the object of perception or abstract reasoning, it is perhaps desirable, with caution, to stimulate the imagination: and in this view the following remarks of Mrs. More appear to us to deserve the attention of all who are concerned in education.

"I would not however prohibit such works of imagination as suit this early period. When moderately used, they serve to stretch the faculties and expand the mind; but I should prefer works of vigorous genius, and pure, unmixed fable, to many of those tame and more affected moral stories which are not founded upon Christian principle. I should suggest the use on the one hand of original and acknowledged fictions; and on the other, of accurate and simple facts; so that truth and fable may ever be kept separate and distinct in the mind. There is something that kindles fancy, awakens genius, and excites new ideas in many of the bold fictions of the East. And there is one peculiar merit in the Arabian and some other oriental tales, which is that they exhibit striking, and, in many respects, faithful views of the manners, habits, customs, and religion of their respective countries; so that some tincture of real local information is acquired by the perusal of the wildest fable, which will not be without its uses in aiding the future associations of the mind in all that relates to Eastern history and literature."

The imagination should early be employed in what is its peculiar field, invention. We do not of course mean, that which has for its object to form combinations with the sole view of pleasing the fancy or gratifying the taste; but that which has in view contrivances to facilitate the purpoes of life, and the acquisition of science. We by no means wish to be understood, that in the early part of education, (and still less in the later,) the imagination should never be actively employed on works of fancy and taste; but in a general way it should be laid down as a principle, that the solid and useful qualities of the mind should be cultivated first, the ornamental as a secondary object. The ingenuity and little inventions of children should be encouraged; and where sufficient scope is given for the play of the faculties, and there is no physical caufe to prevent activity of mind, not a day will pass, even at a very early age, without some employment in which the inventive power of the imagination is concerned. The inventions of children generally arise, in the first instance, from necessity; but, in their little diversions, they often display, (of course, in a low degree,) the excellence of those qualities by which the most important combinations and inventions have been effected. As they advance in mental culture, this exercise of the imagination should be more and more submitted to the guidance of the judgment. Many of the literary and scientific pursuits to which the young are directed, have a tendency to cultivate a philosophical imagination; and they furnish numerous opportunities, which a judicious instructor will carefully employ, of calling forth and exercising in the most important operations.

Some young persons, we must be contented to allow to pass through life, satisfied if we can make them comprehend the combinations and inventions of others; but it is very seldom, where the mind is active and unshackled, and has been properly stimulated and employed by the usual objects of mental pursuit, that it will rest here. Either in the manner in which it attains to its conclusions, or in which it tries and applies them, or in the conclusions themselves, it will leave the track which may have been beaten by others, and shew the exercise of invention. Novelty ought never to be our object, but truth; but it is pleasant to see any indication of ingenuity; and it should be remembered, that combinations and inventions which are not absolutely new, may be so to the individual.

We shall now finish this head with a few more remarks from Mr. Stewart, which may serve as a refarming check upon the irregular or excessive exercise of the imagination; and may lead the judicious parent to the conclusion with which Mrs. Edgeworth ends her chapter on the imagination, that it is a good servant but a bad master.

"It was undoubtedly the intention of nature, that the objects of perception should produce much stronger impressions on the mind than its own operations. And, accordingly, they always do so, when proper care has been taken in early life, to exercise the different principles of our constitution. But it is possible, by long habits of solitary reflection, to reverence this order of things, and to weaken the attention to sensible objects to so great a degree, as to leave the conduct almost wholly under the influence of imagination. Removed to a distance from society, and from the pursuits of life, when we have been long accustomed to converse with our own thoughts, and have found our activity gratified by intellectual exertions, which afford scope to all our powers and inductions, without exposing us to the inconveniences resulting from the multitude of life, we are apt to contract an unnatural predilection for meditation, and to lose all interest in external occurrences. In such a situation too, the mind gradually loses that command which education, when properly conducted, gives it over the train of its ideas; till at length the most extravagant dreams of imagination acquire as powerful an influence in exciting all its passions, as if they were realities.

"When such disorders of the imagination have been long confirmed by habit, the evil may perhaps be beyond a remedy; but in their inferior degrees, much may be expected from our own efforts; in particular, from mingling gradually in the business and amusements of the world; or, if we have sufficient force of mind for the exertion, from resolutely plunging into those active and interesting and hazardous scenes, which, by compelling us to attend to external circumstances, may weaken the impressions of imagination and strengthen those produced by realities.

"When a man, under the habitual influence of a warm imagination, is obliged to mingle occasionally in the scenes of real business, he is perpetually in danger of being misled by his own enthusiasm. What we call good sense in the conduct of life, consists chiefly in that temper of mind which enables its possessor to view at all times, with perfect coolness and accuracy, all the various circumstances of his situation; so that each of them may produce its due impression on
on him, without any exaggeration arising from his own peculiar habits. But to a man of an ill-regulated imagination, external circumstances only serve as limits to excite his own thoughts, and the conduct he pursues has, in general, far less reference to his real situation than to some imaginary one, in which he conceives himself to be placed; in consequence of which, while he appears to himself to be acting with the most perfect wisdom and confidence, he may frequently exhibit to others all the appearances of folly.  

XIII. In every branch of instruction, and in the mode of conveying it, our first consideration should be, its effect upon the understanding. The mental habits formed, rather than the number of ideas acquired, should be considered as the leading object of attention. We have already intimated, that in a subsequent article we shall have an opportunity of fudging some observations relative to the manner of communicating knowledge, particularly of the scientific clats; and we shall conclude our present article with some remarks which may affit in the appreciation of the value of the common objects of instruction in farthering the cultivation of the intellect, supposing that the best modes of conveying them to the mind have been successfully ascertained. We shall not attempt to follow the natural order of them; but shall be guided by that which appears most suitable to our object.

The acquisition of the dead languages forms a leading employment in education; and we trust it will be long before it ceases to be so, though we cannot but regret that it should ever be made an exclusive object. Those who know the intimate connection which subsists between the real command of words, and the noblest exercises of the understanding, will readily allow that the study of language forms a most important auxiliary in intellectual culture. We shall have occasion to specify hereafter what plans of education the study of the classics should be limited; and this will lead us to enter more at large into the importance of the object. We shall content ourselves therefore, in this place, with stating that the general advantages of this branch of instruction are, the cultivation of the habits of patience, of attention, of investigation, of accuracy, of discrimination, and of ingenuity; the possession of a key to the ideas contained in those languages; greater power in the use of our own; and the acquisition of numerous data for that branch of mental philosophy which respects languages.

Geography exercises the memory, and were it only for its subserviency to history, would be highly valuable; but it has other advantages. It may be made the vehicle for various topics of information, and from these adjuncts, it acquires a rank in the scale of utility, to which, separately considered, it would not be entitled. Independently of this, the habit of associating names with things, and of arrangement, which seems likely to be formed by learning geography, entitle it to a place in the early part of education.

"We use the word in its exact though confined sense; and considered as comprehending its adjuncts, the study of it is very important. It leads the mind beyond the narrow sphere of its own observation, enlarges its comprehension, and weakens its prejudices; it forms an interesting link between mere sensation and abstract speculation; it raises the mind above the former, and cultivates and inflates for the latter. Here, however, it obviously borrows its principal utility from what rather comes under the head of civil or natural history, or of natural and mental philosophy."

Natural history, in its various branches, being principally concerned about things, is well adapted for the early stages of mental culture. The study of it forms habits of observation, of attaching distinct conceptions to words (and of frequently of using words correctly), of classification, and of attention to objects not connected with self. In all the stages of mental culture, these ends are answered; it gives additional interest to surrounding objects, and leads us to view them as the works of the great Author of nature. We must add here the words of one of our ablest naturalists, in his introduction to his favourite science. "I would recommend botany for its own sake. I have often alluded to its benefits as a mental exercise, nor can any exceed it in rousing curiosity, gratifying a taste for beauty and ingenuity of contrivance, or sharpening the powers of discrimination. What, then, can be better adapted for young persons? The chief use of a great part of our education is no other than what I have just mentioned. The languages and the mathematics, however valuable in themselves when acquired, are even more so as they train the youthful mind to thought and observation. In Sweden, natural history is the study of the schools by which men rise to preferment; and there are no people with more acute or better regulated minds than the Swedes."

Mathematical science forms a higher step in the gradation of mental culture. The lowest branch of it is arithmetic. Learnt merely as an art, it is not without its utility in the culture of the mind. We, however, consider it as more comprehensively studied, or rather as taught with further views. The commencement of habits of clear perception, of abstraction, of regularity and correctness in practice, of acuteness, of using definite means in order to obtain definite ends, and of acting upon general rules, may reasonably be expected from the proper mode of learning this science. It then becomes an introduction to scientific investigation; and in this view it is peculiarly valuable, from the exact arrangement of our notation, and the certainty of the results of our operations. Algebra perplexes nearly the same advantages, and in addition to them, others more important to a higher degree of mental culture. It generates the power of invention and combination, and it accustoms the mind to general reasoning, at the same time leaving it the power to check and correct that reasoning at every step. Geometry forms a habit of clear and cautious reasoning. It serves as a corrective to the wild flights of imagination, and gives proportionate vigour to the judgment. The higher branches of mathematical science refine, in their effects upon the mind, the one of these elementary branches which they most resemble in their mode of investigation. "I there were nothing valuable in the mathematical sciences for the uses of human life, yet they are well worth our study; for by perpetual examples they teach us to conceive with clearness, to connect our ideas in a train of dependance, to reason with strength and demonstration, and to distinguish between truth and falsehood. Something of these sciences should be studied by every one; and that, as Mr. Locke expressd it, not so much to make us mathematicians, as to make us reasonable creatures."

Another source of the utility of the mathematics, is their subserviency to natural philosophy. To delineate the phenomena of the universe, to investigate their causes and the connection of these causes, are the principal objects of this science. To mention these objects, is nearly all which is necessary to indicate its valuable effects on the mind. The habits of accurate and persevering observation, of investigation, of abstraction, and of correct reasoning, are more or less produced and cultivated by the study of the philosophy of nature. It furnishes abundant scope for the most sublime speculations, and calls forth the noblest exercises of the imagination, yet remains the mind within the limits of reality. It carries us beyond the bounds of sense.
leffens our interest in self by increasing our concern with every thing around us. It enlarges the comprehension of the soul; for it offers for contemplation the laws of the universe. It prepares the student for acquaintance with the human mind; for the strictness with which its investigations are conducted, prevents that wildness of theorizing which is the bane of science, and forms the habit of cautiously attending to phenomena, in order to ascertain the general laws which regulate them. It aids the cause of religion; for it accustomed the mind to seek for the causes of observed appearances, and leads it from design and regularity to infer an intelligent First Cause.

History produces or cultivates the habit of purifying with accuracy a series of connected events or phenomena; of tracing causes from effects, and of observing the operation of causes, either singly, or in their various combinations. The student is concerned about realities, and his judgment is corrected; the web he contemplates is not unfrequently intricate, and his penetration is exercised in unfolding it. He observes the flow operation of moral causes, and he learns patience as to the result of his exertions for the good of others; he sees the efficacy of minute causes operating in conjunction with predisposing circumstances, and he learns prudence in the direction of those exertions. The enlightened study of history prevents the formation, or promotes the eradication of those prejudices which narrow the comprehension of the mind. "There is scarce any folly or vice," says lord Bolingbroke, "more epidemic among the sons of men, than that ridiculous and hateful vanity, by which the people of each country are apt to prefer themselves to those of any other, and to make their own customs and manners, and opinions, the standard of right and wrong, of true and false." This prevents an effectual bar to improvement in the great social concerns of man; and it is apt, perhaps necessarily so, to be accompanied with contracted views of the qualities of those who differ from us in their religious or political sentiments. Now what in one case destroys the illusion tends to displace it in the other. He who has learnt to view the qualities and actions of other nations as not to be despised because unlike those of his own, places himself out of his little narrow sphere of self, and gains a comprehensive habit of thought, which will prevent him from refusing to admire those qualities and actions, which can flatter the tell of reason, in bodies of men, or in individuals who differ from him in their modes of thinking. The study of history is well adapted to the cure of those prejudices. Accustomed to contemplate the history of other nations, to view them in their mutual dependencies and connections, for a time to make their interests our own, we learn to regard the community of which we form a part as itself a part of a still greater community, and without becoming indifferent to its welfare and its excellencies, we acquire the power of discerning the value of opinions and practices which are of foreign growth.

The study of composition derives its value, partly from facilitating our own practice, and partly from putting it in our power, more fully to feel and to appreciate the beauties of the best authors. The practice of composition is highly valuable, because it enables us to benefit others by our mental attainments; to judge of the extent and solidity of those attainments; to command our knowledge; and to make that knowledge clear and substantial. Habits of correct composition are almost necessarily productive of precision in our ideas, of perspicuity in our reasonings; they prevent their perversions from rolling satishe with superficial notions; and they force them to think closely.

The highest scientific object to which the young can be directed, and what indeed should form the last art of education, is mental philosophy, or the philosophy of the human mind, that science which teaches us the laws of our mental frame, which draws us the origin of our various modes and habits of thought and feeling; how they operate upon one another, and how they are cultivated or repressed. The well-directed study of it calls into action and improves the highest intellectual faculties; and while it employs the powers of the mind, it suggests the best means for their culture, and the best mode of their direction. It enables us to trace the intricacies of our own hearts, and points out the proper discipline for their correction. It discovers to us the real excellencies of the mind, and guides us in our efforts for the attainment of them. To success in forming the moral and mental character of others, it is more or less essential; for it disclosesthe nature of our influence over their minds, and the best mode of exercising it so as to bring their various faculties into the best adjusted and most perfect state. Purposed with proper views, and in a proper manner, it lays the best foundation for the highest degrees of intellectual, moral, and religious improvement.

"There are difficulties," to use the words of the great Hartley, "both in the word of God, and in his works; and these difficulties are sometimes so magnified, as to lead to scepticism, infidelity, or atheism. Now the contemplation of our own frame and constitution, appears to me to have a peculiar tendency to lessen these difficulties attending natural and revealed religion, and to improve their evidences, as well as to concur with them in their determination of man's duty and expectations."

The best ground-work for the pursuit of mental science is an accurate judgment, a discriminating, penetrative intellect, and a habit of correct and cautious reasoning; and therefore the best preparatory culture of mind is the study of the various branches of the mathematics and of natural philosophy. But habits of reflection, and good fene, are all which is essential to the beneficial pursuit of mental science; and with these, it will in all cases lead to results highly important to individual welfare and usefulness. The young in particular will be led, by an acquaintance with the practical laws of the mind, to perceive how their present conduct affects their future character and happiness; to perceive the importance of avoiding a frivolous employment of their time without any end beyond mere amusement; to perceive the imposibility of indulging in vicious gratifications without lessening their means of happiness, and checking their progress towards excellence. They will learn how habits are formed, almost imperceptibly, and, when long exercised, how exceedingly difficult it is to eradicate them; they will learn to consider the formation of habits, as requiring, therefore, their utmost circumspection. They will be enabled to discern what habits of thought and feeling are benefial, what useful; what means of happiness should be regarded as of primary value, what should be regarded as secondary only. In short, there can be no hesitation in affirming, that, next to the immediate pursuits of religion, to which the laws of the mind direct, a judicious acquaintance with those laws is the most important means for the right employment of that period of life on which the happiness of our existence in a great measure depends.

I N T E L L I G E N T  T h i n k i n g.  S e e  T h i n k i n g.

I N T E L L I G E N T, any thing capable of being understood, or conceived, by the mind.

Philosophers have invented certain beings which are purely intelligible, and only fitting in the understanding: such are the sola rationis, universal ideas, and other chimeras. The
INT

The intelligible, or intellectual world, is the idea of the world in the divine mind, frequently spoken of by Malebranche.

INTEMPERIES, in the Galenical and Humoral Pathology, the same with dyspepsia, dysphagia, and the opposite of temperament, or temper, crafts. As health was supposed to consist in the proper temperament, or proportion of the four qualities of hot and cold, dry and moist; so the intemperies, or disproportionate prevalence of any one or two of these qualities, or of the four humours, in which they were supposed to be particularly inherent, was deemed the origin of all diseases; and according to the suppos’d predominance of this or that quality or humour, each morbid intemperies received its name. Thus, when heat or bile prevailed, it was called intemperies calota, or biliosa; when cold and phlegm, intemperies frigida, and pituitofa; and so on. (See Semmert, Inl. Medicine, lib. ii. cap. 3.) See HUMORAL Pathology, and GALEN.

INTENDANT, one who has the conduct, inspection, and management of any thing.

There is a little frequent among the French: they have intendants of the marine, who are officers in the sea-ports, whose business is to take care the ordinances and regulations relating to sea-affairs be observed; intendants of the finances, who have the direction of the revenues; intendants of provinces, who are appointed by the king to take care of the administration of justice, policy, and finances, in the provinces; also, intendants of buildings, of houses, &c.

INTENDMENT OF LAW, the sense, intention, or true meaning of the law.

The judges ought to judge according to the common intendement of the law.

INTENTIONS OF CRIMES. In cases of treason, intention proved by circumstances is punishable as if it were put in execution. So likewise, if a person enter the house in the night-time, with intent to commit burglary, it is felony; and an assault on the high-way, with an intent to commit burglary, is felony, and punished with transportation, 23 Car. II. c. 1. 7 Geo. II. c. 21.

INTENSIO, Lat. Intenso, Ital. Intenso, in Mufic. Intemperate sounds are such as are produced with the greatest force, which are loud, and heard at the greatest distance. They are such sounds likewise, as are produced from strings of greatest tension, and which, on that account, vibrate more powerfully.

INTENSION, a term frequently used by the Greek and other ancient writers on music: intentions of the gravitas, were the major harmonics of the accent, in the defending major scale of the gravitas, according to M. Overend’s Manuscripts in the library of the Royal Institution, vol. vi. p. 7, also, vol. ii. p. 213, in which volumes much information on this curious, but almost obsolete subject, will be found.

INTENSIONE, in Law, a writ which lies against him who after the death of the tenant in dower, or tenant for life, and holds out him in the reversion, or remainder.

INTENSIONE, Ital. as prima intensione, in Musci, as well as painting, implies a sketch, a subject, a first design.

INTENSUM DIATONUM. See DIATONIC and GENUS.

INTENT, in Civil Law, signifies to begin or commence an action, or proceed.

INTENTION or INTENSION, in Medicine, that judgment or method of cure, which a physician forms to himself from a due examination of the symptoms.

INTENTION, in Physics, the increase of the power, or energy, of any quality; as heat, cold, &c.

By which it stands opposed to remission; which signifies its decrease, or diminution.

INTENTION, in Metaphysics, denotes an exertion of the intellectual faculties with more than ordinary vigour; when the mind with earnestness fixes its view on any idea, considers it on all sides, and will not be called off by any solicitation.

The schoolmen also speak of terms of first and second intention.

INTENTION, a Term of First, is that which signifies a thing; the primary design of men, in establishing words, being to express things, or the ideas they have of things.

INTENTION, a Term of Second, is that which does not signify a thing, but another term, or sign.

Thus, a tree, a man, &c. are terms of first intention; and the terms in rhetoric, grammar, &c. as figure, kind, &c. are terms of second intention.

INTENTION, Intentio, in the Ancient Music, was used to denote the passage of the voice from grave to acute.

INTENTIONAL QUALITIES. See QUALITIES.

INTER CUM et LUPUM, in Law, words used formerly in appeals, to signify that a crime was committed in the twilight, &c. See inter deum et naturam, &c. This part of a day has derived other denominations: thus, in some parts of England, they call it mock-shadows, corruptly mock-shade; and, in the north, day-light’s gate; others say, lewain bowk and buzzard.

INTERAMNA, or INTERAEMNII, (Terrae) in Ancient Geography, a town of Italy, situated in Latium, very near Campania, on the river Nar, which, from its source to its mouth, served as a boundary between the countries of the Sabines and Umbrians.

INTERCALARY DAY, denotes the odd day inserted in the leap year. See BISEXTILE.

The word is derived from the Latin intercalaris, of cake, calars, which anciently signified, to call with a loud voice: an intercalary day, among the Romans, signifying a day inserted between two other days; which, for that reason, was proclaimed by the priests with a loud voice.

INTERCALATION. See INTERPOLATION.

INTERCAPSULARIA, in Anatom., a name given by some writers to the cavities between the scapula and the vertebra.

INTERCEPTED ANXS, in Conic Sectio, is the same with what is otherwise called the alpha.

INTERCESSION, INTERCESSIO, was used in Ancient Rome, for the act of a tribune of the people, or other magistrate, by which he inhibited the acts of other magistrates; or, even, in case of the tribunes, the decree of the senate. Veto was the solemn word used by the tribunes when they inhibited any act of the senate, or law proposed to the people. The general law of their intercessions was, that any magistrate might inhibit the acts of his equal, or inferior; but the tribunes had the sole prerogative of controlling the acts of every other magistrate, yet could not be controlled themselves by any.

INTERCESSOR, from inter and cepo, I go between, a perfmer who prays, expostulates, or intercedes, in behalf of another.

In the Roman law, intercessor was the name of an officer, whom the governors of provinces appointed principally to raise taxes, and other duties.

INTERCESSOR is also a term heretofore applied to such bishops as, during the vacancy of a see, administered the bishopric, till a successor to the deposed bishop had been elected. See BISHOP.

The third council of Carthage calls these intercessors.
INT

INTERCIDENT PULSE, a term used by medical
writers to express a fort of pulse, in which between two re-
gular strokes there is perceived a third irregular.

INTERCOLUMNIATION, or INTERCOLEUMNIATION,
in Architecture, signifies the space between two columns.

See the plan of Dinosi, in Plate Architecture.

Vitruvius calls it intercolunium; which, according to
that author, is of five kinds: viz. plicaeyle, A, one diam-
eter and a half; splitly, B, two diameters; cutisyle, C, two
and a quarter diameters, which is the most graceful; diysyle, D,
three diameters; and arcysyle, E, four diameters; which
are explained under their proper heads, Pickonstye, &c.
The intercolumniation, or space between the columns to the
arcade F, is seven and a half diameters; and the inter-
columniun wherein there is a space, G, of only one half a
diameter, is called coupling columns, an invention ascribed
to the moderns.

From a medium, some authors have laid down the follow-
ing proportions; in the Tuscian order, the intercolumniun,
is to be four diameters of the body of the column below ; in
the Doric, three; in the Ionic, two; in the Corinthian, two
one quarter; and in the Composite, one and a half.

INTERCOMMONING is when the commissure of two
margins lie together, and the inhabitants of both have, time
out of mind, caused their cattle to feed promiscuously in
certain areas.

INTERCOSTALES, in Anatomy, the muscles which
fill the intervals of the ribs, and are arranged in two
arrows, distinguished by the epithets of external and internal.
This region of the body includes also the levatores costarum
and triangularis sterni.

The intercostal muscles (intercostales) consist of two
thin muscular planes in each of the intercostal intervals, hav-
ing their fibres disposed obliquely, and attached to the margins
of the ribs, which bound these spaces.

The external intercostal muscles are attached by their upper
edges to the outer border of the lower margins of the ribs,
by means of tendinous and fibrous fibres. Their fibres are
directed obliquely downwards and forwards; and they are at-
tached below by an infection exactly resembling the former
unto the upper edge of the succeeding rib. Various blood-
vessels and nerves penetrate them in different parts of the
trunk. Their origin begins at that part of the rib which is
articulated to the transverse process of the vertebra, and is
continued towards the front as far as the junction of the
bone with the cartilage; beyond this point the intervals of
the cartilages are filled with their aponeurotic fibres, which
have similar attachments and direction to the external inter-
costal muscles.

As the fibres of these external intercostal muscles pass
from above obliquely downwards and forwards, they form
upwards the front acute angles with the upper and obtuse
angles with the lower ribs. The posterior fibres are more
aborad than the anterior. The interval placed under the
first rib, between it and the second, is called the first inter-
costal muscle; and those of the following intervals, accord-
ing to the order in which they succeed, the second, third,
&c., to the eleventh.

The external intercostal muscles are covered on their outer
surfaces by most of the broad muscles of the trunk, as the
two pectorals, obliquus externus abdominis, serratus anticus,
and the serrati postici; and in some degree behind by the
facrombialis and longissimus dorsi. They correspond on
the internal surface to the internal intercostals, from which they
are partly separated by the intercostal vessels and nerves.
Near the vertebral column they are covered by the pleura.

The internal intercostal muscles exactly resemble the former
in situation, attachments, and number. They commence
behind at the angles of the ribs, and extend in front to
the ends of the cartilages. They are attached to the inner
edges of the ribs; and their fibres proceed in an oblique course from above downwards and back-
wards, so as to decussate those of the external inter-
atrium. They form thinner Strata than the external intercostals,
are more tendinous, have their fibres less oblique and con-
sequently rather shorter. Sometimes a fasciculus of one
or two of the internal intercostals passes over one rib
to be fixed into the fcond. These are very irregular in
number, size, and situation, and do not require a separate
description: they have however been noticed as distinct
muscles by the name of jurocoiia.

As the external intercostals only reach to the ends of the
bony portions of the ribs, and the internal do not extend
beyond the angles, a small part of the intercostal intervals
in front and behind is filled only by a single Stratum
of fibres; but the remaining and largest part is closed by two
layers.

The internal intercostal muscles are covered by the ex-
ternal, from which they are partly separated by the vessels
and nerves of the same name. Where the former end in
front, the latter are covered by the thin aponeurosis already
described. They are lined on the outside by the pleura.

The levatores costarum (les transverso-coffitens) are small,
thin, and flat fasciculi of a radiated form, placed behind
the external intercostals, from which they are very distinct.
They are twelve in number, as each rib has one. Each
of these muscles has an aponeurotic origin from the apex of
the transverse processes of the corresponding dorsal vertebrae,
or from the ligament connecting the rib to that process;
its fibres pass obliquely downwards and forwards, and,
growing broader, are attached to the upper edge of the
rib immediately below. The levator of the first rib arises
from the transverse processes of the seventh cervical ver-
tebra, that of the second from the corresponding processes of
the first dorsal vertebra, and so on to the twelfth. They
increase in size regularly from above downwards.

Besides these, each of the two, three, or four lower ribs
has a longer fasciculus, arising from the transverse processes
of the second vertebra above it. These are called levatores lon-
giores, to distinguish them from the former, which are named
breviores. They have thin tendinous origins from the trans-
verse processes, pass over the ribs immediately below these
processes, and are inserted into the upper borders of the suc-
ceeding ribs: thus the first levator longior, arising from the
transverse processes of the seventh dorsal vertebra, is fixed to
the ninth rib.

These muscles are placed between the external intercostals
and the facrombialis and longissimus dorsi.

The triangularis sterni (lerno-coffal, lerno-costien) is a
very thin flattened Stratum, of a triangular figure, placed
between the cartilages of the ribs. It is fixed to the po-
llerior part of the edges of the costal cartilage, and of the
second bone of the sternum, as high as the cartilage of
the fourth rib, by aponeurotic fibres, which cover a con-
 siderable portion of the muscle. The fibrous fibres, directed
outwards and upwards, and more oblique as they are nearer
to the upper part, form at first a continuous broad layer,
and then divide into separate portions attached by thin ap-
neeuroes to the third, fourth, fifth, and sixth ribs. It is
continous below with the transversus abdominis; corre-
sponds in front to the cartilages of the four last true ribs,
to the internal intercostal muscles, and to the mammary vessels;
and behind to the pleura, and for a small space to the
diaphragm.

The
The motions produced by the muscles in this region are the elevation and depression of the ribs, which coincide with inspiration and expiration. The agents of elevation are the levatores and intercostal muscles, besides other auxiliary powers. The former, fixed to the transverse processæ, which are immovable, can obviously exert their action only on the ribs, which they elevate and carry outwards. Thus they increase the transverse diameter of the chest, particularly at its lower part, where, on one hand, the muscles are much stronger, and on the other, in consequence of the greater mobility of the lower ribs, the resistance to be overcome is much less. The action of the intercostals in elevating the ribs is much favoured by the mode of attachment of the first and second of these bones. They possess but little power of motion, and therefore form a fixed point, to which the others can be elevated. They are moreover still further fixed, particularly in deep inspirations, by the scalenæ, which may carry them in a slight degree upwards. Both fixators, although the directions of their fibres are so different, act equally as elevators: in fact, as the upper part of the chest is fixed, the lower portion must be moved by these powers. In great inspirations, other muscles attached to the chest, as the pectorales, serræ, &c. assist the levatores and intercostal muscles in elevating and turning outwards the ribs.

The depression of the ribs, or their retraction from the elevated to their former state, is nearly a passive motion: it depends, in the first place, on the relaxation of the elevating powers, and then on the elasticity of the cartilages connected to the sternum. These are twirled in the act of elevation, and immediately recover themselves when this force ceases to act. When the depression is more considerable, as in coughing, in difficult expectorations, in sneezing, cæsæ in which a strong expiration is required for the purpose of expelling much air from the chest, an active power is exerted for drawing down the ribs. The triangularis sterni, which has its fixed point in the sternum, depresses the cartilages of the true ribs. The abdominal muscles fix below the loofe edges of the false ribs, which thus become a fixed point to which the other ribs may be depressed by the intercostal muscles. Thus the latter muscles are elevators or depressors, according as the fixed point is above or below. Moreover, the quadratus lumborum holds down firmly the last rib; and bears the same relation to that bone in great expirations, as the scalenæ do to the two first ribs in deep inspirations. The serratus inferior politius assists the abdominal muscles on these occasions.

The intercostal muscles and the diaphragm seem to form an exception to that general law of the voluntary muscles, by virtue of which, any muscle after long exercise goes into a state of fatigue, requiring for the reparation of its power an intermission of action, which may be particularly observed in sleep. Now the motions of the chest, beginning and ending with life, are never interrupted. This exception is only apparent; each contraction is succeeded by a proportionate relaxation, and the time of activity of the intercostal muscles equals that of their active state. Moreover, the diaphragm and intercostals mutually supply each other’s places: both are said to be employed in inspiration, but sometimes one and sometimes the others are more actively concerned; so that we may consider them in some degree as alternately acting and resting. The intercostals appear to be the most concerned during sleep, and the diaphragm in the waking state. Indeed a considerable contraction of the latter, in some measure, opposes that of the former intercostals, since it tends to contract the lower cir-

The two flrata of the intercostals may contract separately; thus one may reët while the other is employed. Lastly, the levatores may alternate with the latter muscles: thus, although the motions of the chest are constant, their agents, like all the other muscles of the animal life, may be subjected to the law of intermission of action. Hence, if respiration is considerably hurried, and all the inspiratory muscles are brought into action, they are affected with a real latitude, and at last cannot contract without difficulty. In running, where the blood is carried in great abundance to the heart, and mufıes pass quickly through the chest, we then breathe, which is merely experiencing a difficulty in contracting the expired muscles of inspiration. Respiration is then interrupted, as locomotion would be by a fatigued state of the muscles of the lower extremities: and this may even go so far as to produce a real immobility of the inspiratory muscles. a state, which though not dangerous in other instances; is fatal in the respiratory muscles as it suspends breathing. Examples of animals, and even of men falling suddenly dead after great exertions in running, are not extremely rare. Death occurs in these instances, as when the phrenic nerve or the spinal marrow is divided. Those affections of the chest, in which respirations is hurried for a certain time, occasion at first a real insufficiency of the pectoral muscles; and the difficulty of breathing produced by this tired state of the moving organs, succeeding to that produced by the disease itself, prolongs the painful sensation of suffocation. We must distinguish, in these cases, what belongs to the lung, from that which arises from the muscles. After certain hysteric attacks, in which the diaphragm and intercostal muscles have been violently agitated, a real sense of fatigue is experienced in the chest, which can only be moved with difficulty, and not to a sufficient extent for the production of loud sounds, a phenomenon which may be observed after exercise in running. The muscles require rest before they can expel air in a quantity capable of producing strong and distinct sounds.

**Intercostales Arteriae.** arteries which run in the intervals of the ribs: the intercostales venæ are veins corresponding to these. See Artery and Vein.

**Intercostales Nervi.** are the branches of the spinal marrow in the back, which accompany these arteries and veins. The epithet *intercostales* is sometimes also applied to the great sympathetic nerve. See Nerve.

**Intercus.** a word used by some medical writers, to express that fort of dropy more usually called an anaphora.

**Interdict.** a sentence inflicted by a pope, or bishop, suspending the priests from their functions, and depriving the people of the use of sacraments, divine service, and civil burial.

In common law, interdict is also used in the same sense as in the canon law; where it is defined to be, "censure eclesiastica prohibens administrationem divinorum." Interdict is most properly understood of a general excommunication of a country, or city, as appears by the Decretals. See Excommunication.

There is a local and a general interdict: where these two are joined, the interdict is said to be mixed.

This punishment, as well as general excommunications, were but little known till the time of pope Gregory VII. In the year 1169, pope Alexander III. put all England under an interdict, forbidding the clergy to perform any part of divine service, except the blessing of infants, taking confession, and giving absolution to dying penitents.

In excommunicating a prince, all his adherents, that is,
DISCIPLES who retain their allegiance, are excommunicated, and the whole country is put under an interdict. In the reign of King John, the kingdom of England lay under a papal interdict, for above six years together: it began A. D. 1208.

In imitation of the popes, the bishops also soon began to interdict; and it became a common thing for a city, or town, to be excommunicated for the sake of a single person whom they undertook to shelter; but this severity was found to have such ill effects, that they have been obliged to moderate it.

An interdict is denounced, and taken off again, with the same formality as an excommunication.

INTERDICTIONS, in the Roman Law, certain formulae of words by which the prætor, when the possession of any thing was contested between many, ordered or forbade something to be done with it, till the right or property should be legally determined.

Which formulae were called interdicts, because they related to the possession of the thing in the interim, or till the right was ascertained.

They had three kinds of interdicts, prohibitory, reflatory, and exhortatory. Prohibitory, were those by which the judges forbade any one to vex another in the possession of any thing legally belonging to him. Reflatory were those by which the judges appointed any one, who had been expelled out of his estate to be repopulated, before his right was legally ascertained; and this was the same with what they called the re-integrant. Exhortatory were those by which any thing in dispute was ordered to be exhibited; as a testament, &c.

There was also a second division of interdicts; viz. into adspicientes, remittentes, and recuperanda; the first tending to the acquiring a new possession, as the interdict quorum bonorum, &c., the second to the keeping an old one till it was farther determined, as the uti possidetis, &c., the last to the recovering of law, as unde vi, &c.

INTERDICTION of Water and Fire, a sentence anciently pronounced against such as, for some crime, were to be banished.

They were not directly adjudged to banishment; but by giving order, that nobody should receive them, but deny them fire and water, they were condemned, as it were, to a civil death: and this they called legitimam exilium. Livy.

See Exile.

INTEREST, a sum of money reckoned for the loan and forbearance of some other sum, lent for, or due at, a certain time, according to some certain rate.

The sum lent, or forborne, is called the principal, because it is the sum that procures the interest, or from which the interest is reckoned.

Interest is either simple or compound.

Interest, simple, is that counted from the principal only. Let: p represent the principal, n the number of years or parts of a year, r the interest of 1L for a year, and m the amount of the principal p for the time n at the rate r; and since the amount of 1L for one year is 1 + r, the amount of 1L for n years, must be 1 + nr; the interest of the principal p at the rate r in n years must be pn and 1L: 1 + nr; p: p + nr = m the amount; from this general theorem we can easily deduce problems for resolving all the cases that occur in simple interest.

Prob. 1.—Having any principal sum, and time, and rate of interest given, to find the amount: as m = p + pn = p + nr = p + 1 + nr; we shall have this rule: multiply the interest of 1L for a year by the given number of years, add unity to the product and multiply the sum by the given principal; this second product will be the amount required. E. g.

what sum will 567L 1cs. amount to in nine years at 5 per cent. per annum? Here (p = 567.5, n = 9, and r = .05; therefore m = p + 1 + nr = 567.5 + 1 + .05 = 582.875 = 822.17L 6d. Or if it was required to find the amount of one penny at 5 per cent. simple interest in 1780 years; p = 1d., n = 1750, and r = .05, therefore m = 1 + 1 + 80 = 90 d. = 7L 6d.

If the time given does not consist of whole years the fractional part may be easily reduced to decimal parts of a year.

Prob. 2.—Having the amount of any principal at a given rate in a given time, to find the principal; it appears, from the theorem, m = p + 1 + nr, that p = m

i.e., divide the amount by the product of the time and interest of 1L for a year with unity added to it. E. g. what principal will amount to 822L 17L 6d. in nine years at 5 per cent. per annum? Here m = 822L 17L 6d. or 822.875, and n, r as before; therefore m

\( \frac{m}{1 + nr} = \frac{822.875}{1 + .05} = 567.5, \text{or} 567L 1cs. \)

Prob. 3.—Having the amount of a given principal at a given rate, to find the number of years. From the theorem we easily deduce, by transposition and division, \( n = \frac{m - p}{pr} \); viz. subtract the principal from the amount, and divide the remainder by the product of the principal and interest of 1L for a year. E. g. in what time will 567L 1cs. amount to 822L 17L 6d. at 5 per cent. per annum? \( \frac{822.875 - 567.5}{28.375} = 235.375 \). and, therefore, the interest is 5 cents per cent.

Prob. 4.—Having the amount of a given principal in a given time, to find the rate, and consequently the interest per cent. From the theorem we easily derive \( r = \frac{m - p}{pn} \); i. e. subtract the principal from the amount, and divide by the product of the principal into the number of years; e. g. at what rate per cent. will 567L 1cs. amount to 822L 17L 6d. in nine years? Here \( \frac{m - p}{pn} = \frac{822.875 - 567.5}{28.375} = 235.375 \). and, therefore, the interest is 5 cents per cent.

Prob. 5.—The annual interest of any principal p at the rate r, is pn; i. e. multiply the principal by the interest of 1L for a year, e. g. the interest of 75L for one year at 3 per cent. is 75 × .03 = 2.25 = 2L 5s. The interest of 175L 17L 6d. at 5 per cent. is 157.875 (reducing the 172.6d. to decimals of a pound) × .05 = 7.89375 = 7L 17s. 10d. The interest of any principal p at the rate r for n years, is pn; obtained by multiplying the principal, rate, and number of years.

The daily interest is found by dividing the annual interest by 365; thus .03, being the interest of one pound for one year at 5 per cent., divided by 365, the quotient will be .0000806, &c, which is the interest of one pound for one day at the same rate. And .03 = .000080621 is the interest of one pound for one day, at 5 per cent. per annum. The interest for one day, at any rate, being thus found, that interest multiplied by 3, 31, 4, 56, &c, gives the interest of one pound for any number of days; and thus the following table of simple interest for any number of days is easily made.

</table>

Multiply the sum by the number of days, and the product thereof by the rate of interest per cent. Then cut off the two half figures to the right hand, and enter the table with what remains to the left; against which numbers collected, you have the interest for the given sum.

**Example.**—What is the interest of 100l. at 5l. per cent. for 365 days?

<table>
<thead>
<tr>
<th>N. of days</th>
<th>365</th>

<tr>
<td>Mult. by</td>
<td>3 rate per cent.</td>
</tr>
<tr>
<td>1825</td>
<td>0.5</td>
</tr>
</tbody>
</table>

The **Use of the preceding Table.**—When the interest of any sum of money is required for any number of days, look in the table for the number of days, and even with that number, under the given rate of interest, will be found the interest of one pound, for that time, and at that rate; which interest, so found, being multiplied by the principal sum, the product answers the question.

**Example.**—What is the interest of 40l. for 85 days, at 5 per cent. per annum?

In the table, even with 85 days, and under 5 per cent., you find the interest of £1 to be 0.8167/43.8.

Which multiplied by the principal 40l., the product will be 32l. 7s. 6d.

**N.B.** If the principal sums contain shillings and pence, you must reduce them into decimal parts, and multiply accordingly.

When the interest of any sum is required for a number of years and days together, as it frequently happens upon paying off a bond or mortgage, add the interest of one pound for the years at the end of the foregoing table, to the interest of one pound for the odd days, multiply that by the principal sum, and the product will answer the question.

By the assistance of the following table the interest of any sum of money may be obtained, from a million to a pound, for any number of days, at any rate of interest.
INTEREST.

and let it be required to find the amount of the sum \( p \) in \( n \) years at the rate \( r \). Now, supposing the amount of \( 1 \) in one year to be \( 1 + r \), the amount of the same sum in two years will be \( 1 + r \); for \( 1 + r + r = 1 + 2r + r^2 \). In like manner, \( 1 + r + r = 1 + r + r^2 \); the amount of \( 1 \) in three years, and the amount of \( 1 \), by the same rule in \( n \) years will be \( 1 + r^n \). Consequently the amount \( m \) of the sum \( p \) in \( n \) years will be \( p \cdot 1 + r^n \). From this equation we have \( \frac{m}{p} = \left(\frac{1}{1 + r}\right)^n \). Therefore, \( m - \log_{1 + r} p = \log_{1 + r} p \). Let \( \log_{1 + r} p = \frac{1}{r} \) and \( r \) be respectively equal to \( 162.17 \), \(.50 \) and \(.04 \). Then \( n = \frac{162.17}{.04} = 40 \). 

As the amount of \( 1 \) in \( n \) years is \( 1 + r^n \), the amount of the same sum in \( n - 1 \) years will be \( 1 + r^{n-1} \), in \( n - 2 \) years \( 1 + r^{n-2} \), &c.; therefore, if \( 1 \) be the amount at the end of the first year, the series \( 1 + r + 1 + r^2 + \ldots \) will express the amount of \( 1 \) per annum in \( n \) years, which may easily be found to be \( \frac{1}{1 + r^n} \), and \( m \) (the amount of the annual sum \( a \)) will be \( \frac{1}{1 + r^n} \), hence \( a \) will be \( \frac{m r}{1 + r^n} \), and \( n = \log_{1 + r} m + \log_{1 + r} a \). 

In order to find the value of \( r \), let the binomial \( 1 + r^n \) be expanded, &c., and \( \frac{m}{a} \) will be \( 1 + \frac{n - 1}{2} r + \frac{n - 1}{2} \cdot \frac{r^2}{2} + \ldots \). But \( \frac{m}{a} = \frac{n}{2} = \frac{1}{r} \), therefore \( n = \log_{1 + r} \frac{m r}{a} \). 

Example 1.—Let \( a = 20 \), \( n = 40 \), \( r = 1.06 \), and \( \pi = \frac{20}{1.06} \) be 1.944. 

\[ \left(1 + 1.944\right)^{\frac{1}{2}} \times 1.944 \] will be 20. 

Example 2.—Let \( \pi = 1.944 \), \( r = 1.06 \), and \( n = 40 \); \( \pi = \frac{20}{1.06} \) will be 20. 

Example 3.—Let \( \pi = 1.944 \), \( r = 1.06 \), and \( n = 40 \); \( \pi = \frac{20}{1.06} \) will be 20. 

Example 4.—Let \( \pi = 1.944 \), \( a = 20 \), and \( n = 40 \); \( \pi = \frac{20}{1.06} \) will be 20. 

Ex. 3.—Putting \( 1 + r \) and \( m = 1 + r \) respectively, and \( a = 10 \), \( n \) will be \( \frac{1.170333}{1} - 1 = 10 \). 

Ex. 4.—Retaining the same values of \( m \) and \( a \) as in the preceding example, and putting \( n = 10 \), \( e \left( \frac{120.06}{100} \right)^{\frac{1}{10}} \) will be \( .04146 \), \( b \left( \frac{6}{11} \right) \) will be \( .5434 \), and \( r \left( \frac{1.2975}{1} + .0432 \right) - .5434 = .5854 - .5434 \) will be \( .04 \). 

Since \( 1 + r \) is the amount of \( 1 \) in one year, the converse of this expression, or \( \frac{1}{1 + r} \) will be the discount of \( 1 \) for the same time; for if \( 1 + r \) to be received at the end of a year is of the same value with the present payment of \( 1 \) by the rule of proportion \( 1 \) to be received at the end of a year will be of the same value with \( \frac{1}{1 + r} \) now received, that is, \( 1 + r : 1 = 1 : \frac{1}{1 + r} \). By the same reasoning 

Ex. 1.—Let \( a = 20 \), \( n = 40 \), \( 1 + r \) be \( 1.06 \), and \( \pi = \frac{20}{1.06} \) be 1.944. 

Ex. 2.—If \( \pi = 1.944 \), \( 1 + r = 1.06 \), and \( n = 40 \), \( a \left( \frac{1.06}{1.06} \right)^{\frac{1}{10}} \) will be 20. 

Ex. 3.—Retaining the values of \( \pi \) and \( 1 + r \), and putting \( a = 20 \), \( n \) will be \( 1.30103 \times .28878 \) = 40. 

Ex. 4.—If \( \pi = 1.944 \), \( a = 20 \), and \( n = 40 \), \( \pi \left( \frac{20}{1.944} \right)^{\frac{1}{10}} \) will be .06. 

The
The value of \( \frac{1}{1 + r} \), payable at the end of \( n \) years, being
\[
\frac{1}{1 + r}^{n+1},
\]
it's value at the end of \( n - 1 \) years will be \( \frac{1}{1 + r}^{n-1} \), and so on. It follows, therefore, that the present value of the annuity of \( a \) for \( n \) years will be expressed by the series
\[
a \left( \frac{1}{1 + r} \right) + \frac{a}{1 + r} \cdot \frac{1}{r} + \frac{a}{1 + r} \cdot \frac{1}{r^2} + \cdots + \frac{a}{1 + r} \cdot \frac{1}{r^n} = \frac{a}{r} \left( \frac{1}{1 + r} \right)^{n+1} = \frac{a}{r} \cdot \frac{1 - \left( \frac{1}{1 + r} \right)^{n+1}}{\frac{1}{1 + r}} = \frac{a}{r} \cdot \frac{1 - \left( \frac{1}{1 + r} \right)^n}{1 + r} = \frac{a}{r} \cdot \frac{1 - r^n}{1 + r}.
\]

Since \( \frac{a}{r} \cdot \frac{1 - r^n}{1 + r} \) is found, and if \( r = \frac{m}{p} \), it will be
\[
\frac{m}{p} - \frac{1}{1 + r}.
\]

Therefore, \( m \) being given, \( r \) will be found to be
\[
\frac{m}{p} - \frac{1}{1 + r},
\]

and \( r \) will be found to be
\[
\frac{m}{p} \cdot \frac{a}{r}.
\]

Cafe 2. \( \frac{m}{p} \) and \( r \) being given, to find \( n \). Since \( \frac{m}{p} = \frac{1 + r}{1 + i^n} \), the log. \( 1 + r \) and \( 1 + i^n \) will be \( \log. m - \log. \frac{p}{r} \), and the log. \( 1 + i^n \) will be \( \log. \frac{p}{r} \cdot \log. 1 + r \), and consequently \( r \), will be known.

Cafe 3. \( n, r, p \) being given to find \( m \). This is derived from the following case, being \( \log. m = \log. \frac{p}{r} \cdot \log. 1 + r \).

Cafe 4. \( a, m, p \) being given to find \( n \). If \( m \), \( 1 + r^n \) will be known, and since \( r \) is
\[
\frac{m}{p} \cdot \frac{1}{1 + r^n} - 1,
\]

will also be known, and consequently \( 1 + r^n \) will also be known, and log. \( 1 + r^n \) will be given.

Cafe 5. \( a, n, p \) being given to find \( m \). By Cafe 3, \( m \) may be easily found to be
\[
\frac{m}{p} = \frac{a}{r}.
\]

Cafe 6. \( a, m, p \) being given to find \( m \). The value of \( r \) may be derived from one of the preceding theorems, in which \( a, m, p \) are given (being \( b + \sqrt{b^2 - 2bd} \)), and hence \( m = \frac{a}{p} \cdot \frac{1 + r^n}{1 + r} \) will also be given.

Cafe 7. \( n, r, p \) being given to find \( m \). As \( r \) is given, this value is immediately obtained from the following case, being
\[
\frac{m}{p} = \frac{a}{r}.
\]

Cafe 8. \( m, n, r, a \) being given to find \( p \). By Cafe 1, \( r \) is
\[
\frac{m}{p} = \frac{a}{r},
\]

therefore \( p \) is
\[
\frac{m}{p} = \frac{a}{r}.
\]

Cafe 9. \( n, m, r \) being given to find \( p \). Since \( \frac{m}{p} = \frac{a}{r} \). \( p \) will be
\[
\frac{m}{p} = \frac{a}{r}.
\]

Cafe 10. \( n, m, a \) being given to find \( p \). Let the value of \( r \) be given when \( m, n, a \) are given by one of the preceding theorems (being \( \sqrt{b^2 + 2bc - b} \)), and hence \( p \) \( \frac{m}{1 + r^n} \) will then be given.

Cafe 11. \( n, m, p \) being given to find \( a \). Since \( \frac{m}{p} = \frac{1 + r^n}{1 + r}, \) \( r \) will be found to be
\[
\frac{m}{p} \cdot \frac{1}{1 + r},
\]

and consequently \( m \) given; therefore the value of \( a \) may be found from the equation
\[
\frac{m}{p} = \frac{1 + r^n}{1 + r},
\]

Cafe 12. \( m, p \) being given to find \( r \). Let \( \frac{m}{p} \) be substituted for its equal \( \frac{m}{p} \) in the expression
\[
\frac{m}{p} = \frac{1}{1 + r} - 1,
\]

and
and \( a \) will be \( \frac{m \cdot r}{m - 1} = \frac{m \cdot r}{m - \overline{p}} \).

Dr. Masekelyne, in his introduction to Taylor's logarithms, has, with the view of facilitating these operations, had recourse to the tables of logarithmic lines and tangents, by putting \( r = r^2 \), \( A \cdot 1 + r = \sec^n B \), \( A \cdot 1 + r^2 = \sec^n B \), \( B \), &c.; thus, in Case 1, the value of \( r \) becomes \( a \times \frac{m \cdot r}{m - 1} \times \frac{m \cdot r}{m - \overline{p}} \times \sec^n B \).

The expression \( \frac{m \cdot r}{m - 1} \) becomes \( \frac{m \cdot r}{m - \overline{p}} \times \sec^n B \), or \( m \cdot r \cdot \overline{p} \cdot \sec^n B \). But though the expressions appear more simple, I do not know that in general the operations will be found to be much facilitated by these means.

In the preceding case money has been supposed to be improved or discounted yearly. But all these different theorems may, however, be applied to the solution of cafés which require money to be improved or discounted at shorter intervals. Thus, supposing it were required to determine the amount of \( 50 \) at \( 11/2 \) per cent., for the term of 30 years; \( p \) is \( = 50 \cdot n = 2 \times 30 = 60 \), the interest of \( 11/2 \) for half a year is \( 0.02 \), and \( m \cdot \overline{p} \cdot 1 + r^2 \) becomes \( 50 \times 1.01 \times 1 + r^2 = 121.486 \). If improved quarterly it will be \( = 50 \times 1.011 \times 1 + r^2 = 122.2 \).

Again, if it were required to determine the amount of \( 50 \) laid out half yearly, to be improved at \( 11/2 \) per cent. during a term of 10 years. In this case \( m = \frac{a \cdot 1 + r^2 - 1}{1 + \overline{r}} \) will be \( = 5 \times \frac{1.012 \times 1 + \overline{r} = 121.486 \text{ r.} \)} and if it be improved quarterly, it will be \( = 5 \times \frac{1.011 \times 1 + r^2 = 122.2 \text{ r.}} \).

Thus, if money be discounted at shorter intervals than a year, the present value will be obtained from the expression \( 1 + r^4 \), thus, let the present value be required of \( 50 \) payable at the end of 40 years, supposing money to be discounted every half year at \( 11/2 \) per cent. Here \( n \) becomes \( = 2 \times 40 = 80 \), \( r = \frac{0.05}{2} = 0.03 \), and consequently \( \tau = \frac{20}{1.03} = 18.795 \).

Let \( k \) be any fraction of a year in which money is to be improved or discounted, and the amount or present value may always be found from the amount or present value when money is improved or discounted yearly, being the same with such amount or value at \( \frac{r}{k} \) interest for \( k \) of a year. Thus, the amount of \( 50 \) improved half yearly at \( 11/2 \) per cent. for 30 years is the same with the amount of \( 50 \) improved yearly for 60 years at \( 11/2 \) per cent.; the amount of \( 50 \) per annum improved half yearly for 10 years at \( 11/2 \) per cent. is the same with the amount of \( 50 \) per annum improved yearly for 20 years at \( 11/2 \) per cent.; and \( 100 \) discounted half yearly for 40 years at \( 11/2 \) per cent. is the same with \( 100 \) discounted yearly for 80 years at \( 11/2 \) per cent. The different values of annuities, when payable yearly, half yearly, quarterly, or at shorter intervals, may be in the same manner be deduced from the preceding theorems, but these are explained in the article ANNUITIES.

M. De Moivre, M. D'Alembert, and some others, instead of making the interest of \( 11/2 \) for the \( k \)th part of a year = \( \frac{r}{k} \), have chosen to make it = \( 1 + r^2 \), and hence the amount of \( 11/2 \) in \( n \) years, or its present value at the end of \( n \) years, will be the same, whether money be improved or discounted yearly, or at shorter intervals. But the amount of \( 11/2 \) per annum will be to its amount when improved yearly in the constant ratio of \( r \) to \( k \times 1 + r^2 \), and the value of an annuity of \( 11/2 \) will be to its value, when paid yearly, inversely as \( r \) to \( k \times 1 + r^2 \), whatever the length of the term during which the money is to accumulate, or the annuity is to continue. Now, it is well known that the difference between the values of annuities payable yearly, and their values, when payable half-yearly, quarterly, or at shorter intervals, is always lessened as the term is extended, so that if the annuity be perpetual, the values will be the same, whether the payments are made yearly, or in any fractional part of the year; which can never be the case on the supposition above mentioned. When \( n \) is

\[
\frac{1}{r - k \times 1 + r^2} \quad \text{log.} \quad 1 + r^2 \quad \text{r. an annuity payable every} \quad k \text{th part of the year, will be equal to the perpetuity, so that an annuity payable half-yearly, at \( 11/2 \) per cent. for } 90 \text{ years, or quarterly for } 80 \text{ years, will be equal to the same annuity payable yearly for ever. And at } 11/2 \text{ per cent. the annuities will be at equal value if the term be only } 72.2 \text{ years in the one case, or } 67.2 \text{ years in the other. But while these rules, when the term is very long, give the values of annuities payable at shorter intervals than a year too high, they always, on the contrary, and especially when the term is very long, give the amount of a sum much too low. Thus supposing one penny to be laid out at } 11/2 \text{ per cent. compound interest at the birth of our Saviour, or } 1810 \text{ years ago, it will accumulate, when money is improved yearly, to a sum which is equal to } 311,856,000 \text{ globes of solid gold, each equal to the earth in magnitude. When improved half-yearly, to a sum which is equal to } 1,121,470,000 \text{ such globes, and when improved quarterly, to a sum which is equal to } 1,945,680,000 \text{ such globes; so that although in this long time the accumulation is nearly three times greater when money is improved half-yearly, and more than five times greater when improved quarterly than it is when money is improved yearly, yet according to the supposition that } 1 + r^2 \text{ is the amount of } 11/2 \text{ in the } k \text{th part of a year, or } \frac{1}{1 + r^2} = \text{its amount in } n \text{ years, its accumulation will be the same, whether money is improved yearly, half-yearly, or quarterly. It may easily be shown that } 1 + r^2 \text{ is always less than } \frac{r}{k} \text{ or, in other words, that this expression does not give the full interest of } 11/2 \text{ for the } k \text{th part of a year. It is no wonder, therefore, that any theorems derived from a principle so erroneous, should, like the preceding, lead to conclusions which are not only incorrect but absurd.} \]
INTEREST.

To the foregoing, a great number of other cases might be added. But it will be sufficient to give only a few of the most curious and important; some of which having occurred in practice, it would perhaps be improper to omit them.

Theorem 1.—To determine the time in which $1L$ will be doubled by compound interest.

Solution.—Since $1 + r$ the amount of $1L$ at the end of $n$ years is in the case $= 2n$, or the required time, will be

$$\log \frac{2}{1 + r}$$

from which it appears that money doubles itself at $2L$ per cent. in $23\frac{1}{2}$ years nearly; at $4L$ per cent. in $17\frac{3}{4}$ years; at $5L$ per cent. in $14\frac{1}{2}$ years; at $6L$ per cent. in $11\frac{3}{4}$ years; at $8L$ per cent. in $9$ years; at $10L$ per cent. in $7\frac{1}{4}$ years; and at $12L$ per cent. in $6\frac{1}{2}$ years nearly.

Theorem 2.—Supposing money to be doubled by compound interest in $n$ years, required $r$ the rate of interest at which it has been improved.

Solution.—The log. $1 + r$, by the preceding theorem being given $= \log \frac{2}{n}$, the value of $r$ will also be given.

Or, if the hyperbolic logarithm of $2$ be expressed by $h$, it will be found $= 1 - \sqrt{\frac{n - 2}{2}}$

Theorem 3.—Supposing $1L$ to be doubled in $n$ years at the interest $r$, and in $m$ years at the interest $2r$, to find the ratio of $m$ to $n$.

Solution.—Since $(1 + r)^n$ and $(1 + 2r)^m$ are each of them equal to $2$, they will be equal to each other, and consequently $m$ will be to $n$ as log. $1 + r$ to log. $1 + 2r$, or by fluxions and the binomial theorem, as

$$\frac{1}{2} + \frac{1 - r}{4} + \frac{1 + r}{4} + \frac{7 - 9r \cdot r}{24}$$

will be to one very nearly, or still more nearly, as

$$\frac{1}{2} + \frac{1 - r}{4} + \frac{1 + r}{4} + \frac{7 - 9r \cdot r}{24}$$

to one.

Example.—At $3$ and $6$ per cent. $m$ and $n$ are respectively to each other in the ratio of $50946$ to $1$; at $4$ and $8$ per cent. of $50934$ to $1$; at $5$ and $10$ per cent. of $51197$ to $1$; at $6$ and $12$ per cent. of $51417$ to $1$; at $8$ and $16$ per cent. of $51889$ to $1$; at $10$ and $20$ per cent. of $52269$ to $1$, and at $12$ and $24$ per cent. of $52681$ to $1$. From these examples it appears that the higher the interest the greater will be the ratio of $m$ to $n$. It follows also from the expression

$$\frac{1}{2} + 4 + \frac{1 - r}{4} \cdot r$$

&c. that money will not double itself at

$2r$ interest in half the time that it doubles itself at $r$ interest. The truth of this conclusion may perhaps be more satisfactorily proved in the following manner. Since $m : n$

$$\log 1 + r : \log 1 + 2r = \log 1 + r : \log 1 + r + \frac{r}{r}$$

$+ \log 1 + \frac{r}{r}$, we shall have $m : n = 1 : 1 + \frac{r}{r}$.

But this latter fraction must be less than unity, therefore $m$ will always be to $n$ in a greater ratio than as $1$ to $2$.

Theorem 4.—To determine the sum to which an annuity $a$ will accumulate at the end of $n$ years, supposing such an annuity to be received annually, and its interest to be improved half-yearly.

Solution.—The series expressing these accumulations is

$$a \left(1 + \frac{r}{2}\right)^n + a \left(1 + \frac{r}{2}\right)^{n-1} + a \left(1 + \frac{r}{2}\right)^{n-2} + \ldots$$

$$+ a \left(1 + \frac{r}{2}\right) = a \times \frac{\left(1 + \frac{r}{2}\right)^n - 1}{\left(1 + \frac{r}{2}\right) - 1}$$

Example.—Let $a = 500$, $n = 30$, and $r = 0.05$, the foregoing expression would then be

$$\frac{1.025^{30} - 1}{1.025 - 1} \times 500 = 671.967 \times 500 = 33578.35.$$
they are \( a, b, c, d, \) &c. respectively, and the whole amount of them be \( p, \) the time \( t \) will be =

\[
\log p - \log \left( \frac{a}{1 + r} + \frac{b}{1 + r_1} + \frac{c}{1 + r_2} + \text{&c.} \right)
\]

\[
\log 1 + r
\]

**Theorem 7.**—Supposing the sum \( b \) to be now borrowed on condition that the annuity \( c \) should be paid in discharge of it, after the expiration of \( n \) years; for how many years \( t \) should such annuity be continued from that time so as to be an equivalent to the sum \( b \) advanced?

**Solution.**—The amount of \( b \) in \( n \) years being \( b \cdot (1 + r)^n \), and the value of the annuity \( c \) for \( t \) years being

\[
\frac{c}{1 + r_1 t} - \frac{c}{1 + r}
\]

these two expressions, by the condition of the problem, will be equal to each other. Let

\[
\frac{c}{1 + r} = \log d
\]

Thus, if \( b = 1032 \ldots c = 400 \ldots n = 37 \ldots \) and \( r = .035 \), \( d \) will be =

\[
\frac{400 - .035 \times 1032 \times .035}{1032} = 46.4, \text{ and } t = \log(46.4) = 31.4, \text{ that is, if } 1032 \text{ be now borrowed on condition that the debt should be discharged at the end of } 37 \text{ years by an annual payment of } 400, \text{ such payment, computing at } 5/\text{per cent. } \text{should be continued for } 31.4 \text{ years.}
\]

**Corollary.**—If \( c = 1 + r_1 t \cdot b \), the annual payment must be continued for ever; if \( c \) be less than \( b \cdot (1 + r)^n \), the debt can never be repaid.

From any four of the above quantities being given the fifth may be obtained without much difficulty. But it cannot be necessary to pursue this subject further, as the solution of these or any other cases in compound interest may be easily derived from the principles already explained in this article.

A mercantile friend has favoured the editor with the following universal rule for finding the interest upon any sum at any rate, for any number of days:

Multiply the sum by the rate of interest, and multiply that product by the number of days; then divide that product by 36500. The quotient will be the answer.

Now suppose the question to be, What is the interest upon 127l. at 3l. per cent. per annum for 254 days?

\[£. \]

127 at 3 for 254 days.

\[3 \text{ Rate of interest.} \]

\[381 \text{ First product.} \]

\[254 \text{ Days.} \]

\[\frac{1524}{762} \]

\[£. \text{ s. d.} \]

\[36500 \times 96774 (\text{2 L. 13s. c. Answer.} \]

It is evident, that in multiplying 127 by 3, according to the first operation of the rule, the amount is increased one hundred times too much, for the product 381 is only three, and eighty-one hundredths, or 38L the which is equal to 3L 16s. 2½d. or the interest of 127l at 3 per cent. for one year. Therefore, to correct this first error, the product 381 must be divided by 100, and it will be right.

But in following the rule, the first error is continued, and we go on to multiply that product by the number of days, by which it is also evident that the product 96774 includes a second error of 365 times too much, being for days instead of for years, and the amount of the two errors taken together is 100 times 365 times too much, or 36,500 times too much, therefore, to bring it right, it must be divided by that number.

This explains the principle of the first universal rule, which requires three operations, because it is adapted to any rate of interest whatever.

To find the interest upon any sum at 5 per cent. for any number of days:

Rule. Multiply the sum by the number of days, and divide the product by 7300.

**Example.**

What is the interest upon 2745l. for 365 days?

| £.

36500

£. 13s. c. Answer.

Interest.
INTEREST.

Interest at 5 per cent. being the most common rate in Great Britain, may in general be worked as speedily by the above short rule as it can be found by referring to the tables in common use.

The editor's correspondent has never yet met with a short a rule as this, and as 5 per cent. is the general and legal rate of interest in this country, it must be very useful to mercantile persons.

The explanation of the principle of the first rule being understood as above, there can be no difficulty in the last rule, it being derived from it.

When the interest is at any other rate, take the following rule:

Multiply the sum by the number of days; multiply that product by the rate of interest, then divide by 36500.

Example.

What is the interest upon 1612l. for 154 days at 4 per cent?

\[ \frac{1612 \times 154 \times 4}{36500} \]

\[ = \frac{248248}{36500} \]

\[ = 0.680 \]

\[ = 680 \pounds \]

\[ = 6 \text{ s.} \ 20 \text{ d.} \]

\[ = 680 \times 20 \]

\[ = 140 \text{ s.} \ 40 \text{ d.} \]

\[ = 140 \times 4 \]

\[ = 560 \text{ d.} \]

\[ = 560 \times 4 \]

\[ = 2240 \text{ d.} \]

\[ = 2240 \times 4 \]

\[ = 8960 \text{ d.} \]

\[ = 8960 \times 4 \]

\[ = 35840 \text{ d.} \]

\[ = 35840 \times 4 \]

\[ = 143360 \text{ d.} \]

\[ = 143360 \times 4 \]

\[ = 573440 \text{ d.} \]

\[ = \frac{573440}{36500} \]

\[ = 15.707 \]

\[ \approx 15.71 \text{ days.} \]

Any calculation made by the second rule may be proved by the third rule, and vice versâ. Therefore every calculation of interest at any rate whatever, may be made by either of those rules. When an interest account of considerable length is required to be made out, it may be done as much sooner by this method than it can be done by any interest tables whatever, as there are different lines to be cast.

By the following table of rules, interest upon any sum for any number of days at the several rates of 1, 2, 3, 4, 5, and 10 per cent. per annum, may be cast by two operations only, namely, one multiplication and one division.

First, multiply the sum by the number of days, then divide the product by the number standing against the rate of interest, and the quotient will be the answer.

For interest at \(\frac{1}{2}\) per cent. divide by 146000.

\[ \frac{1}{2} \]

\[ = 73000 \]

\[ 1 \]

\[ = 30500 \]

\[ \frac{1}{2} \]

\[ = 20200 \]

\[ 2 \]

\[ = 18250 \]

\[ \frac{1}{2} \]

\[ = 14600 \]

\[ 4 \]

\[ = 9125 \]

\[ 5 \]

\[ = 7300 \]

\[ 10 \]

\[ = 3500 \]

The above rule may be still further shortened in practice by cutting off one figure each from the dividend and the divisor, and in that case it will not in any instance make more than one farthing difference.

Interest is the compensation which the borrower pays to the lender, for the profit which he has an opportunity of making by the use of the money. Part of that profit naturally belongs to the borrower, who runs the risk and takes the trouble of employing it; and part to the lender, who affords him the opportunity of making this profit. Interest has been sometimes confounded with usury; and the latter term, the sound of which is odious, has been occasionally misapplied and estimated on erroneous principles. (See Usury.) Accordingly those who are enemies to interest in general, making no distinction between that and the kind of usury which is criminal, hold any increase of money to be indefinably usurious. This they ground, as well on the prohibition of it by the law of Moses among the Jews, as also upon what is laid to be laid down by Aristotle in a passage, (Polit. l. i. c. io.) suspected to be spurious, that money is naturally barren, and that to make it breed money is prepolleron, and a perversion of the end of its institution, which was only to serve the purposes of exchange, and not of increase. Hence the school divines have branded the practice of taking interest as contrary to the divine law, both
INTEREST.

Both natural and revealed; and the canon law (Decret. l. v. tit. 10.) has proscribed the taking of any, the leaf, inrere for the loan of money as a mortal sin. But it has been observed in reply, that the Mosaic law was clear and a political, and not a moral precept. It only prohibited the Jews from taking usury of their brethren; but, in express words, (Deut. xxxii. 25.) permitted them to take it of a stranger, which proves that the taking of moderate usury, as a reward for the use, for the word signifies, is not immoral in itself; since it was allowed where any but an Israelite was concerned. As to the reason, deduced from the natural barrenness of money, and ascribed to Aristotle, the fame may with equal force be alleged of hounds, which never breed hounds; and of twenty other things, which nobody doubts it is lawful to make profit of, by letting them to hire. And though money was originally used for the purposes of exchange, yet the laws of any state may be well justified in permitting it to be turned to the purposes of profit, if the convenience of society (the great end for which money was invented) shall require it. That the allowance of moderate interest tends greatly to the benefit of the public, especially in a trading country, will appear from that generally acknowledged principle, that commerce cannot subsist without mutual and extensive credit. Unless money can be borrowed, trade cannot be carried on; and if no premiums were allowed for the hire of money, few persons would care to lend it; or at least the ease of borrowing at a short warning which is the life of commerce) would be entirely at an end. Thus, in the dark ages of monarchi-uperbition and civil tyranny, when interest was laid under a total interdiction, commerce was also at its lowest ebb, and fell entirely into the hands of the Jews and Lombards: but when men's minds came to be more enlarged, when true religion and real liberty revived, commerce grew again into credit; and again introduced with itself its inseparable companion, the doctrine of loans upon interest. And, as to any terrors of conscience, since all other conveniences may either be bought or hired, but money only can be hired, there seems to be no greater opprobrium in taking a recompence or price for the hire of this than of any other convenience. To demand an exorbitant price is equally contrary to conscience, for the loan of a horse, or the loan of a fum of money; but a reasonable equivalent for the temporary inconvenience, which the owner may feel by the want of it, and for the hazard of his losing it entirely, is not more immoral in one case than in the other. Indeed, the absolute prohibition of lending upon any, even moderate interest, introduces the very inconvenience which it seems meant to remedy. The necessity of individuals will make borrowing unavoidable. Without some profit allowed by law, there will be but few lenders: and those principally bad men, who will break through the law, and take a profit, and then will endeavour to indemnify themselves from the danger of the penalty, by making that profit exorbitant. Accordingly it is well observed by Grotius, (De Jur. Bell. et Pac. l. ii. c. 12. § 22.) “if the compensation allowed by law does not exceed the proportion of the hazard run, or the want felt, by the loan, its allowance is repugnant neither to the revealed nor the natural law: but if it exceeds those bounds, it is then oppressive usury; and though the municipal laws may give it impunity, they never can make it just.” The exorbitance or moderation of interest depends upon two circumstances, the inconvenience of parting with it for the present, and the hazard of losing it entirely. The rate of interest will be generally in a compound ratio, formed out of the inconvenience and the hazard.

Mr. Locke, Mr. Law, and Mr. Montefquieu, as well as many other writers, seem to have imagined that the increase of the quantity of gold and silver, in consequence of the discovery of the Spanish West Indies, was the real cause of the lowering the rate of interest through the greater part of Europe. Those metals, they say, having become of less value than silver, the use of any particular portion of them became necessarily of less value too, and consequently the price which could be paid for it. This notion appears at first sight very plausible; but it has been contended, not to say refuted, by Mr. Hume and Dr. Smith. It is in vain, says the first of these writers, (Essays, vol. i. eff. iv.) to look for the cause of the fall or rise of interest in the greater or less quantity of gold and silver, which is fixed in any nation. High interest arises from three circumstances: A great demand for borrowing; little riches to supply that demand; and great profits arising from commerce; and these circumstances are a clear proof of the small advance of commerce and industry, not of the scarcity of gold and silver. Low interest, on the other hand, proceeds from the three opposite circumstances: a small demand for borrowing; great riches to supply that demand; and small profits arising from commerce; and these circumstances are all connected together, and proceed from the increase of industry and commerce, not of gold and silver. In investigating the causes and effects of a great or small demand for borrowing, Mr. Hume traces the origin and establishment of the landed interest; and he observes, after tracing the manner in which some persons become proprietors of land, and the influence of a letted revenue on those who are entirely without occupation, that the prodigals among the landholders will always be more numerous than the middlings. In a state, therefore, where there is nothing but a landed interest, as there is little frugality, the borrowers must be very numerous, and the rate of interest must bear proportion to it; the difference depends not on the quantity of money, but on the habits and manners which prevail. By this alone the demand for borrowing is increased or diminished. Were money so plentiful as to make an egg be sold for sixpence; so long as there are only landed gentry and peasants in the state, the borrowers must be numerous, and interest high. The rent for the same farm would be heavier and more bulky; but the landed interests of the landlord, with the higher price of commodities, would dissipate it in the same time, and produce the same necessity and demand for borrowing. The second circumstance, above-mentioned, viz. the great or little riches to supply the demand, depends also on the habits and way of living of the people, not on the quantity of gold and silver. In order to have, in any state, a greater number of lenders, it is not sufficient nor requisite that there be great abundance of the precious metals. It is only requisite that the property, or command of that quantity, which is in the state, whether great or small, should be collected in particular hands, so as to form considerable sums, or compose a great monied interest; this begets a number of lenders, and links the rate of usury; and this, Mr. Hume affirms, depends not on the quantity of specie, but on particular manners and customs, which make the specie gather into separate sums or masses of considerable value. The reduction of interest must proceed from an increase of industry and frugality, of arts and commerce. Besides the peasants and the proprietors of land, there must be another rank of men, who, receiving from the former the rude materials, work them into their proper form, and retain part for their own use and subsistence. As industry increases, and the views of men enlarge, it is found that the most remote parts of the state can afford each other as well as the more contiguous, and that this intercourse of good offices may be carried on to the greatest extent and in-
triciety. Hence the origin of "Merchants," who serve as agents between different parts of the state; and in all the transactions which this business of connecting agency or merchandise occasions, it is necessary and reasonable that a considerable part of the commodities and labour should belong to the merchant, to whom, in a great measure, they are owing. These commodities he will sometimes preserve in kind, or more commonly convert into money, which is their common representation. If gold and silver have increased in the state, together with the industry, it will require a great quantity of these metals to represent a great quantity of commodities and labour. If industry alone has increased, the prices of every thing must sink, and a small quantity of specie will serve as a representative. Trade, says Mr. Hume, increases frugality, and among merchants there is the same overplus of mifers above prodigals, as, among the possessors of land, there is the contrary. Commerce increases industry, as well as frugality. Merchants beg to industry, and by their frugality they acquire great power over that industry, and collect a large property in the labour and commodities which they are the chief instruments in producing. Without commerce the state must contract chiefly of landed gentry, whose prodigality and expense make a continual demand for borrowing; and of peafants, who have no sums to supply that demand. The money never gathers into large flocks or fums, which can be lent at interest. Commerce alone affembles it into considerable fums; and this effect it has merely from the industry which it begets, and the frugality which it inspires, independent of that particular quantity of precious metal which may circulate in the state. Thus an increafe of commerce necessarily raifes a great number of lenders, and by that means produces lownes of intereft. The next consideration is, that this increafe of commerce diminishes the profits arising from that profession, and gives rife to the third circumstance, above-mentioned, requisite to produce lownes of intereft. When commerce has become extensive, and employs large flocks, there must arise rivalships among the merchants, which diminish the profits of trade, at the fame time that they increafe the trade itself. The low profits of merchandise induce the merchants to accept more willingly of a low intereft, when they leave off business, and begin to indulge themselves in cafe and indecit. Low intereft and low profits both arife from an extensive commerce, and mutually forward each other. No man will accept of low profits, where he can have high intereft; and no man will accept of low intereft, where he can have high profits. An extensive commerce, by producing large flocks, diminishes both intereft and profits; and is alfo affailed, in its diminution of the one, by the proportional finking of the other. Thofe, fays our author, who have afferted, that the plenty of money was the caufe of low intereft, feem to have taken a collateral effeet for a caufe; fince the fame industry, which finks the intereft, commonly acquires great abundance of the precious metals. But though plenty of money and low intereft naturally arife from commerce and industry, they are altogether independent of each other. As to the reduction of intereft, which has taken place in England, France, and other kingdoms of Europe, that have no mines, it has been gradual; and has not proceeded, fays Mr. Hume, from the increafe of money, confidered in itself; but from that of industry, which is the natural effeet of the more increase, in that interval, before it raifes the price of labour and provisions. Dr. Smith (Wealth of Nations, vol. ii. p. 39.) concedes in opinion with Mr. Hume, and proposes a very short and plain argument, which, be it known, may serve to explain the fallacy by which thofe have been misled who acribe the lowering of the rate of intereft to the increafe of the quantity of gold and silver. Before the discovery of the Spanifh Well Indies, 10 per cent. feems to have been the common rate of intereft through the greater part of Europe. It has since that time in different countries funked to 6, 5, 4, and 3 per cent. Let us fuppofe that in every particular country the value of filver has funked precisely in the fame proportion as the rate of intereft; and that in thofe countries, for example, where intereft has been reduced from 10 to 5 per cent., the fame quantity of filver can now purchase juft half the quantity of goods which it could have purchased before. This fuppo- fition will not, as Dr. Smith believes, be found any where agreeable to the truth, but it is the most favourable to the opinion here examined; and even upon this fuppoftion it is utterly impoffible that the lowering of the value of filver could have the smallest tendency to lower the rate of intereft. If 100l. are in thefe countries now of no more value than 50l. were then, 120l. must now be of no more value than 5l. were then. Whatever were the caufes which lowered the value of the capital, the fame muft necessarily have lowered that of the intereft, and exaftly in the fame proportion. The proportion between the value of the capital and that of the intereft muft have remained the fame, though the rate had never been altered. By altering the rate, on the contrary, the proportion between these two values is necessarily altered. If 100l. now are worth no more than 50l. were then, 5l. now can be worth no more than 12l. 10s. were then. By reducing the rate of intereft, therefore, from 10 to 5 per cent., we give for the use of a capital, which is fuppofed to be equal to one-half of its former value, an intereft which is equal to one-fourth only of the value of the former intereft. Any increafe in the quantity of filver, while that of the commodities circulated by means of it remained the fame, could have no other effeet than to diminish the value of that metal. The nominal value of all sorts of goods would be greater, but their real value would be precifely the fame as before. They would be exchanged for a greater number of pieces of filver, but the quantity of labour which they could command, the number of people whom they could maintain and employ, would be precifely the fame. The capital of the country would be the fame, though a great number of pieces might be require for conveying any equal portion of it from one hand to another. The funds for maintaining producative labour being the fame, the demand for it would be the fame. Its price, or wages, therefore, though nominally greater, would really be the fame, they would be paid in a greater number of pieces of fiver; but they would purchase only the fame quantity of goods. The profits of flock would be the fame both nominally and really. The profits of flock are not computed by the number of pieces of filver with which they are paid, but by the proportion which those pieces bear to the whole capital employed. The common proportion between capital and profit would be the fame, and confequently the common intereft of money; what can commonly be given for the use of money being necessarily regulated by what can commonly be made of it. The intereft of money, keeping pace always with the profits of flock, might be greatly diminished, though the value of money, or the quantity of goods which any particular fum could purchase, was greatly augmented. In countries, fays our ingenious autor, where intereft is permitted, the law, in order to prevent the extension of ufury, generally fixes the highest rate which can be taken without incurring a penalty. This rate ought always to be somewhat above the lowest market price, or the price which is commonly paid for the use of money by thofe who can give the moft undoubted security. If this legal rate should be
be fixed below the lowest market rate, the effects of this fixation must be nearly the same as those of a total prohibition of interest. The creditor will not lend his money for less than the use of it is worth, and the debtor must pay him for the use which he runs by accepting the full value of that use. The legal rate, though it ought to be somewhat above, ought not to be much above the lowest market rate. If the legal rate of interest in Great Britain, for example, was fixed to be as 8 or 10 per cent., the greater part of the money which was to be lent, would be lent to prodigals and projectors, who alone would be willing to give this high interest. Where the legal rate of interest is fixed but a very little above the lowest market rate, sober people are universally preferred, as borrowers, to prodigals and projectors. Then a great part of the capital of the country is thrown into the hands in which it is most likely to be employed with advantage. The ordinary market price of land depends everywhere upon the ordinary market rate of interest. If the rent of land should fall short of the interest of money by a considerable difference, nobody would buy land, which would soon reduce its ordinary price. On the contrary, if the advantage should much more than compensate the difference, every body would buy land, which would soon raise its ordinary price. When interest was at 10 per cent., land was commonly sold for 10 and 12 years' purchase. As interest fell to 6, 5, and 4 per cent., the price of land rose to 20, 25, and 30 years' purchase. As to the legal interest in this country, it has varied and decreased for 200 years past according to the accession of trade, the introduction of paper credit, and other circumstances. The 5th, 37 Hen. VIII. c. 9, confined interest to 10 per cent. In the reign of Edward VI., religious zeal prohibited all interest. The statute of Henry VIII. was revived by the 1st of Elizabeth, cap. 8, and 10 per cent. continued the legal rate of interest till the 21st of James I., when it was reduced to 8 per cent. It was reduced to 6 per cent. soon after the reformation, and by the 12th of Ann. stat. 2, cap. 16. it was brought down to 5 per cent. yearly, which is now the greatest legal interest that can be taken. But yet, if a contract which carries interest be made in a foreign country, our courts will direct the payment of interest according to the law of that country, in which the contract was made.

**INTEREST.** Interest, in Law, is commonly taken for a chattel real, as a lease for years, &c. and more particularly for a future term; in which sense it is said in pleading, that one is possessed of interesse termini: therefore an estate in lands is better than a right or interest in them. But in legal understanding, an interest extends to estates, rights, and titles, that a man hath in or out of lands, &c. so by grant of his whole interest in such lands, a reversion therein, as well as possession, in fee-simple, shall pass.

**Interest on legacies.** In case of a vested legacy, due immediately, and charged on land or money in the funds, which yield an immediate profit, interest shall be payable thereon from the tellator's death; but if charged only on the personal estate, which cannot be immediately got in, it shall carry interest only from the end of the year, after the death of the tellator. If a legacy be devised, and no certain time of payment mentioned, and the legatee be an infant, he shall have interest for the legacy from the expiration of one year after the tellator's death; but if the legatee be of full age, he shall have no interest but from the time of the demand of the legacy. Where a legacy is payable at a day certain, it must be paid with interest from that day.

**Interest, Punitory.** See **Punitory.**

**INTEREST of no Interest,** a denomination applied to insurances made without having any property on board the ship, in which large sums were insured. The Nat. Geo. II. c. 37. enacted that all such insurances should be null and void. See **Marine Insurance.**

**INTERESTED WITNESS.** See Witness.

**INTERESTING,** in the Suppl. to the folio Encyclopædia, has been made an article for the Beaux Arts, without the least allusion to music. But dull and uninteresting music is, perhaps, more tiresome than the same degree of inidity in painting and poetry. You can quit a picture or a book whenever you please; but at a public performance of music, you have no escape from the bad composition or performance. A young composer, ambitious of fame, and of endearing himself to the public, should never write for writing sake, he should not feize his pen without ideas, without a subject. There is no art which has more alluring means of obtaining attention. Grace, pathos, fire, fancy, hilarity, rich harmony, and learned modulation, cannot all have admission in the same piece; yet it is absolutely necessary that at least some of these excellencies should predominate throughout a regular movement. And where a composer, not certain of his fertility and powers of pleasing, has hastily committed his thoughts to paper, he should flit it up in his desk for at least nine years, if not nine years; at the end of which he should perform it as the production of a stranger; then ask himself what interest he thinks his piece would excite in an intelligent and impartial audience; and if self-love is not the blindest of all loves, he will perceive where he is dull, and where genius and abilities are wanting. **INTERFEMINEUM,** a word used by some to express the perineum.

**INTERFERE,** in the Manoe. A horse interferes, when the sides of one of his shoes strikes against and hurts one of the fetlocks. See **Cutting.**

**INTERJECTION,** in Grammar, an expression used to denote some sudden motion or passion of the mind; as oh! or a! These exclamations, uttered in a strong and passionate manner, are confidered by some writers as the first elements or beginnings of speech.

As the greatest part of the expressions used on these occasions are taken from nature alone, the real interjections in most languages are monosyllabic: and as all nations agree in those natural passions, so do they agree in the signs and indications of them; as of love, mirth, &c.

Some deny the interjections to be words, or any part of speech; and make them mere natural signs of the motions or passions of the mind, expressed by these hortatory sounds, several whereof brutes have in common with us: but as there are passions, and must be represented in discourse, the interjection has a good foundation in nature, and is a necessary part of speech.

Mr. Harris observes, that interjections coincide with no part of speech, but are either uttered alone, or else thrown into a sentence, without altering its form, either in syntax or signification; and that they are not so proper parts of speech, as adventitious sounds; certain voices of nature, rather than voices of art, expressing those passions and natural emotions, which spontaneously arise in the human soul, upon the view or narration of interesting events. Hermes, p. 285.

Mr. II. Tooke, in his "Divertions of Purley," excludes interjections from the parts of speech; and affirms, that "the dominion of speech is erected upon the downfall of interjections." See **Grammar.**

The Greeks confound their interjections with adverbs, and the Hebrews confound them with their adverbs and prepositions; calling them all by the general name particle.
INTERIM, a term borrowed from the Latin, signifying in the mean time. It was first brought into popular use by Charles V in 1548, in order to compose the disturbances of Germany.

The interim of that prince was a kind of ordinance, or regulation, to be observed in the empire with regard to the articles of religion then controverted, till such time as they should be determined by a council; and therefore was called interim.

When it was bids before the diet, the archbishop of Mentz, president of the electoral college, thanked the emperor for his unceasing endeavours to restore peace to the church, and in the name of the diet, signified their approbation of the system of doctrine which he had prepared, together with their resolution of conforming to it in every particular. Although the whole diet was amazed at a declaration so unprecedented and unconstitutional, as well as at the presumption of the archbishop, in pretending to deliver the senten of the diet; on a point which had not been the subject of consultation or debate; none had the courage to contradict what he had said. The emperor held the archbishop's declaration to be a full constitutional ratification of the interim, and prepared to enforce the observance of it, as a decree of the empire.

It was said to have been drawn up by two Catholics and a Protestant; but as it retained most of the doctrines and ceremonies of the Romanists, though expreased for the most part in the feoffest words, or in scriptural phrases, or in terms of studied ambiguity, excepting that of marriage, which was allowed to priests, and communion, which was administered to the laity under both kinds, most of the Protestants rejected it. Those who admitted it were nick-named Intermittents, or Adiaphorists. Indeed the interim equally disguised the generality of both parties, the Protestants and Catholics.

Besides this, there were two other interims made: the one called the interim of Leipzic, the other by the divines of Franconia, who, refusing to accept the former, made another for themselves.

INTERIOR. See INTERNAL.

INTERIOR Talus. See TALUS.
INTERLACKEN, in Geography, a town of Switzerland, and capital of a considerable bailiwick, in the canton of Berne: deriving its name from an abbey, situated between the lakes of Biencitz and Thun, and secularized in the year 1528; 32 miles S.E. of Berne.

INTERLINEATION, something inserted between two lines. See DEEP.

INTERLOCUTORY Decree. In a suit in equity, if any matter of fact be strongly controverted, the fact is usually directed to be tried at the bar of the court of king's bench, or at the assizes upon a seignior issue. If a question of more law arises in the course of a cause, it is the practice of the court of chancery to refer it to the opinion of the judges of the court of king's bench, upon a cause stated for that purpose.

In such cases interlocutory decrees or orders are made. See DECREE.

INTERLOCUTORY Judgments are such as are given in the middle of a cause, upon some plea, proceeding on default, which is only intermediet, and does not finally determine or complete the suit. But the interlocutory judgments most usually spoken of, are those incomplete judgments, whereby the right of the plaintiff is established, but the quantum of damages sustained by him is not ascertained, which is the

procurer of a jury. In such a case, a writ of inquiry issues to the sheriff, who summons a jury, enquires of the damages, and returns to the court the inquiry to take, whereupon the plaintiff's attorney taxes costs, and signs final judgment. See JUDGMENT.

INTERLOCUTORY Order, that which decides not the cause, but only settles some intervening matter relating to the cause.

As, where an order is made in chancery for the plaintiff to have an injunction to quit possession till the hearing of the cause; this order, not being final, is called interlocutory.

INTERLOPERS are properly those, who, without due authority, hinder the trade of a company, or corporation lawfully established, by dealing in the same way.

INTERLOPING, the intercepting or disturbing the traffic of a company; or the taking up a new trade, or the employment, to the prejudice of those who were brought up in it.

INTERLUATION, in Musick, the thinning of a wood, or letting in light between, by lopping or cutting away boughs.

INTERLUGE, an entertainment exhibited on the theatre between the acts of a play, to amuse the spectators while the actors take breath, and shift their dresses; or to give time for changing the scenes and decorations.

In the ancient tragedy, the chorus sung the interludes, to shew the intervals between the acts.

Interludes, among us, usually consist of songs, dances, feats of activity, concerts of music, &c.

Aristotle and Horace give it for a rule, that the interludes should consist of songs built on the principal parts of the drama; but since the chorus has been laid down, dancers, buffoons, &c. ordinarily furnish the interludes.

INTERMEDIATE, is usually understood of the space of time elapsed from any certain point to any other.

In Chemistry, those substantials are called intermediate, by means of which, other substantials, incapable of uniting together of themselves, may be united.

INTERWING, in Poultry, is a hawk's mewing, from the first change of her coat till the turn white.

INTERMEZZO Ital. INTERMEDIER, Fr., a piece of music, a dance, or a short dramatic scene, generally between two performers of different sexes, exhibited between the acts of a serious opera, to vary the entertainment, and to relieve and enliven the audience, that may be too much oppressed and dispirited by tragic scenes of great interest.

The ancient Romans had fates performed between the acts of their regular comedies, and these were afterwards exhibited as farces at the end of pious pieces.

Tragicomedies had a very early admission on the stage at Bologna, during the 17th century; as Andromeda, Tragicomedia, fr. by Girolamo Gicobbi, maestro di cappelli of San Petronio, and founder of the Academy de' Filomani, in that city, was performed in 1610; and Amor vuol Gioventu, Schizzo drammatico, at Viterbo, 1659. Musica di Giambarbina Mariani, 1659. But the only real burlettas which we have met with are Gorelio, Drama Burlesca, fet by the famous Pitlochi, 1672, which was represented at Venice by little figures of wax: I dos Diogeno, drama burlesca per musica, and Afrigina in Baja, Schizzo drammatico per musica, were both performed at Ferrara, 1687.

There are intermezzi, says Rouelle, that are true comic or burlesque dramas, which detach the audience from the interest of the principal piece, without tafle or reaon. As the dance in Italy is never analogous to the drama, they are obliged to admit it on the stage as an intermezzo: "but this
is not what I blame; on the contrary, I think it may be useful to efface, by an agreeable dance, the melancholy impressions left by the events of a grand serious opera; and I see plainly that the subject of this dance should have no connection with the piece; but what offends me, continues the citizen of Geneva, is that they destroy all the interest that has been excited, and render each act a new piece. We suppose he means that the ballet should be given at the end, not in the middle of the opera.

INTERMITENT, a thing which ceases its action for some time; which time is called the interval.

INTERMITENT, in Medicine, any animal motion or action, which ceases and returns at intervals. The period of cessation is termed the interval, or intermission.

Thus those fevers which, after continuing several hours, altogether go off, and again return at certain intervals, as of one, two, or three days, are called intermittent fevers, in contradistinction from those which go through their course with little variation, or with regular diminution and aggravation only; the former being called continued, the latter intermitting fevers. See Fever, and Ague.

Various other disorders, besides the acute fevers just mentioned, put on the intermittent form; such as head-ache, especially the homocoria, or head-ache of one side of the head, the mewing, and sometimes the tic douloureux; and pains, feated in various other parts of the body, as in the liver, bladder, uterus, &c. It is extraordinary, and does not easily admit of any explanation, that, in parts of the body, suffering severe organic disease, and actually injured in their structure, the pain connected with this disorder sometimes becomes regularly intermitting with intervals of absolute freedom from the distresses; while of course no variation can have occurred in the morbid structure. Such intermissions we have witnessed in cancerous and ulcerated conditions of the womb; and, in suppuration in the brain.

But, indeed, it is equally difficult to account for the fact in all instances; and no speculations have yet enabled us to explain, why the vessels of any part, (as of the supra-orbital notch, in the case of mewing,) or of the whole system, (as in a gout,) should take an extraordinary action at regular but distant periods, and continue only their ordinary action in the intervals: whether the parts be actually diseased in structure or not, the periodical recurrence and cessation of increased vascular action is equally inexplicable. Dr. Darwin has ingeniously endeavoured to refer these periodical changes to the influence of our diurnal habits, in regard to activity and sleep, exhaustion of senoral power and invigoration, and to the diurnal periods of heat and cold, light and darkness, &c. upon all the actions of our frame. That these circumstances greatly influence the operations of the animal body, cannot be doubted: and were all the periods of action and intermission diurnal only, we might admit the generalization as correct. But it is not easy to discover how the very frequent intermissions of disease, which continue for tertian periods, that is, during an interval of forty-eight hours, and still more those which continue for quartan periods, of twenty-four hours, can be referred to this general law. See Darwin, Zoonomia, vol. 1. feet. 36.

The bark of the cinchona, and some other bitter vegetable substances, is well known. posesses a considerable degree of power, when administered during the intermissions, for preventing the recurrence of disease, if this class. But a remedy has been added to the list of the materia medica, which seems to have a specific virtue of arresting all intermittent affections: we mean the arsenic, which had long been used as an universal nostrum, under the appellation of the "tablets of ague-drop," but which was first prepared in a safe and manageable form by the late Dr. Fowler, of York, and is now introduced into the pharmacopoeia of the College of Physicians of London. This medicine has not only been administered with decided benefit in intermittent fevers; but also in the intermittent head-ache and mewing, with the most marked successe. And we have found it, in more instances than one, speedily arrest the intermittting pains in diseased uterine, and other organic painful distresses. In a word, arsenic appears to have a specific remedial power over periodical disorders. But in cases of organic disease, its influence is of course confined to the periodic pains connected with them, and is not exerted upon the fixed and continued affection.

The term intermittent is also applied to the pulse, when, after an indefinite number of beats, it stops during the time of one pullation, or lores a stroke. This is sometimes a formidable symptom, when connected with other signs of affection of the brain, or of the heart itself; but it is more commonly of minor import, being connected with indigestion, and a general irritability of the sytem, and is removable by correcting the state of the bowels, and other organs concerned in the chylopathic process. See Pulse.

INTERMITTING SPRINGS, in Natural History, or ebbing and flowing wells, are phenomena which attracted a great deal of attention in former times, and several works on natural philosophy contain explanations of the principles on which they might, by a proper application of the sytem, be made, by art, so as afterwards to be self-acting: it can scarcely be doubted but some of the intermittting springs were natural, or produced their ebbing and flowing or intermission, without the assistance of art, perhaps that on the N.W. side of Tideswell town in Derbyshire, which formerly existed and gave the name to the town, may have been of this number; and perhaps also Laywell springs at Brixham, in Devonshire, may have been natural; but Mr. Farley, in his recent Report on Derbyshire, (vol. i. p. 288.) states the ebbing well at Barmoor, between Callelston and Chapel-en-le-Frith, on the skirt of Peak forest, in Derbyshire, to occupy the site of an old stone-quarry, in the nighthlime rock, and to be evidently the work of art; he also mentions an artificial well of this kind lately made in the parish of Chapel-en-le-Frith. See Spring.

INTERNAL ANGLES, are all angles made by the sides of any right-lined figure within.

In a triangle, as $\triangle ABC$, (Plate VIII. Geometry, fig. 134.) the angles $\angle BAC$ and $\angle ABC$ are particularly called internal and opposite, in respect of the external angle $\angle BMC$, which is equal to them both. See Internal Angles.

The internal angle, is also applied to the two angles formed between two parallels, by a line intersecting them parallel, on each side the intersecting line.

Such are the angles $\angle 1$ and $\angle 2$, and $\angle 3$ and $\angle 4$ (Plate VIII. Geometry, fig. 142.) formed between the parallels $OP$ and $QR$, on each side of the intersecting line $ST$.

The two internal angles are always equal to two right angles.

The internal and opposite angles, are also applied to the two angles $\angle 1$ and $\angle 2$, formed by a line cutting two parallels.

These are respectively equal to $\angle A$ and $\angle B$, called the external and opposite angles.

The internal and opposite angles, are also applied to the two angles $\angle 3$ and $\angle 4$, formed by a line cutting two parallels.

These are respectively equal to $\angle A$ and $\angle B$, called the external and opposite angles.

INTERNAL AFFECTION, Denomination, Ears, Modes, Orthography, Place, Sense. See the tabulates.

INTERNAL PLANTS, in Hering, according to M. Werner (New Theory of Veins, Transl. p. 154.), the internal drawings, or sections as they are called in this country, of the mines and the flates, or of rocks in which they occur. Sections of particular districts, formed into tablets inhibed

N 42 with
with the principal rocks and minerals of such districts, have long been made by Mr. White Watson of Bakewell, in
Derbyshire, Mr. Elias Hall of Caffeleton, Brown and Co.
of Derby, and others, but it has justly been objected to all
the tablets or sections of this kind which we have seen, that
they represent some imaginary hill or mountain, instead of
being in any way proportioned to, or made to represent, the
actual strata and outline of any district. Now that mineral
surveying, or the methods of obtaining a knowledge of the
interior of stratified districts, as well as of ascertaining
whether they are so stratified, has been fully explained in
the Report to the Board of Agriculture on the County of
Derby, by Mr. John Fares, tenor, and illustrated by a sur-
vey of that interesting and difficult county, we hope that
the making of accurate and natural representations or tablets
of the interior, or sections of different districts, will be at-
ttempted. A very neat and interesting way of disposing a
tablet of a gentleman's mineral strata in his estate, is in the
front of his chimney-piece, instead of the flat or carved mar-
bol slab now generally used. Mr. William Milnes of
the Butts in Ashover, in Derbyshire, has employed Mr. W.
Watson to make him such a chimney-piece, which forms a
very interesting object as well as a subject of contemplation to
his friends and visitors.

INTERODIUM, in Anatomy, the space between two
articulations. It is only applied to the fingers, where it is
employed in naming some of the muscles; at present it is
used only in the extensors of the thumb, which are called
extensor primi, and secundus internodi pollicis.

INTERODIUM, in Botany, the space that is between two
knots, or joints, of the stalk of a plant; or, gr. of the stalk
of straw of wheat, or other corn.

INTERNUS MALLEI, in Anatomy, one of the muscles
of the ulna, called more commonly tenor tympani.

SEE EAR.

INTEROSSEI, a number of small muscles of the hands
and foot, so named from being situated in the intervals of the
metacarpal and metatarsal bones.
The interossei of the hand are seven; viz. two for each of
the three middle fingers, and one for the little finger.
The abductors and the adductor of the thumb supply the places
of the interossei in that member; and the adductor offers meta-
carpi indicis holds the place of an internal interosseous mus-
cle in the little finger. The interossei produce the lateral
motions of the fingers to which they correspond; they may
therefore be most conveniently arranged as abductors and
adductors of their respective fingers. More commonly,
however, they are divided into two classes, according as they
are placed towards the palm or the back of the hand, and
distinguished by the names of interossei interni priores or
palmares, and externi posteriores or dorsales. In this distri-
bution, the internal class contains four muscles, which are
named by Albinus, 1, indicis prior, and 2, posterior; 3, prior
annularis; 4, prior auricularis; the external has only three;
viz. 1 and 2, prior et posterior digitii medii; 3, posteri-
orum annularis. Sometimes they are distinguished numerically,
beginning from the thumb. The abductor indicis, or hand-
interosseus, (see ABDUCTOR,) forms the first external in-
terosseus of Soemmerring; who therefore enumerates four
external interossei. This anatomist makes only three in-
ternal interossei; the 1d, internal interosseus of Albinus,
being one of the heads of Soemmerring's first external inter-
oseus. Both classes are called by some French writers
metacarpo-fus-phalangens.

INTEROSSEI OF THE FORE-FINGER. The abductor (prior indicis
of Albinus, one of the heads of the first external interosseus
of Soemmerring and others) is attached to the radial flat
surface of the metacarpal bone of the fore-finger; it forms
a tendon towards the finger, which is inserted, in common
with that of the abductor indicis, into the radial side of the
metacarpal end of the first phalanx of that finger, having
also a slight connection to the extensor tendon; the radial
artery dips into the palm of the hand between this muscle
and the abductor indicis.

The adductor of the fore-finger (posterior indicis, Ab.)
is placed towards the palm of the hand. It arises from the
ulnar flat surface of the 2d metacarpal bone, and from the
ligaments which unite that to the trapezoid bone. At the
end of the metacarpus it forms a small flat tendon, passes
over the articulation of the index and metacarpus, the side
and back part of the first phalanx, the articulation between
the first and second phalanges, and the dorsal surface of the
2d phalanx. On the middle of the latter bone, it meets at
an acute angle with a corresponding tendon of the lumbrics,
and the two tendons unite into a broader one, which is
lightly contracted and inserted into the middle prominence
of the back of the third phalanx. About the middle of the
first phalanx, or rather sooner, it becomes united to the
broad tendon of the extensor, from which it separates a little
before the termination of that tendon.

This connection is formed by a thin and broad tendinous
expansion, which closely covers the articulation of the index
with the metacarpus.

INTEROSSEI OF THE MIDDLE FINGER. The abductor (prior di-
giti medii) is placed towards the back of the hand: it ar-
ises from the ulnar side of the second, and radial side of
the third metacarpal bone; and has a middle tendon, in
which two oblique rows of fibres terminate. The course
of its tendon corresponds exactly to that of the preceding,
and is united, at its termination, to that of the foregoing
muscle.

The adductor of the middle finger (posterior medii digitus)
is placed also towards the back of the hand, and has a sim-
ilar form to the last muscle. It arises from the third and
fourth metacarpal bones, and is inserted in the manner
already described.

INTEROSSEI OF THE RING-FINGER. The abductor, (prior annu-
laris, Ab.) placed towards the palm, is attached to the ra-
dial side of the fourth metacarpal bone, and to the ligaments
which connect it to the carpus. It terminates in a tendon
ending as already described. The adductor (posterior an-
nularis) is placed towards the back of the hand, arises from
the ulnar side of the fourth, and from the radial side of the
fifth metacarpal bone, and has a middle tendon placed be-
tween two planes of fibres, and inserted like the preceding
ones.

INTEROSSEI OF THE LITTLE FINGER. This finger has only
an abductor (prior auricularis), which arises from the radial
surface of the fifth metacarpal bone, and from the ligaments
joining it to the carpus. Its tendon has a course and inser-
tion like those of the former.

The expansions of the interossei, where their tendons
begin to join those of the extensors, are connected by many
fibres to the capsules of the joints formed between the metac-
arpal bones and the phalangeal; their aponeuroses are also
strengthened by the tendons of the lumbrics. The rela-
tions of the interossei to the surrounding parts may be
considered in a general view. On the sides they correspond
to the metacarpal bones, and they are reciprocally in con-
tact with each other. They are covered in front by the tendons
of the flexor profundus, by the lumbrics, and, so far as
the three first are concerned, by the adductor pollicis. They
are retained, towards the end of the metacarpus, by the an-
terior transverse palmar ligament, at the level of which they
are
are all directed backwards. On the posterior surface the first interosseus is subcutaneous; the others are covered by thin aponeuroses attached to the corresponding metacarpal bones, separating the interossei from the extensor tendons, and in their intervals from the integuments. Their expanded tendons are placed between the phalanges and the skin.

Thee muscles seem to perform, as their primary use, the adduction and abduction of the fingers. They serve to fix the extensor tendons; which, not being covered by any fibrous sheaths, required this lateral support. They partake of the function of the lumbricales; when the two interossei of any finger act together, the extensor tendon is drawn in the diagonal of their direction. If the fingers are extended, they will be fixed more firmly in this position; but if they are already bent, the flexion is increased by the action of the interossei, which exert themselves to much the more effectually, as their tendon falls perpendicularly in the moving part. From the course which the tendons pursue, along the sides to the backs of the fingers, they will have the effect of extending the middle and lateral joints. If the fingers are fixed, these muscles may bend the metacarpus to them.

The *interossei* of the foot hold the same relation to the metatarsus, as those of the hand do to the metacarpus; and are arranged into an internal and an external class, or a superior and an inferior; of which the former is placed towards the back, and the latter towards the sole of the foot. They are the adductors and abductors of the toes; and are, when number, three internal, and four external. Of these, six belong to the three middle toes, and one to the little toe, their place being supplied, in the great toe, by its proper muscles.

The *interossei* are the adductors of the third, fourth, and fifth toes. They agree very nearly in their mode of origin, figure, course, termination, and action. They are small and tendinous at their commencement; grow gradually thicker and broader, then again decrease, and form long and flat tendons at the digital end of the metatarsus. They all pass forwards from the metatarsus towards the toes, and end at the tibial sides of the metatarsal extremities of their respective toes, near the terminations of the lumbricales. Their tendons are closely connected to the capsules of the first joints of the toes, to those of the lumbricales, and of the extensors. The first arises from the posterior part of the under surface of the second metatarsal bone on its tibial side; the second from the corresponding part of the fourth, and the third from that of the fifth metatarsal bone. The two latter are so connected to the sheath which contains the tendon of the peroneus longus.

The *external interossei* are 1 and 2, the adductor and abductor of the second toe, 3, the adductor of the third, and 4, the abductor of the fourth. The three latter resemble each other, and resemble also the external interossei of the hand, in having double origins; each of them has two heads, arising from the two contiguous metatarsal bones, tendinous at their commencement, uniting at acute angles in a middle tendon, which passes forwards to the toes. The tendons are thicker and broader than those of the internal interossei, connected in the same way to the capsules of the first joints, and inserted in the same manner, but on the opposite sides of the first phalanges. The abductor of the second toe has its larger origin from rather more than the posterior half of the third metatarsal bone, on its outer or peroneal surface; the smaller head comes from the opposed surface of the second bone. The abductor of the third toe has a larger origin from the fourth, and a smaller from the third bone; and the abductor of the fourth has the same relation in its origin to the fifth and fourth metatarsal bones. The abductor of the second toe differs from the other external or superior interossei, in arising from one bone only: its origin is derived from more than the posterior half of the inner or tibial surface of the second metatarsal bone; its insertion is similar to that of the others.

The interossei of the foot have the following relations to the surrounding parts: On the back of the foot, they are covered by the tendons of the two extensors, and by a very thin aponeurosis, which is sometimes scarcely sensible, and which is extended in the intervals of the metatarsal bones. In the sole they are in contact with the muscles of the great and of the little toe, with the tendons of the flexor longus digitorum and the lumbricales, and with the deep-seated plantar vessels. On their sides they correspond to each other, or to the metatarsal bones.

The motions produced by these muscles are analogous to those of the corresponding ones in the hand. In the first place they are adductors and abductors of their respective toes. They may act as flexors of the first phalanges through the means of their tendons affixed to these bones, more particularly when the first joints are already slightly bent; for they are then directed obliquely or perpendicularly to the moveable point, with which, in the extended state, they are parallel. By the portions, which they detach to the extensor tendons, they may affect the extension of the last phalanges; but it is necessary that the extensors should have previously acted in some degree, to carry the last phalanx upwards and backwards, and this motion is then increased by the interossei. They serve also, as in the hand, to fix the extensor tendons laterally.

*Interosseus*, an epithet of certain organs of the body, particularly in the fore-arm and leg, which are situated between two bones. The interosseous artery of the fore-arm is a branch of the ulnar, and is divided into an anterior and a posterior interosseous branch. In the leg, the peroneal artery is sometimes designated by this term. The interosseous ligaments are aponeurotic expansions attached to the opposed edges of the bones of the arm and leg, and filling up the intervals between these bones. See *Artery* and *Extremities*.

**INTERPLEADER, Bill of, in Law.** is where a person who owes a debt or rent to one of the parties in a chancery suit, but, till the determination of it, he knows not to which, desires that they may interplead, that he may be safe in the payment. In this last case it is usual to order the money to be paid into court, for the benefit of such of the parties to whom, upon hearing, the court shall decree it to be due. But this depends upon circumstances; and the plaintiff must also annex an affidavit to his bill, swearing that he does not collude with either of the parties.

**INTERPOLATION, a term used by critics in speaking of ancient writings and manuscripts, in which some spurious additions or alterations have been since made.**

To establish or ascertain an interpolation, P. Ruinart gives as the five following rules 1. That the piece supposed to be interpolated appear to have all the antiquity it pretends to. 2. That there be good proofs that it has been interpolated. 3. That the supposed interpolations agree to the time of the interpolator. 4. That the interpolations do not touch the foundation of the work; and that they be not too frequent, nor entirely disfigure the piece. 5. That the restitution made, agree perfectly to the rest of the work.

Interpolations have occasioned several of the various readings in the New Testament. Michaelis, in his "Introduction to the New Testament," and also other writers, have suggested how these were introduced, and how they may be distinguished from the original text. E. G. If for a passage

*"Song of Songs*
that is not absolutely necessary to the construction, various readings are found that differ materially from each other, we have reason to suspect its authenticity; and that all the readings are interpolations of transcribers, who have attempted by different methods to supply the seeming deficiency of the original. An interpolation is sometimes betrayed by the circumstance of its being delivered in the language of a later church. To this purpose Michaelis observes, that in the time of the apostles the word “Christ” was never used as the proper name of a person, but as an epithet expressive of the ministry of Jesus, and was frequently applied as synonymous to “Son of God.” The expression, therefore, “Christ is the Son of God,” (Acts, viii. 37) is a kind of tautology, and is almost as absurd as to say Christ is the Messiah, that is, the Anointed is the Anointed. But the word being used in later ages as a proper name, this impropriety was not perceived by the person who obscured the passage on the text. If one or more words, which may be considered as an addition to a passage, are found only in MSS., but in none of the most ancient versions, nor in the quotations of the early fathers, we have reason to suspect an interpolation. Acts, viii. 39, “παρακλησεως παντων ἐν τω τρισχολείω τοῦ ἐφεκτο- 
τος ἀπό τῆς φρουρας,” is an instance of this kind, where the words between the crotchets are probably spurious. Interpolations of considerable length are occasional sometimes in the following manner: The owner of a MS. makes a note in the margin, either explanatory of some passage of the narrative in the text, or containing an account of some event that was handed down by tradition; which MS., being afterwards transcribed, the copyist writes text and notes without distinction in the body of his work. “I am perplexed,” says Michaelis, “that John, v. 4, a very fugacious passage, and omitted in a very great number of MSS. has been introduced in this manner into our present text, and that this scholion was written originally not in Greek, but in some oriental language.” The disputed passage in 1 John, v. 7, may probably be a specimen of this kind of interpolation. Its spuriousness has been shown by Sir Isaac Newton, in a letter to Le Clerc, first published in London in 1754, and more correctly by Dr. Horsey in 1755, from the author’s original copy. (See his edition of Newton’s Works, vol. v. p. 455–551.) This letter, says Dr. Marsh, is left known as it deserves, as the immortal author has displayed in it as much critical knowledge, as penetration in his mathematical inquiries. The question has been likewise examined, and with great impartiality, by Bengal, in his “Apparatus Crucianus,” p. 458–482. 2d ed.; and the dispute has been satisfactorily terminated by the eminently learned Porson, in his “Letters to Travis,” published in 1791. See Various Readings.

INTERPOLATION. In Algebra, is used for the finding an intermediate term of a series, its place in the series being given; and the method of doing this is called the method of interpolations.

When the algebraic equation of the series is given, the term required, whether it be a primary or intermediate term, may be found by the resolution of affected equations; but when this equation is not given, as it often happens, the value of the term sought must be exhibited by a converging series or by the quadrature of curves.

When the first, second, and other successive differences of the terms of a series become at last equal, the interpolation of any term of such a series may be found by Sir Isaac Newton’s differential method.

The method of interpolation was first invented by Mr. Briggs, Savilian professor of Geometry at Oxford, and applied by him to the calculation of logarithms. His principles were followed by Dr. Wallis, who made several ingenious applications of this theory; and by Reginald and Monton, in France. Sir Isaac Newton, in lemma 5. lib. iii. Phil. Princip. Mathem. gave a most elegant solution of the problem for drawing a curve line through the extremities of any number of given ordinates; and in the subseuent proposition applied the solution of this problem to that of finding from certain observed places of a comet, the place of it at any given intermediate time. Dr. Waring, who adds, that a solution still more elegant, on some accounts, has been since discovered by Mr. Nicholls. Nicholls and Stirling, has also resolved the same problem, and rendered it more general, without having recourse to finding the successive differences.

The theory of interpolation is of very extensive use, not only in pure analysis and geometry, but in various other subjects of mathematical inquiry and computation, and particularly in astronomy; we shall therefore endeavour to explain the principles upon which it is founded, and shew its application in a few cases to practical operations.

First, then, let a, b, c, d, e, f, &c. represent any series of similar quantities, and let the difference between the first and second, the second and third, the third and fourth, &c. terms, be taken; and these several remainders will form what is called the first order of difference; then again, let the differences of these differences be taken in the same way; and the differences of these last again the same, and so on, which will give the following result, observing, that for the convenience of exhibiting the operation, we have only retained the first remainders in each successive subtraction.

The now-coefficients of these terms are respectively the same as those of the co-efficients of the binomial, and the order of their generation evidently follows the same law, and therefore we may conclude with equal certainty, that the i-th difference of any series of quantities will be expressed by the formula

\[
a - nb + n(n - 1) & e - n(n - 1)(n - 2) d \\
\ldots & \\
+ n(n - 1)(n - 2)(n - 3) e - & c.
\]

Now it is obvious, that if the given quantities be such, that any order of their differences become equal to o, that any one of those quantities may be accurately expressed in functions of the others; thus, for example, suppose the fourth difference to become zero, that is

\[a - 4b + 6c - 4d + e = 0\]

then will

\[e = \frac{-a + 4b + 4d - e}{6}\]

and it is obvious that any other of these quantities might be expressed in a similar manner; and therefore, if all those quantities but one be known, that one may be ascertained. Thus, by way of illustration, suppose we had the three squares \[10^2 = 100, \ 8^2 = 64, \ \text{and} \ 7^2 = 49,\] and the square of 9 was required; since the third differences of squares equal o, we should have \[9^2 = \frac{100 + 3 \cdot 64 - 49}{3} = 81,\] and the
the fame is obviously true of any terms of which the differences vanish.

But if the differences do not vanish, then any intermediate term found by this method only approximate towards the true result, which is however sufficiently correct in a number of cases; thus, in finding any logarithm, of which those confecutive to it are given, the above formulæ may be successfully employed; for though, in fact, the differences of logarithm never become zero, yet their fourth differences are so small, that by confederating them as 0, the error will not affect the truth of the result to 6 or 9 places of decimals.

Ex. Given the logarithms of 101, 102, 104, 105, to find the logarithm of 103.

Here, calling the log. of 101 = a, of 102 = b, 103 = c, 104 = d, and 105 = e; and considering the fourth differences of these logs = 0; we shall have from the formula

\[ a + 4b + 6c - 4d + e = 0 \]

\[ e = \frac{4(b + d) - (a + c)}{6} \]

Hence the following computation:

\[ \log. 101 = 2.00843214 = a \]
\[ \log. 102 = 2.00890020 = b \]
\[ \log. 104 = 2.01702383 = d \]
\[ \log. 105 = 2.02118953 = e \]

\[ 4.0256335 = b + d \]

\[ 16.1025340 = 4(b + d) \]

Subtr. \[ 4.0255107 = a + e \]

\[ 6.12077033 \]

\[ \log. 103 = 2.0128372 \text{ as required.} \]

This method of finding the intermediate logarithms between others that are known, though of little importance in the present state of the sciences, was of very essential service to the original computers; and to whom the invention of it is due, or more properly to Briggs alone, who seems to have been the first that entered upon the investigation of this theory.

This doctrine is applied with great success in various astronomical operations, and is the means of saving in many cases immense laborious calculations. Thus, for example, in finding the places of some of the planets, whose motion is not very rapid, it will be sufficiently accurate to find their places by calculation for every fourth or fifth day, and then by means of the method above described, their places for all the intermediate days may be found by interpolating; between the known terms, which method will give a result much nearer the truth, than by proportional parts, because this supposes a uniformity both in motion and time, which is not correct.

Again, in computing the moon's place for any particular hour, supposing its place for every day at noon to be given, the method of interpolations may be applied with great success, the results having scarcely any sensible difference from those that arise from actual computation, and we may thus frequently avoid one of the most laborious of astronomical calculations.

By this means also, the place of a comet at any particular time may be ascertained, from observations made on it prior to, and subsequent to, that precise period, as also the times of the eclipses and other phenomena, which are determined much more accurately by this method than can be done by proportional parts, for in this, we are obliged to suppose that the sun's declinations increase and decrease proportionally to the distance of this body from the equinoctial point; which is evidently a false hypothesis. In fact, astronomy has derived more applause from this theory than any other of the mathematical sciences, although it has been applied to other purposes with very great success; but in order to render its application thus general, a much more accurate and extended investigation of the theory than that which has been at present mentioned becomes necessary, and of which we propose to give a full view in the subsequent part of this article.

The general problem to be resolved in all these cases is this: Given two series of numbers, which correspond with one another, according to a certain law, and of which one may be called the series of roots, and the other the series of functions, to find an intermediate number, between two functions, which shall answer or correspond to a given intermediate number between two roots. This problem is treated of in all its generality by Newton, in his "Methodus Differentialis," and by Stirling in his "Traités de Summation, &c." See also Lacaille's Astronomy, and a paper by Mayer in the Acta Petrop. tom. ii. page 103; also an excellent memoir by Lalande, transmitted to the Academy of Sciences of Paris for 1761; in which he has shown that in calculating the moon's place, and much more that of any other of the heavenly bodies, whose motions are more regular; it will always be sufficient to consider only the third differences, and in many cases only the second differences will be requisite, and sometimes only the first; in fact he has shown how, and to what degree of accuracy, the method of interpolation may be employed in most cases. The same author has also a very complete article on this subject in the Encyclopédie Méthodique where, in explaining the nature of astronomical interpolation, he says, suppose a series of numbers 0, 1, 3, 6, 10, 15, 21, &c. of which the differences are unequal, but follow a certain law, being in fact in arithmetical progression as 1, 2, 3, 4, 5, 6, &c.; that the second differences are constant, and equal to unity. Now if we take the alternate terms of this series, as for instance 0, 3, 10, 21, &c., the first differences will be 3, 7, 11, &c. and the differences of these differences will be constant, and equal to 4; that is four times greater than before; because in doubling the interval, we have for the first difference the sum of 1 and 2, and in the other the sum of 3 and 4; hence it follows that the second difference increases in the ratio of the differences between 2 and 3, and 1 and 4; the increafe, therefore, being equal to three times the first, this second difference will be equal to four times that; and if we took every third number, the second difference would be 9, and so on.

Thus, in general, the second differences incease as the square of the intervals of the numbers; and hence we have the following rule for supplying the intermediate terms of a series of numbers of which the law of their generation is uniform.

For example, let there be four numbers which may represent longitudes, observed at the interval of 12 hours, each; and of which the three differences are 78, 223, and 366, so that their second differences will be constant, and equal to 144; according to the following table:

<table>
<thead>
<tr>
<th>Hours</th>
<th>Nos.</th>
<th>1st Diff.</th>
<th>2nd Diff.</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0</td>
<td>78</td>
<td>144</td>
</tr>
<tr>
<td>12</td>
<td>78</td>
<td>223</td>
<td>144</td>
</tr>
<tr>
<td>24</td>
<td>366</td>
<td>366</td>
<td></td>
</tr>
</tbody>
</table>

Such
INTERPOLATION.

Such an example is the most simple that can be conceived in interpolation, but simple as it is, it is all that is required in astronomy, even for the motion of the moon, which is the most irregular of all the planetary bodies; such at least is the assertion of Lalande in the article of the Encyclopédie above quoted.

Now knowing the above numbers, or observed longitudes, for every 12 hours, it will be easy, by means of the above rule, to find the same for every six hours; for since, in this case, the second differences ought to be only one-fourth of those above, that is 36, it will therefore only be necessary to construct a series of numbers beginning at 0, whose second differences are 36, and whose second term shall be 78; therefore \( \frac{28 - 36}{2} = 21 \) is the first term of the differences; and all the other terms will be found by adding successively to this, the second constant difference 36; thus

<table>
<thead>
<tr>
<th>No.</th>
<th>long.</th>
</tr>
</thead>
<tbody>
<tr>
<td>0.21</td>
<td>78, 171, 300, 465, 666.</td>
</tr>
</tbody>
</table>

But if, instead of interpolating one term between each of the given numbers, it had been required to interpolate two terms, then we must have taken a ninth part of the above second difference, viz. 16, and found from hence a series of numbers whose second difference should be 16, and the third term of the series = 78. Now in order to find this series, it will be sufficient to find the first term of the 2d difference, as all the rest that is required may be determined from this; suppose, then, this term to be \( x \), which is also the first term of the required series, then the second will be \( 2x + 16 \), and the third \( 3x + 48 \); whence \( 3x + 48 = 78, x = 10 \); which gives for

\[ \text{1st diff.} \quad 0, 26, 42, 58, 74, 90, 106, \&c. \]

<table>
<thead>
<tr>
<th>No.</th>
<th>long.</th>

</thead>
<tbody>
<tr>
<td>0.10</td>
<td>36, 78, 136, 210, 300, 406, &amp;c.</td>
</tr>
</tbody>
</table>

and on similar principles may the interpolation in any other case be effected with the same degree of ease and accuracy; that is, generally, in order to interpolate any number of terms \( n \), between any two given terms of a known series, we must divide the second difference of the given series by \( (n + 1) \), in order to have the second difference of the new series; and then again in order to obtain the 1st differences, we have this formula; where \( d = 1 \text{st term} \), \( d' = 2 \text{d difference} \),

\[ \text{1st term} \quad \text{1st diff.} = \frac{d}{n + 1} + \frac{n \cdot d'}{2}, \]

which may be more conveniently expressed in terms of the 1st and 2d differences of the given series as follows; \( d = 1 \text{st difference} \), \( d' = 2 \text{d difference} \), \( d'' = 3 \text{d difference} \), then the 1st term 1st diff. of the new series, becomes

\[ \frac{2d' (n + 1) + n \cdot d''}{2 (n + 1)}, \]

and this term being thus determined, all the others are readily obtained; and consequently also all the intermediate terms which were to be interpolated. The consideration of second differences, which render the interpolation fo extremely easy, is, as we before observed, sufficiently exact for the greater part of astronomical calculations, particularly in the construction of tables; it was thus that Sharp in 1695 calculated his table of right ascension and declination for every degree of latitude and longitude; having first calculated trigonometrically the same for every fifth degree, the other intermediate degrees having been ascertained by means of the theory of interpolation. Mouton also, on similar principles, calculated the declination of the sun for every minute of longitude in seconds and thirds, having first found trigonometrically the same for every degree. In general, whatever be the nature of the calculation, it will be sufficient to ascertain rigorously by trigonometry, or otherwise, terms at such a distance that their third differences may become zero, or so small that no sensible error will arise in considering them as such, and then all the intermediate terms may be supplied by the theory which has been invented.

Lalande has published in the "Connaissance des Tems for 1771," a very commodious table for abridging the kind of operations, and there is another still more extended in the "Recueil des Tables de Berlin."

The same theory of second differences may also be conveniently applied to correct calculations and observations, that is, by ascertaining the uniformity of the remainders or differences.

For example, a series of observations being submitted to this test, ought to have a certain order of their differences uniform, and if in any place such a uniformity is not observed, one difference being greater, or less, than another, it may be concluded with certainty, that some error has been committed in the corresponding observation; the correction of which may be readily made, without repeating the observation; Lalande has also given, in his memoirs above-mentioned, general formulas of correction, for such cases, and which may be applied with the greatest facility, and the correction computed to the utmost possible accuracy.

On nearly the same principles as the foregoing, the extraction of roots, as the square root, cube root, &c. may be effected with great ease, by knowing certain equivalent roots. The application in this case being extremely simple, it may not be amiss to enter a little into the explanation of it.

Let

\[ (x^2 + 1) = x + \frac{1}{3} x^3 - \frac{1}{9} x^5 + \frac{5}{81} x^7 - \frac{10}{243} x^9 + \&c. \]

\[ (x^2 - 1) = x - \frac{1}{3} x^3 - \frac{1}{9} x^5 - \frac{5}{81} x^7 - \frac{10}{243} x^9 + \&c. \]

represent the cube roots of any three consecutive numbers, the differences of which are

\[ \left\{ \begin{array}{c} \frac{1}{3} x^2 - \frac{1}{9} x^4 + \frac{5}{81} x^6 + \frac{10}{243} x^8 + \&c. \\ \frac{1}{3} x^2 - \frac{1}{9} x^4 + \frac{5}{81} x^6 + \frac{10}{243} x^8 + \&c. \\ 2d. \end{array} \right\} \]

In the same way, was it necessary, we might have found the third and fourth differences, and so on; but in the case we shall suppose, of \( x' > 1000 \), or \( x < 1 \), this second difference is sufficiently exact, and even the second term of this second difference is so small, that it may be omitted without affecting even the eleventh place of decimals, for taking \( x = 10 \), we have \( \frac{20}{243} x^4 = \frac{2}{24300000000} \), which, when converted into a decimal, will not give an effective figure before the 11th place; we may, therefore, without any sensible error, call \( \frac{2}{9} x^3 \) the second difference, which will remain constant for several terms, while our extraction is not carried farther...
Farther than to eight decimal places. Supposing, therefore, the cube root of any two consecutive numbers greater than 1000 to be known, that is, \(\sqrt[3]{a} = x\), and \(\sqrt[3]{a+1} = x+1\); the first difference is ascertained by simple subtraction, and the second difference is found by the formula \(\frac{2}{9a^2} = \epsilon\); and with these data, we may calculate eight or ten of the submultiple roots, when a new computation becomes necessary.

This is not, however, the simplest manner of employing the formula that have been deduced, because it requires the knowledge of two consecutive roots, whereas it will be sufficient to have the roots of numbers equidistant from each other, and by means of which the first and second differences may be readily obtained, and the successive extractions will thus become so many simple checks upon each other. Suppose, for example, that we know the cube roots of 2000 and 2008, that is, \(\sqrt[3]{2000} = a\), and \(\sqrt[3]{2008} = b\); and if we required to find the roots of all the intermediate numbers; calling the first difference \(d\), and the second difference \(\frac{2}{9a^2} = \epsilon\); then the cube roots will stand thus:

\[
\begin{align*}
\sqrt[3]{2000} &= a \\
\sqrt[3]{2001} &= a + d \\
\sqrt[3]{2002} &= a + 2d - \epsilon \\
\sqrt[3]{2003} &= a + 3d - 3\epsilon \\
\sqrt[3]{2004} &= a + 4d - 6\epsilon \\
\sqrt[3]{2005} &= a + 5d - 10\epsilon \\
\sqrt[3]{2006} &= a + 6d - 15\epsilon \\
\sqrt[3]{2007} &= a + 7d - 21\epsilon \\
\sqrt[3]{2008} &= a + 8d - 28\epsilon = b.
\end{align*}
\]

And since this last root ought to be equal to the known root \(b\), we have a secure check upon all the preceding part of the operation; or more properly, this condition may be employed for finding the first difference \(d\), and the check be made upon the submultiple difference; for since \(a + 8d - 28\epsilon = b\), we have \(d = \frac{b + 28\epsilon - a}{8}\). This operation will be better understood from the following work at length.

Given the cube root of 6280 = 18.449582727, and of 6288 = 18.45714356, to find all the intermediate roots between those numbers.

By logarithms we find \(\sqrt[3]{6280} = 18.449582727\), and \(\sqrt[3]{6288} = 18.45714356\), to find all the intermediate roots between those numbers.

By logarithms we find \(\sqrt[3]{6280} = 18.449582727\),

\[
\begin{align*}
6280 &= 18.449582727 \\
979223 &= \text{difference} \\
6281 &= 18.4503608949 \\
979147 &= \text{difference} \\
6282 &= 18.4515410066 \\
979012 &= \text{difference} \\
6283 &= 18.4525258278 \\
978897 &= \text{difference}
\end{align*}
\]

\(\frac{1}{12} \times (a - 1) = \frac{1}{12} \times (1.2) = \frac{1}{12} \times (2)\), 

which

\[\text{Cube root } 6234 = 18.453495987, \quad 978902 \text{ difference} \]

\[6235 = 18.45447787, \quad 978907 \text{ difference} \]

\[6236 = 18.45546484, \quad 978902 \text{ difference} \]

\[6237 = 18.45634357, \quad 978907 \text{ difference} \]

\[6238 = 18.45721573, \quad 978902 \text{ difference} \]

And thus may the extraction be carried on at pleasure, by simple addition or subtraction; the cube roots of certain intermediate terms being first known. It is unnecessary observe that the above successive differences are found by subtracting always 1000 from the former root.

At present we have only considered the elementary principles on which the theory of interpolation is founded; it will be proper, however, before we conclude this article, to give some idea of the general form and results obtained from these simple and obvious truths, by Newton in his "Methodus Differentialis," and by Stirling in his celebrated "Tractatus de Summis et Interpolatione Serierum Infinitarum," published in 1730, both of which works are worthy of their celebrated authors.

Let us imagine a right line given in position, on which let there be erected any number of ordinates parallel to one another, and at equidistances, which ordinates may be conceived to represent the terms of a regular series, continually increasing or decreasing; and one and the same curve will pass through all their extremities, the equation of which will be determined from the given equation to the series; that is, from the equation expressing generally the relation between any two or more successive ordinates; and if this equation be finite, the equation of the curve will also be finite, and consequently an absolute interpolation of the series may be effected; for this is nothing more than assigning to every particular abscissa, its corresponding ordinate, and this will always be the case if any order of the differences become equal to zero; thus, in all kinds of figurate numbers, as triangulars, square, pentagons, &c., the curve passing through their summits will be the common conical parabola. But if, as is frequently the case, one or more differences become zero, then the algebraic equation of the curve cannot be found, and consequently no interpolation can then be made, except by means of an infinite series, the quadrature of some curve, or some other approximation.

Let there be proposed, for example, the series 1, 2, 27, 64, &c., the general interpolation of which is required. This series is no other than that of the natural cubes, and therefore the method which we are about to follow is wholly unnecessary in this case, but the example is chosen in order to illustrate the general method, which is applicable in all cases, even when the terms of the series appear to follow no certain law. We first write the terms of the proposed series in one line, then the differences of these in the next, and then again the differences of these, and so on, till the last order of differences become all equal, or such that no sensible error will arise in considering them as such; then considering \(z\) as any abscissa, the first terms of the successive differences will be the coefficients of the series of terms

\[
\begin{align*}
\text{Cube root } 6234 &= 18.453495987, \\
6235 &= 18.45447787, \\
6236 &= 18.45546484, \\
6237 &= 18.45634357, \\
6238 &= 18.45721573, \\
6280 &= 18.449582727 \\
6281 &= 18.4503608949 \\
6282 &= 18.4515410066 \\
6283 &= 18.4525258278 \\
978902 &= \text{difference} \\
978907 &= \text{difference} \\
978902 &= \text{difference} \\
978907 &= \text{difference} \\
978902 &= \text{difference} \\
978907 &= \text{difference} \\
978902 &= \text{difference} \\
978907 &= \text{difference} \\
12 z_1 \left(\frac{1}{12} \times (1.2) = \frac{1}{12} \times (2)\right) &= \text{coefficient of the series of terms}
\end{align*}
\]

\[\text{D o which}
\]
INTERPOLATION.

which expression will then represent the corresponding ordinate to the absciss $z$; and consequently the interpolation of the series may be made general. Thus in the example proposed,

<table>
<thead>
<tr>
<th>Series</th>
<th>1</th>
<th>8</th>
<th>27</th>
<th>64</th>
</tr>
</thead>
<tbody>
<tr>
<td>1st diff.</td>
<td>7</td>

<td></td>
</tr>
</tbody>
</table>

Therefore, considering $y$ as the corresponding ordinate to the absciss $z$, we have

$$e = 1 + 7z + \frac{12}{1} z (z - 1) + \frac{6}{1 \cdot 2} z (z - 1)(z - 2),$$

or

$$y = 1 + 3z + 3z^2 + \frac{z^3}{1 \cdot 2 \cdot 3},$$

as it ought to be, from the nature of the series. If, therefore, now we had to interpolate a term between each of the given ones, these terms would be $(1 \frac{1}{2})$, $(2 \frac{1}{2})$, $(3 \frac{1}{2})$, $(4 \frac{1}{2})$, &c.

And the same method is applicable in all cases, but it sometimes admits of abbreviation, if the law of the series can be determined, and therefore this should be the first consideration when the law is not evident.

Let there now be proposed the series

$$1, \frac{1}{2}, \frac{3}{5}, \frac{5}{10}, \frac{35}{28}, \text{&c.}$$

where the law is not obvious, the interpolation of which is required.

<table>
<thead>
<tr>
<th>Series</th>

</tbody>
</table>

Hence assuming $y$ for any ordinate corresponding to any proposed absciss $z$, the equation of the curve passing through the summits of the ordinates, will be

$$y = 1 - \frac{1}{2} z + \frac{3}{8} z (z - 1) - \frac{5}{16} z (z - 1)(z - 2),$$

$$= - \frac{63}{256} z (z - 1)(z - 2)(z - 3)(z - 4).$$

But as the object of our inquiry is more particularly directed to the finding of the first interpolated term, represented above by $x$, we must make $z = \frac{1}{2}$; whence the above is reduced to

$$x = - \frac{1}{4} a + \frac{3}{16} b + \frac{15}{36} c + \frac{35}{64} d, \text{&c.}$$

in which series the order of formation of the co-efficients is obvious, $a, b, c, d, \text{&c.}$ being representatives of the preceding terms; and hence, by the summation of the series, the value of $x$ is found equal to $0.6452$, and consequently by a little attention it will be seen that the series is produced from the successive multiplication of the terms of the series $\frac{1}{2}, \frac{3}{4}, \frac{5}{6}, \frac{7}{8}$; in which the order of formation is manifest, and the interpolation of this, except for the term between 1 and $\frac{1}{2}$, is evident; the other interpolated terms being $\frac{2}{3}, \frac{4}{5}, \frac{6}{7}, \text{&c.}$: let then the term between 1 and $\frac{1}{2}$ be $x$, then the series after interpolation will be

$$1, \frac{1}{2}, \frac{2}{3}, \frac{3}{4}, \frac{4}{5}, \frac{5}{6}, \frac{6}{7}, \text{&c.}$$

and as the proposed series is generated from the continued multiplication of the series $1, \frac{1}{2}, \frac{3}{4}, \frac{5}{6}, \text{&c.}$; so will the interpolated terms required, be generated from the continued multiplication of the interpolated terms of this last series, which will therefore be

$$x, \frac{2}{3}, \frac{2}{3}, \frac{4}{5}, \frac{2}{3}, \frac{4}{5}, \frac{6}{7}, \text{&c.}$$

All, therefore, that is required, is to find the value of $x$, from which any interpolated term may be determined; and it may be further observed, that the term $x$ of the above generating series must necessarily be the second term of the required series after interpolation, or that term which falls between 1 and $\frac{1}{2}$. Let therefore the differences be taken as follows, viz.

$$\frac{5}{16}, \frac{35}{28}, \frac{63}{256}, \text{&c.}$$

from what has been before observed, the interpolation of the proposed series is now complete, being as follows:

$$1, \frac{1}{2}, \frac{2}{3}, \frac{1}{2}, \frac{1}{2}, \frac{2}{3}, \frac{3}{4}, \frac{4}{5}, \frac{5}{6}, \frac{4}{5}, \frac{3}{4}, \frac{2}{3}, \frac{1}{2}, \frac{1}{2}, \frac{2}{3}, \frac{3}{4}, \frac{4}{5}, \frac{5}{6}, \text{&c.}$$

If it had been required to interpolate two terms between each of the given terms, it would have only been necessary to have assumed $z = \frac{1}{2}$, and $\frac{1}{2}$, as is evident: and therefore needs no illustration.

Hence we see that the general equation of any curve, made to pass through the summits of any number of equidistant ordinates, $a, b, c, d, \text{&c.}$ will be

$$y = a + (b - a) z + (c - 2b + a) \frac{z (z - 1)}{1 \cdot 2} + (d - 3c + 3b - a) \frac{z (z - 1)(z - 2)}{1 \cdot 2 \cdot 3} \text{&c.}$$

which is Newton's formula in his "Methodus Differentialis." The limits of our article will not admit of a farther development of the theory of interpolation, we must therefore refer the reader, who wishes for more complete information, to that work.
**INTERPRETATION of Laws** depends on more equitable and excellent principles than those which prevailed among the Romans, who, when any doubt arose upon the construction of their laws, flouted the cafe to the emperor in writing, and took his opinion upon it. To interpret the legislature, says judge Blackstone, to decide particular disputes, is not only endless, but affords great room for partiality and oppression. The fairest and most rational method to interpret the will of the legislator is by exploring his intentions at the time when the law was made, by signs the most natural and probable. These signs are either the words, the context, the subject-matter, the effects and consequence, or the spirit and reason of the law. Words are generally first understood in their usual and usual signification. If words are dubious, their meaning may be established from the context. Thus the preamble often refers to the construction of an act of parliament; and the comparison of one law with other laws, made by the same legislator, and bearing some affinity or relation to the subject, will answer a similar purpose. As to the subject-matter, words are always to be understood as having a regard to it. With respect to the effects and consequence, the rule is, that where words bear either none, or a very absurd signification, if literally understood, we must little deviate from the received sense of them. But after all, the most universal and effectual way of discovering the true meaning of a law, when the words are dubious, is by considering the reason and spirit of it; or the cause which moved the legislator to enact it. From this method of interpreting laws by the reason of them, arises what we call equity; which see.

**INTERPRETER**, a person who explains the thoughts, words, or writings, of some other, which before were unintelligible.

The word *interpretes*, according to Iisdore, is composed of the preposition *inter*, and *partes*, as signifying a person in the middle between two parties, to make them mutually understand each other's thoughts. Others derive it from *inter* and *præs*, i.e. *sides*, q. d. a person who serves as security between two others, who do not understand one another.

There have been great debates about interpreting scripture. The Romanists contend, that it belongs absolutely to the church; adding, that where she is silent, reason may be consulted; but, where she speaks, reason is to be disregarded. The Protéstats generally allow reason to be the sovereign judge, or interpreter, though some among them have a strong regard to fynod, and others to the authority of the primitive fathers. Lastly, others have recourse to the spirit within every person to interpret for them; which is what Bochart calls *sensus spiritus*. It is, or at least, ought to be, the fundamental principle of all Protèstats, and indeed of all Christians, that every man should interpret scripture for himself, admitting no compulsory or controlling authority, but at the same time availing himself of all the assistances which others may afford for directing his inquiries and determining his judgment. "Let every man," says scripture itself, "be fully persuaded in his own mind."

**INTERREGNUM**, the time during which a throne is vacant, or a kingdom without a head.

In hereditary kingdoms, as England, there are properly no interregnums. (See Right of CROWN.) In elective kingdoms, the interregnums are extremely liable to faction and disorders.

**INTEREX**, a magistrate who governs during an interregnum, or in the interval between the death of a monarch and the election or inauguration of his successor.

This magistrate was established in old Rome, and was almost as ancient as the city itself. After the death of Romulus there was an interregnum of a year, during which the senators were each interrex in their turn, five days apiece.

After the establishment of consuls, and a commonwealth, though there were no kings, yet the name and function of interrex were still preferred; for when the magistrates were absent, or when there was any irregularity in their election, or they had abdicated, so that the comitia could not be held, provided they were unwilling to create a dictator, they made an interrex, whose office and authority were to last five days; after which they made another. To the interrex was delegated all the regal and consulary authority, and he performed all their functions. He assembled the senate, held comitia, or courts, and took care the election of magistrates was according to the rules. Indeed, at first it was not the custom of the interrex to hold comitia; but at last we have no instance of it in the ancient Roman history.

The patricians alone had the right of electing an interrex. This office fell with the republic, when the emperors made themselves masters of every thing.

**INTERMENT, INTERMENT, or Entombment, the act of interring, i.e. burying, or laying a deceased person in the ground. See Burial.**

The excommunicated are not to be interred in holy, i.e. in consecrated ground. The ancients did not inter their dead; they burnt them, as the Indians do at this day. See Burning.

The Abyssinians, in lieu of interring their dead, flung them up in the bodies of trees, dug hollow for this purpose.

Gardeners also inter, or earth up, celery, endive, and lettuce, to blanch, or whiten, and make them the tenderer.

To inter wild flocks in ditches, is what Columba calls *deponere semina fœbibus*. There are some seeds, as willows, olives, &c. which grow very well, by interring their trunks, i.e. cutting a trancheon, or piece, off at both ends, and planting it in the ground; which is what the Latin call *inimum transeuntibus, talibus ferris*. The fleeing from the fire.

**INTERROGATE, a judicial act performed by a judge, or commissioner deputed to examine or question a party; who first gives his oath, that he will answer truly to everything he is interrogated.**

**INTERROGATION, in Rhetorick. See EROTESIS.**

As to the difference between interrogation and exclamation, (which see) we may observe, that interrogations are often employed with propriety in the course of no higher emotions than naturally arise in pursuing some cloze and earnest reasoning; whereas exclamations belong only to stronger emotions of the mind, as surprise, admiration, anger, joy, grief, and the like. Both interrogations and exclamations, and all passionate figures of speech, being natural signs of a meditated
and agitated mind, when properly used, operate upon us by means of sympathy. Hence it follows, that the great rule with regard to such figures is, that the writer attend to the manner in which nature dictates to us to express any emotion or passion, and that he give his language that turn and no other; above all, that he never affect the style of a passion which he does not feel. Interrogations may be used with freedom; but nothing has a worse effect than the frequent and unmeaning use of exclamations to which raw and juvenile writers are addicted. They render compositions rigid to excess.

**INTERROGATION**, in Grammar, is a point which serves to distinguish such parts of a discourse, where the author speaks as if he were asking questions. Its form is this (?).

**INTERROGATORIES**, in Law, are particular questions demanded of witnesses brought in to be examined in a cause, especially in the court of chancery. And these interrogatories must be exhibited by the parties in suit on each side; which are either direct for the party that produces them, or counter on behalf of the adverse party; and generally both plaintiff and defendant may exhibit, direct, and counter or cross interrogatories. They are to be pertinent, and only to the points necessary; and either drawn or perused by counsel, and to be signed by them. See Commission to examine witnesses, and Examination of witnesses. See also Contempt.

**INTERRUPTED SUTURE**, in Surgery. See SUTURE.

**INTERRUPTION**, in Manners of Proportion, denotes the same with disjunction.

It is noted thus (?), and signifies the breaking off of the ratio in the middle of four disjoint or discrete proportionals: as A : B : C : D; that is, as A is to B fo is C to D. See Ratio. Proposition, &c.

**INTERSECTION** is also a figure in Rhetoric, wherein a person breaks off his discourse suddenly, to throw some passion.

**INTERSECT** was applied to quantities, when the exponents of their powers are radical quantities. Thus \( z^x \), \( z^m \), &c. are intersected quantities. See Function.

**INTERSECT**. in Males, the cutting of one line or plane by another; or the point or line wherein two lines, or two planes, cut each other.

The mutual intersection of two planes is a right line. The centre of a circle is in the intersection of two diameters. The central point of a regular or irregular figure of four sides, is the point of intersection of the two diagonals. The equinoaxes happen when the fun is in the intersection of the equator and the ecliptic.

**INTERSOILING**, in Hydraulics, the laying one kind of soil, or mould, upon another; as clay on land, sand on earth, &c.

**INTERSPERSUMS VACUUM.** See Vacuum.

**INTERSPIRAN** is, in Anatomy, small muscles placed in the intervals of the spinous processes of the vertebrae, and distinguished as belonging to the neck, back, or loins.

**INTERSPIRALS colli**, interspinous, epineux du col, are arranged in pairs, as the processes, to which they are connected, are bifurcated. There are six pairs, of which the first is placed between the spinous processes of the second and third cervical vertebrae, the second between the third and fourth, and so on to the fifth, which is found between the first cervical and first dorsal vertebrae. Their surfaces are flattened, and they have some resemblance to lengthened figures; on the outside, they are in contact with the multi-

**fuidus spine; on the inside, the two muscles composing the pair are in contact; their upper and lower edges are fixed to the spinous processes which bound the intervals containing them.**

With the exception of a few short aponerotic fibres at their extremities, they are entirely flabby. By approximating the spinous processes, they extend the cervical portion of the spine.

**Interpinnales dorsi**, epineux du dos. Small muscles are sometimes placed between the spinous processes of the lower lumbar vertebrae; but they are more frequently absent.

**Interpinnales lumbarum**, epineux des lombes. These are in number, seldom deficient, tendinous at their extremities, and attached above and below to the spinous processes of the lumbar vertebrae. They are covered at the sides by the multifidi spinae. The first is placed between the twelfth dorsal and first lumbar vertebrae; the fifth between the last lumbar and the sacrum. They produce in the loin the same effect as the corresponding muscles do in the neck.

**INTERSTELLAR**, a word used by some authors to express those parts of the universe that are without, and beyond, the limits of our solar system.

In the interstellar regions are supposed to be several other systems of planets moving round the fixed stars, as the centres of their respective motions; and if it be true, as it is not improbable, that each fixed star is thus a sun to some habitable orbs, that move round it, the interstellar world will be inimitably the greatest part of the universe.

**INTERTEIES, or INTERDUES**, in Architecture, those small pieces of timber which lie horizontally between the jambers, or betwixt them and the tail, or raftin plate.

**INTERTRANSVERSI**, in Anatomy, or intertransversarii, or intertransversales, are small muscles belonging to the spine, placed in the intervals of the transversal processes of the vertebrae, and distinguished in the different regions of the spine by the additional terms of colli, dorfi, and lumbarum.

**Intertransversi colli**, intertransversarii, petits transversaires du col. These muscles are distinguished into anterior and posterior, as the transversal processes to which they are attached, are bifid at their ends. The anterior ones are fixed in number; the first is placed between the transversal processes of the first and second vertebrae, and the fifth between those of the fifth and seventh. They are flattened in their figure, and the first is longer than the succeeding ones. On the front, they are covered by the rectus capitis major anticus; behind, they are in contact with the anterior branches of the cervical nerves; their upper and lower margins are attached to the transversal processes.

The posterior intertransversi are five in number, the first being placed between the transversal processes of the second and third vertebrae, and the fifth between those of the fifth and seventh. They very much resemble the preceding muscles. They correspond in front to the anterior branches of the cervical nerves, and are covered behind by the spinosus, transversalis colli, and facrimbals. Their margins are fixed to the transversal processes. They are almost entirely flabby. By drawing the transversal processes together, these muscles will incline the neck laterally.

**Intertransversi dorfi**, petits transversaires du dos. These resemble in the back the corresponding muscles of the loins, but are smaller; they are placed between the points of the transversal processes. Some of the lower ones are of a con- spicuous size; they become gradually more slender and tendinous, and, in the upper part of the back, appear more like thin tendons than muscles. In the latter situation they often do not exist. In front they lie on the intercostal muscles.
IN

mucous, and they are covered behind by the longissimus dorfi and facroglutealis; above and below they are fixed to the transverse processes. They produce the lateral inflexions of the dorsal vertebrae.

*INTERTRANSVERSI HUMERARUM,* transversaires des loumes. These are small muscular planes filling the intervals between the transverse processes of the lumbar vertebrae. Their number is five, the first being placed between the last dorsal and the first lumbar vertebra, and the last between the fourth and fifth lumbar vertebrae. They are thin, flattened, and quadrilateral. They correspond in front to the quadratus lumborum, and behind, to the facroglutealis; their upper and lower edges are fixed to the transverse processes. They are almost entirely flexible. Their office is that of inclining the vertebral column towards one side, or of restoring it to the erect state after it has been fo inclined.

**INTERTRIGO,** in Medicina, παζρηθος of the Greeks, signifies an erythematous affection of the skin, a smooth, shining redness and tendermess of the part, chiefly from friction.

The *intertrigo* most commonly arises in those parts of the surface, which lie in contact with each other, and are liable therefore to considerable attrition during motion; or in those which are subject to friction and pressure from other causes; and more especially when, at the same time, any acrid fluid is present. Whence it is very frequent about the top of the thighs and the perineum of infants, when the clothes in which they are wrapped become wetted with the urine. Similar affections of the skin are also liable to occur in persons who take exercise on horseback, or in the feet of those who have walked a considerable distance, especially in tight shoes, and in the backs and shoulders of ticket persons, long confined to bed. The first of these varieties, which occur in the *placa* or duplicatures of the skin, or originate from the attrition of the bandsages impregnated with urine, &c. Sauvages has called *Erythema intertrigo;* the latter from friction of the clothes, or bed, he denominates *Erythema paratritism.* 

See his Nofol. Method. Cl. i. Genus 11. fpec. 5 and 6.

Dr. Willan also treats of the former varieties of the disorder under the same head. When speaking of erythema, he says, we may rank under the present article that species of intertrigo which is produced in some persons by the attrition of contiguous surfaces, as beneath the breasts, round the *axilla,* in the groin, and at the upper part of the thighs, and is attended with a glibry and fettic fecution. The *intertrigo* is most troublesome when it affects the thighs; it commences where they are in contact with the fafer, and extends upwards to the groin and *nates,* round the *ferotum,* and down the hollow of the thigh. In places where the friction is strongest, the redness is continuous, but it terminates at the edges in a mixed colour, such as characterizes efflorescences generally. This complaint is most frequent in very warm weather, and affects persons of the gonfous temperament, especially those who are copulent. It sometimes terminates in the *prurigo,* or *gloefia ferotula.* An appearance analogous to the *intertrigo,* is produced by acridious discharges in persons labouring under dysestheny, gomorrhia, &c.; in females affected with flour album, or urine *fourth,* and in infants, from the fistulas of the umbilical, &c. with which their clothes are almost constantly stained. (See Willan on Cutaneous Diseafes, p. 491.)

He adds, to the morbid state of the skin with excoration, or of irritable ulceration, as several writers both ancient and modern have done; and therefore excludes from the intertrigo, those ulcerate varieties included in the 6th species, or *Erythema paratritism,* of Sauvages.

For the solution with tepid water is necessary to allay the heat and uneafiness which attend this complaint, to remove the viscid secretion from the surface, and to prevent excoration. When the skin is fretted by the discharge of an acrimonious fluid, some relief is obtained by the application of dry absorbent powders; in case of abrasion and ulcers, the elder-ointment may be applied with much advantage.

**INTERTWISTED SUTURE.** See SUTURE.

**INTERVAL,** the distance or space between two extremities, either in time or place.

The word comes from the Latin intervalum, which, according to Hildreth, signifies the space *inter s. et murum,* between the ditch and the wall; others note, that the flaxes or piles, driven into the ground in the ancient Roman bulwarks, were called *vinda,* and the intervals or vacancy between them *interwilla.*

**INTERVAL, Angle of.** See ANGLE.

**INTERVALS, Lucid.** See Lucid.

**INTERVAL, in Music, the difference between two sounds, in respect of acute and grave; or that imaginary space terminated with two sounds differing in acuteness or gravity. When two or more sounds are compared in this relation, they are either equal or unequal in the degree of tone; such as are equal are called *intervalia,* with regard to each other, as having one tone; the other, being at a distance from each other, constitute what we call an *intervalum* in music; which is properly the distance in time between two sounds.

Intervals are distinguished into *simple* and *compound.*

**INTERVAL, Simple, is that without parts, or division; such are the octaves, and all that are within it; as the second, third, fourth, fifth, sixth, and seventh, with their varieties.

**INTERVAL, Compound, consists of several lesser intervals; such are all those greater than the octaves; as the ninth, tenth, eleventh, twelfth, &c. with their varieties. But this distinction, it is to be observed, regards practice only, because there is really no such thing as a lealf interval. Besides, by a *simple* interval is not meant here the least practiced, but such as though it were equal to two or more lesser, which are in use, yet when we would make a sound move so far up or down we always pass immediately from one of its terms to the other. What is meant then by a *compound* interval will be very plain; it is such, whose terms are in practice taken either in immediate succession, or such where the sound is made to rise and fall from the one to the other, by touching some intermediate degree; so that the whole becomes a composition of all the intervals from one extreme to the other.

What we here call a *simple* interval, the ancients called a *diphon,* and the compound they call a *tertius.*

Each of these had its differences; even of the simple there are some greater, and others lesser: but they are always discordant; but of the compound, or tertius, some are concord, others discordant. Unions, it is plain, cannot possibly have any variety; for where there is no difference, as in unison, which flows from a relation of equality, it is plain there can be no distinction: unities therefore must all be concords. But an interval depending on a difference of tone, or a relation of inequality, admits of variety; and to the terms of every interval, according to their particular relation or difference, make either concord or discordant. Some indeed have restrained the word *concerto* to tertiius, making it include a difference in time: but this is precarious; for as the word *co* connotes an agreement of sounds, it is certainly applicable to unius in the first degree. Intervals, it is plain, may differ in magnitude, and ther may be an infinite variety, according to the possible degree of time; for there is no difference to great or to little, but a greater or a
lefs may possibly be conceived. It is true, with regard to practice, there are limits, which are the greatest and least in intervals our ears are judges of, and which may be actually produced by voice or instrument.

The degrees of tone are proportional to the number of vibrations of the sonorous body in a given time, or the velocity of their courses and recourses. Now these differences in tone constitute, as has been already said, the intervals in music: these therefore must be greater or less, as the differences are; and it is the quantity of these which is the subject of the mathematical part of music. Those intervals are measured, not in the simple differences, or in arithmetical ratios of the numbers expressing the lengths or vibrations, but in their geometric ratios; so that the same interval depends on the fame geometrical ratio, and vice versa. It is, however, to be observed, that in comparing the equality of intervals, the ratios expressing them must be all of one species; otherwise this absurdity will follow, that the same two founds may make different intervals. To describe the particular methods of measuring the inequality of intervals would be too tedious: this one rule may be observed, that, to determine in general which of two or more intervals are the greatest, take all the ratios as proper fractions, and the least fraction will be the greatest interval.

The ancients were extremely divided about the manner of measuring intervals. Pythagoras and his followers measured them by the ratios of numbers. They supposed the differences of gravity and acuteness to depend on the different velocities of the motion which causes sound; and therefore concluded, that they could only be accurately measured by the ratios of those velocities. Which ratios are said to have been first investigated by Pythagoras, on occasion of his paffing by a smith's shop, and observing a concordance between the sounds of hammers striking one another.

Aristoxenus opposed this. He thought reason and mathematics had nothing to do in this cafe, and that fene was the only judge in the dispute; the other being too subtile to be of any use. He therefore determined the octave, fifth, and fourth, which are the most simple concords, by ear; and by the difference of the fourth and fifth he found out the tone; which, once settled as an interval the ear could judge of, he pretended to measure every interval by various additions, and subtractions, made of these mentioned, one with another: but this method is very inaccurate.

Ptolemy keeps a middle course betwixt the two: he finds fault with the one for despising reason, and with the other for excluding fene; and shews how these two may mutually assist each other in this matter. Malcolm.

Intervals are founded on certain ratios or proportions expressible in numbers, which may all be analyzed into the prime numbers 2, 3, and 5. And all intervals may be found from the octave, fifth and third major, which respectively correspond to those numbers. These are the musician's elements, from the various combinations of which all the agreeable variety of relations of sounds results.

This is the modern system; and a late author affirms us, it may be looked on as the standard of truth; and that every interval that occurs in music is good or bad, as it approaches to or deviates from what it ought to be, on these principles. He observes, that the doctrine of some of the ancients seems different. Ptolemy, for instance, introduces not only the primes 2, 3, 5, but also 7 and 11, 13. Nay, he seems to think all fourths good, provided their component intervals may be expressed by super-particular ratios. But there are justly exploded concepts; and it seems not improbable, that the contradictions of different numerical hypotheses, even in the age of Aristoxenus, and their inconsistency with experience, might lead him to reject numbers altogether. Dr. Pepus, in Phil. Trans. N. 481, p. 267, 268.

M. Euler defines an interval, the measure of the difference of an acute and grave found. Tentamen Novae Thesauri Music. p. 72 and p. 127.

Suppose three founds a, b, c, of which c is the acute, a the most grave, and b the intermediate found. From the preceding definition it appears, that the interval between the founds a and c is the aggregate of the intervals between a and b, and between b and c. Therefore, if the interval between a and b be equal to that between b and c, which happens when a : b :: c : d, the interval between a to c will be double the interval a to b, or b to c. This being considered, it will appear that intervals ought to be expressed by the measures of the ratios constituting the founds forming those intervals. But ratios are measured by the logarithms of fractions, the numerators of which denote the acute founds, and the denominators the grave. Hence the interval between the founds a and b will be expressed by the logarithm of the fraction b/a, which is usually denoted by log b/a, or, which

comes to the fame, 1/b - la. The interval therefore of equal founds, a to a, will be null, as 1/a - 1/a = 0. The interval called an octave, or disparation, will be expressed by the logarithm of 2, and the interval of the fifth or disjunct, will be log 3/2. From whence it appears that these intervals are incomparable: so that no intervals, however small, can be an aliquot part, both of the octave and fifth. The like may be said of the intervals /z, 1/z, and others whose logarithms are dilatilar. But intervals expressed by logarithms of numbers, which are powers of the fame root, may be compared. Thus, the interval of the founds 27:8, will be to the interval of the founds 9:14, as 3 is to 2: For log 2/3 = 3/5, and log 2/3 = 21/3. Euler, ibid. p. 74.

But though the logarithms of numbers, which are not powers of the fame root, be incomparable, yet are the logarithms of ratios of uch may be found. Thus the measure of the octave is log 2/1 = log 3/2 = 1/2, and the measure of the fifth is log 3/2 = 0.1760913, which is the interval of the octave will be that of the fifth, nearly as 20.108300 to 1760913; which ratio being reduced to smaller terms, in the method explained under the head Ratio, will give us those simple expressions for the ratio of the octave and fifth: 2 = 1, 3/2, 5/3, 7/4, 12/7, 17/10, 29/17, 41/24, 53/31, which last is nearly the truth. Euler, ibid. P. 75.

In like manner intervals may be divided into any number of equal parts: for this purpose we need only divide the logarithm of the proposed interval into the fame number of parts, and then find its correspondent number by the tables. The ratio of the number to found, to unity, will give the required ratio of the divided interval to its proposed part, thus. Let the third part of an octave be required; its logarithm will be 0.1003443 = 1/2. The ratio corresponding nearly to this will be 63 : 50, or less, accurately, 29 : 23, or 5 : 4, which last expresses the third major; and this is by the less knowing taken for the third part of an acute octave, and seems to be such on our harpichords and organs, where from C to E is a third, from E to G another, and from G to A' another third. But the more intelligent know, that G and A ought not to be reputed the same found, since they differ by a diesis enharmonica, which is nearly equal to two commas.

M. Euler has inserted a table of intervals in his "Tentamen Novae Thesauri Music." He supposes the logarithm or measure of the octave to be 1.000000, whence the logarithm of
of the fifth will be 0.554962, and the logarithm of the third major will be 0.321928: from these the measures of all other intervals may be found. But as it has been customary for musicians to measure their intervals by commas, we shall here insert a table of intervals, with their measures in commas; where we suppose the logarithm or measure of the comma \(\frac{1}{4}\) to be 1.00000, hence the logarithm of the octave \(\frac{1}{2}\) will be 55.79763, that of the fifth \(\frac{3}{4}\), and lastly, that of the third major 17.96282. From these all the other intervals may be found in the manner expressed in the table; where the first column shews the names of the several intervals; the second, the proportions of sounds forming these intervals; the third, the composition of these proportions from the primes 2, 3, and 5. The smaller figures marked above, and somewhat to the right of the larger, indicate the power to which the number expressed by the larger figures is raised. Thus \(2^{17/2}\) shews that the seventeenth power of 2 multiplied by 3, and divided by the eighth power of 5, will produce \(\frac{17}{2}\) in the second column, and that this is the proportion expressing the interval called ecfalon in the first column. The fourth column of the table contains some simple signs of some of the intervals, as \(b\) for hyperboche, \(d\) for diesis, &c. and the fifth column shews how the intervals arise from others: thus over again all femitone major, I find in the fourth column 5, which is here only an arbitrary mark for this femitone; and in the fifth column I find the formula \(s + d = IV - III\), which signifies that the femitone major is equal to the sum of the femitone minor and diesis, or to the difference between the fourth and the third major. Observe, that the comma is marked by a dot (\(\cdot\)); when this is placed over the letter or other symbol, it signifies that the interval is supposed to be heightened by a comma; and on the contrary, when the point is placed below, it signifies that the interval must be diminished by a comma; thus \(l = T\) signifies that the tone minor increased by a comma is equal to a tone-major, and vice versa. \(T = t\) shews that the tone-major diminished by a comma is equal to the tone-minor. The signs +, - , =, are here taken in the same sense as in algebra, to signify addition, subtraction, and equality. So likewise the dot placed between two numbers, or between a number and the symbol of an interval, signifies that the interval is to be multiplied by the number. Thus 2, IV shews that the fourth is doubled; and thus 7 = VI - S = 2. IV = VIII - T, shews that the letter that seventh is equal to the sixth major and femitone-major, or also to two fourths, or to the octave when the tone-major has been taken from it. Lastly, the sixth column of the table shews the measures, or logarithms of the ratios in the second column. These are not the common logarithms of the tables where 1.00000 is the logarithm of 10. But here \(1.00000\) is assumed as the logarithm of \(\frac{1}{2}\), or of the comma, as before mentioned. These logarithms are easily derived from the common, of the large tables of Vlacq, or Briggs: thus the logarithm of 2, or the octave = 0.3010299957; the logarithm of 3, of the fifth = 0.1760912590; and lastly, the logarithm of \(\frac{3}{2}\), or of the third major = 0.6969100136. Now these logarithms being severally divided by the logarithm of \(\frac{3}{2}\), or the comma = 0.0073952039; the quotients will give the number of commas in an octave = 55.79763; in a fifth = 32.63952; and in a third major = 17.96282. Hence all the rest may be found by addition and subtraction only. Here follows the Table.

### A Table of the Musical Intervals with their Measures.

</table>

The limma, apotome, telephonic, ditonum, semidiapente, and tritons, mentioned in this table, by the names of limma, apotome, &c. of the Greek scale, are such as are either mentioned by the ancients, or at least occur in their scales, whereas fourths are divided into two tones and a limma, and where the octave consisted of five times and two limmas.

The term redundant, in the table, is applied to such intervals as exceed the truth by a comma; and such as fall short of the truth by a like quantity, are called deficient. Intervals that exceed true diatonic intervals, by a femitone minor, are said to be superfluous; and those which fall short by the same quantity, are said to be diminished. Where an interval exceeds a true diatonic interval by the quantity of two femitones minor, we have called it an extreme superfluous interval; and if it falls short by the same quantity, the appellation of extreme diminished interval is given it. Thus, if from A to D ascending be a true fourth, and from D to B a true fifth, then if D be supposed raised by a comma, from A to D will be a redundant fourth, and from D to B a deficient fifth. From A to D & will be a superfluous fourth.
and from $D \times a$ to $a$ will be a diminished fifth. In like manner, from $A$ to $D^{2}$, will be a diminished fourth; and from $D$ to $a$ a superfluous fifth. From $A$ to $D^{2} (D$ double sharp) will be an extreme superfluous fourth; and from $A$ to $D^{2} (D$ double flat) will be an extreme diminished fourth. In like manner from $D^{2} a$ to $a$ will be an extreme diminished, and from $D$ to $a$ an extreme superfluous fifth. Such intervals are not to be met with in the practice of music; but if the division of the octave into 31 parts were once established, as it ought for the perfection of music, such intervals as these here mentioned will necessarily occur in the scale. Vide Phil. Trans. N. 481. p. 275, 274. See GENUS.

This table, among other uses, will facilitate the examination of any proposed scale, or interval. Suppose, for instance, it were required to examine some of Tottie's divisions of the fourth, as his diatonic mollie, which makes $\frac{1}{2} + \frac{1}{2} + \frac{1}{2} = \frac{3}{4}$. Take the logarithm of $\frac{3}{4}$ from the common tables, and divide it by the logarithm of $\frac{1}{2}$, the quotient will be 10.75, which gives the measure or number of commas, and its parts contained in an interval expressed by $\sqrt{\frac{1}{2}}$. Look for the square measure of intervals to 10.75 in the table, it will be found to be 10.3958, which answers to the interval of two femitones major, or, of the diminished third, as practitioners call it. But Tottie's exceeds this by 0.16, or about $\frac{1}{6}$ of a comma. The next interval in Tottie's division is $\frac{1}{3}$, which is a true tone minor. The third is $\frac{3}{4}$, which will be found to be 3.93 commas, that is, a femitone minor and $\frac{1}{6}$ of a comma, or a femitone minor redundant by near $\frac{1}{6}$ of a comma. But this is much out of tune. In the common, and in Huygens's temperatures, the femitone minor is increased only by about $\frac{1}{6}$ of a comma. Vide Tottie's Harmon. p. 92, apud Wallis Opera, tom. v.

INTERVALS, Concinus. Discords are distinguished into concius and inconcious intervals: the concius are such as are fit for music, next to, and in combination with concius; being never very agreeable nor disagreeable in themselves; but having a good effect, as by their opposition they heighten the more essential principles of pleasure; or as by their mixture and combination with them, they produce a variety necessary to our being better pleased. See CONCINUS.

The other discors that are never used in music, are called inconcious.

INTERVAL, Diminuished, is a defective interval, or an interval which is short of its just quantity by a lesser femitone. Thus from $C$ to $E$ being a third major, if $E$ be lowered by a femitone minor, we shall have $E$, and then from $C$ to $E$ is called a diminished third, in the language of practical musicians, and occurs frequently in their works. But, strictly speaking, in this case, the note $E$ must be lowered more than a femitone minor.

INTERVAL, Harmonical, is an interval, or difference of two sounds which are agreeable to the ear, whether in conciusness or succession.

Harmonical intervals, therefore, are the same with concors; which see.

They are thus called, as being the only essential ingredients of harmony.

INTERVALS, in the New Method of Husbandy, denote the wide spaces, commonly about five feet, which are left between any two of the double, treble, or quadruple rows. See HUSBANDRY.

INTERVALS, in the Military Art, are the spaces left between each regiment in camp, and likewise between each tent.

INTESTATE, a person who dies without making a will. An heir ob intestato, is a person who inherits an estate by some other right than that of will or testament.

Hereafter, those who died intestate, were hold infamous, and accursed; in regard, by the canons of several councils, every person was enjoined to bequeath a part of his estate (and Matthew Paris says, it was at least to be a tenth part) to the church, for the safety of his soul; which a person who neglected to make a will, and to leave this legacy to the church, was judged to have abandoned. Several councils took on them to command the priests to follow dying persons to be charitable to the church; and this they did continually, that absolution and the viaticum were denied to those whom they could not prevail on; so that they made no difference between these intestates and self-murderers; and they were alike denied Christian burial. Du Cange adds, that all who died without absolution, without receiving the viaticum, and without leaving gifts to the church (even though they died suddenly), had their effects seized, as unconfecrated to the use of the church, bilhop, &c. See ADMINISTRATION and TESTAMENT.

In the English law, there are two kinds of intestates: the one de facto, which are those who make no will at all; the other de jure, called also quafi intestatis, which are those who make a will; but such an one as is null and void, either from the executors refusing to act, or from some other cause: in which case they are judged to die as intestate, quafi intestatis.

And the 22 & 23 Car. II. c. 10, commonly called the statute of distribution, appoints a distribution of intestates' estates, (except of farms covert, which are left as at common law, Stat. 29 Car. II. c. 3, § 25.) after debts and funeral expenses are paid among the wife and children of the deceased, or for want of such, among the next of kin, &c. and the act of parliament does immediately upon the death of the intestate vest an interest in the persons entitled: so that if any one dies before the distribution, though within the years, his share shall go to his executors and administrators; and not to the survivors or next of kin to the intestate. (1 Lev. Abr. 487. See Administration.) By this statute the mother, as well as the father, succeeded to all the personal effects of their children who died intestate, and without wife or issue: in exclusion of the other sons and daughters, the brothers and sisters of the deceased. And so the law shall remains with respect to the father; but by statute 1 Jac. II. c. 17, if the father is dead, and any of the children die intestate without wife or issue, in the lifetime of the mother, and each of the remaining children, or their representatives, shall divide his effects in equal portions. See Custom of London.

By the same statute it is enacted, that one-third part of the surplusage of the estate of any person dying intestate, shall be distributed to his widow, and the residue among his children by equal portions, or among such persons as legally represent his children, in case any of them be then dead, excepting such children or children (not being heir at law) who shall have any estate by the settlement of the intestate, or shall be advanced by the intestate in his lifetime, by portion or portions equal to the share which shall by such distribution be allotted to the other children, and in case their portions have not been equal, they shall be made fo as nearly as possible out of the same surplusage. But the heir at law is to have an equal part in the distribution with the rest of the children, without any consideration of the value of the land which he hath by descent or otherwise from the intestate. In case there be no children nor legal representatives, one moiety of the said estate shall be allotted to the widow of
the intestate, and the residue distributed equally to every of
the next kindred of the intestate, who are in equal degree,
and those who legally represent them; provided that there
be no representations admitted among collaterals, after
brothers and sisters children: and if there be no widow, the
said estate shall be wholly distributed in equal shares among
the children, or if there be no child, to the next of kindred
in equal degree, and their legal representatives. But no
such distribution of the goods of an intestate should be made
until after one year be fully expired after his death, and those
to whom distribution is made, are required to give bonds
with sufficient securities, to refund in case of debt.

This statute of distributions bears a near resemblance to
our ancient English law, "de rationabili parte bonorum," which
Sir Edward Coke himself (2 Inst. 33.), though he
doubted the generality of its restraint on the power of devising
by will, held to be universally binding (in point of con-
ference at least) upon the administrator or executor, in the
case of either a total or partial intestacy. It also bears
some resemblance to the Roman law of succession "ab intestato;" which,
and because the act was also penned by an eminent

The duodenum is that part of the intestine included between
the pylorus and the point at which the canal escapes from
the transverse mesocolon. It is placed in the neighbourhood
of the vertebral column, between the two layers of the
mesocolon, which are connected to it by a loose cellular
substance.

The large end of the pancreas is very closely attached to it.
From the pylorus it turns backwards, and to the right, un-
der the neck of the gall-bladder, which touches it: hence it
frequently has a yellow tint in the dead subject. This,
which may be called the first portion of the duodenum,
forms a distinct angle with the second, which
defends almost perpendicularly behind the upper layer of the
mesocolon connected to it by a loose cellular medium. Its po-
terior surface corresponds to the right side of the vertebral
column, and to the front of the right kidney: its inner
dge to the pancreas. The third part makes a turn at the
lower end of the kidney, or about the third lumbar vertebra,
passes from right to left across the vertebral column, in front
of the aorta and vena cava, behind the superior mesenteric
veins, and below the pancreas. At the left side of the
abdomen it again turns forwards and towards the right,
escapes from behind the inferior layer of the mesocolon,
and takes the name of jejunum. This division of the in-
testinal canal forms a kind of half circle, of which the con-

The anterior surface of the intestine only is covered by
peritoneum; the posterior aspect being attached to the neigh-
boring organs by cellular substance. In the part near the
pylorus, the covering membrane adheres closely to the mu-

The peculiarities of the duodenum are its incomplete pe-
}
its connection to the pancreas, and receiving the secreted fluid of that gland and the liver. Its figure is perhaps less regularly cylindrical, and there are some differences in the mucous membrane.

The arteries of the duodenum are derived from the gastro-duodenal branch of the hepatic, and from the superior mesenteric: the veins join some of the trunks, which contributed to the formation of the vena portærum. The absorbing vessels pass to the glands at the root of the mesentery. The nerves come from the celiac ganglia.

Second Division of the small intestines — This part of the canal, which is very loose and movable, forms numerous turns, and its convolutions fill up the space between the bladder and uterus below, and the large intestine above and at the sides; the latter part almost encircles the space in which this division of the canal lies. As the cæcum and the sigmoid flexures of the colon do not touch below, the small intestine descends in its interval, in greater or less quantity, into the pelvis. The umbilical and hypogastric regions of the abdomen are chiefly occupied by these convolutions; which accommodate themselves, by their perfect mobility, to the numerous changes produced in this space. A dilated state of the stomach causes them to descend; when the bladder, rectum, and uterus are empty, much of the intestine is found in the pelvis; but when these organs, and particularly the latter, are dilated, the intestine ascends: in a word, it passes into any space that remains open for it. The transverse arch of the colon bounds the space occupied by the small intestine above: the lumbar portions of the large intestine, fixed to the back of the abdomen, allow the convolutions to pass in front of them, and to correspond immediately to the abdominal parietes. The latter limit and confine it in front, and are separated from it only by the greater omentum.

A broad fold of peritoneum, called the mesentery, connects it in its situation to the abdominal cavity; this consists of two layers, which receive the intestine between them, and give it a smooth external coat. This fold is attached to the back of the abdomen, in an oblique line, extending from the left lumbar to the right iliac regions; here it is about six inches broad. It expands so considerably as to be broad enough on the opposite or front margin, to be attached to the whole length of the jejenum and ileum. In consequence of this great breadth of the anterior part, the mesentery itself, in this situation, forms a vast number of longitudinal plaits. The flat surfaces of the mesentery are smooth, and contiguous to the intestinal convolutions. The depth of the mesentery, from its posterior or fixed, to its anterior or loose edge, is greatest in the middle, and gradually diminishes towards either end. Its structure and attachments are such as to prevent the intestinal convolutions in a certain relative position, and at the same time to allow in the whole a considerable liberty of motion: it prevents the intestines also from becoming entangled in the motions of its individual parts.

It is composed of two membranous layers, produced from the peritoneum. The latter membrane, after lining the posterior and right portion of the abdomen, when it arrives at the root of the mesentery, is reflected from behind forwards, instead of being continued to the left side. That, which has lined the posterior and left division of the cavity, is also reflected from behind forwards, instead of passing in front of the vertebrae. These laminae, turned towards each other, form the two surfaces of the mesentery; they separate at the intestine, and leave a cylindrical tube, in which that canal is contained. They are connected by a layer of cellular membrane, containing more or less feet, and the arteries, veins, and nerves of the jejenum and ileum, as well as the abdominal vessels and their glands.

The intestinal convolutions have no fixed situation, but are formed, destroyed, and renewed, carried upwards, downwards, &c. according to the general or particular motions of the canal: yet the concavity of each turn is always at the mesenteric edge, and its convexity at the ileal margin of the gut. The very loose attachment to the sides of the cavity, and the apparently irregular order in which the convolutions of the intestines are disposed, seem at first sight to prevent us from affixing any particular direction to this part of the canal. But if we put out of the question the great mass of the turns, and examine the parts where it begins and ends, and consider at the same time the direction of the mesentery, we shall find that the canal altogether passes obliquely from above downwards, and from the left towards the right side. It begins in fact on the left side of the transverse mesocolon below the superior mesenteric vessels, and it terminates in the right iliac region, where it is fixed to the side of the cæcum.

A transverse section of the intestine presents an elliptical area, of which the smaller circle corresponds to the mesentery, and to the larger to the ileal edge of the intestine. Considered in its whole length, the mesenteric or attached edge is concave; the ileal margin convex. The small trunks of the blood-vessels enter on the former; their minute ramifications, and the fine origins of the absorbents, are observed on the latter.

Sometimes small blind pouches, or appendices, varying in length from a few lines to three or four inches, are connected to the small intestine. It is very uncommon to see more than one in a subject. They are cylindrical or conical towards the extremity, communicate freely with the rest of the canal, and completely agree with it in structure. There can be no doubt that they are originally formed parts, and not produced by any morbid extension of the intestinal parietes. They are often mentioned under the name of diverticula.

When moderately dilated, the intestine measures more than an inch at its largest diameter, and less at the smallest. When it is completely dilated, the figure is circular.

The coats are thinner than in the stomach or in the large intestine: they are thickened at the beginning, and grow gradually thinner to the end. They appear proportionally thicker, when the intestine is in a contracted state. It is more flabby, elastic, and dark coloured; in a word, firmer and thicker in perfectly healthy men than in women or valentinarians. When it is asserted that the canal is so many times the length of the body, we only mean to give a general notion of its extent: for there is no relation between the stature of individuals and the volume of their gallbladder viesera.

The distinction of the jejenum and ileum is quite arbitrary: there are no marks showing the termination of one, and the beginning of the other; but the two ends of the canal differ obviously in several points. Winslow gives the former name to the upper two-fifths of the tube, and the latter to the lower three-fifths.

Organisation of the small intestines — It consists, like the stomach, of three distinct strata or coats, connected by cellular substance: these are most clearly seen on the cut edge of the part, after a simple incision, when the difference of colour and density enables us to distinguish them easily. Boiling and maceration in proof spirit render the distinction of the intestinal coats more easy.

The first or external coat is a serous membrane, consisting of
of a production of peritoneum. The two layers of the
mucenrry separate at the concave edge of the intelle, fur-
round it, and are continued into each other at the convex
side. It covers, therefore, the whole external surface, except-
ning the narrow strip where the two layers are separated.

This serous membrane is very thin, so as to be nearly
transparent, and possesses no fibres: the mucosal fibres and
the blood-vessels can be seen through it. Its external surface
is moist, and perfectly smooth; while the internal, connected
to the subjacent fibres by cellular substance, has a rough
appearance.

The mucosal or second coat of the intelle consists of
two strata of fibres. The external, which is thin and small,
forms a longitudinal direction, while their fibres can hardly be
seen except at the convex edge of the gut. The internal is
much more considerable; its fibres are more numerous,
and they surround the intelle in a circular manner, so as to cut
the former at right angles. These fibres are the most dif-
tinctly marked about the duodenum: they grow more flender,
polished, and colourless, and are therefore hardly observable near
the valve of the colon.

The third or internal covering is a mucosal membrane, gen-
erally called by anatomists the villous coat of the intelle: it
is always covered in a greater or less degree with a mucosal
fluid. This is connected to the mucosal stratum by a very
copious, white, and rather loose cellular substance, the
mucosal coat of many anatomists. The trunks of the blood-
vessels and absorbents of the mucosal surface are contained
in this in great numbers, and give to it the appearance of
considerable vacuolality. It not only connects the mucosal
and mucosal coverings together, but also unites the duplica-
tures of the former. Through the intervals of the mucosal
fibres it joins the cellular substance connecting the
serous and mucosal coats. When carefully separated, it has
the appearance of a fine cotton on both surfaces: and this
appearance may be still more strikingly produced by cutting
off the membranous knot to the intelle, inverting the tube
and inflecting it forcibly, when the air will penetrate into the
whole cellular structure of the organ. If the part be mac-
cerated, after separating by dissection the mucosal and muco-
sal coats, the water distends the cells and exhibits the struc-
ture very clearly.

The mucosal membrane is much longer than the two other
coats, and it is consequently collected, throughout the whole
channel, into folds, by which the difference of length is com-
penated. These are not like the rugae of the stomach,
formed only in the contracted, and disappearing in the dis-
tended state of the organ; but they belong to the essention
structure of the part, and exist therefore under all circum-
cstances. They are mostly transverse in their direction; that
is, they cut the long axis of the gut at right angles; and
they are called valvulae conniventes, although they have not,
not can possibly exist any thing like the action of a valve.
They begin about an inch from the pylorus, are small, and
longitudinally disposed in the duodenum. They then assume
a more regular arrangement, are numerous and large, and
nearly parallel, towards the end of the intelle they gra-
ularly become smaller and fewer, and have again in great
part of the ileum a longitudinal disposition. Near the valve
of the colon the gut is almost straight.

The valvulae conniventes may occupy from one to three-
fourths of the diameter of the canal, but rarely extend
through the whole circle; they are often joined by small
communicating folds, and frequently are bifurcated at their
extremities. When short, they are narrow, and are broader
in proportion as they are longer: they are broadened in the
middle and narrower at the extremities. Their breadth may
be from half a line to three lines. They are so completely
unfolding, that they yield readily in either direction to any
impelling force, and are applied against the surface of the
canal. As they depend entirely on the cellular substance,
they are destroyed by separating the mucosal membrane and
drawing it out: the surface then becomes smooth, and very
much exceeds the length of the other coats.

The situation, length and breadth, direction, number and
form of the valvulae conniventes, can be very well observed
in a gut inflated and dried; but their natural appearance,
their thickness, softness, &c. are best seen in an inverteb
intelle floating in water.

When the surface of the mucosal membrane is attentively
examined, it is found universally covered with very delicate
and minute folds and projections, so as to give it a flocculent
appearance; these are named villi. They are more numerous
and large in the commencement of the canal, and decrease
in number and size towards the opposite end. In some ani-
males, as the dog, these villi are remarkably long and nu-
merous, so that the surface of the mucosal membrane com-
pletely resembles velvet.

When the blood-vessels have been successfully injected,
microscopical examination discloses other irregularities on
these villi, and shews us that the whole conflits of a close
net-work of valvular communications. Each villus contains
moreover numerous absorbing vessels, so that they have been
regarded as the great organs of absorption, containing the
mouths by which the lacteals take up the chyle from the
intelle. Anatomists have amused themselves much with
attempts to detect the actual openings of the lacteals upon
the villi. Lieberkuhn thought that he could see, by the
aid of the microscope, an opening into each villus leading
into a small mucosal cavity in the centre, which he called
the ampulla. Hufan did not admit this structure, but
conceived that the vessels begin by simple apertures, in
the number of one or more on each villus. Mr. Cruikshank
met with a subject, in which the lacteals and villi were re-
markably loaded with chyle, and he examined these parts
with the microscope. Many of the villi were so full that
they seemed like white vehicles, without any distincion of
particular veins. "In some hundred villi," says he, "I saw
a trunk of a lacetal, forming or beginning by radiated
branches. The orifices of these radii were very distinct
on the surface of the villus, as well as the radii themselves,
seen through the external surface, passing into the trunk of
the lacteal: they were full of a white fluid. There was
but one of these trunks in each villus. The orifices on the
villi of the jejunum, as doctor Hunter himself said, (when
I asked him, as he viewed them in the microscope, how
many he thought there might be,) were about fifteen or
twenty on each villus: and in some I saw them still more
numerous." Anatomy of the Absorbing Vessels, chap. 11,
and plate 2.

It has been calculated, that the surface of this mucosal
membrane, when allowance is made for all its inequalities,
exceeds that of the common integument.

Numerous mucosal glands are situated on the external sur-
face of the mucosal membrane of the small intelle: their
ducts open on the internal surface of the organ. These
parts are always small, and in many cases are not demon-
strated without some difficulty. They are most advan-
tageously examined by cutting up the gut, and holding it
against the light; they are distinguished by their compara-
tive opacity. Several exist in the duodenum; in the jejunum
they are fewer, but they increase in number again in the
ileum, are collected into considerable mafles, and are par-
ticularly numerous towards the end of the intelle. They
varyl in size: some are rounded, others compressed; the larger are generally placed higher, the smaller are placed closer together in collections of different extent. The openings of the excretory ducts of the larger ones on the mucous surface of the intestine are frequently constrictive. They seem to possess a very fibrous structure; we can observe in them merely a net-work of minute vascular ramifications, which deposit their secreted mucus in a simple excretory tube.

According as these bodies are found single, or in collections, they have been called glandulae subileonae or gubernaculi. Again, they have been named in different parts, after persons who first described them, glandulae Peyers and Brunnii.

The arteries of the jejunum and ileum are derived from the trunk of the superior mesenteric; the veins all end on the mesenteric root of the large intestine. The blood in these veins has been observed to have white breaks in it; but this is not peculiar to the mesenteric vessels. Fluids injected into the mesenteric veins easily traverse on the mucous surface of the intestine.

The suprarenal absorbing vessels have their origin in the ferous submucous, anatomically very frequently with each other, and with the deplanted ones, pass through the mesentery in a superior and inferior set, and enter the mesenteric glands. The deeper-seated absorbing arteries, arising from the wall of the mucous surface, are called the vasa or chyliferous vessels; they are often dilated in a varicose manner to a considerable size: their trunks accompany those of the blood vessels in the cellular substance on the surface of the mucous membrane, and in so very frequently with each other, and with the superficial ones, both here and in the mesentery, fo as to form a complete network, and then proceed to the glands. They are very numerous in the duodenum and jejunum; but are fewer in the rest of the canal; they form a plexus in the mesentery, proceed from gland to gland, becoming larger and larger, and still communicating together. Collected into large trunks, they arrive at the under and back surface of the pancreas, and are united with the absorbing vessels of the ileum, ileum, and liver in the glands and plexuses situated about this part. They then bend downwards, forming new plexuses, and arrive at the glands placed about the duct, uniting with all the trunks from the other abdominal vessels, from the pelvis and lower extremities; they then ascend again to terminate in the thoracic duct.

The mesenteric glands, amounting in number to one hundred or more, even to one hundred and fifty, are chiefly placed on the superior mesenteric artery, either scattered and separated, or in a more close arrangement. They are fewer and smaller towards the lower part and right portion of the mesentery and intestine, than on the upper and left part. They are closely flattened, with a round or oval circumference; and the larger are placed irregularly among the small ones. They have a brownish red color, but are poorer and small in adults than in infants. When full of chyle they are whiter.
