STOW, John, in Biography, an industrious antiquarian and historian, was the son of a merchant-taylor in London, and born about the year 1525. About the year 1560 he composed the annals of the English history, and to this object he sacrificed his trade and domestic concerns; travelling on foot to several cathedrals and other public establishments, in order to examine records, charters, and ancient documents. He also purchased, as far as he was able, old books, manuscripts, parchments, &c. of which he published a number of valuable works. But being dispossessed of many of his books, he was obliged to inter his studies, and to renew his application to business with a property that had been much lessened. Benefactions, however, from Dr. Parker, archbishop of Canterbury, enabled him to prosecute his studies; but being suspected of an attachment to popery, he was banished from the city for several years, and as having possession of many pious books of superstition. His study was searched by order of Dr. Griesal, bishop of London, and many pamphlets were found in it, which discovery fixed upon his character the reproach of a suspected person; and two years after, an unnatural brother, who, having defrauded him of his goods, was a defounder of taking away his life, preferred against him above 140 articles before the ecclesiastical commission. But the infamous character of the witnesses who were engaged to prove the charges, caused him to be acquitted. His first work, undertaken at the request of the powerful favourite, Robert Dudley, earl of Leicester, had been already published; and as it had been dedicated to the said nobleman, his countenance was of service to him in his prefixed circumstances. This was "A Summarie of English Chronicles," first printed in 1565, and several times reprinted. This book contained an account of every English king from the era of the fabulous Brutus, down to his own time, with a list of all the principal magistrates of London from the Conquest. It was afterwards continued by Edmond Howes, who printed several editions, so that the work must have been popular. In 1575 he left his high patron, archbishop Parker, but his mind was so ardently engaged in his antiquarian studies, that he prosecuted them with unintermitting diligence and zeal, amidst all the inconveniences and difficulties of penury. In 1583 he presented a petition to the lord mayor and court of aldermen, stating that for 25 years he had been employed in compiling and publishing divers pamphlets, recording the memorable acts of famous citizens, and that he contemplated the publication of a larger summary, and soliciting encouragement and assistance; and four years after he presented another petition, requesting a pension, or some other benefaction; but it does not appear whether or not he succeeded in his applications.

To the improvement of the second edition of the Chronicles published by Hollingshed in 1587, Stow largely contributed; and he also supplied corrections and notes for two editions of Chaucer. His "Survey of London, &c.," on which he had been long employed, appeared in 1598, and a second edition was prefixed to the public before his death. It was several times reprinted, with successive improvements, and has been the basis of all the subsequent histories of the metropolis. For his large Chronicle or History of England he had been for 40 years collecting materials; but he only lived to print an abstract of it in 1600, entitled "Flores Hafioriarn, or Annals of England," 4to. dedicated to archbishop Whitgift. Edmond Howes published from his papers a folio volume, entitled "Stow's Chronicle," but this does not seem to contain that "far larger work," mentioned by Stow, and which he left in his study fairly written out for the press. It is said to have come into the possession of Sir Symonds Dews, but is not found among his MSS. in the British Museum. Stow having spent his patrimony, and acquired no certain income, sunk into wretched penury in his old age, and was under a necessity of applying for public charity; and James I., "by one of the meanest acts of his very mean reign," granted a licence, authorizing him, then in his 78th year, "to repair to churches, or other places, to receive the graces and charitable benevolence as well as the bounty of the people." In the amount of this bounty, we may form some conjecture from the collection in the parish of St. Mary Woolnoth, which reached the sum of 7s. 6d. The city of London was not more liberal than the sovereign of the country; and it must reflect no small degree of reproach upon it, that it could not extend its liberality towards its own historian. Stow, oppressed by poverty and painful diseases, obtained a release in the year 1605, at the age of 80 years. His aspect is said to have been cheerful, and his behaviour mild and courteous. In his writings, "says one of his biographers, "he displayed a sincere love of truth, and great diligence in investigating it, with the moral feelings of a worthy man. His brother antiquarians speak of him with respect; and, if he ranks, in point of style and matter, with the inferior class of historians, he may claim the praise of humble utility."—Biog. Brit. Gen. Biog.

STOW, in Geography, a township of Middlesex county, in the state of Massachusetts, incorporated in 1683, and containing 889 inhabitants; 26 miles N.W. of Boston.—Also, a township of Vermont, in Chittenden county, about 25 or 30 miles E. of Burlington, containing 650 inhabitants.

STOW, one of the eight townships into which Cumberland county, in New Jersey, is divided, containing 1039 inhabitants.—Also, a river of New Jersey, which runs into the Delaware, N. lat. 39° 28'. W. long. 75° 26'.

STOWAGE, the general arrangement of the several materials by which a ship is to be laden, with regard to her figure, magnitude, and solidity.

The knowledge of stowing a ship's hold with propriety requires
requires the greatest attention of the skilful mariner; for although it is well known that ships in general will not carry a sufficient quantity of sail, till they are laded so deep that the line of flotation is well with the extreme breadth amidships, or nearly so, yet there is more than this general knowledge required; for should the cargo consist of very heavy materials, as lead, iron, &c., and they be unskilfully flowed too near the bottom, it will place the centre of gravity too low; and although this will enable her to carry a great prew of sail, she will nevertheless roll heavily, and consequently rill the lodging of her masts. On the other hand, should the cargo be light, it is very evident that, without a sufficient quantity of heavy ballast, or other materials of like weight, flowed low down in the vessel, the ship would be in that state, that the centre of gravity would be raised too high, whereby the vessel is rendered incapable of carrying sail without being exposed to the danger of overfletting.

Thus the whole art of flowing or lading a vessel, therefore, consists in placing the centre of gravity to correspond with the trim and shape of the vessel, so as neither to be too high nor too low; neither too far forward, nor too far aft: thus it will be readily seen, that all the weightier part of the cargo should be placed as near the midships as possible, flowing low down in the vessel, at the fore-part of the vessel, and likewise close aft: hence, if the vessel be judiciously flowed, the wind neither roll nor pitch heavily, and will be enabled to carry a good sail and ply well to windward, especially if due regard has been paid to these qualities in the construction of the vessel. See BALLAST.

Stowage Room, in Hop Management, the apartment or place constructed for receiving and containing the hops, after they have been dried, until they are ready or in proper condition for bagging. It has a suitable hole made in some part of the floor, round which a frame of wood is placed, so as to exactly fit the corners of the bags, which are securely fixed all round to it, for the convenience of flowing the hops into them. See Hop.

Stowe, in Geography, a parish in the county of Buckingham, England, three miles N.W. of the town, is noted for the magnificent seat of the marquis of Buckingham. Peter Temple, esq. was the first of the family who settled at Stowe in the year 1554, and who erected a manor on the estate; but this was taken down and rebuilt by Sir W. B. R., who died in 1569. His son, lord Cobham, enlarged the manor, running a new wing, adding two wings; but the late marquis of Buckingham, and his father, earl Temple, made still greater alterations and improvements at this place. The whole front, of regular and uniform architecture, now extends 916 feet, of which the centre is 454 feet. It consists of a centre, or body, with two wings, connected by apartments. A flight of 31 steps leads to the grand saloon, an oval apartment, 60 feet by 40, surrounded by Scaliola columns, imitative of Sicilian Jasper. The panells, cornices, and dome, are all adorned with sculpture and other ornaments, to produce a splendid effect. A statue gallery, 50 feet by 32; a statue gallery, 70 feet by 24; a library; and several drawing rooms, dining-rooms, &c. constitute the principal floor. A library, fitted up to receive Saxon MSS. and old literature, has recently been formed here from the desigms of John Soane, esq. Most of the apartments are enriched with pictures, and fitted up in a splendid style. The gardens or pleasure-grounds of Stowe are, however, more celebrated than the mansion; they consist of 400 acres, and present a great variety of surface, scenery, and objects. In some places they display bold cliffs, with narrow and winding valleys; the principal of which is filled with a broad and pellucid lake. In one part this forms a cascade, and over it is a Palladian bridge. In different parts of the garden are several ornamental buildings, confiding of temples, columns, &c. The beauties and characteristic features of this justly noted seat have been extolled in the poetry of Weel, Pope, and Hammond; and are fully describ'd in an octavo volume, published in 1797, entitled "A Description of the House and Gardens of Stowe," with thirty-three plates, most of which were drawn and engraved in a tasteful style by T. Midland. An account of it is also given in the first volume of the Beauties of England and Wales.

Stowey, near Frome, a small market-town in the hundred of Williton and Freemans, in the county of Somerset, England, is situated eight miles W.N.W. from Bridgewater, and 140 miles W. from London, at the foot of Quenstock hills, on the banks of a rivulet, which passing through Fiddington, falls into the Bridgewater river at Combwich. The town consists of three streets, and was returned to parliament, in the year 1811, as containing 179 houses, occupied by 620 persons. A weekly market is held on Tuesdays, and an annual fair for cattle. Here is a small market-cross, of an octagonal form, standing on eight small round pillars, with a clock, and a bell, which is rung to proclaim the opening up of the town. There is a small market-cross, of an octagonal form, standing on eight small round pillars, with a clock, and a bell, which is rung to proclaim the opening up of the town. As the church stands a quarter of a mile from the town. "Stowey is a reputed borough, the inhabitants whereof have long held their houes and lands of the castle by burgage. The castle stood on a hill to the westward of the town, and near it was a church dedicated to St. Michael; but both are now ruined, so that no vestige remains of either but the castle-ditch; the site of the castle being pastoral-ground." The present church, St. Mary's, is a substantial edifice, having at the west end an embattled tower, 70 feet in height, with a turret at one corner. Colloft's History of Somerset, vol. iii. p14.

Stow-Market, a town in the hundred of Stow, and county of Suffolk, England, is seated at the junction of three rivulets, which form the river Gipping. In 1801 it contained, according to the parliamentary report, 283 houses, and 1763 inhabitants; and by the report of 1811, these appear to have increased to 2000 persons, and 401 houses. Stow-Market is certainly a flourishing town, and contains many handsome houses, especially near the market-place. The church is a spacious and beautiful building, with a square tower, surmounted by a new spire, of two stories high, which, though of wood, has a light and neat appearance. In this church are interred several of the Tyrrell family, of Gipping-Hall, in this hundred. Here also is the monument of Dr. Young, once vicar of this place, and tutor to the immortal Milton. The contiguous parish of Stow-Uplands, which has neither church nor chapel, is now consolidated with Stow-Market; but they have full distinct officers for each parish.

The county meetings for Suffolk are chiefly held in this town; and here is a manufacture of fanning, ropes, twines, and hampen, which has succeeded that of fluffs and bome-bazenas. Being well situated for the barley trade, the market of this town is much frequented by the farmers, and much business is done in the malting line. A principal source of the prosperity of Stow-Market is the navigable canal from this place to Ipswich, which was opened in 1793.

It is sixteen miles in length, and has fifteen locks, each sixty feet long, and fourteen wide; three of these are built with timber, and twelve with brick and stone. The total expense of this undertaking was 26,980l. Independently of its utility, this canal is an ornament to the town. There are about 150 acres of hop-plantsations in this neighbourhood.
STO

An old manor-house, called Abbot's-Hall, together with the manor of Stow-Market, were given by King Henry II. to the abbey of St. Oysth, in Essex; but was granted, 38 Henry VIII., as part of the poffeifion of that monastery, to Thomas Darie. The house of industry for the hundred of Stow stands on an eminence, about a mile from the town. It has rather the appearance of a gentleman's seat than of a receptacle for paupers. It was erected at an expenditure of more than 12,000l. and was opened in 1791.

Bookhall, near Stow-Market, was the birth-place of Sir William Copping, lord mayor of London in 1512. At his death, he bequeathed half of his large property to charitable purposes; the other half was devoted to his relations. Finchborough-Hall, in the parish of Great Finborough, was built in 1795, by the present proprietor and lord of the manor, Roger Pettitward, esq. An embowered walk leads behind the hall to the church, which contains several monuments of the Wollaston family, formerly proprietors of Finborough; and particularly one to the memory of William Wollaston, author of the "Religion of Nature delineated," who resided and is interred here. He was born in 1659, at Coton Clifton, in Staffordshire, and died in 1724.

The hamlet of Gipping derives its name from its situation near the source of one of those springs that form the river Gipping. It was once the seat of the ancient family of Tyrrle, whose residence, Gipping-Hall, is now held by Sir John Shelly, bart. Haugley was formerly a market-town, out of the ruins of which Stow seems to have risen. Near the church stand the remains of a very strong castle, constructed to have been built by the Saxons. The figure of the building approaches that of a square, fortified with a deep ditch, or moat; and, except on the north side, a proportionable rampart, full-entire. Towards the north, upon a high artificial hill, a steep ascent, and also surrounded with a deep moat, flood the keep; of which the foundation, now remaining, is very thick, and apparently circular. On the west side, a large oblong-square space seems to have contained some outwork of the castle. The ground occupied, or inclosed by all these works, exceeds seven acres. The manor and park of Haugley formerly belonged to Charles Brandon, duke of Suffolk; from whom they devolved by purchase, or exchange, to the crown; and were afterwards granted to Sir John Sulyard, of Wetherden. The manor is very extensive, and the lord formerlypossessed a power of trying all causes in his own court of oyer and terminer. Beauties of England and Wales, vol. xiv. Suffolk, by F. Shooben.

STOW-ON-THE-WOLD, a market-town and parish in the hundred of Welfordminster, and county of Gloucester, England, is irregularly built on the summit of a high hill, the base of which is about three miles in diameter. From this elevated situation it is generally said to want three elements out of the four; fire, earth, and water: air it possesses in plenty, and, though uncommonly sharp, it is reputed to be very healthful. Water is scarce, especially since the decay of an horizontal windmill at the north end of the town, which formerly raised it from a very deep well, and forced it through pipes to the houses. The charter for the market was granted, in the fourth year of Edward III., to the city of Evesham; by which establishment for part of the manor was held in the time of Edward the Confessor; and within a century, it had obtained possession of the remainder. The manor now belongs to Edmund John Chamberlayne, esq., a descendant of a respectable family of Norman extraction, who settled in the hamlet of Maugersbury, on the east side of Stow, in the time of queen Elizabeth; and one of whom, Edmund Chamberlayne, esq., was sheriff of this county in the 39th year of that sovereign.

The church is a well-built edifice, apparently the workmanship of different periods during the fourteenth and fifteenth centuries. It consists of a nave, aisles, and chancel, with an embattled tower on the south side, 82 feet in height, which, from its lofty situation, constitutes a principal object through a circumference of many miles. The arches are pointed, and supported by clustered pillars. At the east end is a rich window of quatrefoils; and at the west a window of ovals, with two trefoils in each. Several monuments and inscriptions, to the memory of the Chamberlaynes, are contained in this edifice; and in the midst of the chancel is a large altar-tomb, in remembrance of Duke Haftings Key, of Ebington, an officer on the part of Charles I., who died in the year 1645. His effigy in armour is engraved on the slab which covers the tomb.

The principal charitable institutions are an almshouse for nine poor persons, and a free-school; both situated on the south side of the church-yard. The former was founded under the will of William Chestre, dated as early as the sixteenth of Edward IV. Ailmer, or Ethalmer, earl of Cornwall and Devon, in the tenth century, the reputed founder of the original church in this town, is also said to have erected an hospital here, which Rudder mentions as being yet charged in the First-fruits office with the annual sum of 132. 4d. The population of Stow, as returned under the act of 1811, amounted to 1188; the number of houses to 264: the latter are mostly low, and built with stone, and have generally a very ancient appearance. The principal manufacture is that of flax.

At Adlethrop, or Adelthorpe, about three miles east of Stow, is the seat of James Henry Leigh, esq., a lineal descendant of Sir Thomas Leigh, to whom the manor, which had previously belonged to the abbey of Evesham, was granted in the year 1554. The manor is a very ancient building, but has been much enlarged, and otherwise improved. The pleasure-grounds have been laid out by Mr. Repton. About three miles south of the town is an old encampment, called an Inman-camp.—Beauties of England and Wales, vol. v. by J. Britton and E. W. Bralyce.

STOWRE, in Rural Economy, a term signifying a round of a ladder; a hedge-latch; also the flaves of the sides of a waggon, in which the eave-rings are fastened. It also signifies a staff or round stick, such as a tuck or rack staff.

STOWS, in Mining, are seven pieces of wood, set upon the surface of the earth, fastened together with pins of wood. See Spindle.

STRABANE, in Geography, a post-town of the county of Tyrone, Ireland, situated on the river Mourne. It is a flourishing town, and has a good market for many articles, especially linen cloth. Its canal, connecting it with the navigable river Foyle, is a principal cause of its prosperity, which is daily increasing. Strabane, before the union, was represented in parliament. It is 101 miles N.N.W. from Dublin.

STRABANE, two townships of Pennsylvania, one in Adams' county, the other in that of Washington; the latter containing 2595 inhabitants.

STRABISMUS, strabismus, in Medicine. See Squinting.

STRABO, in Biography, a celebrated geographer, was born at Amafax, a city of Pontus, but in what year we cannot ascertain. From his acquaintance with C. Gallus, preferent...
prefect of Egypt; and from his having composed his geography in the fourth year of the emperor Tiberius, we may infer that he flourished in the century B.C.; and Blair assigns his death to the year 25 before the commencement of the Christian era. It appears that he studied grammar and rhetoric at Nysa, and that he was instructed in the principles of the various sects of philosophers in several of the most celebrated schools of Asia. He owns himself a Stoic, and he followed their dogmas. Of the general course of his life little is known; but he appears to have been a vast traveller, and to have visited most of the countries which he describes. Besides his Geography, contained in seventeen books, which was written in his advanced age, and which is highly valued, he was the author of some historical works, which have been lost. His Geography, though since the time in which he lived it must be imperfect and erroneous in various particulars, is very useful for the illustration of the history and writings of the ancients; more especially as he interjects many philosophical remarks, which indicate a cultivated mind, and many short narratives, which serve to satisfy youth with acquaintance with the history and antiquities of remote periods.

Several editions of a Latin version of Strabo appeared before the Greek text was printed. Of the Greek and Latin editions, the first that claims commendation for its erudition was that of II. Cafaubon, fol. Genev. 1587, and Paris, 1620. That of Janfson al Velomeoven, cum notis variouis, Amst. 2 vols. fol. 1707, is much esteemed, though not very correct. An Oxford edition has lately appeared, under the inspection of Mr. Falconer. Fabr. Bibl. Grec. Gen. Biog.

Strabo frequently mentions music, and the illustrious musicians of antiquity, with great respect. He places Zeno at the head of all science; and says, that the principal invention of the poet does not consist in teaching, but in delighting mankind. Whereas, according to the more ancient fages, poetry was a first philosophy, which conducted youth through a plesant path to prudence, morality, manners, human affections, and social laws; while the moderns of our times (adds Strabo) say, that wisdom is only to be found among poets; on which account, the cities of Greece teach poetry to youth before all other things, not only for pleasure, but as a useful and virtuous discipline. In the same manner, musicians, while they are teaching to sing and play on instruments, making this faculty a profession, are called masters, and correctors of manners. And this was not only the opinion of Pythagoras, but is manifestly demonstrated by Aristoxenus; and for this reason Homer placed a musician over Clytemnestra, as a guardian and guide of her conduct. All this has been copied from Strabo by Athenaeus, l. c. 17.

But though a grave and solid writer, and a Stoic, Strabo has related a story in his fourteenth book, which throws a ridicule, not only on an eminent individual musician, but on the pretended lovers of music. He says that in Greece, near Bargilla, on the sea-coast, there was a market-town in a barren country, in which the inhabitants subsisted chiefly on fish; and a great performer on the cithara passing that way, willed to display his talents in public. On notice being given, the inhabitants assembled in great crowds to hear him. But soon after he had begun to perform, on hearing the fish-market bell, the audience hurried away, and left the citharist only one solitary person behind, who had not heard the bell, for he was deaf. The musician complained of his ill-treatment, butfinished by saying to the remaining gentleman, "Kind sir! I thank you for your politeness, in staying after all the rest had left me; but I perceive that you are a man of taste, a true lover of music, and did not run away in the midst of my performance, merely because the fish-bell rung." "What do you say? Why, has it rung?" demands the deaf gentleman: and the performer answering in the affirmative—"Oh, then, I wish you a good day, sir!"—and hastened to the market as fast as he could.

STRABRAGY, in Geography, a bay on the north coast of Ireland, in the peninsula of Inishowen, and county of Donegal. It is south of Malin head, and the village of Malin is situated on it.

STRACAIA, a town of Walachia; 18 miles N.W. of Krajova.

STRADA, FAMIANO, in Biography, a celebrated Italian writer, born at Rome in 1572, who entered into the society of Jesus in 1592, and became professor of eloquence in the Roman college, where he resided till his death in 1659. His most famous work was a "History of the Wars in the Low Countries," in Latin, consisting of two decades: the first, comprizing the events from the death of Charles V. to the year 1573; and published in 1654; and the second, as far as 1590, published in 1647. Strada's work was criticized with some severity by Cardinal Bentivoglio; and it is allowed to have been more the production of a rhetorician than of an impartial and correct historian. The style, however, is animated, and the language pure, though defective in the good taste of some other modern Latinists. It was attacked with virulence by Gaspar Scipionius, in his "Infamia Famiani Strade," which injured his own reputation more than that of the historian.

The "Prolusions Ad Arabicam" of Strada, containing various dissertations on literary subjects, is an ingenious and elegant performance, particularly admired for its imitations of the most celebrated Latin poets. Addifon pronounces this effusion to be "one of the most entertaining, as well as the most just pieces of criticism he had ever read;" and he has made it the subject of three papers in the Guardian. Tirabocchi. Gen. Biog.

STRADA, or STRADANUS, an eminent painter of a good family, was born at Bruges in the year 1536; and after residing in his own country, visited Italy for further improvement in painting. At Florence he was employed in some considerable works, and thence he went to Rome, where he painted at the palace of Belvidere in concert with Dan. da Volterra and Fr. Salviati. In compliance with the invitation of Don John of Aufris, he visited Naples, and accompanied his patron to Vienna, where his pencil was employed in commemorating that great officer's military exploits. He afterwards fixed his residence at Florence, where he became the head of the Florentine academy of painting; and he died in 1604. Besides history-pieces, he painted animals, hunting, and battles, in a noble style, with good drawing, and an agreeable tone of colouring. Although he may be considered as a competitor in a variety of respects with the celebrated artists of his time, he could never direct himself wholly of the Flemish taste which he had imbibed in his youth. Many of his pieces are engraved. Pilkington.
was announced in Handel's advertisement among the other
tingers of his troop in the following manner: "Signora
Strada, who hath a very fine voice, a person of singular me-
rit." This finger had many prejudices to combat on her
first arrival in this country; the enemies of Handel were of
course unwilling to be pleased with any part of the ent-
tertainment he had provided for the public; the abilities of
Cuzzoni and Faustina had taken possession of the general
favour; and Strada's personal charms did not allude her much
in conciliating parties, or dispelling the eye to augment the
pleasures of the ear; for she had so little of a Venus in her
appearance, that she was usually called the pig. However,
by degrees she subdued all their prejudices, and fended herself
into favour, particularly with the friends of Handel, who
used to say, that by the care he took in composing for her,
and his instructions, from a coarse finger with a fine voice,
he rendered her equal at least to the first performer in
Europe.

She first appeared in the opera of "Lotharius;" and in
examining the original score, her first air, "Quel cor che
mi donasti," seems chiefly calculated to display her fine
and brilliant voice, for which there are more than thirty occasions
given in the course of the song.

The Strada performed for Handel at Oxford, in the ora-
torio of Athalia, and in his three first oratorios that were
publicly performed in London. She left England in 1741,
and returned to Italy, leaving behind her great, and,
believing, well-merited fame, for the accuracy and spirit of her
voice.

STRADAN, in Geography, a town of Prussia, in the
province of Oberland; 3 miles N.W. of Eylau.
STRADANEN, a town of Prussia; 6 miles N. of
Lick.

STRADAUN, a town of Prussia, in Natangen; 9
miles S.W. of Marggrabowa.
STRADALLY, a post-town of Ireland, in the
Queen's county, on the mail-coach road to Cork, by way of
Cahel. There is a charter-school here for 50 boys, and
the town is neat, and tolerably flourishing. It is 59 miles
S.S.W. from Dublin.

STRADELLA, Alessandro, of Naples, in Biogra-
phy, was not only an excellent composer of the seventeenth century,
but a great performer on the violin, and besides these qualifications, he was possessed of a fine voice, and an
exquisite manner of singing. His compositions, which are
all vocal, of which we are in possession of many, and have
examined a great number more in other collections, seem
inferior to any that were produced in the last century, except
by Carissimi; and, perhaps, if he had enjoyed equal longevity, he would have been inferior in no respect to
that great musician.

Though it has been said by Bourdelot, in his "Histoire
de la Musique," tom. i. p. 41. and by others after him, that
Stradella was engaged by the republic of Venice to compose
for the opera in that city; it does not appear by the correct
and regular lift of the musical dramas performed at Venice
from the year 1637 to 1730, that an opera, or any part of
an opera, of his composition, was ever performed in that city.
Nor does his name occur as a dramatic composer for any
other part of Italy, in the "Drammaturgia" di Lione
Allacci, augmented and continued to the year 1755. His
compositions are chiefly miscellaneous, consisting of single
songs, cantatas, duets, trios, and madrigals of four and
five parts. One opera, and one oratorio, include the whole
of his dramatic music, sacred and secular, which we have
been able to find.

This musician, probably at an early period of his life, having
acquired great reputation at Venice by his talents, was em-
ployed by a noble Venetian to teach a young lady of a noble
Roman family, named Hortensia, to sing. This lady, on
whose nature had beflown a beautiful person and an exquisite
voice, notwithstanding her illibritious birth, having been
instructed from her friends, had submitted to live with this Ve-
netian in a criminal manner.

Hortensia's love for music, and admiration of the talents
of her instructor, by frequent acces, soon gave birth to a
passion of a different kind; and, like Heloïsa, she found,
that though at first

Guilteles she gaz'd, and listen'd while he sung,
While science flow'd seraphic from his tongue);

"From lips like his the precepts too much more,

They music taught—but more, alas! to love!

and accordingly she and her master became mutually en-
married of each other. Before their secret was disclosed,
of which the consequences might have been equally fatal to
Stradella with those which followed the discovery of Abe-
lard's passion, they agreed to quit Venice together, and fly
to Naples; and after travelling in the most secret manner
possible, they arrived at Rome in their way to that city.
The Venetian seducer, on discovering their flight, deter-
mined to gratify his revenge by having them assassinated in
whatever part of the world they could be found; and
having engaged two desperado ruffians to pursue them, by
a large sum of ready money, and a promise of a still greater
reward, when the work was accomplished, they proceeded
directly to Naples, the place of Stradella's nativity, sup-
posing that he would naturally return thither for shelter,
preferably to any other part of Italy. But after seeking him
in vain for some time in that city, they were informed that he
and the lady were still at Rome, where she was regarded as his
wife. Of this they communicated intelligence to their em-
ployer, affurting him of their determination to go through
with the business they had undertaken, provided he would
procure them letters of recommendation to the Venetian
ambassador at Rome, to grant them an asylum as soon as
the deed should be properly executed.

After waiting at Naples for the necessary letters and in-
structions, they proceeded to Rome, where, such was the
celebrity of Stradella, they were not long before they dis-
covered his residence. But hearing that he was soon to con-
duct an oratorio, of his own composition, in the church of St.
John Lateran, in which he was not only to play, but to sing
the principal part; and as this performance was to begin at
five o'clock in the evening, they determined to avoid them-
selves of the darkness of the night when he and his miltrefs
should return home.

On their arrival at the church, the oratorio was begun,
and the excellence of the music, and its performance, joined
to the rapture that was expressed by the whole congregation,
made an impression and softened the rocky hearts even of
these savage beasts to such a degree, as to incline them to
revisit; and to think that it would be a pity to take away
the life of a man whose genius and abilities were the delight
of all Italy—an inliance of the miraculous powers of mo-
dern music, superior, perhaps, to any that could be well au-
thenticated of the ancients.

Both these affinities being equally affected by the perform-
ance, alike inclined to mercy, and accosting him in the
street when he quitted the church, after complimenting him
upon his oratorio, confessed to him the business on which
they had been sent by the Venetian nobleman, whose miltrefs
he had stolen; adding, that charmed by his music, they had
changed their minds; and then, advising him and the lady
to fly to some place of safety as soon as possible, they determined to relinquish the rest of the reward that was promised them, and tell their employer that Stradella and his mistress had quitted Rome the night before their arrival in that city.

After this wonderful escape, the lovers did not wait for new counsel to quit Rome, but set out that very night for Turin, as a place most remote from their implacable enemy and his emissaries. And the affinias returning to Venice, told the enraged Venetian that they had traced the fugitives to Turin, a place where the laws being not only few, but the difficulty of escaping so much greater than in any other part of Italy, on account of the garrisons, they should decline any further concern in the business. This intelligence did not, however, incline the offended nobleman to relinquish his purpose, but rather stimulated him to new attempts: he therefore engaged two other affinias in his service, procuring for them letters of recommendation from the abbé d'Estrade, at that time the French ambassador at Venice, addressed to the marquis de Villars, ambassador from France to Turin. The abbé d'Estrade, struck with the resolves of the Venetian ambassador, protection for two merchants, who intended to reside some time in that city, which being delivered by the new affinias, they paid their court regularly to the ambassador, while they waited for a favourable opportunity to accomplish their undertaking with safety.

The duchies of Savoy, at this time regent, having been informed of the sudden flight of Stradella and Hortensia from Rome, and their arrival at Turin, and knowing the danger they were in from the vindictive spirit of their enemy, placed the lady in a convent, and retained Stradella in his palace, as a situation apparently so secure, Stradella's fears for his safety began to abate; till one day, at six o'clock in the evening, as he was walking for the air on the ramparts of the city, he was set upon by two ruffians, who each gave him a stab on the breast with a dagger, and immediately flew to the house of the French ambassador, as to a sanctuary.

The assault having been seen by numbers of people who were walking in the same place, occasioned such an uproar in the city, that the news soon reached the duchies, who ordered the affinias to be hunted, and the marquis de Villars having been informed by the surgeons that he would recover, in order to prevent any further dispute about the privileges of the corps diplomatique, suffered the affinias to escape.

But such was the implacability of the enraged Venetian, that never relinquishing his purpose, he continued to have Stradella constantly watched by spies, whom he maintained in Turin. A year being elapsed after the cure of his wounds, and no fresh disturbance happening, he thought himself secure from any further attempts upon his life. The duchess regretted, interesting herself in the happenings of two persons who had suffered so much, and who seemed born for each other, had them married in her palace. After which ceremony, Stradella having an invitation to Genoa, to compose an opera for that city, went thither with his wife, determining to return to Turin after the carnival; but the Venetian being informed of this motion, sent affinias after them, who watching for a favourable opportunity, rushed into their chamber early one morning, and stabbed them both to the heart. The murderers having secured a bark, which lay in the port, by instantly retreating to it, escaped from justice, and were never heard of more.

This tragic event must have happened considerably later than 1670, the date that has been affixed to it by all the liberal writers who have related the story. For being in possession of the drama which he set for Genoa previous to his murder, which is entitled "La Forza dell' Amor paterno," and dated Genoa, 1678, it appears that the dedication of this opera to Signora Tereza Raggi Saoli, was written by Stradella himself. And at the conclusion of the editor's advertisement to the reader is the following eulogium on the composer of the music: — "Battendo il diritto, che il concerto di pari perfezione sia valore di un Allemandro, cioè del signor Stradella riconosciuto senz' altro contratto per il primo Apollo della musica." — "Nothing further need be offered in defence of the work, than to say that it had received the advantage of the perfect melody and harmony of an Alexander, that is, of signor Stradella, indubitably acknowledged to be the magnus Apollo of music."

His oratorio of "San Giovanni Battista, a 5, con ari...mendi," which is generally believed to have saved this charming composer's life, being minutely described, and in a manner reviewed, in Burney's History of Music, vol. iv. p. 105, we must refer our curious readers to that work, where a considerable part of this oratorio is printed, together with a list of other excellent productions by this admirable master, preferred in different collections in our public and private libraries; and the more we examine the productions of this gifted musician, the more we are convinced that Purcell made him his model; not in detail, in order to imitate his passages, but in his general style of composition. Purcell was extremely fond of writing upon a ground-bass, a species of chaconne, which the Italians call basso coffrente, and the French basse-contreinte: and in Stradella's oratorio, it appears that more than half the airs in that admirable production are built upon a few bars or notes of base perpetually repeated. Purcell may have been influenced to exercise his powers in such composed and difficult enterprises as themes, by viewing the works of an author, who, according to tradition, was his greatest favourite; but he has never made use of the fame ground, or series of notes, in any of his numerous compositions of this kind: indeed Purcell's ground-basses are not only new, but in general more pleasing and difficult to treat, than those of any other composer of his time.

Stradella, in Geography, a town of Italy, near the Po; 9 miles E.S.E. of Parma.

Strafford, a township of America, in Orange county, Vermont, containing 1805 inhabitants; 20 miles N.N.W. of Norwich.

Strafford, a county of New Hampshire, watered by branches of the Piscataqua and Merrimack, containing 41,595 inhabitants. The chief towns are Dover and Durham.

Stragnes, a town of Sweden, in Sudermanland; 31 miles W. of Stockholm.

Strather, a town of Scotland, in the county of Argyll, situated on Loch Fine, opposite to Inverary.

Strahlstein, in Mineralogy, Attilianite, Jameston.

Ambibolite Atitace, Hauy. This mineral is classed by Hauy with hornblende, on account of the identity which he supposes to exist in the forms of the primitive crystals of both:
both: this identity is, however, denied by the count de Bournon. Werner makes a distinct species of strahlenstein, which he divides into four sub-species: common austinolite, glassy austinolite, granular austinolite, and effusible austinolite. The three former appear to differ only in their structure; the latter more nearly resembles achatolite.

The colour of austinolite is principally leek-green or grass-green, but sometimes olive-green and greenish-white.

Common austinolite, Gemeiner strahlenstein, is never regularly crystallized: it occurs in beds in rocks of gneiss, mica-flate, and talcous slate, and in small veins or disseminated in trap-rocks. It has a divergingly foliated, or promiscuously radiated structure, with a double cleavage, forming oblique angles. Its internal luster is shining; it is more or less translucent or transparent; it fractures glass, and melts before the blow-pipe into a greyish-green or blackish glass. The specific gravity of this mineral is about 3.4.

Glassy austinolite, Glaseriger strahlenstein, occurs massive and crystallized in very oblique four-sided prisms; the edges are generally truncated. The crystals are small, and most frequently either divergingly aggregated, or reiting on each other. In the fibrous varieties, the fibres are sometimes parallel. The luster is vitreous, slightly inclining to pearly. The crystals are translucent, and very brittle. Before the blow-pipe it melts with difficulty into an opaque, green-coloured glass.

The constituent parts of this mineral, from Zillerthal, in the Tyrol, as given by Langier, are:

- Silex: 50
- Magnesia: 19.25
- Alumine: 0.75
- Lime: 0.15
- Potash: 0.25
- Oxyd of iron: 11.00
- Oxyd of manganese: 0.50
- Oxyd of chrome: 3.00
- Carbonic acid and water: 5.00
- Lofs: 0.15

Granular austinolite, Korniger strahlenstein, occurs massive, in large, coarse, and small granular distinct concretions, along with precious garnet and quartz, in the Salzpe and Tainach, in Stria. The luster is shining and vitreous. The cleavage is double; the structure in the direction of the principal joint is foliated. The cross-fracture is splintery. It is hard and brittle. It is fairly translucent.

Effusible austinolite, Effusatiger strahlenstein, Werner. Austinolite aciculaire, Haitiy. The colour is a greenish-grey, which passes into sky-blue, and into olive-green, and yellowish-brown and liver-brown. It occurs in distinct wedge-shaped concretions, composed of acicular crystals, which are diverging or radiated. It is opaque, or slightly transluent on the edges. Internally the luster is glintening and pearly. It is soft, rather delicate, and breaks with difficulty. The specific gravity of effusible austinolite is 2.8, Karsten; according to Kirwan, 2.759. It melts with difficulty into a black or dark green-coloured glass. The constituent parts, according to Vanquelien, are:

- Silex: 47.0
- Lime: 11.5
- Magnesia: 7.3
- Oxyd of iron: 20.0
- Oxyd of manganese: 10.0
- Lofs: 4.4

The variety of which the analysis is given, is composed of thin, elastic and flexible crystals, and is called by Saffure byfolite. It occurs in Norway, Sweden, in the Hartz, and various alpine districts, in rocks of gneiss, mica-flate, and granular lime-flint; it occurs also near Maraffon, in Cornwall. The colouring matter of crystallized austinolite appears from the analysis of Langier, to be chrome; this is also, in all probability, the colouring matter of the other varieties. The hexagonal prisms of austinolite are commonly of a beautiful green, imbedded in white talc. Austinolite occurs at Glenelg, in Inverness-shire, and in the Isle of Skye, and disseminated in trap, in Shropshire. The mineral with which austinolite or strahlenstein is most likely to be confounded, is thellite or epidote. For the distinctive characters of each, see Thellellite.

STR. STRAIGHT, STRAIGHT, or STRAIT, in Hydrography, a narrow channel or arm of the sea, shut up between lands on either side, and affording a passage out of one great sea into another.

There are three kinds of straits. 1. Such as join one ocean to another. Of this kind are the straits of Magellan and Le Maire. 2. Those which join the ocean to a gulf: the straits of Gibraltar and Babelmandel are of this kind, the Mediterranean and Red Sea being only large guls. 3. Those which join one gulf to another; as the strait of Cape, which joins the Falus and the Euxine, or Black Sea.

The passage of straits is commonly dangerous, on account of the rapidity and opposite motion of currents.

The most celebrated strait in the world is that of Gibraltar, which is about one hundred and thirty miles long, and twelve broad, joining the Mediterranean sea with the Atlantic ocean.

The straits of Magellan, discovered, in 1520, by F. Magellan, were used some time as a passage out of the North into the South sea; but since the year 1616, that the strait of Le Maire has been discovered, the former has been diffused; both because of its length, which is full three hundred miles, and because the navigation of it is very dangerous, from the waves of the North and South seas meeting in it and clashing.

The strait at the entrance of the Baltic is called the Sound; which see: that between England and France, Le pas de Calais, or the Channel. There are also the straits of Babelmandel, of Weigats, of Jello, of Anian, of Davis, and Hudson, &c.

Straight is also used, in Geography, for an ilemus or neck of land between two seas; preventing the communication thereof.

Highwater is a name applied to the straits of the North Sea.

STR. Straight, or Straight, in Geography, a river of America, which runs into the Ohio, N. lat. 38° 38'. W. long. 84° 2'.

STRAIKS, in the Military Art, are strong plats of iron, fix in number, fixed with large nails, called streik-naile, on the circumference of a cannon-wheel, over the joints of the fellow, both to strengthen the wheel, and to save the fellows from wearing on hard ways or streets.

STRAIN, or SPRING, a violent extenstion of the fine or tendon of some muscle. See SPRING.
STR

STRAIN, among horses and other animals, an over-dilatation of the muscles, proceeding from slips, blows, or from hard riding in the horse. It may be observed, that in all strains, the muscular or tendinous fibres are over-stretched, and sometimes ruptured, or broken.

It is evident, that in all violent strains, either of tendons or muscles, whatever opinions may have been entertained of bathing and anointing with favourite remedies, which often succeeded in slight cases, where perhaps bondage alone would have answered; the latter, with properly relieving the relaxed fibres till they have thoroughly recovered their tone, are chiefly to be depended on; and frequently some months are necessary for effecting the removal of the complaint. All such violent strains of the ligaments which connect the bones together, especially those of the thigh, require time, and turning out to graze, to perfect a recovery. External applications can avail but little here, the parts affected lying too deep, and so surrounded with muscles, that neither applications nor medicine can penetrate to them. The foaler, in these cases, the horse or other animal is turned out to graze, the better, as the gentle motion in the field will prevent the ligaments from thickening, and of course the joint itself from growing stiff; nor do we believe that firing, so commonly practised with horses in this case, is of half the consequence as rest, and turning out for a considerable time, which is indeed always advised at the time the horse is fired. Where the shoulder is over-strained, the horse or animal does not put out the leg like the other; but, to prevent pain, sets the found foot hardly on the ground, to serve the other, even though he be turned short on the lame side, which motion tries him the most of any. When trotted or run in hand, instead of pulling the leg forward in a right line, the animal forms a circle with the lame leg; and when the horse stands in the stable, that leg is advanced before the other. The same is the case with other animals. In order to remove this lameness, they should first be bled, and the whole shoulder be well bathed, three times a day, with verjuice, or vinegar; but if the lameness continue without swelling or inflammation, after resting two or three days, it has been recommended that the muscles be well rubbed for some time with opodeldoc, or embrocations compounded of camphor and turpentine, or vinegar, camphor, and spirits of vitriol. Where inflammation and swelling are present, the use of camphorated farinaceous washes may frequently be beneficially employed two or three times in the day, cloths wet with them being applied to the parts.

Strain, in Music, is a section or portion of an air or tune of two or more sections; as first strain, second strain; and sometimes the term implies the whole air; as a beautiful, pleasing, or disagreeable strain.

"That strain again;—it had a dying fall."

STREND SUGAR. See Sugar.

STRAINING. See Sugar.

STRAINING, in Phystiology. See Lungs.

STRAISIN, in Geography, a town of Austria; 7 miles N.W. of Pirawarthe.

STRAIGHT. See Straight.

STRAITS of Calais, one of the twelve departments of the second or northern region of France, composed of Artois, Calais, and Boulogne, lying in N. lat. 50° 30', between the department Du Nord and the British Channel, containing in territorial extent 7,042 square leagues, or 3,28 square leagues; Vol. XXXIV.

or 37 French leagues in length and 15 in breadth, or about 90 English miles in length from N.W. to S.E. and 90 in breadth, and 56,061 inhabitants. It is divided into rix circles or districts, 43 cantons, and 923 communes. The circles are Boulogne, containing 71,304 inhabitants; St. Omer, with 66,763; Bethune, having 64,669; Arras, with 36,380; St. Pol, with 76,061, and Montreuil, including 70,883 inhabitants. According to Haltenbrat, the number of circles is 8, of cantons 85, and of inhabitants 525,789. The capital is Arras. A ridge of low hills extends from Abbeville to Boulogne. The soil of this department is, in general, fertile, yielding all sorts of grain, flax, and pastures.

STRAKES, in Ship-Building, are the regular ranges of planks on the bottom and sides of the ship, or the continuation of planks joined to the ends or butts of each other, and reaching from the stem to the stern-post: the lowest of the over the bottom, called the garboard-strake, is let in to the rabbit of the keel, and into the stem and stern-post. The lowest strake inside is called the timber-strake, which is wrought about eleven inches from the side of the keel, and has a rabbit in the upper edge to receive the ends of the timber-boards.

They say also, a ship beats a strake, that is, when the inclines to one side the quantity of a whole plank’s breadth.

STRAKES, or Streaks, in Mining, are frames of boards fixed on or in the ground, where they wash and dries the small one in a little stream of water, hence called a framed ore.

STRAKONITZ, in Geography, a town of Bohemia, in the circle of Prachatitz; 54 miles S. of Prague. N. lat. 49° 17'; E. long. 13° 50'.
particulars geometry and fortification, he was well versed in various other branches of science. Gen. Biog.

STRALSUND, in Geog., a city of Germany, and capital of Swedifh Pomerania, situated in a strait which passes between the continent of Pomerania and the island of Rugen, founded in 1209, by Jaro Mar, the first prince of Rugen, for the security of his territory on the continent, but soon afterwards destroyed by the dukes of Pomerania. It is a very strong place, being surrounded by the sea so as to be accessible only by bridges, and well fortified. It is the residence of the king's governor-general, of the regency, and war office; and the place where the states of Swedish Pomerania hold their meetings. Its magistracy was ennobled, in 1714, by Charles XII. king of Sweden; and in 1720, king Frederick I. extended the like honour even to the members of the council. It was formerly one of the principal Hanse towns. It has undergone several revolutions; and in August 1807, it was taken by the French; 113 miles N. of Berlin. N. lat. 54° 20'. E. long. 13° 8'.

STRAMBURG, a town of Mecklenburg, in the circle of Pomerania; 30 miles E. of Prerow. N. lat. 50° 31'. E. long. 18° 11'.

STRAMMEHL, or STRAMEN, a town of Hinder Pomerania; 36 miles W. of New Stettin. N. lat. 53° 42'. E. long. 15° 32'.

STRAMONIUM, in Botany, supposed to be a corruption of atyraeum, or mid-nightshade. See Datura.

Datura, in the Materia Medica. See Datura.

Datura, in the Materia Medica.

Under the article now referred to, it has been observed that the plant has been known as a powerful narcotic poison; its congener, the D. metel, is thought to be Euphorbiaceae (strychnus manicus) of Theophrastus and Dioscorides, and is therefore the species received by Linnaeus into the materia medica. In the recent flate, the stramonium has a bitter taste, and a smell somewhat resembling that of poppies, or, as Herbgus says, narcotic, especially if the leaves be rubbed between the fingers. By holding the plant to the nose for some time, or sleeping in a bed where the leaves are fired, giddiness of the head and stupor are said to have been produced. The deleterious effects of the plant, and more especially of the seeds, have been manifested in various instances: and those of the seeds have, in some cases actually upon record, been fatal. Their coprophilous efficacy has been shamefully applied to purposes the most licentious and dishonourable. The effects of the stramonium as a medicine, are to be referred, says Dr. Woodville, to no other power than that of a narcotic. The extract, he says, has been the preparation usually employed, and from 1 to 10 grains, and upwards, a day; but the powdered leaves, after the manner of those directed by hemlock, would seem, he thinks, to be a preparation more certain and convenient. Externally, the leaves of stramonium have been used as an application to inflammatory tumours and burns. Some have thought they have derived benefit from smoking stramonium in asthma and shortness of breath.

STRAND, in Geography, a town of Sweden, in Warmeland; 56 miles N.W. of Carlstadt.—Allo, a town of Norway, in the province of Bergen; 20 miles S.W. of Romdal.—Allo, a town of Sweden, in Warmeland; 20 miles N.W. of Carlstadt.—Allo, a lake of Norway, in the province of Agerhus; 75 miles N.W. of Christiansia.

STRAND, North, a strait of the North sea, between the island of Benbecula and North Uist.

STRAND, South, a strait of the North sea, between the island of Benbecula and South Uist.

STRAND, in Sea Language, denotes one of the twirls or divisions of which a rope is composed. See Rope.

A rope is said to be stranded, when one or more of its strands are so damaged as to be cut through, or nearly so.

Strand also implies the sea-beach: hence a ship is said to be stranded, when, by tempest or bad weather, she is run on shore. This is oftener the case than need be, if proper alinement was given, or one of the following methods were practiced for the safe removal of ships driven on shore. For this purpose, empty casks are usually employed, by being lashed round her under her bottom, to float off the vessel; or a temporary cauing built round her outside, of flanchions and deals caulked, especially if she is small, and at the same time near the port to which it is proposed to conduct her. In other cases, the following method, adopted by Mr. Barnard, will answer. (See Philosophical Transactions, vol. lxx, part 1.) On January 1, 1779, (says Mr. Barnard), in a most dreadful storm, the York East Indianman, of 800 tons, homeward bound with a pepper cargo, parted her cables in Margate road, was driven on shore within one hundred feet of the head and thirty feet of the side of Margate pier, then drawing twenty-two feet six inches water, the flow of a good spring-tide being only fourteen feet at that place.

On the 3d of the same month I went down to affit getting off the ship. I found her perfectly upright, and her sheer (or side appearance) the same as when first built, but funk to the twelve-feet water-mark fore and aft, in a bed of chalk mixed with a thick blue clay, exactly the shape of her body below that draught of water; and from the rudder being torn off as the ship coming on shore, and the violent agitation of the sea after her being there, her stern was so greatly injured as to admit free access thereto, which filled her four days equal to the flow of the tide. Having fully informed myself of her situation and the flow of spring-tides, and being clearly of opinion she might be again got off, I recommended, as the first necessary rep, the immediate discharge of the cargo; and in the progress of that business, I found the tide always flowed to the same height on the ship; and when the cargo was half discharged, and I knew the remaining part from the ship was to draw more than eighteen feet water, and while I was observing the water at twenty-two feet six inches by the ship's marks, she instantaneously to seventeen feet eight inches; the water and air being before excluded by her pressurie on the clay, and the atmosphere acting upon her upper part equal to fix hundred tons, which is the weight of water displaced at the difference of those two draughts of water.

"The moment the ship lifted, I discovered she had received more damage than was at first apprehended, her leaks being such as filled her from four to eighteen feet water in an hour and a half. As nothing effectual was to be expected from pumping, several cuttles or holes in the ship's sides were made, and valves fixed thereto, to draw off the water at the lowest ebb of the tide, to facilitate the discharge of the remaining part of the cargo; and, after many attempts, I succeeded in an external application of sheep-skins sewed on a fail, and thrust under the bottom, to stop the body of water from rushing so furiously into the ship. This business being effected, moderate pumping enabled us to keep the ship to about fix feet water at low water, and by a vigorous effort we could bring the ship so light, as (when the cargo should be all discharged) to be easily removed into deeper water. But as the external application might be disturbed by so doing, or totally removed by the agitation of the ship, it was absolutely necessary to provide some permanent se-
curiosity for the lives of those who were to navigate her to the river Thames. I then recommended, as the cheapest, quickest, and most effectual plan, to lay a deck in the hold, as low as the water could be pumped to, framed so solidly and securely, and nearly so tight, as to swim the ship independently of her own leaky bottom."

"Beams of fir-timber twelve inches square were placed in the hold, under every lower-deck beam in the ship, as low as the water would permit: these were in two pieces, for the convenience of getting them down, as also for the better fixing them of an exact length, and well bolted together when in their places. Over these were laid long Dantzic deals of two inches and a half thick, well nailed and caulked. Against the ship's sides, all fore and aft, was well nailed a piece of fir, twelve inches broad and six inches thick on the lower, and three inches on the upper edge, to prevent the deck from rising at the side. Over the deck, at every beam, was laid a cross-piece of fir-timber, six inches deep and twelve inches broad, reaching from the pillar of the hold to the ship's side, on which the shores were to be placed to refit the prefire of the water beneath. On each of these, and against the lower-deck beams, at equal distances from the side and middle of the ship, was placed an upright shore, six inches by twelve, the lower end let two inches into the cross-piece, and the upper end of every lower-deck beam, was placed a diagonal shore, six inches by twelve, to ease the ship's deck of part of the strain, by throwing it on the side. An upright shore of three inches by twelve was placed from the end of every cross-piece to the lower-deck beams at the side, and one of three inches by twelve on the midships' end of every cross-piece to the lower-deck beam, and nailed to the pillars in the hold. Two firm tight bulkheads, or partitions, were made near the extremes of the ship as possible. The ceiling or inside plank of the ship was securely caulked up to the lower deck, and the whole formed a complete floor, with a flat bottom within itself, to swim the outside leaky one; and that bottom being deprived six feet below the external water, refitted the ship's weight above it equal to five hundred and eighty-one tons, and safely conveyed her to the dry-dock at Deptford."

As to the manner in which stranding affects matters of insurance, see Risk.

Where a vessel is stranded, justifies the peace full command confinable near the sea-coast to call almsness for the poor and famine, and the officers of men of war are to be aiding and afflicting. 12 Anne, cap. 18.

**STRAND and Stream**, in *Ancient Culisse*, a freedom from all impositions upon goods or vessels by land or water.

**STRANDSOGEN**, in *Geography*, a town of Norway, in the diocese of Bergen; 8 miles E.N.E. of Stavanger.

**STRANDT, North**, one of the three islands which were inhabited by the Saxons in the days of Trollem; the other two being Bufen, N. of the mouth of the Elbe, W. of Ditzmaria, looking towards Melborn, above two miles broad and nearly three in length, and containing three or four parishes, with as many villages; and Holy island, i.e. sacred island, the most celebrated and the most frequented of the Saxon islands situated in the German ocean, not 40 miles distant from Eiderstadt, and rather farther from the mouth of the Elbe, divided into Klif and Duknen or Downs, which two parts are separated from each other by a channel deep enough for vessels of a moderate bulk, and about three-fourths of a mile broad, annexed to the crown of Denmark in 1714. North Strandt was formerly torn from South Jutland by the violence of the storm. It is situated opposite to Helium and above Eiderhade, from both which it is separated by intervals of sea. This island was formerly about twenty miles long, and in most parts seven miles broad; it contained twenty-two parishes, and was noted for its agricultural produce as well as its fish; but since the time of the Saxons it has suffered much from inundations of the sea, and there is now remaining of Nordstrand only the small parish of Felsworm, which owes its safety to the height of its situation. See Nordstrand.

**STRANGALIDES**, in *Surgery*, hard tumours in the breast from milk.

**STRANGE, Sir Robert, in Biography**, an eminent English engraver, was born in one of the Orkney islands in 1721, and placed at a proper age with a painter in Edinburgh. When the Pretender landed in Scotland, he entered into the rebel army, and after the battle of Culloden, he concealed himself for some time in the Highlands. Returning to Edinburgh, he passed over to France, and settled at Rouen, where he acquired reputation by the productions of his pencil. At Paris, whither he removed, he placed himself under the instruction of Le Bas, who excelled in engraving with what is called among artists the "dry needle." In 1751 he settled in London, and acquired the reputation of being the father of historical engraving in this country. He visited Italy in 1765, and by his admirable drawings of the capital produced in that city, recommended himself to those who were capable of duly appreciating his talents and performances to such a degree, that he was admitted a member of all the principal Italian academies, and also of that of painting in Paris. The stains of his early political errors and misconduct having been effaced, he was patronized at the English court, and in 1787 received the honour of knighthood. After a course of the most indefatigable labour in the practice of his art, he died in 1792. Besides a number of other works, he left fifty capital plates from pictures of the most celebrated masters of the Italian schools. Seckerist, as he was known to his friends, copied from eight copies of the best impressions of every plate which he engraved, he collected them into as many volumes, and prefixed to each two plates of himself, one an etching, the other a finished proof, from a drawing by I. Bap. Greuze; together with an introduction on the progress of engraving, and critical remarks on the pictures from which the engravings were taken. The force and clearness of his burin were perhaps scarcely ever surpassed, and gave a permanent value to his works. The moral character and manners of Sir R. Strange are spoken of by his biographer in the warmest terms of approbation. His whole property, acquired by honourable industry, was considerate, and bequeathed to his family. Mem. of Sir Robert Strange.

**STRANGER, in Law**, deates a person who is not privy, or party, to an act.

Thus, a stranger to a judgment, is he to whom a judgment does not belong; in which sense the word stands directly opposed to party or privy.

**STRANGERS' KEY**, in *Geography*, a small island among the Bahamas. N. lat. 26° 45', W. long. 78° 0'.

**STRANGFORD**, a port-town of the county of Down, Ireland, on the west side of the strait connecting the lough of Strangford with the Irish sea. On the opposite side of the strait is Portaferry, a flourishing town; but Strangford is properly the sea-port, being the place in which is the customhouse, and where revenue officers attend. In the reign of queen Elizabeth, a castle was maintained here for securing the quiet of the county. A ferry-boat maintains the communication between the town, which is in the barony of Lecale, and Portaferry, which is in the district called The Ards. Strangford is 80 miles N.N.E. from Dublin.
STRANGFORD Lough, formerly called Lough-Conn, in the county of Down, Ireland, is the largest fall-water lake in Ireland, covering upwards of twenty-five thousand acres. The tide flows directly up to Newtown-Ardes, at the extremity of it, and there are several pleasant and useful creeks at both sides. In some parts the water is sufficiently deep for any ship, but the entrance is a long strait, through which the tide rushes with great rapidity; and in it are some rocks, especially that hоsіl called the Bar, near the entrance, which renders it dangerous to fall into it without a favourable wind and tide. In the lough there are a great number of little islands, which maintain large herds of cattle, and great numbers of fowls and upon which immense quantities of fowl are raised. The towns of Newtown-Ardes, Killalaugh, and Cumber, on its shores, have linen markets. There is a herring-fishery on the lake, but the herrings taken in it are said to be inferior, with respect to fatness and flavour, to those taken at sea. The fishery along the neighbouring coast employs above four hundred boats. The inhabitants of the shores of the lough derive considerable emolument from making kelp, which is esteemed better than that made on the sea-shore. So industrious are they, that they draw stones from the fields and spread them on the shores, in order to make the kelp-growth being obtained from rocks and stones. The name Strangford, or Strongford, is said to have been derived from the rapidity with which the sea runs into the lake, which renders the passage from Strangford to Portaferry somewhat difficult. Young's Tour. Campbell's Polit. Surv. &c.

STRANGLES, in the Mange, is a collection of foul humours formed in the body of a young colt, which are voided by the nostrils, or by a suppuration of some glands or knots that lie between the bones of the lower jaw, and are driven before the hoofs of the horse. The false strangules happen in old horses that have not well called the strangules. See GLANDERS.

STRANGULATED HERNIA, in Surgery, a rupture, or hernia, in which the protruded visceræ suffer such a degree of pressure, that very urgent and dangerous symptoms are excited. See HERNIA.

STRANGULATIO, a word used to express that kind of suffocation which is common to women in hysterical disorders, and for the straitening of the intine in hermaphrodites.

STRANGULATORIA, in the Materia Medica, a name by which Avicennia, and some other authors, have called the darovicum, or leopard's bane.

STRANGURY, in Surgery, a difficulty and pain in making water. See URINE, Retention of.

STRANKOWITZ, in Geography, a town of Bohemia, in the circle of Prachatitz; 4 miles S. of Wodanady.

STRANRAER, a royal borough in the district of the Rhyns, and shire of Wigton, Scotland, is situate at the eastern extremity of the bay of Loch-Ryan, and has an excellent natural harbour, called the Roa; where flotillas of large busses can anchor in safety. The town is divided, nearly in the centre, by a little rivulet, over which there are several stone-bridges. Many good houses have lately been erected here, also a handsome town-hoose, and a prison. It is a port of the customs, of which all the maritime parishes of the Rhyns are members. Here is also a post-office; and a church was erected for the parish in 1785. In the town are ruins of a castle, now uninhabited, but which has been of considerable height and subsidence. The employment of the town is chiefly the coasting-trade; but some vessels are engaged in fishing. At one period, a coarse cloth, called Galloway plaiding, was much manufactured in this neighbourhood; but the American war greatly injured it. Since that event, the fame persons have engaged in the linen manufacture. Coal is imported thither from Ayr, or Irvine, by sea, and is used by the higher classes; but the chief fuel is turf or peat, brought from a distance of three or four miles. Stranraer is endowed with a market, and three annual fairs; and, in conjunction with the boroughs of New Galloway, White-horn, and Wigtown, sends one member to parliament: it has also separate jurisdiction, and its municipal government is conducted by a provost, two bailies, a dean of guild, and fifteen counselling. The population of this place, in the return of 1811, was estimated at 153 in 1813; and the accounts, who occupied 287 houses.—Carlile's Topographical Dictionary of Scotland, vol. ii. Beauties of Scotland, vol. ii.

STRAP, among Surgeons, a fort of band used to stretch out limbs in the setting of broken or disjointed bones. See BANDAGE.

STRAP, or Strap, in Rigging, a wreath of rope spliced round blocks, or used to encircle a yard, or any large rope, by which tackles, &c. may be connected to them.

STRAP, in Rope-making, is composed of a number of yarns plaited together with an eye at one end, to put a Rick through; it is hanked up being obtained from rocks and stones. The name Strangford, or Strongford, is said to have been derived from the rapidity with which the sea runs into the lake, which renders the passage from Strangford to Portaferry somewhat difficult. Young's Tour. Campbell's Polit. Surv. &c.

STRAPADO, or Strappado, a kind of military punishment, in which the criminal's hands being tied behind his back, a hoop is hoisted up on top of a long piece of wood, and let fall again almost to the ground; he being afterwards hoisted on the hoop, his arms are dislocated. Sometimes he is to undergo three strapados, or more.

The word is formed from the French strapede, which signifies the same, and which is supposed to come from the old verb straper, to break, extirpate; or from the Italian strappada, of the verb strappare, to wrest by force.

STRAPAZINO, in Ornithology, the name of a bird of the wheat-ear kind, with a white rump and tail, and of a dull-brown-yellow color on the head and neck; its underparts are variegated with black and yellow, and its back is longer, and of a brownish-yellow color; throat, breast, and belly, of a yellowish-white. It is common in Italy, and is frequently brought to market among the small birds. Bellonius de Avibus.

STRAPPING POSTA, are polls placed near the locks, round which the boatsmen wind their rope, and check the velocity of the boat's motion before it enters the lock, and thus prevent damage.

STRASALDO, in Geography, a town of Italy, in Friuli; 2 miles E. of Palma la Nova.

STRASBERG, a town and lordship of Germany, belonging to the abbey of Buchau; 19 miles W. of Buchau.

STRASBURG, a city of France, and capital of the department of the Lower Rhine. The place, according to some statements, contains 49,056, and the canton 49,056 inhabitants, on a territory of 70 kilometres, in one commune; but others say it has 40,000 houses, and 60,000 inhabitants. This city is situated at the confluence of the Ill and the Bruich, about a mile from the left bank of the Rhine. Before the town, on the road of Alsace, and at the end of the capitol of Alzé, and the fee of a bishop, who was a prince of the empire. Its name, which it received about the 14th century, denotes the
the “town of the street,” because it lay on the high road from France to Germany. It is well fortified with a citadel by Vauban, the outworks of which reach almost to the Rhine. It has six gates, and 200 streets, mostly narrow; eight bridges across the Ill, and one of wood, 3900 feet in length, over the Rhine, supported by an island in the middle, on which is a strong castle. A canal is made from the Bruch to the Rhine, and by means of a sluice the country may be inundated to the distance of 1500 toises. The cathedral is a beautiful Gothic structure, founded in the year 1015, and finished in 1275; the fleche, built 165 years after the cathedral, is 115 feet high, wrought in the form of a pyramid, combining solidity with delicacy. The clock, constructed on the plan of a celebrated mathematician, named Dafypodius, but now decayed, exhibits the motions of the planets, as well as the hours of the day. This city was formerly imperial; but in the year 1683, it was taken by Louis XIV., and yielded to him by the peace of Ryswick; who, however, granted to the inhabitants all their privileges and immunities which, on war, they were not to pay anything to the king, but all the imports were to be expended in the support of the city. Strasbourg has an university, governed by twenty professors, who are Lutherans, and another of Roman Catholics. The public magazines are filled every year, and the poor are carefully supplied by the magistrates. The military hospital is a handsome building, and the city infirmary will receive 800 patients of both sexes, without distinction of religious opinions; besides which, there are two houses of orphans, a foundling hospital, and a hospital for venereal complaints, a lazaretto for epidemic diseases, a house of charity for mendicants, an anatomical hall and cabinet, a botanical garden, a public library, a military school, &c. Before its union with France, the Lutherans only exercised public employments; after that the Catholics were admitted to a share. From its situation, Strasbourg is a place of considerable commerce; here are manufactures of tobacco, china, steel, lace, carpets, cloth, leather, &c. The revenues are paid to amount annually to the sum of a million of livres; and in the year 1767, a plan was formed to embellish the city, coupled with the regularization of streets, and building houses in a state of uniformity. The Lutherans have seven churches, in one of which a most beautiful mausoleum of white marble was erected to the memory of the great Archduke Saxo, in the year 1777. The chapter of the cathedral was founded in the year 1015, to be composed of 24 nobles of the rank of counts. The episcopal territory beyond the Rhine was, in 1801, given to the marquis of Baden; 75 poils E. of Paris. N. lat. 48° 35', E. long. 7° 45'.

Strasburg, a town of Polish Prussia, in the territory of Culin, on the right side of the Drabnitza; 30 miles N. of Thorn.—Allo, a town of the duchy of Carinthia, on the Gurck; 12 miles N. of Clagenfurt.—Allo, a town of the Ucker Mark of Brandenburg; 12 miles N. of Prenzlau. N. lat. 53° 31', E. long. 13° 44'.—Allo, a town of Bohemia, in the circle of Bohemia; 12 miles N.N.W. of Jung-Buntzel.—Allo, a town of Welfphalia, in the county of Stolberg; 4 miles E.N.E. of Stolberg.

Strasbourg, a post-town of Virginia, in Shenandoah county, on the N.W. branch of the north fork of Shenandoah river, containing a handsome German Lutheran church, and 60 or 70 houses; 77 miles N.E. by N. of Staunton.—Allo, a township of Lancaster county, Pennsylvania, situated on an eminence, in the centre of a fertile and well cultivated country, containing 2710 inhabitants; 8 miles E. of Lancaster.—Allo, a settlement of Kentucky; near the Bullit Lick.

Straschnitz, a town of Bohemia, in the circle of Boleflau; 2 miles N. of Melnik.

Straseburg, or Staretz, a town of the duchy of Stiria; 11 miles N. of Marburg.

Stratis, or Stasites, a stone described by the writers of the middle ages, and famed for its medicinal virtue of promoting venery, afflicting digestion, and the like, and that whether taken inwardly, or outwardly, it is not easy, from the accounts they have left us, to guess what stone they mean.

Strasko, in Geography, a town of Moravia, in the circle of Brunn; 24 miles N.W. of Brunn.

Strasnitza, a town of Moravia, in the circle of Hraditch; 14 miles S.S.E. of Hraditch.

Strass, a town of Austria; 2 miles N.E. of Meinflau.

Strassau, a town of the archbishopric of Salzburg; 10 miles N.N.E. of Salzburg.

Strata, in Antic Geography, a country of Asia, in Syria, north of Palmyra, and near it.

Strata, in Geography, plural, (sing. stratum, Latin). A stratum properly denotes a bed or layer of stone, or mineral matter, the length and breadth of which greatly exceed the thickness. Geologists at present commonly use the plural term, strata, in a more limited sense when describing the structure of a rock or mountain: if it be formed of very thick masses of different kinds of stone, as lime-stone, slate, &c.; it is said to be composed of beds; and if any of these beds are divided into smaller layers, by seams running parallel with their upper and lower surface, the smaller layers are called strata, and the bed is said to be stratified. This distinction is merely made for the convenience of description, as we could not, with propriety, say a stratum was stratified.

Where a series of layers, or beds of different substances, as coal, sand-stone, and shale, cover each other, if the beds do not exceed a few yards in thickness, they are called strata; and the hill or mountain composed of such layers, is also said to have a stratified structure. The German geologists would restrict the term to homogeneous beds of rock which are subdivided into parallel layers; but for this limitation there does not appear any sufficient reason. Those hills or mountains which are composed of alternate parallel layers, or strata of different substances, are as truly stratified, as those which contain strata of one kind of stone only. The structure of the globe, as far as we are acquainted with it from the intertectures made by rivers, by the action of the sea upon the coast, and by mining operations, consists of a succession of beds of different kinds of stone, which generally increase in thickness as we descend deeper. The upper beds are commonly distinctly stratified; but in the lowest beds, all traces of stratification are generally lost; indeed their thickness is often so great, as to prevent our seeing the upper and under surface in any one place; and the seams or partings run in such various directions, as to preclude us from obtaining a knowledge of their structure. In various parts of the world, the lower beds appear to have been elevated and pulfed through the upper strata, forming lofty mountains and chains of mountains, on the summits of which the upper strata lie in an inclined position. And even at a considerable distance from large ranges of mountains, the strata rise in the direction towards them. On the eastern side of England the strata rise towards the mountains on the south-west, as we shall again have occasion to notice in describing the strata of England.
By the rise or inclination of the strata, and by the inequalities of the earth's surface, we obtain a knowledge of the nature and succession of the different beds to a far greater depth than it is possible to reach by sinking mines. Let us suppose a series of strata covering each other to the depth of two miles; if their position were horizontal, the lower strata would be inaccessible to our research, as few mines have been sunk to one-fourth of that depth; but if the whole series rises in one direction, the lower strata will come to the surface somewhere in that direction. See Plate II. Geology, fig. 1, where the letters a, b, c, d, e, represent different strata covering each other in an inclined position, and rising to the surface in succession, the lower stratum, e, forming the most elevated part of the series at f.

Stratification, in its simplest form, may be conceived, by placing a closed book with the back resting upon the table, and raising the opposite edges a little; the book may represent a thick mineral bed, and the leaves a series of strata. A line drawn from the upper edges to the back will be the dip of the strata, and its angle with the table the angle of inclination. Another line, drawn any where parallel to the back, and at right angles with the dip, will represent what is called the line of bearing, or level of a stratum. As every stratum rises to some part of the horizon, and dips to the opposite part, it is evident that the edge or top of such stratum, if unbroken, will come to the surface somewhere, and will be visible, if not hid by soil or loose materials subsequently thrown over it. (See Plate II. Geology, fig. 1. a, b, c, d, e.) The part of a stratum which rises to the surface, is called by miners its outcrop, or baffle; and this baffle or edge of a stratum, may not unfrequently be traced over a considerable district. Though stratification, in its more simple forms, may be easily conceived; yet in nature we frequently find the strata much broken, and thrown out of the original position by large fissures, filled with mineral matter of a different nature from the rock which they intersect. These fissures, called dykes or faults, throw down the strata on one side several hundred feet, or, what is the same thing, elevate them on the other side; and in such instances, a whole series of strata that may exist on one side of the fault, will be entirely wanting on the other side, and yet no trace of this disturbance may be visible on the surface. When a district is thus broken by faults, and intersected by valleys cutting the strata in different directions, it becomes exceedingly difficult to trace their true position, or to form a distinct notion of their arrangement from what appears on the surface. We shall explain some of the difficulties which oppose our knowledge of the true position of the strata. Let us suppose a section to be made by a river-courbe, or any other caufe, in a stratified mountain (Plate II. Geology, fig. 2.) if the section run parallel with the line of bearing of the strata, and no other part of the series be exposed to view at the station a, the strata will appear to be perfectly horizontal, and would be described as such by a superficial observer. Another section, made at right angles with the line of bearing, would show to the spectator placed at b, the true angle of inclination which the strata make with the horizontal level. Any intermediate section formed between the lines G and E, would give an inaccurate view of the true inclination of the strata; and as it can very rarely occur that the section is in the exact line of the dip, all descriptions of the inclination of strata, which have not been corrected by a series of observations, are liable to much error.

When the strata are bent or broken by faults, and an excavation is made by a river laying bare the baffle edges, the same stratum may be brought to the surface in various parts of its course, and with various apparent angles of inclination. Mr. Farey, in the 1st vol. of his Report of Derbyshire, has given a series of diagrams, representing a great variety of forms in which the strata may present themselves to the surface when intersected by faults. Thence the student of mineral geography would do well to consult, but they do not admit of abridgment.

Even where the strata are unbroken, and rise regularly, the inexperienced observer may not unfrequently mistake their true position. See Plate II. fig. 6, which represents the baffle edges or out-crops of the lower strata, rising from under the upper strata at see, and forming elevated ridges. If the surface is covered with soil or vegetation, the rock may be only visible in wet places, as at the quarry a below, and at the summit of the hill near f; if the stratum at a be of sandstone, for instance, and the rock at f granite, he may mistake the true position, and describe the granite as being incumbent on the sandstone. This is one of the errors which young geologists, as Saufure observes, most frequently commit.

The inclination of strata is seldom perfectly conformable to the curvature of the surface formed by hills and valleys, but is often in an opposite direction. (See Plate II. fig. 5.)

In this section, it may be observed that the stratum a forms a high ridge on one side of the valley, and forms also the summit of the hill on the opposite side. Incidences of this kind not unfrequently occur.

The strata sometimes take a waving course, rising with the surface of the hills on one side, and declining with them on the other. See Plate II. fig. 3.

Besides the regular rise of the strata in one particular direction, they have often small undulations and inequalities, owing to some cause which operated in their original formation. If they were now laid in an horizontal position, they would not be perfectly flat; but would present an undulating surface when viewed on a large scale.

Sometimes, instead of rising towards the summit of a hill, the strata are depressed towards the centre, forming a series of basin-shaped concavities, placed one within the other, as represented in Plate II. fig. 4, each stratum having the form of a shallow inverted cone or trough, the edges of which may be traced all round the mountain. The strata in the hill of St. Gilles, near Liege, are inclined in this position: the height of the hill is three thousand two hundred feet; it contains sixty-one beds of coal, alternating with other strata. The coal strata in various parts of England take a similar form.

In some situations, we find a series of strata lying in a position nearly horizontal, and covering beds or strata of a lower rock, which are considerably inclined, or which present great inequalities of surface, as represented in Plate II. fig. 7. The strata round Paris, which are supposed to be of fresh-water formation, rest in this manner upon the chalk. The latter rock, in various situations, is seen rising through the upper strata, as represented at a. Where a series of strata are level horizontally, other strata that are inclined, the upper are evidently of later formation, as the lower beds must have acquired their present angle of elevation before they were covered by horizontal strata.

Where a series of strata are nearly horizontal, and extend over a considerable district, intersected by deep valleys, the same stratum will make its appearance at nearly the same level in distant mountains. There is a striking instance of this in the vicinity of Pittsburgh, in Pennsylvania; a thick stratum of coal, we are informed, may be traced through many of the
the hills, at the same height above the valleys. (See Plate III. fig. 3.) a b c d represent the position of the coal stratum; in this situation, coal may be worked round the hills on all sides, by levels open to the day, and procured with little trouble. Owing to the horizontal position of the coal, it forms the bed of a river-course for several miles. Though these strata are nearly horizontal, they decline a little to the centre of the hills, as represented in Plate II. fig. 4. Hills in which the original continuity of the strata may be fo distinctly traced, by observing their identity on the opposite sides of valleys on the same level, serve as monuments to mark the progress of disintegration caused by rivers and torrents; for there is no doubt that these valleys have been excavated by the water-courses that flow through them.

Where the strata on opposite sides of a valley incline in different directions, some sudden disruption has in all probability opened a passage for the water, and aftiffed in the original formation of valleys.

In situations where regular parallel strata rise at a considerable angle of elevation, resting on unfretated elevated rocks (see Plate II. fig. 6.), it is reasonable to believe that the lower rock, c, has been forced up after the strata a b c were deposited, and that they were elevated with it.

The distribution of the spoil may appear to be of two kinds, the one in which the strata have been raised in a vertical direction, the other in which this vertical motion has been combined with a lateral motion, whereby they have been crushed, and in some instances folded over each other. The most common of these dislocations is the vertical one, as represented at fig. 8. Where a series of strata on one side of the fault have been elevated, or, what is the same, where the strata on the other side have been depressed; the corresponding strata on each side will flow the extent of the elevation or depression. Where the angle of inclination of the strata is greatly changed by a fault (as represented fig. 7), a lateral motion has been combined with the vertical one, or the pressure has been confined to particular parts of the strata. In some instances, a whole series of strata have been heaved out of their original position, and overturned, whereby the uppermost strata now occupy the lowest part of the series. In some instances, this heaving has been more entirely vertical, and declining to opposite parts of the horizon, their position nearly resembling that of the rocks of a flank spread open. A remark of this kind, in the Isle of Wight, will be subsequently noticed. Similar phenomena are noticed in the schistose mountains of Switzerland; but in those mountains, it may perhaps be regarded as the effect of crystallization on a grand scale, rather than an arrangement of strata, as these rocks are not regularly stratified.

Where the strata suddenly take a vertical position, or where they are broken in a zigzag form, as represented in Plate II. fig. 9. a b c d, we may infer that they have been compressed by a force acting in a horizontal direction, or laterally. In some of our coal mines, this zigzag position of the strata is occasionally observed; and at Akin, near Valenciennes, there is a remarkable instance of this derivation of the coal strata, nearly similar to fig. 9, in which the same letters represent the same strata as are shown on the opposite sides of the coal strata, nearly similar to fig. 9, in which the same letters represent the same strata as are shown on the opposite sides of the coal strata. The whole are covered with horizontal strata of chalk, marl, and clay, deposited at a subaqueous period.

That considerable portions of the earth's surface have not only been raised or depressed, but also moved in a horizontal direction, is made still more evident by the horizontal displacement of metallic and other veins. (See Varina, Metallic and Mineral.) Fig. 10. represents the general plan of a vein, a, running from west to east, until its continuity is broken by a river, or cleft course, which has thrown the vein several fathoms northward. Now it is obvious that the ground on one or both sides of the river course must have been carried north or south along with the vein. Nor are instances of such a lateral motion of the earth unfrequent during violent earthquakes.

The Extent of Strata.—That many of the strata extend over large tracts of country, is a fact sufficiently established by observation; but it appears to have been known but very recently. Among the miners in the coal districts it had indeed been observed, that the same beds of coal might frequently be traced to a considerable distance, until they came to the surface, and, in the miners' language, cropped out: but with respect to other strata of sandstone and lime-stone, etc., though a considerable similarity might be observed between the stone of different districts, it was not generally suspected that they were parts of one continuous stratum. The method of identifying a stratum by the fossils it contains, and by its connection with the upper and lower strata, is a discovery of the present age.

If each stratum preserved the same level where it rises to the surface, there would be no difficulty in tracing it in different districts; but from the curvatures and faults already explained, it frequently happens that a stratum, by its appearance, may be completely covered for many miles, and by some sudden break be brought to the surface again, at a much greater elevation, or may be found in sinking shafts in mines at a considerable depth. Before the means of identifying strata had been ascertained, it was impossible to obtain a knowledge of the mineral geography of an extensive district. Even with our present knowledge, it is frequently difficult to ascertain with precision the identity of strata in different countries, except those which are well characterized by fossils remains, or by some remarkable peculiarity of structure or composition.

The extent of strata is more limited in the line of their inclination, or dip, than in what is called the line of bearing, and would be still more contracted in that direction, were they not frequently thrown down by faults. We can make this more intelligible by referring to Plate III. fig. 2, which represents a section of the great stratum of argillaceous limestone called lias, which rises from the level of the sea, near Bridport, in Dorsetshire, and extends by Lyme to the river Aa, where it terminates: in this form, covered with a bed of green limestone, it is said, that a similar bed may be traced through France to the Pyrenees; but though the composition and external character are nearly the same, it may be proper to observe, that there is a considerable difference in the fossils of the English and French lias.

When the strata descend in the line of their dip or inclination, to what extent they may stretch under the surface in that direction is unknown, but in all probability they do not continue to descend very far at the same angle, but are bent in an opposite direction, and terminate at a distance more or less remote. The coal strata, as before described, often present this curvature; after descending to a certain depth, they
STRATA.

Of rife to the opposite point of the horizon, forming basin-shaped concavities, as represented in Plate II. fig. 4.

The upper strata above the coal formation are arranged in a similar manner in numerous instances; but as they are never excavated by mines, like the coal strata, their position has been little attended to, after their disappearance below the surface.

It is frequently observed, that in a series of contiguous strata, there is often that general semblance and connection, which implies a natural relation; hence such strata are classed together, and are described as one formation. "We may conceive one flab of stone to be composed of different laminae, which, though not exactly of the same nature, either with respect to colour, consistence, or substance, yet all contribute to the formation of the same flab; the individual characters of which are easily recognized by their united semblance." Geological Essay by Dr. Kidd.

Thus we may conceive the chalk formation to include beds that are not chalk, but which generally accompany it; and the same with respect to the formations of lias, sandstone, slate, &c.

The German geologists assert, that the principal rock formations are universal, meaning that the spread over the whole of the earth's surface, encircling it like the coat of an onion, and this universality they contend for, both in the lower unstratified, as well as the upper stratified rocks. This opinion does not appear warranted by facts; for though the lower beds of rock, such as granite, slate, &c., have a considerable sameness in different countries, yet there is often great diversity both in their nature and the order of their succession. And with respect to the upper stratified rocks, we believe that in no two different parts of the world which have yet been examined, do the same series regularly occur. According to the observations of Humboldt, chalk and roe-stone, which occupy a considerable space on the western side of Europe, are no where to be found in America. It is now admitted, that some series of strata are local formations, because no similar series have yet been found. On the same grounds, we might regard most of the upper stratified rocks, as local formations of greater or less extent.

All geologists are agreed, that our present continents were once covered with water. This is proved by the remains of marine animals imbedded in the strata which lie on the summits of the highest mountains. From these remains it is also evident, that the upper stratified rocks were deposited under water. Now whether the ocean retired, or the continents were raised from beneath, it is obvious that the sea must have filled the present valleys and lower parts of the continent, forming numerous lakes or inland seas; and we conceive it to be more probable, that different series of strata were deposited in each of these lakes, constituting what may be called local formations; and this will explain why we generally find different series of strata on the opposite sides of a chain of mountains. The order of succession of the different strata which are most nearly allied, and which may be regarded as constituting one formation, as well as the order of succession of the greater beds themselves, presents considerable diversity in different districts, though we do not where find the lower beds covering the upper formations. This will be better understood, by supposing a series of strata, 1, 2, 3, 4, 5, 6, 7, 8, &c., arranged as they are here numerically placed, No. 1 being the uppermost. We frequently find the strata 1 or 2, resting immediately upon the strata 7 or 8, and all the intervening strata, 3, 4, 5, 6, to be wanting; but we never find the lower strata, 7 or 8, resting upon 1 or 2, except in situations where the strata have been thrown down and overturned. Where any series of strata are wanting, a question naturally arises, have they been carried away by some sudden inundation, before the upper strata were deposited, or have they never extended to that place? In some instances, we are certain that the strata have been carried away from particular situations, as in some of the excavations which have formed valleys, in forming the strata that terminate on one side of the valley may be different from those on the opposite side; but it is exceedingly difficult to suppose, with some geologists, that the strata, which now cover but a small portion of the earth's surface, were once spread over it universally. We might ask, where have the materials been carried to and deposited? This difficulty will be removed, if we admit that each stratum has been formed in bafs or lakes of limited extent, though these bafs, in some instances perhaps, may not be less than the bafs of the present Mediterranean sea.

The subfusces of which the strata are principally composed, are argillaceous, calcareous, or siliceous earth, which are generally more or less intermixed or combined; but the calcareous and siliceous strata often contain the earths nearly pure. Siliceous earth is more abundant in the lower than in the upper strata. Argillaceous strata are often combined with saline and inflammable matter, and give rise to mineral springs. Calcareous or bituminous matter is more frequently combined with alumine or clay than with the other earths. Most of the soft argillaceous strata contain iron pyrites, from the decomposition of which, the waters springing from them are generally rendered more or less hot.

To this decomposition, and the heat which is evolved, some geologists attribute the increased temperature of warm springs. (See Temperature of the Earth and of Springs.) Others suppose volcanic fires to owe their origin to the same source. (See Volcanes.) We consider this cause as inadequate to the explanation of these awful phenomena; but it cannot be denied that we have numerous instances of pyritous strata taking fire when exposed to the air and moisture. The cliffs near Charnwood, in Dorsetshire, composed of beds of pyritous clay, took fire spontaneously at a guards in a hot dry season; they continued to emit flame at intervals for several years. Watfon's Chemical Essays, vol. i. p. 197.

A pyritous clay or shale near Whity, of a similar composition, sometimes takes fire spontaneously, when masses which fall from the cliff get moistened with sea-water.

To the partial decomposition of pyritous strata, which takes place when they are penetrated by mines and have access to air, we may ascribe the generation of carburetted hydrogen gas, that frequently occasions such tremendous explosions. See Ventilation of Mines; where we propose to give an account of the various methods that have lately been devised to prevent the fatal accidents from impure air.

Strata of clay being water-tight give rise to springs, as they arrest the water that percolates through porous strata, and convey it to other situations. The inclinations of the strata before described, with the breaks and inequalities, render the globe habitable, by distributing the waters over the surface; and a knowledge of stratification is absolutely necessary to conduct the operations of draining or watering extensive districts with success, and in the easiest manner. Hence Mr. Elkington gained such merited celebrity as a drainer. As the different strata which rise to the surface decompose, they form the materials of the soil, and according to the nature of the earths of which the strata are composed, the soils are more or less fruitful or fertile. Thus, a knowledge of the strata might frequently be of great use to
STRATA.

the agriculturalist, and enable him to combine the earth of one stratum with that of another in its vicinity, to ameliorate his soil, and ensure its permanent improvement. In the selection of stone for architecture, a knowledge of the composition of strata would also be of the greatest service. See Stone for Architecture.

Organic Remains in Strata.—We have before had occasion to notice, that the strata are to a great depth generally characterized by the remains of animals or vegetables, in what is called a petrified state, the organic structure being distinctly visible, although the animal or vegetable matter is almost entirely removed, and its place generally supplied by calcareous or siliceous earth. Since the attention of geologists and naturalists has been directed to the investigation of these organic remains, it has been discovered that few, if any, are perfectly similar to those species of animals or vegetables that resemble them in the most numerous species, and even genera of animals, are discovered in some of the strata, which no longer exist upon our planet.

The important discovery, that certain animal or vegetable remains are confined to particular beds, above or below which they are rarely if ever to be found, was first, we believe, made by Mr. William Smith of Mitford, near Bath, and has since been confirmed by the observations of Cuvier and other naturalists and geologists.

These organic remains are more abundant in the upper than the lower strata; and in the lowest beds of rock which have yet been examined, no traces of organic remains have been found. Hence such beds of rock are supposed to have been formed prior to the existence of organised beings, and have received the name of primary. We may however observe, that between those strata which abound in organic remains, other strata are frequently interjected, in which no such remains occur: hence we may infer, with some probability, that the processes, by which some of the strata were consolidated, have obliterated all traces of organic existence; and the mere absence of vegetable or animal remains in a stratum is not sufficient to prove that there was not an existence at the period when it was deposited. It is, however, remarkable, that the organic remains that occur in the lowest strata in which they have been observed, are those of shellfish and zoophytes; and it is only in the upper strata that we meet with the remains of animals possessing a more complex organisation; nor do we find the remains of viviparous land quadrupeds, except in the very uppermost strata.

These organic remains, intimated at various depths, inform us that the strata were deposited over each other at dissimilar intervals of time; and likewise that each stratum in which they occur, or under which they are found, was once the uppermost stratum of the globe: for it is obvious that the different animals, whose remains are imbedded in any stratum, must have had time to grow and perish, before another stratum was deposited upon it. The existence of different species in particular strata, proves that the materials of such strata were not brought there by any sudden inundation: for this would have mixed together indiscriminately the remains of vegetables or animals. It has been well remarked by Cuvier, that the existence of these organic remains, proves that the plants and animals lived in the sea, and formed there in succession: for, without them, we have not the least evidence that they were not contemporaneous formations.

By these organic remains in the different strata, we are also made acquainted with the great changes which must have taken place in the condition of our planet in remote ages. The uppermost stratum in England, and various parts of Europe, is formed of alluvial soil. In this soil the remains of quadrupeds of vast size, such as the elephant, the rhinoceros, the tapir, the mastodon, the elk, &c. are frequently found. Many of these are different from any existing species. These remains prove that dry land existed in the vicinity, and that Europe was then inhabited by species of animals at present unknown. Remains of vegetables are also found in alluvial soil; but in the calcareous rocks, on which the alluvial soil rests, we discover no remains of land animals or vegetables, but abundance of marine organic remains. At a still greater depth, in an argillaceous lime-stone called fossil, and in the beds of clay which accompany it, we meet with the bones of amphibious oviparous quadrupeds, such as the alligator, and with remains of unknown marine animals, different from those in the upper stratum; and also with a few vegetable remains. Under this stratum a series of strata occurs, composed of sand-stone, coal, &c. not less in some parts than one thousand yards in thickness: and throughout the whole of this series in England, not a vestige of animal existence can be traced, except one thin stratum containing muschel-shells; the remains in the other part of the series being exclusively vegetable.

Below this series of strata we meet with thick beds of lime-stone, in which no trace whatever of vegetable existence occurs; but we find again the remains of marine animals exclusively. These remains are generally less numerous as we descend lower; and in the lowest, beds of crystalline lime-stone are no longer discernible. That great and successive changes must have taken place in the condition of our planet, is proved by the succession of land animals, marine animals, and vegetables, at great depths under each other. The sagacious physiologist Cuvier, whose researches in comparative anatomy eminently qualified him for the investigation of these fossil remains, has given the following interesting statement of the general inferences to be drawn from them, relative to the former state of the world.

"The level parts of the earth, when penetrated to a very great depth, exhibit horizontal strata, composed of various subtilties, generally containing immeasurable marine productions. Similar strata, with the same organic remains, form the stratified hills to a great height. Sometimes the shells are so numerous, as to constitute the entire mass of the stratum; they are most frequently in such a perfect state of preservation, that even the smallest retain their most delicate parts, their sharpest ridges, and their finest and tenderest processes. They are found in elevations far above the level of the ocean, and in places where the sea could not be conveyed by any existing cause. They are not only included in loose sand, but are often imbedded in the hardest stones. Every country, every continent, every island of any size, exhibits the same phenomenon. We are, therefore, forcibly led to believe that the sea has, at one period, covered the present land: it must also have remained there for a long time, and been in a state of tranquillity; which circumstance was necessary for the formation of deposits so extensive, so thick, and containing exuviae so perfectly preserved. An accurate comparison of their contexture, and frequently even of their composition, cannot detect the slightest difference between the subtilty of these shells and the shells which still exist in the sea: they have, therefore, all come from the sea. Hence it is evident that the rains, or reversion, containing the sea, has undergone some change, either in extent or in situation, or in both. The traces of revolutions become still more apparent and decisive, when we approach nearer to the great chains of mountains. Many beds of shells are still found: some of these are even larger, and more solid. The shells are numerous, and perfectly preserved; but they are not of the same species with those which are found in the upper strata.
STRATA.

Strata. The lower strata, containing these organic remains, have various degrees of inclination, and are sometimes situated vertically. They form the ridges of secondary mountains, and do not rest upon the horizontal strata of the hills at their base, but, on the contrary, dip underneath them. When we dig through the horizontal strata, in the neighborhood of the inclined strata, the latter are invariably found below. Sometimes, when the inclined strata are not too much elevated, they are surmounted by horizontal strata; the inclined strata are, therefore, more ancient than the horizontal, and, in many instances, appear to have been raised into their inclined position before the horizontal strata were placed upon them. If we institute a more detailed comparison between the various strata, and those remains of animals which they contain, we shall soon discover full more numerous differences among them, indicating a proportional number of changes in their condition. The sea has not always deposited mineral strata of the same kind. It has observed a regular succession as to the nature of its deposits: the more ancient strata are more uniform and extensive; and the more recent are more limited, and more variation is observed in them at small distances. Thus the great catastrophes, which have produced revolutions in the basin of the sea, were preceded, accompanied, and followed, by changes in the nature of the fluid, and of the substrata which it held in solution; and when the surface of the sea came to be divided by an arched series of ridges of different changes took place in every separate basin. Amidst these changes, it must have been almost impossible for the same kind of animals to continue to live; nor did they do so, in fact. The species, and even their genera, change with the strata; and although the same species occasionally recur at small distances, the shells in the lower strata have forms peculiar to themselves: they gradually disappear, and are not seen at all in the upper strata, till les in the existing seas. In our present seas, indeed, we never discover their corresponding species, and even several of their genera are not to be found. On the contrary, the shells of the lower or more recent strata resemble, as it respects the genus, theof which still exist in the sea; and in the last formed and loofest of these strata, there are some species which the eye of the most expert naturalist cannot distinguish from those which at present inhabit the ocean.

"If we examine with greater care, we shall discover among the more recent strata, or those which are nearest the surface, some in which land animals are buried under heaps of marine productions. Thus, the various catastrophes of our planet have not only confined the different parts of our continent to rise by degrees from the basin of the sea; but it has also frequently happened, that lands which had been laid dry have been again covered by water; either in consequence of these lands sinking down below the level of the sea, or of the sea being raised above the level of the land. The particular portions of the earth also, which the sea has abandoned by its last retreat, had been laid dry once before, and had supported quadrupeds, birds, plants, and all kinds of terrestrial productions; it had subsequently been inundated by the sea, which has since retired, and left the land to be occupied by its present inhabitants. The changes which have taken place in the production of the shelly strata, have not, therefore, been entirely owing to a gradual and general retreat of the waters; but to successive irruptions and retreats, the final result of which however has been an universal depression of the level of the sea. Thence irruptions and retreats of the sea have neither been slow nor gradual: most of the catastrophes which have occasioned them have been sudden: this is proved with regard to the laft of them, the traces of which are most confpicious. In the northern regions it has left the carcasses of some large quadrupeds, which the ice had arrested, and which are preferred to the present day, with their skin, their hair, and their flesh. If they had not been frozen as soon as killed, they would quickly have been decomposed by putrefaction. The breaking to pieces and overturnings of the strata, which happened in former catastrophes, showed plainly that they were sudden and violent, like the laft; and the heaps of debris which are found in various places among solid strata, demonstrate the vast agitation excited in the mafs of waters. Life, therefore, has often been disturbed on the earth by dreadful catastrophes,—catastrophes which, in the commencement, have perhaps moved to a great depth the entire crust of the globe, but which have since ascended generally, and to a smaller depth. Numberless living beings were the victims of these catastrophes; some have been destroyed by sudden inundations, others have been laid dry in consequence of the bottom of the sea being instantaneously elevated; their races have even become extinct. The strata in every part of the globe bear the impress of these great and terrible events so distinctly, that they are visible to all who are qualified to read their history in the monuments they have left behind."

In one part of the work from which we have made the above extract, Cuvier speaks of "animal and vegetable productions which belong to the land and to fresh waters," as being found "in the midst of the most ancient secondary strata." This may be true with respect to vegetable remains, which are occasionally found in some kind of slate; but we do not recollect an instance, either cited by Cuvier himself, or by any geologist of reputation, nor has any instance come within our own observation, of the remains of land animals imbedded in the "most ancient strata," though they are sometimes found in caverns. The remains of amphibious animals occur in strata below the chalk, as the lasi, which may be considered as very ancient, compared with the surrounding chalk; but we have never heard of remains of land animals in the strata subjacent to the lasi, either in the sand-flone of the coal formation, or in the alpine lime-flone. Animal remains in the caverns of the alpine lime-flone may be of very recent date, as these caverns are sometimes closed by the deposition of stalactites. See Stalactite.

It is a fact particularly delerving of notice, that no human bones or works of art have been discovered in any of the strata, or even in the uppermost alluvial ground, containing the remains of quadrupeds most nearly resembling existing species. It is true that human bones and implements of industry have occasionally been met with at great depths in mining operations; but under circumstances which satisfactorily prove, that they had been left there when mines were formerly worked in the same situation. The absence of human remains appears to indicate, that man was one of the latest inhabitants of the globe, and agrees with the orders of creation described by Moses in the book of Genesis. Public curiosity was recently excited by a fossil human skeleton brought to this country from Guadaloupe. It is imbedded in a layer of calcareous flint, composed of smooth particles of shells and coral; but on enquiry, it is found that the rock, in which this skeleton with other human bones occur, is situated on the sea-coast, below the present high-water mark, and immediately under the volcano called the Soufrière. The bones contain a part of their animal matter, and all their phosphat of lime. On the shores of the Mediterranean, and particularly in the gulf of Meffia, heaps of loofe sand become conSolidated in a few years. We are not to be surprized, therefore, that in a volcanic island like Guadaloupe,
Guadalupe, subject to violent convulsions from earthquakes and impetuous hurricanes, that human bodies should occasionally be discovered which have been covered by sand, that has subsequently become indurated.

It is not a little remarkable, that a recent formation of minute shelly sand-floite, exactly similar to that of Guadaloupe, has since been discovered on the coast of Cornwall.

From St. Ives to near Padstow, the country has been overwhelmed with sand confining of comminuted shells: in many places it is drifted into hills of 50 feet elevation. Among the Arundel papers, there is mention of an extensive parish being partly buried under driving sands in the twelfth century. It is also known by oral tradition, that whole farms have been overwhelmed at a period not very remote; and at this very day, upon the shifting of the sands, the tops of houses may be occasionally seen. This loose sand, on various parts of the coast, is becoming indurated, and pausing into a compact rock. At New Haye its hardness is so considerable, that it requires a great force to break it; and it is generally employed for building and other useful purposes. According to a paper of Dr. Paris on this subject, read before the Royal Geological Society of Cornwall, the solidification is caused by the infiltration of water impregnated with the various materials of the decomposing slates through which it flows.

"Where a stream of water passes through the sand-floite, there the process of induration is more rapid. Although the iron forms but a small portion of the different foreign substances which analyze into the composition of the sand-floite, it is probably the principal cause of its induration, a very small quantity being sufficient for the purpose."

The Cornish sand-floite contains fragments of slate; but where these are wanting, it bears so striking a similarity to the sand-floite at Guadaloupe, in which human skeletons are found, that even with a lens no difference can be perceived.

**Strata, Formation of, or Stratification.** The description of the strata we have here given, refers to those rocks denominated secondary. All geologists are agreed, that these are generally distinctly stratified; but with respect to the stratification of the lower rocks, denominated primary, much diversity of opinion has prevailed. Some geologists have asserted, that granite is the most frequently stratified, and others deny the fact. The difference is, we believe, rather founded on theory, than on an accurate observation of nature. Those geologists who contend for the occasional stratification of granite, suppose that stratification necessarily implies the aqueous formation of the rocks in which it occurs; and as this mode of formation constitutes a leading character of the Neptunian System, (see System of Geology,) wherever they have found granite or other rocks intersected by seams nearly parallel, they have described them as stratified. Parallel seams alone are no decisive proof of the aqueous mode of formation, as rocks of undoubted volcanic origin are sometimes intersected by such seams.

Globular balls of granite and basalt are also intersected by concentric parallel seams, which cannot be called stratification, if we mean the term to imply a succession of deposits spread over each other by water. In all probability, these seams are formed either by horizontal prelur, or by an internal arrangement of the particles analogous to crystallization. Some geologists, desirous of extending the process of stratification to the lower rocks, have confidently asserted, that all rocks, of what is called primitive or clay-slats, are distinctly stratified, and that the flat cleavage is always in the direction of the strata. From an extensive examination of these rocks in various districts, we have no hesitation in asserting that the reverse of this is the fact, not a single instance having come under our observation, where the flat laminae of true roof-slats were parallel with the direction of the bed of strata itself, but generally make it in an angle of 50 or 60 degrees. We have seen flake-rocks, which for several miles presented the appearance of strata; tabular masses of considerable thickness, rising at an angle of 80°, which might have been described as regular strata; but on pursuing the same, we observed the vertical tables resting upon a bed of lime-flats not more than 20 yards in thickness, and inclined at an angle of about 50° upon a lower bed of horn-flats. The lime-flats were distinctly stratified, and contained the remains of encrinites in the middle stratum. See Plate III. Geology, fig. 4.

What were supposed to be strata, were here evidently the vertical seams in a very thick bed of slate, resting upon the lime-flats at a moderate angle of elevation. It not unfrequently happens, that vertical laminae of roof-slats rest upon a bed of slate nearly horizontal; and under the horizontal slab, the laminae of the slate will be nearly vertical, the same as in the upper slate; but in all strata-rocks, the upper and lower part must have the same inclination in the same place; and where the seams run in a different direction to that of the beds, we are certain that they are not what have been called strata seams, or regular partings of the strata, but rents or fissures, either the result of crystallization or of mechanical separation. The remarkable convolutions which some of the slate-rocks in Devonshire and in Scotland present, are not the bendings of regular strata; for if so, the upper and lower beds would have nearly the same form, whereas we often find these bendings only in one part of the rock.

To what cause this waved structure in rocks may be owing, whether to a crystalline arrangement, or to pressure during the original formation, or whether produced by the action of moisture and change of temperature, is uncertain. We know that rocks and flats, after exposure to the weather, often present marks of internal configuration, that were not discernible when they were first exposed. It may not, however, be improper to state, that we have seen a piece of the Devonshire slate, which as a fragment of a flake-rock whatever; but after it had been submitted to intense heat in a furnace, it acquired a regular schistose structure, and the laminae assumed the waved form so commonly seen in the slate-rocks of Devonshire.

The German geologists have denominated the parallel stratified rocks *flaite rocks* (see Rock); and though in nature there may frequently be observed a gradation from regularly stratified to unstratified rocks, yet the structure of the upper rocks differs so much from that of the lower, that we conceive it would be better to restrict the term stratification to the former, or the flat rocks, as it is only in them that we can trace regular parallel seams or partings to any considerable extent. The partings in granite and the lower rocks, though they may be regular for a small distance, generally intersect each other in different directions, or entirely disappear in the body of the rock.

In what manner the strata were formed and consolidated we are subject to inquiry involved in much uncertainty, as we can observe no processes precisely analogous to the present time. The data which we may safely assume to guide us in this subject are as follows: The strata are not arranged over each other according to the specific gravity of the substances of which they are composed, a stratum of heavy flint being frequently placed above one that is much lighter. Hence we may infer, that the materials of the strata were not
not mechanically suspended in the same fluid, if so, the heaviest would have sunk the first, and we should find the strata arranged in the order of their respective density or weight. Neither can any regular gradation be traced in the crystalline texture of the strata; though viewed on a large scale, the lower strata may be described as being more crystalline than the upper; yet we may frequently observe a stratum, perfectly crystallized, placed both over and below other strata, in which no trace of crystallization is perceptible; hence we may also infer, that the materials of the strata were not all in a state of chemical solution at the same time. From the appearance of different organic remains over each other, we may further infer, that the strata were formed in succession at different intervals of time.

These are the principal data that we can at present safely asume. The disciples of Wares contend, that we are warranted by existing phenomena in concluding that the materials of rocks and strata were held in solution in a fluid which once covered the highest parts of the globe; that the lower beds of rock were chemically deposited in a crystalline state; that as the water retired it became agitated; and contained an intermixture of the fragments of pre-existing rocks, and thus the succeeding beds were formed partly of chemical and partly of mechanical deposits; that at this period the lower orders of marine animals were first created. As the waters retired still lower, they became more turbid, and contained a larger portion of fragments mechanically suspended, and thus the upper strata were principally mechanical depositions. Against this hypothesis, the objections which may be urged appear insurmountable. We know of no fluid which could hold all the different materials in solution of which rocks and strata are formed; and if such a fluid could be supposed to exist, it must have covered the earth to an incalculable depth, and it may be asked where has it retorted to? Nor can we conceive that a fluid holding such an immense quantity of heterogeneous materials in solution, could at the same time support animal life.

-Other geologists suppose, with Dr. Hutton, that our present rocks and strata have been formed from a pre-existing world.

By the decomposing effects of the elements, and the agency of floods and torrents, the materials of former mountains and continents have been broken down and carried into the seas, where they subside, forming different beds and strata. These have been subequently consolidated by the operation of a central fire, which they suppoese to exist countless in the earth, and to have periods of greater or less activity, determined by causes with which we are unacquainted. By the operation of this fire, the lower beds were fused under great compression, and subsequently crystallized; and by its expansive power, these beds were in many parts raised from the depths of the ocean, piercing through the upper strata, and forming the lofty mountains of our present continents. According as the strata were more or less distant from the central fire, they were more or less acted upon, and hence we find in general that the upper strata are less crystalline than the lower.

They further suppose that a similar process is taking place at present, and that the heaviest rocks are constantly wearing down, though their diminution be less perceptible than that of softer and less elevated strata; and that these fragments, in the form of sand, mud, or loose stones, are carried down by rivers and floods, and spread over the bottom of the seas, forming the materials of future strata, to replace the present, which are supposed to be in a state of confinant decay.

It is difficult to conceive how the different substances of which the strata are composed, could by this process be so distinctly separated as we frequently find them, particularly beds of coal, sandstone, clay, and shale. In the coal strata, we find many delicate vegetable productions, with the form perfectly preserved; and in the upper calcareous strata, we frequently meet with shells, having the most delicate spines, in a perfect state, which could scarcely be the case, had the strata been originally the fragments of rocks, carried by rivers and floods into the ocean. It has before been observed, that the strata are not arranged according to the specific gravity of their component parts; the heaviest stones are not the lowest; nor in a series of strata do we find the upper always less perfectly crystalline than the lower. That some of the lower rock formations have been fused and crystallized by the agency of fire, and that the same cause has broken the crust of the globe, and deformed or removed the upper strata by which they were covered, is rendered probable by present appearances in various parts of the world; but we think that the latter theory does not explain in a satisfactory manner the formation of the upper strata of rocks.

A celebrated modern mineralogist, M. Patrin, has attempted to revive the notions of Kepler, that the globe is a living body, and contains a circulating vital fluid. He goes still further, and asserts that a process of assimilation is carried on in it, the same as in animated bodies. It possesses instinct and volition even to the most elementary molecules, which attract and repel each other, according to sympathies and antipathies.

Each kind of mineral substance is capable of converting immense masses of matter into its own peculiar nature. The mountains are the respiratory organs of the globe, and the rivers its organs of secretion.

By the latter, it decomposes the water of the sea to produce volcanic eruptions. The veins in strata are canals or absefices in the mineral kingdom.

M. Patrin has supported this singular theory with much ingenuity, in various articles in the "Nouveau Dictionnaire de Géologie Naturelle." That part which relates to the vitality of the earth will probably gain but few profetlites; yet we do not consider it irrational to suppose that the earth may be the great laboratory in which the minerals on its surface were prepared. That the internal parts of our planet are not inert, is proved by the numerous active and extinct volcanoes, many of which appear to have been connected. See VOLCANO.

The variation of the magnetic needle may probably be owing to processes that take place within the earth.

Mr. Bakewell, in the second edition of his Introduction to Geology, supposes that the materials which form most of the strata, were originally dissolved or suspended in a fluid which has been thrown out of the numerous extinct volcanoes scattered over the globe. Their mouths or craters are of immense size; the crater of the ancient volcano of Teneriffe occupies ten square leagues; and the observations of numerous travellers confirm the assertion of Humboldt, that there is no active volcanic crater at all to be compared in size with those that are extinct: it cannot be doubted that the quantity of matter ejected was proportionate to the mighty openings through which it was thrown out. The only inferences we have of actual rock formations, are volcanic; beds and strata more than thirty miles in length, and of considerable breadth and thicknessi, have been spread over the surface of the globe in our own times; and according to M. Humboldt, the farther back we trace these eruptions, the greater is the similarity between the masses of lava, and
STRATA.

those rocks which are considered by geologists as the most ancient.

"The enormous ancient volcanoes whose craters are many leagues in extent, had doubtless an important office to perform in nature; and it is unreasonably to believe, that the earth itself is the great laboratory and storeroom, where the materials that form its surface were prepared, and from whence they were thrown out, in an enormous, aqueous, or gelatinous state, either as melted lava, or in solution, or mechanically mixed with water in the form of mud, or in the comminuted state of powder or fand. The largest active volcanoes in South America, throw out earth intermixed with water in the state of mud, which hardens and forms the earth. The vaft fissures or rents that interfet the different rocks, may also have served for the passage of subterraneous matter rising to the surface. These are generally filled with fluids, which earth constitutes two-thirds of the crust of the globe. Calcareous or crataceous matter has also been ejected during aqueous eruptions in Sicily. Beds of lime-stone may have been formed by similar eruptions. Nor is it necessary to suppose that these aqueous eruptions were always sudden, and attended with violent convulsions; for when a passage was once opened, they may have riven slowly, and been diffused in a tranquil state; and by gradual condenfation, may have enveloped the most delicate animals or vegetables, without injuring their external forms. Long intervals of repose between these great eruptions may have allowed time for the growth and decay of animals, whose remains are found in different strata; whilst the formation of other strata may have taken place under circumstances incompatible with organic existence. The sucession of aqueous and igneous eruptions, would account for the alternation of volcanic rocks with strata of aquatic formation; and thus the two theories of Werner and Hutton may both be true to a certain extent, and agree with existing facts. However vast these operations may appear, they link into insignificance, when compared with the bulk of our planet itself. If a three-feet globe were to contain within it a fluid capable of acquiring solidity by exposure to the air, and were this fluid from time to time to exude through minute cracks or punctures, and form over different parts of the surface succedaneous coats of varnish, whose aggregate thickness was less than that of a wafer, this would be a greater change with respect to the artificial globe, than the formation of all the rocks and strata with respect to the earth; and the numerous dislocations and fractures, by subidence or other causes, are no more, in comparison to the magnitude of the earth, than the cracks or inequalities of this superficial varnish would be to a globe of that diameter."

That various agents have operated in the formation of strata and the lower rocks, is, we think, proved by the appearances they present. This is now acknowledged by some of the leading supporters of the Wernerian school of geology, who formerly contended for the aqueous formation of rocks. Professor Jameson, in a paper published in the second volume of Transactions of the Wernerian Society of Edinburgh, considers stratification as the result of a crystalline process, and the strata as forming the natural cleavage or folia of the globe, which he supposes may be a large polygonal crystal; and the angles of inclination which the strata make on a great scale, may form the planes or sides of the crystal. According to this theory, the strata are contemporaneous. The organic remains of different species of animals over each other prove, however, as has been before observed, that such strata were formed in succession at different intervals of time; and every theory which excludes time as one of its elements, must be obviously defective. That the structure of the lower rocks is the result of crystallization, and that they may have had a contemporaneous formation, has been maintained by other geologists. Though the strata containing organic remains must have been placed over each other in succession, yet their present order or conformation may according to the theory of Dr. Hutton, have been produced by the action of forces at a subsequent period, previously to which, they might form beds of sand, marle, or mud. The conformation, both of the upper and lower strata, may thus have been contemporaneous. See System of Geology.

The effects of great and long continued pressure have not, we think, been sufficiently attended to in the speculations of geologists; perhaps, also, many inexplicable processes in the mine kingdom may be effected by the electro-chemical action of the different strata themselves forming an immense natural voltaic pile.

STRATA of England. Little was known of the strata of England before the present century, nor will this appear surprising, when we consider how recently geology has been cultivated as a science. Some knowledge of stratification was essential to guide mining operations, particularly in the coal districts; and much local information existed among practical miners in different parts of England, but it was intermixed with many absurd or erroneous opinions; and whatever might be its value, it was generally lost with its proctor. So early as the year 1684, an incorrect attempt was made by Mr. Lillier to direct the attention of the public to this subject, and he suggested the plan of a coloured map of England, representing, by different colours, the characters of the rocks. "I am of opinion," he says, "that certain upper foils, if natural, infallibly produce certain minerals, and for the most part in a certain order." Phil. Tran. 1684.

This was an important step in the science of geology, had it been properly followed; for it is now ascertained, that the nature of the soil depends upon the quality of the strata which lie nearest the surface in each district.

Another gentleman, of the name of Mitchell, in a paper of the Phil. Tran. 1722, in describing the sand-beds near Woburn, in Bedfordshire, in which the fuller's-earth is dug, expresses his belief that the sand beds extend into Buckinghamshire and Oxfordshire, from appearances which he notices in the different counties. "This," he adds, "confirms what has been said of the regular disposition of the earth into strata, or layers of matter, commonly through vast tracts, and from whence I make a question, whether fuller's-earth may not probably be found in other parts of the same ridge of sand-hills, among other like matter." Here we have the suggestion of a valuable fact, since fully confirmed,—that certain minerals are peculiar to certain strata,—and where we discover the same stratum in a different district, there is rational ground for expecting the recurrence of the same minerals which it was known to contain elsewhere. In a practical view, this is the most valuable part of the science of geology: it does not appear, however, that the suggestion of Mr. Mitchell was attended to at the time. About forty years afterwards, the Rev. J. Mitchell, of Thornhill, near Wakefield in Yorkshire, published a valuable paper on earthquakes in the Phil. Tran. 1759, from which it appears that he had a correct notion of the general structure of the earth's surface, (so far as relates to the upper stratified rocks), derived probably from the observations of the coal-miners in his vicinity; but he made no attempt to elucidate the geology of England from his own observations.

Mr.
STRATA.

Mr. J. Whitehurst was the first person in England who described the geology of an extensive district from actual examination. His "Inquiry into the original State and Formation of the Earth," contains a valuable account of the stratification of Derbyshire, from the coal strata to the lower mountain limestone, illustrated by numerous sections. Whatever may be thought of his speculative opinions, the work remains a monument of the author's industry and ability. He had the merit of first pointing out the manner in which geological examinations should be conducted, before the name of Werner was known either in this country, or on the continent.

Mr. J. Williams, a native of Wales, and a practical miner, published a work, entitled "The Natural History of the Mineral Kingdom," about the year 1780. The treatise contains considerable information respecting the coal strata, at that time little known.

Some short account of the geology and mineralogy of particular counties has since appeared, particularly Mr. Keir's description of the coal districts in Staffordshire, published in Dr. Plott's Staffordshire, and Dr. Townson's account of Shropshire.

Some mineralogical facts occasionally occur in the Reports of the Agricultural Society; but, in general, the mineralogy of the English counties, as given in these Reports, is exceedingly imperfect, and scarcely any notice is taken of the geology. From this remark there are some striking exceptions, particularly the report of Derbyshire, by Mr. J. Farley, and that of Cheshire, by Dr. Holland. The latter gives an excellent description of the slate district.

Mr. Farley has taken a wider range, and besides adding much information to what Mr. Whitehurst had given on the geology of Derbyshire, has extended his observations into the neighbouring counties, accompanied with an original and valuable geological map of the county of Derby, and the parts adjacent.

Some papers on the geology of particular parts of England, have appeared in the Transactions of the Geological Society of London. The first map containing an outline of the geology of England, was, we believe, published by Mr. Bakewell in 1813, accompanied with a description of the more important features of the mineral geography of South Britain. He divides England and Wales into three districts: the alpine district ranging along the western side, the low district on the eastern side, and the middle district lying between the alpine and the low districts.

As the rocks and minerals in each of these districts, when viewed on a large scale, differ sufficiently to warrant this division, we shall, for the sake of perspicuity, adopt it in our description of the strata of England.

The low district of England is marked on the map by a line which extends from the south-west of Dorsetshire in a waving direction to near Bath, and from thence a little east of Leicester and Nottingham, towards Doncaster and Tadcaster, and passing north of York, terminates near Scarborough. All that part of England to the eastward of this line is particularly characterized by the absence of any regular beds of coal, or metallic veins. This district is principally covered by thick beds of sand, clay, and gravel, chalk, roe-limestone, calcareous sandstone, and argillaceous or magnesian limestone. Few of the hills rise more than seven hundred feet above the level of the sea. Chalk may be considered as the prevailing rock, particularly on the eastern side of this district.

The stratification is more regular on the eastern than on the western side, and the general rife of the strata is to the south-west, at a small angle of elevation.

The beds in this district may be classed under four principal formations.

1. Beds covering chalk, consisting of alluvial soil, gravel, sand, and clay.

2. Chalk; consisting of soft chalk, hard chalk, and chalk-marl.

3. Green and red sand-beds, with roe-limestone or oolite. An argillaceous limestone, called lias. In the northern counties, magnesian limestone occupies the place of lias.

The three latter are separated in many places by beds of clay or sand of considerable thickness, and by occasional strata of lime-limestone. The alluvial soil, gravel, sand, and clay that cover the chalk strata, are the uppermost in the series of English strata, but they do not occur regularly. Some of them are considered as local fresh-water formations. The beds of gravel are frequently of considerable extent and depth, and consist of rounded siliceous pebbles, principally flint and chert, but sometimes containing also pebbles of Jasper, cornelian, imperfect agate, and chalcedony. The flint and chert pebbles have, in all probability, been derived from the chalk formation; and those who have observed the transition of flint and chert into perfect chalcedony, in the green sand covering the hills near Sidmouth, in Devonshire, will not think it necessary to seek for another origin for the chalcedony or agate found in the gravel-beds on the eastern side of England. The processes of siliceous infiltration appears to be going on at the present day, though we are unacquainted with the means by which it is effected. In the channels of gravel are found aggregations of siliceous nodules in a siliceous paste, forming a pudding-limestone of a compact texture, that a fracture will often take place with as much ease through the nodule, as through the substance in which it is enveloped. Some of these nodules are marked with impressions of marine animals, and are supposed to be casts. Petrified bones and large shells are sometimes found in the gravel, but generally in a mutilated state; they belong principally to the chalk and under strata, out of which they have probably been washed. Thin beds of gravel, intermixed with flinty loam and calcareous marl, form the upper covering in some parts of this district, particularly on the vale of Thames. They are remarkable for containing the remains of large quadrupeds, as the elk, the stag, the hippopotamus, and elephant.

A large collection of these bones was recently discovered in the grounds of Mr. Trimmer at New Brentford. The foils consisting of sandy loam, in which were no fossils; secondly, sandy gravel, containing small shells, and a few mutilated bones of land animals; thirdly, calcareous loam, in which were found the horns and bones of the ox and deer, with river-shells; forthwith, patches of peat earth, which contained the bones and teeth of elephants, resembling those both of the African and Asiatic elephant, with bones of the ox and teeth of the hippopotamus; fifthly, a watery gravel, resting on London clay. The latter contained wood penetrated by the teredo, with nautilus and other fossils, exclusively of marine origin. Phil. Trans. 1813. See Petrifications.

The beds immediately covering the London clay, though of recent date compared with the lower strata, were deposited under a very different condition of the globe from the present, when England and the continent of Europe were inhabited by animals no longer existing in these latitudes, and of which some of the species are every where extinct. The London clay, sometimes called the blue clay, is the bed on which the city of London stands; it is of very considerable thickness, varying from three to five hundred feet. It consists of tough blue and reddish clay, intermixed with sandy clay and sand. It abounds with beautiful fossils in particular
STRATA.

ticular parts of the bed: among these, the most remarkable are nautili in high preservation, fossil crabs, with teeth and bones of fishes; but it does not contain ammonites, encrinites, or belemnites. Iron pyrites, felonite, fulphate of iron, and phosphohate of iron, are contained in the London clay; and also radiated sulphate of barytes, and sulphate of magnesia. The Highgate archway was cut through this bed.

The septaria or balls of which Parker's cement is made, are found in various parts of the London clay, and were supposed to be peculiar to it; but similar balls of argillaceous lime-foam, divided by seams of calcareous spar, occur also in other strata, and are equally useful for the preparation of cement. Many wells have been sunk in this bed of clay to a great depth. The water in the upper part of the bed is invariably impure, but on arriving at the sand under the blue clay, it commonly springs up in great abundance, and is extremely soft and pure. In many of the manufactories in the metropolis this water is now used, being purer than the Thames water.

Since the discovery, at Paris, of a local formation of marine strata, alternating with other strata supposed to be formed under fresh water, the fossils in the London clay have been examined with more attention, and are found to resemble those of the lower marine strata round Paris. The basin in which the London clay is deposited over the chalk, extends from the vale of Thames to the north-east, over the counties of Middlesex, Essex, Suffolk, and also Yarmouth. A similar bed of clay covers the chalk in the Isle of Wight, and on the south coast from near Poole in Dorsetshire, to Brighthelmstone in Sussex, extending several miles inland. In some parts of the Isle of Wight, this clay is covered with a regular series of strata, of limited extent, which do not occur in any part of England, but which nearly resemble the remarkable strata round Paris. We shall give a concise description of these at the close of this article, before the account of the Paris strata.

A bed of sand, of very variable thickness, is generally interposed between the London clay and the chalk. A stratum of silicious sand-foam, called grey wheatere, frequently occurs in this sand. The beds here described have but lately attracted the attention of geologists; being claffed with alluvial soils, they were supposed to be of very recent origin. In the Wealden system, chalk is described as the most recent formation of lime-foam, and every thing over it was scarcely deemed deserving of notice. Even of the chalk strata, and the various beds which occur between chalk and the sandstone formation, covering coal, very little was generally known before Mr. John Farey gave a short description of the upper series of the British strata, in the first volume of his Agricultural Report of Derbyshire.

Mr. Farey stated that he had derived much information from Mr. William Smith of Mitford, near Bath, where a map of the strata of England has recently been published. We shall subjoin Mr. Farey's description, beginning with the chalk on which the London clay and sand rest; to which we shall add some observations, to elucidate more fully the arrangement of the strata on the eastern side of England. Those who are deficient in tracing the course and extent of the strata minutely, we recommend to consult Mr. Smith's map before referred to. That part of it which comprises the eastern and midland counties is more particularly deserving a careful examination.

"The upper or siltish chalk is a thick stratum of soft or free chalk, with numerous layers of flint nodules, and great variety of echini and other organisied remains. The extremities of this stratum are to be found with us in the Isle of Wight, in Hampshire, and at Flamborough-Head, in Yorkshire.

"The lower or hard chalk is without flints; its beds increase in hardness near the bottom, where a white freestone is dug, as at Trottohine in Bedfordshire, and numerous other places; that brought from near Ryegate, and now revered as a stone on this stratum fouth of London, is used as a fire-stone.

"The chalk marl next succeeds, which varies much in its appearance, sometimes resembling chalk when first exposed, in other places appearing as a blue clay.

"The Aylesbury lime-foam strata, with green sand-beds, are remarkable for their large cornea ammonites, numerous horse-head muscles, entrochi, and other shells, glosopetrae, &c. Sand strata succeed, and several clays, which have no very decided character, except one of them, which contains a thin bed of dark-coloured lime-foam, almost entirely composed of small turbinated shells, called Suffolke marble, of which the slender pillars in Westminter Abbey, and most of our cathedrals, are made.

"The next characteristic stratum, owing to its forming a ridge through the country, is the Woburn sand, a thick ferruginous stratum, which, below its middle contains a stratum of fuller's-earth: this is the thickest and most pure in Aylesbury and at Hogfity-End, ten miles north-west of Woburn. The upper part of this sand is frequently cemented by the oxidized iron into car-foam, and the lower part contains fragments of filicified wood. The chalk-clay succeeds. It is generally blue, inclining to black, and is of great thickness. It has towards its top several beds of chunch, a soft chalk-like stone in appearance, whence the name. Numerous large gryphites, and small pointed belemnites, cornea ammonites, &c. are found above the chunch. The lower part frequently contains beds of bituminous slate or clay. The vale of Bedford, the fens of Cambridgeshire, Lincolnshire, and Yorkshire, are almost entirely situated upon the great plains formed by the gradual endings of the chalk-clay out of this stratum. The Bedfordshire lime-foam succeeds; it has blue clay-beds interposed, and abounds with small gryphites, and other shells. Buckingham, Stony-Stratford, Newport-Pagnel, and Bedford, stand upon this stratum.

"A thick clay succeeds, and then the rag-foam of Barnack, composed almost entirely of minute shells. It is so called, because stones were dug from hence for many of the most ancient and best-preferred churches and buildings in the eastern counties.

"The lime-foam and grey slate strata of Stonefield, Colly-Weiton, and numerous other places, next succeed; they abound with glosopetrae, and other organic remains. Below is a stratum of sand.

"The Bath free-foam strata form a most characteristic range through England, from Dorsetshire to the Humber in Yorkshire. Stamford, Ancaster, and Lincoln, are upon this stratum. The upper part is generally a white or light grey lime-foam; then the oviiformed lime-foam, or oolite of Bath, Ketton, &c. succeeds, below which is a great thickness of light yellow free-foam, which abounds with curious shells and fossils. Below this, sand with beds of clay occurs; and then the free-foam of so many hues of yellow and red, which is dug near Northampton, and numerous other places in this range.

"A great number of beds of sand and clay succeed, which admit of no precise description in a general account.

"Lias, clay, and lime-foam. This bed is of considerable thickness, forming generally a light-yellow tenacious surface; cold, and much disposed to hills, when laid down in
STRATA.

in pasture. Thin flint of lime-flint, called blue lias, occur with the clay; some of these make a lime which is superior to any other that is known for sluces, locks, and other water-works, on account of its property of letting almost immediately, even under sea-water, and continuing to harden.

"Watchet and Aberhaf, on opposite sides of the Bristol channel, Southam in Warwickshire, and Barrow on Soar in Leicestershire, are particularly famed for this lime. The blue lias is remarkable, owing to the pentacrinos, the bones, scaly fish, and other fossils it produces; it remains throughout all the whole extent. It has perhaps the best marked and most important geological characters of any flint in the British series.

"In the lower part of the lias, a succession of other lime-flint flintas often occur, called white lias. The lias does not exist in one continuous range north of the Humber, though detached portions of it occasionally occur." The lias is many of the southern counties rests upon red marl or sand-flint.

We are not to conclude that all the different beds described by Mr. Farey, constantly occur under each other on the eastern side of England. In some places, many of the beds are entirely wanting; thus, in some parts of Dorsetshire, the green sand, which forms the under flint of chalk, rests immediately upon the lias, as in the vicinity of Lyme; and all the different beds of red-flint and sand-flint, are wanting. Further west in Devonshire, the same sand, with its various fossils, may be seen resting on the red marl.

This will be better understood by referring to Plate II. Geology, fig. 1, and Plate III. fig. 2. In Plate II. fig. 1, a is supposed to represent the chalk, b the green sand, c the oolite, d the lias, and e the red marl, arranged in the order in which they occur over each other, where all these formations exist; but in some situations, the flint, b, of green sand extends beyond the flint c, and covers a part of d and e. In Plate III. fig. 2, we have represented the arrangement of the strata, as they occur from the east of Bridport in Dorsetshire, to near Sidmouth in Devonshire. The green sand, b, may be seen rising from the sea; east of Bridport it is soon succeeded by the dark clay, and lias d d d, on which it rests. This flint extends beyond Lyme to the mouth of the river Axe, where it terminates at M. A little to the west of Lyme, L, the green sand is covered by chalk-rocks of limited extent, e, at Penhay. The lias which rises to the south-west is broken by numerous small faults, and is thus continued along the coast for several miles. Beyond the river Axe, at M, the flint appears to have been thrown down considerably, and another mass of chalk is brought to the level of the sea at Beer, a a, where it forms fantastic cliffs, perched with caverns. West of the village of Beer, the green sand covers the hills of red marl, without the intervention of the lias. Patches of the same bed of sand are seen resting upon the summits of some of the hills west of Exeter, covering the fame red marl, particularly on the summit of Haldon-hill; thus a formation nearly allied to the chalk is brought almost in contact with the granite of Dartmoor.

The thickness of the different formations varies considerably in different parts of their extent.

The Rev. J. Townsend, in a work entitled "The Character of Mofs indicated as an Historian," has given the result of his inquiries respecting the thicknesses of the flint from the chalk on the south coast to the coal districts of Somersetshire. The difficulty of meeting with good sections of the flint uncovered, and the varying thicknesses of each, make such calculations uncertain. They may, however, deference notice as approximations to truth.

The following is a condensed statement of his measurements.

On this statement, Mr. Bakewell, in his Introduction to Geology, observes, that "the chalk in some situations is nearly one thousand feet in thickness, and the flint which cover it in the Isle of Wight more than fourteen hundred feet. If, therefore, we add one thousand feet to the above estimate for the London clay-chalk, and minor flint which have been omitted, this would make the depth of the flint in the vale of Thames to the flint containing coal, about one thousand yards. If we suppose the lower flint accompanying coal to extend regularly under calcareous sand-flint and chalk-rocks, it would be an interesting inquiry to determine the accuracy of this statement; and when the coal fields in the north are exhausted, it may become an object of public concern. Nor would the expense for various complete trials in different situations exceed that of the present national expenditure for one week."

In the succession of flintas, the lower formations rise west of each other, and it is only where they are uncovered by the upper formations that they are visible.

The flint of the low district appears to have been formed subfequently to most of the great convulsions that have broken the lower flintas, and we know where meet with those dykes or veins of bafalt which intersect and disturb the flint of the coal formation. There is, however, one instance of a disturbance of the flintas above and below the chalk, as remarkable as any which occur in the lower stratified rocks. It may be seen at Alum bay, in the Isle of Wight, and has been described by Mr. Webber in the second volume of "Transact. of the Geological Society of London." The chalk and the clay incumbent upon it pass under the channel, called the Solent, from Hampshire, and rife in the middle of the lound, forming a range of hills, which extends from Culver Cliffs on the east, to the Needles on the west. The chalk flintas are here nine hundred and eighty-seven feet in thickness, the flintas above the chalk fourteen hundred and eighty-one feet; these, with about six hundred feet of lower flintas, are all thrown out of their original position, which was nearly horizontal, and are now almost vertical. That they were once nearly horizontal, may be proved by their occurring in that position a little further south, but still more satisfactorily by the flints found in one of the vertical beds of loose sand, of which there are several layers extending from the bottom to the top of the cliff. The flints have been rounded by attrition, are from an inch to eight inches in diameter, and appear to belong to the chalk. "Now it is inconceivable (says Mr. Webber) that these flints could have been originally deposited in their present position; they distinctly point out the former horizontal direction of the series; there are no signs of particular disturbance in these beds; the whole series appears, therefore, to have been moved together." The enormous force required to upheave such a mass of flintas not only through the Isle of Wight, but in Dorsetshire, must have been
STRATA.

been sufficient to change the surface of the country, to form or destroy extensive lakes, and perhaps to separate England from the continent. The effects of this convulsion may be traced beyond Litworth in Dorset. This singular displacement of the upper strata is represented in Plate III. Geology, fig. 5, and will be further described at the close of the present paper.

The district described as the middle district, containing, in various parts, rock-salt, iron-stone, and coal, extends from the line above described, to the mountains on the western side of England, called by Mr. Bakewell the Alpine district, which ranges from Cumberland to Devonshire. The western boundary of the middle district cannot be so well defined as that of the low district, owing to the numerous branches from the mountains on the west, which in some parts extend into it.

The strata in the middle district are principally composed of argillaceous sand-rove, siliceous sand-rove, and shale, with beds of coal and iron-rove. In the northern and midland counties, the lowest stratum of this district is a coarse quartzose sand-rove, sometimes resting on a thick bed of argillaceous sand-rove. Few metallic veins occur in any of these strata; none of the hills rise higher than 1500 feet above the level of the sea, the highest part being the eastern moorlands of Yorkshire, formed of beds of aluminous schists, covered by a coarse sand-rove. The succession of strata in the middle district is more various than in the low district. The line in the southern counties, and the magnesian lime-rove in the northern, form the eastern boundary. The metalliciferous or mountain lime-rove forms the under stratum on the west from Northumberland to South Wales and Somersetshire. In Devonshire, almost all the strata of the middle district are wanting, and the red marl or sand-rove fills up the space from the line to the clay-rove, which rests immediately on granite. The red marl is in many parts of that county covered with the green sand of the chalk formation, very near to the granite, as at Haldon, west of Exeter.

The strata of the middle district are in some parts broken by the lower rocks of the alpine district which rise through them, as at Charnwood Forest, in Leicestershire, where a range of hills, composed of slate, schist, and porphyry, extends for about ten miles in a south-east and north-west direction, and is bounded on the eastern side by the line of the Charnwood Forest hills represent those of North Wales and Cumberland in miniature. Rocks of a similar formation range to the westward, through Warwickshire into Shropshire and Wales, though they scarcely appear above the surface. In rocks of this formation near Atherstone, beds of manganese have recently been discovered.

The mountain lime-rove of the alpine district forms hills of considerable elevation in the north of Derbyshire. It is intermixed with beds of a basaltic amygdaloid, provincially called toad-stone. The latter are by many geologists supposed to be of volcanic origin, and have a considerable resemblance to lava. In other parts of the middle district, the strata may be traced rising regularly to the south-west, from the line or magnesian lime-rove to the alpine district. An estimate of their total thickness has been taken in Derbyshire, from the magnesian lime-rove on the east, to the fourth bed of mountain lime-rove, from which it appears, that the total depth taken on a level line is 1510 yards. In the whole of this range there are 30 different beds of coal, varying in thicknesses from 6 inches to 11 feet, the total thickness of the coal being 20 yards.

Vol. XXXIV.

A similar admeasurement had been taken of the coal strata of Northumberland and Durham, from the magnesian lime-rove on the eastern side of the latter county, to the mountain lime-rove on the west, by Mr. Weitgarth Forster. This admeasurement comprehends the beds of mountain lime-rove, which are there intermixed with beds of quartzose sand-rove and argillaceous shale, to the sand-rove of Cumberland, which rests upon the slate of the alpine district. The strata interposed between the beds of coal are various kinds of coarse or fine-grained siliceous sand-rove, argillaceous sand-rove, and shale. The latter is provincially called slate, and the sand-roves are called sandstone. We shall give from this admeasurement the thickness of each bed of coal, and its depth from the upper stratum, supposing them to lie horizontally.

Red sandstone not sunk through.

The total thickness of these strata in this estimate is about 300 yards, including the beds of mountain limestone. The total thickness of the 24 beds of coal may be taken on the average at 48 feet, of which eight beds are of sufficient thickness to be worked. There are 20 beds of limestone and one of imperfect limestone, making a total thickness of about 180 yards. The great whin stratification, or gil, as it is called, is supposed to be a regular stratification. It is exceedingly various in its thicknesses. Where it is seen on the banks of the river Tees, near Tees Force, it forms rude basaltic columns of considerable size. As the strata rise to the south-west, the different beds of coal make their appearance on the surface on the western side of Northumberland and Durham, but they are thrown down by faults, which have considerably disturbed their regularity. The arrangement and succession of the strata in this part of our island may be seen in Plate III, fig. 1, which represents a section of England taken by Mr. Baker, and copied from the second edition of his Introduction to Geology. It commences from the German ocean, where the magnesium lime-stone of the low district, A, is seen rising above the level of the sea, L.L. Proceeding west, we come upon the coal strata B B; before we reach Durham, they continue across the country to near Waddington, rising in succession to the west or south-west, but are much broken by faults. Here various beds of coarse sandstone or grit, finer crystalline sandstone, and indurated shale, succeed in the same direction: they contain a few seams of coal. Metalliferous lime-stone soon makes its appearance farther west, C C; but no where forms those immense cliffs, more than 80 or 100 yards in height, which we meet with in Craven, in Yorkshire, and in Derbyshire. Nearly the lowest bed of lime-stone is 42 yards in thickness: it extends from Melmerby Scar into Westmorland. The whole of the strata, C C, is interbedded with veins of lead and zinc, which are very productive in the great lime-stone, but produce less as they pass through the sandstone strata, and rarely produce any ore in the shale.

The highest point of the metalliferous limestone district is Croas Fell, a mountain on the western side of Durham, about three thousand feet above the level of the sea. It is composed of various beds of limestone, alternating with sandstone and shale, and is covered near the summit with the lower series of strata of the coal formation. It is intersected by a great vein of lead ore running east and west. A great fault, called the Burtruford Dyke, filled with whinstone or basalt, runs north and south, and throws down the strata to the west side of it, to the amazing depth of one hundred and sixty yards. (See X.) The strata, as they approach it, rise at an angle of about twenty-five degrees. Defending the western declivity of Croas Fell, we come to the red sandstone rock, the lowest of the beds in Mr. Forster's measurement, before given. It is marked D in the section, and extends beyond Penrith. The red sand-rock bounds the alpine district of Cumberland, marked E E. The mountains of this district surrounding the lakes of Cumberland and of Westmorland are not striated: they are composed of slate, hornstone, porphyry, greenwacke, greenstone, sienite, and granite. Beyond these mountains, on the west, we meet with stratified hill-country coal, extending to the Irish channel, marked F.

The mountains in the vicinity of the lakes contain metallic veins, and beds of copper, manganese, and lead. The strata on the western side dip towards the sea, and coals have been worked for more than a mile under the sea at Whitehaven. The pit was filled by a very high tide, which rode above the shaft, and buried the workmen and the works.

The alpine district of England is composed of these rocks, which, by the German geologists are called primary and transition rocks. (See Rocks.) In these, few traces of regular stratification can be observed, though they are frequently divided into tabular masses, which have been mistaken for strata. These rocks form the foundation on which the stratified rocks of the middle and low districts are laid. They are composed of greenwacke, lime-stone, slate or clay-slate, granite, porphyry, sienite, and greenstone. Many of them appear to be composed of an intermixture of the above rocks, and have no well-defined character.

The alpine district is composed of groups of hills and mountains, which, viewed on a grand scale, may be considered as forming one chain, extending on the western side of England and Wales from Cornwall to Cumberland, and
STRATA.

from thence to the northern extremity of Scotland. It is broken into three parts by the intervention of the Bristol Channel, and the low grounds of Lancashire and Cheshire. They are denominated by Mr. Bakewell the Northern, the Cambrian, and the Devonian range.

The northern range enters Cumberland from Scotland, and passing through that county and Westmoreland, extends into Northumberland and Durham. It continues along the western side of Yorkshire and Derbyshire, and into Staffordshire.

The loftiest mountains of the Cambrian range extend through Caernarvonshire and Merionethshire; they decline in height as they pass through South Wales, and on the borders of the Bristol Channel are covered with regular stratified rocks of the coal formation, comprising an extensive coal field one hundred miles in length, and from five to twenty in breadth, ranging from Pembrokeshire into Monmouthshire.

The Devonian range commences in Somersetshire, and passes through Devonshire into Cornwall. The highest point of this range is formed by the granitic rocks of Dartmoor. Granitic rocks of less elevation range through Cornwall to the Land's End, but they are covered in many parts with slate, provincially called "killar" in Cornwall, and "shillet" in Devonshire. The slate, or shillet, in Devonshire, is covered on its eastern side by red sandstone: in many parts a red bafatic amygdaloid is interposed between the red sandstone and the slate, and may be seen rising through the former in the vicinity of Exeter. From tradition, and from prevalent appearances, it is rendered probable, that a large extent of country on the western side of Cornwall has been washed away by the fury of the Atlantic ocean, which is impelled with impetuous violence on the coast. If the granitic rocks were ever covered by stratata similar to those on the eastern side of England, they were too lofty to form the ravages of the ocean. The granite of Cornwall forms a barrier which protects the southern shores of England from the rapid encroachments of the sea, by breaking the violence of the western tides; yet the land is gradually and constantly diminishing along the line of coast from Cornwall to Kent. In the short period of a single life, this diminution is scarcely noticed, except by those whose estates adjoin the sea; but in the lapse of centuries, the outline of the country is changed, and its surface sensibly reduced. Of this, we might cite numerous instances, both on the southern and eastern coasts. Whitsby abbey, in Yorkshire, offers a striking proof: it was built, on an elevated plain, in the year 666, at which time it was more than a mile from the sea; at present it is very near the edge of a perpendicular cliff, which is continually falling down as the sea excavates the base.

FRESH-WATER STRATA.—We have before mentioned, that a series of stratata occur in the Isle of Wight, resembling the stratata in the vicinity of Paris, but which do not occur in any of the English counties. These stratata lie in a horizontal position on the northern side of the island, and are distinctly visible in a hill called Headon, adjoining the vertical stratata of chalk before described. The hill is about four hundred feet in height. The lower bed (see Plate III. Geology, fig. 3,) is of beautiful white sand, and abounds with fragments of very many shells, over which is laid a bed of dark-clay, K, and upon this a series of beds of sandy calcareous and argillaceous marls, L. Some of them, according to Mr. Webster, consist almost wholly of the fragments of fresh-water shells, as the limineous, planorbid, cycloform, and others resembling helices and mytilus. This he denounces the lower fresh-water formation. In this formation in the Paris basin, the gyppum beds are situated. Over the lower fresh-water occurs a stratata consisting of clay and marle, M, which contains a great number of shells, wholly marine. Ten of the species agree with those in the London clay. Most of them appear to have undergone but little change; and some of the species can scarcely be distinguished from recent shells. Some of the shells are very delicate, but in a high state of preservation, thus showing that they must have lived near to the spots where they are now found.

In other parts of this stratata are banks of large fossil oyster-shells, the greater part of which are locked into each other in the way in which they usually live, and many have their valves united. It is therefore evident, that these oysters have not been removed from a distance, but their present situation. The fossils are nearly allied to those in the upper marine formation in the Paris stratata.

The upper fresh-water formation rests immediately on the lower, and is the most remarkable one in the series. It occurs about half way up the hill at N, and is about forty feet in thickness. It is a calcareous bed, every part of which contains fresh-water shells in great abundance, without admixture of marine exuviae. Many of the shells are in high preservation, and the animals appear to have lived near the places where they are found, as the shells are so friable, that they could not have been removed from their native situation without being broken.

This stratata appears to have extended over the whole northern part of the Isle of Wight, but it has not yet been observed in the Paris basin, called calcaire d'eau douce. The external characters of the stone in both countries are sufficiently different from any known rock, to render them distinguishable even without the shells. Over this stratata is another bed of clay, eleven feet in thickness, containing numerous fragments of a small nondescript bivalve shell. Other calcareous stratata, containing a few fresh-water shells, succeed. The whole is surmounted by a bed of alluvium, O, forming the summit of the hill.

There is one remarkable difference between the fresh-water stratata over chalk, in the vicinity of Paris and in the Isle of Wight. In the latter, there is a total absence of fossiliferous formations, so abundant in the former. The lime-stone impregnated with fossil, and containing a burl-stone, covers half the bottom of the Paris basin. (Transactions of the Geological Society, vol. ii.) Though the shells in these stratata are considered by Mr. Webster and other naturalists as undoubted fresh-water shells, yet as they differ more or less from those of existing species, it may be asked, are we certain that animals which bear a close resemblance to fresh-water shells, might not formerly have been inhabitants of the ocean? Or might not these animals have been brought in a living state to their present situations by rivers or inundations, which emptied themselves into the sea? If we admit that they are really fresh-water shells, and the beds which cover them contain exclusively marine shells, we must also admit that the places where they are found have been successively covered with seas or lakes of salt and fresh water, after the formation of the London clay. To explain this, it is not necessary to suppose a general riming of the ocean, or an alternate subidence and elevation of the land. Lakes in the vicinity of the sea might have their barriers
STRATA.

rriers broken down by earthquakes, and closed again by deposits of sand and gravel, by which the nature of the waters would be changed. If the strata in the hill of Heaton were once the bottom of a lake, one great revolution, at least in the state of this part of the globe, must since have taken place, by which level of the sea has been changed, and the surface of the land cut down and excavated, leaving no external trace of its original outline.

Strata round Paris. The geology of the country round Paris resembles, in a considerable degree, that in the vicinity of London. The capitals of both empires are situated over the same substratum of chalk, covered by a deposition of more recent strata: thus the geologist may regard the inhabitants of each as children of the same soil; and it were surely more wise to urge this as a plea for mutual amity, than to make the geographical position of the two countries a motive for eternal hatred, and exclaim with a late British senator

"Littora litoribus contraria, fluviibus undas,
Imprecor arma arma pingunt ipoque nepotes."

En. 4.

"Our clifs, our coasts, our waves opposed to theirs,
May the same fate descend to all their heirs."

Dryden.

The basin in which the upper strata round Paris are deposited is of considerable extent. The total thickness of the beds over chalk is about 700 feet. A very interesting account of these beds, and the extraordinary fossils they contain, has been published by Cuvier and Brongniart, in the "Geographie Minéralogique des Environs de Paris," from which we shall extract the particulars most deserving notice.

The country in which Paris is situated is perhaps the most remarkable that has yet been observed, both from the succession of different beds, and from the extraordinary organic remains they contain; millions of marine shells, that alternate regularly with fresh-water shells, compose the principal strata. Bones of land animals, of which the genera are entirely unknown, are found in certain parts; other bones, remarkable for their large size, and of which similar genera exist only in distant countries, are found in the upper beds. No country can afford more instruction respecting the last revolutions that terminated the formation of the present continents. Though chalk is the foundation, it rises to the surface, only a few situations being covered with other beds, in the following order:

1. Chalk with flint.
2. Phric clay and lower sand.
3. Coarse marine lime-flint, or calcaire grofsère. The place of this is sometimes occupied with the lower sand-flint, N° 4.
4. Lower marine sand-flint.
5 & 6. Lower fresh-water strata, gypteous clay and gypsum, containing bones of quadrupeds, and a bed of oysters.
7. Sand and sand-flint, without shells.
8. Upper marine sand-flint.
10. Upper fresh-water formation, with mill-flint.
11. Alluvial soil, ancient and modern, including gravel, pudding-flint, black earth (les marnes argileuses noires) and peat.

1. Chalk.—This chalk agrees in external characters with that found in other countries. It occurs in indistinct horizontal strata; in which we observe either interrupted layers, or tuberose-shaped masses of flint, which pass into the chalk at their line of junction, or kidnies of hard chalk, having the same shape and position with the flint. This formation is well characterized by the petrifactions it contains, which differ not only in the species, but sometimes also in the genus, from those that occur in the coarse lime-flint. Two species of blemnites occur in the chalk, and these appear to be different from those found in the lime-flint, and are considered to characterize it.

The chalk forms the bottom of the basin, in which are deposited the different formations that occur around Paris. Its surface must have presented numerous inequalities before the present strata were deposited over it, because we observe promontories and islands of chalk rising through the newer formations. In Plate II. Geology, fig. 7. we have given a section of a similar arrangement of the strata, a representing the chalk, b, b, b, the newer strata.

2. Phric Clay.—All around Paris we find the chalk covered with a deposit of platific or potter's clay, which is dug and used in the manufacture of different kinds of pottery. This clay varies in colour, being white, grey, yellow, red, and black; sometimes it contains a layer of sand, and very rarely a few organic remains, such as cytherea, turritellæ, and bituminous wood; they sometimes occur in the purer clay; and in some places fragments of chalk have been observed in it. It is neither intermixed with the chalk at its line of junction with it; nor is it more calcareous, where in contact with that mineral, than at a distance from it: hence Cuvier conjectures that it has been deposited after the chalk, and is therefore a late or late formation.

3. Coarse marine Lime-flint, with marine Sand-flint. This formation presents much greater variety than the chalk. Several different strata, or series of strata, such as lime-flint, clay-marle, lime-flint-marle, and flate-clay, occur in it. These are arranged in a determinate order, and the strata of lime-flint are well characterized by the petrifactions they contain; the same system of strata always possessing the same species of petrifactions.

The lowest or first series of strata of the coarse lime-flint formation is very sandy, and sometimes contains a substance resembling green earth; it is still better characterized by containing a great variety of well-preferred shells, many of which still retain a pearly lustre, and differ more from the present existing species than those in the upper strata of this formation.

The following are the petrifactions enumerated by Cuvier and Brongniart, as occurring in it:

Nummulites lavigata, Lacinia, and nummulis. These are always found in the lowest part of the bed. Madrepores, at least three species. Algae, three species. Carpophyllum, three simple and one branched species. Fungites. Cerithium giganteum. Lucia lamellosa. Cardium perulifum. Voluta cithara. Crassafilia lamellosa. Turrinita multifulca. Oftrea fibula. Oftrea cymbula. The second series of strata is still very rich in shells; nearly all the bivalves found by M. Defrance at Grignon belong to it. It also contains a few impressions of leaves and stems. The most characteristic petrifactions of this series of strata are the following: Cardita avicularia. Orbitolina plana. Turrinita imbecula. Terebellum convolutum. Calymene trochiformis. Pecten pulvinatus. Citherae nita. Citherae elegans. Milolites, very abundant. Cerithium; probably several species; but neither the apudium and petroclisium, nor cinetum and plicatum, which latter belong to the second marine formation that covers the gypsum.

The third series of strata is less abundant in petrifactions, and contains fewer species than the two preceding. The following have been observed. Milolites, very rare.
STRATA.

The strata of the second and third series sometimes contain beds of sand-flone or mafes of horn-flone, filled with marine shells. In some cases the sand-flone takes the place of the lime-flone. Land-shells and fresh-water shells (limnea et cyclostome) have been observed in this sand-flone, but only where it lies immediately under the fresh-water lime-flone. The sand-flone and horn-flone containing marine shells, rest either immediately on the marine lime-flone, or are contained in it. The following list contains the names of those species of petrifications which occur most frequently in the sand-flone. Calyptra trochiformis. Oliva laumontiana. Ancilla caesalipera. Voluta harpula. Fusis bulboformis. Cerithium ferratum. Cerithium tuberculatum. Cerithium coronatum. Cerithium lapidum. Cerithium mutable. Ampullaria acuta or spirata. Ampullaria patula. Nucula deltoida. Cardium lima. Venericardia imbricata. Cytheres nitida. Cytherea elegans. Cytherea tellinaria. Venus callosa. Lucina cirrincina. Lucina faxorum. Two species of oyster, still undetermined; the one appears allied to atherina dilata, to offera cylindrical, while the other to offera symbalicus.

The fourth forms of strata, consist of hand calcareous marle, soft calcareous marle, clayey marle, and calcareous sand, which is sometimes agglutinated, and contains horizontal layers of horn-flone, crysals of quartz, and rhomboideal crystals of calcareous spar, and small cubical crysals of fluor spar. Petrifications occur very rarely.

4. Siliceous Lime-flone, without Shells.—This formation occurs with the coarser marine lime-flone, on the same level with it, and in no instance is either above or below it. It rests immediately on the plactic clay. It consists of strata, not only of a white lime-flone, but also of a grey, compact, or fine granular lime-flone, which is penetrated in all directions with flexes, and its numerous cavities are lined with siliceous flataclites, or quartz crysals. A characteristic mark of this rock is its wanting petrifications of every kind, both of fresh water and salt water. A species of mill-flone sometimes occurs in it, which appears to be siliceous lime-flone, deprived of its calcareous ingredient by some agent unknown to us. This mill-flone must not be confounded with that which occurs in the upper beds.

5 & 6. Gypsum of the fresh fresh-water Formation.—The fresh-water formation is not entirely of gypsum, but contains also beds of clay-marle and calcareous marle. These are arranged in a determinate order, when they all occur together, which is not always the case. They lie over the coarse marine lime-flone; and the gypsum, which is the principal mass of the formation, does not occur in wide extended tables, like the lime-flone, but in finge conical, or long mafes, which are sometimes of considerable extent, but always sharply bounded. Montmarte presents the best example of the whole series of the formation, and these three beds of gypsum are to be observed superimposed on each other.

The first bed consists of alternate layers of gypsum, folia calcareous marle, and of thin platy argillaceous marle, or adhesive flate. The layers of gypsum are thin, and full of crysals of selenite; and in the clay-marle, or adhesive flate, imbedded menilite occurs. Wherever this bed rests immediately on the sand of the marine sand-flone containing the shells, it contains sea-shells. The former bottom of the sea, however, appears to have been frequently covered with a bed of white marle, on which the lower beds of gypsum rest; and this bed is filled with fresh-water shells. The second bed resembles the first, and only differs from it in being thicker, and containing fewer beds of marle. The only petrifications it contains are those of fishes. In the lower part of this bed, we for the first time meet with single kidnies of celeline, or sulphate of frontian. The third or upper bed of gypsum is by far the greatest; in several places it is more than fifty feet thick. It contains few beds of marle, and at some places, as at Montmarte, it lies almost immediately under the soil. The lower strata of this upper gypsum contains flint, which appears to be intergraded with it, and to pass into it by imperceptible gradations, facts which shew their contemporaneous formation. The middle strata of this bed split naturally into prismatic concretions, with many fides. The uppermost strata, of which five generally occur, and extend to a great distance, are thinner than the others, and are intermixed with marle, and also alternate with beds of it.

Numerous quarries are situated in this upper gypsum, which daily afford skeletons or single bones of unknown quadrupeds. To the north of Paris they are found in the gypsum itself, where they are hard, and simply covered with marle; and to the south of Paris, similar remains, but in shells and of shells, of the genera lymeaneus and planorbis, are met with. The two latter do not differ very much from those found in the marxes of France; a fact which seems to shew that this marle, as well as the subjacent gypsum, have been deposited from fresh water. In the numerous and thick beds of clayey and calcareous marle which rest upon this white friable marle, petrifications are so rare, that we cannot form any satisfactory opinion as to their formation. It is in the white friable marle that the fresh-water shells, which principally characterize this formation, are found. The first fresh-water formation neither contains mill-flone nor flint, only menilite and wood-flone. Over the beds of clayey and calcareous marle there rests a bed of yellowish flaty marle, three feet three inches thick. Kidnies of earthy celeline, or frontian, occur in the lower part of it; higher up we meet with a bed of small bivalve shells, which are referred to the genus eipheres; and between the uppermost layers of the marle, other species of eipheres, with cerites, spherites, and bones of fish, occur. This bed is not only remarkable on account of its great extent, (having been traced ten leagues in one direction, and four leagues in another, and throughout the whole being of the same degree of thickness,) but also because it marks the upper boundary of the fresh-water formation, and the beginning of a new marine formation. All the shells that occur in the marle above this bed belong to the ocean.

A great bed of greenish clayey marle, without petrifications, rests immediately over the yellowish marle, and contains geodes, kidnies, and clayey calcareous marle, and also celeline. Immediately over these follows a bed of yellow clay-
STRATA.

clay-marle, which abounds in fragments of marine bivalve shells, cerites, trochites, machites, cardites, venites, &c., and fragments of the tail of two species of ray have also been found in it.

The beds of marle which rest over these contain fossil marine shells, but only bivalves; and in the uppermost bed of calcareous marle, immediately under the clayey sand, there occur two distinct beds of oysters; of which the uppermost contains large and thick oysters, and the upper which (is sometimes separated from the under by a thin bed of white marle without shells) contains numerous small thin and brown oyster-shells. This latter bed of oysters is very thick, is divided into many layers, and is scarcely ever wanting in the hills of gypsum.

These oysters appear to have lived on the same spot where we at present find them, because they are arranged as we find them in oyster-banks in the ocean; and the greater number of them are whole, and with both valves. The formations sometimes terminate with a bed of clayey sand, in which no petrifications occur.

Such are the beds which, in general, constitute the gypsum formation. In the following table are enumerated the petrifications that belong to the gypsum, and to the marine marle which rests upon it.

**Fossil Quadrupeds in Gypsum.**

**Genus 1.** Paleotherium, or ancient wild beast. This animal is arranged, according to Cuvier,

Cl. Mammalia.

Ordo Pachydermata.

Pone tapirum et ante rhinocerotem et equum ponens—To be placed in the natural system after the tapir, and before the rhinoceros and horse.

The five species discovered in the gypsum quarries are,

1. Magnum, the size of a horse.
2. Medium, the size of a hog.
3. Cralium, the size of a hog, varying in the form of the feet.
4. Curtum, the size of a hog.
5. Minus, the size of a sheep.

It may be proper to observe, that remains of five other species of this animal have been found in different parts of France, of which one equals in size the rhinoceros.

**Genus 2.** Anoplotherium, or beast without weapons.

Inter rhinocerotem aut equum ab una et hippocotamum, suem, et camelum, ab altera parte ponendum.—To be placed between the rhinoceros and horse, on one side; and the hippopotamus, hog, and camel, on the other.

1. Commune, size of a small horse.
2. Secundarium, size of a hog.
3. Medium, size of an antelope.
4. Minus, size of a hare.
5. Minimum, very small, the jaw only discovered.

A pachydermatous animal, allied to the hog:

Canis Parisenis.

Diadelphis Parisenis.

Viverra Parisenis.

Birds, three or four species.

Reptiles. Trionix Parisenis, and another tortoise, with a species of faurius, which appears to be a crocodile.

Three or four species of fish.

Molluscous animals. Cyclostoma mammia:

In the upper white marle are palm, fragments of fishes, limnas, and pianorbes.

**Marine Formation.**

The shells of these petrifications are generally in a powdery state, or we have only their mould or impression.

Almost all these shells are broken, and difficult to ascertain. The two species of cerites of the marine formation, which cover the gypsum, do not appear to occur anywhere else.

The two beds of oysters are often separated from each other by snails without shells; and although we cannot say, with any certainty, whether or not the particular species here enumerated are shells that belong more to the one bed than the other; yet it cannot be doubted that the oysters of this marle do not occur in the coarse lime-stone, and that they are more nearly allied to the species at present living in our seas, than to those found in the lime-stone.

7. Sand
STRATA.

7. Sand and Sand-stone without Shells.—The first are often of considerable thickness, and are intermixed with beds of sand of the same nature; and both are often so fine, that they are used in manufactures.

8. Superior marine Sand-stone and Sand.—This varies in colour, compactness, and even in composition, being sometimes a pure friable sand-stone, sometimes intermixed with clay, and its place is occasionally occupied by a thin bed of calcareous sand filled with shells. This sand-stone contains marine shells, which approach most nearly to those species met with in the calcareous marble over the Pyrenees.

9. Mill-stone without Shells or argillaceous Sand.—This formation consists of iron-shot, clayey sand, with greenish, reddish, and whitish clay, marl, and mill-stone.

This mill-stone is quartz, containing a multitude of irregular cavities, which are traversed by silexaceous fibres, disposed somewhat like the reticular texture in bones. These cavities are sometimes lined or filled with red ochre, clay, marl, or clayey sand; and they have no communication with each other. Most of the mill-stones found near Paris are a red or yellowish tint, but the rarer and most esteemed varieties have a blueish shade of colour. The blue variety is most highly prized, because it affords the whiteest coloured flour; and a mill-stone of this kind, six feet and a half in diameter, sells at 1200 francs. We never observe in its cavities any silexaceous stalactites or crystallized quartz; and this character enables us to distinguish in hard specimens this mill-stone from that found in the silex-stone of Normandy.

It is sometimes compact. It has been analyzed by Hecht, (see the Journal des Mines, No. 22, p. 533, and appears to be almost entirely composed of silica. Another character of the mill-stone, properly so called, is the absence of all fossil, animal, and vegetable productions, whether of fresh or salt-water origin. Mill-stones are formed by cutting pieces of these stones, and joining them together, and confining the whole with an iron hoop. They are called burr-stones. All the best mill-stones used in England are formed of the French stones.

10. The upper fresh-water formation is composed of silex and lime-stone. These substances sometimes occur independently of each other; in other instances, they are intimately mixed together. The nearly pure fresh-water lime-stone is the most common; the next in frequency is the mixture of silex and lime-stone; the large masses of fresh-water silex are the rarest. The silex is sometimes a nearly pure silex; sometimes approaches to pitch-stone, or to jasper; and, lastly, it has a corroded state, when it has all the characters of true mill-stone, but is in general more compact than the mill-stone without shells.

The lime-stone of this formation is white or yellowish-grey; sometimes nearly friable, like marl or chalk; sometimes compact and solid, with a fine grain, and a conchoidal fracture. The conchoidal varieties are rather hard, but easily broken into sharp-edged fragments, somewhat like flint, so that it cannot be cut. These characters apply only to the lime-stone near Paris; for at a considerable distance, the lime-stone occurs very compact, of a greyish-brown colour, which readily cuts and polishes. The lime-stone of Mont Ablar, near Orleans, which contains bones of the palæotherium, belongs to this formation. Even the hardest varieties of this lime-stone, after exposure to the air for a time, soften; and hence it is used as a marble for manufacturing the ground. All the varieties, both hard and soft, are traversed by empty vermicular cavities, whose walls are sometimes of a pale green colour. Where the silexaceous minerals and the lime-stone are intermixed, the latter is always corroded, full of cavities, and its irregular cells are filled with calcareous marl. The essential character of this formation is, that it contains fresh-water and land shells, nearly all of which belong to genera that now live in our moraines; but it contains no marine shells, at least in such places as are distant from the subjacent marine formation. Of the shells, the potamiids, helicites, and limnocorncus, are the petrifications that most frequently characterize this second fresh-water formation: the cyclothomum mummas has never been found in it. There are also the following vegetable and other remains: dicotyledonous woody strata of trees filled with silk, stems of arundo or tibba, articulated stems resembling the thorn, pediculated ovoidal grains, canaliculate cylindrical grains, olive-shaped bodies with an irregular streaked surface. The first or lowest fresh-water formation, on the contrary, has its characteristic petrifications, but never contains potamiids or helicites. The second fresh-water formation extends for thirty leagues to the south of Paris; and a similar formation has been met with in the departments of Cher, Allier, Nièvre, Cantal, Puy-de-Dôme, Tarn, Lot, and Garonne, in the south-east of France; and, more rarely, it has been discovered in the Roman states in Tuscany, and in the vicinity of Ulm, Mayence, Silesia, and in some parts of Spain.

11. Alluvial Soil.—This appears also to be a deposit from fresh water: it consists of variously coloured sand, marl, and clay, and of mixtures of the three, coloured brown and black, with carbonaceous matter; also of rolled marls of different kinds. What particularly characterizes this alluvial soil is the occurrence of large organic remains, as trunks of trees, with bones of elephants, oxen, deer, and large mammals. Although this formation is new, in comparison with those we have just described, yet it is of high antiquity with regard to man, as its formation extends to a period not far removed from the earliest date of our history, when the earth supported vegetables and animals different from those that at present live in these or other countries of the globe. The alluvial substances around Paris occur in two different situations: they either cover the bottom of valleys, and consist of sand, loam, or peat; or they form wide extended plains of gravel and sand, which lie high above the present river-courses. It is difficult to distinguish the alluvial mud, situated at a distance from the valleys, from the fresh-water formation; and it even, in some places, seems to pass into it. It appears, however, to be older than that of the valleys.

Strata, in many respects similar to those of the Paris and London basins, also occur in other parts of Europe, but have not been accurately examined. Nor have we any correct account of the upper strata bordering the Appennines in Italy: these are known to contain, in great abundance, the fossil bones of elephants, rhinocerotes, hippopotamus, whales, chalcos, and dolphins.

A calcareous breccia occurs in many of the stratified lime-stone rocks that border the Mediterranean sea: it is not stratified, but fills up fissures and chasms. The breccia consists of fragments of lime-stone (not water-worn or rounded), intermixed with the bones of ruminating animals and land-shells, cemented together by an ochry calcareous sublimate. Most, but not all, of the bones belong to species of quadrupeds now existing in the vicinity. According to Cuvier, the bones and fragments of rock fell into the rents of the rocks successively, and became united together by the accumulation of sparrie matter. The formation of these breccias is probably recent, compared with that of the upper stratified rocks, or even the alluvial soil that contains remains of unknown animals; but it may
still be regarded as of ancient date, since nothing shows that similar breccias are formed at the present day; and those of Corsica contain fossil remains of unknown animals. In selecting fossils remains to characterise strata, we must most carefully distinguish those which are imbedded in the original rock from those which occur in fissures, or cavities, that have been subsequently closed or filled up, as the latter may sometimes be of very recent date.

Strata Scams. Those partings or divisions that run parallel with the strata are so called by some geologists, to distinguish them from the oblique or perpendicular rents by which a stratum of stone is generally divided. The perpendicular rents that run in the direction of the dip of a stratum, are provincially called *fanes*; and the crofs rents, *cutter*.

See Coal and Strata.

Stratagem, *stratagem*, formed from *stratēgos*, a chief, or command an army, a military wile, or a device in war, surprizing or deceiving an enemy.

Stratagemas, or delusions practised towards an enemy, free from perfidy either in words or actions, or frauds laid for him consistent with the rights of war, have always been acknowledged lawful, and have had often a great share in the glory of celebrated commanders; though artifices of this kind have in various instances proved unsuccess-ful. In the use of stratagemas, however, we should regard not only the faith due to an enemy, but also the rights of humanity, the introduction of which would be pernicious to mankind. Some nations, even the Romans, for a long time professed to despise every kind of artifice, surprize, or stratagem in war; and others have proceeded so far as to give notice of the time and place for giving battle. This was the practice of the ancient Gauls. (See Livy.) It is said of Achilles, that he was for fighting openly, and not of a temper to have made one of those who were shut up in the famous wooden horse, which proved fatal to the Trojans.

"Ille non includus equo, Minerva, sacra mentito, mal feriatos Troias, et letam Priami choreis. Fellaris Atalans; sed palam captis gravis, &c."

Hor. lib. iv. Odys. vi.

In this conduct there was more generosity than discretion. It would indeed be very laudable, if, as in the frenzy of duels, the only business was to display personal courage; but a war is made to defend our country, to prosecute by force what is unjustly denied us; and the ends means are also the most commendable, provided they be not unlawful and odious. (Verg. Aen. ii. v. 390.) The contempt of artifices, stratagemas, and surprizes, proceeds often, as in the case of Achilles, from a noble confidence in personal valour and strength; and it must be owned, that when an enemy may be defeated with open force, in a pitched battle, there are greater hopes of having quelled and reduced him to sue for peace, than if the advantage was owing to surprize; as Livy (lib. xiii. cap. 47,) makes those generous senators say, who did not approve of the manner of proceeding against Perseus, as not altogether finer. Therefore, when plain and open courage may secure a victory, there are occasions when it is preferable to artifice, because the advantages gained to the state are more solid and permanent.

Vattel’s Law of Nations, &c. b. iii.

The ancients dealt very much in stratagemas; the moderns wage war more openly, and on the square. Frontinus has made a collection of the ancient stratagemas of war.

Stratarchimetry, formed from *stratēgos*, army, number, and *metron*, measure, in War, the art of drawing up an army, or any part of it, in any given geometrical figure; and of expressing the number of men contained in such a figure, as they stand in array, either near hand, or at any distance assigned.

Strategus, *stratēgos*, in Antiquity, an officer among the Athenians, of which there were two chosen yearly, to command the troops on the fleet.

Plutarch says, there was one chosen from out of each tribe; but Pollux seems to say, they were chosen indiscriminately out of the people. The people themselves made the choice; and that on the last day of the year, in a place called Pyx. The two stratēgoi did not command together, but took their turns day by day; as we find from Herodotus and Cornelius Nepos. Sometimes, indeed, as when a person was found of merit vastly superior, and exceedingly famed in war, the command was given to him alone: but it was ever a rule, not to put any person in the office but whose estate was in Attica, and who had children, that there might be some hostages and securities for his conduct and fidelity.

Constantine the Great, besides many other privileges granted to the city of Athens, honoured its chief magistrate with the title of *Megas Stratēgos*, *Magnus Dux*.

Stratford, in Geography, a township of America, in Coos county, New Hampshire, on the E. bank of Connecticut river, incorporated in 1773, and containing 359 inhabitants; 48 miles above Hanover.—Allo, a pleasant poft-town of Connecticut, in Fairfield county, on the W. side of Stratford river, containing two places for public worship, and 2855 inhabitants; 14 miles S.W. of New Haven. This township, the "Cupheag" of the Indians, was settled in 1638, principally from Massachufetts.—Allo, a river formed by the junction of the Housatonic and Naugatuck. See Housatonic.

Stratford-upon-Avon, a town of Warwickshire, England, is noted, in the literary annals of Great Britain, as the birth-place of the inimitable Shakespeare; and is also poeified of considerable interest, from its local history and situation. It is a large, populous, and respectable town; but though in a manufacturing district, is neither annoyed nor benefited by manufactories of any description. The town occupies a considerable space, and is disposed in twelve principal streets, on the western bank of the river Avon; over which is a long bridge of fourteen arches. The great road from London to Birmingham passes through the northern side of the town; other turnpike-roads branch off towards Warwick, Coventry, and Alcester, and to different parts of Northamptonshire, Oxfordshire, Worcestershire, and Gloucestershire. In 1811, according to the population report, the town and parish of Stratford contained 553 houses, and 2842 inhabitants.

The existence of this town may be traced to a period as remote as three centuries anterior to the Norman conquest; at which time, a monastery existed here in the possession of the church of the Wiccians; supposed to have been founded soon after the conversion of the Saxons to the Christian faith. In the commencement of the eight century, this convent was annexed to the bishopric of Worcester; when the manor of Stratford obtained some degree of consequence, and was rated in the Norman survey at the sum of 25l. In the reign of Richard I., a charter was granted for a weekly market on Thursdays, which is still continued; this was followed by several other grants for fairs, of which there are now three annually. In the time of queen Elizabeth, this town was greatly dilapidated by fire, and in the succeeding reigns, was again in imminent danger.
danger of undergoing the same fate. These ravages, at a period when its buildings were chiefly constructed of wood, must have been in the highest degree fearful and alarming. The civil war of the 17th century, was an important period in the history of all the principal towns in Warwickshire. In 1643-5, a party of the royalists was stationed at Stratford, but were driven from the town by the superior force of the parliament's army; who destroyed one arch of the great bridge, to prevent the returning incursions of their opponents. This precaution, however, failed; the loyalists again approached Stratford, and it afterwards became the residence of the queen, Henrietta Maria, till she departed to meet Charles I. near Edgehill.

The principal buildings in this town are, the great bridge, already noticed; the church; the chapel of the Holy Cross; the town-hall; and a seat of lord Middleton. The church, which is collegiate, though the college buildings are now destroyed, is a spacious and venerable structure, dedicated to the holy Trinity; of a cruciform description, with a square tower at the intersection of the transept, of curious and early architecture, upon which is raised a stone spire. The interior consists of a nave, two aisles, a transept, and a chancel; and contains some curious and interesting relics of sculptural antiquity. On the north wall of the chancel, are the monument and bust of the great poet, a particular description of which, with his life, are inserted in a previous part of this work, under the article SHAKESPEARE. Several large monuments of the families of Combe, Clopton, &c. are also preserved in this church. Against the north wall of the lady's chapel, is one adorned with armorial ensigns, consisting of two figures in alabaster, of William Clopton, esq. in armour, and Anne, daughter of sir George Griffith, his consort; bearing on the slab, the dates of 1592 and 1596. Another monument of the same family, with alabaster figures, coloured to resemble life, is erected against the east wall of the same chapel, to the memory of George, earl of Totnes, and baron of Clopton, with his countess, bearing the dates of 1630 and 1636. The chancel contains a monumental effigy of Mr. John Combe, who is traditionally said to have been fatized by Shakspeare, in an epitaph written upon him in his life-time. From the consideration of this church, on the margin of the Avon, is it supposed by Leland, that it is built on the site of the monastery of Streeteford: and Dugdale thinks that, with the exception of the south aisle, it was erected about the time of William I. The guild of the Holy Cross is a fraternity of which, and partly religious, was established here as a public institution in the year 1569, by Giffard, bishop of Worcester, under the name of "The Hospitall of the Holy Crofs in Stratford." This fraternity had also particular municipal privileges granted them. The chapel of these brethren, excepting the chancel, was rebuilt in the latter part of the reign of Henry VII. by sir Hugh Clopton; it is a handsome structure, in the ornamental style of the age, and contains several curious paintings in fresco on its walls. Drawings have been made of these, and etchings published by Mr. Fisher, coloured after the originals. Attached to this building are a hall for the brethren of the guild, almshouses for twenty-four poor persons of both sexes, and a free grammar-school for children, natives of the borough. The guild and fraternity were dissolved at the general suppression of religious houses; but the school and almshouses are yet continued, and the guildhall is used for the meetings of the corporation.

New-Place, at one period a principal building in the town, was originally erected by sir Hugh Clopton, in the time of Henry VII.; and after passing through the family of Yorke, XXXIV.

Underhill, was, in 1597, bought by Shakspere, who first gave it the name of New-Place, which it retained till its demolition in 1759, soon after the destruction of the famous mulberry-tree. The town-hall, first erected in 1633, was a lofty edifice, built on semi-circular arches, and supported by round columns, with a cupola on the top. Above was a room, used as a magazine for arms and ammunition; which being in the year 1642 much damaged by the explosion of a barrel of gunpowder, was partly taken down in 1767, and the present building erected in the year following. This, from the circumstance of its being dedicated to Garrick's jubilee, in 1769, to the memory of Shakspeare, was then denominated Shakspeare Hall. The building is of the Tuscan order, containing a room of 60 feet in length, decorated with large paintings, particularly two, by Wilton and Gainborough, of the inimitable poet, and of Garrick, by whom they were prefixed in 1769. The outside of the hall is also ornamented with a statue of the "Warwickshire Bard," likewise given by the same celebrated character. Below the great room are the kitchens, and two dungeons, or places of confinement. The house in which the great poet was born, is partly standing in Henley-breet. It is now converted into two, although originally but one tenement; and other houses altered by modern repairs. Stratford-upon-Avon is in the parish and division of Old Stratford, and hundred of Barilew; having separate jurisdiction, and is governed by a mayor, recorder, high reeve, twelve aldermen, twelve capital burgesses, a town-clerk, and other officers.

Stratford-upon-Avon is possessed of many local advantages, and from its situation upon the great road leading from London to Holyhead, from the numerous other roads which meet at this place, and from its having a navigable river from the Severn, and a lately completed canal from hence to that of the Worscester and Birmingham, which thus opens a communication by water with the northern part of the kingdom, it may be naturally expected that Stratford will become a flourishing town.

Independently of Shakspeare, and others of no mean, though far inferior note, we find several highly respectable characters, to whom this town has given birth and name; viz. John de Stratford, archbishop of Canterbury, lord chancellor of England, and regent of the kingdom, in the reign of Edward III.; Robert de Stratford, his brother, also lord chancellor of England, and bishop of Chichester, who died in 1526; John de Stratford, bishop of London, a nephew of the above prelates, and bishop of London in the same memorable reign; men who sufficiently make a very conspicuous figure in the history of that eventful period.

It remains to be noticed, that in this town was celebrated Garrick's jubilee to the honour of Shakspeare in the year 1769, a performance which very much absorbed the public attention. It continued three days, though the incessant rains considerably obstructed the intended ceremonies, as well as those which were exhibited. Mr. Garrick was peculiarly eminent in his recital of the "Ode," which gave unbounded satisfaction.—History and Antiquities of Stratford-upon-Avon, by R. B. Wheler, 8vo. 1806. Eight engravings. Guide to Stratford-upon-Avon, by R. B. Wheler, 8vo. 1814, with a plan of the town.

ted
read about a mile on each side of the road. Till of late
years, the east side of the town was in the parish of Wolverto
on, and the west side in that of Calverton. They are now
two different parishes, denominated St. Mary Magdalen, or
the east side of Stony Stratford, and St. Giles, or the west
side. A market was originally granted for this town to the
Vereis in 1460, and in 1663, Simon Bennett, lord of the
manor of Calverton, procured a charter for a market (which
is still held on Friday), and four fairs: there are now only
three. The town has twice suffered much injury by fire;
first in the year 1730, when 53 houses were burnt down;
second in 1742, which consumed 13 houses, and the body
of the church of St. Mary Magdalen, which has never been
rebuilt. The Sunday which followed was the flung, is yet flaying.
The damage was estimated at 10,000l., towards which,
4293l. were collected by a brief, and nearly 3000l. by sub
scription. The church of St. Giles was originally built as
a chantry chapel in 1451, and was endowed in 1483. This
church (except the tower) was rebuilt in 1776, by Mr.
Hiome of Warwick. Near this structure is a neat market-
place. According to the returns under the population act
of 1811, the East side parish contained 113 houses, 520 in-
habitants; the West side parish 211 houses, 968 inhabitants;
and the total of 366 persons, occupying 321 houses.
The chief support of the town is derived from the number of
travellers who are continually passing through it: the
principal employment of the women is lace-making.

The inhabitants are divided into several religious deno
minations: the greater number are Baptists, who have a
meeting-house in the town: the Independents have a place
of worship at Potter’s Ferry, a neighbouring village. A
guild was founded in the town, in 1461, by John Eedy and
others. Here are several charitable establishments, parti-
icularly one of 70l. per annum for apprenticing poor children.
In 1676, two Sunday schools were opened, in which up-
wards of 300 children receive the rudiments of education,
under the superintendence of the minister, churchwarden,
and a committee of subscribers. At the lower end of the
town formerly stood a cross, in memory of Eleanor, queen
of Edward I., but it was destroyed in the civil wars. At
this town Richard III., then duke of Gloucester, took pos-
session of the person of the unfortunate young monarch
Edward V., who was then with his attendants at an inn.
An act for paving and lighting Stony Stratford paft in 1612.
Lytton, Mason, in his Beauties of England and Wales, vol. i.
by John Britton and E. W. Braye.

Strathford-le-Bow, a parish in the hundred of Ousillun,
and county of Middlesex, England, was formerly a part of
the parish of Stepney, but separated from it in 1720.
The name of Stratford is derived, in common with other
places so entitled, from the source of an ancient ford, on
a Roman highway. Its distinction of Bow, according to
Leland, was given on account of a bridge "arched like
unto a bow," which was built across the river Lea at a
distant period. This parish extends along the eastern banks
of the above river, whilst Hackney, Bethnal-Green, Step-
ney, and Bromley, bound it on the other side. It contains
about 456 acres of land; of which 218 are arable, and
the remainder is occupied by pastures, marshes, and nur-
series. The soil consists chiefly of clay and loam, whilst
moor, black-moor, and heath abound in the hilly parts. No account of this parish
is found previous to 1333, when it was laid waste by the
English army, after a battle near Loudon-hill. On the
south side of the river Avon, a Roman road may be traced
for several miles. Here are also some chapels dedicated
to different saints.—Carpenter’s Topographical Dictionary of

Strathbeg, a river of Scotland, in the county of
Sutherland, which runs into loch Eribol.
STR

STRATHBOGIE. See Huntley.

STRATH-BRAND, a valley of Scotland, in the county of Perth, W. of Dunkeld.

STRATHMORE, a river of Scotland, in the county of Sutherland, which runs into Loch Hope.

STRATHNAVER, a district of Scotland, in the N.E. part of Sutherland.

STRATHY, a river of Scotland, in the county of Sutherland, which runs into the North Sea; 3 miles S.E. of Strathy Head.

STRAY HEAD, a cape of Scotland, on the N. coast of the county of Sutherland; 31 miles E. of Cape Wrath. N. lat. 58° 39'. W. long. 5° 50'.

STRATIFICATION, in Chemistry, an operation by which bodies are placed in a condition to act mutually upon each other, by being arranged layer by layer, stratum super stratum, as is practiced by metallurgists, and marked in books of chemistry with S.S.S.

STRATIFICATION, in Geology, the arrangement of mineral matter in parallel layers or beds. See STRATA.

Gen. Ch. Cal. Sheath inferior, of one leaf more or less divided, variously ribbed or keeled, permanent. Perianth superior, of one leaf, tubarum at the base; its limb in three deep, equal, erect segments, deciduous. Cor. Petals three, rounded, rather spreading to as long as the perianth. Stam. Filaments from fix to twenty, inserted into the receptacle of the flower, short, awl-shaped; anthers vertical, linear, simple. Pist. Germen inferior; elliptic-oblong; styles fix, deeply cloven, as long as the stamens; stigmas fimbri. Peric. Berry coated, oval, from fix to ten cells, and as many angles, tapering at each end. Seeds numerous, obovate, in two rows.

Eff. Ch. Sheath cloven. Perianth superior, in three deep segments. Petals three, Berry with fix, or more, cells.

Ofb. The anthers are occasionally imperfect in some flowers, the stigmas in others. The parts of the flower differ widely, with respect to number, in different species. Damafonium of Schreber, Willdenow, &c. has a leafy stem, though more numerously, divided sheet, with a corresponding number of angles and segments, its stamens moreover being but fix or eight, while the cells of the fruit are more numerous than in the original Stratiotes. All things considered, we prefer keeping this genus entire, as well as leaving it in the clades where Linnaeus, after repeatedly considering the subject, had determined to let it remain. This genus is very nearly allied to Hydrocharis. See that article.

1. S. aloides. Water Aloe, or Common Water Soldier. Linn. Sp. Pl. 754. Willd. n. 1. Fl. Brit. n. 1. Engl. Bot. t. 379. Mill. Illuftr. t. 50. Fl. Dan. t. 337. (Mili-taria aizoides; Ger. En. 825. Lob. Ic. v. 1. 375.)—Leaves sword-shaped, channelled, with a prominent rib, and fringed with sharp prickles.—Native of ditches, ponds, and flow streams in the north of Europe. Abundant in the feney parts of England; flowering in July, and sometimes entirely occupying the surface of the water, excluding all other plants. This herb is truly floriferous and perennial, though each root flowers but once. The parent plant, rooted in the mud after flowering, sends out buds of leaves, and the ends of long runners. These rise to the surface, form a fibrous appendage, root, bloom, and then sink to the bottom, where they implant themselves in the mud, sometimes ripen seeds, and always become the parents of another race of young offsets. The leaves are all radical, forming a star-like tuft, as in Aloes, Sedum, Saxifraga, &c. They are smooth, brittle, vorticaceous, and pulilucid, about a span long, with very sharp faw-like teeth. Flower-flats several, short, compressed, smooth, each bearing one erect white flower, an inch in diameter, from a deeply divided, or two-leaved, compressed head. Stamens twenty, connected with their base. Styles fix, 2. S. acrooides. Indian Water Soldier. Linn. Suppl. 268. Willd. n. 2. (Acorus marinus; Rumph. Ambon. v. 6. 101. t. 75. f. 2.)—Leaves sword-shaped, flat; slightly ferrated at the end. Sheath bearded.—Native of the islands of the Indian ocean, wherever the shore is flat and sandy. The root is perennial, somewhat tuberous and jointed, like that of an Acorus. Leaves radical, four feet long; crowded, linear, thick-edged, very smooth, entire, rounded at the end, and somewhat ferrated thereabouts. Stalk simple, single-flowered, smooth, three or four feet high. Sheaths of two leaves; their keel groove, with fibres towards the top. Petals fimbri, white, tinged with red. Filaments scarcely any. Anthers twelve, linear, acute, compressed. Berry ovate, compressed, hairy, as big as a hen’s egg, of from four to fix cells. Seeds fourteen or more. There appears no reason to think, with Willdenow, that the anthers above described are nectararies.

3. S. nymphaoides. Shield-bearing Water Soldier. Humboldt and Bonpland M.S. Willd. n. 3. "Leaves roundish, petalate, floating as well as the stem." Found in India, in the Calcutta district. Root perennial. Stem round, floating. Leaves entire. Stamens axillary, of two leaves, with one or two flowers, which are twice the size of S. aloides.

4. S. albispira. Broad-leaved Water Soldier. Linn. Sp. Pl. 754. Mant. 405. Sm. Exot. Bot. v. 1. 27. t. 15. (Damafonium indicum; Willd. Sp. Pl. v. 2. 276. Ait. v. 2. 331. Roxb. Coromand. v. 2. 45. t. 15. Curt. Mag. t. 1201. Ottel amelh; Rheed. Hort. Malab. v. 11. 95. t. 46.)—Leaves broad-ovate, entire. Sheath slightly divided, with several dilated ribs.—Native of ponds in the East Indies. Dr. Roxburgh sent it to the late lady Amelia Hume, in whose flow it flowered in the autumn of 1804. The root is tuberous, perennial, with many long simple fibres. Stem none. Leaves on long radical foot-flats, almost heart-shaped, bluntish, entire, many-rubbed, smooth. Flower-flats simple, angular, almost as long as the leaves, each bearing a solitary white flower, of very short duration, not unlike a Trillium in size and general aspect. The sheath, an inch or more in length, is closely attached to the stem, in the same way as the anther, with a small appendage to it. Stamens eight, with vertical, linear, orange columns. Styles eight,
eighth, with cloven, linear, yellow fīrmus. Berry cylindri-
cal, winged by the sheath, having eight cells, and numerous
elliptical seeds.

This species being so very variable as to number, in the
parts of fructification, and two of the foregoing ones dif-
fering so much from each other in that particular, prove the
characters derived from hence, in this genus, to be of no
value. S. sidero, moreover, in itself, overthrows whatever
depends on sexual distinctions. The only mark by which
Damasium could be kept separate, is the sheath being of
one leaf, very slightly divided. The number of its lobes
and angles is too uncertain to be depended upon.

STRA, in Biography, a philosopher of Lampsacus,
who succeeded Theophrastus in the Peripatetic school, and
took charge of it in the 3rd year of the 13th Olympiad,
B.C. 286, and predeceased it 18 years, with a high degree of
reputation for learning and eloquence; and from his attach-
ment to natural philosophy, he obtained the appellation of
"Physicus." Ptolemy Philadæus chose him for his pre-
ceptor, and recoumed his services with a present of 80
talents. None of his works have reached our time. His
constitution was feeble, and it is said that he lost the
powers of perception before his death, which happened
about the end of the 12th Olympiad. In his opinion
concerning matter, Strato departed essentially from the
sytem both of Plato and Aristotle, and he is said to have
approached that system of atheism, which excludes the
Deity from the formation of the world. From Cicero
(Denat. Deor. l. i. c. 13.) we learn, that he conceived
divine power to be seated in nature, which possesses
the causes of production, increase, and diminution, but is
wholly destitute of sensation and figure: and the fame
author, in his Tuscul. Quæst., informs us, that he had nothing
in common with the atomic principles of Democritus,
but ascribes every thing to certain natural motions and librations.
Brucker gives the following abstract of his opin-
ions: that there is inherent in nature a principle of motion,
or force, without intelligence, which is the only cause of
the production and diffusion of bodies: that the world
has neither been formed by the agency of a deity, distant
from matter, nor by an intelligent animating principle,
but has arisen from a force innate to matter, originally excited
by accident, and since continuing to act, according to the
peculiar qualities of natural bodies. It does not appear,
that he expressly either denied or allerted the existence of a
divine nature; but in excluding all idea of deity from the
formation of the world, it cannot be doubted, that he in-
directly excluded from his system the doctrine of the ex-
istence of a Supreme Being. Strato also taught, that the
feet of the soul is in the middle of the brain, and that it
only acts by means of the senses. Brucker by Enfield,
vol. 1.

STRA, in Ancient Geography, a town of
Asia Minor, in the mountains of Caria; in which was a
theatre. It was founded by the Macedonians, and derived
its name from Stratonice, the wife of Antiochus Soter.
It preserved its liberty for a long time under the Romans,
and the emperor Adrian partly rebuilt it. It was encoun-
tered by ramifications of mount Taurus. Jupiter Chry-
saerus had a temple near this city, where deputies of the
inhabitants of the towns of Caria annually assembled to offer
sacrifices, and to tranflect the affairs of their federative
republic.

STRA, or STRATONICEA, a town of Asia
Minor, near mount Taurus; called Stratonice ad Taurum by
Strabo, in order to distinguish it from the Stratonices of
Cara.
bathing are accommodated with lodgings. There has of late years been a considerable increase in the trade of this place: the chief exports are timber, bark, and oats; the imports, coal and lime-flour from Wales, and grocery, &c. from Bristol. The harbour, on account of its sands, is beset with reefs from 50 to 60 tons; but some of from 80 to 90 tons occasionally enter it: one of upwards of 90 tons was built here in 1813. Great quantities of sea-fish are carried from Bude for manure, not only into the neighbouring markets, but to several places in the north of Devon. Stratton derived some degree of historical importance from the great victory obtained in its immediate vicinity, in the early part of the civil war, by the forces of Charles I., commanded by Sir Ralph Hopton, over those of the parliament, under the earl of Stamford. The latter was encamped on a steep hill, with thirteen pieces of cannon, and 5,400 men; and early on the 16th of May, 1642, was attacked, with a very inferior force, by the royalists, who ascended the hill in four places at once, and after a desperate conflict, met together on the summit about 3 o'clock in the afternoon, having entirely cleared the hill of the enemy, and taken their camp, baggage, ammunition, and cannon. Sir Ralph, in consideration of his eminent services in this battle, which are specified in his patent, was created lord Hopton of Stratton. After his death, Charles II. (then in exile) in 1658 created sir John Berkeley, to whose courage and good conduct the victory has been chiefly attributed, baron Berkeley of Stratton: this title became extinct in 1773. In 1797, lord Dunfanville was created baron Basset of Stratton, with remainder to his daughter and her issue male. Lytton's Magna Britannia, vol. iii.

Stratton, a township of America, in Windham county, Vermont, about 15 miles N.E. of Bennington, containing 265 inhabitants.

Stratusch, a river of Walachia, which runs into the Siret at Adrud.

Stravadium, in Botany, a moft barbarous name, taken from the Samnivadus of the Hortus Malabaricus, and used by Jullien, Gen. 326, to designate a genus separated by him from the Linnean Eugenia, chiefly because of its racemofer inoffensiveness and angular shape. It contains Eugenia racemosa and acutangula, with Butonis alba of Rumph. Ambon. v. 3, which, though quoted for the former by Linneus, appears in Jullien's opinion to be distinct.

Stravaganza, Ital. a word exalted into a musical term by Vivaldi in the early part of the last century. Vivaldi, a Venetian, and a musician of the Lombard school, with much rapidity of bow and finger, was a voluminous composer, not only of solos, fantasias, and concertos, for his own instruments, but operas for the theatre and masses for the church. In our younger days, the fifth concerto of Vivaldi, composed of rattling passages in perpetual semiquavers, was the making of every player on the violin, who could mount into the clouds, and imitate not only the flight, but the whistling notes of birds. His last set of twelve concertos are, with due propriety, filled his Stravagancies; being full somewhat more extravagant, capricious, and eccentric than the rest. But this rapidity and difficulty are only comparative with the other strains of Corelli, Albinoni, Alleti, and Tedeschi; it was all plain failing, at the rate of ten knots an hour; there was no difficulty of softhenuto, expression, or modulation to encounter. See Vivaldi.

Straubing, in Geography, a town, with a castle, of Bavaria, situated on the Danube, and containing a collegiate church, and four convents, and having also a church without the town; 43 miles N.W. of Passau. N. lat. 48° 47'. E. long. 12° 30'.

Straublich, a town of Bavaria, in the bishopric of Bamberg; 13 miles N.E. of Bamberg.

Strausch ιΕγιδους, in Biography, a German mathematician and Lutheran divine, was born at Wittenberg in 1632, and after a course of education in his native place, he removed to Leipzig, where he continued two years, taking, on his return, the degree of master of arts. In 1652 he became assistant of the philosophical faculty, disputing on the occasion "De Periodo Juliano," and on other chronological subjects. In 1659 he was made professor of mathematics, and having obtained the degree of doctor in divinity, he was appointed, in 1664, to be professor of history. In 1669, having declined other invitations, he accepted the invitation of the senate at Danzig, to be professor of theology, and pastor of the church of the Holy Trinity, and removed thither; but as he experienced much opposition from the Catholic and Calvinistic inhabitants, he accepted, in 1675, a call to Hamburg. In his voyage thither, he was captured and carried to Colberg. As soon as he recovered his liberty, he made an attempt to go to Hamburg by land, but was arrested at Stargard, by order of Frederic-William, elector of Brandenburg, because he had preached too violently against the Calvinists. On this occasion he was thrown into prison, where he remained three years, never during that time shaving his beard; and he might have been doomed to a longer confinement, if the people of Danzig, and even the Calvinists themselves, had not interceded for him, and obtained his release in 1678. He then returned to Danzig, regained his former employments, and there died of the jaundice in 1682. At the request of the theological faculty at Wittenberg he wrote in defence of the Lutheran doctrine, for which he was a fervent advocate. His mathematical works are, "Geographia Mathematica;" "Doctrina Astrorum Mathematica;" "Tabulae per Univerian Mathethin Summopere necessarum;" "Tabulae Sinuum et Tangentium et Logarithmorum." His other productions consist chiefly of dissertations relating to chronology and scriptural subjects. Gen. Biol.

Strauersdorff, in Geography, a town of Austria; 9 miles W. of St. Polten.

Straviko, a town of European Turkey, in Bulgaria, on the Black sea; 40 miles S.E. of Ivanell.

Strausberg, a town of Brandenburg, in the Middle Mark; 33 miles W. of Cuftrin. N. lat. 52° 38'. E. long. 13° 53'.—Also, a town of Germany, in the county of Schwartzburg Rudolstadt; 6 miles W. of Sonderhausen.

Strausfurth, a town of Saxony, in Thueringia; 4 miles S. of Weißenfels.

Straussberg, a town of Brandenburg, in the Middle Mark; 13 miles S.E. of Bernau. N. lat. 52° 37'. E. long. 13° 52'.

Strausseneck, a town of the duchy of Sturia; 12 miles S. of Windisch Gratz.

Straw, in Agriculture, the common name of the stalk or stem on which grain grows, and from which it is threshed, or of any other similar material. The first is an article of cattle food, which requires some management in order to confine it to the greatest advantage, and with the most economy. In employing it for forage-cattle, or other stock, it should constantly be made use of when first threshed out; as by keeping it gets musty, and is not by any means eaten so well or completely by cattle: in this view, the threshing out large quantities at a time by the threshing machines, and

and
STRAW.

and flacking, or putting it up in other ways, is unfavourable to the perfect consumption of the fodder, and the thriving of the farm-flock. There is likewise another point necessary to be regarded in respect to this article as fodder, which is, that the inferior sorts should be first and recourse to, and afterwards those of the better kind. And in giving it, too much should not be placed before the animals at once. It has been observed by Mr. Marshall, in his "Rural Economy of Yorkshire," that straw, of every kind, is there bound upon the threshing floor. This, when straw is not used at the time of threshing, would, he thinks, in any country, be good economy; straw in trusses is much better to move, lies in less room, and retains its flavour longer than loose straw does. In a country where cattle in winter are universally kept in the house, and foddered at stated meal-times, the binding of straw becomes, he thinks, essential to good management. Each truf, provincially "fold," contains an armful, as much as the arms can conveniently "fold;" and this is the usual meal for a pair of cattle. Thus the buisness of "foddering" is facilitated, and a waste of straw avoided.

It has been remarked by Mr. Young, that if the cattle are fed with straw, it should be done with attention. The belt farmers in Norfolk are generally agreed, he says, that cattle should eat no straw, unless it be cut into chaff mixed with hay; but, on the contrary, that they should be fed with something better, and have the straw thrown upon them, to be trodden into dung: and he is much inclined to believe, that in moist, if not in all cases, this maxim will prove a just one. The common calves of straw-feeding are, of cows, young cattle, or black cattle just brought in, and not yet put to fasting. With regard to cows, the food is certainly, he thinks, insufficient, which lets them down so much in flesh, that when they calve, and are expected to yield productively, they lose a considerable time, and that perhaps the most valuable, in getting again into flesh, before they give their usual quantity of milk; but if they have been well and sufficiently wintered, they are half furred, and yield at once adequately. And that for young cattle, it is still worse management; for their growth is flunted, and they never recover it. It is his opinion, that black cattle from poor mountains had better be put to fast, than eaten than when, and, again, care must be taken that the system be not deranged by it. If well fed, and the beasts be not large, they may be cleared off between harvest and the end of November; but if they are wintered on straw, this may not be effected, and the farmer may be forced to put himself to the expense of corn or oil-cake, to feed beasts not of a fine to pay well enough for those articles. The evil is less if he has plenty of turnips or cabbages; but for these he may have other applications. In so far as regards the quality of the farm-yard dung, all this reasoning becomes still more forcible; for from straw-fed cattle, the farmer will, at the end of winter, find perhaps a large heap, of so poor a quality, that it will go but a little way in manuring his fields; whereas, one load of dung made by fat or well-fed cattle, will be equal to two or three of such as have been fed poorly. But cut chaff, one half hay and the other half straw, affords very well, especially with some sort of succulent food. And it has been stated by the author of the "Synopsis of Husbandry," that bean-straw, if well harved, forms a very hearty and nutritious diet for cattle in the winter-time, and both oxen and horeses, when not worked, will thrive upon it; sheep also are very fond of browsing upon the pods, and the chaff is a very nutritious manger-meal. Mr. Young also suggets the great importance of putting beans in sufficiently early, and the reaping food enough, as the straw, well harved, is worth from 2£ to 3l. per acre; and that Mr. Arbuthnot's teams, which were always hard-worked, never had a truf of hay while the bean-straw lasted. Pea-straw, or haalm, when well got in, is likewise, in a great measure, equally nutritious, if cut into chaff, and given in that way as a fodder.

However, it has been stated by Mr. Marshall, that he met with an idea that cattle may be fattied with straw; or, in other words, may be served with it in too great plenty. It has been observed, that after a dry summer, when straw is scarce, and the cattle have it dealt out to them regularly, in not too large quantities, they do better than when,after a plentiful year, it is thrown before them in profusion from the threshing floor, not through the superior quality of the straw in a scarce year; as these effects have been observed to be produced from the same straw. This subject is by no means unintereasting to those who winter large quantities of cattle: he has observed in Yorkshire, where cattle are tied up, and of course are regularly fed, that they in general do better at straw, than cattle in the south of England, where they go loose among a much greater plenty; but whether the profit from this warmth, from their refting better, from the breed of cattle, or from their being regularly fed and eating with an appetite, he will not pretend to decide.

But where this sort of fodder can be wholly consumed by the store-flock, it is probably a better method to make use of it in that way, than by letting the yards with it, as the manure is without doubt much superior, and other articles, such as fern, &c., may, in many cases, be provided as little as with straw. And the quantity of manure, where an abundance of straw is at command, that may be raised by littering animals that are feeding and fattening in the fields or yards, especially where much green food is used, is very great, and often of vast importance to the farmer, as has been stated in considering the means of fattening animals. Therefore, the use of straw, both as the food of cattle and for litter in the yards, must be of very great importance to the farmer in a great many instances. See STALL-Feeding.

The use of straw, of wheat-straw, which is often permitted, is not unfrequently a matter of great advantage in different situations. The use of the cut straw, or haalm, of pulp crops, has lately, too, been found very great in the feeding out or fattening different sorts of cattle and other animals.

It has been lately stated, by Sir Humphrey Davy, that dry straw of wheat, oats, barley, beans, and peas, and spoiled hay, or any other similar kind of dry vegetable matter, is, in all cases, useful manure. That, in general, such substances are made to ferment before they are employed, though it may be doubted whether the practice should be indiscriminately adopted.

In examining this material chemically, from four hundred grains of that of the dry barley kind, he obtained eight grains of matter soluble in water, which had a brown colour, and tasted like mucilage. And from the same quantity of wheat-straw he gained five grains of a similar substance.

It is thought that there can be no doubt that the straw of different crops immediately plunged into the ground, affords nourishment to plants; but that there is an objection to this method of using straw, from the difficulty of induding and completely burying such as is long, and from its rendering the humusy soil, or in a littery state.

Where straw is made to ferment, it becomes a more manageable
manageable manure; but there is likewise, on the whole, a great loss of nutritive matter. More manure is perhaps, it is thought, supplied for a single crop; but the land is left improved than it would be, supposing the whole of the vegetable matter could be finely divided and mixed with the soil.

It is usual, it is said, to carry straw that can be employed for no other purpose to the dunghill, to ferment and decompose; but that it is worth experiment to ascertain, whether it may not be more economically applied when chopped small by a proper machine for the purpose, and kept dry until it is ploughed in for the use of a crop. In this case, though it would decompose much more slowly, and produce less effect at first, yet it is thought, would be much more lasting, and perhaps ultimately more beneficial.

**Straw, Pea, Hacking of,** the cutting up and reaping of the pea crop, in the haum, in the field, when down by the drill or hand, in the firmed manner. It is performed by means of two hooks of the reaping kind, by one of which the straw or haum is held up from the ground, while it is cut off by the other in a sort of hacking mode, and then laid into small heaps, or, as they are often termed, wads.

**Straw and Hay Ropes for protecting and preserving Fruit-tree Blossoms and other Crops,** in Gardening, the means of guarding or securing them, by such materials, from the effects of severe frosts, and other causes of mischief, injury, and destruction, to which they are liable and exposed. This is a method which is stated to have been practiced with great success in the more northern parts of the island, in different years entered in the Memoirs of the Caledonian Horticultural Society.

It is to be effected, as soon as the buds of the trees begin to have a turgid and swelled-out appearance, by placing and fixing up poles before the walls, about a foot from them, at four to six feet distance from each other; the lower ends being sunk a little into the ground, and the upper ones rising so as just to reach below the copings of them; securing the tops of those at each end of the particular spaces or divisions, by means of a strong nail or half-fall, to either the walls or copings, in order that the ropes may be kept tight and firm. Then, having the necessary quantity of straw or hay ropes ready prepared, the work is begun by fixing one of them near the top to one of the outside poles, proceeding horizontally to the other, padding the rope on from pole to pole, and taking a turn of it round each, until it is reached, where it is made secure. When at eighteen, or, if necessary, twenty, another line of rope is begun again, and carried across in exactly the same manner; and so on until within from eighteen inches to three feet, as may be requisite, of the ground is reached, when the work is completed. The method is said to be both cheap, and, so far as experience has gone, extremely efficacious. Besides, as the covering does not much intercept the rays of light or of the sun, it may be applied early, and be let remain, although the fruit be let, until the weather becomes settled, towards the middle or end of the month of May. In the first trial of this method, a peach tree had been covered, on a wall where there were many others. A heavy fall of snow took place afterwards in the beginning of the above month, and on the morning after this fall, about five o'clock, the thermometer was at two degrees and a half below the freezing point: the consequence was the loss of the whole uncovered crop, except a few fruit which were protected by the foliage of the trees; while the tree that was covered and protected produced a fine crop of fruit.

As the writer is of opinion that the parts of fructification are not unfrequently hurt before the flower is expanded, he advises that the ropes be put on at a sufficiently early period.

Where poles are scarce, the ropes, it is said, may be fixed in a perpendicular manner, the upper ends being fastened by a proper nail to the wall, and the lower or bottom ones by a peg firmly driven into the ground. But in this way, the ropes are very apt to beat off the flower-buds in times of high winds.

The branches of different evergreens, as well as old fish-nets, as those of the herring and other kinds, have been employed for the purpose of protecting fruit-tree blossoms, but nothing that has yet been tried has been found to answer the end so well as these kinds of ropes. Besides, they are cheap, and to be obtained in almost any situation. However, woollen nets, which are much recommended for this use by some, the writer has never had the opportunity of trying. Such nets are probably too expensive for common practice in these cases.

It has also been found, that these sorts of ropes are very useful in protecting and preserving other early garden crops from the effects of the cutting frosty winds and severe frosts which often prevail in the early spring season; such, for instance, as early peas, beans, potatoes, kidney-beans, and some others; which is done simply by fixing them along the front of the different rows, by means of pegs or pins driven firmly into the ground.

It is probable that this cheap and ready method of protecting and preserving fruit-blossoms, and crops of other kinds, may be practiced and had recourse to in preference to those of a more expensive nature; as nets of several sorts, canvas, and some others, that are in pretty common use, in many situations and circumstances, especially in the more northern parts of the kingdom.

**Straw, Collar, in Rural Economy,** a fort of collar stuffed or formed wholly of this material, instead of that of the hair kind, which is the most suitable and proper for the purpose. It is a fort still much employed in some backward districts. In Cornwall, the draught-harness for horses and other animals in the ploughs, as well as the harrows, often consists; it is said, of a straw collar, called there a brow, with wooden cellars-trees, to which are fastened rope-traces.

**Straw, Cutter, in Agriculture,** a name sometimes applied either to the perfor or implement by which straw is cut into chaff. See Chaff-Cutter.

In order to save labour as much as possible, the power of water and steam has lately been much applied in the cutting of straw for chaff.

**Straw, Drains,** a term applied to those sorts of surface-drains which are filled with straw in some way or other. See Surface-Drain.

**Straw, House,** a name applied to the place for piling up straw. These contrivances are very convenient in most situations.

**Straw, Ricks,** a term used for such as are formed of straw of different kinds. See Stack.

**Straw, Twisting Machine,** the name of an engine or contrivance for twisting straw into ropes, for the purpose of filling the drains in some cases of surface under-draining. See Surface-Draining.

**Straw-Yard,** that fort of yard about farm-houses which is defined for the reception of the straw after the grain has been threshed out of it. It also sometimes signifies the yard which is prepared and littered with straw for the use of neat cattle and other animals, as well as the yards into which saddle and other horses are taken during the winter season, to be fed on straw and other similar matters, in a cheap manner,
strewberry, in Botany and Gardening. See Fragaaria. See also Summer Fruit.

Sir Joseph Banks, in a paper inserted in the first volume of the Transactions of the Horticultural Society of London, in speaking of the revival of the old neglected mode of managing strawberries, remarks, that the custom of laying straw under plants of this kind, when their fruit begins to swell, is probably very old in this country: the name of the fruit, it is thought, bears testimony in favour of this supposition, for the plant has no relation to straw in any other way, and no other European language applies the idea of straw in any shape or manner to the name of the berry, or to the plant that bears it. Consequently, that the name strawberry perhaps originated in the use of this practice in its management.

In respect to this custom or practice, it is noticed by the writer, that when he came to Spring-Grove, his country residence, in the year 1779, he found this practice in the garden there. John Smith, the gardener, who was well known among his brethren as a man of more than ordinary abilities in the profession, had used it at that place many years; he had learned it, it is said, soon after he came to London from Scotland; probably at the neat-houses, where he first wrought among the market-gardeners; it is therefore thought to be clearly an old practice, though now almost obsolete.

However, its use in preferring crops of this sort of fruit is flattered and recommended as very extensive: it shades the roots from the sun; prevents the wafte of moisture by evaporation; and consequently in dry times, when water is scarce, and watering necessary, makes a lefs quantity of it suffice than would be used if the sun could act immediately on the surface of the mould; besides, it keeps it, is said, the leafruit from refting on the earth, and gives the whole an air of neatness, as well as an eftect of real cleanliness, which should never be wanting in this sort of culture, or in a gentleman's garden.

It is further stated, that the strawberry-beds in the above garden, which have been measured, for the purpose of ascertaining the expense incurred by this method of management, were about twenty-five feet long, and five feet wide, each containing three rows of plants, and, of course, requiring four rows of straw to be laid under them. The whole consists of fix hundred feet of beds, or one thousand eight hundred feet of strawberry plants, of different sorts, in rows. The quantity of straw for strawing these beds, which was consumed in the year 1806, was, it is said, the long straw of twenty-fix trifles, for the short straw, being as good for the purposes of litter as the long, but less applicable to this use, is taken out; if then on the original twenty-fix trifles, fix be allowed for the short straw taken out and applied to other uses, twenty trifles will, it is said, remain, which will last this year ten-pence a truf, or fixteen shillings and eight-pence, which is one penny for every nine feet of strawberries in rows. And from this original expenditure, the value of the manure made by the straw when taken from the beds must be deducted, as the whole of it goes undiminished to the dung-hill as soon as the crop is over. The cost of this practice cannot, therefore, if is supposed, be considered as heavy: in the above year, not a single flower fell; it is said, at the above place, from the time the straw was laid down, until the crop of scarlets was nearly finished, at the end of June. The expense of strawing was therefore, it is noticed, many times repaid by the saving made in the labour of watering, and the profit of this sav-
seem to be deserving of more attention than has yet been bestowed upon it.

**Strawberry.** _Bram and wild eating_ are common in pastures, heaths, and hedge-banks. The latter is the parent of the cultivated kinds, and which has a most delicious fruit.

See **Fragaria**.

**Strawberry-Blite.** See Blitum.

**Strawberry-Queiral.** See Potentilla.

**Strawberry-Spinach.** See Blitum.

**Strawberry-Tre.** See Arbutus.

**Strawberry-Trefoil.** See Trefoil.

**Strawberry Bay,** in Geography, a bay which is neither large nor deep, on the coast of a small island in the gulf of Georgia. N. lat. 48° 36'. E. long. 37° 34'.

**Strawberry Gap,** a mountainous pass in Pennsylvania, 42 miles W. of Philadelphia, on the road to Lancaster.

**Strawberry River,** a river of North America, so called from the great quantities of strawberries that grow on its banks; which runs into lake Superior to the W. of God-dard's river, N. lat. 46° 40'. W. long. 91° 44'.

**STRAW,** in *Rural Economy,* a term signifying the dock of a horse without the hair; also the tail of slaughtered cattle or sheep, where the skin is removed.

**STRAY,** in Geography. See Yenlade.

**STRAY.** See Estray.

**STREAK-FALLOWING,** in Husbandry, a particular sort of tillage. The way of doing it is to plough one furrow, and leave one, so that but half the land is ploughed, each furrow that is filling on that which is not; when this is flurred, it is then clean-ploughed, and laid off smooth, that it will come at sowing time to be as plain as before. This is done when lean or poor lands are not fayrd enough to bear clean tillage, nor fayrd enough to lie to get foward. The intent of this tillage is to keep the fun from scorching them too much; but in many places they think this wears the land too fayrd, and therefore are not fond of having recourse to it.

**STREAKY CHEESE,** in Rural Economy, that sort which is of a streaky nature or kind, in consequence of being made from a mixture of old and new curd, or of two sorts, which have different proportions of colouring matter in them, that gives them a streaky appearance. The practice of mixing curds of different kinds and qualities should be carefully avoided in cheese-making. See Dairying.

**STREAM Anchor.** See Anchor.

**STREAM Cable.** See Cable.

**STREAM-Tin,** in Mineralogy. Particles or masses of tin-ore found beneath the surface of alluvial ground in low situations, or in valleys, are called *stream-tin* in Cornwall and Devonshire, from the processes used to separate the earthy matter from it, which consists in palling a stream of water over it. The particles of stream-tin are generally rounded by attrition. The ore is of the best quality, and is sometimes intermixed with particles of native gold. See the following articles, and Tin.

**STREAM-Works.** The alluvial repositories of tin-ore are called stream-works. (See the preceding article.) They consist of beds or strata of particles, and rounded pieces of tin-ore, covered by alluvial deposits of sand or gravel. The formation of these repositories in Cornwall is owing to the soft decomposing state of the rocks, which are interfaced by metallic veins. Tin-fence or tin-ore polishes great hardness and specific gravity, and when carried down by rivers or floods, is separated from its matrix by the action and re-action of the water, and spread into layers, which are afterwards covered by beds of sand, clay, or gravel, over which another layer of stream-tin is sometimes found covered with an upper deposit of alluvial matter. That stream-tin has been carried down to the situations in which it now occurs, is proved from another circumstance,—fragments and masses of rock are found with it, which, in many instances, serve to identify the rock from whence it came, being different from the rocks in the vicinity, and often polishing some characteristic appearance by which it can be immediately known to the miners of the country. Almost all the rocks of Cornwall are in a state of rapid disintegration, and have evidently been much more than at present at some former periods. Many of the stream-works or repositories are of very ancient date, as they occur considerably below the present level of the rivers. Human skulls, and the horns of the elk, or stag, have been found in the beds of land which cover them. In the stream-works near St. Auffle, pieces of native gold, from the size of a bean to that of an hazel-nut, were occasionally found; and a piece of a vein of quartz from the same place, about one-third of an inch thick, containing imbedded globules of native gold, the size of large shot, is in the possession of Mr. Hennah, of Plymout h; the latter is important, as proving that gold once existed in regular veins. In St. Blasey Moor there is a depth of twenty feet of alluvial soil. The first stratum next the surface is composed of gravel resting upon mud; the succeeding stratum is gravel, containing a little tin-ore; this lies upon a bed of dark combitubulous peat-earth. Immediately under this lies a bed of stream-tin, about five feet thick. Great part of this stream-tin had been wrought out at a very remote period, and before iron utensils were in use; for several wooden pick-axes, made of oak, holm, and box, were discovered in it a few years since. Stream-works sometimes extend under the sea on the coast of Cornwall. One of the moat remarkable of these works is in a branch of Fal-mouth harbour. That variety of tin-ore called wood-tin is found in stream-works, but is not at present met with in regular tin-veins.

In some parts of the mining districts of Derbyshire, lead-ore is met with in alluvial depositions. Mr. Farey, in his Derbyshire Report, p. 173, mentions a bed of lead-ore, 2 thick, being taken out of a gravel at the top of a hill in the village of Wyanton, which proves that masses of lead-ore have in former times been carried far from their native situations; and the reason why they are not more frequently found, arises from their being foter and more perishable than tin-ore. Many of the alluvial repositories of gold have a similar origin to the stream-works of Cornwall. The gold, being heavy and imperishable, has remained, while the materials in which it was imbedded have been washed away. See Vein.

**STREAMING,** or **Stream-Works,** denotes the management of the stream-tin. The first part of this business is, after securing the ground which contains it, to sink a hatch, or shaft, three, five, or seven fathoms deep, to the rocky shelf or clay on which the tin is stratified. If, upon trying a shovel of it, it be worth working, the operator digs an open trench in the lowest part of the valley, which he calls a level; and this serves to drain off all water from the workings. Those places that are rich in ore are called lead-ing-streams, or live-streams. The stream-tin is felled off that he calls the over-burden, i.e. the loose earth, rubble, or stone which covers the stream; and the stream-tin is dug up and washed at the same time, by casting every shovel of it into water, and before it is washed, it is sieved through a sieve, which is inclined plane of boards of the water to run off, about six feet wide, four feet high, and nine feet long; in which, with shovels, they turn it over and over again, under a cascade of water which washes through it, and separates the waste from the tin, till it becomes one half
tin. The beft of the tin is collected by its inferior gravity, in the head of the tye, under the cascade; and the refuse and foil are cast into the beds of adjacent rivers, or buried under the gravel and stones that form the interior strata. This kind of tin is dressed by washing it again in a smaller tye, called a gounce, with a less current of water, and greater care. The richer part is put into large vats, and the wafe is dressed again, till what remains becomes refuse; the tin is then sifted through wood or wire sieves, which separate the greater and smaller particles: the small left in is put into another firmly woven horse-hair sieve, called a diluter, by which it is made saleable.

Some of the nodules of tin are smelted as they come out of the tye; but those which are mixed with water, as well as the refuse of the poor tin, which were in the tails of the tye and gounce, are triturated and pulverized in the flamping-mill, so that all waste may be cleared from the tin by several abolutions, as in the dressing of mine-tin. See Drifting of Ores.

Besides these stream-works, there is another fort, occasioned by the refuse from the flamping-mills, &c. which are carried by the rivers into the lower grounds, and after lying some years and collecting there, yield some money to the laborious drawers, called lappiors, probably from the Cornish word lappor, or dancier, from the method of moving up and down with naked feet in the puddles, to separate the tin from the refuse. Stream-tin is then carried to the blast-furnace, called the blowing-house, in which a fire is made with charcoal, excited by two large bellows, which are worked by a water-wheel. The tin and charcoal are laid in a furnace, made by moor-flanes and clay, well cemented and cramped together with iron, called the cage, flatum super flatum, in such quantities, that from 8 to 12 cwt. of tin, by the consumption of from 18 to 24 sixty-gallon packs of charcoal, may be smelted in a tide, or twelve hours' time. The tin is forced out by the blast of the bellows, through a hole at the bottom of the earth, into a moor-flame trough, called the float; whence it is laded into lefs troughs or moulds, each of which contains about 3 cwt. of metal, called flabs, blocks, or pieces of tin, in which fire and form it is sold in the market in Europe. This on account of its superior quality, is known by the name of grain-tin, which formerly fetched a price of 7s., and of late is advanced to 10s. or 12s. more per cwt. than mine-tin is sold for, because it is smelted from a pure mineral by a charcoal fire; whereas mine-tin is usually corrupted with some portion of mordic, or other minerals, and is always smelted with a bituminous fire, which communicates a harth sulphurious quality to the metal. Fryce's Mineral. p. 136. &c.

STREAMERS, in a Ship, the same with pendants; which see.

STREAMS, Made, in Agriculture, such as are formed for the use of land, live-stock, or other rural purposes, by means of art. Much improvement of this sort remains to be accomplished, it is thought, in all mountain-fort situations, on the lower flages and parts of hills, and, in fact, wherever water can be fully commanded, which may often be readily done, by making canals and pailages for streams, and diverting the natural ones into them, leading them to unwatered grounds, for the various intentions and purposes of supplying water to villages, farmsteads, and lands in the state of grafs, as well as in some cafes to lands under the plough. Upon a large entire domain, situated in this manner, a proprietor may, it is said, operate at will, and accommodate the whole of his different farms in the manner that may be the most conducive to the general interest of the whole property.

In the case where a river or brook of water is capable of being spread over an extent of country, in which properties are much divided and intermixed, the aid of parliament and commissioners, it is thought, may be necessary, in order to direct and appoint the branching out of the common stream in such a manner, as may be most proper and equitable, as well as to see that the whole be completely performed and fulfilled, and for settling disputes, and regulating what time and experience may render further necessary. In circumstances where the proprietors are few and unanimous, commissioners and trustees alone may only be necessary for the purpose, and trouble and expense be thereby saved.

It is remarked by the writer of "Rural Economies of different Distriets," that not uplands only are susceptible of this form of improvement, but even low-lying vale lands, marshes, and rich feeding grounds, are not unfrequently defective of good water for pasturing-of stock; especially in the summer season, when it is most wanted.

The methods of conducting improvements in this intention are, in some measure, different according to circumstances, and the nature and situation of the grounds; but it is seldom necessary that each homestead, and each pasture or other ground, should be supplied with a constant stream. Where the quantity of water is small, in proportion to the demand for it, it may be distributed by turns among the farms and the fields, as their several occasions may require. The drinking places are likewise to be rendered proper and suitable to the supply, or the manner in which it is distributed. Where there are continual streams, the animals may drink at dilutions of their channels, or at troughs or other contrivances placed across or put along the sides of them. But where the supply is only occasional, large receptacles or receiving places, as ponds and reservoirs, become necessary, which are to be replenished from time to time, as may be requisite.

STREAMS, Mill, in Rural Economy, a term commonly applied to the leads or runs of water which conduce the moving powers of this sort of machinery, and which are mostly formed by means of art. In most of the mountain diarrietas, whether in Scotland, in Wales, or in the west of England, where the mills are, for the most part, of the over-foot kind, streams of this sort, commonly of the artificial kind, are almost everywhere to be met with, some of which are of very considerable length, and the antiquity of which cannot now be ascertained. In that diarrietas, too, where under-foot mills mostly prevail, these sorts of streams are not unfrequently to be found, as conducing the water which is to put them in motion.

Wherever cuts for streams or leads of this nature are to be formed, it should constantly be done in a secure and safe manner, so that no water may in any way be wasted or lost.

STREETHAM, in Geography, is a parish in the east half hundred of Brixton, and county of Surrey, England, which derives its name from its situation near the great Roman road from Arundel to London; the word, in Saxton, signifying a dwelling on the highway. The manor of Tooting-Bec, in this parish, was in the seventeenth century in the possession of the family of Howland; but since, it has passed by marriage to that of Rufiel, and is now the property of the duke of Bedford, who bears the title of baron Howland of Streatham. The ancient manor-house was a few years since pulled down, and the green-house and part of the offices converted into a residence. On the side of the common, between Streatham and Tooting, is Streatham-park,
pork, the property of Mrs. Fiozzi, relict of the late Henry Thrale, esq. The grounds comprehend about 100 acres, and are surrounded by a gravel-walk and shrubbery, nearly two miles in circumference. In the church are two monuments, with inscriptions by Dr. Johnson, to the memory of Mr. Thrale and Mrs. Salusbury, mother of Mrs. Fiozzi. Mr. Lysons, in his Environs of London, vol. i, notices a man of singular character, who was buried in this place in 1772, named Ruffel, and who had passed for a female; from this disguise, his age could not be precisely ascertained, but according to his own account he was 108.

On Lime Common, in Streatham parish, in 1660, a spring was discovered of a mild cathartic quality; the water from which was sent in large quantities to some of the hospitals in London. This parish was, in 1811, computed to contain 440 houses, and 3759 inhabitants.—Beauties of England and Wales, vol. xiv, Sury, by F. Shoberl.

STREBERNICH, a town of European Turkey, in the fanaticat of Bofinia, called "Argentina," from the silver mines found in its vicinity; 70 miles W. of Belgrade.

Female, on a separate plant, Cal. as in the male, permanent. Cor. none. Pist. German superior, roundish; style long, deeply divided into two branches; stigma simple. Peric. Berry roundish, two-lobed, of two cells. Seeds ovate, foliarly.

STREENDON, a town of Sileisia, in the principality of Meissen; 14 miles N. W. of Meissen.

STREHAJA, in Geography, a town of Walschia; 18 miles E. of Czernitz.

STREHLA, a town of Saxony, in the margravate of Meissen, on the Elbe; 14 miles N.W. of Meissen.

STREHLEN, a town of Sileisia, in the principality of Bries; 16 miles W.S.W. of Bries.

STREIDORFF, a town of Austria; 5 miles S.S.W. of Ehrnfurtum.

STREIGHT. See STRAIGHT.

STREIN, or STRIENUS, in Biography, an Austrian baron, with the title Von Schwartzenaus, was born about the 1508. The first object of his attention was jurisprudence, but afterwards, under the care of Francis Hotman, he prosecuted the study of Roman antiquities with such fidelity and success, that in the twentieth year of his age he composed a work "De Gentibus et Familias Romanis," which was published at Paris in 1593, fol. by Henry Stephens; and "Stemmata Gentium et Romanarum Familiarum," inserted in the 7th volume of "Graevi Thesaurus Rom. Ant." He also wrote "Commentarii de Rob. Belarmini Scriptis atque Libris," and published, without his name, "A Defence of the Freedom of the States of Holland." He died at Vienna, according to De Thou, in 1601, but, as Baillet says, in 1600. He was a decided and steady friend to the Protestant communion. —Gen. Biogr.

STREITBERG, in Geography, a town of Austria; 12 miles S.S.W. of Ebenfurth.—Alto, a town of Germany, in the principality of Culmbach, in the Burghausen; 30 miles S.W. of Breslau. N. lat. 49° 45'. E. long. 11° 10'.

STREITDorf, a town of Austria; 8 miles N. of Korn Neuburg.

STREITFORT, a town of Transtilvia; 13 miles N.N.E. of Foggara.

STRELEN, a town of Saxony, in the margravate of Meissen; 15 miles N. of Meissen.

STREITZ, Great Streitz, or Weisse Streitz, a town of Sileisia, and capital of a circle, in the principality of Oppeln; 14 miles S.E. of Oppeln. N. lat. 50° 27'. E. long. 17° 15'.

STREITZ, Old Streitz, a town of the duchy of Mecklenburg, situated in a marshy district; founded by Otho and Ulrich, counts of Furttenberg, in the year 1329, and entirely destroyed by fire in 1757 and 1676. Duke Adolphus Frederick re-sided here, but when his palace was burnt down, in 1712, he built another in the vicinity, at a place called "Glinke," and in 1733 founded a town adjoining to it, under the name of "New Streitz," supposing that in time it would be enlarged, that Old and New Streitz would become one place. Streitz gives name to one branch of the house of Mecklenburg, called Mecklenburg-Streitz; 50 miles W. of Stettin. N. lat. 53° 23'. E. long. 15° 18'.

STREITZ, Little, a town of Sileisia, in the principality of Oppeln; 14 miles S. of Oppeln.

STREITZ, a town of Scotland, in the county of Perth, built in 1763, for soldiers discharged after the German war; 10 miles N. of Perth.

STREITZ, in Botany, was so named by Sir Joseph Banks and the late Mr. Aiton, as a just tribute of respect to the botanical zeal and knowledge of the present peer of Great Britain, a prince of the house of Mecklenburg-Streitz. Few percognos of so elevated a rank have ever loved the study of nature more, or cultivated it so deeply. See the conclusion of the article Lightfoot.—Ait. Hort. Kew. ed. 1. v. 1. 285. ed. 3. v. 2. 154. Schreb. Gen. 796. Wild. Sp. Pl. v. 1. 1189. Mart. Mill. Dict. v. 4. Thum. U u 2. Prodr.

Gen. Ch. Cal. Common Sheath, inferior, of one leaf, channelled, pointed, widely spreading, many-flowered; partial ones lanceolate, shorter than the flowers. Perianth none. Cor. superior, irregular, of three lanceolate, acute petals; the lowermost boat-shaped; two upper ones bluntly keeled. Neckary of three leaves; the two longest equal, rather shorter than the petals, broad at the base, then tapering, with a folded wavy border, embracing the flowers and stamens, half arrow-shaped towards the top, with a thick dorsal appendage; the third leaf much shorter, ovate, compressed, keeled. Stam. Filaments five, inserted into the receptacle, thread-shaped, three of them embraced by one leaf of the nekary, two by the others; anthers terminal, linear, erect, parallel, about as long as their filaments, concealed in the nekary. Pfd. Germen below the corolla, oblong, bluntly triangular; stamens thread-shaped, the length of the stamens; stigma three, apical, ranging above the nekary, erect, gleued together in an early state. Peric. Capsule woody, oblong, slightly triangular, obtuse, of three cells and three valves, the partitions from the centre of each valve. Seeds numerous, nearly globose, hairy, ranged in two rows along each partition.

1. S. angustifolia. Great White Strelitzia. Thunb. Prodr. 45. Wildl. n. 2. Ait. n. 1. (Heliconia alba; Linn. Suppl. 157.)—Flower-tall half the length of the footstalks, which are scarcely twice the length of the oblong erect leaves. Native of the Cape of Good Hope, from whence it was brought to Kew by Mr. Masson in 1791. It flowers in the flower, from February to May. The root is perennial, with long and thick fibres. Leaves radical, about six feet long, resembling those of a Musa. Flowers white, bearing but a small proportion to the magnificent foliage.

Though this is what the younger Linnaeus meant by Heliconia alba, his specific character is erroneous, and the synonymy of Rumphius belongs to a species of Heliconia, not well ascertained.

3. S. angustifolia; Ait. n. 5.—Flower-tall, as well as the footstalks, seven times as long as the lanceolate leaves.

4. S. parviflora; Ait. n. 6.—Flower-tall, as well as the footstalks, twenty times as long as the linear-lanceolate leaves.

Native of the Cape of Good Hope, flowering in our flowers in the spring. Sir Joseph Banks, who has for nearly fifty years been indefatigable in enriching the gardens of this country, is recorded as having introduced this superb flower in 1773. Its habit resembles a Musa or Canna, except in the want of a stem. The leaves are smooth, rigid, and coriaceous, erect, on long, straight, stout, nearly cylindrical, smooth, radical footstalks, sheathing at the base. The form of the leaf itself is usually ovate, acute, entire; wavy or crisped at the base, especially on one side; furnished with a firming mid-rib, which tends off several simple, oblique, parallel, transverse veins. Scales one or two, at the top of the cylindrical, simple flower-tall, nearly horizontal, thick and rigid, purplish and thin at the edges, acute, four or five inches long, each containing many flowers, which expand in succession. The orange-coloured petals, three or four inches long, are strikingly contrasted with the blue-purple stamens, both together composing one of the most brilliantly coloured flowers in nature. We presume to think the S. ovata of Hort. Kew. does not deserve to be marked as even a variety, nor do the figures quoted answer to the character. The angustifolia, recorded as having been cultivated by the marquis of Rockingham in 1778, we can aver to be a mere variety of the Regina. If we mistake not, it was given to the marquis by Mr. Bamber Galcoyne. Of this we are certain, that offsets of the original root, in the flowers of the late marchioness, where for many successive years we have observed them, gradually diminishing in the size and breadth of their leaves, became first S. angustifolia, and then parviflora, of Hort. Kew. Similar varieties may indeed have been fresh imported from the Cape, but this does not prove their specific difference. In some specimens the leaf dwindles to a mere point.

3. S. farinosa. Mealy-tall Strelitzia. Ait. n. 4.—"Stalk rather longer than the footstalks, which are half as long again as the oblong leaves, unequal at the base."—Native of the Cape. Flowering in the flowers at Kew in February and March. It was introduced by Sir Joseph Banks in 1795. With this we are unacquainted, and therefore cannot prejudice to judge how far it is specifically distinct from the foregoing.

Strelitzia, in Gardening, affords a plant of the herbaceous, exotic, perennial kind, of which the species cultivated is the Canna-leaved Strelitzia (S. reginae). Method of Culture.—These plants are raised from seeds brought from their native situation, and sown in pots of good fine mould, being plunged in a hot-bed to get them up: the plants, when of some growth, should be removed into separate pots, and be replanted in the bed, in the fall; afterwards, when the plants are large, they should have plenty of mould, that the roots may be extended into the rotten tan, and in that way render them more strong for blowing their flowers: it may likewise sometimes be raised from the roots, when they are suffered to strike in the above manner: it is said to succeed better in the dry flower and conservatory departments.

This is highly ornamental among flower-plants.

STREME, in Geography, a river in Brandenburg, which runs into the Oder near the S. of Rathenow.

STREW, in Antiquity, new-year's gift; presents made out of respect on new-year's day, as an happy augury for the ensuing year.

The ancient lawyers derive the word hence, that these presents were only given vires flumen: Symmachus adds, that the use of them was first introduced by king Tattius, Romulus's colleague, who received branches of vervain gathered in the sacred grove of the goddess Streuna, as a happy preface of the beginning year. Angrily, a pound of gold was given to the emperors every new-year's day, by way of frons. Du-Cange observes, that frons, or frima, denoted a kind of tribute which the people of Dalmatia or Croatia paid to the Venetians, or to the kings of Hungary, whom they obeyed voluntarily.

STRENBERG, in Geography, a town of Austria; 10 miles E.S.E. of Ens.

STRENG, a river of Brandenburg, which runs into the Havel at Brandenburg.

STRENGNAS, or STROGOMAS, a town of Sweden, in the province of Sudermanland, situated on the Meier lake: it is the seat of a bishop, and has a celebrated gymnium,
STRENGTH, 

It has been said that the strengths of different animals of the same species, or of the same animal at different times, are in a triplicate proportion of the quantities of the maws of their flesh: the whole strength of an animal being the force of all the muscles taken together; therefore, whatever increases the strength, increases the force of all the muscles, and of those serving digestion, as well as others. See MUSCLE.

Yet, though the truth of this observation be allowed, the quantity of blood may be increased in such circumstances as to abate the strength. The equilibrium between the blood and vellere being destroyed, wonderfully lessens the strength. The sudden suppression of perspiration, though it increases the quantity of the blood, as it must considerably do by, it lessens the strength; because the retained matter, being what ought to be evacuated, alters the texture of the blood, as to make it unfit for muscular motion.

Suppose the increase of quantity to be connected with an extraordinary vividness, the quantity of small separable parts decreasing as the vividness increases, the quantity of animal spirits separated in the brain will be less; and the tension of the fibres being in proportion to the animal spirits forced into them, they will not be able to counterpoise the great weight of the blood, and so the strength will be diminished.

Bellini proves, that if the blood be so vitiated as to increase or diminish strength, it amounts to the same if the blood were in a natural state, but its quantity increased or diminished in the same proportion; so that the blood, when vitiated, may so impair the strength of the muscles, as even to spoil digestion, and yet, in some cases, it may be so vitiated as to help digestion, and increase strength.

M. de la Hire, in a calculation of the strength of a man in drawing and bearing, shews, that the strength of an ordinary man walking in an horizontal direction, and with his body inclining forwards, is only equal to twenty-seven pounds; which is much less than one would have imagined.

He adds, that this force would be much greater, if the man were to walk backwards; and that it is for this reason, that watermen fetch their casks from before backwards: and though, he observes, the gondoliers of Venice fetch them the contrary way, yet this is, because they choose to lose the advantage of strength, to have that of seeing the place they are going to, in the numerous turns and canals they there meet with.

It is known by experience, that a horse draws, horizontally, as much as seven men; consequently, his strength will be 189 pounds. A horse, as to pushing forwards, has a great advantage over a man, both in the strength of its muscles, and the disposition of the whole body; but the man has the advantage over the horse in ascending. M. de la Hire shews, that three men, laden with 100 pounds a-piece, will ascend a pretty steep hill with more ease and expedition than a horse laden with 300 pounds.

Hakewell, in his Apology, p. 238, furnishes us with abundance of instances of extraordinary strength.

STRENGTH, in Grammar and Rhetoric, denotes such a disposition or arrangement of the several words or members, as shall bring out the sense to the best advantage, render the impression which the period is designed to make most full and complete, and give every word and every member their due weight and force. A sentence, as Dr. Blair observes, may be sufficiently clear, and possess the requisite compactness or unity; and yet, by some unfavourable circumstance in its structure, it may fail in that strength or liveliness of impression, which would have been produced by a more happy arrangement. The first rule, which this writer gives, for promoting the strength of a sentence, is to divide it of all redundant words and members. The second rule is to attend particularly to the use of copulatives, relatives, and all the particles employed for the sake of connection. The third rule is to dispose of the capital word or words in that part of the sentence in which they will make the fullest impression. The fourth rule is to make the members of sentences go on rising and growing in their importance above one another; which kind of arrangement is called a climax (which see); in other words, a weaker alteration or proposition should never come after a stronger one; and when a sentence consists of two members, the longer should, generally, be the concluding one. The fifth rule is to avoid concluding sentences with an adverb, a preposition, or any inconsiderable word; because such conclusions are always withering and degrading. Besides particles and pronouns, any phrase, which expresses a circumstance only, always brings up the rear of a sentence with a bad grace. Another rule, relating to the strength of a sentence, is this: that, in the members of a sentence, when two things are compared or contrasted to each other, where either a resemblance or an opposition is intended to be expressed, some resemblance in the language and construction should be preferred; for when the things themselves correspond to each other, we naturally expect to find the words corresponding too. We might here add, that the sound, harmony, and easy flow of the words and members of sentences, contribute to promote their strength and effect. This rule comprehends the choice of words, and their arrangement; the order and disposition of the members, the cadence or close of sentences, and the sound of words as adapted to their signification. For the illustration and application of these rules, we refer to Blair's Lectures, vol. i. and Murray's Grammar, vol. i. See Style and Numbers.

STRENGTH and STRESS of Materials, in Mechanics, is a subject of very considerable importance, and one which, of all the branches of this useful science, is the least understood. We have, indeed, two or three distinct theories by different authors, for estimating the strength of beams, and other materials, according as they are placed in this or that position; but it unfortunately happens that we owe all these theories to men who have not themselves made any experiments, and have, therefore, no better foundation than mere hypotheses, and consequently are not only discordant among each other, but totally at variance with practical results. The authors to whom we more particularly allude in this place, are Galileo, James Bernoulli, Leibnitz, Euler, and Lagrange; names certainly of the first eminence as philosophical mathematicians, and whose respective investigations, while we only contemplate the analytical processes of them, are highly honourable to the genius and talents of their authors; but when we consider them with reference to their practical application, we are obliged to admit that they are almost entirely useless. Had the materials the properties these authors suppose, viz. that they were perfectly elastic in one case, or perfectly rigid and incompressible in another, then we should doubtless find the results such as have been deduced; but we know that, practically, none of these properties are found to have place. We know of no bodies either perfectly hard, or perfectly elastic; we know of no bodies that are either wholly
STRENGTH OF MATERIALS.

wholly incomprehensible, or inextensible; and, consequently, of none to which these theories will apply; being each founded upon some hypothesis, which necessarily involves one or other of these principles as their bases. There is, however, another class of men to whom we are indebted for many varied experiments; but not one of them, we believe, has ever attempted to establish any theory, as founded upon the facts which these experiments have established. Of the latter classes are more particularly to be distinguished Marotte, Parent, Belidor, Mulchenbroeck, and Buffon, particularly the latter, who, with Du Hamel, was employed by the French government in making experiments on a very considerable scale; but unfortunately M. Buffon conducted them rather as a natural philosopher than as a mathematician, and, therefore, did not deduce from them those useful practical results, which might a priori have been expected. Our countryman, Emerson, also made some experiments on the strength of various materials; but little confidence is, we believe, to be placed on his determinations. They appear to have been made in too gross a manner to be at all dependent upon, to form the groundwork of any calculations; as, in some cases, they nearly double the strength which has been found by other and more accurate experiments; while, in some, they make it not more than half. Thus, Emerson says, that a piece of oak, 1 yard long and an inch square, when supported at its two ends, bore, before breaking, 330 pounds; whereas Belidor makes the strength only 187 pounds; and we have repeated the experiments on several pieces of oak of the same dimension, and have found a very accurate agreement between them, and the mean given by the latter author, viz. 187 pounds. The direct strength of cohesion of the different woods given by Mulchenbroeck and Emerson are also much at variance with each other; and though we ought not perhaps, in such a case, to give our entire confidence to either, yet the care Mulchenbroeck appears to have taken, and the minuteness with which he describes the processes he employed, cannot but incline us to adopt his results, in preference to Emerson's, till some farther experiments have been made, that, from their number and accuracy, may inspire us with greater confidence. Such a course of experiments is now carrying on at the Royal Military Academy, Woolwich, by Mr. Barlow of that establishment; and as nothing will doubtless there be wanting to render the course complete, either with regard to the facts and the observations applied to the workmanship that may be required, the publication of them will doubtless be very interesting, as the means of supplying a great defideratum amongst the scientific engineers of this country. "This subject," says Dr. Robison, "is of so much importance, that in a nation so eminent as this for invention and ingenuity in every species of manufactures, and in particular so distinguished for its improvements in machinery of every kind, it is somewhat singular that no writer has treated of it in detail, which its importance and difficulty demand. The man of science, who visits our great manufactories, is delighted with the ingenuity which he observes in every part, the innumerable inventions which come even from the individual artificians, and the determined purpose of improvement and refinement which he sees in every work-shop. Every cotton-mill appears an academy of mechanical science; and mechanical invention is spreading from these fountains over the whole kingdom. But the philosopher is mortified to see this ardent spirit fo cramp'd by ignorance of principles, and many of these original and brilliant thoughts obscured and clogged with needless and even hurtful additions, and a complication of machinery which checks improvement, even by its appearance of ingenuity. There is nothing in which this want of scientific education, this ignorance of principle, is so frequently observed, as in the injudicious proportion of the parts of machines, and other mechanical structures; proportions and forms of parts, in which the strength and position are in no wise regulated by the strains to which they are exposed, and where repeated failures have been the only lessons."

Without entering here upon the subject of corpuscular attraction, and the law of cohesion which the particles of bodies observe, according to their different arrangements, a topic that would carry us far beyond the limits we can assign to this article, and on which, after all, so little factitious information is to be expected, we shall proceed to examine the different strains to which a body may be exposed, and its tendency to refit fracture, according to its magnitude, form, and position.

A piece of solid matter may be exposed to four different kinds of strain, viz.

1. It may be torn asunder by some force applied in the direction of its length; as in the case of ropes, lathetters, king-poles, tie-beams, &c.

2. It may also be crushed by a force applied in the direction of its length; as in the case of pillars, polls, and truss-beams.

3. It may be broken across by a force acting perpendicularly to its length; as in joists, levers, &c.

4. It may be wrenched or twisted by a force acting in a kind of circular direction at the extremity of a lever, or otherwise; as in the case of the axle of a wheel, the nail of a prief, &c.

On the direct Cohesion of Bodies.—The first of these strains is by far the most simple, as to its physical operation; though it is that of all others, perhaps, that comes least under the consideration of a mechanic or engineer; and when it is the subject of contemplation, if any former experiment can be had recourse to, it is sufficient for his purpose; as no possible cause can be ascribed, nor any reason offered, for supposing that, in such cases, the strength varies directly as the area of the section of fracture, and thus independent of the length or position; except, indeed, so far as the former may increase the weight or force, when the body is supported in a vertical direction, or in any other position where the weight of the body itself increases the pressure. The action of the portion of the body is equally liable to fracture, being throughout stretched by the same force. But this supposes a perfect uniformity of corpuscular action, or of the attraction of cohesion, which is probably not the case in any body in nature; and, therefore, as the longest body, may be supposed to offer the greatest diversity in this respect; it may hence happen that the longest body is the weakest, and it is probably to this circumstance we must attribute the popular notion of our mechanics, that a long rope is easier broken than a shorter one of equal quality and thickness. It is a fact perhaps drawn from experience, but it is one which cannot be introduced into the science of mechanics; for we must there suppose the body of uniform texture, and draw all our inferences from that source; and this obviously leads us to the above conclusion, viz. the strength of bodies, exposed to strains in the direction of their length, is directly proportionate to their transverse area, whatever may be their figure, length, or position.

As to the irregularities to which we have above alluded, they doubtless arise from a thousand circumstances, with which we are wholly unacquainted; in metals, it depends upon
STRENGTH OF MATERIALS.

Upon their purity, the heat at which they are melted, the moulds in which they are cast, the manner in which they are left to cool, and many others, which totally escape our observation, since they produce different degrees of cohesion between the particles, which, as far as our observation can extend, are circumstance in every respect in the same manner, being all blended in one mass, and indistinguishable one from the other.

It has been ascertained from experiment, that by forging a metal, or by frequently drawing it through a small hole in a steel-plate, its cohesion is considerably increased; a fact which, though it seems to be too simple a statement, appears to us to be perfectly reconciliable with what might be expected to have been expected in the increased density which this operation is known to produce. Admitting the parts to be placed at equal distances from each other, after wire-drawing or forging, as we suppose them to be before, their lateral distances will decrease as the cube root of their densities, and consequently the number that are brought in contact in equal sections, are as the 3d power of the density; the strength, therefore, ought to vary in the same ratio: as to the distances in the direction of the length, we do not conceive that it increases the strength; it may render the substance less liable to rupture in the first instance; but if, as in all probability the case is, the particles are ultimately removed to a greater distance before the fracture takes place, the same ultimate force will be requisite to separate the parts, however close the contact might be in the original state of the body; that is, when first submitted to the experiment.

We are unacquainted with the real increase of strength that may be obtained by the processes above alluded to; and more particularly with the lateral approach of the particles, which may be greater than would arise from a uniform distribution of them; and are therefore unable to say how far the increased strength agrees with what we have hinted may arise from the increased cohesion of the particles. Leads which is said to become harder by wire-drawing, has its cohesion tripled; gold, silver, and brass, have also their cohesion nearly tripled; and copper and iron have theirs more than doubled. How far these facts can be satisfactorily explained by the greater contiguity of the particles laterally, we cannot pretend to say, but it certainly will account for a considerable part of the increased strength.

Experiments on the direct cohesion of all bodies, and particularly metals, are attended with considerable difficulty, in consequence of the enormous weights that are required in producing separation in bars of any considerable dimension: we have, however, a few results of this kind, which we owe to Mülchenbroeck, and other experimentalists, the principal of which are contained in the annexed table, all reduced to the section of a square inch.

It is very remarkable, that almost all mixtures of metals are stronger, or more tenacious, than the metals themselves, much depending upon the proportion of the ingredients, and these proportions are different in different metals. The following are some of those which Mülchenbroeck allerts to produce the greatest strength.

<table>

These results are very useful, provided they could be securely depended upon; but we could wish to see similar experiments repeated by other philosophers: not that we wish to undervalue the labours of Mülchenbroeck, to whom the arts are much indebted for many valuable deductions, but much irregularity takes place in experiments of this kind, that it is only in a multiplicity of them, complete accuracy, or even an approach towards it, is to be obtained.

The gun-founder might derive considerable information from a well-directed course of experiments of this kind, as well as the plumber and engineer; it appears from the above, that a mixture of copper, whose strength does not exceed 37,000 lbs., with tin, whose strength is 60,000 lbs., is a mixture produced, whose strength is from 60,000 lbs. to 64,000 lbs., at the same time that it is harder, and easier wrought; and as to the objection that has been advanced against it, of being more fusible, we refute it nothing more than a false idea arising out of a very common error, that field-ordnance is liable to become fusible with rapid firing: we have been informed by very experienced artillery officers, that nothing of this kind ever happened, the damage which the piece sustains at the muzzle being merely due to the rubbing and knocking of the ball in its passage out of the gun.

Having said thus much with regard to the direct cohesion of metals, we must now attend to another very important subject; viz. the strength of timber.

The cohesion here is probably of a very different kind, and subject even to more inequalities than that of metals; much depends upon the soil where the tree grows, and a considerable difference is found between different parts of the same tree;
STRENGTH OF MATERIALS.

The wood immediately surrounding the pith or heart of a tree, is said by some to be the weakest, particularly if the tree is old; others, especially Buffon, affirm the contrary; the fact probably is, that up to a certain age it is strongest at the heart, but that afterwards these parts become weaker, or begin first to feel that decay which ultimately pervades the whole. In many experiments which we have made, we have always observed that the heaviest pieces (and there is a very considerable difference in this respect in different parts of the same tree) are the strongest; and, generally speaking, the part nearest the centre and towards the root has the greatest specific gravity.

1. The wood of the north side of all trees in our climates is said to be weaker than that of the south, and the south-east side the strongest: we are, however, much inclined to doubt the fact, as it relates to forest-trees. In trees particularly situated, with regard to exposure on one part more than another, something of the kind may have place; but trees in a forest, which experience very little difference in this respect, we are inclined to think, from some observations, have but a slight difference of strength depending upon their northern or southern direction. It is true, generally, that that wood is the strongest whose annual plates are thickest, the ligneous fibres being stronger than the trachea, or air-vessels; and, therefore, the more of the fibrous parts there are contained in any given dimension, the greater is the strength: but this is much more obvious in some woods than in others, and most of all, perhaps, in ash, in which we have seen a very remarkable difference in this respect. In very close-grained wood it is scarcely perceptible.

The only author who has enabled us to judge of the accuracy of his experiments is Murchenbroeck, who has described very minutely his apparatus, and his method of performing the experiments. The pieces employed for this purpose were parallelepipedons, cut down in the middle to 1/4 of an inch square, or 1/16 of an inch section. These results, reduced to the section of a square inch, are as follow:

<table>
<thead>

</tbody>
</table>

Emerson, in his Mechanics, gives us also a series of results, but they are unlike the former, as they do not exhibit the utmost strength, but what may be safely suspended on a square inch; yet as we may presume that each of those weights are in the same proportion to the greatest strength, they ought to enable us, in some measure, to compare the relative strengths of the different woods given by these two authors. Emerson's table is as follows; viz.:

<table>
<thead>
<tr>
<th>Wood</th>
<th>Lbs.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Oak, box, yew, plum-tree</td>
<td>7850</td>
</tr>
<tr>

</tr>
<tr>
<td>Cherry, hard</td>
<td>4760</td>
</tr>
<tr>
<td>Alder, as, birch, willow</td>
<td>4290</td>
</tr>
</tbody>
</table>

With regard to the absolute results in these two tables, we do not, of course, look for uniformity; the one exhibiting the ultimate strength, and the other the weight which a rod of an inch square may support with safety: but in the relative strength of the different woods, some coincidence might have been expected; we find, however, considerable difference in this respect. The latter author gives us no particulars, and we are therefore rather inclined to give the preference to the former, who has been very minute in his description, as well as careful in making the experiments; yet some sublunary experimentalists have not been able to find equal strength: thus M. Petit fays on the authority of his own observations, that the strength of oak is 17,500 lbs.; whereas Murchenbroeck makes it 17,300 lbs.; and we must add, in confirmation of the former, that in the experiments to which we have before adverted, as at this time in progress at the Royal Military Academy, Woolwich, the strength of oak has been found but little exceeding 9000 lbs.; the specific gravity of it being 774. We have not this datum in either of the above cases; yet we conceive it to be a very important one, as we have always found the strength of wood of the same thickness, to depend a great deal upon its weight and specific gravity. The former experiments give for the strength of ash 17,000 lbs., and fir from 15,000 lbs. to 13,000 lbs., both considerably different from Murchenbroeck's tabular results.

On the Resiliency of Bodies, when pressed longitudinally.

It is obvious that a body, when pressed endwise, by a sufficient force, may be crushed and destroyed; and this may take place, either by a total separation of the matter of which it is composed, or by bending it, whereby it is broke across: if the length or height of the body is very inconsiderable with regard to its other dimensions, the former is the almost certain result; but if its length be much more than its breadth and thickness, it generally bends before breaking, and in this case the operation is not very different from what takes place in beams supported at each end, and loaded in the middle; a subject which will be treated of in a subsequent part of this article. We have some very intricate analytical investigations on this subject by Euler and Lagrange. These authors have both treated the problem on the principles first promulgated by James Bernouilli, in his investigation of the properties of the elastic curve; but as we doubt very much whether they can be applied to any useful practical operations, we must beg to pass them over in this place, by merely referring such of our readers who are desirous of consulting the investigations of these two very able mathematicians, to the original works. Euler's first memoir will be found in the appendix to his "Methodus inveniendi
STRENGTH OF MATERIALS.

inveniendi lineas curvas maximi et minimi, &c." 1744.
A second memoir is published in the Berlin Transactions for
1757, and a third in the Acta Petro. 1778. Lagrange's
papers are given in the Turin Memoirs for 1770-1, and in the
Memoirs of Berlin for 1769.

As to the experiments that have been made on this kind of
strain, there are few from which much practical information
may be obtained. M. Petit says, that his experiments,
and those of M. Parent, shew that the force necessary for
crushing a beam is not equal to that which will tear it
asunder. He says that it requires something more than 600
on any square line of sound oak to crush it. But experi-
ments made on such small pieces cannot be depended upon ;
and when they are made on pieces of greater dimensions, the
weights become so enormous, as to render them nearly im-
practicable; it is therefore fortunate that we have little oc-
casion for very accurate information on this head: what is
more defirable to be acquainted with is, the resistance which
a pillar or post will offer to compression before bending; the
length being taken into consideration; for it is obvious, both
from theory and practice, that the length of the beam must be an important datum in
this kind of strain, although it is not in the former, vis. in
opposing being drawn asunder; it is therefore very defective to
state the requisite forces in both cases to be equal, or in
fact to state any proportion whatever between them.

M. Girard, in his "Traité Analytique de la Réistance
des Solides," Paris, 1796, details a great variety of ex-
periments made on beams of fir and oak of considerable di-
ensions, by means of a certain machine constructed for the
purpose. But as these experiments were not made so much
with a view of breaking the pieces submitted to the presure,
as to measuring their deflections, and estimating what the
author calls, after Euler, their absolute and relative elas-
ticity; they do not furnish us with the kind of results above
alluded to, as having been attempted by MM. Petit and
Parent.

Through the whole course of M. Girard's experiments,
much irregularity was observed, so much, indeed, as to ren-
der it very doubtful whether any number of experiments
could furnish us with certain and conclusive results; and if
experiments fail in this respect, it is wholly useless to look
to any assistance from long and laborious analytical in-
vestigations. The following table contains many of the most im-
portant experiments of this author on oak-beams; the first
column registers the number of the experiments; the second,
third, and fourth, the length, depth, thickness, and weight of
the beams; the fifth and sixth the distance of the greatest
deflection from the bottom or foot of the beam; the former in
the direction of the greatest thickens or depth; and the
latter in the direction of the less thickens or breadth; the
seventh and eighth columns contain the measure of the greatest
deflection, or vered line of the curve; the former of the depth,
and the latter of the breadth; the ninth column exhibits the
weights under which the several deflections were observed,
and the tenth and last column the time between the first
weight being applied and the observation. It should be ob-
erved, that M. Girard has given several more measures of
deflections, weights, &c. than we have copied; we have, in
all cases, taken his third and last two, and omitted the
intermediate ones.

The experiments marked with an asterisk broke under the last
registered weight; the others did not, and most of the latter

nearly recovered their original form after being unloaded for
some hours. The deflections marked + and — are those in
which the beam took a double curvature.

The other experiments of this author (the details of which
occupy nearly 50 quarto pages) were made on the trans-
verse strain, or rather on the deflection caused in beams by
loading them in the centre with different weights, their ex-
tremities being supported on two props.

The oak-beams were the same which had been submitted
to the longitudinal pressure, as exhibited in the following
table, and which were not broken in those experiments;
the third table contains the results of similar experiments on
fir-beams of larger dimensions; and the two subseqent

tables, similar ones on what the French workmen call bois
de brin, that is, pieces which have been simply squared from
the branches, or trunk, corresponding with what our work-

men call &c.

In all these cases, the deflection was found to follow very
nearly the ratio of the weights with which they were loaded,
multiplied by the square of the length of the piece, and to
be inversely as the square of the depth into the breadth.
The fir-beams gave much more uniform results than those of
oak, which is accounted for from the more regular and
uniform organization of the former wood.

M. Girard endeavours to connect the results with those
on the longitudinal pressure, for which purpose he gives us
the following formulae, vis. let \( f \) denote half the length
of a beam, supported at each end and loaded in the middle, and
let \( h \) half that weight be denoted by \( P \), and \( b \) the quantity
of the beam's deflection; also \( 
\frac{\pi^2 E k b}{4 f^2} \)
and the weight \( Q \), under which the same beam will begin
to curve, when pressed endwise, will be expressed by

\[
Q = \frac{\pi^2 E k b}{4 f^2},
\]

or, by substituting for \( E k b \), we have

\[
Q = \frac{\pi^2 P f}{12 b}.
\]

We cannot, however, say how far this formula will ap-
ply, it being very difficult to ascertain the commencement
of deflection in the actual experiment.

M. Girard gives us also two other formulae, for estimating
the deflection of oak and fir beams, when loaded in the mid-
dle by a weight, and supported at each end, vis.

\[
\frac{P f^3}{3 b} = (11784451)(f + 0.3) a b^2
\]

for oak,

\[
\frac{P f^3}{3 b} = (8161128) a b^2
\]

for fir,

where \( P \) is half the weight, \( f \) half the length, \( b \) the deflec-
tion, \( a \) the depth of the beam, and \( b \) its breadth.

These apply only to rectangular beams; and, in order
to render them general, the author uses the principles of
Leibnitz, whereby the errors of the latter are connected with
them in such a manner as to render the formula entirely
utile for practical cases.

Vol. XXXIV.    Girard.

STRENGTH OF MATERIALS.

The reader will perceive considerable irregularity in many of the above experiments, both with regard to the height at which the deflection begins, the quantity of it, and its direction; being sometimes in the line of the greatest thickness, and sometimes in that of the leaf, but more commonly in both. It will also be observed, that some of the beams broke under less pressure than others, of the same or less dimensions, bore without any apparent injury.

We cannot enter here into a farther explanation of the experiments, nor shall we attempt to illustrate the theory which the author seems desirous of establishing, both because it would carry us beyond our limits, and that, at the same time, we are very doubtful of its accuracy. When the only deduction is a mean drawn from a great variety of very irregular results, it is of little use to the practical engineer. He had much better be furnished with the several experiments, and thence form his own judgment of what dimensions will best suit his purpose, according to the particular object he may have in view; and in this respect, vis. in the detail of the experiments, rather than in theory deduced from them, we ought to esteem the value of this author’s labours, which have been very great, and are deserving of high commendation.

The only experiments, besides the above, that appear entitled to any notice, are those of M. Gaunthez, in the fourth volume of Rozier’s Journal de Physique.

This engineer exposed to great pressures small rectangular parallelepipeds, cut from a vast variety of stones, and noted the weights which crushed them. The following table exhibits the medium results of many trials, on two very uniform kinds of free-stone, one of them among the hardest, and the other among the softest, used in building.

The first column contains the length, the second the breadth, and the third the area, of the section, in lines, or twelfths of inches; the fourth is the weight in ounces which crushed the stone; and the fifth the whole numbers, which nearly expresses the number of ounces borne by each square line.

Very little can be deduced from these experiments. The first compared with the third, and the fifth with the sixth, should furnish similar results; for the first and fifth are respectively half of the third and sixth, but the third is three times stronger than the fifth, while the sixth is only double the strength of the fifth.

In all these results, the strength increases faster than the area of the section, and that a square line can carry more and more weight, as it is a part of a larger surface; but in the experiments on the soft stone, the strength seems to increase more nearly in proportion to the surface.

These experiments are doubtless upon too small a scale to be of any essential service to the practical engineer: the pieces of stone ought certainly to have had a square inch of surface at least, and the weight which would have been necessary to crush them would not have been so enormous, but that some very simple mechanical apparatus might have been made sufficient for the purpose; and if any tolerable uniformity were observed in pieces of that size, some useful conclusions might possibly be drawn from the experiments.

But we think little confidence can be placed in those made on pieces of such small dimensions. According to M. Gaunthez’s deductions, a pillar of hard stone of Givry, whose section is a square foot, will bear with perfect safety 664,000 pounds; and its extreme strength is 871,000 pounds; and the leaf, as observed in his experiments, 460,000 pounds. The soft bed of Givry stone had for its least strength, on the same surface, 187,000 pounds; for its greatest, 311,000 pounds; and for its safe load, 240,000 pounds.

Good brick will carry with safety 320,000 pounds, on a free foot; and chalk, 300,000 pounds.

Besides the above experiments on the force necessary for crushing stone pillars, M. Gaunthez made others on their strength of direct cohesion, as well as on the transverse strain. He found that a prism of hard Givry stone, of a foot section, was torn asunder by a weight of 4500 pounds; and that, when firmly fixed in a horizontal wall, it will be broken by a weight of 56,000 pounds, suspended at the distance of twelve inches from its junction; and, if it rests upon two props, a foot distant from each other, it requires 365,000 pounds laid on its centre to produce the fracture.

We shall merely observe here, that these results are very inconsistent with each other; and that some mistake, or some very unaccountable irregularity, must have taken place in the experiments, that it should require so much more weight, acting at the distance of a foot, to produce the separation, than when the force acted at no mechanical advantage whatever, as in the case of direct cohesion.

Very different to the above have been the results of such experiments as we have performed on different kinds of wood. An oak rod of an inch surface requires a weight of about 9000 pounds to produce the fracture; while the same, or a similar rod, fixed in a wall, and acted upon at the distance of a foot, is broken with a weight of 152 pounds, and sir, which will bear 13,000 pounds on a square inch, suspended vertically, is broken with a weight of 136 pounds.

We are aware, that in different materials, a different law may be observed between the strength of direct cohesion and the resistance of the same body to a transverse strain; but it is absolutely impossible to have the difference stated by M. Gaunthez. A good course of experiments is, therefore, much wanted on materials of this kind.

We ought perhaps to observe, that we have not had an opportunity of consulting the work in which M. Gaunthez’s experiments were originally given. Our numbers are drawn from Dr. Robison’s account of them, in the work to which we have before referred.

On the transverse Strain and Strength of Beams, &c.—The most usual strain, and, therefore, the one with which it is most important for us to be well informed, is that by which a body is broken across, from the action of a weight being perpendicularly or obliquely to its length, while the beam itself is supported at its two extremities, or by one end and being firmly fixed in a wall, or other solid and immovable body. Galileo, to whom the physical sciences are so much indebted, was the first who connected this subject with mathematical principles, and endeavoured to trace the law of strength which different bodies possessed, in proportion to their length, breadth, depth, form, and position. It appears that this philosopher was led to these observations, in consequence of a visit that he made to the arsenal of Venice, and the results of which were published in his Dialogues in 1635. Galileo supposed solid bodies to be composed
composed of small fibres applied parallel to each other, and
fought, or assumed, at first, the force with which they re-
flitted the action of a power to separate them, applied
parallel to their length; and thence readily deduced that
their reftaintse, in this direction, was directly as the area
of the transverse perpendicular section, that is, to the num-
ber of fibres which compose the body. He then consider-
ed in what manner the same fibres would oppose a force ap-
plied perpendicular to their length; and concluded, that
when a beam is fixed horizontally in a wall, the reftaintse
of the integral fibres is proportional to their sum, mul-
tiplied into the arm of a lever, which is always a certain
part of the vertical dimension of the solid in its plane or
area of fracture. This general principle is, in fact, adopted
by most writers on this subject; but that which is peculiar
to Galileo is, that he supposed the reftaintse of each fibre
to be the same, and, therefore, in a wholly independent
of their quantity of extension at the moment of rupture.
Supported on the result of these reftonings, and guided by
the genius for observation, which he possessed in an eminent
degree, he illustrated many of the proceedings of nature,
which the more ancient philosophers had left unnoticed;
as well as certain anomalies, or which then appeared as such,
in the works of art. To some of his observations on this sub-
ject we may have occasion to advert, in a subsequent part
of this article; but at present we shall confine ourselves
to the illustration of his particular theory. It will be pro-
bably seen, however, that a few of the terms which more
commonly occur in the course of our investigations.

We have already explained what is to be understood
by the absolute strength of a body, or its strength of direct
cohesion; viz. the number of pounds weight necessary to
produce a fracture of its parts, when applied in a direction
parallel to its length.

And as to the words strength, stress or strain, they are
used, the former to denote the force or power with which
any mass or body reftills a breach or change in its state,
which a pressure or stroke upon it has a tendency to pro-
duce; and the latter are used indiscriminately to express the
force which is exerted on any such mass, and tending to
break it. Thus, every part of a pillar is equally strained
by the load which it supports; and hence it is evident that
we cannot make any structure fit for its purpose, unless the
strength, in every part, be at least equal to the stress laid
on, or the strain exerted in that part; and hence the ne-
cessity of an acquaintance with the nature of the reftaintse
of bodies, in order that we may not have our structure deficient
in strength, nor over-burdened with useless materials; which
latter, carried to excess, may be the cause of producing the
mischiefs they were intended to prevent.

In order to illustrate the theory of reftaintses of bodies,
when exposed to a transverse strain, according to the hy-
pothesis of Galileo, let RSTV, (Plate XXXIX. Meth-
ematics, fig. 1.) represent a solid wall, or other immoveable
mass, into which the beam, C G, is inserted; and let W
represent a weight sufficient from its other extreme-
ity. Then supposing the beam to be inerupably strong in
every part, except in the vertical section A B C D, the
fracture must necessarily take place in this section only,
and, according to the hypothesis of this author, it will
turn about the line C D, whereby the fracture, commen-
cing in the line A B, will terminate in the former, C D.
Galileo also further supposes, that the fibres, forming the
central horizontal plates or lamina from C D to A B, act
with an equal force in refilling the fracture, and, therefore,
differ in their energy only as they act at a greater or less
distance from the fulcrum C D. Now, from the known
principles of the lever, it is obvious that the equal forces
acting at the several distances o a, o b, o c, o d, &c. of the
lever o, will offer reftaintses proportional to their respective
distances; and, therefore, that the sum of all these re-
ftaintses, that is, of the confluent forces, of each particle
into its respective distance, is the force which must be over-
come by the weight W, acting at the distance o K.

This will, perhaps, be better understood by referring to
fig. 2, where A C I F represent a section of the beam C G,
and r, r', r", &c. are so many small equal weights acting
at the several distances C M, C M', C M", &c.; then denoting
each of these weights by the constant quantity f, the sum of
all their energies or reftaintses will be expressed by A C
.+ C M f + C M' f + C M" f + &c. = f x (A C +
C M + C M' + C M" + &c.) This, however, supposes the
section A C D B (fig. 1.) to be rectangular or that the
number of fibres in each horizontal lamina are equal in
number. When the beam is triangular, cylindrical, or
having any other than a rectangular section, the several
small weights must be proportional to the breadth of the
section at the point where it is supposed to act: the illus-
tration, in this case, however, is equally obvious.

Since then the whole reftaintse to fracture is made up of
the sum of the reftaintses of every particle or fibre acting at
different distances on the lever C A, which is supposed to
turn upon C as a fulcrum, there must necessarily be some
point in that lever, in which, if all the several forces were
united, their reftaintse to the weight W would be exactly
the same as in the actual operation, and this point is the cen-
tre of gravity of the section, as is readily demonstrated as follows.

Let A B C (fig. 3.) represent the section of any beam
whatever, F H any variable abscissa = x, and D E the cor-
responding double ordinate = y; then, by what is stated
above, the energy, or force, of all the particles in the line
D E, will be as D E x F H, or as x y, and consequently
the fluxion of that force will be y x x, and therefore the
sum of them = f y x x, or fluxion of y x x; also y x = area
A B C; whence, assuming G to be the centre of energy
fought, we must have F G x f y x = f y x x, whence

F G = f y x x
f y x,

which is the well-known formula for the centre of gravity.

Hence refults the following very simple theory for the
strength of beams placed firmly in a solid wall, or other
immovable body; viz. that "the weight necessary to pro-
duce the fracture, is to the direct force of cohesion of all
the fibres in the section, as the distance of the centre of
gravity of that section from the point where the fracture
termimates, to the length of the beam, or distance of the
weight from the same point."

Nothing more simple can be defined as a general theory,
but unfortunately it is founded on hypotheses which have
nothing equivalent to them in nature: in the first place, it
assumes the beam to be inerupably strong, and inerupably
strong, except at the section of fracture; secondly, that the fibres
are inextensible and incompressible; and thirdly, that the
beam turns about its lowest point, when fixed at one end,
or its upper, when supported at both; and, consequently,
that every fibre in the section is exerting its force in refilling
extension; and, lastly, (if this be not implied in our second
objection,) that every fibre acts with equal energy, what-
ever may be its quantity of extension. Now, with regard
to the fist of these suppositions, it is obvious that no beam of
timber, nor any other body, is perfectly inerupably strong; nor
STRENGTH OF MATERIALS.

any (and more particularly timber) whose fibres are not both extensible and compressible; and, consequently, a beam of such matter will not turn about its lowest point as a fulcrum; and, lastly, the supposition of every fibre exerting a centesimal restance, independently of its quantity of extension, if it be not incorrect, is of that nature which ought not to be assumed, without first being verified by experiment. Such being the inaccuracy of Galileo's hypothesis, it necessarily happened, as soon as it was attempted to compare it with experiments, (which the author himself had never done,) that it was found defective. The first, we believe, who did this was Mariotte, a member of the French Academy in 1680; and what he published on the subject engaged the attention of many celebrated mathematicians of that day, particularly Leibnitz; who, after examining the theory of Galileo, published his own thoughts on the subject. He had frequently remarked that the rupture of a body, whatever it may be, is always preceded by a certain degree of inflection, from which he concluded, contrary to the former opinion, that every body was composed of extensible fibres, and asuming the principle first laid down by Dr. Hooke, viz. "ut tenso farcis," he concluded that every fibre, instead of acting with an equal force, exerted a power proportional to its quantity of extension, or, which is the same, proportional to its distance from the line about which the beam was supposed to turn; but he still considered the fibres to be incompressible, and consequently that the beam turned about its lowest point. Thus, to use a similar illustration in this case that we have done in the former; instead of the fracture being opposed by the action of the equal weights at r, r', r", r"', &c., as in fig. 2, the re-action was supposed to be equal to the several equally decreasing weights at r, r', r", r"', &c., &c. The only alteration which this new supposition introduced into the final result was, the removal of the centre of energy, C, to a point nearer or farther from the centre of motion, according to the figure of the body; and this new point is found to be distant from that axis, by a quantity equal to the product of the distances of the centre of gravity, and centre of oscillation of the area of fracture, from the axis of motion, divided by the depth of the section.

For let ABC (fig. 3.) represent the section of fracture on any beam; F H = x, any variable abscissa; and D E = y, the corresponding double ordinate; allo make C F = d, and let f represent the absolute and ultimate force of a fibre at C, in the moment of rupture; then, since the force of each fibre is supposed to vary as its extension, or as its distance from F, we have:

\[
\frac{f y' y}{d} = \text{the force of a particle at H; and the number of particles acting at this distance being } y, \text{ we shall have } \frac{f y' y}{d} \text{ for the sum of the forces of all the fibres in the line D E; but this force, acting upon the lever at the distance H F, its resistance will be } \frac{f y' y}{d}, \text{ and hence the sum of all the restances of every fibre in the section will be } \int \frac{f y' y}{d} \text{; now this is to be equal to the direct cohesion of all the fibres acting at some required distance F I; that is, } F I \times \int \frac{f y' y}{d}, \text{ an expression which is exactly equivalent to the general expression } \int \frac{f y' y}{d}, \text{ for the centre of oscillation of a body, multiplied by } \frac{f y' y}{d}, \text{ the general expression for the centre of gravity, divided by } d. \text{ Hence, as these centres are known in most bodies which come under our consideration in the present subject, it will be useful to avail ourselves of them in determining what may properly be called the centre of energy, or centre of tension.}

This being the case, both theories gave the same results, so far as related to the comparison of the strength of similar beams, but of different dimensions; thus, from both, it was shown, that beams of the same depth and breadth were to each other, in point of strength, inversely as the length; that when the length and depth were the same, the strength varied as the breadth; when the breadth and length were the same, the strength was directly as the square of the depth; deductions which have been found to agree very nearly with experiment. There were, however, some expressions arising out of these two hypotheses which were totally irreconcilable with each other. In the first place, although the proportions were the same, the absolute strength in the one case, was to that in the other as 2 to 3, in rectangular beams; and in triangular beams, the disagreement was still more striking; also, according to Galileo, the strength of a triangular beam, with its edge upwards, was to the same with its base upwards, as 1 to 2; and, according to Leibnitz, as 1 to 3; whereas, as we have found from numerous experiments, it is stronger in the former position than in the latter, at least in woods of some kinds, and probably in all.

These anomalies led James Bernoulli to investigate the question de novo. This philosopher observed, that at the instant a body is broken across by a transverse strain, such as we have all along supposed, a part of the fibres is in a state of extension, as assumed by Leibnitz, and a part in a state of compression, a circumstance which had not before been introduced into the consideration of the question: he moreover doubted of the propriety of the principle, ut tenso fic vis, employed by Leibnitz, and made some experiments, whereby he proved that this is not, at least, a general principle; but the only effect of his observations and experiments went no farther than proving that Leibnitz's theory was inadmissible, for he substantiated no other in its place, except so far as his theory of the elastic curve (a problem which grew out of the present question) may be considered as applicable to this subject; had he pursued the idea he seems first to have promulgated, of a part of the fibres being compressed, and a part in a state of tension, and consequently that the line about which the beam turns is somewhere within the area of the section of fracture, we might have expected, from his extraordinary talents, a complete solution of this very interesting problem; instead of which, he contented himself with stating a few general observations, and pointing out the difficulty of the determination of the neutral axis, or of that line which sufers neither compression nor extension, which is the principal desideratum for establishing a correct theory; and in that state he left the question, and in that state it has ever since remained.

The only other attempt, that we know of, at establishing a new theory, is that given by Dr. Robison, under the article Strength, in the Encyclopaedia Britannica. This author
STRENGTH OF MATERIALS.

The author has taken into his consideration the areas of compression and of extension; but for want of experiments, is unable to assign the position of the neutral axis: we suspect, also, an important error in the principle which he has laid down, viz. that notwithstanding the beam really turns about what he properly calls a neutral axis, yet that in our investigation, we must compute the effect of the rotation, as if it was made about the centre of compression. We were much struck with the singularity of this assertion, and have, we believe, proved its fallacy in various experiments.

There is no doubt, from various experiments, and particularly from those of Du Hamel, when a piece of timber is submitted to the transverse strain we are considering, that only a part, and probably but a small part, of the whole number of fibres, has a tendency to refit the fracture by means of their tension, while the rest of the fibres act merely from their resistance to compression. Du Hamel was, we believe, the first author who demonstrated the fact by experiment. He took eighteen bars of willow, two feet long, and half an inch square, and supporting them by props under their ends, he broke them by weights hung on their middle. Four of them broke with the weights 40, 41, 47, and 53 pounds, the mean of which is 45. He then cut four others of them through one third of their depth on the upper side, and filled up the cut with a thin slip of harder wood, stuck in pretty tight. These were broken with weights of 48, 54, 52, and 50 pounds, the mean of which is 51. He then cut four others half through, and these required 47, 49, 50, and 46 pounds to break them, the mean of which is 48; the remaining four were cut to two thirds of their depth, and their mean strength was 42 pounds.

In another set of his experiments we have the following results, viz.

Six bars of willow 36 inches long, and 1/2 inch square, were broken at a medium with 525 lbs.

Six bars cut one-third through, and the faw-cut filled up with a slip of hard wood, stuck in, broke with 557 lbs. at a medium.

Six bars cut half through, and the cut filled up in the same manner, broke 442 lbs. before the fracture; and

Six others cut three-fourths through, broke with 530 lbs.

A batten cut similarly to the latter, that is to say, three-fourths through, when nearly broken, being unloaded, and a thicker slip put into the cut, in order to fill up the part which had been compressed, so as to bring the batten straight again, but without straining it, broke afterwards 577 lbs.

It will be remarked, that in these experiments the bars appear to have been stronger after being cut one-third through, than when whole; and even when cut half through, they still bore more than when they were entire. This seems to have arisen from the faw-cut being filled up with a harder wood, which rendered the beam stiffer than when in its natural state, by opposing a greater resistance to compression; and this may account for his beams being nearly as strong when cut three-fourths through, as when whole, as we have reason to believe, that there are very few woods, if any, in which the neutral line lay so near as within one-fourth of the bottom. We have made similar experiments on fir, and some other kinds of wood; and found that some beams of fir, 30 inches long, 2 inches deep, and 1 inch thick, broke with 882 lbs. 871 lbs. 852 lbs. respectively, the mean being 864 lbs. We then cut three other similar beams five-eighths through, and having filled up the cut with slips of pear-tree, found their strengths equal to 808 lbs., 846 lbs. and 835 lbs. of which the mean is 830 lbs.; these proved that the neutral line was nearer the bottom than three-eighths, because the pear-tree wedges, being softer than the fir, the deflection of the beams was throughout greater, which shewed that they had loft in stiffness by the cutting; whereas Du Hamel's beams had gained stiffness from the circumstance of being filled up with wood harder than themselves: after all, however, this kind of experiment is not the best calculated for detecting the position of the neutral axis.

From what has now been stated, it is very obvious, that the theories both of Galileo and Leibnitz must be extremely defective, so far at least as they propose them to be employed in ascertaining the absolute strain that a beam will bear, when acted upon transversely by any weight, whether as supported at its ends, or by having one end fixed in a wall, as we have hitherto supposed. And as to the theory which Dr. Robison has advanced in the place above referred to, although it doubtless approaches much nearer to the truth, it is still, we conceive, incomplete; first, for want of experiments, from which alone the neutral axis can be determined; secondly, because he has not affixed the law of compression and tension, which is necessary for determining those centres in the section of fracture; and thirdly, because (as we have before stated) he supposes the rotation to be made about the centre of compression, instead of its being made about the neutral axis, and assigning the whole resistance to fracture to the extended fibres, instead of considering one half of it as due to compression and tension respectively. It is true that this may make no difference in the results, while we confine our investigation to rectangular beams, but it makes an important difference in triangular and other formed beams; in which cases, although it agrees better with experiment than the theories of either Galileo or Leibnitz, it is still very defective, as it gives greater strength to beams of a certain form, and in certain positions, where experiment shews them to be the weakest.

We cannot submit any of the formulæ of this author to consideration, as they are merely general symbols, in which the indeterminate letters are to be supplied by numbers drawn from experiments; but in the two former, the expressions are determinate, and they may therefore be submitted to calculation, and the results compared with those that have been drawn from actual experiment; but before we proceed to this comparison, it will be proper to consider the relative strains that a beam is subject to, according to the manner in which it is supported; a consideration that is independent of any particular theory of resistances, and one in which different authors have come to very contradictory conclusions.

1. A beam having one end firmly fixed in a solid wall, will bear the same weight at its extreme end, as if the beam passed through the wall to the same length, and was loaded by an equal weight at its other end; its bearing in the wall being in the latter case supposed to be reduced theoretically to a line, and practically to such a bearing as will not damage the beam by cutting it. Fig. 6.

This will be evident to such of our readers who are conversant with the laws of motion, and who are familiar with the idea, that "action and re-action are equal and contrary," but to others it may not be amiss to offer a few observations, by way of illustration.

Let A P C, and A' P' C', (fig. 7) be two detached levers, supported on the props P, P'; and let us suppose their ends at C, C', to be held towards each other by a rope or cord C C'.
STRENGTH OF MATERIALS.

C C. Now if we suppose the lever A P C' to be fixed by any means to the position shown in the figure, while the other lever, A P C, is loaded with the weight W, and free to turn about P, the cord or fibre C C' will be stretched exactly in the same manner as the fibre at C (fig. 6.), when the beam is fastened foldy in the wall; and if, instead of supposing the first lever, A' P' C', to be fixed, we now suppose it loaded with a weight W' = W, and free to turn about P'; then the fibre C C' will be in all respects circumjacent like the fibre at C (fig. 6.), when the beam is supped to pass through the wall, and a weight W' = W, acting in the direction A' P', will be produced.

But it is obvious that in fig. 7, the tension of the cord or fibre is the same in both cases; the only difference being, that the re-action of the fixed lever A P C', in the first instance, (and which is exactly equivalent to the force or energy of the weight W,) is, in the second, supplied by the action of an equal weight acting at an equal distance P P'; and, consequently, whatever weight acting at the extremity is found sufficient to break a beam when firmly fixed in a wall, it will require an equal weight hung on at each end of a similar beam of double length, when relying on a prop in the middle, to produce the fracture. And the forces W and W', which we have seen is necessary to overcome the re-actions at D and C, an equal weight, W, must be added to overcome the equal re-action in the section E F; therefore the whole weight is equal to double that which would break the beam when only loyally supported at its two ends.

2. And hence again it follows, that whatever weight will be just sufficient to break a beam when firmly fixed in a wall, a double weight will be required acting in the middle point, of a similar beam, of double length, supported on two props, as in fig. 8; for it will be exactly the same as to the mechanical action, whether we consider the weight as acting at E, and the beam turning about P and P', or whether we suppose a fulcrum at E, and the beam turning about that point by means of weights W, W', pulling over the pulleys Q, Q', and each equal to half the centre-weight W, and the latter is evidently the same as the action of the weights W, W', fig. 6, only that they are acting in an opposite direction.

3. When a beam is loaded on any other point than its centre, and having its extremities resting on props, the strain upon it will be as the rectangle of the two unequal parts, and therefore the strain will be the greatest, or the strength of the beam the least, when the weight acts at the centre.

4. Let the weight W press upon the beam at C (fig. 9.), then is the weight equal to the preusses upon A and B; and the preuss upon A = \( \frac{W \times BC}{AB} \), while the preuss upon B = \( \frac{W \times AC}{AB} \); but the re-action of either point of support is equal to the preuss upon it, and this may be considered as a force acting at the point C, as upon the arm of a lever; so that the forces at C, is as the preuss at either point of support its distance from C, that is, the preuss is as \( \frac{W \times BC}{AB} \times AC \), or as \( \frac{W \times AC}{AB} \times BC \), which are manifestly equal to the one to the other; but as W, and A, B, are given, the forces varies as the rectangle; or if we suppose the ultimate strength of fibre the same, then W will vary inversely as the rectangle; and as the rectangle is the greatest when the parts are equal, therefore in the same case the strength of the beam will be the least.

The same thing will obtain, if the weight be equally diffused through the whole of the beam; for in this case, as in the former, the sum of the preusses upon A and B will be equal to the whole weight; and if \( \omega \) be the weight of the part BC, its preussure upon A will be \( \frac{\omega \times \frac{1}{2} BC}{AB} \), and this referred back to the point C, will give \( \frac{\omega \times \frac{1}{2} BC}{AB} \times AC \) for the stresss, which therefore varies as the rectangle BC \( \times AC \), as before.

4. When a beam is firmly fixed at both ends, as in two walls, or otherwise, the weight necessary to break it will be double of that which would produce the fracture if the ends were only supported.

Let ABCD (fig. 10.) represent a beam firmly fixed at each end, which is to be broke with a weight hanging upon itscentre-point, as at E. Now, first let us suppose the beam cut through at E, so as to offer no resistance, and suppose the weight to be hung on so as to act equally upon the arms DE, CE, then W must be equal to double that which would break one part, as is obvious; and this is the same as would break the whole beam, when only supported at its ends by one prop, consequently when the beam is whole in the section E, before the weight W, which we have seen is necessary to overcome the re-actions at D and C, an equal weight, W, must be added to overcome the equal resistance in the section E F; therefore the whole weight is equal to double that which would break the beam when only loyally supported at its two ends.

5. When a beam is fixed with one end in a wall, at any given oblique angle, the weight necessary to produce the rupture, is to the weight which would break the beam, if fixed horizontally, as radius to the cofine of the angle.

Let ABCD (fig. 11.) represent a beam fixed in a wall at the angle shown in the figure; let D E be the vertical direction of the weight, and let this weight be represented by the line D E, and resolve this into the two forces D B and B I, the former perpendicular, and the other parallel to the beam A B; then it is obvious, that D B only will denote that part of the weight which is effective in producing the fracture, and that a weight which is to W, as D B is to D I, would break the beam when placed horizontally; therefore conversely, the weight necessary to break the beam in this position is to that which would break it when fixed horizontally, as D I to D B; or as radius to the cofine of the angle of inclination of the beam to the horizon.

Most authors, indeed all we have ever read, make the strength in this case as the square of the radius to the square of the cofine; because the area of fracture is greater in the proportion of radius to cofine, which blended with the mechanical effect of the lever, gives rad.** coff.; but the result of experiment by no means justifies such an hypothesis, nor does a physical consideration of the subject render it necessary, the number of fibres being the same in both cases.

We may now bring under one point of view the deductions drawn from the preceding propositions; viz.

1. The strength of a beam fixed with one end in a wall, and loaded at the other end, is to the strength of a beam of the same length, supported on two props, and loaded in the middle, as 1 to 4, or to a beam of double the length, loaded in the middle, as 1 to 2.

2. The stresss upon a beam, arising from the same weight placed at different points, is as the rectangle of the two parts; and, therefore, the strength of the beam, or its resistance to fracture, will be inversely as the same rectangle; and, con-
STRENGTH OF MATERIALS.

consequently, the forces is the greatest, or the strength the least, when the load is placed in the centre.

3. The resistence to fracture in a beam supported only at its extremes, is to the resistence of the same when fastened at both ends, as 1 to 2.

4. The forces upon a beam, arising from any oblique action upon the portion of the circumference, or on the resistence will be in this case as radius to the cofine of the angle.

These results are all independent of any particular theory of resistence, or rather, they form a part of every one; but they require certain modifications when applied to the determination of the absolute strength of beams. While they are merely used for ascertaining the proportional strengths, for the purposes of building, machinery, &c., they may be properly employed in the forms above given; it will be proper, however, to point out a few of the modifications to which we have alluded, as it will tend to clear up some apparent anomalies which have arisen in the experiments of M. Buffon, Belidor, Parent, Petit, &c.

In the first place, then, it will have been observed, that all our deductions have been made upon the supposition, that the beam prefers its rectilinear form and original position, and no account whatever has been taken of the deflection which it experiences from the horizontal or oblique line in which it is first supposed to be placed; nor is it necessary to attend to this circumstance whilst our views are carried no farther than determining the proper dimensions of timbers, in buildings, mechanical contrivances, &c., because these are never submitted to strains that cause any important deflections; but when we attempt to reconcile theory with the result of experiments in which the beams are absolutely fractured, we must no longer omit the introduction of these particulars into our investigations.

Indeed, therefore, of supposing a beam fixed at one end in a wall, and loaded at the other, to retain its horizontal position, as in fig. 6, we must consider it as being very considerably deflected out of that position, as in fig. 12; and if we here, for the sake of perspicuity, represent the resisting force of the fibres to fracture by a weight W, it will be obvious that, in order that P and W may be in equilibrio, the weight W must be to the weight P, not simply in the inverse ratio of the arms A I, A C, but as these differences into the lines of their respective angles of direction; that is, as A I ×

\[ \text{sin. A I} : \text{A C} \times \text{sin. A C} : : \frac{A C}{A I} \times \frac{A I}{A C} = \frac{A C}{A I} ; \]

whereas our former result was \( \frac{A C}{A I} \); the weight therefore required to break a beam in this position, is greater than what we found it to be in the case where no deflection was considered, in the ratio of the cofine of the angle's deflection radius.

This is sometimes a very important quantity; as we have seen beams of three feet length, and two inches square, deflected twelve or fifteen inches, that is to say, to the amount of one-third of their length, or 20°: and the cofine of 20° is to radius as 93 to 100.

The reverse of this happens when a beam is loaded in the middle, and supported at its extremities on two props; for in this case the re-action of the props is not made, as we have supposed, in a direction opposite to the vertical action of the weight, but perpendicular to the arms of the lever.

The beam ABCD (fig. 13.) is therefore kept in equilibrio with respect to its strain, by the action of three forces, viz. the weight W, the quantity and direction of which may be denoted by the diagonal S G, viz. the diagonal of the parallelogram, of which P S, P S, are two adjacent sides, and which equally denote the quantity and direction of the reaction of the props; which will therefore be greater than \( \frac{1}{4} W \); the quantity we have suppos'd in our former investigation, in the ratio of S F' to S F; that is, in the ratio of radius to the cofine of the angle of deflection.

Hence it appears that when a beam is fixed at one end, and the computed weight necessary to break it is \( W \), the real weight that must be employed will be \( W \frac{\text{cof. } D}{\text{cof. } D'} \); D denoting the angle of deflection; but when the beam is supported at both ends, and the computed weight \( W' \), and the angle of deflection \( D' \), then the real weight will be \( W' \frac{\text{cof. } D}{\text{cof. } D'} \).

Hence, supposing the former beam to have the same breadth and depth, but only half the length of the latter; we shall have, according to the preceding theory, \( W' : W : : 1 : 2 \); whereas, from this modification of it, the analogy is \( W' : W : : 1 : 1 \) cof. D. cof. D', which (if the beams are small in proportion to their length, as was the case with those of M. Parent) is quite sufficient for reducing the ratio to 3 or 4:6, as found by that author.

Again, with regard to a beam having its two ends solidly fixed, its strength, according to our preceding investigation, as compared with an equal beam supported at both ends, is as 2:1; but this supposes the three fractures to take place at the same time, or that the same deflection that is necessary for producing the fracture at F (fig. 10.) will also at the same time cause the fracture to happen in the two sections DA, CB; but this, like the preceding, will not apply to the ultimate result; as the deflection of the half beams A F, B F, is found in experiment to be nearly double that of the whole beam A B; and therefore, supposing the deflection to be as the weight, as it is in fact very nearly for a considerable time, it will only require, in addition to the weight that would break the beam, when supported at its ends, such a weight as would produce the deflection in the half beams, equal to that at which the supported beam breaks; that is, about half the dead weight; and, consequently, the ratio of the strength of the fixed beam to that which is merely supported, instead of being as 2 to 1, will be reduced to that of 5 to 2, or 4:6, as found in the experiments above referred to, as well as in those of Belidor, as published by him in his "Science des Ingenieurs." M. Parent found that a beam supported at one end only in a wall, and another of double length supported at both ends, and an equal beam fixed at both ends, broke with weights which had very nearly the proportion of 4:6, and 9:1: whereas the theory, which takes no account of deflection, gives 4:8, 16; but what is stated above, shews that Parent's numbers are those which ought to be found by experiment; and the same explanation renders the results in the following table of Belidor also perfectly reconcileable with each other.

We have also, since the above was written, made several experiments of the same kind, in order to compare the strength of beams according to the manner in which they were supported or fixed, at one end or both; and according as they were fixed horizontally, or at different angles of inclination; and in all those cases the results answer very nearly to what the preceding theory requires. Thus a beam of fir fix feet long and two inches square, supported at each end, broke with 744 lbs.; and the mean of several experiments on similar pieces of the same dimension fixed at each end, require 1105 lbs.; and the fragments of the same, three feet long, broke with one end in a wall, required at a medium 400 lbs.; the ratio of which numbers are not very different from those above stated.

Y y

Belidor.
By a comparison of these results, we find
1. From a comparison of experiments 1 and 3, that the strength is proportional to the breadth.
2. Experiments 3 and 4 shew that the strength is proportional to the square of the depth.
3. Experiments 1 and 5 shew the strength to be nearly in the inverse ratio of the length.
4. Experiments 5 and 7 shew the strength proportional to the breadth and square of the depth.
5. Experiments 1 and 7 shew, by combination, that the strength is in the ratio of the area of fracture into the depth, and in the inverse ratio of the lengths.
6. Experiments 1, and 2, as also 5 and 6, shew that the strength of beams fixed at both ends is in a ratio of those which are only supported in the ratio of 3:2.

We have shewn that this last proportion is about what ought to result from experiments; although no theory that we know of introduces this consideration.

Another discrepancy between theory and experiment is, where the strength ought to be inversely as the length, it is, in fact, in the above experiments, but is very remarkable in those of M. Buffon; and though our preceding remarks will explain very satisfactorily this deviation, we are almost afraid to offer it as an illustration; after seeing it treated as an inexplicable paradox by some writers of the first eminence: Dr. Robison, for example, says, "the engineer will carefully keep in mind the important fact, that a beam of quadruple length, instead of having one-fourth of the strength, has only about one-fourth; and the philosopher should endeavour to discover the cause of this diminution, that he may give the artizan a more accurate rule of computation."

In another place he attempts to account for it from physical considerations, viz. that the trees being strongest at the root end; Buffon's longest pieces were broke in the weakest part, which however does not appear quite certain, as we cannot tell from which end his shortest pieces were cut; he also thinks, that the curvature being greatest in the longer pieces, may also be a cause of the deficiency above alluded to. We are not disposed to deny that these may both have an influence; but it certainly appears to us, that instead of looking for a physical explanation, what we have before remarked with regard to the deflection is quite sufficient to account for the anomaly on pure mathematical principles. We have seen, that if W be the computed weight, independent of deflection, the absolute weight will be W cof. D, D being the angle of deflection; and as this deflection, both from theory and practice, is found to increase as the square of the length; it follows, that when the length is quadrupled, the depth of deflection will be sixteen times greater; that is, the sine of the angle of deflection will be sixteen times more in one case than in the other, while the radius will be only four times longer; and therefore, the angle is in one case about four times what it is in the other, (supposing in a rough way the angle to vary as the sine). Consequentially, if W x cof. D is the weight which breaks the shorter beam, 4W x cof. 4D ought to be that which breaks the longer one; and this we presume will nearly, if not entirely, account for the decrease of strength in Buffon's experiments. We cannot perceive but that this reasoning is perfectly legitimate, yet we are astonished that it should not have occurred to so keen a mathematician as the one to whom we have alluded, or to some of the writers on this subject, and on this account we offer it with some hesitation.

The following table contains the result of Buffon's experiments, which are by far the most valuable of any that have yet been made, both on account of the number of them, and the size of the beams that were employed. The dimensions are given in metres, and the weights in kilograms, as reduced by M. Girard, except that we have not always retained the same number of decimals; these may be reduced to English measure by observing, that 1 metre = 3.281 English feet, and 1 kilogram = 2.20462 lb.

</table>
STRENGTH OF MATERIALS.

It remains now for us to offer a few observations with regard to the relation between the strength of direct cohesion, and the strength of beams submitted to transverse strains; but, unfortunately, we have very little on which to rest any theory in this respect. We know of no experiments that have yet been made with a view to this determination, except those to which we have referred, as being at present in progress at the Royal Military Academy, and these are not yet sufficiently forward to enable us to offer any decided theory.

According to Galileo's theory, if \( f \) denote the strength of direct cohesion, that is, the number of pounds necessary to break a bar of one inch square; \( a \) the area, in inches, of the section of fracture; \( d \) the depth of its centre of gravity from the edge about which the beam is supposed to turn; and \( l \) the length, also in inches; and \( W \) the required weight, then

1. When the beam is fixed at one end in a wall,
   \[
   W = \frac{fa}{l}.
   \]

2. When the beam is supported at both ends, then
   \[
   W = \frac{4fa}{l}.
   \]

3. When the beam is fixed at both ends,
   \[
   W = \frac{8fa}{l}.
   \]

The weight in both the latter cases being suppos'd to rest on the middle of the beam, and in the first at its end. When the weight acts at any other part of the beam, the stress varies directly as the rectangle of the two parts, or the strength is inversely as the distance.

According to Leibnitz's theory, if \( a \) is the area, \( l \) the length in inches, and \( f \) the strength of direct cohesion in pounds, on a square inch, as before; also \( D \) the depth of the section of fracture, \( \Delta \) the distance of its centre of oscillation, and \( d \) that of its centre of gravity from the point about which the beam turns, then

1. When the beam is fixed at one end,
   \[
   W = \frac{fa \Delta d}{D}.
   \]

2. When the beam is supported at both ends,
   \[
   W = \frac{4fa \Delta d}{D}.
   \]

3. When the beam is fixed at both ends,
   \[
   W = \frac{8fa \Delta d}{D}.
   \]

From these general theorems it is usual to draw a variety of corollaries as to the strength of beams of different forms, and in different positions. Thus, from the former, it appears that a triangular beam, fixed with one end in a wall, with its edge downwards, or supported at its two ends, with its base downwards, has double the strength of an equal beam laid the contrary way, i.e., with its base down in the first case, and upwards in the second; and Leibnitz's formula makes the strength three times as much; whereas experiment proves that the beam is weaker in both these cases, where, according to their theory, it should be so much stronger.

Similar erroneous conclusions are also drawn from these theorems, with regard to hollow cylinders, not bored through the axis, but on one side of it, the strength, according to the above, being greatest when the beam is made to turn about the thinnest part: but here, again, experiment shews it to be weakest in that position.

With regard to the hollow cylinder bored through its axis, the above theorems, though they are still inaccurate with regard to the proportion between the direct cohesion and the transverse strain, are not much out in respect to the proportional strength, according to the size of the bore, and the thickness of the sides: in fact, both sets of theorems give the same results, with regard to the proportional strengths, as depending upon the lengths, depths, breadths, &c. of the beams, while the same remain of the same form, and rest in the same position; it is in the comparison of different formed beams with each other, or different positions of the same beam, where the defects is the most obvious, and particularly with regard to all beams, as depending upon the strength of direct cohesion. On this account, we shall dispense with the corollaries and deductions above referred to, as being more likely to mislead than to instruct the engineer, although we thought it right to mention them; and if we cannot supply them with well established rules and formulae, we will at least endeavour to point out how such may be obtained.

We have already stated that the beam, instead of turning about the line \( CD \) (fig. 1), as suppos'd by Galileo and Leibnitz, really turns about a line within the area of fracture, as shewn by the section, fig. 5; viz. instead of turning about the lower point \( C \), the beam will turn about some other line, represented in the figure by \( n \), the situation of which is unknown, but whose position is absolutely necessary to be determined, in order to establish a correct theory of the strength of beams. According to Du Hamel's experiments on willow, it is at about one-third the depth from \( A \), and therefore, that we have made, make it about the same for fir: and though there may be some difference in this respect, in woods of different kinds, it is probably not far from that point in any.

Now all the fibres between \( n \) and \( A \) are those only which are in a state of tension; the others between \( n \) and \( C \) being in a state of compression; while the fibres in the line, of which the section is \( n \), will be neither compressed nor stretched; on which account this is commonly called the inner line, or neutral axis. Hence we see, that in the theories of Galileo and Leibnitz, the strength of beams, as deduced from the strength of direct cohesion, must far exceed the real strength, not more than one-third of the fibres, which they suppose, being employed to refit the fracture at least by tension; also the centre of tension being at one-third of the distance they have assumed, these combined would make the real strength only one-ninth of the computed strength. But as we may suppose that exactly one-half of the entire force is employed in producing the compression, that is, that the beam turns about that point where the resistance to compression is equal to that of tension, this reduces it to \( \frac{4}{3} \) times; that is, the computed strength is about \( \frac{4}{3} \) times greater than it would be, if the neutral line were, as we have suppos'd, at one-third of the depth from the upper surface of the beam.

This defect is common to both these authors, after conceding to each his own particular law of tension; that is to say, to Galileo, that every fibre acts with the same energy; and to Leibnitz, that the tension is as the forces. But both of these suppositions must be erroneous; and we must say, that, independent of experiments, we should certainly have been inclined to adopt the latter; but we are convinced, from a great multiplicity of results, that Galileo is much nearer, if not exactly conformable to the actual operations...
STRENGTH OF MATERIALS.

operation. However difficult it, therefore, may be to account for this equality in the force of tension on physical principles, we must adopt it as a fact deduced from experiment, and leave to the philosopher the explanation of its existence.

Our limits will not admit of reporting here the nature of the experiments, nor the calculations founded upon them, which led to this determination; but we hope soon to see them laid before the public in another form. We can only give here the result, which, as far as it is at present ascertained, is as follows:

The centre of tension and centre of compression are nearly or exactly coincident with the centre of gravity; and the neutral line, whatever may be the figure of the section, is so positioned, that the rectangle of the area of tension into the distance of its centre of gravity from the said line, is to the rectangle of the area of compression into the distance of its centre of gravity as $I$ to $3$.

From which theorem, the neutral line for any formed beam may be determined, and the absolute strength may then be found as follows, viz.: Let $d$ denote the distance of the centre of tension from the neutral line, $a$ the area of tension, and $I$ the length of the beam, all in inches; $D$ the angle of deflection, and $f$ the strength of direct cohesion on a square inch; then, without considering the increased length of lever,

1. When the beam is fixed at one end,

$$ W = \frac{3fa}{l} \times \text{cof. } D. $$

2. When the beam is supported at both ends,

$$ W = \frac{8fa}{l} \times \text{cof. } D. $$

3. When the beam is fixed at both ends,

$$ W = \frac{12fa}{l} \times \text{cof. } D. $$

And when the beam is fixed at one end at any angle, formula (1) will still apply; only increasing or decreasing the angle of deflection by the quantity of the first angle of inclination, according as that inclination is downwards or upwards.

And when the beam is supported, or fixed, at both ends, and either refting obliquely, or acted upon by an oblique force; the two latter formula become:

4. For the beam supported at each end,

$$ W = \frac{8fa}{l} \times \text{cof. } D. $$

5. For the beam fixed at each end,

$$ W = \frac{12fa}{l} \times \text{cof. } D. $$

Where I denotes the angle which the direction of the force makes with the direction of the beam.

Note 1. It should be observed that the preceding theorem, for determining the neutral line, is principally drawn from experiments on fir-beams. A different ratio than $1:3$ may be necessary in other kinds of wood; but at present that ratio has not been found.

Note 2. The deflection $D$, as we have before observed, is not a necessary datum in estimating the strength of timber, for any practical purposes of building, &c.; it is merely introduced in order to reconcile theory with the result of experiments made upon the absolute and ultimate strength in which case, particularly in long beams, it becomes an important quantity, and must not be omitted; and in all cases where it is required, it must be drawn from some prior experiment on the same kind of wood, by means of the following theorem, viz.: Let $I, d$, and $D$, represent the length, depth, and deflection of any beam; and $I'$ and $d'$ the length and depth of any other beam, whose deflection $D'$ is required; then,

$$ D' = \frac{I'}{I} \cdot \frac{d'}{d} \cdot D. $$

See the several works referred to in the beginning of the article, by Bernoulli, Euler, Lagrange, &c.

We shall now illustrate these theorems by a few examples.

Example 1.—The strength of direct cohesion on a square inch of fir being 15,000 lbs., required the weight necessary to break a rectangular bar 30 inches long, 2 inches deep, and 1 inch in breadth; when fixed at one end in a wall, and the weight acting at the other; the deflection, computed from other experiments, having been found to be 5 inches.

First, to find the neutral line: here, since the section is a rectangle, the centres of tension and compression are each on the centres of their respective areas; therefore, call the depth of tension $x$, the depth of compression will be $2-x$; which also denote these areas; and we must have, therefore,

$$ x^2 + \frac{(2-x)^2}{2} = 1 + \frac{3}{2}; $$

or $3x^2 = 4 - 4x + x^2$; or $x^2 + 2x = 2$.

Whence $x = -1 + \sqrt{3} = .732 = a$;

and $\frac{.732}{2} = .366 = d$;

$$ \tan. \text{ of deflection} = \frac{5}{30} = \frac{1}{6} = .1666666. $$

Whence the angle $D = 5^\circ 34'$, and its cosine = .9860; therefore, by formula 1,

$$ W = \frac{2fa}{l} \times \text{cof. } D = \frac{2 \times 13000 \times .732 \times .366}{30 \times .986} = 235 \text{ lbs.} $$

Example 2.—Required the weight that would break the same beam when supported at each end, rejecting the deflection, which is very inconsiderable.

By formula 2,

$$ W = \frac{8fa}{l} = \frac{8 \times 13000 \times .732 \times .366}{30} = 928 \text{ lbs.} $$

Example 3.—Required the weight that would break the same beam fixed at each end. Rejecting the deflection, we have from formula 3,

$$ W = \frac{12fa}{l} = \frac{12 \times 13000 \times .732 \times .366}{30} = 1492 \text{ lbs.} $$

Note.—We have here assumed 13000 for the force of direct cohesion; this, however, rather exceeds the greatest strength of fir, which varies from 10000 to about 15000 lbs.

Example 4.—Assuming the direct cohesion at 13000, and the specific gravity of fir 720; how long must a beam be that is two inches deep, and one inch broad, which, fixed with one end in a wall, will just break with its own weight?

Let $a$ be the required length of the beam, in inches; its weight
STRENGTH OF MATERIALS.

weight will be \( \frac{2x \times 720}{1728} \) ounces, or \( \frac{90x}{1728} = \frac{5x}{96} \) pounds;

and this weight will have the same effect as if it acted all at
one point in the centre of the beam, or at the distance \( \frac{1}{2} x \).

Hence, by substituting \( \frac{5x}{96} \) for \( W \) in formula 1, we have

\[
x^2 = \frac{2 \times 15000 \times 732 \times 366}{96} \times \frac{1}{x}
\]

or \( 5x^3 = 192 \times 2 \times 13000 \times 752 \times 366 = 133728 \).

Whence \( x = \sqrt{\frac{133728}{5}} \) inches, or 47 feet. In this

case, the angle of deflection is not introduced.

When the deflection is considered, as it should be in this
case, we find it to be from the data of example 1, and the
theorem for the deflection, as

\[
\frac{30}{5} = \frac{1}{x} \cdot \frac{5x^3}{3600}
\]

Whence the cosine

\[
\cos \theta = \sqrt{\left(1 - \frac{25x^3}{1800}\right)}
\]

and the above

equation becomes

\[
x^2 = 2 \times 15000 \times 732 \times 366 \times \sqrt{\left(1 - \frac{25x^3}{1800}\right)}
\]

which produces a cubic equation, whence the value of \( x \) may
be determined.

It remains now to add a few particulars relative to the
transverse strength of stones and metals, but our information
on this head is limited; very few experiments having yet
been attempted, except those of Mr. Banks on bars of caft-
iron, and a few made by Dr. Robison on small pieces of
marble.

Mr. Banks has, at various times, made many experiments
on the real and comparative strength of oak, fir, and iron.
He found that the worst on weakest piece of dry heart
oak, 1 inch square and 1 foot long, bore 660 lbs., though
it was much bent, and 2 lbs. more broke it. The strongest
piece he tried of the same dimensions broke with 974 lbs.;
the worst piece of deal bore 460 lbs.; but broke with
a little more.

With respect to caft-iron, he concludes that a bar of
the weakest kind, an inch square and a foot long, would break
with 2100 lbs.

The following are some of the experiments he mentions.

See Banks on Power of Machines.

Experiment 1.—Two bars of caft-iron, 1 inch square and
3 feet long, were placed upon a horizontal bar, so as to
meet in a cap at the top, from which was suspended a scale;
these bars made each an angle of 45° with the base-plate;
and, of consequence, formed an angle of 90° at the top:
from this cap was suspended a weight of 7 tons, which was
left for 16 hours, when the bars were a little bent, but very
little.

Experiment 2.—Two bars, of the same length and thick-
nesses, were placed in a similar manner, making an angle of 24°
with the base-plate: these bore four tons upon the scale: a
little more weight broke one of them, which was observed
to be a little crooked when first put up. In this case, the
pressures would be as the sines of the angles of elevation,

\[
\sin 24° : \sin 45° = 2 \times 720 : 96
\]

1. Rib 29 feet 3 inches span, a segment of a circle
3 feet high in the centre; it supported 99 cwt. 1 qr. 14 lbs.;
it funk in the middle 34 inches, and role again three-fourths
when the weights were removed: the same rib was after-
wards tried without abutments, and broke with 55 cwt.
9 qr. 14 lbs.

2. Rib 29 feet 3 inches span, a segment of a circle
3 feet high in the centre; it supported 100 cwt. 1 qr. 14 lbs.,
and funk 1 x in the middle. The same rib was afterwards
tried without abutments, and broke with 64 cwt. 1 qr. 14 lbs.
The thickest of these ribs is not specified; but the ex-
periments prove that each rib exerted little more than half
the strength when the abutments were removed.

Mr. Banks made some experiments on the strength of caft-
iron, at Meffrs. Aydon and Elwell’s foundery, Wakefield.
The iron came from their furnace at Shelf, near Bradford,
and was cast from the air-furnace; the bars 1 inch square,
and the props exactly 3 feet distant; one yard in length
weighed exactly 9 lbs., or one was about half an ounce less,
the other a little more; they all bent about an inch be-
fore they broke.

1. The first bar broke with
2. The second bar with
3. The third bar with
4. A bar made from the copper
5. A bar equally thick in the middle, but the
ends formed into a parabolic form,

The fame gentleman made many other experiments, and
concludes, from the whole, that cast-iron is from 3\( \frac{1}{2} \) to 4\( \frac{1}{2} \)
times stronger than oak of the same dimensions; and from
5 to 6\( \frac{1}{2} \) times stronger than deal.

We shall only observe here, that Mr. Banks’s pieces of
oak exceed very considerably the specimens that we have
had an opportunity of trying, while his fire falls somewhat
short of ours.

It was our intention, in conclusion, to have added a few
examples illustrative of the several rules and principles laid
down in the preceding pages; and also investigations re-
relative to the form of beams possessing equal strength through-
out, or beams of equal resistance; but as this article has
already exceeded the usual limits, we can merely state the
results, and must leave the investigation to the reader; or
we may refer him to Gregory’s Treatise of Mechanics,
where all these subjects are investigated at length.

As the bream upon any beam submitted to a transverse
strain is directly as the length, and the strength directly as
the breadth into the square of the depth; it follows, if the
sections are so proportioned to the lengths, that the breadth

into the square of the depth is always as the length or distance from the point where the weight acts; that every part of the beam will be equally strong, in which case it is laid to be a beam of equal refinance: hence, when a beam is fixed with one end in a wall,

1. If the breadth is the same throughout, the lengths must be as the square of the depths; and consequently the vertical sides of the beam will be parabolae.

2. If the depth is the same throughout, the breadths must be as the lengths, and the upper and lower sides of the beam will be triangles.

3. If the several sections be circles, the cubes of their diameters (which is equivalent to the breadth into the square of the depth) must be as the lengths; and the curve will be the cubic parabola.

4. The strongest beam that can be cut out of any cylindrical beam or tree, is that in which the breadth into the square of the depth is a maximum; which will be the case when the squares of breadth and depth, and the square of the cylinder's diameter, are to each other as the numbers 1, 2, and 3.

As to our fourth head, relative to the wrenching or twisting of a body, very little that is satisfactory can be advanced; according to Mr. Banks, a cat's-iron bar an inch square, and fixed at one end, will break by the twist when 631 pounds are furnished by a wheel of two feet diameter, and made to act upon it; though some have required more than 1000 lbs. in similar situations, to break them by the twist. The strength to resist the twisting strain is as the cube of like lateral dimensions.

STRENGTHENERS, Corrombantes: such medicines as add to the bulk and firmness of the solids. Strengtheners differ from cordials, as a bandage does from a flint-brush; the latter are such as facilitate and drive on the vital actions; but the former, such as confirm the flatus, and maintain the solids in such a condition, as to exert themselves into action on all proper occasions, with the greatest force and vigour.

The continual wails which constant motion makes in the constitution, were not for frequent and proper supplies, would soon wear the body quite out. The attritions and abrasions of the circulating fluids would quickly carry away the canals in which they circulate, were not somewhat furnished in their composition, which is fitted to fall into, adhere with, and recruit, that which is washed off. And those particles must be much more disposed to do so, whose adhesions are greatest, when once they come into contact; such are those of bodies we call platinous, and which easily form themselves into jellies, and flax-like consistencies; for the parts of such bodies are very light, by the over-proportion of their surfaces to their solidities, by which their motions are both more languid when in circulation; and, when they stop, their cohesions will be much the stronger, with whatsoever they happen to fall into contact. See Nutrition.

Medicines of this tribe are therefore of great service in hysteric, where the swift motion of a thin, sharp blood, wears away the substance of the body, instead of nourishing it; for they not only retard the inordinate motion, but give such a weight and confidence to the juices, as fits them also for nourishment. There are likewise other caustics which may weaken the solids, by admitting or occasioning them to relax too much.

Whatsoever, therefore, acts as a stimulus, and cribs and corrugates the fibres into a more compacted tone, which most sufferers and pointed bodies do, will remove such weaknesses, and increase strength; and as too much moisture may also contribute to such a relaxation, what has no other quality but that of absorbing, and drying up such superfluous humidities, may deserve, though accidentally, to come under this denomination.

An artificial method of procuring a powerful, safe, and innocent strengtheners is the following. Put half a pound of fine Peruvian bark, reduced to a subtile powder, into a long or tall glass body, and pour upon it two quarts of spirit of wine; shake them well together, and let them in a lumber two or three days, or till the spirit of wine is of a fine purple colour; pour off this tincture, and press the pieces very strongly, to get it all away; then return the powder into the same vessel, and pour upon it two quarts of strong white wine; let this in lard for two or three days, then pour off this tincture; mix it with the former, and putting the whole into a glass body, distil off a great part of the spirit of wine; then put the remainder into a glass earthen pan, and evaporate it to the form of an extract, adding, toward the end, three ounces of syrup of orange-peel.

This is the invention of Charaz, and seems the best preparation of bark known. Beside all the common celves in which the bark is given, this preparation may be tried in other weakening distempers as well as intermittents fevers, as the inconveniences attending the taking of the bark in substance are obviated by this preparation, which is equally powerful and innocent. It may be aromatized at pleasure with any of the essential oils. Shaw's Lectures, p. 232.

STRENGTHENING PILLS. See Pills. Strengthening Bands of Sea-Shores, in Rural Economy, the securing of them against the force, power, and effects of floods and high tides. This fort of protection is much wanted in many situations and sea-coast districts in different parts of the kingdom, and is capable of being performed in various ways in different circumstances and cafes. See Sew-Wall, and Embankment.

STREINITZ, in Geography, a town of Bohemia, is in the circle of Bolefor; 3 miles W. of Jung Buntzelt.—Alto, a town of Bohemia, in the circle of Chrudim; 6 miles N.E. of Politza.

STRENUA, in Mythology, a goddess among the Romans, of an opposite character to the goddess of "Sloth," who, according to St. Augustine, made men to over-acet, and who had a temple at Rome. The goddess of sloth was named Marcia, and Streuna and Ageronia inspired their votaries with vigilance and courage. The chapel of Streua was situated, as Varro informs us, near the Via Flacc.

STREPTOSUS, the name of a diapper common to the inhabitants of some parts of the Alps, in which the face, neck, and arms, are fo deflected with flatulencies, as to make a noize, when struck, like a dry bladder half deflected with wind.

STREPSICEROS, in Zoology. See Ovis.

1. S. filopes.—Gathered by sir Joseph Banks, in the tropical part of New Holland. A grass with the aspect of an Arrhida or Stipa, differing from the latter genus in the want of an articulation between the awn and its glume. Brown.

1. S. amplifolius. Heart-shaped Streptopus. Redouté Liliac. t. 359. (S. ditortus; Michaux n. 1. Pursh n. 1. Uvularia amplifolia; Lim. Sp. Pl. 436. Wild. Sp. Pl. v. 2, 93. Ait. Hort. Kew. v. 2, 246. Wald. et Kitaib. Hung. v. 2, 182, t. 167. Polygonatum ranwum; Ger. Em. 904. Laurus alexandrae; Mattth. Valgr. 516, bld.)—Smooth. Leaves heart-shaped, clasping the stem, entire and incised-edged. Anthers with a fimbriate point.—Native of Bohemia, Hungary, Dauphiny, Switzerland, &c. as well as in sandy mountainous woods from Canada to Pennsylvania, flowering in May and June. The root is fibrous and perennial. Stem erect, twelve or eighteen inches high, herbaceous, branched, leafy. Leaves alternate, sessile, pointed, many-ribbed, two or three inches long, clasping the stem with their rounded heart-shaped base; paler and rather glaucous beneath. Flowers pendulous, greenish-yellow, the size of our Lily of the valley, each on a solitary, axillary, unbranched, slender, smooth stalk, not half so long as the leaf, with a complete convolution in the middle, not expressed in Matthioli’s cut. Berry orange-coloured, the size of a pea, with a thin rind. We cannot but prefer the pretension of the original specific name, after the correct example of M. Redouté, instead of Michaux’s new one which is not peculiarly applicable to the present species.

2. S. rufus. Rosy-coloured Streptopus. Michaux n. 2. (Tortula rufa; Wild. Sp. Pl. v. 1, 146. Ait. Hort. Kew. v. 1, 146.)—Native of the East Indies. Found by Dr. Roxburgh, only in the vicinity of Samulcotth, on the terraces of old walls of pagodas, flowering during the wet and cold feasts. This plant is not put to any use. While young it is not inedient, though resembling *Verbena laevis* Linn. The root is perennial. Stem rather shrubby, perennial, with rough, flaky, leafy, opposite branches, from two to four feet high. Leaves opposite, flarked, heart-shaped, serrated, one or a half or two inches long, clothed with brownish bristles. Flowers white, in very long, simple, terminal, minutely bracteate, *pales*, the leaf from the fork of the branches. Fruit the size of a pea, drooping, clothed with the rough brown calyx.

There being a very well-established genus of mosses long ago named *Tortula*, see that article, we cannot account for Willdenow’s name for the present genus being preferred in Hort. Kew. to that already published by Mr. Dryander himself.

STREPTOPUS, from *reptio*, twisted, and *sua*, a foot; because of a peculiar twist about the middle of each flower-stalk.—Michaux Boreali-Amer. v. 1, 200. Pursh 232.—Clas and order, Hexamnia Monogynia. Nat. Ord. Sarmentaeae. Linn. Aparagi, Juss.

Gen. Ch. Cal. none. Cor. inferior, somewhat bell-shaped, smooth, of five lanceolate acute petals, reflexed at the point. Nectary a furrow along the middle of each petal. Stam. Filaments five, awl-shaped, much shorter than the corolla, inserted into the base of each petal; anthers oblong, pointed, erect. Pfl. Germen superior, globular; style longer than the filaments, slightly triangular, erect; stigma three, very short, obtuse. Peric. Berry nearly globular, smooth, with a thin skin, of three cells. Seeds several, though but few are perfect, nearly ovate, with a naked scar.

Obf. This genus is more allied to *Coronilla* than to *Uvularia*; it is distinguished from the former by its polypetalous corolla, with nectiferous funnels; from the latter by having a berry, not a capsule, and the want of an appendage, or tunic, to the scar of each seed.

Vol. XXXIV.

3. S. lanuginosus. Downy Streptopus. Michaux n. 3. Pursh n. 3.—“Somewhat hoary and woolly. Leaves sessile, pointed, slightly heart-shaped. Flower-flasks in pairs, on a very short common stalk.”—On high mountains, from Pennsylvania to Carolina, flowering in June. The leaves are abrupt, with longer points than the two former. Flowers thrice the size of the others, yellowish-green, resembling an *Uvularia*. Berries red, scarcely perishing more than one or two seeds.

Neither of these two latter species have, as yet, found their way into the gardens of Europe.

STRESI, Gros, in Geography, a town of the island of Rügen; 9 miles S.E. of Bergen.

STRETCH. When at sea they are going to hoist the yard or hale the sheet, they say, *Stretch forward the sheets*; meaning, that part which the men are to hale by, should be put into their hands, in order to their haling.

STRETCHER, in Sea Language, a sort of flax fixed athwart the bottom of a boat, for the rower to place his feet against, in order to communicate a greater effort to his oar.

STRETCHING, in Navigation, is generally understood to imply the progression of a ship under a great surface of sail, when close-hauled. The difference between this term and *flanking*, consists apparently in the quantity of sail, which, in the latter, may be very moderate; but in stretching generally signifies excess: as, we saw the enemy at day-break stretching to the southward, under a crowd of sail, &c. Falconer.

STRETENSE, in Geography, a town of Ruffia, in the government of Iurusk; 52 miles E.N.E. of Nertchink. N. lat. 51° 23'. E. long. 118° 14'.

STRETHAM. See Streatham.
STRETTENBEN, a town of the duchy of Carinthia; 6 miles E.S.E. of Preuburg.

STRETTO, Ital. in Music, to contract, shorten, as in a fugue, where, to carry on some new subject arising out of the original theme, the proporta, or short subject, may be shortened, provided enough is left to recall the hearing of the whole.

STRETTON, Church, in Geography. See Church-Stretton.

STRETWARD, in Our Old Writers, an officer whose business it was to take care of the streets, like our surveyor of the highways, or rather scavenger.

STREIBER, in Ichthyology, a name given by many to the fifth called by authors after pisicus. Gfuen, in particular, calls this fish gabisus aper.

STREUFFDORF, in Geography, a town of Germany, in the principality of Coburg; 4 miles S. of Hilberhausen.

STREWING of Peas, in Agriculture, the name of a method of sowing, in which the peas are made to stir the peas in by hand, and the usual measure is about three bushels to an acre. They should be sown about six weeks after Christmas, and the furrows be made about sixteen inches apart. The peas must be regulated according to the nature of the soil and the circumstances in which the land is. It is a neat mode of sowing in many cafes. See Peas.

STREWING-Plough for Peas, &c. A small light kind of plough, constructed with a light wheel to the sowing part, by means of which that operation is directed and regulated, and a double breast part, in order that the earth or mould may, at the same time, be turned to both fides in making the furrow or drill for the peas or other feed. It usually makes the furrow, drill, or opening, to the depth of about three inches, and feeds in width, at the top, being wrought hollow. It is sometimes made fo as only to form the drills, the peas being dropped or fried in by the hand. It is also occasionally contrived so as to drop the peas from a box fixed in the hind part of it, as it proceeds in drawing the furrow or drill.

STREY, in Geography, a river of Germany, which rises in the county of Henneberg, and runs into the Saal, 2 miles N. of Munnerrott, in the duchy of Wurzburg.

STRIE, in the Ancient Architecture, the lift, fillets, or rays, which separate the fringes or flutings of columns.

STRIATULA, in Natural History, a name given by Mr. Lhuyd to a species of foliaceous plants of the fern-kind, remarkable for their flattened appearance.

STRIBILIGO, a name given by some authors to any sort of cutaneous efflorescence.

STRICK, in Commerce, a corn-measure in Bohemia = 4 viertels = 16 maffels = 192 fiedels. It contains 5383 French or 616 English cubic inches. Hence 33 frieks of Prague are = 100 English bushels. See Table XXXI. under Measures.

STRICKLE, or STRIKE, an instrument for striking off the outer moisture of corn.

STRICKLE, in Agriculture, a provincial term applied to the wooden contrivance which is placed upon the extremity of the shaft of the felythe for whetting it with.

STRICKLESS, in Rural Economy, a name sometimes given to the tool by which the bushel is struck.

STRICTUS, in Anatomy, the name of a sphencter.

STRICTURES of the Oesophagus. Chronic inflammation of the membrane which lines the oesophagus, extending by degrees to the muscular coats of the part, increases the thickness of its parietes. This change may happen to such a pitch, that the diameter of the canal is rendered as small as that of a quill, and the aliment cannot be swallowed without great difficulty. In this state, deglutition may become so obstructed, that the patient is threatened with the danger of dying from defect of nourishment. Formerly, there was no other means of supporting him but the feeble resource of nutritive cyphers. The small number of absorbents, however, which proceed from the internal surface of the large intestines, and the slowness of cutaneous absorption, made nutritive cyphers and baths almost useless; but in modern times, elastic gum catheters are always capable of affording material relief, if not of accomplishing a perfect cure.

The catheters intended for this sort of cases are firm and easy of introduction when the filet is in them; and flexible and not at all incommoding when the filet is withdrawn after their introduction. In general, they ought to have the diameter of the largest bougies of the urethra, or even equal in diameter to the little finger. After being oiled, in order to make them more smooth, they should be passed through one of the nostrils, and when their end has arrived in the pharynx, opposite the Isthmus faucium, the filet must be withdrawn with one hand, while the other part of the instrument is pulled on with the other. Should it bend against the posterior parietes of the pharynx, the surgeon must pass his thumb and fore-finger into the mouth, and take hold of it. With these it is to be directed, so that it may not enter the larynx, but descend along the oesophagus.

It is obvious, that when the catheter is not provided with the filet, it can hardly overcome any powerful obstacle. It sometimes flops at the place of the obstruction, and bends upon itself. In a case of this description, Bovier overcame the resistance, by making use of a silver catheter, which he introduced through the mouth, and for which he afterwards substituted an elastic gum catheter. The latter was also passed through the nasum and brought up into the nostril by means of Belloq's probe. This ingenious modification of the common method, says Richerand, should always be followed, when unusual difficulty is experienced in making the elastic catheter pass from the nostril into the pharynx, and resistance in the situation of the obstruction is difficult to overcome.

The elastic gum catheter being placed in the nostril, creates very little inconvenience, and it is fixed with a bit of thread put round its upper end, and fastened to the patient's cap.

In this way, Richerand fed one man whose oesophagus was compressed throughout its whole extent, by enlarged lymphatic glands. They had acquired such magnitude, that no solid nor liquid food could pass. Richerand easily introduced through the left nostril an elastic catheter without the filet. An assistant supported the patient's head upon his breast. The instrument bent back against the back of the pharynx, and Richerand was then obliged to guide it with his fingers, which he passed into the patient's mouth. It defended a long way into the oesophagus, separating the parietes of the part, which were forced too much against each other by external pressure. The instrument was fixed in this position, and a quantity of rich soup
foup was daily injected through it. The introduction of the elastic tube became so easy, and the patient so habituated to it, that it was often taken out, the students, and even other patients, being able to put it in again and feed the patient. After some months the man died of emaciation, the glandular swellings being too far advanced to admit of diffusion.

Obstruction depending upon a thickening of the parietes of the cesophagus, must be discriminated from that which arises from the compression of the neighbouring glands; a cafe, in which the introduction of instruments is much more easy. The disease, however, is then more afflicting, as it is generally incurable; while, by perseverence in the use of the elastic gum catheter and bougies, the cesophagus may be dilated like the urethra, and the thickening of its coats diminished. See Richerand's Nefrographe Chirurgicale, tom. iii. p. 314. edit. 2.

Sir Everard Home considers fistulas of the cesophagus as very analogous to those of the urethra. He observes, that this passage being wider at one time, and narrower at another, in order to be fitted for conveying the different kinds of food into the stomach, it is nearly under the same circumstances, with respect to the formation of fistula, as the urethra. If a bougie of a proper size be introduced down the pharynx, it will often be flopped by the fistula just behind the thyroid or cricoid cartilage; for, from Sir E. Home's remarks, it would appear that the obstruction is generally as high up as this situation. However, there are other cases, in which the obstruction is only of a spasmodic nature, and in these a bougie may be passed quite down. It is curious, that fistula high up in the cesophagus often occasion ulceration in this tube very low down towards the stomach, just as fistula in the urethra excite ulceration in that passage towards the bladder. This is most apt to occur, when fistula of the cesophagus have been of long continuance, and may arise from the efforts in retching, which frequently comes on, and must strain the parts already deprived of their natural actions, and of the benefit of the secretions with which they are lubricated in the healthy state. When such ulceration takes places, the characters of the original disease are lost; and when the ulceration extends upwards, the fistula itself may be destroyed. A bougie introduced under such circumstances will, in general, have its point entangled in the ulcer; and when so skilfully directed as to go down into the cesophagus, it will meet with a difficulty while it is passing the commencement of the ulcerated part of the cesophagus, and another impediment where it leaves the ulcer, and enters the found portion of the cesophagus below. These two refulences may lead to the supposition, that there are two fistula, while, in fact, the only one is above the ulceration, as already described.

According to Sir Everard Home, true fistula of the cesophagus, like those of the urethra, occupy very little extent of the passage, consisting of a transverse fold of the passage, and being attended with very little thickening of the adjacent parts. These latter circumstances are such as render the disease capable of receiving benefit either from simple or armed bougies.

Sir Everard Home has found, that a bougie can be more easily introduced into the cesophagus, when the tongue is brought forwards out of the mouth. He remarks, that when a bougie is passed with a view of learning the nature of the cafe, and it passes down to the distance of eight inches, measuring from the cutting edge of the front teeth in the upper jaw, its extremity has gone beyond the usual seat of fistula.

The method of treatment practiced by this gentleman, consists either in occasionally passing a common bougie through the fistula, and employing one of larger size in proportion as the dilatation of the obstruction allows, or else in introducing, at proper intervals, one armed with the argent nitrat. See Fréct. Obs. on Strictures, &c.

Spasmodic fistula of the cesophagus have received much benefit from the use of blisters. In other instances we have the highest opinion of the good effects of elastic gum bougies or catheters, as recommended by the continental surgeons. Such instruments at once prevent all necessity for any action in the diseased part, and operate mechanically by their prelure in producing an aborption of the fistula.

Strictures in the Uretbra. See Uretbra.

Stridor Dentum, a grinding of the teeth. Proper Alpinus, in his treatise De Praefer. Vit. et Mort. Aegrot., tells us, that a stridor dentum, which he calls a convulsion of the teeth, has been frequently observed to be a mortal symptom; and he confirms his observations by the authority of Hippocrates.

Striga, in Botany, so called by Lourêiro, from the slender and spare habit of the plant, appears, by the description of that writer, not to be distinct from the Hopea of Vahl and Willdenow; see that article. Indeed it appears to be the very same species, as far as we can judge from the materials before us.

Striga, among the Romans, a space or interval in a crop, a hum of feet long and fifty feet broad, used for currying and rubbing down the horses.

Striga is also used for a furrow drawn out at length, for a long row, or series of any thing, and by surveyors for a long measure.

Strigau, in Geography, a town of Sileia, in the principality of Schweinitz; 9 miles N.W. of Schweinitz. N. lat. 50° 50'. E. long. 16° 22'.

Strigel, Victorinus, in Biography, a German divine, and one of Luther's early disciples, was born at Krautheim in 1554. He studied at Friburg and Wittenberg, and at the latter place took his degree of master of arts in 1554, and, by the advice of Melanchthon, then commenced a course of lectures. But the war obliged him to remove to Magdeburg; thence he went to Frankfort, and in 1548 was made professor of theology at Jena. In 1555 he attended the controversy concerning good works at Eifenach; and taking part in a dispute with Flacius concerning free will, he was imprisoned on account of it at Leuchtenburg; but after some time he obtained his liberty, and permission to teach again at Jena. Soon after he removed to Leipzig; next to Amberg; and then to Heidelberg, where an apoplexy terminated his life in the year 1560. His works, besides poems, consist chiefly of commentaries on various parts of the Bible. He also wrote "Annotations on Josephus, Justin, Ariote, and Cicero;" edited "Oraciones veteres Graeci de Gloria Ecclesiae;" "Theodoreti Dialogi III. Gr. et Lat.;" and "Basilii Hexameron." He was also author of "Ratio legendi scripta Prophetaet et Apostolorum;" and of a Latin version of the Book of Wisdom, which is inserted in "J. A. Fabricii Codex Vet. Test. Pseudoepigraphus." A long dissertation on the life and writings of Strigel was published by C. E. Weismann at Tubingen, in 1732. Gen. Biog.

Strigendorf, in Geography, a town of Sileia, in the principality of Neisse; 5 miles S.W. of Grotkau.

Striges, in the Ancient Architecture, are what in the modern we call string.
They were thus denominated, as being supposed to have been originally intended to imitate the folds or plaitis in women's robes; which the Latin calls friga. The fillets or plaitis between them were called fride.

STREGGO, ALESSANDRO, in Biography, a Florentine gentleman and musical composer in the service of the grand duke Cosimo II. of Medici. He was a lutenist and voluminous composer of music of various kinds, but chiefly vocal. Morley frequently mentions and cites him in his Introduction. He is much commended by Garzoni in his "Piazza Universale," and by the historians of Italian poetry, Credi and Quadro, as one of the earliest composers of music in Italy for the stage. In the preface to "Defcrizione degli intermedi fatti nel palazzo del gran Duce Cosimo," persons were in the presence of the Grand Duke, to see and hear the music of the affectations of the nobility, called eccentri a ufficiale, l'anno 1563; it is said that the music to these interludes, which seem to have been only madrigals, was set by Alessandro Striggio, nobilissimo gentiluomo Mantovano.

His madrigals, in six parts, were published at Venice in 1566. A copy of these is preserved in the Christchurch collection at Oxford. Some of them, however, were printed seven years earlier in the 200 Libro de le Mule, from which we offenses several in the British Museum; but we do not find them remarkable either for genius or science. There seems an attempt at irregularity, in accelerating the parts, but cleerness is wanting in the harmony, and accent in the melody; the subjects of imitation were neither new nor striking at the time they were composed; and the modulation is almost wholly confined to two keys. Compared with the best compositions of his time, they would only be allowed, perhaps, to be good for a dilettante.

STRIGLIL, an instrument used among the ancients in their baths, and at some of their gymnastic exercises.

It served to abrade the sweat, or other fowds, from the body. Persons who entered the baths, or to ufe any of these exercifes, when they entered the gymnasium, put off their clothes in the apodyterium; after which, such of them as intended to box, wrestle, or to ufe any of the more violent exercifes, went into the apodyterium, where they were anointed, and thence returning into the place where the dust was, they were sprinkled with this as they padded along, and then entered upon their several exercifes; after this they returned to the apodyterium, where they had the sweat and fowds wiped off from their bodies by the alpita with an iron sponge.

The fowds taken off from the body, and confisting of oil, dust, and sweat, were preferred for medicinal purpofes, and we find them used among the old physicians.

The frigilis were of the shape of a gardener's knife; they were made of different materials, as ivory, horn, gold, silver, iron, bras, and the like; but in some after-times the word was only used to signify a linen cloth, or a piece of fpunge, which every one carried about him for his own ufe. The fowds, faved for medicinal purpofes, were called frigilis.

Gen. Ch. Cal. Perianth inferior, of one leaf, bell-shaped, with five small teeth. Cor. of one petal; tube cylindrical, the length of the calyx; limb in five deep, linear-oblong, apparently but slightly spreading segments. Nechier a short cylindrical tube, of one leaf, hairy at the summit, bearing the anthers. Stam. Filaments scarcely any, except the necular be fo consider'd; anthers ten, erect, linear, beaksprinkled on the inner surface with faxy hairs. Pet. German superior, ovate; style triangular, the length of the stamens; stigma three, prominent, globose, combined. Peric. Capsule of six cells. Seed solitary.

Ed. Ch. Calyx five-toothed. Corolla in five deep segments. Nechier tubular, shorter than the tube of the corolla, hairy, bearing the stamens. Anthers linear, erect. Fruit of six cells, with solitary seeds.

Gathered by Joseph de Jussieu in Peru. Cavanielles describes it from one of his dried specimens. The stem is thrubby, with round, downy, rubsy, leafy branches. Leaves alternate, elliptical, entire, three or four inches long, single-rinded, veinly, on short thick stalks; smooth above, clothed with reddish down beneath. Flowers in axillary simple clusters, shorter than the leaves. Ripe fruit unknown.

STRIGMENTUM, the fifth, dirt, or fowds, abformed from the skins of those that bathed in the baths and places of public exercices among the ancients, or from the walls of bathing-places, or statues set up in them.

These were all referred for medicinal purpofes, and were procured by three kinds of means; the first or bath fragments, consisted of the sweat, oil, and fowds, collected in those places. The second kind was the ftrigments of the paiftra, consisting of the fame things, with the addition of dust, which was thrown upon the bodies of the persons before they entered on those exercices. The third kind was that collected from the walls of the gymnasium, and from the statues, of whatever materials they were made, which were placed there. Hence the nature of the first and second kinds might always be ascertained, but that of the third was very different; for as it was often collected from brafs and copper statues, it partook of the nature of the tract, or erus, of those metals which were collected from them with it.

These fragments were suppos'd to be of a heating, drying quality, and difficult; they were, therefore, used for dissolving the parotides, and for condyloplastis of the anus. Those of the paiftra were used to diffuse collections of matter about the joints; and applied in the manner of a cataplasm, were said to be of great use in the fcaffitias; and those collected from the walls and statues were used to clean old ulcers.

STRIGONIENSIS TERRA, earth of Strigonium, in the Materia Medica, a red earth of the bole-kind, found about the gold-mines of Strigonium in Hungary, and used in some places as an astringent and vulneraric.

The characters by which it is known from the other earths are these. It is but of a coarse and impure texture, and lighter than most of the boles; in colour it is of a strong but dull red, and is of a tolerably smooth surface. It is apt to crumble to pieces between the fingers, and dries the skin in handling. It melts freely in the mouth, and has a remarkable smoothness, but very little the disagreeableness in its taste, and leaves a sensible grittiness between the teeth. It is sometimes veined and spotted with small molecule of an earth, like the white varieties of the red French bole. It makes a slight effervescence with aqua fortis, or any other acid menstruum, and suffers no change of colour by burning. Hill.

STRIGOSULA, in Natural History, a name given by Mr. Lhuyd to a species of fowble-oyster-shell.

STRIGOSA, in Geography, a town of Hungary, situated in a valley betwixt hills covered with vines, supposed to
to be the ancient "Strigonium," where St. Jerom was born; 8 miles W.N.W. of Clakatharn.

STRIKE, in Commerce, a measure of corn in London, &c. of which are = 80 buhelles = 20 cooms = 10 quarters = 2 ways = a last.

STRIKE is also a measure containing four buhelles; two of which make a quarter.

A strike of flax is as much as can be heckled at once.

STRIKE, or STRIKING, is a sea-word, variously used. When a ship in a fight, or upon meeting with a man of war, lets down, or lowers her toptails, at least half-mast high, they say, She strikes: meaning, the yields or submits, or pays her devoir to that man of war, as the paffes by. See JERMO, SAIL, and SALUTE.

When a top-mast is to be taken down, they say, Strike the top-mast.

And when anything is let down or lowered into the hold, they call it striking down into the hold.

Also, when a ship touches ground in a foal-water, they say, She strikes.

STRIKING a Hull. See HULL.

STRIKING a Nell. In the Manage, is to drive through the horse’s shoe, and the horn or hoof of his foot, and to rivet it for holding on the shoe.

STRIKING a Vin. See BAR.

STRIKING. The punishment appointed by our laws, 23 Hen. VIII. c. 6, for striking in the king’s palace, where his royal person refines, by which blood is drawn, is perpetual imprisonment, and fine at the king’s pleasure; and also loss of the offender’s right hand, the solemn execution of which sentence is preferred in the statute at length. See Lord-STEWARD.

But striking in the king’s superior courts of justice, in Westminister-hall, or at the assizes, is made still more penal than even in the king’s palace. By the ancient common law, before the Conquest, striking in the king’s courts of justice, or drawing a sword therein, was a capital felony; and by our modern law, a strike or a blow in such court of justice, whether blood be drawn or not, or even assaulting a judge, sitting in the court, by drawing a weapon, without any blow struck, is punishable with the loss of the right hand, imprisonment for life, and forfeiture of goods and chattels, and of the profits of his lands during life.

By 5 & 6 Edw. VI. cap. 4, if any person shall maliciously strike another with any weapon, in any church or church-yard, or shall draw any weapon with an intent to strike another with it, he shall upon conviction, by verdict of twelve men, or by his own confession, or by two lawful witnesses, at the assizes or féemes, be adjudged to have one of his ears cut off; and if he have no ears, he shall be burned in the cheek with a hot iron, having the letter F, by which he may be known for a fray-maker and fighter; and besides shall be ijsa iads excommunicated.

STRIKING or PITHING of Animals, in Rural Economy, the method of suddenly slaughtereth or killing them for domestic purposes, by the use of a small sharp spear-pointed knife struck in to as to divide the spinal marrow, instead of the more painless and cruel practice of knocking them on the heads, and breaking and mashing the parts by means of the hammer-headed axe, as is generally the custom, to the great danger of the operator, and the disgust of the spectator. See PITHING.

It is deplorable, on several accounts, that this sudden mode of killing near cattle, and other forts of animals, by striking into and dividing this vital part, should become the common one in all slaughter-houses, and other places; and, especially, as removing the apparent cruelty, and lessening the sufferings of them, more than in the other or the ordinary practice. This method, which has long been universal, in a great measure, on the continent, especially in Portugal, Spain, and some other parts, as well as in some of the West Indian islands in our possession, has, within these few years, been tried in this country, in some instances, with complete success; and the flesh of the beasts so killed has been found equally good, if not better, than that of those slaughtered in the usual manner; and that as the operation is capable of being performed quietly, and without any sort of alarm to the animals, all accidents and bruises are avoided, which not uncommonly take place in forcing them into a proper situation and position, for receiving the stroke or blow, when they are to be knocked down, and killed in that way.

It has been stated by the writer of the Corrected Report of the Agriculture of Shropshire, that a butcher at Wifbeach, in Lincolnshire, practiced this mode several years ago, in consequence of the representations made to him of it, by captain Clarkton of the navy, who had seen animals so slaughtered for the use of our fleet, when at Jamaica: that, after his death, Smyth, another butcher of the same place, adopted the same method: and that, in the year 1796, he (the writer) procured, by favour of Mr. Clarkson, so distinguished for humanity, the following account, which he had from Smith, who informed him, that he killed all his bullocks by striking them in the spinal marrow. The line was drawn by a line on the bend of the neck, about an inch and a half distance from the horns, or places for them, and the centre of this line were found, this center or spot would be the place where the knife should enter, in striking the animals. That the knife which makes use of is not in the form of a dagger, nor is it stricken or thrust in with any great force: it is rather larger than a common penknife, but the blade is permanently fixed in the handle. In the act of striking, the handle is taken into the hand, and the fore-finger placed downwards of it and the blade, towards the point, merely in order to direct it in the operation. The person who uses the knife or instrument takes hold of one ear of the beast with his left hand, while with his right he strikes it in the proper place with the knife or tool. In the same instant the bullock drops, and it apparently out of all sensation of pain. He was informed also, that it is not only in a thousand times that any person misfles the right place; though perhaps an apprentice or foreman may at first, or in the beginning. But the rule, on the whole, is so certain, that it may be laid hardly ever to fail. However, if it should at any time, the knife is at least fo near the proper place, that by the smallest motion or alteration of its position, without withdrawing it, it may find its proper way, and finish the work. In this case, it is supposed, there would hardly be the pain of two seconds to the animals. However, in speaking to Smith’s apprentice on the subject, he was assured by him, that he had no difficulty in finding the proper spot for the purpose, and that the beasts drop instantly. This practice obtains pretty generally on the Lincolnshire side or bank of the Humber river, as at Barton, and several other places. Calves, sheep, pigs, and other animals, are flayed to have been killed in the same manner.

Notwithstanding this account, the want of due precision in the manner of performing the operation has prevented, or thrown some doubt upon its utility, especially in so far as tenderness and humanity towards the animal are concerned; for though the beast may be managed completely by this mode of performing the operation, yet, without sufficient correctness and exactness in its execution, it is not so certain that
that its sense of feeling may be wholly destroyed. Indeed the contrary would seem to be the case, from the ingenious and well directed inquiries and experimental trials of Dr. Du Gard of Shrewsbury, who has shown, that though the spinal marrow may be divided, the nerves that supply the organs of respiration and most of the sensory remain uninjured. But if the division be made sufficiently high up towards the cavity of the skull, so as to separate the medullary substance above the origin of the nerves which supply the diaphragm, it would appear, from the equally ingenious and correct experiments of others, as Hunter, Home, &c. that the animals may infallibly be killed in the most certain and effectual manner; and that by performing this operation in the same way, it will be attended with constancy and perfect success.

It is not improbable, indeed, that an instrument might be contrived by means of a strong spring, somewhat in the manner of that used in cupping, but only with one blade, that might, on being properly applied, force itself suddenly into the brain even, and thus infallibly complete the business; or the operation might probably be performed in an equally complete, convenient, and more expeditious manner, by the discharge of a small pistol, loaded in some proper way for this purpose, and suitably directed.

In some of these ways the present brutal, beating, hammering, and disgusting practice may probably be got quit of, which, for many reasons, is highly desirable, and that although the practical utility of such distempers, in a disease which is so speedily fatal, may not be immediately apparent, it is necessary to notice them, that by particularly observing the other morbid changes with which they are sometimes or always accompanied, the appearances which affected the animals while alive, and the circumstances which preceded the attack, a perfect history and knowledge of all the forms and variations of this very destructive disease may be obtained.

Some think that, besides the above noticed parts, the heart, lungs, and liver, sometimes the pancreas is primarily affected in this disease, as easily perceived by the dark and livid appearance of the peculiarly affected part; and the body becomes swollen, in some cases, with a collection of air in the cellular parts and belly.

In each of these two divisions, classes, or kinds of this disorder which have been noticed above, there are several varieties, as below.

The first variety of the first kind, or that of bowels, as it is often called, the stomach being the principal seat of the disease, may be said to be a fort of gastritis; or inflammatory state of that organ. In it the belly is prodigiously swelled, the carcass much discoloured, and a four pituitary matter diffused throughout the whole body, especially the flesh parts of it. The fatty matter appears the least changed; but although it melts down into a greasy state, it has always a bloody appearance, from which, it is said, it cannot be cleared. On opening the body, it emits a strong smell of the sulphureous kind, which is characteristic of the disease, and from which it has sometimes been named, as well as from the place of its chief seat, and the stench and bowels are prodigiously discharge with air, having the same intolerable stench. A general redness pervades the whole bowels. The two first stomachs are rarely the particular seat of the disease, the third only occasionally; but the fourth, and especially that part of it leading to the intestines, known by the name of pylorus, is constantly much thickened, inflamed, or even mortified. The matter of food found in the stomach, especially the third, is mostly quite dry, and may, it is said, be crumbled to powder between the fingers. The kidneys are completely mortified, and
and resemble a mass of putrid gore. The liver too is much affected, but the heart and lungs only partake in some degree of the general redness.

It is remarked, that this is the most common kind of this sort of sicknees, is peculiar to sheep of the hog kind on the first setting in of frost, is not to be distinguished during the life of the animal, but by the excessive swelling of the belly, and is almost always speedily fatal.

Another variety of this kind, that most nearly resembles the above, is that where, instead of the stomach, the small guts are inflamed and mortified, and which may be denominated a sort of enteritis, or inflammation of the bowels.

In this, the carcase is much less swelled, and not nearly so blue and putrid, and, in fact, the chewed griss in the bowels is very stiff, and almost quite solid to the feel; the stomach is scarcely affected in the leaf, but the small intestines are mortified, black, soft, and almost quite rotten, the inflammation having evidently originated in one of the latter folds of the same. In one or two instances, a small fold or doubling in the intestines was noticed, which, by some wind passing through them, had forced its way through the thin texture that covers them, and by which the fat hangs. This was of air, quite black and mortified, as were several of the folds above it. Indeed it is thought to be plausibly enough, conjectured by Mr. J. Hog, a writer on the diseases of sheep, that this variety of the disorder is caused by a twist or intussusception of the intestines, produced by enlarged and hardened lumps of purulent obstructing all passage through them.

It is said only to attack hog-sheep, which have plenty of griss when the weather is mild, during storms of snow, when their walk is much circumscribed, and when they are confined to the tops of the heather, bent, and other dry sapphire food. It is not, it is said, so speedily fatal as the preceding variety of this diseas, and the cloak of the diseas sometimes linger a day or two in great agony, without appearing much swelled. It is sometimes termed the dry brezy.

A third form or variety of this diseas, which has sometimes its chief seat in the urinary bladder, may be considered as a sort of cystitis, or inflammation of that part. The appearances of the disorder, it is said, in this form, resemble those of the first of the above varieties, and that the putrid tant of the carcase is nearly the same.

And in a fourth form or variety of this kind, sometimes in the belly, and being opened, the whole bowels are found swimming in bloody water, although none of it is contained in the intestines. The gall-bladder is contracted and shrunk to a size scarcely to be observed, and is almost empty of bile. The membranes connecting it with the other parts are inflamed. The urinary bladder is always empty, but not found ruptured in the Gates examined by Mr. J. Hog, as he had been to subject the writer on the subject. The smaller apartment of the stomach had some purple spots on it, which were thicker than the rest of its substance. This variety, having the peritoneum, which covers the whole intestines, and lines the cavity of the belly, as the principal seat of the diseas, may be considered as a sort of peritonitis, or inflammation of that membrane or covering.

It is said that it may be known, during the life of the animal, by the swelling hanging low, instead of rising up at each side of the back, as in the first of the above varieties, and by an evident feeling of fluctuation, when the one hand is applied flat to one side of the belly, while the opposite side is struck by the palm of the other hand.

In the fifth variety of the second division or kind of this diseas, often termed sicknees in the first and blood, or the fifth of the whole diseas, in some instances, and those the most violent, no one part of the stomach or bowels seems, it is said, to be more affected than another. There is a general redness over the whole, and the flesh of the animal is quite tender and soft, soon assuming a greenish hue. In this case, the disorder may be said to be a sort of phrenitis, or inflammation of the brain, which partakes of the affection, and the vesseles of which are red and turbid, exhibiting, with the exception of the blacknees, the same appearance as that mentioned in the bowels. In all cases where this is observed after death, the diseas, it is said, has been very quickly fatal, seldom exceeding four, or at most six hours from the first apparent affection of the animal.

Another variety of this nature, which is the fifth of the diseas, or that sort of sicknees which is fested in the bowels, is not so readily discerned in the living animal; nor does it affect the carcase so much, it is said, if blood be let. There seems to be a tendency, it is thought, in the blood itself to decompose and putrefy, and not unfrequently there are appearances of inflammation on the membranous coat that lines the breast, when the diseas may be said to be a sort of pleuritis; or on the diaphragm, when it may be termed a diaphragmatitis; and the distemper on the whole has a strong resemblance to pleurisy.

In these two varieties of this kind, whether they be distinct ones or not, the whole body is said by Mr. J. Hog to be bowed and swelled like a loaf; that the fore-legs are certainly the worst; that the kidneys are in the same state of mortification as in the two first of the above or varieties; that the appearances and the smell are the same; that the sheep are carried off by it in the same short space of time; and that it is the same as the black sheald in young cattle beginning to feed on fodder and dry herbage, when the grasses fail in the west of Scotland. It is also noticed, that all the old sheep and lambs are most affected, although the hogs that fall in May, are carried off by this sort or variety of the diseas, although individuals die of it at the same feast, when they are dying in great numbers of the bowel-sicknees. But that, on the whole, the mortality is not nearly so great, not indeed above one-tenth or one-twentieth of that occasioned by the other.

In respect to the causes of the diseas, although some few old sheep and lambs may occasionally perish and be destroyed by it, it may be considered, on the whole, as a diseas pecu-

nary, and that the founder these are bred, and the higher condition they are in, the more apt it is to break out among them, the more violent are its ravages, and the sooner do they die when attacked by it. Heath sheep too are supposed to suffer more from it than the white-faced and fine-wooled breed. On setting in feversly, it not unfrequently carries off one-tenth of the young sheep. But it is not half so fatal by the plan of pasturing the hogs with their mothers, it is said, as that of herfelling or rearing them by themselves, on account of the differences in their habits which are thus produced. Though some sheep die of the diseas at all feasons, its ravages are chiefly confined to the winter months, commencing sooner or later, as the state of the weather may be. But it seldom prevails much until after the vegetation has been checked by the early autumn frost; and is the most destractive towards the close of the year: when at that period there is any sudden change from mild to frosty weather, or if rain in the day be succeeded by frost in the night, and especially when accompanied by hoar-frost, it is, it is said, particularly fatal. It becomes less frequent after steady frost sets in, but again carries off a few towards the

end
end of the spring, and some suppose the deaths more frequent a day or two before the change in the weather actually takes place.

The disease may be immediately caused or brought on by means of frozen grafts. The spots of ground where frolick mists settle deep on the softer grasses, are, it is said, very dangerous for young sheep to feed and lie upon, as well as those of dry pastures, which are heavily loaded with hoarfrost. The effects of grafts eaten in this state, on the tender bowels of hog-sheep, resemble, it is supposed, those of frozen potatoes eaten by black cattle, which immediately engender prodigious quantities of noxious gales, and quickly bring on inflammation and mortification.

The necroticity of sheep working and eating on places, already bared and fouled, in heavy storms of snow, is another immediate, and not unfrequently destructive cause of the disease, as in these circumstances they eat any thing that comes in their way, as rotten fern, fog, roots, spratt, and other coarse plants, or whatever they can get at.

Some have supposed that pet sheep, and those that have shelter in the night-time, are seldom affected by it; but it has been asserted by Mr. J. Hog, that he has seen many instances of domestic sheep, termed petty, dying of the disease; and that in some northern districts, where the small flocks of sheep are nightly housed the year round in fear of frosts, it rages with uncommon ferocity.

In regard to soils or grounds, those which are barren, dry, and unfenced, such as the ley heathery kind, are the most liable to have the sheep affected with the disease. But all kinds of pastures, which have one part of the herbage fine, and the other coarse, are liable to cause the disease, and to have great loss from it. Those likewise which have a sweet juicy food in a flosed and impure condition in different parts of them, or spots of luxuriant grafts, and that of sheep tallow, as old walks, and other places, are very dangerous. The animals nauteate tallow-grafs, it is said, uninjured by the frost, when they eat it in quantities evidently dangerous to them. Where the food that is produced is in the most confluent state of fat growth, the sheep in the pastures are the most safe from this disease.

In respect to the cure of the disease, in consequence of the fuddledness of its attack and fatality, it is probably almost impossible, as nearly one half the sheep attacked by it, are said to be dead before they are discovered to have been affected. Notwithstanding this, however, a great number of remedies for it have been proposed at different times, and highly extolled for the certainty of their success; but they have been found of little avail. Some of them, indeed, have contributed to aggravate the disease rather than to remove it, as those of the spirituous, mustard, and some other kinds. But if, in any instance, a cure is at all possible, it can only be effected, it is said, by such means as are calculated to counteract and remove inflammation, and those employed in the very infant or onset of the disorder. Of these means, blood-letting is perhaps chiefly to be depended upon, and the veins in the tail, on the sides of the forelegs, and the stables of the eyes, may be opened for the purpose.

At the first symptoms of the cooling refrigerant kind, such as nitre, and cathartic purging ones of the saline fort, with caftor oil, infusions of lenses, and others of a similar nature, may be given; and proper crytlers may be thrown up, in some cafes, with more effect: when, if the bleeding should be full and free, and the purging or evacuation of the bowels suitable, some hopes of the recovery of the animal may be entertained. When the sheep do recover, they are however always weak, and require much care and attention to get them through the winter feason.

Another mode of treatment for this disease has been advised by Mr. J. Hog, on the ground of actual experience, but which appears very inconsistent and improper. This is, in the first place, if the animal be found in time, to give it a severe heat, by running it: if this be not successful, he knows nothing that will. It is to be so well hunted, as that it does not immediately afterwards lie down on leaving it, or if this be the case, it should be in the house. This means has been discovered by chance, it is thought, but has not been properly acknowledged.

Bathing in warm water for ten or eight minutes at least, has also been recommended; after which a quantity of water-gruel, mixed with butter or some other soothing ingredient, may be administered as an injection or otherwise.

Great care is, however, to be taken that none of these means are used in the fourth of the above varieties of the disease, or that of the watery kind, as they occasion infant death.

Much more is, however, to be done by the means of prevention than those of cure in this complaint. These are many, such as the proper plans of managing the young hog-sheep in rearing them, as has been seen above; the preserving the vegetation of the pasture herbage as much as possible by proper stocking and feeding such lands; the providing proper supplies of green succulent food for the stock; the proper moderate use of turnips, as by this means the losses by the disease have been greatly prevented and lessened in different cafes; the sheltering and protecting them well; the net allowing them to be over-heated by exertion; the careful removal of all forts of coarse rank grafts in the pastures; the destruction of the ley heather in the winter hog-pastures by burning or other means; the moving the sheep about early in the morning; the bleaching the hog-sheep previously to the season of the disease attacking them a small extent; and some others. Many think great advantages are derived in this way, by pasturing the young and old sheep of the flocks all together, as by such a mode the disease has been almost wholly eradicated, and prevented where it had been introduced. And that great benefit arises from having the pasture-grounds for the sheep, especially the hogs, all of the same quality or kind, whatever it may be. These several points are fully considered and explained in an excellent paper on this disease, inserted in the third volume of the "Transactions of the Highland Society of Scotland," by A. Duncan junior, M.D., to which the inquirer is referred.

**Striking off Wheat-Leaves, or Flagging, a practice or operation performed in some districts, as in Ayr, for thinning and clearing away the large broad leaves of strong full wheat-crops. In executing this sort of work, the men, with fickle or reaping-hooks that have sharp edges, when these crops are very heavy, with broad luxuriant leaves, move regularly through the fields of them, and strike off many of these leaves, in order to lighten the tops of the plants, with the view of preventing their being beaten down by rain. It should, it is said, be done carefully, or damage may ensue from it. This curious practice is, however, very little known or employed in other districts, and probably but seldom necessary in any cafes.**

**Striking off Above-Mill Machine, an instrument or machine contrived for the purpose of striking off or clearing pasture-grounds of these sorts of hills, which are sometimes very injurious**
injuriously and troublesome in them. It consists of a sort of
strong wooden frame, about five feet by four in the square,
which has handles behind, and is rounded off a little in the
front parts, in order to be drawn along the surface of the
land with facility; having the under parts set with a kind of
coulters or cutting-blades, which readily flake and take off
the hills as it moves along, in an even and neat manner.

A representation of it may be seen in the first volume of
the Corrected Report of the State of the Agriculture of the
County of Middlesex, published by the Board. [\textit{Striking or Suckling of Hemp and Flax, in Rural Eco-}
\textit{nomy}, the means of beating and preparing them over the
wooden rump or flock, so as to render them soft, and clear
of the shaves or shawy matters that hang about them.
[\textit{Striking of Meat}, the practice or first operation in curing
it with salt. The smallest-faced sort of salt is thought to
be the best for this purpose, whether it is in the dry
or moist manner. See \textit{Salt}.

\textit{Striking-Watch}. See \textit{Watch}.

\textit{Striking-Wheel}, a clock, the fame with which
by some is called the pin-wheel, because of the pins
which are placed on the round or rim, (which in number are the quo-
tient of the pinion divided by the pinion of the detent-wheel.)
In sixteen-day clocks, the first, or great wheel, is usu-
ally the pin-wheel; but in such as go eight days, the second
wheel is the pin-wheel, or striking-wheel. See \textit{Clockwork}.

\textit{Strilek}, in \textit{Geography}, a town of Moravia, in the
circle of Hradisch; 14 miles N.W. of Hradisch.

\textit{Strillozza}, in \textit{Ornithology}, a name by which some
authors have called the \textit{emberiza alta}, or bunting, or per-
haps a bird somewhat different from our bunting, and com-
mon in Italy; for it is not yet ascertained, whether the stril-
lozza specifically differs from the bunting, or only by some
accidental variegations.

\textit{Strimba}, in \textit{Geography}, a town of European Tur-
key, in Moldavia; 18 miles N.W. of Birlat.

\textit{Strimiz}, a town of Bohemia, in the circle of Leit-
meritz; 18 miles W. of Leitmeritz.

\textit{Strimon}, or \textit{Emboli}, a river of European Turkey,
in Romania, which runs into the gulf of Contoza, 6 miles
S. of Enyros.

\textit{Strindlen}, a town of Norway, in the province of
Droneheim; 3 miles N.E. of Droneheim.

\textit{String}, in \textit{Music}. See \textit{Chord}.

If two strings or chords of a musical instrument only differ
in length, their tones, that is, the number of vibrations
they make in the same time, are in the inverse ratio of their
lengths. If they only differ in thickness, their tones are in
the inverse ratio of their diameters. As to the tension of
strings, to measure it regularly, they must be considered
fretched or drawn by weights; and then, \textit{ceteris paribus},
the tones of two strings are in a direct ratio of the square
roots of the weights which fret them; that is, \( c_1 e \), the
tone of a string fretted by a weight \( 4_1 \), is an octave above
the tone of a string fretted by the weight \( 1 \).

It is an observation of very old standing, that if a viol or
lute-string be touched with the bow, or hand, another string
on the same, or another instrument, not far from it, if in
unison to it, or in octaves, or the like, will at the same time
tremble of its own accord. See \textit{Unison}.

But it is now found, that not the whole of that other string
thus trembles, but the several parts, severally, according as
they are unisons to the whole, or the parts of the string for
which. Thus, supposing \( A B \) to be an \( A \) and \( B 
\) upper octave to \( c \), and therefore an \( c \) unison to each half of it, stopped at \( b \);

\begin{align*}
1 & 1 & 1 \\
2 & b & 2
\end{align*}

If, while \( a \) is open, \( A B \) be struck, the two halves of this
other, that is, \( a b \) and \( b c \), will both tremble; but the
middle point will be at rest; as will be easily perceived,
by wrapping a bit of paper lightly about the string \( a c \), and re-
moving it successively from one end of the string to the other.
In like manner, if \( A B \) were an upper twelfth to \( a c \), and,
consequently, an unison to its three parts \( a 1, 1 2, \) and \( 2 c 
\); if, \( a c \) being open, \( A B \) be struck, its three parts \( 1, 1 2, \) and \( 2 c \), will severally tremble; but the points \( 1 \) and \( 2 \) remain
at rest. This, Dr. Wallis tells us, was first discovered by
William Noble, of Wadham College; and after him, by Mr.
T. Pigot, of Wadham college, without knowing that Mr.
Noble had observed it before. To which we may add,
that M. Sauveur, long afterwards, proposed it to the Royal
Academy, at Paris, as his own discovery, as it is like
enough it might be; but upon his being informed, by some
of the members then present, that Dr. Wallis had pub-
lished it before, he immediately resigned all the honour

This phenomenon is better explained under the articles
\textit{Harmonique}, \textit{Vibrations}, \textit{Fundamental}, and
\textit{Genera}.

We shall add to the article \textit{Strings}, musically consi-
dered, D'Alembert's definition of the term \textit{corde fonore} in the
original edition of the Encyclopédie, and copied by Rousseau
in his \textit{Dictionaire de la Musique}.

\textit{Corde fonore} is any string fretted
right, whence a musical tone can be produced.

"If a string is screwed tight in any one of its parts, it
moves to a certain distance from the right line it formed in
its quiescent state, returning afterwards, and vibrating back
and forwards, by its elasticity, like a pendulum put in motion.
Further, if this string is of a substance equally elastic in
all its parts, so that the undulation is communi-
cated to the whole string, in vibrating it will produce a
sound, and its sound will always accompany its vibrations.

Geometrical have discovered the laws of these vibrations,
and musicians those of the sounds which they produce.

"It has been long known by experience, and, to a certain
degree, by reason, that, \textit{ceteris paribus}, strings vibrate with
more or less rapidity, in proportion to their length; that is
to say, the ratio of their lengths is always inerse to that
of the number of the vibrations. Dr. Taylor, a celebrated
English geometer, was the first who demonstrated
the laws of the vibrations of strings with exactitude, in his
learned work, entitled "Methodus incrementorum directa
et invera," 1715; and these fame laws have likewise been
demonstrated by John Bernoulli, in the second volume of the
"Memoires de l'Acad. Imperial de Petersbourg."

From the formula (adds Rousseau) which results from
these laws, and which may be found in the Encyclopédie,
art, \textit{Cordes}, I shall draw the corollaries following, which
serve as principles to the theory of music.

1. If two strings of the same matter are equal in length
and thickens, the number of the vibrations in equal times will
be as the roots of the numbers which express the ratio of the
tension of strings.

2. If the tensions and the lengths are equal, the number
of the vibrations in equal times will be in the inverse ratio of
their thickens, or diameter of the string.

3. If the tension and thickens are equal, the number of
vibrations in equal times will be in the inverse ratio of their
lengths.

For the intelligence of these theorems, it seems neces-
sary to observe, that the tension of the strings is not repre-
sented by the weight or press为客户生成的文本内容。
From the laws of the vibrations of strings, are deduced those of the sounds which result from them. The more vibrations a string makes in a given time, the more acute is the sound; and the fewer vibrations a string makes, the more grave it is. So that sounds reciprocally follow their vibrations; their intervals are expressed by the same ratios, which reduces all music to calculation.

It appears by the preceding theorems, that there are three ways of changing the tone of a string: namely, the length, thickness, and tension. What these alterations produce successively upon the same string, may be produced at once on different strings, in giving them different degrees of length, thickness, and tension. This method combined is that which is practised in the fabrication and tuning of all stringed instruments, relative to the fixed length of the strings by pins and bridges, or the changeable lengths by pegs and a nut; and the pressure of the fingers, which act like moveable bridges of a monochord. See Harmonics.

Another property, not less surprising, of a tuneable string is, that if the finger which divides it into its aliquot parts touch the string lightly, without pressing it down to the finger-board, and a part of its vibrations are suffered to be communicated to the upper portion of the string, at such time, instead of the whole string sounding, or the usual part of it next the bridge, the found only of the greatest common aliquot will be heard. See Harmonics.

The word corde, in French, is used frequently in compositions for the fundamental sounds of the key; and the dispositions which alter the modulation in the baie, or prolong a phrase, are often called harmonic chords.

Strings, in Ship-Building, is a brake or frakes withinside, under the gunwale, and answering to the sheer-frakes without-side: it is scarified in the name manner as the sheer-frake, and bolted through the ship's side into the sheer-frake between the drifts, for the purpose of greater strength, as this part requires all the security that is possible to be given, in order to affit the sheer.

Strings of Metal, a term used by our miners to express those thin and small veins of ore, into which the beds or veins degenerate toward their terminations. These are from an inch to a tenth part of an inch in thickness, and run through the solid rocks to a great distance. The ore in them is usually very pure and rich, and as they lie in the rocks, communicating with the larger veins of ore, they resemble the several small brooks and rivulets in a hilly country, which by degrees uniting all their streams, form the rivers.

STRING-HALT; among Horset, an involuntary and convulsive motion of the muscles, which extend or bend the hough. When it seizes the outside muscles, the horse stumbles, and throws his legs outward; but when the inside muscles are affected, his legs are twitched up to his belly. Sometimes it is only in one leg; sometimes in both. It generally proceeds from some strain or blow, and the removal often is difficult, and seldom attended with success; though, in the beginning, a string-halt may be removed with good rubbing, and the use of fomentations, with daily but moderate exercise. The last refuge is usually the fire, which some say has been known to answer, at least so far as to prevent absolute lameness in particular cases. A similar affection sometimes takes place in that cattle, which is to be removed nearly in the same manner.

STRINSIA, in Ichthyology, a name given by authors to that species of the gadus, which is called by some lota, and by others mystus flavoventris; by us in English the coal-pout. Olaus Magnus calls it the borbolus.

STRIP, at Sea. A chase is said to strip himself into short or fighting fails, when he puts out his colours in the poop; his flag on the main-top; his foremasts or pendants at the end of his yard-arms;furls his sprit-sail; peeks his mixen; and slings his main-yard. In which case, the chaser must prepare himself for fight.

Strip, To, is to unrig a ship, or divert the masts of their machinery and furniture, otherwise called dismantling.

Strip, To, in Rural Economy, a term signifying to drain the raft milk from cows.

Striped Stalk, See Stalk.

Striped Velvet. See Velvet.

Stripping, in Agriculture, a term applied to the operation or practice of scrimming or taking off a thin portion of the surface of lay or other ground, in a fort of alternate manner; a thin flise or piece of the turfy or other surface, to the breadth of from four to five inches, being cut up and turned over on to an adjoining portion of solid surface of the fame breadth, in performing the work: by this means, though the turfy or other surface be half of it stripped or cut up and turned, the whole is completely covered over, presenting a stripped or ribbed-like appearance; which, in some places and districts, is termed ribbing, but in others it has different other names given to it.

This is a practice which is common in most of the southern counties of the kingdom.

Stripping of Hop-Poles, in Rural Economy, the practice of clearing and removing the waffe binds from about them after the hops have been picked, by untwisting and drawing them off from the poles, which is readily executed. It is an operation that should always be performed as soon as possible after the produce has been gathered, as much injury is done to the poles by letting the binds remain long twifled about them while they are lying upon the moist ground. The price of tripping poles of this kind of this fort of incumbrance, is most commonly about three shillings the acre. When the stripping of the poles has been completed, they are ready for being pointed and put up in stacks. See Stacking and Staking of Hop-poles.

Stripping of Paring-Share, in Agriculture, that fort of stripping or paring contrivance which is fixed upon ploughs for the purpose of tripping, paring, or taking off the surface or fward of lay-ground, in some cafes, in breaking it up. It is made in somewhat the manner of a paring-flock, and rendered extremely sharp in the cutting parts or edges. It is formed of different sizes; but has sometimes considerable breadth, and is capable of being put upon different common ploughs. It is a tool or contrivance which is much used in Devonshire and Cornwall, and which may, on different occasions, be found useful, and of considerable benefit in the performance of such fort of work in different other districts of the country. See Sock-Paring.

Strippings, in Rural Economy, a word made use of to signify the last milk of cows, or the frothings or afterlings.

STRITHAGEN, in Geography, a town of France, in the department of the Orte; 8 miles N.W. of Rodluc.

STRIVALE, in Ichthyology, the name used by many for the fish more usually known by the name of aper, the boar-fish.

STRIVALLI, in Geography, two rocky islands in the Mediterranean, anciently called "Strophades," which, according to the representations of the poets, were the abode of the Harpies; now inhabited by a few monks; 46 miles S. of Zante. N. lat. 37° 29'. E. long. 21° 12'.

STRIX, the Owl, in Ornithology, a genus of birds of the order Accipitres; of which the generic character is as follows: Bill hooked, no cere; nostrils oblong, covered with
STRIX.

with bristly recurved feathers; the head, auricles, and eyes, large; the tongue is biform.

The birds of this genus fly abroad by night, and prey on small birds, mice, and bats: their eyes are weak by day, and generally closed, during which time, if discovered, they are pelted by small birds: their legs are usually downy to the toes; outer toe retructile; auricles large, covered with a membrane; outer quill-feathers serrate on each edge; the claws are hooked and tawny.

The alliance between the genus Strix and that of Falco (which see) is extremely strong, so much so, that by some authors, owls have been considered as a kind of nocturnal hawks, differing, as Linnaeus observes, from those birds, in the same manner as moths differ from butterflies; the one being chiefly nocturnal, and the other diurnal. These are separated into two fections, viz.: those that have ears or horns, and those that have none. These horns are lengthened feathers on each side the head, and are capable of being more or less erected, at the pleasure of the bird. To these Dr. Shaw has added another division, under the name of Accipitrine owls, or such as, from their general habit, are more nearly allied to hawks than the others. Gmelin enumerates fifty species, but Dr. Shaw describes more than sixty.

Species.

A. Eared.

Bubo; Great Owl, or Rufous Horned Owl, variegated with black, brown, and ash-coloured spots and freckles. The specific character given by Gmelin is, body tawny. There are three other varieties: 1. Body darker, with blackish wings. 2. Legs naked. 3. Blackish-yellow, variegated with white. This is the largest species of owl, and but little inferior in size to an eagle. Its general colour is rufous or ferruginous, varied with larger and smaller spots and markings of brown, black, and grey; together with innumerable freckles or minute specks of the same colours. It is found of a deeper or lighter hue, according to various circumstances of age, health, and climate: the larger wing and all feathers are obscurely varied by dusky transverse bars; the bill is black, the eyes are very large, and of a bright red or golden orange-colour; the legs are short and strong, thickly clothed, down to the very claws, with fine, downy, and fuscous plumage; the claws are extremely large, strong, and black.

This species, including the varieties above enumerated, appears to be very generally diffused throughout the temperate and northern parts of the old continent, and is even suppos'd to occur both in North and South America. In this country it is rarely seen; in Germany it is rather common. It preys, in the manner of eagles and the larger falcons, on hares, rabbits, and almost all kinds of birds, and builds its nest among the crags of rocks, or among ruined edifices, and lays, as it is suppos'd, rarely more than two eggs, which are larger and rounder than those of a hen, and of a rufous colour, blotched with variegations not much unlike the bird itself.

Owls have usually been regarded as birds of ill omen, and superstitiously considered as messengers of woe. This is the case in the new world as well as the old. The Athenians, among the ancients, seem to have been free from this popular prejudice, and to have regarded the owl with veneration rather than abhorrence, considering it as the favourate of Minerva. The owl thus venerated appears to have been a variety of this species, which is said to be common in many parts of Greece. The Romans viewed the owl with detestation and dread. It was held sacred to Proserpine: its appearance foreboded unfortunate events, and according to Pliny, the city of Rome underwent a solemn purification in consequence of one of these birds having accidentally strayed into the Capitol.

Virginia; Virginia Owl. Body above brown, varied with fine, zigzag, tawny, and cinereous lines; beneath pale-asph, with transverse brown streaks; throat and sides of the breast orange, streaked with brown. This is the constant of America, and is life than the last. According to Mr. Edwards, it approaches in many respects nearly to the greatest horn or eagle owl: the bigness of the head in this seems not at all inferior to that of a cat; the wing, when closed, measures, from the top to the ends of the quills, full fifteen inches; the bill is black, the upper mandible is hooked, and overhanging the hither, as in eagles and hawks, having no angle in them, but plain on its edges; it is covered with a thin, in which are placed the nostrils, and that skin hidden with a finely kind of grey feathers, that grow round the back of the bill; the eyes are large, having circles round them, broad, of a bright shining gold-colour; the space round the eyes, which may be called the face, is of a light brown colour, confusedly mixed with orange, gradually becoming dusky where it borders on the eyes; over the eyes it has white strokes; the feathers that compose the horns begin just above the bill, where they are intermixed with a little white, but as they extend onwards beyond the head, they become of a red-brown, clouded with dusky, and tipped with black; the top of the head, neck, wings, and upper side of the tail, are barred across with bars of dusky-redish; the greater wing-feathers and the tail are barred across with dusky bars of half an inch in breadth; the feathers between the back and wings are orange-coloured, tipped with white; the fore-part of the neck and back are bright brown, inclining to orange, which grows fainter on the sides; this brown part is spotted with pretty large dark spots; the middle of the breast, belly, thighs, and under-side of the tail, are white, or faint ash-colour, barred transversely with dusky lines pretty regularly; the inside of the wings is coloured and variegated to the same manner; the legs and toes, almost to the ends, are covered with light ash-coloured feathers; the ends of the toes and claws are of a dark horn-colour.

This species occasionally varies in the cast of its colours, which are sometimes darker, with fewer variegations in its plumage. It is found in North America, as high as Hudson's Bay, frequenting woody districts, and uttering, it is said, a most hideous noise in the woods, not unlike the howling of a man, so that passengers, beguiled by it, sometimes lose their way.

Scandinacia; Scandinavian Owl. Body whitish, with black spots. It inhabits the mountains of Lapland, and is the size of a turkey.

Zeylonensis; Ceylon Owl. Body above reddish-brown, beneath yellowish-white; circles on the face reddish-brown, streaked with black. It is, as its name denotes, an inhabitant of Ceylon, where it is called Rusa Aha. The length of this species is nearly two feet, and its weight about two pounds and three quarters. The bill is horn-coloured; the irida yellow; the upper parts of the bill of a pale reddish-brown; the under parts yellowish-white; each feather appearing to be streaked and barred with a dusky-black; the ears of the horns are short and pointed; the prime quills and tail are barred with black, white, and pale-red.

Sinensis; Chinese Owl. Body reddish-brown, with waved black lines, beneath streaked with reddish-black, and barred with white. It inhabits China: the bill and legs
legs are black; secondary quill-feathers with four blackish bars.

Coromanda; Coromandel Owl. Body above greyish-red, with reddish-white spots; beneath pale-red, with small semilunar black spots. It is found in India. The bill is black; the irides yellow; legs reddish; cheeks white; quill and tail feathers barred with reddish-white.

Ario; Red Owl. Body above ferruginous, beneath cinereous; wings with five white dots. It is not quite a foot long. It inhabits New York, and as low as the Carolinas; and lives in the woods near the coast. The female is said to differ in being brown and ferruginous.

Mexicana; Mexican Owl. Body variegated with brown and black. It inhabits Mexico, where it is called by the name of Ticonde. Its colour is a variegation of black and brown.

American; American Owl. Head and body above cinereous, beneath rufous; rump white, spotted with black; wings and tail rufous, with cinereous and grey tranverse lines. This is an inhabitant of America, and is supposed by Buffon to be a variety of S. otus, which is the next to be described.

Otus; Long-eared Owl. This, in its general appearance, is very strikingly allied to the S. subo, but in size it is far inferior. It is about fourteen inches and a half in length. The general cast of the colours inclines more to ferruginous on the breast and underparts, with a mixture of white in the front of the head and thighs. This bird is fond of woody and rocky solitudes, and is not observed to build any nest of its own, but contents itself with a deft nest of a butcher or magpie, and usually lays five eggs. The young are at first entirely covered with white down, and begin to acquire their colours at the expiration of about fifteen days. In several parts of Italy is found a variety of this bird, which differs in being somewhat larger, and in having the plumage mixed or varied in a considerable degree with ash-colour; the bend of the wing and the coverts white, and the tail is marked with zigzag black lines. The long-eared owl is considered as a pretty general inhabitant of Europe, and though far less common in our own country than some other species, it is not of uncommon occurrence. In North America it is found to inhabit the woods at a distance from the sea-coast, and has been observed at Hudson's Bay, preying chiefly on birds, with much cunning; and often approaches the dwellings of the inhabitants.

Brachytoon; Short-eared Owl. Horns short; body above brown; the feathers edged with yellow; beneath pale-yellow, longitudinally streaked with dusky. This species is found in our country, in divers other parts of Europe, also in America and Siberia. This bird was first accurately described by Mr. Pennant, whose account is as follows. The length of the short-eared owl is about fourteen inches; the extent is three feet; the head is small and hawk-like; the bill is dusky; weight fourteen ounces; the circle of feathers that immediately surrounds the eyes is black; the larger circle is white, terminated with tawny and black; the feathers on the head, back, and coverts of the wings, are brown, edged with pale dull yellow; the breast and belly of the same colour, marked with a few long, narrow streaks of brown, pointing downwards; the thighs, legs, and toes, are covered with plain yellow feathers; the quill-feathers are dusky, barred with red; the tail is of a deep brown, adorned on each side; the shaft of the four middle feathers with a yellow circle, which contains a brown spot; the tip of the tail is white. The horns of this species are very small, and each consists of only a single feather; these it can raise or depress at pleasure, and in a dead bird they are with difficulty discovered. This bird is much more rare than the long-eared owl; both are solitary birds, avoiding inhabited places. These species may also be denominated long-winged owls; the wings, when censed, reaching beyond the tail; whereas in common kinds they fall short of it. The short-eared owl is a bird of passage, and has been observed to visit Lincolnshire in the beginning of October, and to retire early in the spring; so probably, as it performs its migrations like the woodcock, its summer retreat is Norway. During the day, it lies hidden in long old grass; when disturbed, it seldom flies far, but will alight, and sit looking at any person who happens to be present, at which time the horns may be seen very distinctly. It has not been observed to perch on trees, like other owls; it will fly in search of prey in cloudy and hazy weather. Farmers are fond of seeing these birds in their fields, as they soon clear them of mice. It is frequently found on the hill of Hoy in the Orkneys, where it flies and preys by day, like a hawk. This bird in Hudson's Bay is called the moule-bawk. It never flies, like other owls, in search of prey, but flies quietly on the slum of a tree, watching the appearance of mice. It breeds near the coast, making its nest with dry grays upon the ground, and migrates southwards in the autumn.

Mr. Latham gives a different description of this species, which is common in the northern and woody parts of Siberia; it frequently rushes blindly towards such fires as are light by night, and afflicts the persons near them. It is very fierce, and not at all wanting in courage, and will even attack the sportsman endeavouring to secure it. Mr. Latham says, that the ear-feathers or horns in reality composed of several feathers, and do not consist of one only on each side, as is commonly supposed; and their power of elevation is not very great.

Braulii; Brevi Owl. Body above pale rufous-brown, spotted with white, beneath whitish, with rufous-brown spots. It inhabits Brazil, and is about the size of a thrush. Bill, irides, short feet, and toes, yellowish.

Nasi; Mottled Owl. Body grey, beneath pale, both spotted with black and rufous; feathers of the head and breast dotted with black. It is found at New York, and is twelve inches long.

Indica; Indian Owl. Black-dusky; wing-coverts grey, wing black lines; breast buff, with small arrow-shaped spots. Inhabits Ceylon, and is seven inches long.

Zoreia; Sardinian Owl. Feathers of the ears eight or nine, bill greenish-yellow. It inhabits Sardinia and Italy; the toes are naked, seven inches long; it is solitary, does not migrate, and makes a howling noise.

Carniolica; Carniolick Owl. Body whitish-ash, with blackish spots and tranverse stripes. It inhabits Carniola, and makes its nest in hollow trees and rocks.

Demina; Yak Owl. Body red, of a small size. It inhabits the forests upon the Ural. It resembles the S. xubo in colour and form, but is much less; it weighs scarcely a pound; it builds its nest in fissures of rocks and hollow trees.

Pulchella; Siberian Owl. Body grey, variegated with brown, rufous, and white. It inhabits Siberia, and is nine inches long.

Scops; Little Horn-Owl. Ears of one feather each. This inhabits Europe; is seven inches and a quarter long, and preys on field-mice. In the dead body the ears are scarcely conspicuous; the colour varies according to the age, grey, rufous, brown or blackish; the legs are spotted with brown; the toes and claws are brown. This is a species
of uncommon elegance, and of a small size. The general disposition of its colours is similar to that of the eagle owl, but with a mixture of grey, which predominates on the breast and belly of the bird; it varies, however, considerably in the cast of its colours, according to the circumstances of age and sex; and when young it is said to be wholly grey: the irises are also said to be of a pale yellow in the young, and deep yellow or even hazel in the old birds; the legs are covered to the toes with speckled grey and brown plumage. The scope is a native of the warmer parts of Europe, and is of a migratory nature. In France it is said to arrive and depart at the same time with the swallow. At particular times great flights arrive, and wage war against field-mice, in those years when these animals happen to be unusually numerous. In Italy, its favourite residence is in gentry rising, wooded regions, but not among lofty mountains, and it lives chiefly on insects and earthworms. During the day it continues in the shade of the woods, perched on a branch, and remains motionless, with its ears or tufts erected; in this state it will permit a very near approach, and then only retires to hide itself afresh among the branches. Towards the dusk of the evening it emerges from its retreat, perches on a tree in some open spot, and begins its cry, which consists of a quick and often repeated whistle. It is a solitary bird, and is said to be as choosy in the selection of its eggs, to the number of five or six, in the hollows of trees. In Italy, the young are full-grown by the beginning of July, when they follow their parents during the night for food, till they are able to feed themselves, and to procure grasshoppers, beetles, and other insects. When this period commences, they leave their parents, and each lives separately. They remain in Italy till October, at which time they become very fat, and would be good food, but for a peculiar smell attaching to the flesh. When taken very young, they become by constant attention familiar, and to a certain degree affectionate, but this courtship only goes on so long as their dependence is necessary for their support. After that period is elapsed, their familiarity subsides, their confidence diminishes, and at length they make their escape, and seem to fly from mankind as the general tyrant of nature.

B. Earls.

Nyctea; Snowy Owl. Body white, with a few brown lunate spots. This is found in Europe, America, and Asia, and is often seen by day, especially near banks and lakes, on the herons, hares, mice, and sometimes carrion; makes a howling noise; in winter it is often snow-white. It has a variety of notes, the bill and claws are black. According to Mr. Pennant, this species varies greatly in weight, being from three pounds to a pound and a half. It inhabits the coldest parts of America, even as high as the remote mountains in the icy centre of Greenland, from which it is known to migrate to the shores. It adds horror even to that country, by its hideous cry, resembling the voice of a peron in deep distress. It is rare in the temperate parts of America, and rarely seen at all in the United States. It is very common in Hudson's Bay, Norway, and Lapland. It has no dread of the utmost rigour of the season, but bears the cold of the northern regions the whole year. It flies by day, and is scarcely distinguished from the snow; it falls perpendicularly on its prey; feeds on white grous, and probably on hares; hence its Swedish name barfjung. In Hudson's Bay it is almost domesticated, harbours in places near the tents of the Indians. It is scarce in Russia, but rather common on the Ukrainian mountains, and all over the north and east of Siberia, and in the Asiatic empire, even in the hot latitude of Astrakan. In Kamtchatka it is very numerous.

Tengmalmi; Swedish Owl. Body grey, with small round spots. It inhabits Sweden, and is the size of a blackbird.

* Nebulosa; Barred Owl. Head, neck, breast, back, and wing-coverts, brown, spotted with white; the belly and vent are of a dirty-white, streaked with brown; the tail is marked with brown and whitish bands, whitish at the tip. It inhabits Hudson's Bay and New York; sometimes, but rarely, in England. It is two feet long, and feeds on mice, hares, and cranes.

Ferspicillata; Spectacle Owl. Head white, smooth, downy; body above, area of the eyes, and chin, brownish; beneath reddish-white; the breast is barred with reddish-brown. It inhabits Cayenne, and is twenty-one inches long.

Cinerea; Sooty Owl. Head, neck, and wing-coverts, sooty, with dirty-white lines; breast and belly white, with large oblong dusky brown spots. It inhabits Hudson's Bay; is two feet long; flies in pairs, and preys on mice or hares. The bill is whitish; irises yellow; the tail is marked with oblique brown and dirty-white streaks; a part of the skin from the chin to the vent bare of feathers.

* Cucuma; Spotted Owl. Body brownish, back and tail-coverts white, spotted with dusky; breast and belly of a dirty-white, with reddish lines crossing each other. This is also found in Hudson's Bay: it is two feet long: forms its nest of moss on the ground, and preys on mice and small birds: its flesh is considered as excellent food.

Cunicularia; Coquinabro Owl. Body above brown, beneath white; legs warty and hairy. It is found in Chili; is the size of a pigeon; flies in pairs, sometimes by day; and preys on insects and reptiles; it lays four eggs, variegated with white and yellow, in long subterranean burrows. The irises are yellow; the body above spotted with white.

Aluco; Aluco Owl. Head rufous; irises black; first quill-feathers ferrate. This is found in divers parts of Europe; is about fifteen inches long; lives during summer in woods, in winter near habitations; it feeds on mice.

Sylvestris; Auffriarian Owl. Body variegated white and brown; the space round the eyes is white, the irides red. It inhabits Auffria; is of the size of a fowl; the covering of the head is an elegant radiant wreath of white feathers.

Alca; White Owl. Body above tawny, spotted with grey; beneath white, black and tail feathers rufous, the latter tipt with white. It inhabits Auffria, as does the next.

Noctua; Rufous Owl. Body pale rufous, with longitudinal brown spots; the irises are brown.

Rupa; Ferruginous Owl. Body rufous, spotted with brown; the irises are blueish. It inhabits the woods of Iridia.

Soloniensis; Solonefe Owl. Body above black-brown mixed with tawny, beneath white; tail white, with blackish lines crossing each other near the tip. This inhabits France, and is fifteen inches long. Crown, and outward circle of feathers round the face, variegated with reddish and white; toes horn-colour.

* Flamma; Common Owl. Body above pale yellow, with white dots, beneath whitish, with black dots. It inhabits Europe, America, and Northern Asia, and is about fourteen inches long.

Barbata; Mountain Owl. Space round the eyes and chin black. Bill and irises yellow; body cinereous; primary quill-feathers ferrate on both edges.

* Stridula; Tawny Owl. Body rufous, the third quill-feather
feather is longer. It inhabits Europe and Tertiary, and is nineteen ounces in weight.

* Ulula; Brown Owl. Body above brown, spotted with white; tail-feathers with linear white bands. A variety is much smaller, though some writers confine these two varieties as merely the male and female of the same. This species inhabits Europe and Newfoundland, and is about fourteen inches long. With respect to the general manner of the brown owl, or Ulula, as called by Pennant, the webbed owl, the naturalist observes, that by night these birds are very clamorous, and when they hoot, their throats are greatly inflamed. In the dusk they approach our dwellings, and will frequently enter pigeon-houses, and make great havoc in them. They destroy numbers of leverets, as appears by the legs frequently found in their holes; they also kill abundance of moles, and fink them with as much dexterity as a cook does a rabbit.

Arctica; Arctic Owl. Body rufous-brown, above spotted with black, beneath streaked with narrow brown lines; bill, orbits, and band under the wings, brown. It inhabits Sweden, and is eighteen inches long.

Funerea; Canada Owl. Body brown, with a few large white spots above, beneath white, with transverse narrow brown bars; the tail is long, with broad brown and narrow white bars. This species is found in many parts of Europe and North America. The head is black, with white points; five first inner quill-feathers not spotted on the outer edge; the irids are yellow.

Hudsonia; Hawk-Owl. Feathers above brown, with white edges, beneath white, with transverse black lines; the bill and irids are golden. This bird, says Edwards, who was the first discoverer of it, rather larger than a sparrow-hawk, and has much the air and manner of a hawk, from the length of its wings and tail; but the form of the head and feet clearly shew it to be near of kin to the owl kind. The birds of this species fly and prey at noon, which is contrary to the nature of most of the owl kind. The bill is like a hawk's, but without angles on the sides, of a bright reddish-yellow. Mr. Edwards was told that the eyes are of the same colour. The spaces round the eyes are white, a little shaded with brown, and dappled with small, longish, dusky spots; the outides of these spaces, towards the ears, are encompasshed with black; without that again is a little white; the bill is covered almost with light-coloured bristle feathers, as in most of the owl kind; the top of the head is of a very dark brown, spotted finely with little regular round spots of white; round the neck, and down to the middle of the back, is dark brown, the feathers seeming to be tint with white; the wings are of a brown colour, the quill and covert feathers being finely spotted on their outer webs with white; the three quills next the body are not spotted, but have whitish tips; the feathers between the back and wing are painted with broad transverse bars of brown and white; the inner coverts of the wing are white, with transverse lines of brown; the quills within are of a dark ash-colour, with white spots on both webs; the prime quill is spotless, and without on its outer web, and hardly any of that reflecting back of the point of the outer web, as is observed in owls; the rump and covert-feathers of the tail are dark-brown, transversely barred and mixed with a lighter brown; the tail on the upper side is dark brown, and ash-coloured beneath, composed of twelve feathers, the middlemost longer by two inches acros than the very outermost; it is barred acro by seven or eight transverse narrow bars of light brown; the breast, belly, thigh, and coverters under the tail, are white acros, with narrow brown lines in a regular manner; the legs and feet are wholly covered with fine soft feathers of the colour of the belly, but the variegating lines are smaller; the claws are sharp, crooked and pointed, and of a dark brown colour. There was, says Edwards, another of this species brought with this, which was a little bigger, and differed something in colour, which he imagines was the female of this. These were natives of Hudson's Bay, where its native name is Caprascacc. It preys on white partridges and other birds, and is so bold as to stand near the former with his gun, and will sometimes carry off a partridge after it is shot, before the sportsman can come up to it. Pennant, in his Arctic Zoology, says this species is common to North America, Denmark, and Sweden; it never hatches above two at a time, which for months after flight remain of a rufous-brown colour.

Uralensis; Ural Owl. Body whitish, with longitudinal brown spots in the middle of each feather. It inhabits the mountains of Ural, in Siberia, and is the size of a hen. The bill is of a wax colour; the irids and eye-rids are black; orbits ash; the rump is white; the tail is long and wedged.

Accipitrina; Caspian Owl. Body above yellowish, beneath yellowish-white, both sides with longitudinal blackish streaks, belly dotted with black, irids citron. This inhabits near the Caspian sea; and is the size of the brown owl. The bill is black; wings beneath and vent white; quill-feathers outside yellowish; within white testellate with black; the tail is rounded, shorter than the wings, blackish barred with white, and whitish at the sides.

Javanica. Body cinereous, in a few places reddish, with black and white spots; beneath it is of a dirty-white, mixed with reddish and black spots.

Nova Zealandia; New Zealand Owl. Irids yellow; body above brown, spotted with white; beneath it is tawny. There is a variety of which the body is brown, the feathers edged with tawny; the tail is brown, with paler bars; orbits tawny. It inhabits New Zealand: is eleven inches long; the bill is horned, with a black tip.

Cayennensis; Cayenne Owl. Body streaked with reddish, and transversely waved with brown; the irids are yellow. It inhabits Cayenne, and is the size of the fierce-owl. The bill is horned, claws black.

Dominicensis; St. Domingo Owl. Body beneath rufous; breast a little spotted. It inhabits St. Domingo; resembles the brown owl: bill larger, stronger, and more hooked.

Tolchiquati; New-Spain Owl. Irids pale-yellow; body above variegated with black, pale-yellow, white and tawny; beneath white. It inhabits New Spain. The bill, claws, and lower wing-coverts, black.

Chichicatl; Mexican Owl. Body tawny, variegated with brown and black; the eyes are black, the eye-rids blue. It inhabits New Spain, and is about the size of a ham.

Acadica; Acadia Owl. Body above bright bay, spotted with white; beneath dirty-white, mixed with rufous. It inhabits North America, and is seven inches long. The bill is brown, the irids yellow, crown with pale spots; orbits cinereous; toes brown.

Pasarina; Little Owl. Quill-feathers with five rows of white spots. There are two other varieties.

1. Smaller, eyes surrounded with white circles. 2. Larger; wings variegated with brown and yellow; the chin is white; the bird is twelve inches long. This species is found in many parts of Europe, but is rare in England. It appears to vary not only in the cast of its plumage, but in the colour of its irids, which, in some specimens, are said to be of a darker colour than those in which the irids are yellow. The passerine owl frequents ruins, and is said to deposit its eggs in such
such situations more frequently than in trees. It is a bird of a very wild disposition, and the young, when taken, even in the earliest stage, soon exhibit a ferocious character, and differ totally in temper and manners from those of the scoops, or little horned owl. 

*Larissus*: White-fronted Owl. Body rufus-brown, beneath paler; forehead white; quill-feathers barred with black and white. It inhabits North America, and is five inches long. The eye is bluish, tint with black; the tarsi are yellow; a semicircular white line behind the ears to the crown; lower part of the belly and legs cinereous; claws black.

**STROAKING**, a method of cure which some people have adopted in certain diseases, consisting in a mere application of the hand to the part affected, in the way of friction or rubbing.

*This* friction has very considerable uses in many diseases, is allowed. But as to the particular efficacy of the stroak of particular persons, we see little foundation for it in nature. Experience, indeed, seems to afford some, to which we do not well know what to object.

Mr. Thereby, in the Philosophical Transactions, No. 256, p. 332, or Abr. vol. iii. p. 11, gives several very remarkable instances of cures performed by that famous stroakker, Mr. Greatrix, and adds, that when Mr. Greatrix stroaks only for pains, he uses nothing but his hand; but that for ulcers, or running fowes, he uses spithe on his hand or fingers.

**STROBILES**, a word used by surgical writers to express a pledge of a twirled form.

**STROBILITAE VINUM.** See VINU.M.

**STROBILUS**, in *Botany* and *Vegetable Physiology*. *Strobilus*, or *Strobilus*, a name applied by the Greeks to the cone of a fir-tree, and adopted in the same sense by modern botanists, for every seed-veil of the same structure and character. (See PERICARP.) *A Strobilus*, or Cone, is a catkin, hardened and enlarged into a seed-veil, usually of a woody texture; sometimes rather coriaceous; rarely pulpy. In the most perfect examples of this sort of fruit, the seeds are closely shelled by the scales, as by a capsule, which, when dry, separate and spread, so as not to be brought together again, except by immersion in water. Thus the seeds, generally winged, are enabled to escape in the wind. Of the various species of Fir, Pimms, as well as the Cypress, and their allies, are examples. In the Birch and Alder, the Strobilus has a kind of capsule to the seeds, within the scales. The catkins of Poplars and Willows do not produce Strobilus, each of their scales being annexed to a flaked bivalve capsule, totally distinct therefrom. The *Platanus*, *Liquidambar*, and *Comptonia*, have globular catkins, in which bristles or tubercles supply the place of scales, and are far analogous to a real Strobilus. In *Juniperus*, the structure of whole fruit, in its origin, is exactly analogous to that of Pimms, what should be the scales of a Cone, become juicy instead of woody, and compose a soft homogeneous berry, in which the seeds are imbedded.

**STROBNITZ**, in *Geography*, a town of Bohemia, in the circle of Bechin; 4 miles S.S.W. of Gratz.

**STROBUS**, among the *Ancients*, a kind of mirror which bore to a height by many windings and turnings, and used by the Barbarians; instead of which the Romans wore the *apex*, which had a high but straight top.

**STROBUS**, in *Ancient Geography*, a town of Macedonia; which was a Roman colony.

**STROCAL**, in *Glyze-makings*, a long iron instrument like a fire-hoe, used to empty the metal out of a broken pot into a whole one.

**STROCHA**, in *Geography*, a town of the duchy of Stettin; 4 miles W. of Rottenman.

**STROEIA**, in *Geography*, a town of Denmark, in the island of Zealand; 6 miles S.W. of Fredericksburg.

Gen. Ch. Cal. Perianth inferior, of four ovate, acute, deciduous leaves; the two outer ones concave; inner flat. Cor. Petals four, laeacolate, all turned to one side, vawry, with claws the length of the calyx; sometimes wanting. Neurary of one leaf, ligulate, lanceolate, ascending, infected into the elongated receptacle towards its base; its tube slender, longer than the petals. Stam. Filaments five, sometimes but four, thread-shaped, unequal, infected into the stalk of the germen, two in the middle, three below, longer than the neurary; anthers oblong, erect. *Pyl*. Germen on a stalk exceeding the length of the germen, ascending, oblong; style none; stigma sessile, obtuse. *Peric.* Berry coriaceous, flaked, cylindrical, of one cell and two revolute valves. Seeds numerous, kidney-shaped, compressed, smooth, imbricated in three rows, imbedded in pulp. Eff. Ch. Petals four, or none. Neurary ligulate. Calyx of four leaves, deciduous. Berry coated, flaked.

1. *S. farinosa*. Mealy Stroemia. Vahl. Symb. v. 1. 50. Wildl. n. 1. (Cabad farinosa; Forlk. cent. v. 3. n. 12.)—Leaves oblong, mealy. Flowers with petals, and five flaments.—Native of Arabia. A shrub, with round branches, which, when young, are covered with a glaucous powder. *Leaves* alternate, on very short stalks, half an inch broad, entire, obtuse, without veins, flat, bejinkinkled, especially at the back, with a glaucous powder. *Stipulas* none. *Clavules* terminal, of six or eight *flowers*, drooping in the bud. *Petal* four, undulate. *Neurary* white, small; its limb revolute, narrower than the tube.—The Arabs call this plant *Afal*, *Korah*, or *Sarab*, and consider it as a counter-poison, with which intention they either chew the young and moist tender shoots; or eat them dried and pulverized.

2. *S. tetrandra*. Tetradromous Stroemia. Vahl. ibid. Wildl. n. 2. (Cleome fruticosa; Linn. Sp. Pl. 927. Burm. Ind. 1. 46. f. 3.)—Leaves elliptic-oblong, obtuse, with a small point, naked. Flowers with petals, and four flaments.—Native of the East Indies. *The stem* is shrubby, round, branching, leafy, smooth. *Leaves* nearly two inches long, flaked, green and smooth on both sides, with one rib, and many oblique veins. *Clavules* terminal, simple. *Flowers* near an inch in diameter; as far as can be judged from a dried specimen, they appear of a pale red, or yellowish. The *germen* are infected far up the stalk of the germen, but still much below the latter, so that this flower is by no means gynandrous.

3. *S. glandulosa*. Glandular Stroemia. Vahl. ibid. Wildl. n. 3. (Cabad glandulosa; Forlk. cent. v. 3. n. 13.)—Hair and viscid. Leaves roundish. Flowers without petals.—Native of Arabia, where it is called *Tamanin*. The *stem* is shrubby, with round branches, clothed, like the whole plant, with glandular hairs. *Leaves* rough, entire, pointed, brittle, half an inch broad. *Clavules* terminal, from four to five drooping flowers. *Fruit* rough with club-shaped bristles.

4. *S. rotundifolia*. Round-leaved Stroemia. Vahl. ibid. Wildl. n. 4. (Cabad rotundifolia; Forlk. cent. v. 3. n. 11.)—Leaves
STR

- Leaves orbicular, smooth. Flowers without petals.-

Frequent about Lobelia, in Arabia, and known by the name of _Kudahb_. This is a large tree, with thick, round, smooth, often emarginate, leaves, an inch broad, on round footstalks, which are half an inch long. _Clusters_ terminal, of eight or ten erect flowers, defoliate of petals, but furnished with an ovate, broad, flat _nectary_, tawny above, yellow beneath, green and slender at the base. _Stamens_ inserted near the bottom of the stalk of the _germen_. _Fruit_ two inches long, hanging by a stalk half that length, cylindrical, smooth, green, uneven, the thickness of a goose-quill; the valves, when they expand, are red on the inside. _Seeds_ black, in a red dry pulp.

STROEMSHOLM, in Geography, a town of Sweden, in Westmanland, on the Malart lake; 54 miles S.W. of Upsal. N. lat. 59° 30'. E. long. 16° 14'.

STROGELAVACCA, a town of Italy, in Friuli; 8 miles N. of Concordia.

STROKE, in Sea Language, a single sweep of the oars in rowing. Hence they say, _row a long stroke_, which is intended to push the vessel forward the more readily.

STROKESMAN is the person who rows the hindmost oar in a boat, and gives the stroke which the rite are to follow; so that all the oars may operate together.

STROLL, in Agriculture, a term provisionally applied to a narrow flake of land.

STROM, in Geography, a town of Norway; 14 miles S.S.W. of Bergen.—Ales, a town of Sweden, in Jamtland; 47 miles N.E. of Östersund.

STROMA, Island of, is situated in the Pentland Firth, about a league from the shore of Caithness, and county of Caithness, Scotland. It is a low islet, of a mile in length, and half a mile in breadth, and usually contains about thirty families. It is very productive in corn; but the principal employment of the inhabitants is connected with the sea. Fuel in this, as in most of the other Scottish islands, is difficult to be procured, whence the islanders are obliged to supply themselves with moss from the mainland. Here is a school, and the inhabitants regularly cross the Sound to the church. On the west of Strom a is a vast cavern, at about thirty yards from the beach, stretching down to a level with the ocean, the waves of which pour into it by a narrow opening. In stormy weather, the spray of the waves is tossed above the summits of the western rocks in such torrents, as to run in rills to a reoverflow on the opposite shore; and this, with the addition of the rain-water, is sufficient to keep a grain-mill in motion during the winter. From the influence of the salt particles continually floating in the air of Strom, the dead bodies of the sealers were preferred from putridity for many years, and some of them were exhibited in a chapel, as antiquities. The claim to the island of Strom was once contended by the earls of Orkney and Caithness, and decided in favour of the latter, because venomous animals were found to live here and die in the Orkneys. The name of Strom or Storma, is significative of the impetuous currents that prevail around the islet.—Carlile's Topographical Dictionary of Scotland, vol. ii. Beauties of Scotland, 8vo, vol. iv.

STROMATEUS, in Ichthyology, a genus of fishes of the order Apodes: the generic character is as follows. Head compressed; teeth both in the jaws and palate; body oval, broad, slippery; tail forked. There are three species.

FIATOLA. Body beautifully barred. It inhabits the Mediterranean, and has two romachs.

FARU. The back is of a gold-colour; the belly is silvery.

This is chiefly found in South America and Transvaal; it feeds on lesser fish and oysters; the body is slender, covered with small thin deciduous scales; the flesh is white, tender, and reckoned very delicious food. Its other and minor characters are, that it has a middle-fixed head, flopping, above brownish; the eyes are large and the pupil black; the iris is marked with a white ring and another yellow one; the mouth is small; the jaws equal; teeth small and sharp; lips strong and movable; tongue smooth, broad; aperture of the gills very large, the cover of one piece, and surrounded with a membrane; the lateral line nearer the back, broad, silvery; vent nearer the mouth than the tail; the fins are long, scaly, rigid, white at the base, and edged with blue; the rays are soft and branched.

CUMARA. Back blue; belly white. It is found in the fresh waters of Chili; is about a span long, and not crooked with stripes.

Besides the above species enumerated by Gmelin, Dr. Shaw mentions the following.

CINNARUS, or ash-coloured Stromateus with a forked tail; the lower lobe longer than the upper. The body of this species is of a more rhomboid form than that of the others, and the fins are somewhat more extended or pointed: the tail is more deeply forked, the lower lobe considerably exceeds the upper in length; the colour of the whole animal is cicereous, with a cast of yellow on the sides of the head and the base of the fins and tail; the pectoral fins are tinged with red. It is a native of the Indian seas, and grows to about the length of a foot or more, and is about two inches in thickness; it is considered as excellent food, but the largest specimens are the finest flavoured. The bones are said to be of a soft or nearly cartilaginous nature; the residents in India use this fish both in its fresh and salted state, prepared in various ways. The trivial name with them is Pamperl.

ARGENTEUS; Silvery Stromateus. The lobes of the tail of this species are equal. It is of the same general form with the preceding, but with rather shorter fins and tail; the lobes of the latter being both of equal length; the mouth is situated considerably beneath the muzzle, which is thick and round; the colour of the whole animal is bright silver, with a blueish or dullish tinge on the back and fins; the scales are small, thin, and easily deciduous. It is a native of the same seas with the preceding, and is in equal estimation as an article of food.

NIGER; or Black Stromateus. This species is entirely black. It is, however, very nearly allied to the former in shape, but the mouth is placed in the usual manner, the upper part of the muzzle not rising above it, as in that species; the colour of the whole animal is blackish, with a silvery cast about the back and sides of the head; the scales are small, and the lateral line, as in others of the genus, is curved in the direction of the back. It is a native of the Indian seas, and not regarded in much estimation as an article of food, on account of a popular prejudice entertained against it from its colour, as well as from its feeding on onicci (see Oniscus), which are occasionally found in its mouth.

Dr. Shaw observes, that there is a considerable degree of general resemblance between the habits of the genus Stromateus and that of chondrodon; but as the species of the Stromateus are defilute of ventral fins, they cannot be placed in the same artificial order, and must rank among the apodes. "The same is the case with some other genera which are naturally allied to fishes placed in very different orders. This forms the greatest objection to the Linnean arrangement of fishes; it would, however, be difficult to prove that a more natural
natural distribution would lead to a reader investigation of the animals."

STROMBERG, in Geography, a town of Germany, in the bisbopric of Munster; 20 miles S.E. of Munster. N. lat. 51° 45'. E. long. 8° 15'.—Allo, a town of France, in the department of the Rhone and Mofelle, and chief place of a canton, in the district of Simmer. The place contains 6644, and the canton 70431 inhabitants, in 25 communes; 26 miles W. of Mentz. N. lat. 40° 55'. E. long. 7° 40'.

STROMBOLI, one of the Lipari islands, or the first of the Eolian isles to the north-east. It was called Strongylus (Strongylus) by the ancient Greeks, from its round figure; and was celebrated for its extraordinary volcano, the eruptions of which admit only of short, but periodical intermissions. This island is distant from Sicily 50 miles, and its fires are discoverable at the distance of at least 100 miles. From the quantity and colour of the smoke, and the magnitude of the explosion of the volcano, the people of the country are enabled to foretell the winds which will be propitious or adverse to mariners. Eolus, who is said to have reigned in the Lipari or Eolian isles, is fabulously denominated the king of the winds, probably, as some writers have conjectured, because, from the changes in the smoke and eruptions of the volcano, he was able to predict what winds would blow. (See Eolus and Lipari.) Spallanzani, who had an opportunity of making observations on this volcano, is said to have been much inclined to receive implicitly all that the people of Stromboli do positively assert concerning it, more especially as the mariners of the other Eolian isles are of a different opinion. Accordingly it is a prevalent expression among the mariners of Felicuda, "Stromboli non fa marinaro," i.e. Stromboli will not make a feaman. The whole shore of Stromboli, to the east and north-east, examined by Spallanzani, is composed of a black volcanic sand, which, according to M. Dolomieu, is an aggregate of fragments of shoers; and with these shoers, which are entirely perfect, and exist as such in the form of detached magnets, Spallanzani discovered with a lens a number of small transparent and vitreous bodies, of a yellowish-green tincture, insensible to the magnet. This sand extends into the sea, to the distance of more than a mile from the shore, and probably to a greater distance. This sand easily penetrates through it; for by digging in any part of the shore to a little depth, sea-water is found, somewhat thickened by passing through the sand. This sand dries up that part of the island which fronts the east and north-east, extending on one side to the sea, into which it stretches, and on the other to the summit of the mountain; and it owes its origin partly to the immediate ejections of it by the volcano, and partly to the pieces of scoriaceous lava thrown out by it, which being very friable, and abounding in shoers, is easily decomposed, and becomes pulverized in this sandy matter. The sand is found principally near the volcano; but as it is easily moveable, it is carried by the wind to the valleys and lower grounds, quite to the sea. Under this covering lies the firm texture of the island, that is, the solid lavas, which are visible on several steep declivities, that have been stripped of the sand, either by the action of the rain-water, or of that of the winds. The surface of the island is about nine miles in circumference.

The crater of this island is suppos'd to have been anciently situated on the summit of the mountain, and the lavas which had contributed to its formation had flowed from that crater. Stromboli differs from Etna and Vesuvius, on the sides of which are mountains of an inferior size, owing their origin to fire, by being entirely a single mountain, except that its top is divided into two summits.

Hence it appears that there have been none of those eruptions in its sides, which generate leffer mountains, or hills, of a conical form. From various testimonies collected by Spallanzani, he concludes that the volcano of Stromboli has burned for more than a century where it now burns, without any sensible change in its situation. The highest of the two summits of Stromboli, which inclined to the south-west, at the other does to the north-east, was estimated to be elevated about a mile above the sea. These summits have no crater, nor any vestiges of such; but these vestiges are sufficiently evident on the sides of the plain that separates them, which here sinks into a cavity, about 300 feet in length from east to west, above 200 in breadth, and 160 in depth. Spallanzani is of opinion that this was the first and largest volcano of Stromboli, which formed the contexture of the island by its lavas, and which, in a great degree, had been filled up and destroyed by the earthy depositions of the rain-waters, the matter ejected into it by the present volcano, and, perhaps, by the falling in of its own sides. Hence he conjectures that the principal volcano had formerly existed on the summit. The edges of the crater, which is of a circular form, and not more than 340 feet in circumference, are composed of a confused mixture of lavas, scoriæ, and sand. The internal sides contract as they descend, and assume the shape of a truncated inverted cone. The crater, to a certain height, is filled with a liquid red-hot matter, resembling melted brass, and which is the fluid lava. This lava appears to be divided into two portions: one, which is, in the interior, whirling, and tumultuous; and the other, that by which it is impelled upwards. When this liquid matter is raised within the crater, and reaches the distance of 25 or 30 feet from the upper edge, a sound is heard like that of a very short clap of thunder; while, at the same moment, a portion of the lava, separated into a thousand pieces, is thrown up with great rapidity, and is accompanied with a copious eruption of smoke, ashes, and sand. A few moments before the report, the surface of the lava is distilled, and covered with large bubbles, some of which are several feet in diameter; and at the same instant, the detonation and fiery shower take place. After the explosion, the lava within the crater sinks, but soon again rises as before; and new tumours appear, which again burst, and produce new explosions. When the lava sinks, it produces little or no sound; but when it rises, and especially when it begins to be inflated with bubbles, it is accompanied with a sound, similar, in proportion to the difference of magnitude, to that of a liquor boiling vehemently in a caldron. When the lava is at its height, the depth of the crater may be about 25 or 30 feet; and when it has subside, about 40 or 50; and, therefore, the greatest rise of the lava may be estimated at about 20 feet.

The component substances of this island are scoriæ, lavas, tufas, pumices, and specular iron. Two species of the scoriæ are of the nature of porphyry; as they are composed of a horn-stone, in which felspar and shoers are incorporated. The third species of scoria belongs to the ancient volcano, and is found, on removing the sand, at a small depth, on the east side of the island, a little above the foot of the mountain; diffused in strata forming one body with the adjacent lavas, which, at some remote period, flowed from the summit of Stromboli into the sea. In this were discovered black shoers and white felspars; the body of its substance not differing from that of the other two kinds. Our author has particularly described the other substances above enumerated. Upon the whole he observes, that this island may be said to be formed, as far at least as externally appears, of scoriæ and lavas; and that the material origin of
and increase of Stromboli is to be attributed to porphyry, which, melted by subterraneous conflagrations, and rarefied by elastic gaseous substances, rose from the bottom of the sea, and, extending itself on the sides, in lavas and scoriæ, has formed an island of its present size.

From the authorities of various writers it appears, that the most ancient accounts of the conflagrations of Stromboli, transmitted to us by history, are prior to the Christian era by about 250 years, the date of the reign of Agathocles, the celebrated tyrant of Syracuse. This volcano burned unceasingly, in the time of Augustus and Tiberius, when Dionysius and Strabo flourished. But after this latter period, a long series of ages succeeds, during which, from want of documents, we are ignorant of the state of Stromboli; and it is not until the 17th century that we again know, with certainty, that it ejected fire; though it is not improbable that it continued to burn likewise during the times in which we find no mention of it in history; on which supposition, its uninterrupted conflagration, for so great a length of time, must indeed appear astonishing. Yet, though it should have ceased for several ages, we know, from various public testimonies, that its continued eruptions cannot have lasted less than 200 years.

That Stromboli contains within its deep gulfs and recesses an immense mine of burning sulphur, we can entertain little doubt, when we consider the streams of smoke, of extraordinary whiteness, a colour which constantly accompanies sulphureous fumes, that rise on the west side of the island, and the smell of sulphur, not only perceptible from them, but from the large cloud of smoke which overhangs the summit of the mountain. The small pieces of that mineral, procured near the apertures whence those fumes arise, are likewise another proof.

Sulphur alone may be sufficient for the nourishment of the volcano, when its flame is animated by oxygenous gas, the presence of which, in volcanic abysses, seems undeniable, from the substances they contain proper to generate it, when acted on by the fire. The long duration, without intermission, therefore, of these conflagrations, may be very sufficiently explained by the immense quantities of sulphur, or, to speak more properly, sulphures of iron which we must necessarily suppose contained in the bowels of the mountain. It is rendered the more probable by the prodigious subterraneous accumulations of this mineral, which have been discovered in various parts of the globe.

Although Stromboli and Lipari (which see) lie nearly under the same degree of latitude, or 38° N., the former is much hotter in summer than the latter, especially near the sea, on account of the strong reflection of the rays of the sun from the large tracts of sand. The winter here is always mild; it never freezes; and snow, which is seldom seen, if it falls one day, melts the next. The sea round the island is frequently agitated by storms to such a degree, that the billows sometimes rise to one-half the height of a rock, on the north-east side of the island, called the rock of Stromboli, 300 feet in height. The shore of Stromboli has neither port nor harbour; and veselis, in case of heavy storms, can only seek some refuge on the back of the island. The vessels employed by the natives are feluccas, which, being extremely light, are easily drawn upon land, and as easily launched again into the sea. Fish here are plentiful and large, particularly the sea-eels and murenas; the fishery, however, produces no branch of commerce, and only serves to supply the island, principally the foreigners who visit it; as the natives usually live on salt meat. Malafey is the greatest article of traffic of the people of Stromboli; they convey it in barrels to Lipari, where they find a ready sale for it. The vines producing the paffolo and paffolina grape, which yield this wine, grow on the sea-shore, forming a chain to the north-east, and are all planted in volcanic sand. The habitations of the islanders are built in the same part, and under the same aspect. They are irregular assemblage of cottages and fishermen's huts. The population of the island amounts to about 1000 persons, and has been for some time increasing; in consequence of which, exertions have been made to enlarge the cultivable ground, by clearing away the weeds. The character of these islanders, by some misrepresented as savages, is nearly the same with that of the inhabitants of other villages at a distance from, and having no communication with, populous cities: they are simple, honest, and, having few ideas, are contented with the little they possess. Here are no stationary birds, though attempts have been frequently made for naturalizing partridges. Rabbits multiply, huskishing, in their natural wild state, in the wooden part of the island: the musket and the ferret are their only enemies. The birds of passage are as at Lipari. Spallanzani's Travels, vol. ii. and iv.

STROMBUS, in Natural History, a genus of the class and order Vermes Teflace. The generic character is, Animal a limax; shell univalve, spiral; aperture much dilated; the lip expanding, and produced into a groove, leaning to the left. These shells in their younger state want the lip, and have a thin turbinate appearance; many of them therefore, for this reason, have been mistaken by authors, and referred to a genus to which they do not belong. There are about forty-five species, divided into separate sections, according as the species have lips projecting, lobed, dilated, or tapering.

Species.

A. Lip projecting into linear Divisjons or Claws.

FUSUS. Shell tapering, smooth, with a tubulate beak and toothed lip. It is found in the Red sea; resembles a murex, in having the beak rather straight; nevertheless it approaches nearer the genus Strombus, in being smooth, and having the lip toothed; the shell is brown, and transversely striate at the base; the pillar is white; the beak is black outwardly.

* Paa PELLECANI; Corvornat's Foot. Lip with four plicate angular claws; the mouth is smooth. It is found in the American and European seas; is about two inches long; the shell is pointed; in colour it is whitish, cinereous, or reddish; within it is white, smooth, and polished; the whorls are tuberculate.

CHIRAGRA. Lip with fix curved claws, and recurved beak. It inhabits the Indian ocean, and is very rare and valuable. The shell is large, brown varieed with white; the back tuberculate; lip striate; it has fix claws, including the beak, which are long; the two hind-ones are divergent and bent outwards.

SCORPIS. Lip with four knotty claws, the hinder one is very long. It inhabits the Indian ocean, and is four inches long.

LAMBI. Lip with about seven straightish claws, and a smooth mouth. There are four varieties of it. It is found chiefly in Asia. The shell is large, brown varied with white; the mouth is reddish; claws not knotty.

MILLERPEPA. Lip with ten infected claws, and subfriate mouth; the back is compressed and gibbous. It inhabits the southern coasts of Asia.

CLAVUS. The shell of this species is tapering, smooth, with a tubulate beak and a simple lip.

B. Lobed.
STROMBUS.

B. Lobed.

LENTIGINOSUS. Lip thickened, and three-lobed on the fore-part; the back is warty, and crowned with tubercles; the beak is obtuse. It is about three or four inches long; and is found in Asia and America.

FASCATUS. Lip entire; the back is crowned with three rows of protuberances, and rosy between them. It is found in divers parts of Africa.

RAMUSUS. Lip thin, rugged, repand above; back orange, transversely striate, and crowned with tubercles; the aperture is polished and white.

GALLUS. Lip mucronate on the fore-part, and very long; the back is crowned with tubercles; the beak is straight. It inhabits Asia and America. It is about six inches long. The shell is sometimes uniformly brown, yellow, or violet; sometimes it is varied with spots and rays; the back is surmounted with smooth ribs, which are sometimes simple, sometimes double; the first whorl is crowned with tubercles, which in the other whorls are more or less conspicuous.

AURUS DIANA. Lip projecting to a sharp point; the back is muricate; the beak erect and acute. It inhabits the southern coasts of Asia, and is three inches long. The shell is thick, and generally variegated with colours.

PUGILUS. Anterior lip prominent, rounded, smooth; the spire is pinnate; beak three-lobed, obtuse. It inhabits South America.

ALATUS. Anterior lip rounded, prominent, smooth; spire unarmed; beak three-lobed, obtuse. It inhabits South America.

MARGINALUS. Lip a little prominent; the back margined, smooth; beak entire.

LUNATUS. Lip a little prominent; back smooth; whorls rounded and equal. This species is found on the southern coasts of Asia, and is about two inches and a half long.

GIGERUS. Lip a little prominent; back smooth; whorls gibbosus, unequal. It is found on the southern shores of Asia. The shell is white, with numerous bands, spots, and clouds; the lip is striate within, and with the pillar it is partly blue and partly red.

ONTUS. Shell ovate, with knotty belts, and a subulate smooth projection. This species is found in the South American ocean; and is about an inch long.

C. Dilated.

LUCIFER. Lip rounded, and entire on the fore-part; the belly is doubly striate; spire crowned with tubercles; the upper one minute. It inhabits South America. The shell is variegated, resembling the next; but is thinner, and armed with much less spines, and thought to be a younger species of G. gigas.

GIGAS. Lip rounded, and very large; the shell is crowned; the belly and spire have conic expanded spines. It is found in divers parts of South America; and is ten inches long and nine broad. The shell is of a beautiful glossy white; within it is of a rich rose-colour.

LATISSimus. Lip rounded, and very large; the belly is unarmed; the spire a little knotty. It inhabits Asia. The shell is solid, fourteen inches long, varietied with brown and white, sometimes radiate; the lip within is white; the mouth rosy.

EPIDERMIS. Lip rounded, short; belly smooth; spire a little knotty. It inhabits southern Asia; and is about three inches long.

MINUS. Lip retuse, gibbous; belly and spire knotty, with knotty plates; aperture two-lipped, smooth. Inhabits Inde; and is about an inch and a half long.

CANARIUM. Shell somewhat heart-shaped, with a rounded, retuse; smooth lip; pillars smooth. It inhabits the southern coasts of Asia.

VITATUS. Lip rounded, short; belly smooth; spire elongated; the whorls are divided by an elevated future. It inhabits Asia; and is about four inches long. The shell is white, with brown bands.

SUCCINCTUS. Lip rounded, retuse; belly smooth, with four, pale, linear, punctured belts. It inhabits different parts of Asia.

SPINOUS. Lip tapering, entire, slightly plaited, and crowned with fine spines; the spire is prickly. It has been found in the only in a fossile state, and very much resembles the Voluta vespertilio, but is not emarginate at the base; and the pillar is not always plaited; the shell is white, with numerous parallel lines, above angular, and crowned with very sharp spines.

FIRENA. Lip continued into a longitudinal cleft ridge. It inhabits India, and is found frequently in a fossile state in Campania.

URCEUS. Lip tapering, short, striate; the belly and spire have knotty plait; aperture two-lipped, unarmed. There are several varieties of this species. It is chiefly found in the Indian ocean, is two inches and a half long; and varies much in colours and marks.

TRIDENTATUS. The shell of this species is thin, white, with orange spots and clouds; the back is smooth and plaited; the beak is violet; the whorls are grooved; the lip is three-toothed. It inhabits the Indian ocean.

DENTATUS. Lip tapering, short, toothed; belly and spire plaited. This is very like the S. urceus.

OSTATUS. Lip very thick, first whorl crowned with tubercles, the interlacement of the tubercles plaited; the next transversely ribbed, the rest transversely striate.

BRONIA. Shell conic, with a mucronate eight-toothed lip and knotty spire. It is about seven inches long; extremely rare. Shell brown, varied with white and blueish clouds. Some authors suspect it is not of this division.

AFFINIUS. Shell transversely striate, gibbous; spire unarmed; the first whorl crowded with tubercles.

LATUS. The lip of this species is a little prominent, and twice emarginate beneath; the first whorl of the spire is smooth in the middle, and transversely striate on each side; the others are crowded with obtuse knobs.

LEVIUS. Shell smooth, silvery, radiate with brown, with obsolete, transverse plaits; the spire is elongated, with inflated rounded whorls.

VEXILLUM. Shell solid and subcylindrical, with alternate, red, and ochraceous bands; lip denticulate within; pillar flat, glabrous, and emarginate at the base. It is found in the Indian ocean, and is extremely rare.

NORWEGICUS. Shell oblong, subulate, white, with round whorls; aperture spreading, ovate; beak ascending a little. This is obtained on the coasts of Norway.

D. Tapering, with a very long Spire.

TUBERCULATUS. Shell ovate, oblong, tuberculate; lip thickened. It inhabits the Mediterranean. The shell is coars; the whorls covered with rows of raised horny dents; lip gibbous; aperture ovate; the beak is very short and recurved.

PALUSTRIUS. Shell smoothish; lip separated behind. It inhabits the Savannah near the Indian ocean. The shell is thick, and yellow or brown, with from twelve to sixteen whorls; the first twice as large as the next; the rest longitudinally plaited, and with from three to five transverse fringes.
STR

AER. Shell smooth, lip separated before and behind. It is found in the seas of Amboyna, and is more than two feet long. It is of a black-brown or bay, within white, very finely striate transversely; aperture ovate; spire subulate, with twelve flattish contiguous whorls.

LINAOTUS. Shell subulate, brown, with seven spiral impressed lines; the aperture is ovate.

PUNCTATUS. Shell subulate, yellowish-white, band striate with red near the future; the lefthand whorls grooved.

VIBEX. Shell subulate, cinerous, transversely striate; whorls nodulous, and marked with red streaks. It inhabits Coromandel; and a variety is found in the Friendly Islands.

VIGURUS. Shell scarred with brown; whorls muricate; aperture ovate. It is found in different parts of Africa; is an inch and a half long.

ACULATUS. Shell brown, tuberculate; whorls minute; lip depressed, crenulate. A variety of this species is named the Hercules club. This species inhabits the maraths of Africa, and is nearly two inches long.

AGONATUS. Shell smooth; the lip very prominent, and margined behind.

DELAOTUS. Shell with transversely striate, black whorls; the outer ones smooth, and with the margin of the lip and the pillar white.

FUSCUS. The shell of this species is brown, with numerous tubercles on the whorls; the lip is separated before and behind, within it is striate with brown.

MARGINATUS. Shell brown; the lowest whorl is edged with white.

LIVIDUS. Shell subangular, with spinous knots; the lip is separated on the fore-part.

STRIOATUS. Shell convex, striate, white, with a few fulvous streaks; the pillar is flattened and inflected.

SUBUTUS. Whorls turned contrary; the shell is thin, and longitudinally striate. It has hitherto been found only in a fossil state in Switzerland.

STROMENTO, Ital. in Myke, an instrument, plu.

STROMENTI, instruments, certain machines contrived to produce musical tones and intervals, in imitation of the scale or gamut used by the human voice. As the organ is the most noble and comprehensive of all musical instruments, its name from the Greek, Oganum, implying only an instrument, it is now underfooted to be the instrumentum, par excellénce; and all music performed on instruments is termed organical. For the three different kinds of instruments of which the tones are produced by wind, string, and percussion, see Instrument.

STROMLINGUS, in Ichthyology, a name given by some writers to the aras of the Greeks, which is no other than the common herring. There is no other difference between the Stromling and herring, but that the former is smaller.

STROMNESS, in Geography, a small town in the island of Pomona, and bailiwick of Orkney and Shetland, Scotland, situated in the south-west part of the Mainland, possessing an excellent harbour. At the commencement of the last century this place was small, and much confined in its commerce, in consequence of an arbitrary assize by the neighbouring royal borough of Kirkwall. This was at last removed by a decree from the supreme court, and the subsequential confirmation of the houfe of lords. After that period, Stromnesses began to increase in size and importance, and is now a place of considerable trade and extent. The population return of 1811, computed the inhabitants of Stromness parish to be 2557, and the houses 424. The inhabitants are tradesmen, shopkeepers, pilots, or shipmasters, and small proprietors of land. Here are a post-office and grammar-school, with a flax-mill, tannery, and breweries; a market for cattle is also held here. The old church of Stromnesses being ruinous and dilapidated, a new one was erected in 1717; but is not now sufficiently spacious: the house built by the Rev. George Graham, the laft bishop of Orkney, is yet standing, with the episcopal arms and date of its erection, 1633, cut in stone above the door. Several tumuli, or barrows, are remaining in this district; and here is a flate-quarry, with appearances of lead and iron ore.—Carlisle's Topographical Dictionary of Scotland, vol. ii. Beauties of Scotland, vol. v.

STROMNESS, a cape on the S. coast of North Ronaldshay, one of the Orkney islands.

STROMOE, one of the Faroer islands, in the Northerna ocean, and the largest; being about 30 miles in length, and 10 in breadth. N. lat. 62° 10'. W. long. 7°.

STROMSOE, a town of Norway, in the province of Aggerhus; 18 miles S.W. of Christiania. N. lat. 59° 44'. E. long. 10° 16'.—Alfo, a small island in the North sea, near the coaft of Lapland. N. lat. 69° 14'.

STROMSTADT, a town of Sweden, in Weft Gothland, on the coaft of the North sea, celebrated for its shellfish; 43 miles N.N.W. of Uddevalla. N. lat. 58° 59'. E. long. 11° 49'.

STRONDEBACH, a river of the duchy of Berg, which runs into the Rhine at Mulheim.

STRONG, a river of Bavaria, which runs into the Sempt, 2 miles E. of Mopurg.

STRONG, a township of America, in the district of Maine and county of Somerhill, situated on the Kennebeck, and containing 424 inhabitants.

STRONG Land, in Agriculture, a term sometimes applied to heavy, thick, tenacious sorts, which are not easily managed when in the tillage state. Some think that strong or heavy lands should always be followed when intended for wheat-crop, as those of the light kind are, when for turnips and barley. Others are of opinion that this kind of land constantly requires to have this sort of tillage for all these different crops, and that the less the light are touched by the plough the better, provided they are kept clean and free from weedy matters, and in good heart.

Strong lands of the clayey sorts are likewise thought by many, not to be capable of being easily kept in order and ameliorated by crops of the green kind, as the feeding them off on the ground poaches and temperers them to such a mortal state, as renders them fitter for the brick-maker, than the growing of corn. But that, when brought into this condition by such crops and too much treading, the clean fallow proceeds is the best and most ready means of restoring them. However, those who are so friendly to the expensive, wafeful, and dissipating practice of the fallow system on these kinds of strong land, should recollect that such a situation can only occur where such lands are very wet in their nature; and that by proper sorts of such crops, draining, and feating upon the proper times and seasons for managing them, every sort of difficulty and inconvenience will be at an end, and such objections to managing them in other ways be of little or no avail. See FALLOWING.

STRONG Place and Pulp. See the subfiantives.

STRONGBOW INDIANS, in Geography, Indians of North America, inhabiting the country about N. lat. 62°. W. long. 124°.

STRONGDEN, a town of Norway, in the province of Drothaim; 42 miles S.S.E. of Drothaim.

STRONGILO, a small island in the Grecian Archipe-
STR

lago: 6 miles S.W. of Paros. N. lat. 37°. E. long. 25° 10'.

STRONGNAS. See Strongnas.

STRONGOLI, a town of Naples, in Calabria Cirta, the see of a bishop suffragan of St. Severina; containing four churches. This was anciently a city of the Brutii, called "Petilia," and said to have been built by Philoctetes, after his return from the Trojan war; 16 miles S.E. of Caria Vecchia. N. lat. 39° 15'. E. long. 17° 15'.

STRONGYLE, in Ancient Geography, one of the Æolian islands. See Stromboli. Also, a name given by Pliny to the island of Naxos. Also, an island of the sea of Delos. 

Also, a town of Spain, on the coast of Beticia.

STRONGYLE, in Geography, a mountain on the N. side of the island of Candia; 8 miles W. of Candia.

STRONYLUS, in Natural History, a genus of the clafs and order Vernes Intelles. The generic character is as follows: Body round, long, pellucid, glabrous; the fore-part is globular, truncate, with a circular aperture fringed at the margin; the hind-part of the female entire and pointed; in the male, it is dilated into loofe, dilatant, pellucid membranes. There are only two Species.

Equinus. Head opaque; the intelline is black. It is found in the stomach of the horse, in great numbers. The male worm is of a pale yellow, with a fine yellowish membrane covering the intellines; the tail is three-leafed, with a small spine or two; the female with white siliform vehicles surrounding the intellines.

Oviform. This, as its name imports, is found in the intellines of sheep.

STRONSAY ISLE, in Geography, one of the Orkney islands in the North sea, and near the northern coast of Scotland, constitutes part of the shire of Orkney and Shetland, and, with the smaller island of Papa-stronfay, forms one parish. At some distant period, it appears to have been divided into three parishes, and remains of four chapels are said to be full standing in different parts of the island. The resident population of Stronfay in 1811, inclusive of the above-mentioned smaller island, was 804, which reduced in 175 houses. The rocks of this place are sandstone, the soil is very productive; in the eastern part are three chalky, earthy strata, which, though rising together, differ in their strength. The inhabitants of Stronfay place much confidence in the medicinal powers of the waters, and in the sea-weed denominated duft. The island abounds with flocks of golden plovers, and other sea-fowl; whilst the rocky coves are much frequented by seals. The principal employment of the inhabitants is the manufacture of kelp-felt from sea-weed, of which it is estimated that nearly 300 tons are made annually.—Carile's Topographical Dictionary, vol. ii. Beauties of Scotland, vol. i.

STRONTIAN, or STRONTIANITE, in Mineralogy, Strontianite carbonates of Hali, a mineral composed of a peculiar earth combined with carbonic acid, so called from Strontian, in Argyleshire, where it was originally found in veins along with galena, heavy spar, and calcareous spar, in a rock of granite. Its colour is generally pale green and greenish-white, sometimes inclining to yellowish-white. It occurs massive and crystallized. The crystals are acicular, fixed or filled in, terminated by low fixed pyramids. The crystals are aggregated in diverging groups. The massive strontianite has a shining, pearly lustre, and a fibrous and radiated structure. The cross-fracture is fine-grained and uneven, and presents a glistering fracture. It is sometimes formless, transparent, and always more or less transparent. It yields easily to the knife, and is brittle. The specific gravity of strontian is 3.675; Klaproth.

Strontian is fusible by the blow-pipe, but becomes white and opaque, and tinged the flame of a dark purplish-red. It is soluble with effervescence in nitric or perchloric acid, and paper dipped in the solution burns with a purple flame. Strontian was first analyzed by Dr. Hope, who described the properties of this newly discovered earth. The constituent parts of the mineral are, according to Dr. Hope:

<table>
<thead>
<tr>
<th>Mineral</th>
<th>Specific Gravity</th>
</tr>
</thead>
<tbody>
<tr>
<td>Strontian</td>
<td>3.675</td>
</tr>
<tr>
<td>Carbonic acid</td>
<td>30.30</td>
</tr>
<tr>
<td>Water</td>
<td>8.5</td>
</tr>
</tbody>
</table>

According to Klaproth, it contains only 0.6 water, and 69.4 of the earth.

This mineral has been found also in Saxony, at Braunfirt, and near Popayan in Peru. Strontian is divided into four sub-species by Werner: foliated celestine, radiated celestine, fibrous celestine, and compact celestine. These are all combinations of strontian with sulphuric acid; this species has been called celestine, on account of its generally inclining to a blue colour. Foliated celestine, strontian sulphate, Hali, sometimes inclines to a reddish-red and pale flesh-red: it occurs massive and crystallized in irregular fixed and eight-sided tables, and in rectangular four-sided tables. The crystals are rather small. The surface of the massive varieties is streaked, and the name is the same with the lateral plates of the tables. The structure is foliated: it has a shining and pearly lustre, and is translucent. It yields to the knife, but is harder than heavy spar: its specific gravity is 3.962. It contains from 54 to 57 strontian, sulphuric acid from 43 to 46, according to the analyses of Vauquelin and Klaproth. This mineral has been found in various situations, and particularly in the vicinity of Britol. Radiated and fibrous celestine differ from the above in their structure merely. Compact celestine has a snow-white or yellowish-white grey or brown colour, and sometimes an ochre-yellow.

It occurs in spheroidal or kidney-shaped masses, imbedded in mottled clay with granite, at Kemptmars near Paris, and is said to form a whole bed in Champagne. It is supposed to be derived from the oxyd of iron. Its specific gravity is 3.597. It consists of:

<table>
<thead>
<tr>
<th>Substance</th>
<th>Specific Gravity</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sulphate of strontian</td>
<td>91.42</td>
</tr>
<tr>
<td>Carbonate of lime</td>
<td>8.33</td>
</tr>
<tr>
<td>Oxyd of iron</td>
<td>0.25</td>
</tr>
</tbody>
</table>

All the varieties of celestine melt before the blow-pipe into a white friable enamel, without feebly tingling the flame. After a short exposure to heat it becomes opaque, and has then acquired a slightly caustic and acid flavour, very different from that which heavy spar acquires by a similar treatment.

STRONTIAN, in Geography, a village of Scotland, in Argyleshire, on Loch Sunart, celebrated for a new species of fofil, called "Strontia." It is in the vicinity of lead-mines, and inhabited by miners. N. lat. 56° 40'. W. long. 5° 38'.

STROOM ROCK, a rocky island in the Orkney of Suna. S. lat. 5° 51'. E. long. 105° 50'.

STROP, in a Ship. See Strap.

STROPHADES, in Ancient Geography, two islands of the Ionian sea, 400 stades from the coast of Peloponnesus, over against and west of Yparia, according to Strabo. His mythologists place the Harpies.

STRO-

Gen. Ch. Cal. Perianth inferior, of one leaf, in five deep, ovate-oblong, acute segments. Cor. of one petal, funnel-shaped; crowned in the throat with ten undivided scales; limb in five segments, each terminating in a very long, taper, more or less contorted, point. Nectary of five scales below the germen. Stam. Filaments five, awl-shaped, short, inserted into the middle of the tube; anthers erect, conveging, arrow-shaped, pointed or awned. Pith. Germen of two lobes; style simple, thread-shaped, dilated upwards; stigma nearly cylindrical. Peric. Follicles.

Eff. Ch. Corolla funnel-shaped, with ten undivided scales in the tube; segments of the limb with very long tails. Nectary of five scales below the germen. Follicles.

Obs. This genus, according to the authors cited, differs from Nerium in the long appendages to its corolla, as well as in the ten undivided, not torn, scales which crown the tube, and the presence of glands below the germen. Ecbites differs from both in having no scales in the tube or throat of the corolla. Four species are described, all tropical shrubs, of a tender trailing habit, with opposite, simple, undivided leaves. The flowers are small and white, on short, mostly aggregated or tufted, flower-flax. They are figured by Decandolle in the Annales du Mufen; and his essay, with the figures, is copied in a periodical French work, entitled Bulletin des Sciences, not at present within our reach. The species are thus distinguish'd.

1. S. farinosis. Decand. n. 1. — Smooth, trailing. Flowers aggregate, terminal and lateral, accompanying the leaves. Corolla nearly bell-shaped. Anthers with elongated capillary points.—Gathered at Sierra Leone, by the late Mr. A. G. Bottle; by Dr. A. C. Wilkins. The branches are very long, round, smooth, purplish, somewhat warty, flowering copiously about their extremities. Leaves flaked, ovate, pointed, entire, quit smooth, two or three inches, perhaps more, in length; paler beneath. Flowers chiefly lateral, in short, forked, opposite tufts. Corolla (if we rightly recollect a drawing once in the possession of Sir Joseph Banks) white, beautifully point'd with purple; its tube is wide, above an inch long; the taper appendages to its limb four times that length, not evidently spiral in our dried specimens, except in the bud. The scales which crown the tube have also long taper points.

2. S. laurifolius. Decand. n. 2. — Smooth, Leaves opposite or ternate. Flowers aggregate, terminal, coming after the leaves. Anthers with elongated capillary points.—Found by Mr. Smeathman at Sierra Leone.

3. S. dichotomus. Decand. n. 3. (Ecbites caudata; Linn. Mant. 52. Wild. Sp. Pl. v. 1. 1240. Burm. Ind. 68. t. 25.) — Smooth. Branches forked. Leaves pointed. Tube of the corolla cylindrical, thrice as long as the calyx. Anthers with very long linear points.—Native of Java, in elevated situations. The Malay name is Musang. The stem is shrubby, fibritated, throwing out long, slender, smooth, twining branches. Leaves on shortish flarks, elliptical with a short point, entire, quite smooth, three or four inches long. Flower-flaeks from the forks of the branches, bearing three or four large, smooth, yellowish or tawny flowers. Segments of the calyx lanceolate, taper-pointed. Tube of the corolla near an inch long; tails of the limb three inches, obtuse, flat, not spiraled after the flower is expanded. The points of the anthers seem to be near an inch long, linear and membranous, cohering in the form of a slender tube.

4. S. biflorus. Decand. n. — Very brily. Tube of the corolla cylindrical, half as long as the calyx. Anthers acute, without points.—Gathered by Mr. Smeathman at Sierra Leone. Every part of this plant, even the calyx, is rough with tawny brily hairs. The corolla is downy; its very long and peculiarly slender tails hairy at the back. Leaves elliptical, pointed; their ribs and veins fringed with long defrilled hairs. Flower-flaeks cymose, forked, with long, lanceolate, obtuse bractes. Segments of the calyx lanceolate, as long as the whole corolla except its tails, which are five or six times as long, measuring about four inches. The flower-tube resembles a long slender hairy pill, nor have the tails, even in that state, much of a spiral aspect. Nothing has been observed of the fruit of this or any other species. There being two separate germen, as in so many of this natural order; and the close affinity of this fine genus to Nerium and Ecbites, leave little doubt of its seeds-offer being similar to their's.

STROPHE, in the Greek and Latin Poetry, a stanza, or certain number of verses, including a perfect quae; succeeded by another, confining of the same number and measure of verses, and in the same disposition and rhythmus, called antistrophe.

STROPHARIUS, among the Romans, a person who prepared and made the opopha. See STROPHIUM.

STROPHIUM, in Botany, and Vegetable Pharmacy, a little curved appendage, as the name imports, to the ear or base of some seeds. It is either of a fungs, glandular, or callous nature, and may be found in Ajonum, Caesia t. 141; but especially in several papilionaceous genera, as Ulex, Spartium, Bassana, and Platysobium. The elastic tuning of the seeds in Oxalis has been mistaken for a Strophium by some botanists.

STROPHIUM, among the Romans, a short swath or band, by which the young women kept down the dwelling of their breasts.

STROPHIUM was likewise a bandage for the head, made of two or three garlands of flowers tied together.

STROPHULUS, in Medicine. See INFANTS.

STROPPEN, in Geography. See SLEIFS, in the principality of Oels; 24 miles W.N.W. of Oels. N. lat. 51° 22'. E. long. 16° 49'.

STROPPO, a town of France, in the department of the Stura; 13 miles S.W. of Saluzzo.

STROPPUS, among the Romans, the thong with which the oars were tied to the scullus.

STROTH, FREDRICK ANDREW, in Biography, a German writer, was born at Triebles, in Swietish Pomerania, in the year 1750; and became first rector of the school of Quedlingsburg, and afterwards had the same office in that of Gotha.
Gotha. He was the editor and translator from the Greek into German of the works of several ancient authors; and a contributor to the German critical journals, particularly those of Halm and Halle. He died, at an early age, in the year 1785. Among his works are enumerated the following: 

1. "Chrestomathie Latina, etc." Quedlin. 1775, 8vo.; 
2. "Chrestomathie Graeca, etc." ibid. 1775, 8vo.; 
3. "Eusebii H. E. lib. x. et, etc., Vit. Conflant. lib. iv. etc." Hal. 1779, 8vo.; 
5. "T. Livii Oper. Pentas L., etc., Lib. 1780; 
6. "Pentas II." Goethe, 1783, 8vo.; 
7. "Theocriti Idylli Graec. etc." ibid. 1782, 4to.; 

STROUD, in Geography, a river of England, which runs into the Severn, 5 miles S. of Gloucester.

STROUD, a market-town in the hundred of Bisley, and county of Gloucester, England, is situated 10 miles south from Gloucester, and 102 miles west from London, on the ridge of a declivity near the confluence of the river Frome and the Slade-water; and may be considered as the centre of the clothing manufacture in this part of the country. All the surrounding valleys exhibit a continued range of villages, or hovels, inhabited by poor people engaged in trades. Though the scenery of this district is beautiful, yet the steep ascent, and irregularity of the ground, render the roads fatiguing to the traveller. At the time of the Domedal day survey, this manor appears to have been comprehended in the adjoining parishes of Bisley: it now belongs to Peter Watts, Esq. The church, which consists of a nave, chancel, and side aisles, with a tower and spire at the west end, has been erected and repaired at different periods. An endowed school, and several charity-schools supported by subscription, have been established here. The inhabitants of this parish, as returned to parliament in the year 1811, amounted to 5221; the number of hovels to 1184. A weekly market is held on Fridays, and two fairs annually. John Canton, an ingenious natural philosopher and mathematician of the 18th century, was born at Stroud in the year 1718.—Beauties of England and Wales, vol. v. by J. Britton and E. W. Brayley.

STROUD’S BAY, a bay on the north-west coast of Barbadores; 6 miles N. of Speight’s Town.

STROUDSBURG, a town of America, in the road from Lexington in Kentucky to Virginia; 17 miles N.E. of Lexington.

STROUD-WATER. See Stroud, supra, and Casco Bay.

STROYL, in Agriculture, a term applied to couch, or other weeds; or the roots of weeds either harrowed or raked up upon the land.

STROZZI, Tito VESPAIANO, in Biography, a Latin poet of the 15th century, belonging to the famous Florentine family of that name. He was one of four sons, whose father caused them to be well instructed in public literature. Tito studied in poetry and eloquence under Guarino, at Verona. He married in 1470, and was made a cavalier by duke Borso. He furnished some considerable offices at Ferrara, and was employed as the ambassador of duke Hercules at the papal and other courts. His death is said to have occurred in 1505. He wrote many Latin poems, amorous, serious, and satirical; and having planned a long poem in praise of duke Borso, he wrote ten books, but did not live to complete it. Aldus printed a collection of his productions, but many more were left in MS. As an author he displayed a degree of facility and elegance, which was not common soon after the revival of literature.

STROZZI, ENCO, son of the former, who was occupied, like his father, in the magistracy of Ferrara, but excelled him in the province of literature. He is highly commended by Caligiani, in his funeral oration, as an admirable writer in prose and verse, both in Latin and Italian; and in Greek also he wrote a poem on the war of the Giants, which happily imitated the style of Homer. His moral qualities were much esteemed, and he was the distinguished patron of literature and merit. Duke Hercules I., who was much attached to theatrical spectacles, employed Strozzi in planning them. He was likewise the heir of cardinal Bembo. Having married a lady, named Barbara Torella, to whom a pension of high rank was attached, the disappointed lover caused him to be assassinated, in 1508, with circumstances of peculiar aggravation. His Latin poems are reckoned among the most elegant of that period. They were printed, together with those of his father, at Venice in 1513, and at Paris in 1530. Tiraboschi. Gen. Biog.

STROZZI, FILIPPO, a Florentine of an ancient and opulent family, and one of the richest citizens of Florence, in the early part of the 16th century, became related, by his marriage with Clarice, the niece of pope Leo X., to the family of Medici; but by his attachment to the ancient republican constitution of Florence, he could not acquiesce in the arbitrary government of that house. After the death of pope Clement VII., when the sovereignty was possessed by duke Alexander de Medici, he joined the party who aimed at retreating a free government. Failing to obtain support from the emperor Charles V., he attempted to engage Lorenzo de Medici in a conspiracy for assassinating Alexander. Lorenzo objecting to his proposal, that if it failed, his private and family interests should be endangered, Filippo promized, in case of failure, to marry him to two of his own sons. When Lorenzo, in consequence of the deed, fled from Florence, this promise was fulfilled. In order to reestablish the establishment of Cosimo, as Alexander’s successor, Strozzi put himself at the head of a body of troops; but being defeated in the battle of Marone, he was made prisoner. Dreading the torture, of which he was apprehensive for not disclosing his accomplices, he determined to anticipate the trial by suicide. Some facts have once endured the torture with great firmness. A pinnard having been negligently left in his apartment, he made use of it to write upon the mantle-piece the line from Virgil,

"Exoriate aliaquis nostris ex olibus ulteri?"

and then pierced his breast. In his testament, he charged his children to remove his bones from the place of their interment at Florence to Venice, that, after his death, they might be deposited in a free country. He died in 1538. Strozzi possessed the highest dignities at Florence, without price or ostentation; and to such a degree was he attached to the republican equality, that he was offended by being called "Meffire," instead of Philip. "I am," he would say, "neither an advocate nor a cavalier, but simple Filippo, the son of a merchant." His sons, removing to France, engaged in the king’s service, against Charles V., the patron of the Medici. One of them became a marshal of France, and was succeeded in the post by his son. Bayle. Gen. Biog.

STRUCHIUM, in Botany, a name adopted by Browne, we cannot tell with what intention. See Estrulia, and Sparanophorus.

STRUCTURE, in Architecture. See Building.

STRUCTURE, in Architecture.
STRUCTURE of Minerals, in Mineralogy, is one of the most important external characters of minerals. Structure is defined by Brongniart to consist in the arrangement of the integral molecules of a mineral;this arrangement may be more or less regular; it exists in the fibres in whatever fragments it may be broken. (Traité Élémentaire de Mineralogie.) The principal modifications of structure are, according to the French mineralogists, either laminar, lamellar, flatiform, foliated, fibrous, radiated, or compact. Of these, the flatiform more properly belongs to rocks.

The laminar structure consists of larger laminae, or planes; it is by observing the inclination of these planes to each other, that the primitive form of the crystal is discovered. Werner calls the direction in which the planes separate, the cleavage.

The lamellar structure presents smaller laminae, dispersed in different directions, as in flinty marble.

The foliated structure presents thin separable layers, as in slate.

The fibrous consists of minute parallel fibres, as in fibrous gypsum.

The radiated consists of diverging fibres, as in melo-
type.

The compact presents no distinguishable separation into parts, as in Jasper.

Mr. Aikin defines structure "to be that division of a whole into smaller aggregates, which has been made by Nature according to general laws;" and fracture to be "the casual division of a whole into fragments." These characters have been improperly confounded by the Wernerian mineralogists, but are essentially different; the fracture may vary according to the strength of the stroke by which it is produced; the structure is an invariable character. The structure of minerals is either perfectly crystal-
line, imperfectly crystalline, or promiscuous. The crys-
talline structure consists in the regular arrangement of the particles of a mineral into definite symmetrical forms. (See Crystal.) Every perfectly crystallized mineral has parallel planes of section in three or more directions. These planes of section are by some mineralogists denominated the joints. In some minerals these joints are so open, that a flight blow will cause a separation of the parts into regular fragments. In other minerals the joints are concealed, and the planes adhere so firmly, that a fracture will take place in an oblique direction to that of the planes, of which the rock is an example. The joints in one direction may often be easily detected, but may be concealed in another, of which we have an instance in the topaz. In massive specimens, the existence of parallel joints is the only indication of a crystalline structure. In transparent minerals, the direction of the joints may often be detected by turning the mineral slowly round in a very strong light; the internal reflections showing the surface of the planes of section. When this fails, heating the mineral, or a portion of it, red-hot, and allowing it to cool gradually, will often open the joints.

The imperfectly crystalline structure, includes all the varieties of form in which a tendency to crystalline arrangement can be perceived. The first deviation from a regular crystalline structure, is where the joints are more or less curved; this is sometimes connected with a regular external form, as in the spheroidal diamond, and in pear spar; and sometimes occurs massive, as in curved lamellar heavy spar. The next deviation is where the laminae are long and thin, more or less resembling the blade of a knife, and have often a sharp edge on one side. These blade-shaped laminae are rarely parallel, but generally crose, as in common hornblende and cyanite.

The last variety of structure passes into the fibrous, in which the fibres are either parallel or radiated; when radiating on one side, they are called radiiform; when diverging in opposite sides, radiated; and when diverging on all sides, radiated.

In some cases, two different modes of structure are combined, a mineral presenting a fibrous structure in one direction, and a lamellar structure in another.

The promiscuous structure consists of different concretions, forming a maf, either by means of a small proportion of cement, or by a flight degree of mutual cohesion. It may consist of globular concretions, as in roe-flone and oolite, or of granular concretions, as in sand-flones. The granular concretions may be so small, as to be imperceptible without the aid of a lens. When the division of parts is visible in a mineral, it is said to be compact.

STRUCTURE of Rocks, in Geology, denotes the mode of aggregation of the mafes of which rocks are composed: the external structure may be stratified, schistose, tabular, columnar, or globular. The internal structure denotes the mode of aggregation of the substances of which the larger mafes are composed, and may be porphyritic, granitic, amygdaloidal, or conglomerated, &c. See Rocks, and Strata.

STRUCTURE of the Earth. See System.

STRIENSEE, John Frederic, in Biography, was the son of a clergyman of Halle, in Saxony, and born at Halle in 1737. At an early age he manifested very promising talents, and devoted himself to the study of medicine; and having taken his degree of doctor in 1757, he removed to Altona; and there obtained extensive medical practice. Besides the acquaintance he formed with two persons, viz. count Von Ranzau Aichberg and count Brandt, connected with his subfrequent fate, he acquired also, in the course of his practice, the friendship of the widow of the chief marshal of the court to Frederic V.; and thus was honoured with an appointment, in 1768, to be one of the physicians of the king, whom he accompanied in his tour to Germany, France, and England. Soon after the marriage of Christian VII. with Matilda, the English princess, an open rupture succeeded a coolness that was observed to subsist between this prince and the queen. The queen-dowager availed herself of this circumstance, with a view of recovering her lost influence. The misunderstanding between the two queens was increased on the birth of the crown-prince; and the king's tour contribute to lessen his indifference towards his comfort. On his return, the discontent was manifested more openly and decisively; and divided the nation into two parties. The most numerous party was supported by the minister and the principal officers of state; and at the head of it was count Holk, the king's favourite. The queen-dowager had her partizans at Fredericksburg; and some young persons, who had neither influence nor property, took part with Matilda, and entertained hopes that, on account of her youth, beauty, and engaging manners, a reconciliation might be effected between them. The young queen, however, well knowing that these friends had no experience in court intrigues, formed her own plan; and determined to make every possible effort for depriving count Holk of the royal favour, and thus of regaining the confidence of the king. Holk, for his own security, endeavoured to widen the breach between the royal pair; and conceiving that Struensee hated the queen as much as he himself did, he persuaded his royal master to take Struensee with him,
whenever he visited the queen. But, contrary to Holk's expectations, the king became attached to Struensee; and the queen, remarking this change, became gradually familiarized to his company; and her aversion to him was succeeded by an admiration of his talents, his wit, and his extensive knowledge. The crown-prince being at this time inoculated for the small-pox, under the superintendence of Struensee, the queen informed him, that, in recompense of his services, he should be entrusted with the prince's education. Struensee having succeeded in the operation, was made a counselor of conference, with a salary of 1500 dollars, and appointed reader to the king and queen. This new favour succeeded in his endeavours for peace; and complete reconciliation between the king and his royal comfort; which was followed by an indifference, on the part of the former, towards Holk. Bernstorff, the minister, became jealous of Struensee, and attempted, though unsuccessfully, to undermine the confidence reposed in him by the king and queen. Soon after, the court made a tour to Schleswig; and the heads of the different parties composed the royal suite. The queen behaved to both parties in the same courteous manner. Brandt succeeded Holk in the king's favour and confidence; but Bernstorff, though mortified by the loss of his influence over the king, declined making a voluntary resignation. His fate, however, was soon determined, and intimation was given him that his services were no longer necessary. The remaining members of government were dismissed, and the administration was formed by the friends of the queen and of Struensee. During these events, the queen-dowager remained at Friedeburg, watching their progress, and condescending with the discarded ministers. The queen at length obtained a complete triumph. The king behaved to her with the affectionate benevolence which he ever displayed; and Struensee possessed her confidence, and employed all possible means to retain it. The king, naturally of a weak mind, was secluded from society by Struensee; and Brandt was commissioned to keep him constantly occupied with amusements. The king was gratified by this mode of life; the influence of Struensee was augmented; and he at length accomplished his main object, which was that of preventing his majesty from perilously transacting any business with his ministers. In process of time, or towards the close of the year 1770, a complication occurred, which served to place unlimited power in the hands of the young queen and her ministers. Struensee neglected no means to increase his power; and in order to retain it more securely, he prevailed on the queen to commit to his management the whole business of the cabinet. In consequence of this measure, the whole form of the government was new-modelled; and public business was transacted in the king's name, by those immediately around him. But Struensee's paramount power was of no long duration. His boldness, approaching to the highest degree of insolence, degenerated into timidity, when any of his measures were opposed; and though he conducted foreign affairs according to the principles of sound policy, his internal administration, perplexed by avarice or ambition, did not answer the purpose intended. The various measures which he projected for the improvement of the government and country, and which our limits will not allow us to detail, excited disgust and dissatisfaction among persons of every rank and condition, from the highest to the lowest. Struensee, however, was indefatigable in the complicated duties of his office, and sedulously attentive to the education of the crown-prince. Two of his brothers were advanced to stations of importance; one in the new college of finance, and the other in the department of war. Brandt, Berger the physician, and other confidential persons, remained constantly near the king's person, nor were any others, suspected to be adverse to the existing order of things, permitted to have any intercourse with him; so that his indifference to public business gradually increased, and his capacity for conducting it diminished. In July 1771, the queen was delivered of a princess; and as she knew the furnaces, originating at Friedeburg, that were circulated on this occasion, she was not unapprehensive that they might serve as pretenses to wrest from her the power which she had acquired. She was unfortunately deprived of this on Struensee, who, by the advice of his minister, had become an object of detestation. Not content with being enrolled in the list of the Spanish nobility, and being created count, he invented a new title, or that of private counsellor of the cabinet, and with this he acquired a degree of power which had never been enjoyed before by any minister of Denmark. In fact, it was this ambitious minister's aim to annihilate the royal authority; and in the circumstances then existing, and under the pretence of the queen, if he had conducted himself with more prudence, he would have produced the machination on which he had been ruin. His friends, probably foreseeing his fall, became cool and indifferent; and the people in general, while they despised his power, executed his name. A spirit of discontent pervaded all ranks; the sailors and the soldiers complained of his conduct; and the populace joined the malcontents in their opposition and murmurs. The dissatisfaction and tumult that prevailed increased Struensee's timidity: his measures were indecisive, and his situation became every day more dangerous. The British minister, actuated by a respect for the young queen, endeavored to hasten his downfall, and thereby weaken the principality. Accordingly, he offered him a sum of money to enable him to quit the country. The queen, apprehending that her enemies would get the king into their hands, and obtain possession of all the royal power, opposed this measure. A crisis, however, was approaching; and Struensee could no longer refuse or control the counsels and operations of those who were hastening his downfall. Notwithstanding the measures which he adopted for infuring his own personal safety, and which were interpreted by the people into a breach of the sacred trust of his office, everything conspired not only to accelerate his own ruin, but to further the plan which had been formed against the young queen. On the morning of the 17th of January, 1772, the inhabitants of Copenhagen heard, not without astonishment and terror, that this prince, Count Struensee, his brother, Count Brandt, and all their friends and adherents, had been arrested in the night. At 3 o'clock in the morning, succeeding a ball that had been given at court the preceding evening, and after the queen had closed about 1 o'clock with Prince Frederick, colonel Koller, an inveterate enemy of Struensee's, whose regiment was on guard at the palace, informed his officers, after having admitted them into the palace, that he had the king's orders to take the queen into custody. The officers, without requiring to see the orders, which would have defeated the whole plan, implicitly obeyed. Ranzau hurried into the king's bed-chamber, and drawing the curtains so as to awaken him, told him before he had time for reflection, that his life was in danger. "What must we do?" said the alarmed king: "Shall we fly? and by me: give me your advice."—"Sign this," replied Ranzau, "it will save my sovereign and the whole royal family." Thus took hold of his pen, but let it drop as soon as he cast his eye
on the name of his comfort. At length he suffered himself to be perfused; and Ranza, supported by colonel Eich- 
stadt, whose dragoons surrounded the palace, and some other 
officers, carried out the fatal order; and, in a manner the 
most violent and brutal, seized the perf of the unfortunate 
Matilda, and conveyed her in a carriage to the castle of 
Cronenburg. Strueneef's arrest was followed by the ap-
pointment of a commissary for his trial; and the proceed-
ings against him were carried on with great zeal and se-
verity. The indictment, drawn up by the fiscal general in 
very intertemperate language, and delivered to the court on the 
21st of April, 1772, after relating the circumstances of his 
life and character, stated nine articles as capital charges.

"For many years before his fall," says his biographer, who has compiled his article from a variety of original documents, 
and of which we have freely availed ourselves, "Strueneef 
had lived an avowed free-thinker. He was convinced, 
however, of the existence of a Supreme Being, by whom the 
world was created; but he considered mankind as mere 
machines, governed by no moral principle; looked upon 
a future state as an idle dream; and believed that after 
death, a man had nothing to hope or to fear. During the 
first week of his imprisonment, he endeavoured by these 
principles to compose his agitated mind; and giving way 
also to the warmth of his imagination, fancied that a thou-
sand circumstances might occur to liberate him from his 
dangerous situation. He was thus able, for a little time, 
to bear up under his misfortunes, and to assume an apparent 
cheerfulness; but these were merely palliatives, which 
soothing their effect, he soon fell into a state of the most vi-
olent anguish and dismay. At last, however, which he re-
ceived from the celebrated Dr. Munter, (see his article,) 
a clergyman of Copenhagen, who went to see him in prison 
the 18th of March, 1772, laid the foundation for a change 
in his sentiments, which enabled him afterwards to support 
his sufferings with more fortitude and resignation. This 
worthy man discoursed with him proofs of Christianity; 
listened to his doubts and objections, and answered them in 
the mildest yet most forcible manner; and at length gained so 
much upon his heart, that he gave himself up entirely to his 
direction.

"When his trial came on, his advocate, in a short 
written defence, endeavoured to disprove all the charges 
that had been brought against him, with the exception of 
one, which was the di repect personally shown to the 
king. Of this he acknowledged himself guilty, was 
heartily sorry for it, and threw himself on the mercy of his 
offended sovereign. The court, however, which had re-
solved that Strueneef should suffer an ignominious death, 
rejected all representations made in his favour, and on the 
27th of April passed the following sentence: "That after 
his right hand had been cut off, he should be beheaded; 
that his body should then be quartered, and in that state 
publicly exposed; and that his head and hand should be 
affixed to a pole." On the next day, April the 26th, Dr. 
Munter paid him a visit, and informed him that this sen-
tence had in every point been confirmed by the king; and 
that the 28th was the day appointed for its being car-
ried into execution. The unfortunate court heard this 
intelligence with the utmost compo 
sure; and declared, that, in regard to the ignominious circumstances attending his 
doom, he was perfectly easy, as he believed in a future re-
futation. He spent the intervening time in a manner be-
coming his situation, and suffered according to his sentence, 
along with his friend Brandt, who had also been condemned, 
amidst an immense concours of spectato 

STRUFERTARI, among the Romans, persons hired to perform some kind of sacred rites near trees that had been 
thunder-struck.

STRUGA, in Geography, a town of European Turkey, 
in Macedonia; 10 miles S. of Akrida.

STRUM, in Rural Economy, a term signifying the ho 
used in brewing, &c. to keep the tap free. It is common 
ly made of straw cut in a neat short manner.

STRUMAE, formed, as some will have it, from 
strana; because they grow in the form of a 
stratum, stratum aurantium, in Medicina 
and Surgery, tumours arising most usu 
ally on the neck and throat; called also for 
folia, and popularly the evil, or king's 
evil. See SCROFULA.

The Greeks call them χαρακτικά, forces. See EVIL AND 
BRONCHOCLE.

STRUMARIA, in Botany, derived from struma, a wen, 
or swelling; and applied by Jacquin to this hand 
ITEMGENUS 
on account of the tumour at the base of its stye.—"Jacq. 
Kew, c. 2. 212. Lamarck Dict. v. 7. 422. Clas and 
Narcissi, Jull.

Gen. Ch. Cal. Sheath of two, unequal, oval, pointed 
leaves or valves. Cor. Petals six, superior, spreading, 
the three outer ones generally carinated at the back. Stam. 
Filaments six, inserted into the receptacle, shorter than 
the corolla, equal, awl-shaped; anthers oval, or roundish. 
Pil. Germen inferior, triangular, three-furrowed; tyline 
longer than the filaments, inserted from the base to its centre, 
awl-shaped upwards; stigma trifid. Petio. Capsule oval or 
roundish, slightly triangular, with three furrows, three 
cells, and three valves. Seeds numerous, round.

Eff. Ch. Petals six, spreading. Style thickened below 
the middle. Stigma three-cleft. Capsule inferior, roundish, 
of three cells.

Jacq. Ic. Rar. t. 356. Leaves linear-lfork-shaped, flat, 
obtusely rounded at the tip. Stalk round; compressed up-
wards. Stamens the length of the corolla.—Native of the 
Cape of Good Hope, as are all the remaining species— 
Root perennial, bulbous, with narrow fibres. Stalk a foot 
high, simple, erect. Flowers in a fork of umbel, on flcakes. 
Petals white, greenish on the outside and at the tip. 
Sheath shorter than the flower-flanks, pink or reddish.

Ic. Rar. t. 357. Leaves linear-lfork-shaped, flat, obtusely 
rounded at the tip. Stalk compressed. Stamens longer 
than the corolla. It flowers in April and May. Root 
perennial, fibrous. Stalk more than a foot in height, erect. 
Flowers in a handsome umbel. Petals white, pink on the 
outside. Sheath reddish.—The filaments of this species 
as well as of the last adhere to the base of the stye. It is also 
very similar in habit, but differs in having more flowers 
and much longer flmannas.

Ic. Rar. 358. Leaves linear, waved in an oblique manner. 
Petals flat.—It flowers in May and June.—Root perennial. 
Stalk a foot and half high, slender. Nearly waved. Flowers 
in a small umbel, pink-coloured, a little drooping. 
long filaments adhering to the base of the stye.

Jacq. Ic. Rar. t. 360. Leaves linear, waved in an oblique 
manner. Petals undulated.—Root perennial. Stalk a foot 
high, erect. Flowers in a loose umbel. Petals narrow, 
undulated, pink at the tip.

5. S. angustifolia. Narrow-leaved Strumaria. Wildl. n. 5. 
Jacq.
Jacc. Lc. Raf. t. 359.—Leaves linear, flat. Germin with three glands.—It flowers in April and May.—Root perennial, small. Stalk a foot high, slender, waved. Flowers irregularly umbellate. Petals white, with a pink line at their back; yellowish before expansion. This species is remarkable for having three glands on the germin.

7. S. spiralis. Spiral-flaked Strumaria. Ait. n. 5.—This species, now very properly referred, in the Hortus Kewensis, to Strumaria, is described in this work under the name of Hemantis spiralis. (See Hemantis.) Mr. Salisbury, in his Paradisi Londinensis, t. 63, considers it as a new genus, and calls it Carpolyza.

STRUMBLE'S HEAD, in Geography, a cape of South Wales, on the N. coast of the county of Pembroke. N. lat. 50° 41', W. long. 5° 12' 30".

STRUMENBACH, a river of Carinthia, which runs into the Gril, 8 miles N. of Tarvis.

Gen. Ch. Cal. Perianth superior, minute, of one leaf, erect, with five sharp teeth, permanent. Cor. Petals five, ovate-oblong, obtuse, spreading. Stam. Filaments none; authors five, united into an ovate body, rather shorter than the corolla, marked with five furrows, and very slightly five-toothed at top and bottom. P. I. Germin inferior, roundish; style awl-shaped, erect, projecting rather beyond the ovary; stigma simple, obtuse. Peric. Berry roundish, umbilicate, crowned with the calyx, of one cell. Seed solitary, roundish.

1. S. maritima. Linn. Sp. Pl. 1316. Jacc. Amer. 218. Wildl. n. 1. (Thymeloea fruticeae, rostrinian folio, flore albo; Plum. Lc. 249. t. 251. f. 1. T. humilorum, folia acutia atroviolaceae; Sloane Jam. v. 2. 93. t. 189. f. 1, 2.)—Gathered by Jacquin in Corapoa, on rocks near the sea, especially in the suburb called by the Dutch de kip. Sloane found his plant near the Palifados, by Port Royal in Jamaica. Nobody since seems to have met with the Strumpfia. Our only knowledge of it is from the accounts and figures of the above authors, and a fragment of Jacquin's original specimen, without leaves or flowers, given us by Sir Joseph Banks, who purchased his American herbarium. The stem is said to be shrubby, erect, three feet high. The branches (in our specimen) are round, closely clothed with fine hoary down, and appearing as if jointed, from the frequent, long hairs, which mark the insertion of the leaves and stipulas, both which originate from one common annular protuberance. The leaves grow three in a whorl, nearly sessile, and are lanceolate, entire, rather above an inch long, said by Jacquin to be very like those of Rosemary. Stipulas alternate with the leaves, spreading, awl-shaped, a line or two in length, dark-brown. Flower-flaks axillary, half the length of the leaves, each bearing about five small flowers, on short partial flaks. Petals white. Berry soft, white, the size of a small pea. The whole plant has a disagreeable, though not powerful, smell.

There cannot be much doubt of this genus belonging to the Campanulaceae, as that order stands in Jfff.; but whether it should still remain there, or be transferred to Mr. Brown's Goodeniaceae, may admit of a question; chiefly because of the berry and foliage habits. The author however feems not very decided in his division of the original order, and his limitations may therefore be received with the more latitude.

STRUMUS, a name given by some of the old Roman authors to the cucubulus, or berry-bearing chick-weed.

It had this name from its being found of service in strumous and scrofulous swellings, when externally applied. The name cucubulus feems to have been derived from the word Sabacaculum, or the winter-cherry, for the ancients esteemed both these plants species of nightshade; and some of them have plainly described the cucubulus under the name of fulmen hoerti.

STRUNKEDE, in Geography, a town of Germany, in the county of Mark; 2 miles N.W. of Catropp.

STRUNTJAGGER, Artic Bird, or Larus parasiticus, in the Linnaean system of Ornithology, is a species of gull found in the Hebrides and Orkneys, with a dusky hooked bill, and narrow nollirs. In the male, the crown of the head is black; the back, wings, and tail, dusky; the hindpart of the neck and lower side of the body white; the tail confits of twelve feathers; the legs are black, small, and scaly; the female is entirely brown. See Larus.

These birds pursue the leffer gulls till they mute for fear, and catch up their excrement, and therefore they are sometime called dung-busters, as well as another species of the gull called marinae.

STRUPT, among the Romans, garlands or wreaths of vevain, with which the flutes of the gods were crowned.

STRUUCHNETZ, in Geography, a town of Bohemia, in the circle of Konigigratz; 8 miles N. of Gfitschin.

STRUFT, a term used by some builders for that brace which is framed into the king-piece and the principal rafter.

STRUITHIA, in Ancient Geography, a town of Asia Minor, in Phrygia, on the confines of Lycaonia.

STRUITHIA, in Botany, a name originally given by Van Royen to the Gnidia of Linneaus; and which being derived from Stisios, a sparrow, appears to have had in view the near affinity of that genus to Paffieria. See Gnidia and Passerina.

STRUITHIO, in Ornithology, a genus of birds of the order Gallin. Bill subconic; nostril oval; wings short, unfit for flight, feet formed for running. There are four species.

Though the power of flying may be considered as the distinguishing characteristic of the feathered tribes in general, yet there are some families to which Nature has denied that endowment, while the feems to have granted it to a few quadrupeds, and even partially to some fishes. It is thus that she displays the extent of her power, by the variety of her productions, and diffuses to be confined within the narrow limits prescribed to her by the systems of philosophers. In defending from the claws of quadrupeds to contemplate that of birds, we find the connecting links, which unite these orders into one chain, very short, and almost imperceptible; for while the flying squirrel, the bat, and some other quadrupeds, are inverteb with the power of flight, and with 3 C 2 other
other properties of birds, the ostrich, dodo, and caffowary, are by their great bulk confined to the ground, and they indicate by their habits, a near affinity to the four-footed animals. Hence, as we defend from those swift and slender birds, which are destined to move in the higher regions of the air, we find them growing, by almost imperceptible degrees, heavier and less agile, till at length, being wholly destitute of the qualities necessary for flight, they are incapable of rising from the surface of the earth.

Species.

Camelus; Black Ostrich. Feet two-toed. This is the largest of all birds, and from this prerogative, in a great measure, is incapable of flight. Its weight is sometimes from eighty to one hundred pounds: from the top of the head to the ground, it is from seven to nine feet; and its length from the beak to the top of the tail eight feet. When walking, it seems as tall as a man on horseback. The plumage of the ostrich, however, as well as its weight, is an impregnable barrier against its rising in the air. The vanes of the wing-feathers are separate and detached, like hairs, and incapable of making any impression on the atmosphere. Those of the tail, and indeed of the whole body, are of the same structure. They are all as soft as down, and utterly unfit not only for flying, but for defending the body of the animal from external injury. The feathers of other birds have their webs broader on the one side than the other, but thofe of the ostrich have the shaft exactly in the middle. The head, the upper part of the neck, sides, and thighs, are covered with a clear kind of hair, which on the head somewhat resembles the bristles of a hog. The thighs of this bird, in which its great strength seems to lie, are large and musculat; and its hard and scaly legs, which are supported by two thick toes, have a considerable similarity to those of the goat. These toes are of unequal size; the inner, which is both longer and thicker, being seven inches in length, including the claw; the other, which is without a claw, is four inches. It is the only bird that poises eye-lids, and these are fringed.

Though the ostrich be a bird known from the earliest ages, little comparatively is related of its life and habits, since the Scriptures, we have been many comparisons drawn from its manners: as an article of food it was forbidden the Jews. It is mentioned by Aristotle as remarkable for its fecundity. In the parched deserts of Africa, where it refires, and where it runs with precipitation on the approach of an invader, it can rarely become an object of close examination. The race of these birds, though extremely ancient, still remains pure and almost solitary. Like the elephant among the quadrupeds, the ostrich constitutes a genus offering few or no varieties, and is perfectly distinguished by characters equally striking and permanent. It is peculiar to Africa, to the neighbouring islands, and to those parts of Asia that lie in the vicinity of the African continent. It is seldom found beyond the distance of thirty-five degrees from the equator; and as it is incapable of flight, it must, like the quadrupeds of these latitudes, have always been confined to the ancient continent. It prefers for its residence those mountains and parched deserts that are never refreshed with rain, a circumstance which tends to corroborate the report of the Arabs, that these birds never drink. Vast flocks of them are seen in these barren and solitary regions. At a distance they are said to appear like an army of cavalry, and often alarm the caravans that are travelling through them.

Among some nations, the eggs, the blood, and the flesh, have been eagerly sought as articles of food. Whole people have obtained the appellation of Struthophagi, from their partiality for this food. The Romans considered the flesh of the ostrich as a delicacy; and the imperial beast and glutton, Heliogabalus, is said to have had 600 of them slaughtered in one day, in order that he might have the brains served up as a dish to pamper his appetite. At present, the inhabitants of Numidus tame and breed them, to live upon their flesh, and sell their feathers. Their eggs are said to contain as much food as thirty of those of a common hen. The beauty of the plumage of this bird, particularly of the large feathers that compose it, are the chief reason why man has been so active in pursuing him into the deserts, at so much expense and labour. The Arabs, who make a trade of killing these birds, formerly converted their skins into a kind of buckler. The ancients used their plumes as ornaments for their helmets. The ladies in the East make them still an ornament in their dresses, and they are not unfrequently used in this country for the same purpose. In Turkey, the Janizary, who has signalized himself by some military achievement, is allowed to assume them as a decoration of his turban; and the sultan, in the fagiaho, when meditating conquests and feasts of a more gentle nature, puts them on, as the most irrefutable ornament of his person.

The spoils of the ostrich being thus valuable as articles of commerce, the hunting of this bird is one of the most serious employments of the Arabs, who train their fleetest horses for the purpose. Although the ostrich be far swifter than the belt courier, yet by hunters on horseback he is commonly taken; and it is said of all the varieties of the chase, this is the most difficult and laborious. The Arab, when mounted, still keeps the ostrich in view, but without rushing him so close as to make his escape to the mountains, but at the same time so as to prevent him from taking food. This is the more readily done, as the bird takes its course in a wavering and circuitous direction, which is greatly shortened by the hunters, who come up behind, and relieving each other by turns, thus keep him still running. After two or three days of fatigue and famine, he becomes exhausted, and the hunters fall upon him by striking him on the head with cudgels, that his blood may not tarnish the luster of his white feathers. When all possibility of escape is cut off, the Arab, with the greatest of patience, continues the expectation that the whole body will then be concealed from their searchers.

Ostriches, though inhabitants of the desert, and possessed of prodigious strength, are, especially if taken young, neither so fierce nor difficult to tame as might be expected. The inhabitants of Dara and Lyibia render them domestic, like herds of cattle, with scarcely any other means than constantly accustoming them to the sight and society of man; to receive from him their food, and to be treated with gentleness. Besides the use of their feathers, ostriches, in their domestic state, are said to be mounted and rode upon in the same manner as horses. It is allowed by Adamson, that at the factory of Podere, he had himself two ostriches, that run faster than a race-horse with a negro each on their backs. Though these birds may be so tamed that they will suffer themselves to be driven in flocks to and from their stalls, and even to be mounted like horses, yet their stupidity is such, that they can never be taught to obey the hand of the rider, to comprehend the meaning of his commands, or submit to his will. From this intractable disposition, there is reason to apprehend that man will never be able to avail himself of the strength and swiftness of the ostrich, as he has availed himself of those qualities of the horse. The voracity of this bird far exceeds that of any animal whatever; for it will devour every thing it meets with, bones, wood, brack, iron, or leather, as readily as it will grain and fruit, which, in its native wilds, are probably its principal food.
STRUTHIO.

The season at which the ostrich lays her eggs varies very much with the temperature of the climate. Those north of the equator begin to lay their eggs in the beginning of July, while those in the south of Africa defer it till the end of December. Climate and situation have also a great influence on their manner of incubation. In the torrid zone, the ostrich is contented with depositing her eggs in a mass of sand, seemingly scraped together with her feet. There they are sufficiently heated by the warmth of the sun, and seed the incubation of the female only for a little time during the night. But although the ostrich be but little engaged in hatching her eggs, she displays, by continually watching for the preservation of her progeny, all the solicitude of a tender mother. In proportion to the coldness of the climate, the ostrich hatches with more avidity; and it is only in the warm regions, where there is no danger of her eggs being chilled, that she leaves them by day, a circumstance from which the very early incurred the reproach of being delitute of parental affection. So far, however, is this from being true, that she continually watches for their preservation, and, so long as they remain in a helpless state, which is always a longer or shorter period, according to the climate. Neither the size of the eggs of these birds, nor the time necessary for hatching them, nor the number of the young, are exactly ascertained. Arrauwari; Cassowary. Feet three-toed; helmet and dew-laps naked. This bird inhabits the torrid zone, and especially the island of Java, whence it was brought into Europe in the year 1797. Its habitat begins in those temperate climates which are contiguous to the precipices of the ostrich; and as it occupies a region more favourable to the multiplication of the human race, its numbers are continually decreasing, in proportion to the increase of the number of its destroyers. Cassowarys are of various sizes; they have been seen as large as six feet high. The Dutch compare the bulk of this bird to that of a sheep. From the shortness of the legs and neck, they are not to tall as the ostrich, but the body has a more heavy and clumsy appearance. The most remarkable trait in the appearance of these birds is a sort of helmet on the head, which reaches from the base of the bill to the crown. The middle or upper eye-rid is furnished with a row of black hairs, which gives the animal a wild aspect, which the large aperture of the beak renders still more fierce and menacing. The head and upper part of the neck are almost naked, being only covered with short hairs, while the chest and thighs have a blue wrinkled skin. The feathers that cover the body of the cassowary, as well as those for flight, are all of one kind, and of the same blackish colour. They are generally double, having two shafts, that grow from one short trunk, which is fixed in the skin. The small fibres of which the vane are composed, have no little adhesion to each other, which the bird, when viewed at a distance, seems clothed with hair instead of feathers. The wings of the cassowary are still shorter than those of the ostrich, and consequently still more unfit for flying. They are furnished each with four hard pointed quills, resembling darts, of which the length is such that, which is about eleven inches, is a quarter of an inch thick at the root. Its feet are also armed with large black claws, which give the animal an appearance of being formed for hostility. But though supplied with weapons that might render it formidable to the rest of the animal world, the cassowary leads a peaceable and inoffensive life. It never attacks others, and nothing short of necessity will make it defend itself. The movements of the cassowary, when travelling, are awkward and heavy, nevertheless it will, in running, outrun the fleetest horse. It is distinguished by the same voracity which characterises the ostrich, swallowing every thing that is offered to it, unless it be too large for the circumference of its throat; and it polishes the faculty of rejecting its food, when disagreeable, with the same dispatch with which it took it in. The female lays a number of soft-coloured eggs, about thirteen inches in circumference one way, and fix the other; they are of a greenish colour, with dark green spots.

NOVÆ Hollandie; New Holland Caßowary. Feet three-toed; crown flat; thanks serrate behind. This, as its specific name imports, is found chiefly in New Holland, and is seven feet two inches long. The bill is black; head, neck, and body, covered with bristly feathers, varied with brown and grey; throat rather naked, blueish; feathers of the body little incurred at the tip; wings scarcely visible; legs brown.

RHEA; American Ostrich. Feet three-toed, and a round callos behind. This bird is so nearly allied to the ostrich, already described, that it has been considered as a representative in the new continent, to which it peculiarly belongs. It inhabits Guiana, Brazil, Chili, and those immense forests that extend northwards from the mouth of the river Plata, and it has been found as far south as the Magellanic Straits. Formerly, these birds were more widely spread over South America; but, in proportion as population increased, these timid animals fled from the habitations, or became thesubjects of superior power. It is by far the largest bird in the new world. The adults are full six feet high, and the thighs of some of them have been known to equal that of a male colossus. Its beak is long, small head, and flat beak, that distinguishes the black ostrich; but in other respects it has a greater resemblance to the cassowary. The shape of the body is oval; and when fully covered with feathers, approaches to rotundity. Its wings are so short as to be useless for flight, but, like those of the ostrich, probably afford assistance in running. The back and rump are covered with long feathers, which extend and form what, in this animal, is called the tail. The whole upper part of the body is covered with grey plumage, and the under with white. The toes are three, all before; behind there is a calous kind of heel, which supports the bird, and is supposed to affix it in running. It polishes the fame velocity which characterises the former species, and its running is attended with a singular motion of its wings. It raises one for some time above the body, and then drops it to erect the other, and so on, as a bird60. It is, however, remarkable for its velocity, that the fowlers are obliged to lay snares in order to catch them; for they may, in vain, chase them with the twiftest dogs.

The rhea shows the fame indiscriminate voraciouwsness with the ostrich; and it is probable that her eggs are hatched partly by the heat of the sun, and partly by incubation. The young, when first excluded from the shell, are so familiar, that they will follow the first person they happen to meet with; but upon growing older, they acquire experience, and become more shy and fulgicious. The flesh of the young rhea is of a white colour, but it might probably be much improved, and the race rendered more abundant by domestication, as has been the case with the turkey and hen, which originally came from the torrid zone. The rhea defends itself with its feet, and calls its young by a kind of hfe.

STRUTHIOOLA, in Botany, derived from Cyphos, the diminutive of Cyphos, a sparrow. This Greek name is expressive of the same idea as Pufferina, to which genus the present is analogous in the shape of its seeds, which are pointed like a sparrow's beak.—Linna. Mant. 4. Schreb. 86.
STRUTHIOPSIS, in Natural History, a name given to a series of flies, of the class of those which do not feed on flesh: these have remarkable short wings, and are always found on flowers and leaves of plants. There are several species of these. The most frequent among us are a white-bodied one with black wings, which cover but a very small part of the back, and with feathered wings; and two others with long bodies, of a dusky grey, streaked with white. These are all early flies, being found in the spring in hedges and bushes.

STRUTHIOPTERIS, in Botany, was so called from ἔτοιμος, in its secondary sense, οὐ τοίμος, or ἔτοιμος, in large and elegant fronds are not unworthy to be compared to the noble plumes of that bird. See ONOCLEA.

STRUTHION, in Natural History, a name given by the Greeks to a plant called by the Latinas lanaria herba, from its use in the manufacture of their wool. Many have supposed the chafeyfa of the ancients to be the same with this plant, but this is an error, for the chafeyfa of the Greeks is the antirrhinum of the Latin, as is plain from Pliny; and the same author tells us that it has leaves like those of an iris, small, narrow, and smooth. All the accounts we have of the struthion is from Dioscorides, who says that it was a kind of thistle, somewhat resembling the sycamor, and having a large root, long, and of the thickness of two or three fingers, and very hard prickles on the leaves. This short account, though not enough perhaps certainly to inform us what the plant was, is yet abundantly sufficient to prove that it was not the chafeyfa, or antirrhinum.

We find the struthion celebrated among the Romans for its virtues; but all the accounts we have of it from them is, that it was a prickly plant, and was very common in the Grecian islands. This, however, is insufficient to convince us of the great error of those who make this plant and the orificeum of the later writers to be the same plant. The orificium is the Smyrnium, or Alexanders, and can by no means be supposed the same species with this prickly plant; yet Macer has made them the same name, and has attributed to the Smyrnium, or Alexanders, the virtues which Theophrastus gives to the struthion.

STRUTHIUM, in the Materia Medica, is used by the modern authors as the basis of the lucern, or dyer’s-weed, a common wild plant with narrow leaves and yellow flowers.

STRUTHIUM is also used by some for the japonaria, or soap-wort. See SAPONARIA.

STRUTT, Joseph, in Biography, an artist and antiquary, the son of a miller at Springfield, in Essex, was born there in 1740, and in 1764 apprenticed to the ingenious but unfortunate engraver, W. Wynn Ryland. In 1770 he became a student at the Royal Academy, where he obtained the gold and silver medals. Connecting antiquities with the practice of engraving, he published, in 1773, a work entitled "The Regal and Ecclesiastical Antiquities of England," containing representations of all the English monarchs from Edward the Confessor to Henry VIII. And of many distinguished personages in their reigns, in their appropriate costumes, taken from illuminated MSS., and annotated with remarkable passages of history. To this succeeded "A Complete View of the Manners, Customs, Arms, Habits, &c. of the English, from the Arrival of the Saxons to the Reign of Henry VIII.," with a short Account of the Britons during the Government of the Romans," in 3 vols. 1774, 1775, 1776, with 157 plates. In 1777 and 1778 he published a "Chronicle of England," designed to extend to six volumes, but discontinued for want of encouragement.
His "Biographical Dictionary of Engravers" next appeared, in 2 vols. 1785, 1786, with 20 plates. His other works are "A complete View of the Dressers and Habits of the People of England from the Establishment of the Saxons in England to the present Time," in 2 vols. 1796, 1799, with 143 plates. "The Sports and Pastimes of the People of England," 1801, with 40 plates. The decline of his health constrained Mr. Strutt to leave the metropolis, and to reside at a farm near Hertford, where he engraved a number of plates for an edition of the "Pilgrim's Progress." His disposition being benevolent and religious, he founded a Sunday school at the neighbouring village of Twain, and devoted much time to reforming the morals of the inhabitants. He afterwards returned to London, where he died in 1802, with an estimable character for moral worth, and for indefatigable industry in elucidating the antiquities of his country. His style of engraving, in which he followed his master, Ryland, was that of dots in imitation of chalk, producing an effect of much softness and harmony. Nicholls's Life. Anec.

STRUYE POINT, in Geography, a cape of Ireland, on the coast of the county of Donegal, a little S. of Inishowen Head.

STRUVIUS, BURCHARD-GOTTHILF, a German jurist and antiquary, son of the preceding, was born at Weimar in 1671, and after a course of education under the most eminent professors at various places, and practicing for some time at the bar, he devoted his time to his favourite studies of public law and history. Upon recovering his health from a state of melancholy, which continued two years, he became librarian at Jena, and afterwards graduated at Hall in philosophy and law; and having fulfilled several offices of service and honour, he died in 1738. His works consist of bibliothecas, biographies, systagmas of history and antiquities, academical disputations, &c. Those that are most known are "Antiquitatum Romanarum Syntagma," 4to. 1701; "Bibliotheca Numismatum Antiquorum," "Biblio.heca Historica felcda," 1705; "Introductio ad Notitiam Rei Literaria," "Syntagma Juris Publici," 4to. 1711; "Syntagma Hist. Germ," 2 vols. fol. 1730; "Historia Mifenfis;" a "History of Germany," in the German language: in all which writings he has displayed profound learning and accurate research. Moreri.

STRUYS BAY, in Geography, a bay on the south coast of Africa: this is merely a large bay, with good anchorage, without shelter, except from north-westerly winds, and exposed to a continued swell and strong current. S. lat. 34° 33'.

STRYBIA, in Ancient Geography, one of the Sporades.

STRHYNOS, in Botany, an ancient name, which occurs in Pliny and Dioscorides, derived from σειρυχων, to overthrow. This appellation was doubtless suggested by the overpowering narcotic qualities of the plant to which it was assigned; στρυχος of the Greeks being a kind of nightshade.

The seeds of this species, well known in our shops as a poison for vermin, by the name of Nuca vomica, are a very potent narcotic, being extremely bitter, and almost fetid. The natives of the East Indies use them in the distillation of intoxicating spirits.—On the continent they are much employed as a medicine, but in this country, where the maxim of physicians is said to be "fatem non nocere," their use is confined to the destruction of noxious animals. The wood is hard and durable. The root is very bitter, and is used to cure intermittent fevers, and the bites of venomous snakes, when that of Naga-nufudie or Lignum colubrium cannot be obtained.

2. S. colubrina. Snake-poison Nut. Linn. Sp. Pl. 271. (Lignum colubrimum; Rumph. Ambin. v. 2. 121. t. 37.)—Leaves ovate, acute. Tendrils simple.—Native also of the East Indies.—From the character given of this species, it may probably be what the Telugus call Naga-nufudie. Indian botanists consider this as a variety of the Nuca vomica. The leaves are opposite, on short stalks, obtuse, lanceolate, three-crefted. Many different sorts of wood are sent to Europe under the name of Lignum colubrum.

3. S. potatorum. Clearing-nut. Linn.Suppl. 148. Roxb. Coromandel. v. 1. 9. t. 5.—Leaves opposite, ovate, acute; mostly five-crefted, veined. Cymae axillary.—Found in the mountainous parts of Madras, flowering during the hot season.—This is rather a large tree, with opposite branches. Leaves very short, on stalks, quite entire, smooth. Stipulas entire, connecting the stalks. Flowers small, yellowish-white, fragrant, in axillary cymes at the termination of the preceding year's shoots. Berry the size of a cherry, dark red, at first tawny-sweet, but afterwards bitter and astringent. The wood is hard and durable, and is used for various economical purposes. The ripe seeds are sold for clearing muddy water, whence the English name.

—Leaves ovate, somewhat pointed, coriaceous, three-nerved; nerves divided. —Native of the tropical part of New Holland, where it was discovered by Mr. Brown, but not in flower.

STREPHONIS, in the *Materia Medica*. See Nux Vomica and *Lignum Calabarium*. The *Faba Sti. Ignatii*, allied to thefe, confitutes the new genus *Ignacia*, which fee.

STREPHONIS, a name given by the ancients to the plant we call *solanum*, or nightshade. (See SOLANUM.) Some of the old authors have all called this *solanum*; and in the times of Theophrastus we find that tithymal and nightshade were fynonymous terms. See *Manicium Strephonis* and *Stramonium*.

STRYCKIUS, SAMUEL, in *Biography*, a German jurif, was born in 1640, at Lentzen, in the marquifate of Brandenburg, studied at Wittemburg, and after travelling in England and the Low Countries, became professor of jurifprudence at Frankfort-on-the-Oder. Having eftablifhed his reputation by his writings, he was appointed prefident of the court of juftices, and elecoral counsellor. Stryckiis occupied feveral posts of highofhonour, and died in 1779, leaving behind him feveral volumes of learned difcourfes on legal fubjects, which were much eftamed.

JOHN SAMUEL, fon of the preceding, was profesfor of law in the university of Hall, of which his father had been director, and acquired reputation by his lecutres and publications. *Moreri*.

STRYE, in *Geography*, a town of Auffrian Poland, in Galicia; 5 miles W. of Halcz.

STRYEN, a town of Brabant; 3 miles S. of Gertrudenburg.—A town, in the ifland of Beyerdland; 8 miles from Dort.

STRYKE. See STRIKE.

STRYMA, or STRYME, in *Ancient Geography*, a commercial town of Thrace, situated near the Litus. It was separated by the lake Ifmania from Maronea.

STRYMALAGA, a town of Indix, on this side of the Ganges, in the number of thofe which were situated between the river Rynuda and the Peafudtomus, according to Ptolemy.

STRYMON, a river which had its fource in mount Hemus, and which formed a boundary between Macedonia and Thrace, before the conquests of the Macedonians had extended the kingdom on this side. At its mouth was the gulf called Strymonicus Sinus.

STRYNKALY, in *Geography*, a little ifland of Denmark, in the Baltic, between Aròe and Langeland. N. lat. 54° 54'. E. long. 10° 36'.

STRYNOE, a little ifland of Denmark, in the Baltic, about 2 miles from the W. coast of Langeland. N. lat. 54° 64'. E. long. 10° 36'.

STRYPE, JOHN, in *Biography*, a voluminous writer of German extraction, was born in the parish of Stepney, near London, in the year 1643, educated at St. Paul's school, and in 1661 entered at Eiufus college, Cambridge, from whence he removed to Catharine-hall. In 1669 he became Master of Arts, and taking orders, was nominated to the perpetual curacy of Theydon-Boys, in Essex, and being afterwards appointed minister of Low Layton, in the fame county, he retained this office during the whole of his life. Having access to the numerous MSS. of Sir Mich. Hickes, fecon-ary to lord Burleigh, he availed himself of them, in his subsequent writings on historical antiquities, to which, probably in confequence of this circumftance, he became zealously attched. His firft publication in this department of literature was entitled "Ecclefialical Memoriaus, relating chiefly to Religion, and the Reformation of it un-der Henry VIII., Edward VI., and Queen Mary I.," in 3 vols. folio, with an appendix to each volume, confifting of original papers, records, &c. The laft of these volumes, which were printed in succeffion, appeared in 1731. The publication of his "Annals of the Reformation of the Church of England," in 4 vols. fol., began in 1701, and were completed in 1731; the laft volume being merely a collec- tion of original papers. His much augmented edition of "Stow's Survey of London" in 2 vols. fol. was published in 1745. The historian, by whom the work was brought down to his own time, and he added maps of all the wards, and illustrative plates, besides various other improvements. In the department of biography, he published separately, in folio volumes, the lives of archbishops Cranmer, Parker, Grindal, and Whitgift, and in three octavo volumes, the lives of sir John Cheke, sir Thomas Smith, and bishop Aylmer. In these works he manifested an indufly and correctnefs, which claimed the repect of prelates and learned perons of his own time, and procured for him feveral small benefices in the church, though he was never advanced to any very limited means which would have been more agreeable to Hackney, where he spent the latter part of a life, prolonged, notwithstanding his unintermitting course of study, to the common age of 94. His death happened in December 1757. Of his works Dr. Birch observes, that "his indufly and fidelity will always give a value to his numerous writings, however deftitute of the graces, and even uniformity, of fyle, and the art of connecting facts." *Biogr. Brit.*

STRZESZYN, in *Geography*, a town of Lithuania, in the palatinate of Mink; 18 miles S. of Róhaczow.

STRZLCE, in *Biography*. See STRZELCE.

STRZOW, a town of Auffrian Poland, in Galicia; 80 miles W. of Lemberg.

STUART, JAMES, in *Biography*, commonly called Athenian Stuart, rofe from an obscure origin, by his talents and indufly, to diftinguished eminence. His father was a native of Scotland, and a mariner of humble station, and his mother a native of Wales. Their fon was born in London in 1713; and his parents, though poor, yet repreffible in character, gave him the best education which their limited means would admit. Being one of four children, left deftitute at their father's death, he was for many years the servant of Hackney, where he spent the latter part of a life, prolonged, notwithstanding his unintermitting course of study, to the common age of 94. His death happened in December 1757. Of his works Dr. Birch observes, that "his indufly and fidelity will always give a value to his numerous writings, however desitute of the graces, and even uniformity, of style, and the art of connecting facts." Biogr. Brit.
visited Venice; and hence they took their course to Pola, in Istria; and when they had examined the interesting remains of antiquity in this place, they returned to Venice. In the beginning of the year 1751 they sailed for Zant, and thence to Corinith, and in the month of March reached Athens. Here they employed themselves, till the latter part of the year 1753, in making drawings and taking measures of the architectural remains to which they had access. At Athens Mr. Stuart became acquainted with Sir Jacob Bouverie and Mr. Dawkins; and the latter, in particular, took pleasure in affording him and his companion patronage and encouragement. From Athens the two artists went to Salonica, where they copied the remains of a fine Corinthian colonnade. Having visited several islands in the Aegean sea, on their way to Smyrna, they returned to England in the beginning of the year 1754. In the year 1762 the first volume of the result of their labours was published under the title of "The Antiquities of Athens measured and delineated, by James Stuart, F.R.S. and S. A. and Nicholas Revett, Painters and Architecs," fol. This work was received with great applause by the lovers of art and antiquity; and though it had been anticipated by the publication of M. Le Roy, which surpassed it in picturesque beauty, yet its superior truth and depth of research gave it a more solid and permanent value. Mr. Stuart, after his return, obtained distinguished patronage in his profession as architect. Lord Anson, who was at the head of the Admiralty, conferred upon him the office of Surveyor of Green-wich Hospital, which he occupied till his death. He was twice married: the first time, at the age of 67 years, to a very young lady, by whom he had four children. The death of one of these, who resembled himself both in mind and body, and who manifested an extraordinary talent for drawing at the age of three years, was followed by a rapid decline of the father's health, who died in 1788, in the 76th year of his age. Two additional volumes of the "Antiquities of Athens" were published after his decease; the second, in 1790, by Mr. Newton; and the third, in 1794, by Mr. Reveley. Gen. Biog.

STUART, GILBERT, LL.D. the son of a professor in the university of Edinburgh, where he was born either in 1742, or in 1743; the date of his birth being uncertain. He was originally intended for the profession of the law; but having acquired reputation, and the degree of LL.D. by an "Historical Dissertation concerning the Antiquity of the British Constitution," he cast his lot among those who are, professedly, writers. With these views he came to London, and for some time contributed to the Monthly Review; but disappointed in his expectations, he returned to Edinburgh in 1774, and commenced a magazine and review bearing the name of that city. Soon after he gained an increase of reputation by publishing "A View of Society in Europe, in its Progrefs from Rudeness to Refinement," of which an enlarged edition in 4to. appeared in 1778. His "Observations concerning the Public Law and Constitution in Scotland" were published in 1779. In this work he introduced a somewhat invidious reflection on Dr. Robertson, characterizing him as being "no where profound;" and indeed he seems to have been jealous of this distinguised historian's literary fame. Dis appointed as candidate for the profefforship of public law in the university of Edinburgh, his feelings were farther irritated; and from that time his leading object appears to have been to set himself in opposition to Robertson, and to deprecate his merits. In 1780 he published "The History of the Establishment of the Reformation of Religion in Scotland," which has been regarded as a spirited and tolerably impartial view of the important events which it details. This was followed, in 1782, by, "The History of Scotland, from the Establishment of the Reformation till the Death of Queen Mary," 3 vols. 4to.

As the rival of Robertson, he enlists himself in this work among the warmest partisans of queen Mary. How far he succeeded in attaining this object, is not our province to determine; but his success was less popular than its opponent; and one of his biographers says, that though "he was not deficient either in acuteness or in diligence, he appears to have been wanting in the moral qualities essential to a writer of history." From this time, and after his removal to London, where he was employed in some periodical publications, his conduct subjected him to ridicule and reproach, and terminated in an incurable illness, under which, after his return to his native country, he sunk in 1786. He poffessed," says the writer of his life already cited, "strong, if not brilliant talents; but his principles were lax, and his temper such as procured him many more enemies than friends." Gen. Biog.

STUART'S ISLAND, an island in the North Pacific ocean, near the W. coast of America, lying in the latitude of 63° 35', and 17 leagues from Cape Denbigh, in the direction of S. 27° W. This island is five or six leagues in circuit; some parts of it are of a middling height, but in general it is low, with some rocks lying off the western part. The coast of the continent is, for the most part, low land, but up the country some part of the land was high. It forms a point opposite the island, which was named Cape Stephens, and lies in lat. 66° 39', and long. 157° 41'. Some drift-wood was seen (see Third Voyage of Capt. Cook) upon the shores both of the island and of the continent; but not a tree was perceived growing upon either. One might anchor, upon occasion, between the north-east side of this island and the continent, in a depth of five fathoms, sheltered from westerly, southwesterly, and easterly winds; but this situation would be wholly exposed to the northerly winds; the land, in that direction, being at too great a distance to afford any security.

STUARTIA, in Botany, received that name from Linnaeus, at the suggestion, as it appears, of Dr. Isaac Lawfon, in honour of the famous John Stuart, 6th earl and then marquis of Bute, who, by his deep and extensive knowledge of this science, and his unbounded devotion to it, merits no common degree to be thus commemorated. His name, thus conferred, will doubtless remain, when others innumerable, unworthily so distinguished, will justly be swept away. Still we cannot converse at the ridiculous supererogation of Koenig, who, ignorant perhaps of the application of Stuartia, established a Butea. See our article Plantæ, where we have hinted that this Butea may, though not on the ground of equal pretension, serve to commemorate, as a lover of plants, the daughter-in-law of the above nobleman. By mistake, Linnaeus and some others have written the above name Stuartia, but we restore the true, and universally well-known orthography.—Linn. Gen. 356. Schreb. 470. Willd. Sp. Pl. v. 3. 340. Mart. Mill. Dict. v. 4. Ait. Hort. Kew. v. 4. 234. Sm. Exot. Bot. v. 2. 101. Pursh 451. Jull. 201. Cavan. Dict. 303. Lamarck Illutr. t. 593. (Malachondron; Mitchell Ephem. Nat. Cur. v. 8. 216. Cavan. Dict. 302. Schreb. 470. Jull. 225. Lamarck Illutr. t. 593.)—Clas and order, Monadelphia Polyandra. Nat. Ord. Ca-namphal. Linn. 8. 104.

five, obturate, concave, spreading, equal, large. Stem. Filaments numerous, thread-felted, shorter than the corollas, disposed in several rows, united at the bottom into a short cylinder, and connected with the claws of the petals; anthers incumbent, of two rounded lobes. Pist. Germin superior, roundish, hairy; styles five, cohering or separate, thread-felted, the length of the flaments; stigmas obtuse. Peric. Capsule superior, ovate, with five furrows, of five cells and five valves, the partitions from the centre of each valve. Seeds one or two in each cell, ovate, smooth, compressed.

Eff. Ch. Calyx in five deep segments. Petals five. Styles five, cohering or separate. Capsule superior, of five cells and five valves. Seeds one or two in each cell, smooth.

1. S. Malachodendron. Common Stuartia. Linn. Sp. Pl. 592. Wild. n. 2. Ait. n. 1. L'Herit. Stirp. 155. t. 73. (Stuartia; Linn. Aet. Upl. ann. 1741. 79. t. 2. Dubam. Arb. v. 2. 283. t. 78. S. virginica; Cavan. Diff. n. 438. t. 159. f. 2. Pursh n. 1. S. marilandica; Andr. Repol. t. 397.)—Petals slightly waved. Styles combined.—Native of swamps in the lower counties of Virginia and Carolina, flowering from July to September. Cultivated by Cateby in England in 1742, but now very rarely seen. It flowered at the mansion of Blandford's in 1804. The stem is shrubby, from five to seven feet high, bulbous, with round, smooth, spreading branches. Leaves alternate, on short stalks, elliptic-oblong, acute, veiny, from two to four inches in length, more or less serrated; smooth, and of a fine green, above; paler, and variously downy, especially about the rib and veins, beneath. Flowers lateral, scarcely axillary, mostly solitary, on short stalks, large and very handsome, with white, concave, wavy, but not jagged or fringed, petals, an inch and a half or two inches long. Segments of the calyx broad and ovate, without any bracts or appendage at the base. Anthers purple. Style united into a cylinder with five furrows, and five short obtuse stigmas.

2. S. pentagona. Curled Stuartia. L'Herit. Stirp. 155. t. 74. Wild. n. 2. Ait. n. 1. Exot. Bot. t. 110. Pursh n. 2. "J. Mill. Ic. t. 5." (Malachodendron ovatum; Cavan. Diff. n. 437. t. 158. f. 2.)—Petals jagged and curled. Styles separate.—On the mountains of Carolina and Georgia, flowering in August. Purf. The precise time of its introduction into the gardens of Britain is not known, this species not having always been clearly distinguished from the foregoing. It was at Kew certainly long before 1785, when we obtained there fine specimens in flower, under the name of S. Malachodendron. Few shrubs are more desirable, yet it is confined to the most choice gardens, being perhaps rather difficult of cultivation, though not very tender as to cold. The stem is five or six feet high, in mode of growth like the last. Leaves deciduous, ovate, acute, variously serrated; smooth above; downy and paler beneath. Flowers axillary, solitary, as large as the former, but of a more greenish-white, or cream-colour, often tinged with red; the margin of their petals deeply jagged, crisped and erose. Calyx with very deep, ovato-lanceolate, hairy segments, accompanied by a pair of lanceolate bracteas, of its own length. Anthers tawny. Germin hairy, deeply five-lobed. Styles quite distinct throughout, a little spreading, smooth. Stigmas recurved, glabrous.

Nothing can be more evident than that these two plants must constitute one natural genus. Indeed their several varieties so nearly approach each other, that the greatest practical botanists have been in the habit of confounding them as one species. Cavallies indeed, an accurate observer, but not accustomed to contemplate the generic characters of plants in a philosophical manner, was decidedly of opinion that these two shrubs must form two distinct genera; for nothing can be more distinct, in theory, than one style and five. L'Heritier judged more correctly, and we have followed his decision. The S. pentagona seems to have taken place of the original Stuartia in our gardens. All that the younger Linæus, the late Mr. Davail, or we know, has at different times had accuracy of the most ingenious English collectors, is the pentagona. A single specimen of S. Malachodendron from Clayton lies in the old Linæus herbarium. This has the styles firmly united, so as to be, in appearance, strictly monogynous. Linæus, not adhering to that circumstance, took the plant for Mitchell's Malachodendron, and hence adopted that name as a specific appellation, which embroils the history of the genus, and might with advantage have been changed by L'Heritier to monogyna.

STUARTIA, in Gardening, a genus which contains a hardy deciduous plant of the North American flowering shrub kind, the species of which is the sturria, or malachodendron (S. malachodendron). It is an elegant shrub, which was introduced here into garden cultivation from Virginia, in the above country.

Method of Culture.—It is capable of being propagated and increased in different ways, as by seeds, layers, and sometimes by cuttings. In the seed method, after the seeds are procured fresh from their native situation, they should be fown, as soon as possible, either in a border of light earth, in an easterly exposure, and covered in to the depth of from about half an inch to an inch; or, where convenient, it would be better and more advantageous to sow them in pots, and to plunge them into a hot-bed of dung or bark, under glases, giving the seeds occasional waterings immediately after being fown, and the young plants when come up, and in their early growth; shading the whole moderately from the effects of the sun, all the while. It is also necessary to be careful in hardening them gradually, in proper time, to the open air, during the summer season; but in the succeeding winter, they should be denuded and kept under a garden-frame, or in a green-house, until the spring, when they should be forwarded as much as possible, by plunging them again into a bark-bed for a month or two, as until towards the approach of the next summer, then gradually again hardening them, and letting them be plunged into the earth of a shady border, until the autumn; at which time they should again be removed under shelter for all the ensuing winter; and in the next early spring they may be potted off separately into small pots, which, if plunged into a bark-bed too, will strike them more expeditiously than where that is not the case; proper waterings and suitable occasional shade being given them; not omitting to harden them as before, continuing to protect them by means of proper shelter for another winter; and in the spring after that, at a time when the weather is settled, they may be ventured to be wholly turned out of the pots, and set out with the balls of earth about their roots, in the full open ground, in not too sunny a situation.

When cultivated by layers, the young shoots should be chosen for the purpose, and be laid down in the early part of the autumn, for the moft part by slit-laying; and in the ensuing spring and summer, in dry times, frequent waterings should be given; and when screenèd by means of moderate shade, in the heat of the summer season, they will root better and more freely, which they sometimes completely effect in the course of one year; when, in the early ensuing spring, they may
may be taken off and potted off separately; when also, if then plunged into any moderately heated hot-bed for a few weeks, they will be forwarded considerably by it; removing them for the whole of the summer to some shady border, and to the shelter of a frame or green-house during the ensuing winter; and in the next spring, they may be set out with balls about their roots into the open ground, where they are to finally remain.

In the cutting method, the cuttings of the young shoots should be planted out in pots of good earth during the spring and summer seasons, and then plunged into a hot-bed, when fame of them will probably strike root, and become proper plants, which are in sufficient time to be transplanted into the open air; and they are afterwards to be managed in the same manner as the seedlings and the layers.

This is a hardy plant, except in the early seedling stage, when it is a little tender, and stands in need of shelter and protection from cold, frosty, winter seasons, as has been seen, until it becomes strong and hardy in the open air; when it will stand coarsely in the open shrubbery quarters without inconvenience.

It affords variety among shrubbery plants, and in collections of the green-house and conservatory kinds.

STUB, in Agriculture, a term signifying the root of a plant, with the top cut off. To stub signifies to grub up the stumps of trees, shrubs, shrubwood, &c.

Stubs, in the Manege, is used for a splinter of fresh-cut under-wood, that goes into a horse’s foot as he runs; and piercing the sole through to the quick, becomes more or less dangerous, according as it sinks more or less into the foot.

Stub-Wood, in Rural Economy, the name of such wood as grows in hedge-rows, and does not properly come under the names of timber, pollards, or thorns, or the young wood that is cut from stubs or fells. It is observed by Mr. Marshall, that the harvesting of this, as of timber, depends on situation, and other circumstances; and that the age or size of cutting must ever be guided by the demand in a given district, whether it be for cord-wood, hop-poles, hoops, flakes, faggot-wood, or other wares; and further, that the mode of disposal is to be determined upon by the succeeding crop. If the land be intended to be appropriated wholly to coppice-woods, it is generally the most eligible way to dispose of the crop as it falls, by one of the modes enumerated for felling timber. But if seedling plants are to be set out for timber stumps, or the young shoots from the stubs to be trained up in the grove manner, it is requisite that a proprietor should employ his own people in reaping the crop, and making it up into such wares as are most saleable and profitable in the particular situations. In regard to the cutting down coppice-woods, the main observances are, to cut them in season, to take off the limbs clean and smooth, with upward strokes of the axe, that the stubs may shoot with the greater certainty; and to cut them off as low as convenience will allow, in order that the shoots may be few and vigorous in their growth.

STUBBEKIOING, in Geography, a town of Denmark, in the island of Falster; 10 miles N.E. of Nyekiisting.

STUBBEN, a small isle on the east side of the gulf of Bothnia. N. lat. 63° 31’; E. long. 22° 51’.

STUBBING, in Agriculture, a term applied to the grubbing up any sort of stub or root, either in woods, hedges, or other places.

STUBBLE, the strawy matter of the cut stalks or stumps of grain, which are left in the field after reaping. The stubble should, in all cases, where it is in any quantity, be collected either for the purpose of thatch or litter. The proper time for cutting over the wheat and rye stubbles is September, when Mr. Young advises their being raked into heaps, for carting home to the farm-yard for litter. The stubble left on the land is not of much advantage as a manure; but carted into the farm-yard, it becomes an excellent manure.

In some parts of Essex, where the wheat stubbles are weedy, they are set fire to in a dry time, and burnt, which is said to be a great destruction to weeds. The bean stubbles, in some places in the same county, when foul, are hand-hoed; and in others they not only hand-hoe them well, but dew-rake and burn the weeds. Some workmen burn stubbles well with a nidget and harrows, by which the weeds are made to rise, and be destroyed by the feed-earth for the next crop. Shimming such stubbles well, too, is often practiced with great success.

Some other modes of managing stubbles, as that of paring them, and others, are likewise in use; but which are mentioned under their proper heads.

STUBBLE-Turnips, a term applied to those sorts of turnip crops, which are grown after the stubbles have been turned down.

The stubbles which have been ploughed after finishing the harvest, and then sown with turnips, come properly round for late spring feed for sheep.

In the Corrected Agricultural Report of the County of Suffolk, it is stated, that about the village of Petworth it is a common practice either to sow stubble-turnips, or rye and tares in mixture, upon the wheat, barley, or oat earth. This admirable practice of throwing in one crop upon the back of another, is thought too good a feature in the management of the district to be passed over without particular notice.

On good dry friable lands, stubble-turnip crops are mostly valuable, and of great utility in the above and other views. See TURNIP.

STUBBLE Break-Plough, a term applied to that sort of ploughing, or paring tool of the spade kind, which is used in some districts in taking off the stubbly surface of lands, in the state of tillage.

STUBBLE Break-Ploughing, a name applied to the unusual and extraordinary practice of paring or having off the surface of lands, in the state of stubble, in some cafes and districts, as Oxfordshire, for the purpose of cleaning them from couch and other weeds, as well as perhaps for some others. The operation is done in a tardy land that is intended for burning; but the depth cut by the workmen is not more than an inch or two at most, which is a singular circumstance, if it have the effect of completely cleaning the ground, which is asserted, and which may be supposed to be the cause; as the farmers would hardly be at such an expense, if the effect did not fully answer their expectations.

The practice might probably be had recourse to in several other districts with great benefit, and be performed in a more ready and cheap manner, by using a harel-plough properly contrived and contructed for the purpose.

STUBBLE-Rakes, the name of a light implement of this kind, contrived with long teeth, sometimes made of iron, used for the purpose of raking up the stubble by the hand.

See Rake.

STUBBLE-ROST, the name of a rake for collecting the stubble together with, which is constructed with wheels, shafts, and a head fet with strong iron teeth, for being employed by means of a horse. It is a very useful and expedient tool for this purpose. See Rake.
STUBBS, George, in Biography, an eminent painter of animals, was born at Liverpool in 1724. He particularly excelled in the knowledge of the anatomy of animals, for which he took great pains in dissection, as well as design. It is unfortunate that the exercise of his talents was confined to portrait animal painting, and particularly of race-horses, as he was capable of much higher productions: witness his picture of Phaeton with the horses of the sun, and those of the horse and lion. His knowledge of the nature and actions of various animals inspired his pictures with peculiar interest. Sometimes his colouring was very good, though never excellent; and he was defective in the execution of backgrounds. His long life was most laboriously and usefully employed. In 1786 he published his Anatomy of the Horse, the most perfect work upon the subject, which he drew, and etched himself, from a natural figure which he dissected for the purpose. He died in 1806, at the age of 82. He was an associate of the Royal Academy.

STUBEN, or STUBNA, in Geography, a town of Hungary, which has some warm baths; and in its vicinity, mines of copper and silver; 6 miles N. of Cremonnitz. Stube, a town of the county of Pluden: 12 miles E. of Pluden.

STUBENBERG, a town of the duchy of Stiria; 9 miles W. of Hardeberg.

STUBENDORF, a town of Silesia, in the principality of Neisse; 3 miles W.S.W. of Ottmachau.

STUBGEN, in Commerce, a liquid measure in many parts of Germany. At Bremen, 45 flugens answer to 38 English gallons. A tonne of beer contains 48 flugens, or 192 quarters. At Hamburg, the ahm is = 40 flugens; and as the ahm contains 10,640 Hamburg cubic inches, or 7300 French ditto, or 883 English ditto, which are 38½ English gallons, 24 flugens are = 23 English gallons. An oxholt (= 574 English gallons) of Bourdeaux or claret wine is reckoned at from 52 to 64 flugens; and a pipe of Spanish wine at from 56 to 100 flugens. A tonne of beer contains 48 flugens, and a small ditto 32 flugens. A quartel of train-oil contains 2 tonnes, or 64 flugens, and is reckoned at 2 centners, or 224 lbs., net weight. See Table XXXII. under Measures.

STUG, in Geography, a town of Bavaria, in the bispohric of Bamberg; 10 miles N.E. of Bamberg.

STUBLANG, a town of Bavaria, in the bispohric of Bamberg; 13 miles N.N.E. of Bamberg.

STUC, or STUCO, in Buildings, a composition of white marble powdered, and mixed with plaster or lime; the whole sifted and wrought up with water; to be used like common plaster.

This is what Pliy means by marmoratum opus, and albarium opus. See Mosaic, &c.

Of this are made statues, busts, baso relieves, and other ornaments of architecture. See Statues.

A flucco for walls, &c. may be formed of the grout or putty, made of good flone-lime, or the lime of cockle-shells, which is better, properly tempered and sufficiently beat, mixed with sharp grit-lane, in a proportion which depends on the strength of the lime: drift-lane is best for this purpose, and it will derive advantage from being dried on an iron plate or kiln, so as not to burn; for thus the mortar would be discoloured. When this is properly compounded, it should be put up in small parcels against walls, or otherwise, to mellow, as the workmen term it; reduced again to a soft putty, or paste, and spread thin on the walls without any undercoat, and well treiwelled. A succeeding coat should be laid on, before the first is quite dry, which will prevent joints of brick-work appearing through it. Much depends upon the workmen giving it sufficient labour, and trewelling it down. If this flucco, when dry, is laid over with boiling linseed oil, it will last a long time, and not be liable, when once hardened, to the accidents to which common flucco is liable.

Liardet's, or, as it is commonly called, Adam's oil-cement, or flucco, is prepared in the following manner: For the first coat, take twenty-one pounds of fine whiting, or oyster-shells, or any other sea-shells calcined, or plaster of Paris, or any calcareous material calcined and pounded, or any aborbent material whatever, proper for the purpose; add white or red lead at pleasure, deducting from the other absorbent materials in proportion to the white or red lead added; to which put four quarts, beer-measure, of oil; and mix them together with a grinding-mill, or any levigating machine: and afterwards mix and beat up the same well with twenty-eight quarts, beer-measure, of any sand or gravel, or of both, mixed and sifted, or of marble or flone pounded, or of brick-dust, or of any kind of metallic or mineral powders, or of any solid material whatever, fit for the purpose.

For the second coat, take sixteen pounds and a half of superfine whiting, or oyster-shells, or any sea-shells calcined, &c. as for the first coat; add sixteen pounds and a half of white or red lead, to which put six quarts and a half of oil, wine-measure, and mix them together as before: afterwards mix and beat up the same well with thirty quarts, wine-measure, of fine sand or gravel sifted, or flone or marble pounded, or pyrites, or any kind of metallic or mineral powder, &c. This composition requires a greater proportion of sand, gravel, or other solides, according to the nature of the work, or the use to which it is to be applied. If it be required to have the composition coloured, add to the above ingredients such a proportion of painter's colours, as will be necessary to give the tint or colour required.

In making the composition, the best lime or hennep, or other oils proper for the purpose, are to be used, boiled or raw, with drying ingredients, as the nature of the work, the season, or the climate requires; and if some cals, beeswax may be subtiliutit in place of oil; all the absorbent and solid materials must be kilned. But the composition is to be of any other colour than white, the lead may be omitted, by taking the full proportion of the other absorbents; and also white or red lead may be subtiliutit alone, instead of any other absorbent material.

The first coat of this composition is to be laid on with a trowel, and floated to an even surface with a rule or darby, (i. e. a handle-flat,) The second coat, after it is laid on with a trowel, when the other is nearly dry, should be worked down and smoothed with floats edged with horn, or any hard smooth substance that does not flain. It may be proper, previously to laying on the composition, to moisten the surface on which it is to be laid by a brush with the same sort of oil and ingredients which pass through the levigating machine, reduced to a more liquid state, in order to make the composition adhere the better. This composition admits of being modelled or cast in moulds, in the same manner as plasterers or statuaries model or cast their flucco work. It also admits of being painted upon, and adorned with landscape, or ornamental, or figure-painting, as well as plain painting. The composition of this flucco, Mr. Liardet obtained a patent in 1773 for fourteen years, the term of which was extended to eighteen years, in consequence of an act of parliament in 1776. For compositions very similar to the preceding, patents were granted.
to Dr. Werk in 1765, Mr. Emerton in 1771, and to Mr. Rawlinson in 1772.

Dr. Shaw informs us in his Travels (p. 296.), that the cement or mortar used in Barbary, which is apparently of the same consistence and composition with those of the ancients, is made in the following manner: They take two parts of wood-ashes, three of lime, and one of fine sand, which, after being well sifted and mixed together, they beat for three days and nights incessantly with wooden mallets, sprinkling them alternately and at proper times with a little oil and water, till they become of a due consistence. This composition, he adds, is chiefly used in their arches, cisterns, and terraces; but the pipes of their aqueducts are joined, by beating tow and lime together with oil only, without any mixture of water. Both these compositions quickly affume the hardnProv. and suffer no water to pervade them: and will, therefore, answer the purpose of flucco.

For other compositions of a like kind, see Mortar, Mortgage for Sun-dials, &c. and Plastering. See also EconoMancy.

STUCIA, in Ancient Geography, a river of Britain, which Mr. Horsey thinks was the mouth of the river Dovi; but both Baxter and Camden imagine it to be Aberlith, or the mouth of the river Ytwh in Cardiganshire.

STICK, in Sail-making, a term used for being fitted.

STUCKAW, or ZUKAW, in Geography, a town of Prussia, in Pomerelia; 16 miles S.S.W. of Danzig.

STUCKUS, John-William, in Biography, a learned divine and philologist, was born in 1542 at the convent of Toessen, in the canton of Zurich; and after a very liberal education, and temporary employment as domestic tutor in a noble family in France, he succeeded, in 1568, to the office of rector in the public school at Zurich; and in 1577 was appointed professor of theology in that city. He died in 1607, having obtained distinguished reputation by various learned works, particularly by his "Scholia on Arrian's Periplus of the Euxine and Erythraean Seas," and "Antiquitatum Convivialium, Lib. IV. in quibus Hebrorum, Crucorum, Romanorum, et aliarum Nationum antiqua Convivorum generae et mores explicantur," fol. Tigur. 1591. Moreri.

STUD, in Rural Economy, the name of the place where fallions and mares are kept to propacage, &c. It further signifies the fallions and breeding mares themselves; also the hormones kept in a stable. See Breeding of Horses, and Mare. See also Stallion.

STUDDING-SAILS, in a Ship, are certain light sails extended in moderate and steady breezes, beyond the skirts of the principal falls, where they appear as wings on the yard-arms: hence some have called them goose-wings. The origin of the name has been variously assigned: some have derived studding from feudal, because the small sails used in cufudding are nearly of the same size and figure with the lower fludding-fails; others have fought its etymology in steddy, because these sails fail the effort of a breeze, and serve to push the ship forward, and to give her head-way; so that, they becomes capable of the power of the helm, and is retained in a steady course: whence studding-fails, afterwards corrupted into studding-fails. Others again derive studding from the Saxen feud, to affish, whence these fails which help the ship's course are called studding, studding, or studding-fails.

The top-mast fludding-fails, or those which are set on the outlde of the top-fails, are spread below by a boom, which fludding out from the extremities of the main and fore-yards, pushes out their lower corners; and their upper edges, which are attached to a light pole, are hoisted up to the top-fail-yard-arms. The lower fludding-fails, which are spread beyond the skirts or leech of the main-fail and fore-fail, are fixed nearly in the same manner; only that the boom, which extends their bottoms, is generally hooked to the chains by means of a gooseneck, or else twines off along with the fail to which it is suspended; being kept steddy behind by a rope called the guy. Falconer.

In the navy lately, an additional fore-top-gallant fludding-fail is to be allowed; and an addition of seven cloths is to be made to one of the fore-fludding-fails, and of two cloths to one of the fore-top-mast fludding-fails: a sail is to be ifued with the latter, to be laced at the bottom, so that it may be hauled out in light winds; and eye-let holes are to be made in the foot of the fail one-third from the tack.

STUDDING-Sail Booms. (See Booms.) In the navy lately, the heels of studding-fail booms are to be reduced from the inner boom-iron, in manner of a top-fail-yard; and a bolt is to be placed at the inner end also.

STUDDING-Sail-Yards. See Yards.

STUDEIN, in Geography, a town of Moravia, in the circle of Iglau; 22 miles N.W. of Iglau.

STUDENullZ, a village and convent of noble Domi- cilians of Germany, in the duchy of Stiiria; 8 miles S.E. of Windisch Grats.

STUDELAND BAY, a bay of the English Channel, a little S. of Poole harbour; deriving its name from a village called "Studland." 6 miles S. of Poole. N. lat. 50° 37' W. long. 1° 28'.

STUFEN, a town of Switzerland, in the canton of Zurich; 9 miles S.E. of Zurich.

STUFF, in Commerce, a general name for all kinds of fabrics of gold, silver, silk, wool, hair, cotton, or thread, manufactured on the loom; of which number are velvets, brocades, mohair, lattins, taffetins, cloths, ferges, &c.

STUFF is particularly used for certain kinds of ftofollen stuffs, used principally for linings, and women's wear, as linseys, ratteens, &c.

STUFF, Bleaching of. See BLEACHING.

STUFF, Cross-grained. See CROSS-GRAINED.

STUFF, Fulling of. See FULLING.

STUFF, in Naval Language, any composition, or melted mass, used to smear or daub the masts, sides, or bottom of a ship. That which is chiefly used for the lower masts is impenetrably, rosin, or varnish of pine: for the top masts, tallow or butter, for the sides, turpentine, varnish of pine, tar, and oil, or tar mixed with oil and red-ochre; and for the bottom, a mixture of tallow, sulphur, and rosin or tar, whase-oil and broken glass, or any part of these ingredients: and this operation is called giving a new coat of stuff to the masts, sides, &c. Falconer. See PAY and SHIP.

STUFF, in Canal, is used for the earth or foil in which they are dug.

STUFFING. See CONSTRUCTION.

STUFFING Drains, in Agriculture, a term applied in some places to the practice of filling them with wood, straw, or other materials, as is the custom in some conduits of surface-draining. See SURFACE-Drain.

STUGEN, in Geography, a town of Sweden, in the province of Jamtland; 25 miles E. of Oterfund.

STUHLINGEN, the capital of a landgrave in Ger- many, belonging to the Furtenberg family; 22 miles N. of Zurich. N. lat. 47° 48'. E. long. 8° 26'.

STUHL-WEISSENBURG, or SERKEZ FEKVERVAR, a royal free town of Hungary, and see of a bishop, situated on mardy
STU

marily ground, occasioned by the river Sarwitz. From this
town run three very large caufeways or moles, among which
are churches, houfes, gardens, and meadows, fo that the in-
habitants of these suburbs are more numerous than thofe of
the town. This was formerly the place where the kings
were crowned, and generally interred; but at prefent its
bief houfes are in ruins, and the town is very much decayed.

The number of inhabitants is estimated at 11,000; 84 miles S.E.
of Vienna. N. lat. 47° 19'. E. long. 17° 50'.

STUHR, a river of Germany, which runs into the
Ochtte, 4 miles N. of Delmenhorft.

STUKELEY, William, in Biography, a physician of
eminenec, and a dilingently antiquified, defended from an
ancient family in Lincolnshire, was born at Holbeach, in that
county, in the year 1687. He received his early education at
the free-school of his native town, and was entered at Benet
college, Cambridge, in 1703; and while an under-graduate,
excited a ftrong propensity to drawing, and to the study of
antiquities. Being intended for the medical profeflion, how-
ever, his principal attention was directed to botany, and the
other collateral fubjefts, which he could pursue at the uni-
versity, until he took the degree of M.B. in 1709. He then
went to London, where he studied anatomy, and acquired a
knowledge of the practice of medicine under Dr. Mead, at
St. Thomas's hospital. He first fettled as a physician at
Bolton, in his native county; but in 1717, he removed to
London. On the recommendation of Dr. Mead, he was
elected a fellow of the Royal Society; and he was one of
the revivers of the Society of Antiquaries in 1718, to which
he acted as secretary for several years. He took the degree
of M.D. at Cambridge in 1710, and in the following year
was admitted a fellow of the College of Physicians in Lon-
don. At this time he published his firft antiquarian effay,
containing a description of "Arthur's Own," and "Gra-
ham's Dyke," in Scotland, with plates. In the year 1722,
being appointed by the College of Physicians to read the
Gulenian lectures, he chose the structure and history of
the Spleen for his fubjeft; and in the following year he pub-
lISHED the substance of his lefions, in one volume, folio,
with plates, under the title of "The Spleen, its Descrip-
tion, Uses, and Diffefes," to which he also subjoined,
"Some Anatomical Observations, made in the Diffefion
of an Elephant." In this work, however, he had not the
credit of much originality; for Haller affirms, that the
plates were copied, without acknowledgment, from Veifius,
and contained several errors. The conceiving of that there
were fome remains of the Elephidian mysteries among the secre-
ts of free-maflory, he became a member of that fraternity,
and was constituted master of a lodge. To this society he
preferred an account of a Roman amphitheatre at Dor-
chester. His propensity to the invefigation of antiquities,
indeed, continued to influence his pursuits; and being
greatly afflicted with the gout, which generally attacked
him during the winter months, he was accustomed to take
various ftrajjes in the spring for the recovery of his health,
which afforded him many opportunities of gratifying his
curiosity. He generally therefore directed his excursions
to thofe places, where the indications of the progress of
Cesar's expedition in this ifland may be traced; and the
collections which he made during these travels, were pub-
lISHED in 1724, in folio, with numerous plates, under the
title of "Itinerarium Curifofum," and a second volume,
containing his description of the Brij, or Cesar's camp at
Piacenas, in 1725.

In the following year, 1726, Dr. Stukeley quitted
London, and settled at Grantham, where he speedily ac-
quired an extensive reputation, and was confulted by the
nobility and principal families in that neighbouring country.
In 1728 he married a lady of good family and fortune.
The fatigues of the profession, however, and the repeated
attacks of gout, which flill harassed him, became at length
too great for his strength, and he determined to enter the
church. He was ordained at Croydon, in 1729, by arch-
bishop Wake; and in the same year was presented, by lord
Delmofor King, to the perpetual benefice of All Saints he Stamford.

About the time of his entering on his parochial currie, in
1730, Dr. Rogers of that place had just invented his orum
arbitrium, which Dr. Stukeley was induced to try, and
having experienced great relief from its use, both in his
own perfon and in others, he was induced to publish an
account of its effects, in a letter to Sir Hans Sloane, in
1753; and in the year following, he printed "A Treatise
on the Caufe and Cure of Gout, from a new Rationale.

Besides fome tracts of minor importance relative to anti-
quities, he published, in 1756, the fifth number of his "Pa-
iegraphia Sacra," or Difcourfes on the Monuments of
Antiquity that relate to Sacred History." In this work,
which he intended to continue, he maintains that the heathen
mythology is derived from facred history, and that the
Bacchus of the poets, for example, is the Jehovah of scrip-
ture, the conductor of the Israelites through the wilderness.

During his residence at Stamford, he arranged his collection
of Greek and Roman coins according to the order of the
inscription history; and from this time his publications were
very numerous.

In 1737 he left his wife, and afterwards married the only
daughter of the learned antiquary, Dr. Gale, dean of York,
and father of his intimate friends Roger and Samuel Gale,
from which period he often spent his winters in London.
In 1740, he published an account of Stonehenge, which
he regarded as a druidical monument. This was followed
by his account of the remains at Abury, in the fame county;
and in these works he incorporated a great part of a
"History of the ancient Celts, particularly the firit habi-
tants of Great Britain," which he had announced as a
separate work. In this "History of Caraffus," in two
volumes 4to, published in 1757 and 1759, he has displayed
much erudition and ingenuity in settling the principal events
of that emperor's government in Britain. He published,
besides, many interesting and valuable tracts, especially
three numbers of "Palieographia Britannica," some papers
refpecling earthquakes, &c. &c. but the left labours of his
life were dedicated to the completion of an elaborate work
on ancient Britifh coins, particularly thofe of Consobrinus,
in which he felicitated himself on having discovered many
new and curious anecdotes relative to the reigns of the
British kings.

Dr. Stukeley was one of the founders of the Egyptian
Society in the year 1741, in which he became acquainted
with the benevolent duke of Montague, who prevailed upon
him, in 1747, to vacate his preferments in the country, and
accept the rectory of St. George's, Queen-square. He
therefore moved his residence again to London, and had a
retirement at Kentish Town. In February 1765, he was feized
with a froke of the palfy, which terminated his valuable
life in the March following, in the 78th year of his age. He
was interred in the church-yard of Erft Ham, in Eilfe, in a
spot which he had chosen when on a visit to the vicar a short
time previous to his death. All his works evidence a pro-
found knowledge of ancient history, tinctured indeed with
that propensity common to his fraternity, of magnifying the
importance of his fubjefts by the allusions of a lively
fancy, and fome credulity. His great proficiency in every
thing connected with druidical history, caused his familiar
friends
friends to designate him as "the Arch-Druick of the age," as an appellation with which he seems to have been flattered; since he concluded a little inscription, which he placed over the door of his retreat at Kentish Town, with words of similar import.

"Me dulcis facture quies,
Obcuro politus loco ;
Leni perfurrar otio
Chyndoaax Druida."

STULP, in Rural Economy, a provincial word, signifying a pot of any kind.

STUM, in Geography, a town of Prussia, in the territory of Marienburg; 6 miles S. of Marienburg. N. lat. 53° 53'. E. long. 18° 52'.

STUM, in the Wine Trade, a term for the unfermented juice of the grape, when it has been several times racked off, and separated from its sediment. The casks are for this purpose well matched, or fumigated with brimstone, every time, to prevent the liquor from fermenting, as it would otherwise readily do, and become wine.

It is this fume of the sulphur from the match that prevents, in this case, all tendency to fermentation, and continues the natural juice of the grape in a sweet state, fit to be readily mixed with wines instead of sugar; for which purpose it is very much used in Holland, and some other countries, as also for giving a new freck, or briskness, to decayed wines. So that very large quantities of this fumus are annually imported to all parts along with the foreign wines; and after the same manner a fumus is prepared in England from the juice of apples which serves the ordinary purposes of the wine-cooper. In preparing this liquor in this state, we see the real use of brimstone, for it could never be done otherwise than by the matching of the casks. Shaw's Lectures, p. 192. See Matching.

STUM, Artificial, an artificial must, or fumus, as good as the natural; and as fit for the re-fermenting, fretting, improving, or making of wines, vintages, and spirits, may be prepared in the following manner:

Take three pounds of fine lump fugar, or such as has been well refined from its treacle; melt it in three quarts of water, and add in the boiling, of Rhenish tartar, finely powdered, half an ounce : this dissolves with a remarkable ebullition, and gives a grateful, acidulity to the liquor: take the vesel from the fire, and suffer it to cool, and you have an artificial must, which in all respects resembles the natural must and sweet juice of a white flavourless grape, when well purified, and racked off from its sediment, in order to make fumus. If this artificial must be flummed, that is, well fumigated with burning brimstone, it becomes a perfect fumus, and may be made of any flavour, at the discretion of the artit. Shaw's Lectures, p. 203. See Must.

STUMBLING, in the Manse, &c. a vice in a horse, either natural or accidental.

The natural arises from the sinews of the fore-legs being somewhat too straight, which cramps the horse, and prevents his using his legs with the necessary freedom and nimbleness. The way to cure him is, to cut him of the cords, i.e. to make a slit on the top of his nose, and with a cornet to raise up the great sinews, to cut them afender, and heal them up again with a proper salve.

The accidental arises from a splint, wind-gall, being foun-
dered, pricked, flubbed, gravelled, &c.

To horse a horse which flumbles is a nice point, as he must be food quite contrary to those which tread only upon the toes of their hind-feet; for his toe must be taken down very much, and also shortened, that he may not meet so easily with impediments and fences upon the roads. This is, however, far from affording any certain relief.

STUMDORF, in Geography, a town of Prussia, in the territory of Marienburg; 6 miles S. of Marienburg.

STUMMING, in Rural Economy, a provincial term, signifying the fuming a cask of cider or other liquor with burning sulphur, which is thus performed. According to Mr. Banker, take a slip of canvas cloth, about twelve inches long and two broad, let it be dipped into melted brimstone; when this match is dry, let it be lighted and suspended from the bung of a cask, in which there are a few gallons of liquor, until it be burnt out: the cask must remain stopped for an hour or more, and then rolled to and fro, to incorporate the fumes of the match with the liquor, after which it may be filled. When stumming is designed only to supress some slight, improper fermentation, the brimstone match is quite sufficient. See CIDRE.

STUMP, a name given to the root part of any solid body, particularly of trees, &c. remaining after the rest are taken away. Where the roots are very large, and obstinately tenacious, it has been advised to blow them up with gunpowder. See BLASTING.

STUMPS. Apple-tree, &c. Grafting upon, in Field Fruit-grounds, the practice of inferring the shoot-iccons of old trees into the stumps of the branches of them which have been properly cut away and prepared for the purpose. When from age, or other causes and circumstances, the heads of these sorts of trees begin to fail and die at the extremities, they are, in some districts of this kind, cut off near the bottom parts of the principal branches or arms, in the stumps of which such ficons are placed by means of crown-grafting. It is remarked, in the Corrected Agricultural Report of the County of Gloucester, that it is not un-
usual to see a fingle stump of fuch trees there bearing eight or ten grafts, and in the whole of a tree from fifty to a hundred. Good new heads are, it is said, formed by this method, where the grafts are not made use of in too great an abundance; and that they come into bearing much sooner than young trees. A flock, from the time of its being grafted, will not probably bear a bushel of apples in twenty years; whereas an old tree, grafted in this way, and properly managed, will bear three times the quantity in half the time; in point of durability, however, it is inferior; and therefore the practice is mostly confined to finge detached trees, and not extended to whole apple fruit-grounds. See Grafting.

STUMP or Stock, Sotching, a term used to signify the fand over which flax and other such materials are broken, beat, and wingleed, in order to render them soft and free from the stem parts in dressing them. It consists of a solid block part at the bottom, with a stem about five feet in height, and a part with a tapering edge upwards at top, over which the substance is held with one hand, while it is stricken or beaten by a properly formed piece of wood held in the other. See Swingle.

STUMPY INLET, in Geography, a channel between two small islands on the coast of North Carolina. N. lat. 34° 24'. W. long. 77° 43'.

STUMSTOWN, a small town of America, in Dauphin county, Pennsylvania, on a branch of Little Swatara, containing a German Lutheran and Calvinist church united, and about 20 houses; 24 miles E.N.E. of Harrisburg.

STUNG, Adder-stung. See ADDER-STUNG.

STUNTED, in Rural Economy, a term signifying fet in the growth; as by bad keep, &c. in animals.

STUPA.
STU

STUPA. See STUPHA.

STUPERFIES, in Medicine, the same as narcotics and opiates.

STUPHA, STUPA, Stupa, sometimes denotes a fomentation.

STUPIA, a name given by some of the writers in chemistry to tin.

STUPKA, in Geography, a town of the duchy of Warsaw, in the palatinate of Lishin.

Stups are numbskulls, occasioned by an accidental bandage that stops the motion of the blood and nervous fluids, or by a decay in the nerves, as in palsy, &c.

STURA, in Ancient Geography, a river of Italy, in Ligonia, which runs perpendicularly into the Orgus, and discharges itself into the Padus towards the N.W., very near Augusta Taurinorum. —Alfo, the name of one of the arms of the Indus.

STURA, in Geography, a sea-port town on the S.W. coast of the island of Negropont. N. lat. 38° 41' E. long. 24° 15'. —Alfo, a river of France, which rises in Mont Cenis, and runs into the Po at Turin.

STURBRIDGE, a township of America, in the S.W. corner of Worcester county, Massachusetts, containing 28,520 acres, bounded by Woodstock and Union on the S. and on the N. by Brookfield; incorporated in 1738, and including 1927 inhabitants. It is famous for its butter and cheese; 22 miles S.W. of Worcester.

STURBRIDGE. See STOURBRIDGE.

STOURBRIDGE, or STOURBRIDGE, the name of a large field or meadow near Cambridge, on the banks of the river Stour, in the parish of Barnwell, celebrated for a fair which is annually held there on the 18th of September, and thirteen following days, under the authority of the university of Cambridge. (See CAMBRIDGE.) Blomfield, in his Colleg. Cantab., remarks, that the name does not arise from a bridge built over the Stour at this place, but from a toll paid at it, for fleers and young cattle. The fair is well attended by trademen from various parts of England; and the different occupations are separately classified in regular streets, or rows of booths, designated by their respective names; as Cook's-row, Bookfeller's-row, &c.; and one division, entitled the Duddery, is allotted to woolen-drapers, mercers, and whole-sale dealers in clothes. Almost every article of wearing apparel and merchandise is here exhibited for sale, and in the evenings the fair is much resorted to by the lower classes, for the purposes of amusement. A court for the prompt administration of justice is always held during the fair, in which the mayor of Cambridge, or his deputy, presides, attended by eight constables, or red-coats, to preserve decorum. The proclamation for this fair is conducted, with great solemnity, by the vice-chancellor, doctors, and proctors, of the university of Cambridge, and the mayor and aldermen of the town, dreased in their official habits. At a short distance S.E. of Stourbridge stands an ancient stone chapel, which now serves as a repository for the relics of the fair.—Beauties of England and Wales, vol. xi. by J. Britton and E. W. Brayley.

STURDY, a disease in sheep, which is of much importance, equally on account of its frequent occurrence, and because it constantly terminates fatally, unless relieved by art.

There are two varieties of it, as stated by Dr. Duncan, junior, in his useful paper on it, in the third volume of the Transactions of the Highland Society of Scotland; the appearances in each of which are as follow. When a sheep is attacked with the first of these varieties of the fury disease, it ceases, it is said, to improve, becomes dull, is apt to loiter behind, and separates from the flock. It does not walk straight forward, but often deflects on one side, or dozes round in a circle. The eyes glare feebly in its head, and seem enlarged, from the pupil being round instead of oval, which in healthy sheep is always the case in the day-time. Its vition is impaired, and it does not see any object which approaches it, until it be very near, when it flirts away, and runs furiously, without any aim. When caught, it is remarkably stupid on being again liberated. In dry weather, it follows eagerly to that quarter from which the wind blows. It has a great reluctance at passing water, as burns or brooks, and cannot easily get through them, but mostly frequents places where it can hear the sound of water. Some time after these appearances have prevailed themselves, in the course of perhaps about three weeks, there appears and is found, on examining the head, by preying on it with the thumbs, a remarkable degree of loftiness at one part of it, where the skull seems to be wanting. But in a few inflexions, no loftiness is to be discovered in any period of the disease, but in either case, if not relieved by a proper operation, the animal loses the power of standing, and dies perfectly emaciated. The continuance of this sort or variety of the disease extends or lasts from two months to a year, as the circumstances of the particular case may be.

The second or latter of these varieties is, however, much more rapid in its progress, in which, in addition to some of the above appearances, a great degree of stupor comes on in a few days, which is followed by total blindness, and no loftiness is ever to be found in any part of the skull or bones of the head.

The appearances on opening the head in the first of the above varieties, are an oval or round bag, which is found lying between the brain and the skull, quite unconnected with any of the surrounding parts, generally situated between or beneath the horns. These bags vary much in size, being sometimes no larger than a plum, while at others they are as big as a goose's egg. They are filled with a clear fluid, like water, sometimes intermixed with a thin crust, when it is of a glutinous or slimy nature. Within, or in the skins of these bags, are seen, according to fome, many little white bodies, nits, or the ova of insects. These are thus described by Mr. W. Hog, which, though in some measure hypothetical, display an accuracy of observation. He is induced to believe, from two or three recent cases and observations, that the dissolution of the brain, &c. is occasioned by numbers of animalcula, which have been noticed to be swimming loosely in the liquor. They resemble ants' eggs, both in shape and colour, but are somewhat shorter. However, as all the animals upon which he made the observation had been dead for some time, so these pus inhabited hair of the brain were also dead; but if they had been living and organized animals, which he has no doubt they were, there would be multitudes of so diminutive a size, as to be quite imperceptible to the naked eye; and he is fully convinced, that if the disease was minutely observed in all its stages by microscopical examination, whatever its beginning was, its progress would be, by the activity of these animalcula, increasing both in number and size.

However, in proportion as the disease advances, the bag increases in size, and by its protrusion causes the brain to decrease, while the skull immediately over the bag becomes soft and disappears, so that nothing intervenes between it and the integuments of the head. Sometimes, but only in those cases where no attempt has been made to cure or remove it, there are many small bags, unconnected with each other, distributed through the brain or cerebral parts.

In the form or variety of the disease, the water is not con-
contained in a bag, but within the substance of the brain, in certain cavities termed its ventricles, and sometimes in the hinder parts, where it joins with the spinal marrow, in which case it is thought to be quite incurable.

Hard substances or excrescences growing out from the inside of the skull, and blows upon the head, occasionally produce all the appearances of real sturdy; but in these cases, no water is to be found in the parts.

The cause of the appearances in this disease is therefore, unquestionably, prelude on the brain, whether it arise from accidental contusion, from a bone excrescence, as in falfe sturdy, or from a collection of water, as in the legitimate varieties of it, as seen above. What, however, gives rise to these collections of water, is not by any means so well ascertained. Inflammation of the brain probably precedes its effusion in the latter variety of the disease; but the generation of the hydatids, or water-bags in the former fort or variety, is not at all understood. The disease is not contagious; neither is it peculiar to any foil. It generally affects sheep of the hog kind in the beginning months of the spring and summer, and is commonly ascribed to copulation, to tempestuous weather, without sufficient shelter.

In regard to the cure of the disease, as the natural termination of it is invariably fatal, unless those rare recoveries which are sometimes the consequence of accidental blows on the head, that probably rupture the bags, be excepted; and more especially as the mutton in this disease is good, the sooner an attempt is made to relieve the animal by the proper operation, the better; for want of which relief, although it is extremely fitful, and not unfrequently successful, thousands of sheep are suffered to perish through carelessness or ignorance. The Cure in these cases may be attempted in three different ways; as by tapping, trepanning, and wiring. Where the bag is seated any where in the crown of the head, some suppose that the most ready and the gentlest method is to tap it in the place where the skull is soft, and to let the water run out. This is most commonly performed by means of an awl, or large corking pin, though an instrument with a small tube in it, termed a trocar in surgery, might be easily contrived and formed, which would drain it off in a more complete manner. By this operation, if the instrument be not pushed too far, the animal is nothing the worse, it is said, whether it recover or not. But what is very remarkable, this plan is not, it is said, successful on all farms alike, of which many instances are known. An old shepherd has often been heard to remark, that in the course of thirty years' experience, not one sheep out of twenty which he had tapped on his own farm had died, while it was very rare that he could cure any one of the neighbouring ones. He constantly performs it with a corking pin. Others affect, that in their neighbourhoods, more sheep have been cured by this operation than by any other, in performing which, the sheep is advised to be laid on its back, and the pin to be inserted in an oblique manner; if water follow, the cure is said to be certain; but even though it should not follow, provided the bag be pricked into, it is often successful in removing the disease.

In the mode of cure by means of trepanning and extracting the bag or cyst, the description of which is accurately given below, there are several circumstances to be carefully attended to.

The animal being properly secured, and the head placed in the most convenient position, the part to be cut being uppermost, the skin is to be divided by an incision an inch and a half in length, crossed by another of the same length at right angles to it. The skull, which is quite soft, is then to be cautiously divided in the same manner, until the bag with the fluid in it appear clear at the bottom of the incision, which it commonly does. The soft skull is now to be turned back, or a bit cut out of it, so as to render the bag completely evident. It should then be taken hold of by a pair of blunt forceps, and be gently moved backwards and forwards, to loosen it from its connections, which are generally very slender. This may also be done by means of a crow's-quill, or any blunt-pointed instrument, carried frequently round it. The nose of the animal is now to be held, so as to restrain its breath, which may force the bag from its situation. The operator is to continue moving and pulling it, flopping the breathing of the sheep at intervals, until it is quite extracted. The skin after this is to be laid neatly down again, and a cloth spread with tar placed and tied over the wound above the dry lint, which is folded and laid on it, to prevent either cold in the spring, or flies in the summer from injuring it. This is to be allowed to remain for two days, when the dressings may be changed, and a bit of cloth spread with hog's-lard, fresh butter, tar, or some other ointment, applied on the wound. The dressings should be changed every second day, for ten days or a fortnight, after which time, in ordinary cases, it will require no more attention, being generally healed up. The skull grows over it in about a month, and then becomes of its usual hardness; and the animal is equally healthy, as if no disease had previously existed.

It is said that the fenes return after the operation in a few hours, and that the next day the sheep seems to be quite relieved.

When, in consequence of rashness or inattention, the bag containing the fluid has been ruptured, which sometimes happens, it is very difficult, and in many cases impossible, to extract the sac. The best practice, in this situation of things, is, it is said, to place the animal in such a position, as that all the fluid may run out and be, discharged; washing the wound with spirits, and trying to extract, if possible, the remains of the sac, then drenching it with a mixture of tar and balsam, or either separately, then turn the animal, which has now lost its stupid appearance, into a good pasture. The damps and cold of nights should be avoided, as they tend to produce inflammation, which very soon destroys the animal. In this case, the admission of the external air, and the irritating dressings, cause the sides of the sac to adhere; this, however, is not always the case, it is said; as after a week or two, the appearances of the disease have been known to return, after the alleviation which the operation constantly produced. When this happens, it is almost impossible to extract the bladder or bag entire, on account of the inflammation, from the cutting causing strong adhesion. In this case the bag may be opened, and a little spirits or port wine injected by means of a syringe, which has been known, in more than one case, to prevent a return of the symptoms. This operation should not, where possible, be performed in hot or very warm weather, as maggots are extremely apt to breed in the wound. In frost, too, inflammation is liable to be produced, which may also at that time render it improper. In these cases, the sheep should be fattened for the butcher as soon as possible.

In respect to the operation of wiring, it is described in this manner by Mr. J. Hog. In case the skull should feel soft in the forehead, then the operation must be performed by thrashing a stiff sharpened wire up each nostril, until it flops against the upper part of the skull. If this mode of cure were not well authenticated by daily experience and observation, it might, it is said, appear a very severe and dangerous operation or practice, as the wire goes quite through...
through the brain in two different places; yet a far greater number of sheep are cured in this way than by any other. The above person has cured many both ways, he says, and killed a part too; but those which he killed were generally with the wire, because, if the other fail of producing the defined effect, the wire is constantly applied to as a last resource; and many have been seen cured by it which were apparently past all means of recovery.

By some of these means, properly made use of, this disease will be found to be mostly capable of being effectually removed.

**STURGEON** (Acipenser fluvo) of Linnaeus, in Ichthyology, a very well-known, large, and fine-tasted fish, caught in many places, and sometimes in the river Thames, being one of those fishes called anadromi by authors, which spend a part of their time in the sea, and a part in rivers.

It never goes into the sea to any great distance, and is never caught there of any very great size. The fish serves for its production; but it is only in large rivers that it grows to its usual size. It is found in the main ocean, in the Mediterranean, Red, Black, and Caspian seas, whence it ascends the rivers connected with them in April and May, to deposit its spawn, which is very abundant.

This fish is admired for the delicacy and firmness of its flesh, which is as white as veal, and extremely good when roasted. It is generally pickled. The sturgeon which we receive comes either from the Baltic rivers, or North America. Those cured at Pillau are reckoned the best, though of late they are rivalled by those brought from America, in the rivers of which country they abound in May, June, and July; at which time they leap some yards out of the water, and, falling on their sides, make a noise to be heard in still weather at some miles distance.

The sturgeon grows to a great size, to the length of eighteen feet, and to the weight of five hundred pounds; but in our rivers it is seldom taken of that bulk; the nose is long, slender, and pointed; the eyes very small, with the nostrils near them; in the lower part of the nose are four cirri; the mouth is placed far beneath, is small, without teeth, and unsupported by any jaw-bones, so that the mouth of a dead fish is always open, but when alive, closed or opened at pleasure by certain muscles; the body is long, pentagonal, and covered with five rows of large bony tubercles; the whole under-side of the fish is flat; on the back, near the tail, is a single fin; and it has also two pectoral fins, two ventral, and one anal fin; the tail is bifurcated, the upper part being much longer than the other; the upper part of the body is of a dirty olive-colour, the lower part tawny; the middle of the tubercles white.

This fish, in the manner of its breeding, is an exception among the cartilaginous fish, being like the bony oviparous, spawning in winter. Cavear is made of the roes, and ichthyocolles of the found of the sturgeon. (Ray and Pennant.) The variety called by Pliny and others Attilius, Adella, Adano, and Adalus, and the Rhodius of Rondeletius, is found in the Po, and also in smaller rivers and lakes. It was held in high estimation by the Romans.

The other species of *Acipenser* are the following: the *A. rubens*, or herlet, with a straitly fabulate finot, cirri near the mouth, and entire lips. It is found in the Caspian sea, and in the rivers connected with it, rarely in the Baltic, and also in the lake Mejer and Pomerania. The *A. bufo* is described under Huso. The *A. schyla* has an obtuse snout and cirri near its apex, with bird lips. It is found in the Caspian sea, and in the lake Oka of Siberia. Some have doubted whether this be a distinct species from the *A. furio* or not. The *A. feletus*, or kolter, has a spatulate somewhat recurved snout, with its cirri near the mouth, and entire lips. It is found in the Caspian sea, from which, in the beginning of May, it ascends in large shoals into the rivers; and it is also common in the Danube. It is very fertile, inasmuch that the female yields more than 300,000 eggs. Sturgeon is reckoned one of the royal fishes.

**STURGEON BANK**, in Geography, a shoal in the gulf of Georgia, extending from Point Roberts to Point Grey.

**STURGEON LAKE**, a lake of North America, on whose east bank is situated Cumberland House, in N. lat. 53° 56', and W. long. 102° 15'. The distance between the entrance of the lake and Cumberland House, is estimated at twenty miles. The mud which is carried down by the Saktchewine river, has evidently formed the land that lies between it and the lake, for the distance of twenty miles in the line of the river, which is inundated during one-half of the summer, though covered with wood. This lake forms an irregular horse-shoe, one side of which runs to the N.W., and bears the name of Pine-island lake; and the other, known by the name already mentioned, runs to the N.E. of it; and is the largest; its length being about twenty-seven miles, and its greatest breadth about six miles. In N. lat. 54° 16', the Sturgeon-weir river discharges itself into this lake, and its land appears to be almost the famed island of rock that forms the N. side of the lake, and also the W. shore of the lake Wimpie, and is almost a continual rapid. Its direct course is about W. by N., and with its windings, it is about thirty miles. It takes its waters into the Beaver lake.

**STURGEON LAKE**, also a lake of North America, N.E. of lake Superior, in N. lat. 49° 35', and W. long. 92°.

**STURGEON CREEK**. See KITTY.

**STURGEON RIVER**, a river of Canada, which runs into lake Huron, N. lat. 44° 51', W. long. 81°.

**STURM**, in Ancient Geography, one of the Sthedeschec.

**STURK**, See STIRK.

**STURKS**, in Rural Economy, a term applied to yearling cattle.

**STURLESON, SNORRO, in Biography**, a celebrated Icelandic writer, styled the Herodotus of the North, was born in the diocese of Dale, in the year 1178. As three years of age he was put to school under the learned John Loftson, a distinguished character at that period, whom he remained till the time of his death, in 1197. Though of noble descent he was poor, till by marriage he so much increased his property, as to become the richest man in the island, excepting the son of his deceased preceptor. He was remarkably fond of parade; and when he went to the courts of justice, was usually attended with several hundred armed men. He possessed fix large farms, and several on a smaller scale. After the death of his father-in-law, in 1202, he removed to Borg, the inheritance of his wife; but in 1209 he went to reside at the farm of Reikhol, in the improvements of which he spared neither time nor expense. He surrounded his manor and church with a very high rampart, to serve as a security in time of danger; and by means of a subterraneous channel, constructed of stone, conveyed water from the neighbouring warm springs of Skríska, to a bath, still denominated after the founder, Snorrolaug, which was paved with hewn stone, and bordered by leats of the same material. This building has survived the depredations of 600 years. In 1213, Snorro was chosen supreme judge over the whole island. About the same period he acquired great reputation abroad by his poetical talents. He composed a poem in honour of the powerful northern earl, Haco Galin, which he sent to him.
the same year from Iceland, and in return for the civil liberty he received many valuable presents. In 1218 he proceeded to Norway, where he was in great favour with the king, Hacon, and several of the nobility. Under the government of this sovereign, he was appointed to various offices, and went several times to Iceland, in order to promote his patron's views in regard to that island. It having been determined to send troops thither from Norway, either for the purpose of conquering the country, or for obtaining satisfaction on account of some acts of violence committed by the inhabitants against Norwegian merchants, Snorro presided over this expedition, by his remonstrances to one of the king's friends; but he engaged, on the other hand, with the assistance of his brother, to bring the island under the king's authority without bloodshed, and promised to send his son to Norway, as a pledge of what he had undertaken. When Snorro set out on this mission, he received, besides other presents, a ship completely equipped. Having returned to Iceland in 1237, nothing farther was done: either Snorro found it impossible to carry his designs into execution, in consequence of disturbances which agitated the island, and in which he himself had a share, or he was wounded, through a view to private advantage, to deceive both the king and his own countrymen. He was at enmity with his relations, among whom were his brother, his nephew, and his three sons-in-law, who had all repudiated their wives. Finding himself too weak to contend with his numerous enemies, he quitted Iceland in 1237, and went again to Norway, where he arrived at the moment when Duke Skule was preparing to deprive his sons-in-law, King Haco, of the crown, and to place himself on the throne in his stead. Snorro deplored the party of the duke, but returned to Iceland in the company of Thorvaldur, a relation of King Haco, by whom he had been raised to the rank of earl; one of Snorro's sons-in-law, but had now become his bitter enemy. In 1240, King Haco sent him a message, after he had got rid of Duke Skule, either to bring Snorro a prisoner to Norway, or to put him to death. At first, Gifur intended to execute his murderous designs at the place where justice, as it was called, was usually administered; but finding this inconvenient, he fell upon him at his residence, where he was assassinated, in the 65th year of his age. Snorro was universally a great and learned man; his "Heimskringla, or Chronicle of the Norwegian Kings," has been printed at various times, and under different forms. A Danish translation of it by Claesen, with Worm's preface, was published at Copenhagen in 1633 and 1637. It was printed at Stockholm in Icelandic, Swedish, and Latin, in 1697, 2 vols. fol. But the most elegant edition is that that of Schöning, published in Icelandic, Danish, and Latin, which was printed at Copenhagen in 1777 and 1783. This was printed at the expense of the crown-prince; the Latin translation and notes were by Schöning; but the Danish is that of Claesen, revised by J. Olausen. By this important work, which throws so much light on the earliest history of Norway, Snorro rendered much service to posterity. But his merit does not rest on this alone, since he is commonly considered as the author of the prose Edda, edited by Rekenius in 1665, which is founded on those old poems said to have been collected by Sæmund, and on that account called "Edda Semundii." The Edda of Snorro is a poetic manual, or sort of Scandinavian art of poetry, consisting of three parts. In the first part, which may be compared to Ovid's Metamorphoses, or Hesiod's Theogony, are related all those fables contained in the works of Skaldas. The second part is a treatise on poetical philology or synonymy, which shews in what manner the Skaldas gave names to different things; and the third, called Skaldas, treats of alphabetical characters, their division, and the relation they bear to musical tones; of poetical licences, metre, &c. The last part has never been published. Notwithstanding the general merit of Snorro, he is described as a cunning and deceitful man; unsteady in his friendship, fond of money, as well as ambitious, and of a violent and quarrelsome disposition. Gen. Biog. STURLITZ, in Geography, a town of Prussia; 18 miles S.W. of Novi. STURM, JAMES, in Biography, was born of a family of eminence at Strasbourg, in 1489, and emigrated at the age of twenty-five into the lenity of his native place. He was an active promoter of the Reformation, and deputed to the imperial diet, assembled on that occasion. When the deputies of the reformed were excluded, in 1529, from the diet at Spire, Sturmius boldly entered his protest against the measure, and on behalf of his confederates and the other confederates, declared, that if good citizens were thus divorced of their privileges, contrary to the customs of the empire, it could not be expected that they should contribute to the public expenses. His protestation on this point gave rise to the appearance of "Protestants." Amongst other offices of important trust, which were committed to him, he was one of the ambassadors sent in 1536 from the states of Germany to Henry VIII. of England. By his influence a college was established at Strasbourg in 1538, and at his death he left to its support a considerable legacy. Seiden, in his "History of the Reformation," avails himself of much valuable information communicated by Sturmius, of whom it is recorded, that being scandalized by the violent disputes among the Reformers concerning the Lord's Supper, he abstained from many years from receiving it. After having several times served his state as mayor, and having been ninety-one years delegated from it on public business, he died in high esteem, at the age of sixty-four. Gen. Biog. STURM, JOHN, was born at Stilea, near Cologne, in 1507, and studied at Liege and Louvain, in which last city he set up a press, and joined Reclus, the Greek professor, in printing several Greek books. In 1528 he transferred his printing-press to Paris, where he delivered lectures on the age marriage, and on logic, and wrote his "Heimskringla, or Chronicle of the Norwegian Kings," which has been printed at various times, and under different forms. A Danish translation of it by Claesen, with Worm's preface, was published at Copenhagen in 1633 and 1637. It was printed at Stockholm in Icelandic, Swedish, and Latin, in 1697, 2 vols. fol. But the most elegant edition is that of Schöning, published in Icelandic, Danish, and Latin, which was printed at Copenhagen in 1777 and 1783. This was printed at the expense of the crown-prince; the Latin translation and notes were by Schöning; but the Danish is that of Claesen, revised by J. Olausen. By this important work, which throws so much light on the earliest history of Norway, Snorro rendered much service to posterity. But his merit does not rest on this alone, since he is commonly considered as the author of the prose Edda, edited by Rekenius in 1665, which is founded on those old poems said to have been collected by Sæmund, and on that account called "Edda Semundii." The last part has never been published. Notwithstanding the general merit of Snorro, he is described as a cunning and deceitful man; unsteady in his friendship, fond of money, as well as ambitious, and of a violent and quarrelsome disposition. Gen. Biog.
STURMUS, the Stars, or Staring, in Ornithology, a genus of birds of the order Passeres, of which the generic character is as follows: Bill fulvate, angular, depressed, bluntish; the upper mandible is entire, somewhat open at the edges; the nostrils are surrounded with a prominent rim; tongue notched and pointed. There are seventeen species.

*VULGARIS*; Common Staring. Bill yellowish; body black, with white dots. This is very common in our own country, and is found in other parts of Europe, Asia, and America. It is about nine inches long, and builds its nest in the hollows of trees, caves of houses, towers, or rocky cliffs; it lays from four to five eggs, which are of a pale-fish-green colour. In the winter season, starlings assemble in vast flocks in marshy places; feed on worms and insects; are very docile, and may easily be taught to speak. The flesh is bitter, and scarcely edible. The other characteristics of this species are, that their quill-feathers and tail are of a dullish hue; the former are edged with yellow on the outer side, the latter with a dirty-green; lesser coverts edged with yellow, and slightly glossed with green; the legs are of a reddish-brown. Male is shining, with purple, green, and gold.

During the winter months, starlings crowd together in such close and well-arranged battalions, that no bird of prey dare to penetrate their ranks. This manner of flight, which is extremely useful in defending them against rapacious birds, renders them a more easy prey to the wiles of the bird-catcher, who dispatches among them a number of birds of their own kind, each having a glued thread tied to its leg, by which some of them are entangled and brought to the ground. Their love of society not only prompts them to associate with birds of their own species, but with others in no way allied to their tribe. In the spring and summer they are frequently seen with crows and crows, and even with pigeons. It is, however, principally towards night that the starlings unite in large companies, as if to put themselves in sufficient force to brave its dangers. Then they assemble in a flock, and after various evolutions, rush with such impetuosity into the midst of the trees, and spend the evening in chattering, till darkness puts an end to their conversation.

In the morning, at day-break, the noisy conference is resumed, till they depart or separate in search of food. Starlings seldom take the trouble of building nests for themselves, but generally take possession of the deserted abodes of some other birds.

Their docility, and the beauty of their plumage, have rendered starlings great favourites. They are frequently taught to speak, and sing long-tunes. Their vocal powers are, however, acquired by education, and in the domesticated, they support a musical character much better than in the wild.

There is in the productions of Nature a continual tendency to variety, which is clearly exemplified in most of the tribes of birds, and which the diffus, and almost inflating characteristics of the starling, have not been able to defeat. Hence naturalists have enumerated five varieties of the common starling; of which the first independently of that already described has a white body; the second is white; the crown, neck, wings, and tail, are black; the third is white, but above the eyes and near the bill are two black spots; and the fourth is cinereous, with black bill and legs.

*CAPENSIS*; Cape Starling. Blackish beneath; the sides of the head are white. It inhabits the Cape of Good Hope, and is the size of the last. The black and the white, which

---

STURMINSTER, or STURMINSTER-NEWTON, in Dorset, is a small market-town in the hundred of Sturminster Newton-Castle, in the Sherborne division of the county of Dorset, England. It is situated eight miles S.W. from Shaftesbury, and 111 miles W.S.W. from London; and is divided into two parts, viz. Sturminster, which lies on the north side of the river Stour, and Newton or Newton-Castle on the south. The latter is a small hamlet, and a divided thingy. Sturminster and Newton seem sometimes to be synonymous names for the same vill; but Newton is often the general name in ancient records, perhaps on account of the manor-house, the occasional residence of the abbots of Glastonbury, being built by the latter. Both these villages consist of one manor, and are joined together by a causeway, and a bridge of five arches over the Stour. Sturminster, if not of Roman origin, was known in the early ages of the Saxons. The ruins of an ancient castle stand on a hill, and are surrounded by a high vallum, and deep ditch, on the south-west and part of the east; near the centre is a small artificial mount, or keep. The manor was held by the abbey of Glastonbury, by a grant from king Edgar; having been formerly bequeathed by Alfred to his son Eadward. Edmund Ironside confirmed this grant in 1016, when it contained seventeen hides. After the dissolution, Henry VIII. gave the manor, rectorcy, and vicarage, to his queen, Catharine Parr. On her death, Edward VI. granted the estate to his sister, Elizabeth, who, when she came to the crown, gave it to Christopher Hatton: after having many intermediate possessors, it finally passed to the noble family of Rivers, in which it still continues. This town, according to the population return of the year 1811, contained 352 houses, and 1451 inhabitants. Two fairs are held annually, and a weekly market on Thursday.

On a lofty eminence, called Hambledon-hill, standing in the parishes of Child Ockford, Shrotton, and Hambledon, are considerable remains of an extensive fortification. Bishop Gibson supposed this camp to have been formed by the Danes; but Aubrey informed that Roman coins had been plopped up on the top of the hill. The eminence is divided by a deep and narrow vale from another, called Hod Hill, situated partly in the parish of Stour-Paine, and partly in the town of the same name, in the form of a Roman D.—Hutchins's History of Dorsetshire, vol. 2. Beauties of England and Wales, vol. iv. by J. Britton and E.W. Brayley.

STURHNOSEN, a town of Prussia, in the province of Pomerania; 17 miles E. of Heilberg.
which are the only colours of this bird, are distributed very like to those of our pies. The bill is thicker and longer than that of the European Starling, and its distinguishing marks are two large white spots of a round form on each side of the head. In the middle of these are placed the two ears.

**Ludovicianus**; Louisiana Starling. The specific characters of these are, that they are spotted with grey and brown, beneath they are yellow; the head and eye-brows are marked with a white line; the chin is black. A variety is variegated with brown, reddish, and blackish, beneath yellow; with a curved black band; the three lateral tail-feathers are white. The starlings of Louisiana are observed in great flocks in the interior regions of North America. By their manner of flight, as well as their shape, they indicate a near approach to our European kinds. The lower parts of the body are yellow, the upper brownish-grey; and they are distinguished by a large dark-coloured spot upon the breast. The American starlings are inferior to those of Europe in the powers of song; they are from nine to eleven inches long; their bill is white, terti with brown; the cheeks are yellow; the wings and tail are of a reddish-grey; the legs also are grey.

**Contraria**; Indian Starling. *Brown*; eye-spot, bar on the wings, and belly, white. It inhabits India, and is thought to be a variety of the *S. canus*. The body of this species is blackish; the rump on the upper part of the neck white; the upper wing-coverts are marked with white spots; the legs are of a pale yellow.

**Cicinnus**; Water-Ouse; Crane. Black, with a white breast. This species is common to our own country, other parts of Europe, and northern Persia. It is about seven or eight inches long; frequents waters, and feeds on aquatic insects and small fish; it is a very solitary bird, and breeds in the holes of banks; makes a curious nest of hay and fibres of roots, lined with dead leaves, and having an entrance of green moss. The chin is white; the tail black; belly ferruginous; in the young bird it is white; the legs are of a pale blue before, and black behind.

**Miliaria**; Magellanic Starling. Grey; breast and chin red. It inhabits the Falkland islands, and is eleven and a half inches long. Behind and under the eyes is a white spot; the lores are red; on each side the neck is a black blotch; the vent and sub-forked tail are black.

**Moritanus**. Cinerous; lower part of the head and chin varied with cinereous and white; belly spotted with reddish hoary; the bill is terti with black. This species inhabits the alpine parts of Persia; it is the size of a common lark, builds in hollow rocks, and feeds on insects.

**Lytca**. Spotted with brown and white, chin and breast scarlet. It inhabits Chili, and is larger than *S. vulgaris*; it builds in holes on the ground, and lays three cinereous eggs, varied with brown; it sings well, and is easily tamed.

**Mexicanus**; Mexican Starling. Blue varied with black. It inhabits South America, and is about the size of the *S. vulgaris*. The bill and eyes are black; irides yellow; the head is small.

**Obscurus**; Brown-headed Starling. Black, but the head is brown, whence its trivial name. It inhabits New Spain.

**Zeylanicus**; Ceylonese Starling. Line over the eyes and one on the sides of the head black; body grey, varied with ochre and white spots and crescents; quill-feathers green; tail marked with green and black lines. It inhabits Ceylon, and imitates the notes of other birds. The bill is black, the head yellowish; the legs are of a blueish-grey.

**Stuc**

**Fuscus**; Brown Starling. *Olive*; eye-band blueish; bill and legs reddish. This is found chiefly in China. The belly is yellowish; the tail long.

**Viridis**; Green Starling. Green, beneath blueish; a tuft of black and white feathers on the front and chin. This inhabits China. Above the front, and behind the eyes, a white spot, and two on the shoulders: quill-feathers and shafts of the tail-feathers white, legs blueish.

**Saniculus**; Silk Starling. Pale-grey; wings and tail black, the former with a transverse white bar; head ochre-yellow. It inhabits China, and is the size of the *S. vulgaris*. Bill and legs orange or red; the plumage is silky.

**Carunculatus**. Bill and legs black; at each angle of the mouth a pendent orange wattles. It inhabits New Zealand, and is ten inches long. The female is of a rufous-brown, with very small wattles. The male is black; the back and wing-coverts ferruginous.

**Collaris**; Collared Starling. Blackish-brown, spotted with brown; the flanks are rufous, the chin is white spotted with brown. This species is found chiefly in Switzerland and Italy; size of a field-fare; it is a solitary bird; wags its tail, feeds on seeds, fings with a very weak voice, and builds on the ground, or in the clefts of rocks. The upper mandible is brown, lower yellowish, terti with brown; breast brownish; the belly is rufous; quill-feathers blackish, the edge at the tip and inner side reddish; tail brown; legs of a horn-colour.

**Dauuricus**. Body above violet-black; beneath ash-white; the head and neck blueish; crown with a violet-black bluish; but in the female it is brown. This species is found chiefly among the oxier plantations of Dauria; it is above six inches long, and feeds on vegetables and insects. The bill is black, and more convex than in others of its tribe; the tongue is blackish; the irides brown; downy eyelids and lores white. The head of the male is cinereous; the back is of a grey-brown; the wing-coverts of the male are black; silky-green; the secondaries terti with white; the quill-feathers are black; the two inner ones terti with white; the primary ones are terti with green; the tail is sub-forked, greenish-black; the coverts violet; legs blueish-black.

**Stuthof**, in Geography, a town of Prussia, in the Frich Neurng; 14 miles N.N.W. of Elbing.

**Stuthy**. See Stuthy.

**Stutinum**, a town of Bohemia, in the circle of Chrudim; 3 miles S. of Chrudim.

**Stuttgarten** or **Stuttgard**, the capital of Wurtemberg, and residence of the king, situated in a delightful country on the Nutenbach, about two miles from the Neckar. The town is not large, but contains two well-built faubourgs. It is the see of a bishop, which was removed from Beutelsbach in the year 1321. The streets are large and straight, and the houses handsome. The royal palace is a magnificent building, and was begun in the year 1746. Stuttgarden contains an academy of painting, sculpture, and architecture, established in the year 1701; and manufactures of fluff, silk stockings, and ribbons.

The origin of this town is uncertain; in the year 1285, it was besieged, without success, by the emperor Rudolph I.; but in 1287, he reduced count Eberhard to such straits, that he was compelled to promise the demolition of the walls of the city. In the years 1520 and 1567, the whole city was surrounded with walls; in 1546 and 1547, it suffered greatly by the Spaniards; in 1634, and the following years, by the Imperialists; and in 1688, 1693, and 1707, by the French: 40 miles N.W. of Ulm. N. lat. 49° 45'. E. long. 9° 18'.

**Stut-**
STUTZENBERG, a town of Austria; 5 miles N.E. of St. Polten.

STUYVER, in Coinage. See Stiver.

STUZZITZA, in Geography, a town of European Turkey, in Macedonia; 80 miles N. of Saloniki.

STY, (Horodeum,) a small inflammatory tumour on the edge of the eye-lids. See Horodeum.

STY, Pig, in Rural Economy, a term used to signify the place where pigs are confined and kept, especially when of the small, rude, unfinished kind, such as are connected with cottages. See Hoo-Sty, Pigery, Pig-Cage, &c.

Improved fies of this fort are made by raising the feeding and sleeping places a little above each other, and both above the yards.

STYCA, in Cordage. See Stica.

STYGIA AQUA, a term used sometimes to express aqua regia; sometimes for the other strong acid spirits.

STYGIAN Liquors, a term which some chemists apply to the corrosive acid spirits, as aqua regia, from their efficacy in destroying or dissolving most bodies.

STYLE, in Botany. See Styline.

STYLE, in Chronology, denotes a particular manner of accounting time, with regard to the return to the reference of 10 days from the calendar, in the reformation made of it under pope Gregory XIII. See Calendar.

Style is either old or new.

STYLE, Old, is the Julian manner of computing, which obtains in some Protestant States, who refused to admit of the reformation.

STYLE, New, is the Gregorian manner, followed by the Catholics, and others, in consequence of that reformation.

The Julian, or old style, agrees with the Julian year, which contains 365.25 days.

The Gregorian, or new style, agrees with the true solar year, which contains only 365.2425 days.

In the year of Christ 2000, there was no difference of styles, but now there has arisen a difference of 11 days between the old style and the new, the latter being so much more accurate to the former; so that when the Catholics, e.g., reckon the 31st of May, those who use the old style reckon the 10th.

There are several places where the new style obtains even among Protestants; and it is not unlikely that the old style may, in time, dwindle quite away.

At the dict of Ratibon in 1700, it is decreed by the body of Protestants of the empire, that 11 days should be retrenched from the old style, to accommodate it, for the future, to the new. And the same regulation has since fallen into Sweden, Denmark, and into England, where it was established by 24 Geo. II. c. 25, which enacts, that in all dominions belonging to the crown of Great Britain, the suppuration, according to which the year of our Lord begins on the 25th day of March, shall not be used from and after the last day of December, 1751, and that henceforth, the 1st day of January every year shall be reckoned to be the first day of the year; and that the natural day next immediately following the 3d day of September 1751, shall be called and reckoned the 14th day of September, omitting the 11 immediate nominal days of the common calendar; and that the several natural days succeeding the 14th, shall be called and reckoned forwards in numerical order from the 14th day of September. Moreover, it is enacted, that all kinds of writings, &c. shall bear date according to the new method of suppuration, and that all courts and meetings, &c. feasts, fairs, &c. shall be held and observed accordingly. And for preferring the calendar in the same regular course for the future, it is enacted, that the several years of our Lord 1800, 1900, 2100, 2200, 2300, &c. except only every 400th year of our Lord, of which the year 2000 shall be the first, shall be common years of 365 days, and that the years 2400, 2800, &c. and every other 400th year from the year 2000 inclusive, shall be leap years, consisting of 366 days. See Bisextile and Calendar.

The following table shews by what number of days the new style differs from the old, from 5900 years before the year of Christ's birth, to 5900 years after it. The days under the sign - (viz. from 6000 years before to 200 years after Christ) are to be subtracted from the old style to reduce it to the new; and the days under the sign + (viz. from 200 to 5900 years after Christ) are to be added to the old style to reduce it to the new.

</table>
STYLE.

STYLE, in Dialling, denotes the gnomon or cock of a dial, raised on the plane of it, to project a shadow.

STYLE, in Grammar, is a particular manner of delivering a man's thoughts in writing, agreeably to the rules of syntax; or, as F. Burner more accurately defines it, the manner in which the words, constructed according to the laws of syntax, are arranged among themselves, suitably to the genius of the language.

This definition fixes the notion of style to something determinate, which before was very vague and arbitrary; whence many authors, even of note, confounded it with syntax itself.

From the definition it appears, that the style supposes or includes the syntax; and that syntax does not extend so far as style; for the syntax may be very just, where the style is wretched.

Indeed, against what particular rule of grammar the fault is committed, it is scarce possible always to determine precisely; the taste and use of a language being so exceedingly delicate and precarious. It is true, a fault in style is not a fault against grammar than is a fault in syntax; only the former is less precise and palpable than the latter.

A very common error in grammarians, F. Burner adds, is to confound two kinds of styles in one; the grammatical style, or that directed by the rules of grammar; and the personal style, which depends less on the grammar than on the person that writes; whether with regard to his particular taste and genius, or with regard to his matter, or the kind or character of his work.

There are a great many differences between the two; the most essential is, that the one may be diversified an infinite number of ways, and the other cannot. In effect, the personal style is naturally variable, according to the different genuses, humour, and complexions.

It is the imagination that affects, that conceives, that proposes, and that expresses things according to its character, which is different in all men; and which is to be varied according to the particular kind of the work.

Hence arise the gay, the grave, the florid, the jejun, the copious, the concise, the poetical, the epistolary, and the burlesque styles.

These personal styles are all independent of the grammatical; and we have authors who excel in the one, yet are miserably defective in the other. The personal style is not under the direction of grammar, but of the imagination, or rather of rhetoric, that art having to do directly with our thoughts, as grammar with our words.

This, however, be it said, that grammar is far from being able to vary the same words of a phrase with equal perfection; and that generally there is but one way of delivering them in the tinct and genius of the language.

But in the personal style, where the imagination comes to be concerned, a sentence may be varied infinite ways, according to the kind of the writing, whether oratorical, poetical, &c.

In a philosophical style, the only end is accurately to explain our thoughts to others; whence the particular rules to be observed by a philosopher, in delivering his doctrines, naturally follow; such as:

1. Not to deviate from the received significations of terms.
2. That the same terms be always taken in the same sense.
3. To fix the meaning of such words as have only a vague sense.
4. To signify objects essentially different, by different names.

From these rules, the use and necessity of terms of art appear, and we see with how little reason they are vulgarly condemned.

5. The philosopher ought always to make use of proper expressions, and use no more words than what are precisely necessary to establish the truth of his doctrines. Wolf. Diff. Prælim. Logic. c. 5.

STYLE, in Jurisprudence, the particular form or manner of proceeding in each court or jurisdiction, agreeable to the rules and orders established in them. Thus we say, the style of the court of Rome, the court of chancery, of parliament, of the privy council.

STYLE, in Music. See STYLO.

STYLE in Oratory and Poetry, is restrained wholly to what F. Burner calls the personal style. Accordingly it may be defined to be the peculiar manner in which a man expresses his conceptions by means of language.

Style has always some reference to an author's manner of thinking. In other words, style is nothing else than that sort of expression which our thoughts most readily assume. Hence, different countries have been noted for peculiarities of style, suited to the different temper and genius of their inhabitants. Thus, the eastern nations animated their style with the florid and most hyperbolical figures. The Athenians, a polished and acute people, formed a style accurate, clear, and neat. The Africans, gay and loose in their manner, affected a florid and diffuse style. The like fort of characteristic differences are commonly remarked in the style of the French, the English, and the Spaniards.

Words being the copies of our ideas, there must always be a very intimate connection between the manner in which every writer employs words, and his manner of thinking; and from the peculiarity of thought and expression which belongs to him, there is a certain character imprinted on his style, which may be denominated his manner. This character results from the whole tenor of his language, and comprehends the choice which he makes of single words, his management of these in sentences, the degree of his precision, and his embellishment by means of musical cadence, figures, and other arts of speech. Although different subje克斯 require to be treated of in different sorts of style; so that the style of orations, for instance, should be different from that of treatises of philosophy; and different parts of the same composition require a variation in the style and manner; yet, amid this variety, we still expect to find, in the compositions of any one man, some degree of uniformity or consistency with himself in manner; or some predominant character impressed on all his writings, which shall be f锭oted to, and shew most, his particular genius and turn of mind. The orations of Livy and of Tacitus differ much in style from the rest of their history; and yet in Livy's orations, and in those of Tacitus, we are able to trace one distinguising manner of each historian; the magnificent fulness of the one, and the sententious conciseness of the other. In general, characters of style were particularly regarded by the ancient critics; accordingly, Dionysius of Halicarnassus distributed them into three kinds, which he calls the orator, the florid, and the middle. By the orator, he means a style distinguished for strength and firmness, with a neglect of smoothness and ornament; for examples of which he gives Pindar and Æschylus among the poets, and Thucydides among the prose writers. By the florid, he means a style ornamented, flowing, sweet, depending more upon numbers and grace than strength; and as instances,
he mentions Hesiod, Sappho, Anacreon, Euripides, and principally Iphocrates. The middle kind is the jul mean between these, comprehending the beauty of both; in which class he places Homer and Sophocles among the poets, and in prose, Herodotus, Demosthenes, Plato, and even Aristotle, thus unaccountably extending his terms to so to comprehend under one article, as to style, Plato and Aristotle. Cicero and Quintilian make a three-fold division of style, though with respect to different qualities of it, in which they are followed by most of the modern writers on rhetoric: the simple, tenue or subtile; the grave or sober; and the medium, or temperament genus discendi: in other words, the low or plain, the lofty or sublime, and the middle, temperate, or equable. See Style, in Grammar, supra.

The several characters are distinguished from one another, both by the thought and by the language.

The low, or simple style, pertains to subjects that are either common things, or to such as should be treated in a plain and familiar way; and, therefore, plain thoughts are most suitable to it, and distingiuished it from the other characters of style. By plain thoughts are meant such as are simple and obvious, and seem to rise naturally from the subject, when duly considered; so that any one, upon first hearing them, would be apt to imagine they must have occurred to himself.

Cicero's account of the flight between Milo and Clodius, in which Clodius was killed, is a remarkable instance of natural plainness and simplicity. Pro Mil. c. 10.

There are two properties of plain thoughts, one of which ought constantly to attend them in common with all beauty, and the other is often necessary to animate and enliven this character. The first of these is juvenile and propriety, which is what reason dictates in all cases; and the other property, which should often accompany plain and simple thoughts, is, that they be gay and sprightly; because the fewer ornaments this style admits of, the greater spirit and vivacity are requisite to prevent its being dry and jejune; care, however, should be taken, lest, while fancy be too much indulged, the juvetness of the thoughts should be overlooked.

As to the language proper for the low style, it may be observed, in general, that the dres ought to be agreeable to the thoughts, plain, simple, and unaffected: elegance, or a proper choice of words and expressions, including both purity and perspicuity, should be an object of primary attention. Epithets should be used sparingly, because they enlarge the images of things, and contribute very much to heighten the style. The composition in this kind of style does not require the greatest accuracy and exactness. A seeming negligence, as it appears more natural, is sometimes a beauty. Short sentences, or those of a moderate length, are best suited to this character. Such a harmony of numbers, proportion of the several parts, and studied cadence, as are evident effects of art, should be avoided: and yet it is necessary to observe some proportions in the members, so that neither the ears be too much defrauded, nor the sense obscured. As to order, the plainest and clearest disposition, both of the words and members of sentences, and what is most agreeable to the natural construction, best suits with this character, of which perspicuity is one of the principal beauties: and a proper connection likewise of sentences, with a regular order in the dependence of things one upon another, very much contributes to this end. As to dignity of language, we may observe that tropes should be used cautiously. Verbal figures, which serve chiefly to enliven an expression, and give an agreeable turn, are often not improper for this character; nor the figures of sentences wholly to be excluded, especially such as are chiefly used in reasoning or demonstration. But those which are more peculiarly adapted to touch the passions, or paint things in the strongest colours, are the more proper ornaments of the higher styles.

Upon the whole, pure nature, without any colouring or appearance of art, is the distinguishing mark of the low style; the design of which is to make things plain and intelligible, and set them in an easy light. And, therefore, the proper subjects of it are epistles, dialogues, philosophical dissertations, or any other discourses that ought to be treated in a plain and familiar manner, without much ornament, or address to the passions. A freedom and ease both of thought and expression, attended with an agreeable humour and pleasantry, are its peculiar beauties that engage us; and as the plain style admits of fewer ornaments than the florid, and has little more to recommend it than its own native beauty and simplicity, the greater is the art necessary to render it agreeable and entertaining.

Middle, or equable style, pertains to subjects that are of weight and importance, and which, therefore, require both a gravity and a degree of expression; and the distinguishing marks of this style are fine thoughts. A fine thought, as distinguished from plain thoughts on the one hand, and lofty thoughts on the other, may be taken to be the same as a fine thought, as distinguished from expression, or of the following properties, viz. 1. Gravity and dignity, an indication of which seems to occur in Cicero's speech to Caesar (Pro Marcell. c. 8.) when he says, "It has often been told me, that you have frequently said, you have lived long enough for yourself. I believe it, if you ever lived, or was born for yourself only." 2. Beauty and elegance: this property is exemplified in the fine compliment which Pliny pays to the emperor Trajan, when he says, "It has happened to you alone, that you were father of your country, before you were made fo." Paneg. c. 21.

3. Delicacy: A delicate thought is that which is not wholly discovered at once, but by degrees opening and unfolding itself to the mind, difcloses more than was at first perceived. To this property Quinellian (Infi. Orat. lib. vii. c. 2.) seems to refer, when he says, those things are grateful to the hearers, which, when they apprehend, they are delighted with their own sagacity; and pleases themselves as though they had not heard, but discovered them. Of this kind is that of Pliny (Paneg. c. 22.) speaking of Trajan's entry into Rome: "Some declared upon first seeing you, they had lived long enough; others, that now they were more deftious to live." 4. Novelty, which is applicable not only to things absolutely new, but to the same thought set in a different light, or applied to a different occasion. Thus Cicero (De Orat. lib. iii. c. 11.) says of Caius: "Caius always excelled every other person, but that day he excelled himself;" and also of Caesar (Pro Marcell. c. 4.), "You had before conquered all other conquerors by your equity and clemency, but to day you have conquered yourself; you seem to have vanquished even victory herself; therefore you alone are truly invincible."

As to the language proper to the middle style, it may be observed in general, that as the proper subjects of it are things of weight and importance, though not of that exalted nature as wholly to captivate the mind, and divert it from attending to the diction; so all the ornaments of speech and beauties of eloquence have place here. Elegance, confining in the choice of single words, of those that are
STYLE.

are most full and expressive, and of proper epithets, and the most accurate composition in all the parts of it, have place here. Periods the most beautifull and harmonious, and of a due length, and wrought up with the most exact order, just cadency, easy and smooth connection of the words, and flowing numbers, are the genuine ornaments, which greatly contribute to form this charachter. But the principal distincion of style arises from tropes and figures. By tropes it is chiefly animated, and raised to its different degrees or charachters, as it receives a less or greater number of them; and those either more mild, or more strong and powerful. As to tropes, those which afford the most lively and pleasing ideas, especially metaphors, suit the middle charachter. Virgil's Eclogues are written in the lowe style, agreeably to the language of the shepherds; and his Georgics in the middle style, suited to the nature of the subject, and the greatest men in Rome, amusing themselves in rural affairs, who were the persons for whom they were designed. Accordingly, in the former (Eclog. v. ver. 37.) the following verse occurs:

"In felix lolium et fleriles nascentur avenae:"

In English:

"Wild oats and darnel grow instead of corn."

In the latter (Georg. lib. i. ver. 154.) the same sentiment is thus expressed:

"In felix lolium et fleriles dominuntur avenae:"

In English:

"Where corn is sown, darnel and oats command."

Upon which some critics have remarked, that where the same fene is intended, instead of the proper word nascentur, grow, the author substitues a metaphor, dominuntur, command.

Figures, both of words and sentences, also belong to this style; which admits of the finest description, most lively images, and brightest figures, that serve either for delight, or to influence the passions, without transport or ecstasy, which is the property of the sublime. The most considerable embellishments, that form the middle or florid style, are descriptions, the profopoeia, similitudes and comparisons, and the antithesis. These, and such like florid figures, are sometimes found in historians, but more frequently in orators; and indeed this middle character, in the whole of it, is best accommodated to the subjects of history and oratory. Cicero has excellently described this style in the following passage: "Est flusus quidam interjectus, intermedius, et quasi temperatus; nec acumen inferiorior nec fulmine utens superiorior, vicinus amborum, in neutro excellens, utriusque particeps." The same author calls it the florid and polished style; as in this all the graces and beauties of language are principally to be used.

Sublime style is that which is the most noble, as well as the most difficult part of the province of an orator; and, indeed, the noblest genius and greatest art are both requisite to form this charachter; but the justest propriety, joined with the greatest strength and highest elevation of thought, is required to complete the true sublime. Lofty and grand sentiments are the basis of this charachter of style; and, therefore, Longinus advises those who aspire at this excellence, to accustom themselves to think upon the noblest subjests. Lofty thoughts are principally those which relate either to divine objects, or to power, wildom, courage, beneficence, and such other things as are of the highest effect among mankind. Of the former sort is Cicero's decleration to Cæsar, in his intercessioun for Ligarius, when he says, "Men in nothing approach nearer to Deity, than in giving life to men:" and an instance of the latter fort occurs on the fame occasion, when he says, "Your fortune has given you nothing greater than a power, nor your nature than a will to fave many." Of the fame kind is the reply of Porus the Indian king, when, after his defeat by Alexander, being brought before him, and asked how he expected to be treated, he answered, "Like a king:" or that of Cæsar chiding the pilot, who was afraid to set out with him in a form, "Quid times? Cæfarem vehis." It is proper to remark, that the true sublime is confident with the greatest plainness and simplicity of expression: and, generally speaking, the more plain and natural the images appear, the more they surprize us. Of this kind is the expression of Cæsar, upon his victory over Pharnaces, "I came, I saw, I conquered." But there cannot be a greater or more beautiful example of this, than what Longinus has taken notice of from Moses: "The legislator of the Jews," says he, (lect. 9.) "no ordinary person, having a just notion of the power and majesty of the Deity, has expressed it in the beginning of his laws in the following words: And God said: What? Let there be light, and there was light. Let the earth be made, and it was made." The image of a thing is sometimes much heightened, when it is expressed in so undetermined a manner, as to leave the mind in suspense what bound it to fix to the thought. An instance of this kind occurs in Milton's description of the fall of Satan. Parad. Loth, book ii.

"—— And to this hour
Down had been falling."

As to the language proper for the sublime style, elegance, composition, and dignity, which comprehend all the properties of style, are to be particularly regarded. With respect to elegance, those words and expressions chiefly contribute to form the sublime, which are most sonorous, and have the greatest splendour, force, and dignity; and they are principally long words, which are preferable to short ones, and especially monosyllables; compound words rather than simple ones; and also epithets, the use of which contributes in a particular manner to this charachter. The force of composition is so great, as Longinus observes (lect. 59.), that sometimes it creates a kind of sublime, where the thoughts themselves are but mean, and gives a certain appearance of grandeur to that which otherwise would seem common. Sublimity arises from the several parts of a period so connected, as to give force as well as beauty to the whole. The periods, therefore, in this charachter of style, should be of a proper length; neither too short, so as to lose their just weight and grandeur; nor too prolix, so as to lose their force, by becoming heavy and unwieldy. And more especially, nothing should be admitted that is superfluous, which very much enervates the force of a sentence. Besides, the order and disposition of the several words and members of a sentence should be regarded; as the different placing of one or two words will sometimes wholly destroy the grandeur of a sentence, and make it extremely flat. Another thing to be attended to in composition, is the connection of words, with regard to the sound; that the pronunciation, in passing from one to another, may be most agreeable to the ear, and best suited to the nature of the subject. Soft and languid sounds are very unuitable to this character; and, in this respect, therefore, our tongue, by its multitude of consonants, is more suited for sublime discourse than some other modern languages, which abound with vowels. The dignity of style depends on the proper
STYLE.

All the qualities of a good style, says Dr. Blair, may be ranged under the two heads of perspicuity and ornament. For all that can be required of language is, to convey our ideas clearly to the minds of others, and, at the same time, in such a dres, as by pleasing and interesing them, shall most effectually strengthen the impressions we endeavour to make.

Perspicuity, considered with respect to words or phrases, requires, according to this writer, these three qualities, purity, propriety, and precision. The former is the use of such words, and such constructions, as belong to the idiom of the language which we speak; in opposition to words or phrases that are imported from other languages, or that are obsolete, or new coined, or used without proper authority. Propriety is the selection of such words in the language, as the bell and most established usage has appropriated to those ideas which we intend to express by them. And as the words which a man uses to express his ideas, may be faulty in three respects; not expressing the idea which the author intends, but some other which resembles it; or expressing that idea incompletely; or, again, expressing it, together with something more than he intends; precision is opposed to all these three faults, but chiefly to the last. The proper opposite to precision is a loose style.

In the construction of sentences, according to this writer, the most essential properties are clearness and precision, unity, strength, and harmony. The first is opposed to ambiguity in the arrangement of words in a sentence; and is to be attained by observing exactly the rules of grammar, as far as these can guide us, and by placing the words or members most nearly related as near to each other as possible, so as to make their mutual relation clearly appear; particularly, that adverbs may always be made to adhere closely to the words which they were intended to qualify; that, where a circumstance is thrown in, it may be determined by its place to one or other member of it; and that every relative word which is used may infantly present its antecedent to the mind of the reader without the least obscurity. In order to preserve the unity of a sentence, the scene, during the course of the sentence, should be changed as little as possible; things, which have so little connection, that they could admit of being divided into two or three sentences, should never be crowded into one sentence; all parentheses in the middle of sentences should be avoided, and the sentence should be always brought to a full and perfect close. The strength of a sentence is such a disposition of the several words and members, as shall bring out the force to the best advantage; as shall render the impression, which the period is designed to make, most full and complete, and give every word and every member its due weight and force. For this purpose, care should be taken to prune the sentence of all redundant words and members; particular attention should be had to the use of copulative, relatives, and all the particles employed in transition and connection; the capital word or words should be disposed of in that place of the sentence, where they will make the fullest impression; the subject most unerring and growing in their importance above one another, so as to form a climax; the conclusion should seldom consist of an adverb, preposition, or any inconsiderable word; and in the members of a sentence, where two things are compared or contradicted to one another, where either a resemblance or an opposition is intended to be expressed, some resemblance in the language and construction should be preferred.

In the harmony of periods, we may consider agreeable found, or modulation in general, without any particular expression, and the found so ordered, as to become expressive of the
STYLE.

the fenile. The first depends on the choice of words, and the arrangement of them, with respect to which no writer equals Cicero, who was fond, perhaps to an excess, of the *plena ac numerosa oratio*.

There are two things on which the music of a sentence chiefly depends, viz. the proper distribution of the several members of it, and the close or cadence of the whole, which should be so contrived, that the sound should be made to grow to the last; the longest members of the period, and the fullest and most sonorous words, being referred for the conclusion. This rule, however, ought to be observed with restraint; for all unmeaning words, introduced merely to round the period, or fill up the melody, *complementa numerorum*, as Cicero calls them, are great blinemies in writing. Of found adapted to the fenile there are two degrees, one the current of sound, adapted to the tenor of a discourse, and a particular resemblance affected between some object and the sounds that are employed in describing it.

The second quality of style is *ornament*, which arises partly from a graceful, strong, or melodious construction of words, and partly also from figurative language, which is prompted either by the imagination or the passions. Figures contribute to the beauty and grace of style, by enriching the language, and rendering it more copious; by bestowing dignity upon style; by giving us the pleasure of enjoying two objects presented together, without confusion; the principal idea, which is the subject of the discourse, along with its accessory, which gives it the figurative drefs; and by giving us frequently a much clearer and more striking view of the principal object, than we could have if it were expressed in simple terms, and divested of its accessory idea. See Figure, Tropes, Metaphor, &c.

With respect to the use of figures, Dr. Blair observes, that neither all the beauties, nor even the chief beauties of composition, depend upon tropes and figures; that, in order to their being beautiful, they must always arise naturally from the subject; that they must not be employed too frequently; and that, without a genius for figurative language, none should attempt it.

This writer considers the various kinds of style; the first and most obvious distinction is that which arises from an author's spreading out his thoughts more or less; and which forms what are called the diffuse and the concise styles. Each of these has its advantages, and each becomes faulty when carried to the extreme. Discourses that are to be spoken, require a more copious style than books that are to be read. Of concisenee, the two most remarkable examples are Tacitus and Montesquieu in *l'Esprit de Loix*. Of a beautiful and magnificent diffusenee, Cicero is the most illustrious instance; Addison also and sir William Temple belong to this class.

The nervous and the feeble are generally held to be characters of style, of the same import with the concise and diffuse. They often coincide, inomuch as diffuse writers have generally some degree of feebleness, and nervous writers will generally be inclined to a concise expression. However, there are instances of writers that, whether of a full and ample style, have maintained a great degree of strength. Livy is an example; and in the English language Dr. Barrow. One of the most complete models of a nervous style is Demosthenes, in his Orations.

The restoration of king Charles II. seems to be the era of the formation of our present style in Great Britain. Lord Clarendon began, sir William Temple polished the language still more, and the author who formed it more than any one into its present state, is Dryden. Since his time, considerable attention has been paid to purity and elegance of style; but it is elegance rather than strength, that forms the distinguishing quality of most of the good English writers.

Style, with regard to the degree of ornament employed, may be divided into three classes; the first, that seems to rank in the following gradation, era, a dry, plain, neat, elegant, and flowery manner. The dry manner excludes ornament of every kind; and content with being understood, it has not the least aim to please either the fancy or the ear. Aristotle is a complete example of a dry style. A *plain* style rifies one degree above a dry one. A writer of this character gives us his meaning in good language, distinct and pure, but seeks no further ornament; either because he thinks it unnecessary to the subject; or because his genius does not lead him to delight in it, or because it leads him to defile it. Dean Swift is placed at the head of those that have employed the plain style; and among our philosophical writers, Mr. Locke comes under this class. The next style makes use of ornament, but not of the highest or most sparkling kind. The attention of a writer of this character is shewn in the choice of his words, and in a graceful collocation of them, rather than in any high efforts of imagination or eloquence. A familiar letter, or a law paper on the driest subject, may be written with neatness; and a sermon, or a philosophical treatise, in a next style, will be read with pleasure. An *elegy* style is the next degree of ornament, and is, indeed, the term usually applied to style, when poissessing all the virtues of ornament, without any of its excelle or defects. To this class we may refer Addison, Dryden, Pope, Temple, Bolingbroke, Atterbury, and a few more.

When the ornaments applied to style are too rich and gaudy in proportion to the subject; when they return upon us too fast, and strive us either with a dazzling lustre, or a false brilliancy; this forms what is called a *florid* style; a term commonly used to signify the excess of ornament. Dryden seems to be often the first writer to be called a florid, and it is not too strong a word. It is not the least pardonable, but even a promising symptom in young people, that their style shoule incline to the florid and luxuriant, but it is not estedile to the same indulgence from writers of mature years. Without a foundation of good fenile and solid thought, the moif florid style is but a childish imposition on the public.

Among the characters of style we may reckon that of simplicity, or a natural style, as distinguished from affection. Simplicity, with respect to style, stands opposed to too much ornament or pomp of language, and in this sense the simple style coincides with the plain or next style. Simplicity, as it regards style, may also denote the easy and natural manner in which our language expresses our thoughts, and stands opposed to affection or ornament, or appearance of labour about our style; and this is a distinguishing excellence in writing. Of this simplicity, Homer, Hesiod, Anacreon, Theocritus, Herodotus, and Xenophon, among the Greeks; Terence, Lucretius, Phedrus, and Cesar, among the Romans; and Tillotson, sir William Temple, and Addison, among English writers, are distinguished models.

Dr. Blair mentions another character of style, which he distinguishes by the name of strong, and which always implies strength, and is not by any means inconsistent with simplicity; but in its predominant character is distinguishable from either the strong or the simple manner. It has a peculiar ardent; it is a glowing style; the language of a man who has an imagination and passions are heated, and strongly affected by what he writes; who is therefore negligent of literary graces, but pours his heart forth with the rapidity and fulness of a torrent. This belongs to the higher kinds of oratory.
oratory; and, indeed, is rather expected from a man who is speaking, than from one who is writing in his closet. The orations of Demosthenes furnish a full and perfect example of this species of style. Among English writers, Lord Bolingbroke has most of this character, though mixed indeed with several defects. Blair’s Lectures on Rhetoric, &c. vol. i. paffim.

As to the choice of style, in the general, the nature of the subject is to determine it. Such style, says Cicero, is to be chosen, as expresses great things magnificently, middle things moderately, and low things subtly, or acutely; but more particularly, as those are three branches of the duty of an orator, to teach, to delight, and to move; the simple style is used to teach, the middle to delight, and the sublime to move.

Again, the simple or low style is fit for comedy; the sublime for tragedy; and the middle for history. Cæfar, it is true, rather used the simple than the intermediate style, but then he wrote commentaries, not a history, as is observed by Tully.

Again, the simple style is fit for exulcories and eleguces; the intermediate style for georgics; and the sublime for epics: which triple difference we easily discover in Virgil, though he sometimes mixes them all in the Aeneid itself, using the simple style in the fifth book, where he describes games, and the intermediate in the beginning of the poem. Care is still to be taken, that the style be not flat and dull, on pretence of being simple.

M. Boileau observes, that in all languages, a mean thought, expressed in noble terms, is better liked than the noblest thought expressed in mean terms: the reason he gives is, that every body cannot judge of the force and justness of a thought; but scarcely any but perceives the meanest of words. The latter we find by our senses, the former only by our reason.

It is neither easy nor necessary, says Dr. Blair, to determine what is precisely the best style. Some general qualities, indeed, there are of such importance, as should always, in every kind of composition, be kept in view; and some defects we should always study to avoid. An ostentatious, a facile, a harsh, and an obscure style, for instance, are always faults; and peripety, strength, neatness, and simplicity, are beauties always to be aimed at. But as to the mixture of all, or the degree of the qualities, or the exclusion of the defects, for forming one peculiar distinguishing manner, no precise rules can be given; nor is it easy to point out any one model as absolutely perfect. Dr. Blair proposes the following directions concerning the proper method of attaining a good style in general: leaving the particular character of that style to be either formed by the subject on which we write, or prompted by the bent of genius. For this purpose, we should study clear ideas on the subject concerning which we are to write or speak; the frequent practice of comparing with attention and care is indispensably necessary: we ought to render ourselves well acquainted with the style of the best authors, and yet, at the same time, be cautious in avoiding a servile imitation of any one author whatever: we should always study to adapt our style to the subject, and also to the capacity of our hearers, if we are to speak in public: and it should be remembered, that attention to style ought not to engross us so much, as to detract from a higher degree of attention to the thoughts. "Cu-ræ-s, " says the great Roman critic, "erunt voli effer efoliatus." Lect. on Rhet. I. II. x. xix.

The chief faults in style are, its being tumid and loud, or cold and puerile, or stiff, or loose, or dry and jejune.

**STYLE.**

**STYLE, a Tumid, is that which is immoderately flustered with big words and sentences; such are those verses of the emperor Nero, ridiculed by Petrus:**

"Torva mimallonea implerunt cornua bombis, Et raptum vitulo caput ablatura superbo.
Baffaris, et lyncem manas flexura corymbis, &c."

**STYLE, Frigid or Puerile, is that which affects certain trilling ornaments, insipid jells, remote and strained allusions, redundant dissertations, &c. Such, e. g. as a Cæsaur’s riding himself; more golden than gold, &c. Of this vice, that passage of Virgil seems guilty:**

"Num capiti potueru capi? Num incensa cremavi Troja viros?"

In the puerile style, the writer runs on in a species of verbosity, amusing his reader with synonymous terms and identical propositions, well-turned periods, and high-sounding words; but, at the same time, using those words in indifferently, that the latter can either affix no meaning to them at all, or may almost affix any meaning to them he pleases. See **Sublime Style, Superb.**

**STYLE, Locois, is that which, wanting articles, numbers, &c. fluctuates here and there, not connected or joined together: or, a loose style, in opposition to precision, generally arises from a superfluity of words; and the great source of it is the injudicious use of synonymous words. This is a fault so frequent, especially in young writers, that it is needed to give inferences of it.**

**STYLE, Dry or Jejune, is that which is destitute of ornament, spirit, &c.**

The ancients made a notable distinction of style, into **Laconic and Asatic.**

**STYLE, Asatic, is that which is very florid, dilatory, and prolix; or where abundance of words are used to express a little matter: thus called by the Greeks from the people of Asia, who affected such redundancies, in opposition to the **STYLE, Laconic,** which is distinguished by its exceeding conciseness, and by comprehending much matter under a few words.

Such, e. g. is that answer returned by the Lacedæmonians, to a long epistle of an enemy, threatening to destroy them with fire and sword: u. f. f. if; that is, do you think, or that returned by the fame people to King Philip, demanding some extravagant thing of them, u. n. n. or that of Cleomenes, the Spartan general, to the ambassador of Samos: "As to what you have said, the first part I do not remember; the middle I do not understand; the last I do not approve." Or that epistle of Archidamus to the Elei, who were preparing war against him. Archidamus to the Eleans: "It is good to be quiet." Or that of Cæsar to the Roman Senate, after his conquering Pharmaces, king of Pontus: "Veni, vidi, vici; I came, I saw, I conquered." See **Style of Dialogues.**

**Style, Epistolary.** See **Epistolary.**

**Style, Historical, is of a middle nature between that of a poet and an orator, differing from both not only in the ornamental parts, but likewise in the common idioms and forms of expressions. As history is a narrative of such facts as are fit to be transmitted to posterity, for the use of mankind, and the better conduct of human life, the first law in writing it is, as Cicero observes (De Orat. lib. ii. c. 15), not to dare to say any thing that is false; and the next, not to be afraid to speak the truth: that on the one hand there be no suspicion of affection, nor of prejudice on the other. The super-
superstructure of these foundations consists partly in things, and partly in the style or language. The former require an order of times, and description of places: and because in great and memorable events, we are disposed to know first their causes, then the actions themselves, and lastly their consequences; the historian should take notice of the springs or motives that occasioned them; and in mentioning the facts themselves, should not only relate what was done or said, but likewise in what manner; and in treating upon their consequences, shew if they were the effects of chance, wisdom, or imprudence. Nor should he only write the actions of great and eminent persons, but likewise describe their characters. As to the style, he says, (De Clar. Orat. c. 75.) that nothing is more agreeable in history than brevity of expression, joined with purity and peripetia. And he adds, in the place above cited, that it ought to be fluent, smooth, and even free from that harshness and poignancy, which are usual at the bar.

Dionysius (Epit. ad Cn. Pompe.) makes decency a principal virtue in an historian; which he explains by saying, that he ought to prefer the characters of the persons, and the dignity of the actions of which he treats; and, therefore, an historical style should be animated with a considerable degree of life and vigour.

Painting and imagery will form no small part of the historian's province, though his colours are not so fine and glittering as those of the poet or orator. He ought, therefore, to be well acquainted with the manners of men, and the nature of the passions, both of which he is often obliged to describe: in the former of which Herodotus excels, and Thucydides in the latter, as Dionysius has observed. From these several requisites, an historical style seems, upon the whole, to agree best with the middle character.

As to composition, which respects the structure of sentences and the several parts of them, Demetrius (De Interp. remark.) remarks, that an historical period ought neither to rise very high, nor sink very low, but to prefer a medium; i.e. these periods should neither be so full and honorious, as are frequent in oratory, nor yet so short and flat, as in dialogue. This simplicity, he says, becomes the gravity and credit of history, and distinguishes it from oratory on the one hand, and dialogue on the other.

The periods best suited for history are those which, being of a moderate length, will admit of just rise and cadency, and may be connected with ease. The harmony of periods arising from such a position of the words as renders the found pleasant and agreeable, ought also to be regarded in history. And as to dignity, which respects the use of tropes and figures, Dionysius says, that history should be embellished with such figures as are neither vehement, nor carry in them the appearance of art. This observation coincides with that of Cicero (De Orat. lib. ii. c. 14.) in comparing Xenophon and Callisthenes, two Greek historians.

Historical style, however, admits of considerable varieties from the different nature and dignity of the subject. The lives of particular persons do not require that strength and majesty of expression, nor all those ornaments of language, which suit an history of the Roman empire: and, accordingly we find the style of Nepos and Suetonius very different from that of Livy: the former being smooth and easy, fearlessly rising above the low character, and the latter often approaching near to the sublime. And other historians have observed a medium between these. Ward's Orat. vol. ii. t. 45.

Style, Lapidary and Marotic. See the adjectives.

Style of an Orator consists of the low, middle, and sublime characters, as they are applied by him in the different parts of his province. The orator has three things in view, viz. to prove what he affirms, to represent it in an agreeable light, and to move the passions; and each of these parts of his province requires a different style. The low style is most proper for proof and information; the middle style is most suited for pleasure and entertainment; because it consists of smooth and well-turned periods, harmonious numbers, with florid and bright figures. But the sublime is necessary, in order to sway and influence the passions. Here the orator calls in all the aids of nature and art; the most raised and lofty thoughts, clothed with the brightest and strongest colouring, enter into this character.

The Introduction scarcely rises above the middle style; and if it carry in it an air of pleasantry and good humour, it is generally the more apt to engage the attention.

The qualities of a good narration are clearness, brevity, and probability. The first arises from the choice of proper words, and such tropes as have been rendered most familiar by use; brevity requires moderate periods, whose parts are but little transposed: and a plain and simple drefs, without ornament or colouring, is best suited to represent things probable: all which are the properties of the low style. In the Proposition there can be no room for ornament. In the cool reasoning and debate of confirmation, the low style is certainly the most proper; but as the orator's method of reasoning often differs very much from that of the philosopher, and he endeavours not only to convince the judgment, but to affect the passions in a great variety of ways; his style is very different according to the nature and circumstances of the cause. The style of confusion is much the same with that of confirmation.

In that part of the conclusion, called disposition, the language ought to be forcible and strong, rather than florid, because brevity and conciseness are necessary qualities. But in the other branch of the conclusion, which is an address to the passions, all the springs of eloquence, says Quintilian, (Inf. Orat. lib. vi. cap. i.) are to be opened. Now we are palt the rocks and shallows, all the falls may be hoisted; and as the greatest part of the conclusion consists in illustration, the most pompous language and strongest figures have place here. Regard, however, must be had in every part of a discourse to the nature of the subject, the time, place, and persons, and other circumstances, by all which the style is to be regulated. Ward's Orat. vol. ii. t. 46. See Style, figure.

Style, ionic, a kind of bodkin of gold, silver, brass, iron, or bone, pointed at one end, for cutting the letters, and flat and broad at the other, for erasing any thing to be altered; with which the ancients wrote on plates of lead, or on wax, &c. and which is still used to write on ivory leaves, and paper prepared for that purpose, &c.

This is the origin of all the other significations of the same word in English. See a dissertation on the Style of the Ancients, in Phil. Trans. N. 150. p. 157. or Eames's and Martyn's Abr. vol. viii. p. 30.

Style, Stylus, in Surgery, denotes a long flexible instrument, which diminishes to a point at one end, so as to be of a conical form; serving either to expand and open, or to be thrust into any part.

The style is frequently to be thrust in red-hot in cancellure, and to be pulled out again immediately; it is put in and drawn out successively, as often as is necessary. In order to do this, it is useful to have two styles, to be put in alternatively.

STYLOPHORUS, in Ichthyology, a genus of fishes of the order Apodes. The generic character is as follows: The
The eyes are pedunculated, standing on a short, thick cylinder; the snout is lengthened, directed upwards, retracted towards the head by means of a membrane; the mouth is without teeth; it has three pairs of gills beneath the throat; the pectoral fins are small; dorsal as long as the back; the caudal short, with spinous rays; the body is very long, and compressed.

This of the singular genus, which consists of a single species, was first described in the year 1788, from a specimen at that time introduced into the Leverian museum, and figured in the first volume of the Linnean Transactions: the engraving is copied by Dr. Shaw in his fourth volume. The following is a description of the species.

Chorobatus, or Silvery Stylephorus, with extremely long caudal threads.

The head of this extraordinary animal bears a distant resemblance to that of the genus Syngnathus; which see. The rostrum, or narrow part, which is terminated by the mouth, is connected to the back of the head by a flexible leathery duplication, which permits it to be either extended in such a manner that the mouth points directly upwards, or to fall back, so as to be received into a sort of cleft formed by the upper part of the head. The eyes are placed at the top of the head; there are of a form very nearly approaching to those of the genus Cancer, except that the columns or panns on which each eye is placed are much broader or thicker than in that genus; they are also placed close together, and the outward surface of the eye, when magnified, does not show the least appearance of a reticulated structure. The colour of the eyes, as well as of the columns on which they stand, is a clear chestnut-brown, with a sort of coppery glint. Below the head, on each side, is a considerable compressed semicircular space, the fore-part of which is bounded by the covering of the gills, which covering seems to consist of a single membrane, of a moderately firm nature. Beneath, on each side, are three small pair of branchiae. The body is extremely long, and compressed very much, and gradually diminishes as it approaches to the tail, which terminates in a finning or procès of an enormous length, and finishes in a very fine point. This finning, or caudal process, is strengthened throughout its whole length, or at least as far as the eye can trace it, by a sort of double fibre or internal part. The pectoral fins are very small, and situated almost immediately behind the cavity, on each side the thorax. The dorsal fin, which is thin and soft, runs from the head to within about an inch and a half of the tail, when it seems suddenly to terminate, perhaps, in the living animal, it may proceed quite to the tail. From this point commences a smaller fin, which constitutes part of the caudal one. The caudal fin is furnished with five remarkable spines, the roots or originations of which may be traced to some depth in the thin part of the tail. The general colour of this fish is a rich silver, except on the flexible part belonging to the rostrum, which is of a deep brown: the fins and caudal process are also brown, but not so deep as the part just mentioned. There is no appearance of scales on this fish. It was from the singular figure and situation of the eyes, that it was given the name of the Stylephorus: the trivial name chorobatus was taken from the extraordinary thread-like process of the tail. It is a native of the West Indian seas, and was taken between Cuba and Martinico, near a small cluster of little islands about nine leagues from shore, where it was observed swimming near the surface. The whole length of this uncommon fish, from the head to the extremity of the caudal process, is about thirty-two inches, of which the process itself measures twenty-two. In Dr. Shaw's fourth volume is a very good representation of it, and in the Linnean Transactions the engraving is of the natural size of the fifth itself.

STYLES OF HUNTING. See HUNTING.

STYLE, Styletto, a small dangerous kind of poignard, which may be concealed in the hand; chiefly used in treacherous affinements.

The blade is usually triangular, and so slender, that the wound it makes is almost imperceptible. The filetto is strictly prohibited in all well-disciplined states.

STYLIDÆÆ, in Botany, a natural order, establisbhed by Mr. R. Brown, Prodor. Nov. Holl. v. 1. 565; and named from its principal genus. (See Stylidium.) Its characters are the following.

Calyx superior, in from two to six deep divisions, either two-lipped or regular, permanent. Corolla of one petal, its limb in five or six segments, irregular, rarely equal, imbricated in the bud; not quickly deciduous. Stamina two; their filaments combined longitudinally with the style, so as to form a column; anthers two-lobed, occasionally simple, lying over the stigma; pollen globose, simple, sometimes angular. Germen of two cells, sometimes but incompletely so, from the shortened partition, containing many seeds, mostly crowned either with a solitary gland in front, or with two opposite ones; style one; stigma either uniovulate or clavate. Capsule of two valves and two cells, with a parallel, occasionally incomplete, partition, which at length separates from the inferior margins of the valves. Seeds attached to the axis of the partition, erect, small, sometimes falcate; albumen of the shape of the seed, fleshy, rather oily; embryo included, minute.

The plants are herbaceous, or somewhat shrubby, not milky, with or without a leafy stem; their pubescence, when present, simple, either headed with a gland, or acute. Leaves scattered, in some infibuses whorled, undivided; their edges naked or fringed; crowded at the root in those species which have no stem. Flowers either spikèd, racemose, corymbose, or solitary, terminal, rarely axillary, their partial flowers-falks generally with three bractées. See Forsteria, Levenshookia, and Stylidium, the only known genera of this order.

STYLIDIUM, was first so called by the writer of the present article, who sent specimens under that name to LABillardiere and Swartz, and the latter published an account of the genus in the Transactions of the Natural History Society of Berlin, v. 5. Labillardiere has also adopted it, and our countryman Mr. Brown has greatly enlarged the number of known species in his Prodrorum. Meanwhile this same genus was published in our Exotic Botany by the name of Ventenatia, now otherwise applied; see that article. Stylidiun therefore is establisbhed, for the curious New Holland genus before us; and refers to the little calix, which supports and combines both anthers and stigma. Loureiro has indeed preoccupied this very name, Fl. Cochinch. 221, in favour of some rubaceous shrub that happened to have a feven-cleft flower; but there is great probability of his genus not being a good one, and we hope our Stylidiun will remain undisputed.—Sm. Introduct. to Bot. 4. A. 16. Swartz to Bot. 5. 343. Swartz Nat. Sertif. Berol. v. 5. Willd. Sp. Pl. v. 4. 146. Labill. Nov. Holl. v. 2. 63. Brown Prodor. Nov. Holl. v. 1. 566. Ait Hort. Kew. v. 5. 222. (Ventenatia; Sm. Exot. Bot. v. 2. 13.)—Cliffs and Order, Gymandria Diandra. Nat. Ord. Cœpitalae, Linn. Jull. Stylidiœ, Brown.

Gen. Ch. Cal. Perianth superior, of one leaf, in two deeply separated lips, one divided, the other three-cleft, permanent. Cor. of one petal; tube cylindrical, varius in length,
STYLIDIUM.

length, often crowded with glands; limb in five unequal, ovate-oblong, spreading segments, one of them a kind of lip, much smaller than the rest, and usually deflexed, mostly accompanied with a small appendage on each side, at the base. Stem. Column linear, longer than the limb, approximated to the lip, curved and recurved, irritable underneath, flying over to the other side of the flower when touched, its summit then becoming deflexed; anthers sessile at the top, of two vertical lobes, subquently greatly divericated, burrtling longitudinally. Pet. German inferior, roundish-ovate; style none, except the column; stigma between the anthers, and at first covered by them, afterwards rather prominent, obtuse, undivided. Sep. Capsule ovate-oblong, or linear, of two cells and two valves, with a parallel incomplete partition. Seeds numerous, small.

This is chiefly a New Holland genus, and highly remarkable for the irritability of the column in every species, as far as has been observed. That part, when touched underneath, at its outer curvature, flies over, by a sudden spring, to the opposite side of the flower, thus scattering the pollen, with force, upon the stigma. The species are forty-five in Mr. Brown's work; Swartz has two East Indian ones, all either herbaceous or somewhat shrubby, with or without a leafy stem. Leaves undivided. Inflorescence various. Corolla purple, white, or violet; rarely yellow; generally clothed externally with glandular hairs; its tube slightly twisted as the flower expands. Brown.

We have remarked in Exot. Bot. that no flower can be more truly gymnandrous, and that Stylidium shrivels the character of the class Gynandria really to exist in nature, which some botanists, contemplating only certain genera, erroneously so clasped, have doubted. We could never take the Gynandria for a natural clafs, or order, on that account, well knowing that not half a dozen of the really natural orders can be absolutely defined by a technical character.

Mr. Brown divides Stylidium into two principal sections, each of which is subdivided into many more. We shall select examples. Three species only have as yet found their way into our garden.

Section 1. Capsule falcate, nearly ovate, sometimes fibrous, sometimes oblong.

S. pilosum. Hairy-flaked Stylidium. Brown n. 1. Labill. Nov. Holl. v. 2. 65. t. 213.—Stalk somewhat branched, clothed with glandular hairs. Leaves flat, lanceolate-swordshaped. Native of the fourth part of New Holland, where it was gathered by both the authors cited. The leaves are numerous, erect, a span long, narrow, acute, smooth, tapering at each end. Stalks hollow, round, erect, a foot and half high, densely hairy. Cluster somewhat composed, of numerous flowers, whose calyx-lips are so deeply divided, that the whole calyx appears to consist of five sharp leaves.

Leaves much shorter, broader, and more spreading, than in the last, without any appearance of footstalks. Cluster of few flowers.

S. graminifolium. Grass-leaved Stylidium. Swartz as above, f. 1. Willd. n. i. Br. n. 7. Ait. n. 1. (Ventenatia major; Sm. Exot. Bot. v. 2. 13. t. 66. "Candollea ferrulata"; Labill. in Ann. du Mul. v. 6. 414. t. 64. f. 2."")—Leaves linear, finely toothed. Flowers nearly spiky. Whole flower-flake hairy. Lip with appendages at the base. Native of the neighbourhood of Port Jackson, as well as of the south coast of New Holland. Sent to Kew in 1803, by Mr. Peter Good. A green-house, perennial, herbaeous plant, flowered on mottled-flake of the summer. The edges of the narrow, rigid, erect leaves, are rough with minute teeth. Stalk from one to two feet high, or more, erect, straight, round, hairy and glandular from top to bottom. Flowers light purple, numerous, nearly sessile, in a long lax spike.

S. lineare. Linear Stylidium. Swartz as above, f. 2. Willd. n. 2. Br. n. 8. (Ventenatia minor; Sm. Exot. Bot. v. 2. 15. t. 67.)—Leaves thread-shaped, compressed, minutely toothed. Cluster simple. Partial flower-flakes nearly as long as the germs. Common flake smooth, fleshy. Lip with appendages at the base. Found near Port Jackson, and sent us with the former by Dr. White. Smaller in all its parts than graminifolium, with flowers nearly in the fame colour, or a little darker. Capsule leaf inflated.

Sec. 1. C. Leaves radical, crowded, without intermediate scales. A few scattered, never umbellate, bracteas sometimes on the flake. Calyx-lips deeply divided. Ten species of Brown, to which we add Swartz's two East Indian ones.

S. peltatum. Spatulate Stylidium. Br. n. 14.—"Leaves spatulate, entire, clothed on both sides with glandular hairs. Cluster many-flowered, smooth, as well as the radical flower-flake. Mouth of the tube clothed with glands. Lip with appendages."—Gathered by Mr. Brown on the south coast of New Holland.

S. glaucum. Glaucaous Stylidium. Br. n. 15. Labill. Nov. Holl. v. 2. 64. 214.—Leaves lanceolate-spatulate, entire, clothed on both sides with glandular hairs. Cluster of few flowers, rather corymbose, smooth; its common flake bearing a few bracteas. Native of the south coast of New Holland. Mr. Brown is not quite certain whether Labillardiere's synonym belongs to this or the last. His figure represents a small species, four or five inches high, with a tuberous root; small flowers, on long, bracteate partial flasks; and a large tuft of radical, nearly lanceolate, leaves, about an inch long, which he says are most glaucaous beneath.

S. tenerum. Little Malacca Stylidium. Swartz as above, f. 3. Willd. n. 3.—Leaves elliptical, obtuse; radical ones crowded. Stalk simple, slightly compressed. Cluster somewhat branched. Native of the East Indies, near Malacca. Stalk or stem an inch or two high, comes half an inch long; the lower ones crowded; upper alternate. Cluster of three or four flowers, simple, sometimes furnished with a short branch. Willdenowia.

Native of Ceylon. Stalk a span high, round, erect. Leaves as long as the stalk, crowded at the root. Bracteas on the common flake few, alternate, very minute. Willd.

Nothing being recorded concerning the calyx or capsule, we cannot be certain that the two last species properly belong to this division, or even to this section.

8 Sec.
S. corymbosum. Dwarf Corymbose Stylidium. Br. n. 32.—"Stalk round, corymbose. Leaves radical, linear, with a brilily point. Calyx-lobes deeply divided."—Gathered on the south coast of New Holland, by Mr. Brown. The stalk is two or three inches high.

Sect. 2. B. Stem leafy. Flowers either alternate or solitary. Calyx-linear, nearly cylindrical, of the same thickness at the top. Four species.

S. inundatum. Water Stylidium. Br. n. 33.—"Stem branched; leafy below its division. Leaves linear. Larger segments of the corolla obvate; smaller linear; mouth naked; lip without appendages, united to the base of the tube."—Discovered by Mr. Brown on the southern coast of New Holland. The stem is only about an inch and a half high.

S. diffusum. Spreading Stylidium. Br. n. 35.—"Stem thread-shaped, branched, loosely spreading. Leaves linear; those of the stem remote. Two larger segments of the corolla divided; mouth crowned; lip without appendages, united to the base of the tube."—Found by Mr. Brown in the tropical part of New Holland.

Sect. 2. C. Stalks single-flowered; from the boas of the crowded bracteas, or leaves, about the top of the stalk or branches. Calyx nearly cylindrical, of equal thicknesses at the top. Three species.

Sect. 2. D. Stem leafy. Clusters terminal. Calyx compressed, lanceolate or linear, contracted at the summit. Five species.

S. brevifolium. Short-flaked Stylidium. Br. n. 40.—"Stalk simple. Leaves thread-shaped, compressed; the upper ones closely crowded. Clutfer flaked, somewhat panicked, with a villain rachis. Calyx lanceolate, downy, with equal valves."—Gathered by Mr. Brown, after the flowers were faded, on the south coast of New Holland.

S. fulcatum. Falcate Stylidium. Br. n. 42.—"Stalk scarcely branched, slightly downy as well as the rachis. Leaves linear. Spike flaked, somewhat racemose. Calyx lanceolate, divaricated, both cells fertile, the uppermost closed, but half the width of the other."—From the same country. Brown.

Sect. 2. E. Limb of the corolla in two principal deep segments, each of them cloven. Calyx linear. One species.

S. albofides. Chickweed Stylidium. Br. n. 45.—"Stem erect. Leaves ovate; the floral ones opposite. Flowers axillary, sessile, solitary, without bracteas."—Gathered in the tropical part of New Holland by Sir Joseph Banks, and seen by Mr. Brown in a dried state only.

STYLIUM, in Anatomy, a procne of the temporal bone. See CRANIUM.

STYLIITUS, column, Sumi Columnaris, or Pillar Saints, in Ecclesiastical History, an appellation given to a kind of solitaryists, who fled into fences upon the tops of pillars, railed for this exercise of their patience, and remained there for several years amidst the admiration and applause of the stupid populace.

Of these we find several mentioned in ancient writers, and
even as low as the twelfth century, when they were totally suppressed.

The founder of the order was St. Simeon Stylites (see Simon), a famous ascetic in the fifth century, who first took up his abode on a column six cubits high; then on a second of twelve cubits; a third of twenty-two, a fourth of thirty-six, and on another of forty cubits, where he thus passed thirty-seven years of his life.

The extremities of these columns were only three feet in diameter, with a kind of rail or ledge about, that reached almost to the girdle, somewhat resembling a pulpit. There was no lying down in it. The faqirs, or devout people of the East, imitate this extraordinary kind of life to this day.

STYLOBATION, or STYLOBATA, in Architecture, the same with the pedestal of a column. It is sometimes taken for the trunk of the pedastal, between the cornice and the base, and then called trunci. It is also called by the name of abacus.

STYLOCORNYA, in Botany, so named by Cavanilles, from roto, a column, and coroa, a crown, because of the club-shaped figure of that organ.—Cavan. Ic. v. 4. 45.—Clais and order, Pandemia Monogynia. Nat. Ord. Rubiaceae, Juss.

Gen. Ch. Cal. Perianth inferior, of one leaf, tubular, with five teeth, permanent. Cor. of one petal, funnel-shaped; tube thrice as long as the calyx; limb in five deep, oblong, equal, widely spreading segments, twice the length of the tube. Stam. Filaments five, very short, inserted into the top of the tube, between the segments of the limb; anthers erect, linear, acute, the length of the limb, heart-shaped at the base. Fil. Germin inferior, globose; style club-shaped, as long as the stamens; stigma simple, acute.
Peric. Berry spherical, pulpy, crowned with the calyx, of two cells; seeds numerous, angular, hard, imbedded in pulp.

Eff. Ch. Corolla funnel-shaped; limb in five deep equal segments, longer than the tube. Berry of two cells, with many seeds, crowned by the calyx. Stigma simple. Anthers erect, pointed.

S. racemos/a. Cluttered Stylocoryna. Cavan. Ic. t. 368.—Found in the Philippine islands, and especially near Corisco, three leagues from Manila, by Louis Nee, in November 1793, when it was laden with flowers as well as berries. This is a small tree, whose trunk is twelve feet, or more, in height, with a grey bark, and an ample tuft of branches.

Leaflets opposite, stalked, elliptic-lanceolate, pointed, entire, smooth, with one rib and many veins, three or four inches long. Flowers about half an inch in length, combined and clasping the stem at the base. Clusters axillary, solitary, alternate, much branched, forked, many-flowered, smooth, with a pair of small awl-shaped bracteas under each subdivision. Calyx smooth. Corolla yellowish-white, hairy in the throat. Berry smooth, the size of a linseed pea.

This genus should be introduced into the Linnean system near Berberis, Wild. Sp. Pl. v. 1. 980.

STYLOY, in Anatomy, from the Latin styi, an instrument employed by the ancients in writing on their tablets, a name applied to some bony processes, and parts connected with them. The styloid processes of the temporal bone is the most remarkable of these: there is also such a process belonging to the radius and ulna. The styloid ligament is the slender thread passing from the styloid processes of the temporal bone to the os hyoideus.

STYLO-GLOSSUS, a muscle of the tongue. See DREGULATION.

VOl. XXXIV.
Linn. Sp. Pl. 1896. Loto pentaphyllo filicinóso villoso
amilis, Anonis non spinosa, foliis, cith infrar gluminosæ et
décoruis; Sloane Jam. v. 1. 186. t. 119. f. 1. Trifolium
n. 2; Browne Jam. 290.—Leaves ovate, fringed; downy
and gluminous on both sides. Spikes of few flowers.
Braétax fringed. Stem downy and gluminous, ereéct.—
Native of fandy rather hilly spots, in the southern part of
Jamaica, often intermixed with the foregoing. Swartz.
This agrees with the former in general habit, except in
growing upright, and in the gluminous, fragrant, more
hispid, blackish surface of the herbage. The Ripulæ are
frecked with red. Flowers yellow, turning red as they
deach, fewer in number than those of the preceding, or
the following. Their færand are purple at the base.
n. 3. (Arachis fruiticosa; Retz. Obs. fæc. 5. 26. Trifolium
procumbens zeylancicum hirfutum, loti facie; Burm.
Zeyl. 226. t. 106. f. 2.)—Leaflets elliptic-oblong, fringed;
rather hairy beneath. Spikes many-flowered. Braétax
fringed. Stem finely downy.—Native of dry situations in
Ceylon and Tranquebar. This is, no doubt, different
enough from the last, being devoid of all rigid gluminous
pubescence, not clothed with aspicyaryed hairy spots; but
there appears more difficulty, as Retzian suspected, in distin-
guishing it from the first species. The fæm is perhaps
as long, but seems procumbent, like that, as Burrman
describes it; not ereéct, as in the specific character given
by Retzian and Wildenow. The branches are numerous, finely
downy. Leaflets tipped with a small point. Flowers,
in the dry species from Konig, tinged with purple.
Swartz Stockh. Tr. as above, t. 11. f. 2. (S. hispida; Pursh
48c. Trifolium hirtum; Linn. by. Pl. rooch; Arachis
spicica; Walt. Carol. 182.)—Leaflets elliptic-lanceolate,
smooth. Spikes of two or three flowers. Braétax linear-
lanceolate, carelessly fringed. Stem smooth on one side;
downy on the other.—In dry gravelly fields and woods,
from Pennsylvania to Carolina, flowering in July and
August. Flowers yellow, small. Pursh. The fæm is
either ereéct or procumbent, leafy, but little branched,
a foot or more in height, very remarkable for having one side
only, opposite to the inflorescence of each leaf, densely downy.
Leaflets above an inch long. Common footstalk short.
Branches with upper fæmata clothed and fringed with strong
yellow bristles.
Swartz Stockh. Tr. as above. (Trifolium guianense;
Aubl. Guian. 2. 776. t. 509.)—Leaves lanceolate, pointed.
Spikes capitate, many-flowered, villous. Stem ereéct,
branched, hairy all round.—Found by Aublet, in the mead-
sows of Macouria in Guiana, flowering in June. The root
is annual. Stem a yard high, branched, very hairy in every
direction. Leaflets near an inch and a half long. Flowers
small, yellow, many together in each short roundish head.
Tube of the calyx very long and slender. Legume hairy, of
one joint only.
STYLUS, in Botany and Vegetable Phylogeny, the style
of flowers, is the part serving to elevate the Stigma above
the Germen. (See those articles.) This is not an effi-
tual organ, many flowers having the stigma, or stigmas, quite
sefsile upon the ember. In such cases the order of the
plant may be determined by the number of those stigmas; wittésis Vitisunm and Sambucus. But
where a single style is present, however numerous the
stigmas may be at its summit, the flower is considered as
monogynous. That impression must take place through
the style, or stigmas, is evident; but it is not as certain that

neither the pollen, nor even its elastic and subtle contents,
can be, in every instance, conveyed all through the style,
to the embryo of the seed. There is much more reason to
presume, that fecundation is accomplished by a sympathy
between the embryo and the stigma. Styles are sometimes
partially or entirely deciduous as the germin ripens, but
they often become enlarged and hardened for a subsequent
purpose. In Clematis, Dryas, &c. they grow out into
feathery wings, serving to waft the seed to a distance; in
Gewm, and many of the umbelliferous tribe, they form
hooks, by which their seeds flock to the coats of animals.
The latter purpose, on the contrary, in various syngene-
fous, or proper compound flowers, is accomplished by
peculiar appendages to the seed itself, the styles of this
family being, if we mistake not, always transient and de-
ciduous; as also in grageis, whose appendages, defined to
a similar purpose, are affixed, not to the seed itself, but to
its enveloping hulks. This last-mentioned natural order
affords a mos remarkable instance of disproportionately long
stigmas in the Maize, Zoa, where those parts resembale a penda
fliik tail, more out of the way, as it seems, of the
pollen, than usual. But the downy, though small, stigmas,
were calculated to meet the copious drops of the copious
duffy flower, which falls from the abundant anthers above.
The Zoa, however, has been well adduced as a wittens,
that the substance of the pollen itself cannot pass through
so long and impervious a part as the style of this plant.
STYMBARIA, in Ancient Geography, a town of Mac-
donia, belonging to the Deuriopas. Strabo.
STYMMATA, formed of γαμέω, I thicken, a word used
by some authors to express the stiff ointments. The an-
cients used the word both for the more solid and stiff oint-
ments, and for the ingredients which gave those ointments
that confinence: they also called by the same name the
several sweet ingredients which they put into their oint-
ments, to give them a fragrancy, and preferve them from
corruption; such were the powders of spikenard, mint,
amomum, and the several spices.
STYMPHALIA, γυμφάλαι, in Antiquity, a festival at
Stymphalus in Arcadia, in honour of Diana, called from
that place Stymphalia.

STYMPHALIA, in Ancient Geography, a country of Mac-
donia, in which was placed the town of Stymphalos.
STYMPHALIDES Aves, in Fabulous Animaity, birds of an
extraordinary fize, which, in their flight, are said to
obfusc the sun. They fed only on human flesh; but Her-
cules, by the help of Minerva, drove them out of Arcadia
by the noise of cymbals.

STYMPHALUS, or STYPHALE, in Ancient Geo-
graphy, a town in the N.E. part of Arcadia, nearly S.E.
of Pheneos, and N.E. of Orchomene. Here was a temple
of Diana Stympalide, and also a statue of this goddess
in gilt wood. The temple was ornamented with the figures
of birds, called Stymphalides, and behind it were statues
of young women with the tails of birds. Near Stymphalus
was a fountain, the water of which, according to Paufani-
as, was conducted by Adrian to Corinth, though a distance of
at least seven leagues, through mountains and across rivers.
—Allo, a river of Arcadia, which commenced a little S.E.
of mount Cyllene, and discharged itself towards the south
into a lake of the same name. This lake was rendered
famous by the destruction of certain large birds, which
Hercules had killed upon its banks. Others say that they
were driven away by the found of Stymphalos. Some have
explained this fable by telling us that robbers laid waste the
country, and robbed passengers on the confines of this lake.
These Hercules with his companions destroyed; and hence,
STY

it is said, sprung the fable of the birds Styphilates, whom
this hero was said to have banished, having invented a kind
of brazen tirisbels to fright them away, and which are said
to have been given to him by Minerva. The crooked
talons that are ascribed to them are perfectly applicable to
robbers, as well as the wings, the head, and iron beak, with
javelins of the same metal, which they darted at those who
attacked them, as we are told by Euripides and Claudian;
the import of which is, that they were armed with lances
and javelins. We are further told, that they were trained
up by the god Mars, to intimidate that they were very war-
like. Hercules contrived a method of dislodging them from
the woods where they sheltered themselves, by frightening
them with the sound of his tirisbels, and thus cut them off.

STYPANDRA, in Botany, a New Holland genus of
Mr. Brown's, named from thorn, thorn, or any similar sub-
stance, and a, a man, because the filaments are densely
bearded or tufted in their upper part. —Brown Prodr. Nov.
Holl. v. 1. 278. —Cliffs and order, Alexandria Monogynia.
Nat. Ord. Coronaria, Linn. Affreadelae, Jaff. Affreadelae,
Brown.

Ch. Cal. none. Cor. of one petal, in six deep,
wide, oblong, spreading segments, deciduous. Stem.
Filaments fix, tapering, curved, and smooth in the lower part,
densely bearded in the upper; anthers oblong, terminal,
attached by their emarginate base, becoming revolute after
the pollen is discharged. Pith. Germin superior, roundish;
tyle thread-like, the length of the filaments; stigma simple.
Peric. Capsule roundish, triangular, of three cells and
three valves. Seeds few in each cell, oval, smooth, with
a naked scar, and a straight embryo.

Eff. can. Corolla in fix deep equal segments, deciduous.
Filaments tapering and smooth at the base; densely bearded
above. Stigma simple. Capsule of three cells and three
valves, with several smooth seeds.

A genus of perennial herbaceous plants. The root
is tuberous, creeping, with clumped, thread-shaped fibres.
Leaves linear-two-angled, straight; those of the stem
in some instances numerous, two-ranked, with close, entire
sheaths; in others few, half sheathing at the base. Flowers
corymbose, or somewhat panicked, their partial filaufs rather
umbellate, jointed under the corolla, blue or white; the
beard of the filaments yellow.

Mr. Brown thinks this genus may possibly hereafter be
divided, its first section being more akin to Diandria, the
second to Anthorium; and that under the latter should be
arranged Anthorium constrictum and cardium of the Flora
Peruviana, p. 67. t. 299.

Seet. 1. Flowers drooping; their partial filaufs without
beards. Stem-leaves two-ranked, with undivided sheaths.
Seeds opaque.

1. S. glabra. Brown n. 1. —All the leaves distinct,
reverted; one of their edges reflexed at the base. —Found
by Mr. Brown near Port Jackson, New South Wales.

2. S. imbricata. Br. n. 2. —Leaves imbricated; their
margins simple at the base. —Gathered by the same botanist,
on the southern coast of New Holland.

Seet. 2. Flowers erect; their partial filaufs bracteated
at the base. Stem-leaves alternate, half sheathing at the base;
radical ones two-ranked, equal. Seeds fibrous.

3. S. capitata. Br. n. 3. —Radical leaves lwoed-shaped,
rough-edged; those of the stem shorter, smooth, below
its first or second division. Branches of the corymb un-
equal. Flower-filaufs umbellate, smooth as well as the cor-
olla. —Found by Mr. Brown near Port Jackson. The
radical leaves are from nine to twelve inches long, either
folded or flat. Flower-filaufs from three to five in each
umbel.

4. S. umbellata. Br. n. 4. —Radical leaves linear,
smooth-edged. Branches of the corymb alternate. Flower-
filaufs umbellate, smooth as well as the corolla. —Native
of the same country. Radical leaves narrow, from four
to eight inches long. Flower-filaufs two or three to-
gether.

5. S. flexa. Br. n. 5. —Radical leaves linear; those
of the stem nearly like them. Stalks of the corymb alter-
nate, rather hispid as well as the corolla. —Gathered by
Mr. Brown, on the southern coast of New Holland. The
radical leaves are either folded or flat; those of the stem
from three to five in number.

STYPHELIA, so named by Dr. Solander, from στύφος,
harsh and rigid, alluding to the habit of all the species.
v. 1. 537. —Ait. Hort. Kew. v. 1. 322. —Cliffs and order,

Gen. Ch. Cal. Perianth inferior, of five, equal, erect,
lanccolate leaves, with four, or more, smaller, imbricated
scales at the base, permanent. Cor. of one petal, tubular,
shortly cylin. Tube nearly ciliated; tube nearly cylindric;
base of the tube within the sepal. —In five deep, revolute
equal segments, bearded on the upper side. Neatly of five
glomerules at the base of the stem. Stem. Filaments five,
thread-shaped, equal, inserted into the tube, and projecting
beyond its orifice; anders incumbent, oblong, of one cell,
burting lengthwise. Pith. Germin superior, roundish,
serrowed, style thread-shaped, longer than the filaments;
 stigma obtuse, notched. Peric. Drupae but slightly succu-
lient, oval or globular. Seed. Nut hard and fould, of five
cells, with a pendulous kernel in each.

Eff. Cal. Outer calyx of four, or more, imbricated
scales. Corolla tubular, elongated, with five internal tufts
of hairs near the bottom; limb revolute, bearded. Fil-
aments prominent. Drupae rather dry, of five cells.

Mr. Brown, in consideration of the vast extent of
the original genus Stypelia in New Holland, almost rivalling
perhaps that of Erica in Southern Africa, has separated
therewith several genera, of some of which we have given
an account in their proper places. (See Leucopogon, Lib-
anthus, Micranthus, Monotoca, Neethamia, Oligar-
threna, Pentachondra, and Stypaxera.) An observa-
tion of the differences in the numbers of the scales of
the outer calyx, termed by him, not exactly in conformity to
Linnaean principles, bracteas; of the smoothness or hairiness
of the limb, or some other part, of the corolla; of the propor-
tion of the filaments, and of the number of cells in the drupe,
which latter character he alone has had sufficient opportu-
nities of examining, has afforded this correct and accurate
observer sufficient means for the establishment of very
commodious, if not always perhaps naturally distinct genera.
Of these, Leucopogon seems to us one of the best, and it is
fortunately very extensive; Monotoca, Neethamia, and Ol-
igarthrena, however, though small genera, are well defined.
The learned author is, nevertheless, so well aware of cer-
tain connecting or intermediate marks of affinity, which con-
cern other genera, that he candidly proposes the arrange-
ment in question for future consideration only. It seems to
us at least as good, and likely to be as permanent, as the
Linnaean genera of the natural order of Aftersella, which
have not yet been differentiated.

The Phylidae are, as Mr. Brown observes, erect or ascen-
ding thyrse, branched, and in general nearly smooth. Their
leaves are scattered, sharply-pointed, on very short foot-filaufs.

Flowers salivary, either drooping or spreading, handfo-

3 G 2

usually
STY

Usually one, rarely two or three, on a stalk. Their necha-
riferous glands are rarely combined. Seven species only, as
far as has yet been discovered, remain in this genus, all
native of New Holland, and all, except one, of New
South Wales, near Port Jackson.

1. S. longifolia. Long-leaved Styphelia. Br. n. 1.—
Leaves lanceolate, elongated, taper-pointed, smooth-edged;
rather concave on the upper side. Branches downy.
A native of the country near Port Jackson, for a fine spe-
cies of this herb. This species has not yet appeared in our gardens. It appears
to be a tall shrub, with many round, straight, downy, leafy
branches. Leaves nearly sessile, broad at the base, thence
becoming slightly ovate, and tapering gradually to a sharp,
straight, pungent point; their length from an inch and a
half to two inches and a half; both surfaces smooth; the
upper even; lower closely fringed with parallel subdivided
ribs. Flowers solitary, nearly sessile, very hand-some. Calyx
smooth, an inch long. Corolla twice as much; as far as we
can judge by the dried specimen, it seems yellowish; or
of an orange hue. The limb is covered on the upper side with
long and slender hairs of its own colour; tube externally
very smooth.

2. S. lea. Gay Styphelia. Br. n. 2.—Leaves elliptic-
oblong, imbricated, glaucous, rough-edged, nearly flat;
shorter than the flowers. Branches downy. Stem eros.
—Gathered near Port Jackson, by Dr. White and Mr.
Brown. The leaves are sessile, about an inch long, various
in breadth; somewhat downy above, at least when young;
faintly fringed at the back. Calyx of the same length,
reddish, finely bearded at the rim. Corolla twice as long,
orange-coloured or reddish, elegantly contrasted with the
glaucous foliage. Stigma somewhat capitate, the stamens,
as well as the filaments, projecting above half an inch beyond
the revolute corolla.

3. S. aspera. Diffuse Styphelia. Br. n. 3.—
"Leaves lanceolate, flat; glaucous and manifestly fringed
beneath; rough, with a tooth-like fringe at the margin.
Stem diffuse, with ascending branches."—Gathered by
Colonel Paterson in Van Diemen's island.

4. S. spicata. Broad-leaved Styphelia. Br. n. 4.—
"Leaves broad-obovate, acute, imbricated, rough-edged;
rather concave above. Flowers almost sessile."—Found by
Mr. Brown, near Port Jackson. We are not certain of
having seen specimens of this, any more than of the last.

Ait. n. 1. (S. viridis; A. and R. Rep. t. 318.)—Leaves
obovate-oblong, flat, obtuse, with a siphon point; smooth
and even above; minutely rough at the margin; spreading
widespread as well as the solitary flowers. —Found near
Port Jackson, by some of the earliest settlers in that country,
who sent seeds in 1791 to Meffre, Lee and Kennedy; and
from these a solitary plant was raised. The perfectly green
flowers, with brown anthers and style, render this species
remarkable. It blossoms in a green-house in the spring,
but requires delicate management with respect to water in
winter, being certain to perish if kept wet at that season
for any length of time. The flum is two feet, or more, in
height, erect, branching, leafy, finely downy. Leaves
rather longer, and more obvate, or obtuse, than in our
second species, and leaf glaucous. Flowers rather longer
than the leaves, but the proportion of their calyx and
corolla forms, in some degree, variable.

Ait. n. 2. And. Rep. t. 72.—Leaves elliptic-lanceolate,
flat, smooth in every part, rather glaucous. Branches
smooth. Flowers approximated, from one to three on each
stalk.—Native of the country near Port Jackson. First
raised, it is said, by George Hibbert, esq. in 1796. A
green-house shrub, flowering from June to August, and
very beautiful. In size it yields to none of the genus.
The crowded leaves are more or less ovate, or elliptic-
lanceolate, paler and finely fringed beneath. Flowers al-
ssembled towards the ends of the branches, but soon fur-
mounted by them; each axillary flum often bearing three
large spreading flowers, sometimes but one or two. The
flowers have six stamens on the rededit. Three of the calyx,
as well as the filaments, rose-coloured; the rest of the flower yellow.

n. 3.—Leaves linear-obvate, slightly revolute; convex and
roughish above. Flowers drooping.—Communicated in a
dry flate, with coloured drawings, from the neighbourhood
of Port Jackson, in 1791, by Dr. White. Sir Joseph
Banks is mentioned as having introduced this plant at Kew
in 1802, but it has not yet bloomed. The flum is bstitial,
with hairy branches and white young. Leaves much smaller
and narrower than any of those above described, with
pungent points like all the rest. Flowers copious, solidary,
regularly splendid and elegant, twice or thrice as long as
the leaves, a little drooping, the hairy segments of their
corolla of a deep rich crimson, the tube paler and yellowish.

Style capillary, very long.

STYPTIC, (20)
formed of 20th, asfringero, in Medi-
ces, asfringo, in Medicinis, asfringere, in Medi-
cine, asfringere; a remedy that has the virtue of stopping
blood, or of binding up the aperture of a wounded velief.

The ferveo, visite, Solomon's seal, &c. are syptics.

There are various styptic waters, and powders of great
efficacy, in most of which vitriol is the principal ingre-
dient.

The usuall styptic water is made of colochoar calcined,
and vitriol dissolved with burnt alum, fugar-candy, the urine
of a young man, &c.

Dr. Colbath's styptic powder has been famed; though
Mr. Cowper, in the Philosophical Transactions, gives us
a number of infusions, in which it was applied with very
little or ill success in human subjects; but he gives us other
remedies for dogs, where it answered well.

M. Turnerfort observes, from the analysis he has made of
styptic and astringent plants, that acids and earths always
prevail in them; though some of them yield an urinous
spirit. On this principle he affers, that their salt is
analogous to alum, and that there is somewhat of salt
ammoniac in their texture. But Chomel notes, that this does
not hold universally.

STYPTIC Powder of Helvetius, in Pharmacy, a composi-
tion of alum and dragon's blood. In the Edinburgh Dis-
pensatory, two parts of alum are directed to be made into
powder with one of the dragon's blood; others use equal

This medicine is said to be extremely servicable in uteri
haemorrhages, either to correct the too frequent re-
turn of the menses, or their too great abundance; also
to stop the bleeding, to which women with child are subje.
ct, and to moderate the flow of the lochia. It has also been
found to have surprizing good effects in the flor albus.

In violent bleedings it may be given in the quantity of
half a drachm every half hour, and it seldom fails of stopping
the bleeding before the quantity of three drachms, or half an
ounce, has been taken.

Heister also, in his "Compendium Medicinae Practicae," p. 143, recommends this powder, or alum alone, with
a decoction of linseed, from Helvetius's "Traité des Peres
de Sang." 

STYPTIC.
SYTY, Easton's, a medicine famous for curing fresh wounds in a very small time, and immediately stopping their bleeding.

The method of curing fresh wounds in a few days without suppuration, where neither nerves, large vessels, bones, nor any of the viscers are concerned, has been a practice long ago used.

The French were a long time very fond of a flyptic ball, made of the filings of iron and tartar, mixed to a consistence with French brandy, which was afterwards published by Helvetius, and from him has been generally known by the name of Helvetius's Flyptic. This was extolled with us as one of the greatest medicines in the world for the cure of wounds, bruises, and external injuries of all sorts; but the author never said so much about it; he only modestly introduced it into the world as a useful thing for a first dressing of fresh wounds with people who lived too far off for the immediate assistance of a surgeon; and he mentions several cafes in which it ought not to be used. In fine, he published it as a good medicine under proper restrictions; but we made it an universal one. The only universal remedy of this kind, that we have had since, is the famous flyptic of Dr. Eaton, which the inventor says is good to stop all manner of bleeding both without and within, without any manner of exception.

Sir Richard Blackmore, soon after the publication of this great secret, wrote a treatise on consumption, in which he highly extols this flyptic of Dr. Eaton, declaring positively, that it will be of more service to the world than all the discoveries that had been made before it. On this Dr. Sprengel, who had before examined Eaton's Flyptic, and judged it to be the same as Helvetius's Flyptic, but not having had the assistance of Helvetius himself, for having been tried and discarded in France, Germany, and Holland, had been set on foot as an universal medicine here, thought it worthy a more strict and public examination, and ordering an apothecary of credit to prepare some of Helvetius's flyptic in the common way, he produced, before a judicious audience, a bottle of that, and another of Eaton's flyptic; and giving them both the same trial, they both answered in the same manner, and proved, beyond all possibility of doubt, that they were in effect the same medicine.

Upon the whole, the virtues of these flyptics externally are too triving to be trusted to, and internally too precocious to meddle with, without the greatest caution. Philos. Trans. N° 383, p. 110.

Ob. Jussieu is doubtless more correct in his idea of the natural order of this genus than Linnaeus, who classed it in an appendix to his Bisornes, and yet thought it allied to Citrus. Although only one or two of the seeds come to their full size in a cultivated, or even a naturalized state, in England or Italy, more may be presumed to be perfected in the warm and arid climates of the Levant. Verrugineum. Storax officinale. Official Storax. Linn. Sp. Pl. 635. Wildl. n. 1. Ait. n. 1. Andr. Repof. t. 631. Woody. Med. Bot. t. 71. Sm. Fl. Grec. Sibth. t. 375, unpublished. Cavan. Diff. t. 168. f. 2. (Styrax; Mill. l. c. t. 260. Camer. Epit. 38. Matth. Valgr. v. 1. 80. Ger. Em. 1526.)—Leaves ovate, bluntish, wavy, entire, downy beneath. Clusters simple, of few flowers. Native of Syria, and mottled parts of the Levant. Mr. Hawkins informs us it is rather common all over Greece and the Peloponnesus, being known under the same name of magnum, in modern Greek. Dr. Sibthorpe found it called coccus, a slight alteration of its ancient appellation. The shrub is naturalized in hedges about Tivoli, and was cultivated in England by Gerarde, before the year 1597. It is occasionally met with in curious collections, being best preferred in a conservatory. A very large tree of this kind, trained against a wall in Chelsea's garden, and covered every year in May or June with a profusion of most elegant flowers, is by far the finest we ever beheld. The stem is bulby, forming a tall shrub, or small tree, with irregular, stowace, round, leafy branches, downy when young. Leaves deciduous, alternate, long, thick, entire, well compared by old botanists to those of a Quince; their upper surface is smooth, of a fine green; lower clothed with hoary flary down, much diminished as to quantity in a garden, the veins spreading from the rib at rather acute angles. Clusters terminating the young, short, lateral, leafy shoots of the present year, simple, downy, bearing from two to five or six white flowers, of the size and aspect of an orange-blossom. Calyx, as well as corolla, white and downy. Fruit leathery, the size of a gooseberry, sometimes ripened in Italy, but never in England, nor are the seeds perfected, even in gardens at Turin, so as to vegetate.

This shrub is chiefly remarkable for producing the valuable and highly fragrant gum called Storax; see that article. We presume the plant to have been cultivated by Adrian, at his celebrated villa near Tivoli, and thus to have become established in the neighbourhood. He is recorded to have introduced some curious exotics into his garden there; and the Abbé Richard, in his Description d'Italie, v. 6. 403, mentions the true Balm-tree, Amyris Balsamofforum, as one of the number; it was this was probably the Styrax only. See Sm. Tour on the Continent, ed. 2. v. 2. 344. De la Lande says, the wood is burnt at Rome in winter to perfume the apartments, a handful at a time being thrown on a brazier.

2. S. grandifolium. Large-leaved Storax. Ait. n. 2. Wildl. n. 2. Pursh n. 1. (S. officinalis; Walt. Carol. 1450.)—Leaves oblong, acute, somewhat toothed; downy beneath. Clusters simple, elongated, many-flowered; their lower flowers axillary. In woods on the banks of rivers, from Virginia to Georgia, blooming from June to August. A fine ornamental shrub. Pursh. Introduced into the English gardens in 1765, by Mr. John Cree. Asim. Michaux and Pursh have well defined this species and the following, though...
Michaux has accidentally written grandiflorum of Aiton, instead of grandifolium. The present species has much smaller flowers, though larger leaves, than the officinale. Its very downy chaffers terminate the young lateral shoot in the same manner, but besides eight or ten flowers, of which each is composed, each of the three or four leaves of the shoot is accompanied by an axillary flower, the middlemost leaf usually by two flowers, all of them drooping. The margins of the leaves are, more or less regularly, furnished with small, dimidiate glandular teeth.

3. S. pulverulentum. Powdery-leaved Storax. Michaux Boreal-Am. v. 2. 341. Pursh n. 2. (S. leucopetalum Curt. Mag. t. 92.)—Leaves obovate, obtuse, entire; powdery or downy beneath. Flowers axillary, with two or three in a terminal cluster. In the woods of Virginia and Carolina, flowering from June to August. Refeembles the lat. Pursh. Cultivated by Mr. Lodgises at Hackney, before 1806. Dr. Simms. We have seen no authentic specimen, but by the figure and description this seems sufficiently distinct from the grandiflorum, having smaller, more oblong leaves, distinct of marginal teeth; much smoother chaffers, consisting of, at most, two or three flowers, the rufous or purplish. The flowers are said to be eight only, but this is not correct.

4. S. Leucogumum Smooth Storax. Ait. n. 3. Willd. n. 4. (S. leucopetalum; Walt. Carol. 140. S. glabrum; Cavan. Dict. t. 188. f. 1.) Michaux Boreal-Am. v. 2. 341. Pursh n. 3. S. americana; Lamarck Dict. t. v. 82. Herb. Linn. f. 28.)—Leaves elliptic-lanceolate, acute at each end, unequally serrated; nearly smooth on both sides. Flowers almost all axillary; solitary or in pairs. In the swamps of Virginia and Carolina, flowering in July and August. Not above three or four feet high. The number of flowers is from six to ten. Pursh. This author thought the present species had not been introduced into Europe; but we have seen specimens in the herbarium of the younger Linnæus, from the English as well as from French gardens, which induce us to believe it the real levigatum of the Hortus Kewenens, introduced by Mr. Cree in 1765, and we therefore preserve that name. The leaves are smaller than in any of the foregoing, and often very deeply, though never uniformly, serrated. We do not find them always smooth, though very pale beneath; some specimens being being sprinkled in that part with minute prominent points, or hairs. Yet such specimens cannot be referred to the latter species. The flowers are almost entirely axillary, solitary or in pairs, small, white, drooping. Calyx somewhat downy at the base; coloured towards the margin. Dr. Garden sent specimens of this plant to Linnaeus, who neglected to describe them.

5. S. Benzoïn. Benjamin Storax, or Gum Benjamin Tree. Dryand, in Phil. Trans. v. 77. 308. t. 12. Willd. n. 3. Woodr. Med. Bot. t. 72. (" Arbor Benzoïnii; Grimm. in Eph. Acad. Nat. Cur. dec. 2. ann. 1. 370. fig. 31." Benjui; Garcia de Horme in Clus. Exot. 155.)—Leaves ovate, pointed, entire; downy beneath. Clusters axillary, compound.—Native of Sumatra. Marsden. Our specimen, said to come from Guiana, was communicated by Mr. T. F. Forster. The plant is a stranger in the gardens of Europe, and is very rare in dried collections. The branches are round, leafy, finely downy and hoary. Leaves about four inches long, and two wide, alternate, flaccid, rather pale; clothed beneath with dense downy, and elegantly reticulated with triply compound prominent veins, the principal of which have at their base a sort of glandular tumour. Footstalks downy, about half an inch in length. Stigmas none. Clusters axillary, solitary, or in pairs, seldom so long as the leaves, alternately branched, with angular, downy stalks, and a few small, oblong, concave, more downy, deciduous bracts. Flowers from six to twelve in each cluster, all turned upwards, white, scarcely so large as the S. officinale. Calyx bell-shaped, downy, with very minute teeth. Corolla four times as long, angular in the bud, somewhat silky, rather than downy. Stamens ten, united at the base into a tube almost as long as the calyx. Germs bristle. Stigma obtuse.

This, the true Benjamin, or Benzoïn, Tree, was first referred to its proper genus by the late Mr. Dryand; who being furnished with a sufficient specimen, could not fail to perceive that it was a Styrax. The valuable perfumed gum, yielded by this tree, is not less evidently akin to the gum Storax, in sensible qualities. (See Benzoïn.) Ray had erroneously supposed it the production of a North American shrub, thence named Laurus Benzoii by Linnæus. (See Laurus.) The latter, in correcting this error, fell into no less a mistake, making the Benjamin-tree a Cronus, in Mant. 2. 297, and a Terminilla, in Suppl. 434. To this he is supposed to have been led by the French name of this plant, Styrax Benzoïnii, or Terminilla. But he gives a better reason for the name, in justification of himself in the Supplementum, where he informs us that a piece of the trunk of the true Benzoin, brought by Thunberg, very closely agreed, in its singular bark, with the tree before him, which grew in the fove at Uspial.

STYRAX, in Gardening, furnishes an aromatic deciduous tree of the exotic kind, of which the species cultivated is the official forrax (S. officinale).

Method of Culture.—It may be increased by seeds obtained from abroad, by sowing them in pots of light earth an inch deep; and as they are of hardy, sonly nature, and rarely come up the first year, the pots should be plunged under a frame during cold weather, and be in the shade in summer, and in the second spring be plunged in a hot-bed to forward them, being careful to give water, and to harden the young plants gradually to the full air in summer, in a shady place during the hot weather, being often watered; and in winter the pots be replaced under a garden-frame, &c. to have shelter from frost; then in spring following let them be potted off separately, and managed as hardy green-house plants for three or four years, when some of them may be turned out into the full ground in a sheltered situation, trained against a south wall, and some may be retained in pots for the greenhouse collection; they afford ornament and variety in their different situations.

STYRIA, in Geography. See Stiria.

STYRNAS, a town of Sweden, in Angeramandland; 30 miles N. of Hernofland.

STYRSA, an island near the W. coast of Sweden, in the North Sea. N. lat. 57° 33'. E. long. 11° 52'.

STYRUM, a town of the duchy of Berg; 4 miles E.N.E. of Duisburg.

STYX, in Mythology, a river of Hell, or Aes, over which was the passage called the hateful passage, from the previous region or suburbs of the realms of death into Erebos.

The Styx is properly a fountain in Arcadia, which flows from a rock, and then forms a stream, that continues for a long time buried under ground; its water was mortal, and this circumstance, according to Pausanias, gave occasion to the poets to make it a river or lake in hell. Styx is represented as a torrent, pouring down a precipice, and then as rolling on, to take its course along the boundaries of Aes. On the hither side, the ghosts or souls of the departed are waiting in a crowd, as Virgil (A. vi. v. 306.)
SUA

v. 306.) has described them; and Erebus commences with the bank on the other side of the river. The sole governor of this part, and director of the passage, is Charon, whose dominion lies where the river has recovered itself from the turbulence occasioned by its fall, and begins to become navigable, and who is represented with his boat, both receiving passers, and landing them on the farther shore. Virgil (Ene. vi. 304.) describes him as strong, and in all the vigour and freedom of old age, melancholy, and with a large rude beard, and mattèd grey hair, and his eyes fixed and fiery. He is represented as carrying over the souls of the departed, one freight after another, according to his own pleasure.

STYX, in the Theogony of Hesiod, was the daughter of Oceanus and Tethys. When Jupiter wanted to be avenged of the Titans, and called all the gods to his assembly, Styx was the first that arrived at Olympus, with her fons, which so much pleased Jupiter, that he conferred high honours upon this goddess, loaded her with presents, ordered her name to be used in the inviolable oath of the gods, and kept her children with his. These children were the offspring of the conjunction of Pallas with Styx.

The name of Styx was so terrible, that the most inviolate oath was to swear by Styx, and the gods themselves were very religious in observing it. Those of them who perjured themselves after taking this oath, were very severely punished. The inviolability of this oath was founded upon the ancient custom of using the water of Styx for the trial of the guilty and innocent, and in the manner of the Jews. When the gods swore by Styx, they were to have one hand upon the earth, and the other upon the sea. Iliad. xiv.

STYX, in Geography, a small branch of Patowmack river, where it is called Cohongoronto; it rises in the Laurel Thickets, in the Alleghany mountains, runs north, and discharges itself opposite to Laurel creek.

SUABO, a river of Africa, which joins the Zambeze, S. lat. 18°. E. long. 35° 30'.

SUADI. See SOAD!

SUAGA, a town of Hindooostan, in Bahar; 45 miles N.W. of Chuprah.

SUADA, a town of Arabia, in the province of Hadjas; 25 miles N. of Medina.

SUAKEM, or SUAQUEM, a small island in the Red sea, near the coast of Nubia, with a sea-port of the same name, anciently called "Theon Soter." This island is situated in a bay, the entrance of which is narrow, and well secured from every wind, with five, six, and seven fathoms water. It belongs to the Turks, and is governed by a pacha. The harbour is able to contain 200 ships. The bottom is mud. The ships can come close up to the shore, quite round the town, and may be laden by laying a plank from the warehouses, to the doors of which the galleys are fastened, with the keels stretching over the streets. The trade is very considerable with both the coasts of Africa, the East Indies, Arabia, and Egypt. By nature, the shoals, rocks, landbanks, and intricate channels, rendered it very secure from the attack of an enemy by sea, and it is likewise well fortified. N. lat. 19° 20'. E. long. 35°.

SUAMPETTA, a town of Hindooostan, in Goleconda; 28 miles N.N.W. of Hyderabad.

SUAN, a town of Hindooostan, in Bahar; 8 miles W. of Bahar.

SUANCES, a river of Spain, which runs into the Atlantic, N. lat. 43° 26'. W. long. 5° 59'.

SUAN-YANG, a city of Corea; 33 1/2 miles W. of Tientsin.

Suard, M. in Biography, a man of letters of the old monarchical school in France, a ci-devant member of the Académie des Sciences, possessed of much learning and good taste in all the fine arts. He and his learned friend the abbé Arnaud were the first to décry the music of Lulli and Rameau forty years ago. But charmed with the new music of Gluck, M. Suard became such an intolerant and exclusive partisan for the worthy Teutonic chevalier, that he fell out not only against Piccini and Sacchini, and all the musicians in the German empire, but all the kingdoms and states of Italy.

SUAZREZ, Francis, a Spanish theologian, was born at Granada in the year 1548. He was at an early age distinguished by an extraordinary memory, though his other faculties arrived very gradually at maturity. Having been admitted into the society of Jesuits, he became a professed in the society's schools at Alcala, Salamanca, and Rome, and at length was appointed first professor of theology at Coimbra. He died at Lisbon in 1617, with such resignation and tranquillity, that his last exclamation is said to have been, "I did not think it was so sweet to die." His indefatigable industry may be inferred from the twenty-three folio volumes of his works, which have been printed at Lyons, at Mentz, and, so lately as the year 1748, at Venice. The principal subject of these voluminous publications is theology. Suarez is accounted the principal author of the system denominated "Congruum," fundamentally that of Molina; by which Suarez attempts to explain, from the concurrence of the divine and human being, how grace infallibly produces its effect, without destroying man's free will. Suarez, being a well-known master of controversy, was defended by pope Paul V. to undertake the defence of the Catholic faith in England, where many of that communion took the oath of allegiance required by James I. His book was entitled, "A Defence of the Catholic Faith against the Errors of the English Sect." In discussing the legality of the oath demanded, the principles which he maintained were those of the civil as well as the ecclesiastical supremacy of the papal see. These gave such offence to James, that he ordered the book to be burnt in front of St. Paul's church, and prohibited it to be read in his dominions. The parliament of Paris also caused the book to be burnt by the common hangman, as containing seditious tenets. An abridgment of the works of Suarez, in two volumes folio, by father Noel, a Jesuit, was printed at Geneva in 1732. Moreiri.

SUARIF, in Geography. See Shuarif.

SUARTSAR, a small island on the west side of the gulf of Bothnia. N. lat. 61° 17'. E. long. 17° 7'.

SUATARA, a town on the E. coast of Borsico. N. lat. 3° 55'. E. long. 116° 38'.

SUB, a Latin preposition, equal to hypo, Gr. ὑπό, Ital.; and below, in English. It is frequently used in old music for intervals, and for measure, or proportions of time.

Padre Martini, after giving a long list of Greek, Latin, and Italian indications for bringing in the answer to perpetual fugues, or canons, in his "Saggio di Contrappunto," lays, besides the enigmatical and mythic indications for the solution of canons chief, or close canons, there are two particles in use, sub and supra, below and above; as ad sub dispa- foro, ad sub dispafero, &c. The particle sub implies that the answer ought to be in the octave, or 5th below the subject or guide. The particle supra or supra, lies frequently occurs, which implies an answer above the prejo, or subject; as it seldom happens that a fugue, or canon, is led off by any other than the principal, or highest part in the composition.

The
The Greek equivalents to sub and supra, are hypo and hyper, which mean.

There is a great deal of useful pedantry in explaining the use that is made of sub in the dictionaries of Broilard, and his translator Graffineau, as to measure, or the proportions of time, subiectus terma, tripla, disjunctivum, or measure of three to four, which is marked after the clef, thus: C ; &c. But these explanations are only to be found in old treatises, or in old music not worth decyphering.

The dimensions and measures of triple time, form the use of bars and dots, are so clearly expressed by numbers at the clef, as to want no other explanation. See Measure, and the Modern Time-table.

SUB is also frequently used in composition, in our language.
E.g. SUB-Brigadier, an officer in the horse-guards, who ranks as cornet. See Brigadier.

SUB-Chantor, an officer in the choir, who officiates in the absence of the chantor, &c.

SUB-Decan, an inferior minster, who anciently attended at the altar, prepared the sacred vessels, delivered them to the deacons in time of divine service, attended the doors of the church during communion service, went on the bishop’s embasures with his letters or messages to foreign churches, and was invested with the first of the holy orders.

They were subordinate to the superior rulers of the church, that, by a canon of the council of Laodicea, they were forbidden to sit in the presence of a deacon without his leave. See Deacon.

According to the canons, a person must be twenty-two years of age to be promoted to the order of sub-deacon.

It is disputed among the Romanists, whether the sub-deaconhood be a sacrament or not; in regard sub-deacons are ordained without imposition of hands, and that there is no mention made of them in Scripture. Yet Bellarmin holds the affirmative side of the question.

By the papal canons, a married man may be ordained sub-deacon, upon condition his wife consent to it, make a vow of continence, and shut herself up in a monastery.

SUB-Dam, a dignity in certain chapters beneath the dean.

SUB-Lieutenant, an officer in the royal regiment of artillery and fusiliers, in which are no ensigns, who is the same as second lieutenant. See Lieutenant.

SUB-Marsh, an officer in the Marshalls, who is deputy to the chief marshal of the king’s house, commonly called the knight-marsh, and hath the custody of the prisoners there. He is otherwise termed under-marsh. Crompt. Jurif. 104.

SUB-Prior, a clausural officer, who assist the prior, &c.

SUB-Ploughing, in Agriculture, the practice of running a plough-share through or below the soil, without turning it; and the plough used for this purpose is called a sub-plough.

SUB-Salts, in Chemistry, salts with lefs acid than is sufficient to neutralize their radicals. When a salt is found to contain an excess of acid, the preposition super is generally prefixed to its name. We are indebted, says Mr. Parkes, in his “Chemical Catechism,” to Dr. Pearon for this mode of distinguishing these salts.

SUB-Soil, in Agriculture, a term often applied to the intervening bed or stratum of earthy or other matters, which lies between the surface-soil, and the base or sub-stratum on which the whole rests. This is very uncertain in regard to its depth in most cases. In some instances, as where the uncultivated part of the earth or land rests or is placed on rock or rocky matter, it may be said, it is supposed, to be wanting; though, in most cases of this nature, a stratum or bed of a gravelly kind, mostly constituted of broken rock and earth, is found between them. And in a variety of cases, a regular bed of gravel, sand, or other similar earthy material, intervenes between the soil and the base or sub-stratum; while in still other instances, a somewhat uniform make of earthy materials reaches to a great depth, and, of course, if any definite depth or thickness of sub-soil is given to it, it must be arbitrary and uncertain in some degree or more.

The nature of the sub-soil, as well as the bases on which it rests, has also very great influence on the productiveness of the land. See Soil.

SUB-Soil Arched Main-Drain, such a drain as has a sort of arch turned over it in maon’s work. These drains are in general much too expensive to be employed in any situation, except as large discharging drains, where the ground is loose and porous, or where open drains cannot be admitted, as in pleasure-grounds, or to convey off water from deep wod-rains. When it comes to the flat kind, it can be readily obtained, these sorts of drains may be formed of them, especially where the quantity of water is not too great.

SUB-Soil Brick-Drain, that sort of deep, under-soil drain which is formed or laid with common or other kinds of bricks, or with some similar kind of materials, in a perfect manner. It is almost always in use for spring-draining. See Spring-Drain.

SUB-Soil Covered Drain, such a drain as is formed in the under-stratum of the land, and which should constantly vary according to the nature of it, and that of the materials which the particular situation affords. These sorts of drains are either hollow or filled, according as they are to receive the water, and the nature of the materials of which they are to be constructed. Moles are the greatest enemies of these drains, especially where their operations arise near the surface. These natural drainers of foils (and valuable labourers in old graslands) require, it is conceived, outlets to their drains, to discharge the rain-water which the foil communicates to their runs; otherwise they would be liable to be drowned in their own works, or to be driven from them, in a wet season. When we see, it is found, if open drains, ditches, and rilles, pierced with mole-holes. Covered drains are equally favourable to their purpose; and doubtless are in common use, where moles inhabit the sub-drained lands.

There is another source of injury in field-mice to filled drains. They not only, it is said, molest against them, in the manner of moles, but make their lodgings, it is apprehended, among the rough, open materials.

SUB-Soil Hollow Drain, such a drain as is formed in the under foil without being filled. It is observed by a late writer, that in cases where the water is to enter the drain at its base, as in that of rising waters, hollow drains are preferable to those which are filled, especially where the bore has been used; as the water immediately finds an open channel to receive it. Mr. Elkington recommends, in difficult cases at least, to bore by the side of the drain, not in the middle of the floor. If the bottom of a drain, which is perforated on the side, were made hollow, or diluting, not flat, the mouths of the bores would be out of the way of the current of the water. If the bottom of a drain be not firm enough to sustain the current, common pantiles would make an eligible floor for a perforated trench. And it is added, that where the drain is to collect the water at its sides, from the stratum in which it is formed, a depth of absorbent materials may be required; and here drains of lye expense will generally answer the de-
to be received, the two kinds may be profitably united in
many instances, it is supposed.
But these sorts of drains may be formed in different ways,
and of various materials. When constructed of stone, it has
been rated by Mr. Marshall, that in districts where thin, flat
stones are abundant, and in caves where the sub-soil is deep, and
of a loose, friable texture, fissure-walled drains, formed
with wide flat stones laid at the bottom, a dry wall raised on
each side with the refuse splinters of the same rock, and co-
verted with flat stones at the top, are eligible.
It is remarked, that in Devonshire, where thin flat stones
and rough pebbles are equally plentiful, it is common to
place the former, trianglewise, at the bottom of the trench,
and then to fill in, above, with the latter; thus forming, at
a moderate expense, a drain that is equally adapted to waters
rushing at the base and thole which are collected from the sub-
soil. They are much firmer, and less expensive, than the
more common square drains that are formed with two side-
stones, set on edge, and a wide, flat, covering stone, which
is an unstable fabric, compared with a triangular drain.
It is further stated, that hollow drains may also be made of
common bricks, but generally at a great cost. This has led
to the invention of draining-bricks of various forms. And
in a country where clay is plentiful, and stones are scarce,
they may be profitably used. In places where manufactur-
aries of draining-bricks are not established, and where the
length of drains required is not great, a flooring of common
plain tiles, and, along these, a line of common ridge-tiles,
would form an efficient channel for almost any purpose
of working-drains. Where water is to be collected from a sub-
soil, which, though absorbent, parts with its superfluous mois-
ture reluctantly, and where pebbles are wanting, a covering of
clean rough gravel, or other hard and open materials, would
be found useful in this, as in every other species of hollow
drainage. See Spring-Drain.
SUBAH, or Sourah, a term used in India as synoni-
mous with province. See CIRCAR.
Accordingly, Subadar, or Suboddar, denotes the governor
of a province: the term is also applied to a black officer,
who ranks as captain in the Company's troops, but ceases to
have any command when an European officer is present.
SUBALTERN, formed from sub and alter, another, an
inferior officer, or one who discharges his post under the com-
m mand, and subject to the direction of another.
Such are lieutenants, sub-lieutenants, cornets, and ensigns,
who serve under the captain.
We also say, subaltern courts, jurisdictions, &c. Such
are those of inferior lords, with regard to the lord para-
mount; hundred-courts with regard to county-courts, &c.
For the subaltern persons in an epic poem, F. Boiss ob-
serves, there is no necessity to be very strict: in preferring
every one's character.
The patriarchs, M. St. Evremont tells us, had several
wives, who did not all hold the same rank; but there were
several subalterns to the principal wife.
SUBALTAR GENUS. See GENUS.
SUBAPOUR, in Geography, a town of Bengal; 40
miles N.N.E. of Ilamabad.
SUBARKAN, a town of Asiatic Turkey, in the go-
vernment of Diarbekir, on the Euphrates; 75 miles E.S.E.
of Kerkisch.
SUBARMALE, among the Romans, a coarse and thick
kind of cascof cloth worn by the soldiers under their arms, in
order to keep them from being hurt with their weight.
SUBBRA, in Geography, a town of Bengal; 20 miles
W. of Rogouaptour.
SUBBUTEO, in Ornithology, the name of a bird of the
hawk kind, called in English the ringtail; the male of which
has been supposed to be the hen-barrier. Some authors
give it the name of Bocypterus acutipennis. See Boardy.
SUBCLAVIAN, in Anatomy, the great arterial and
venous trunks belonging to the upper extremity. See Ar-
tery and Vein.
SUBCLAVIAN Anencephaly, in Surgery. For an ac-
count of the recent operations for their cure, we refer to the article Subcutaneous.
SUBCLA VIUS, (sulco-clavicular,) in Anatomy, a small
muscle, lying, as its name implies, under the clavicle. It is
narrow and elongated, and reaches from the under surface of
the clavicle, where it arises by tendinous and fleshly fibres,
obliquely to the cartilage of the first rib, in which it is in-
serted by a strong tendon. The pectoralis major covers it
in front; also a thin aponeurosis extending from the edge
of the clavicle: behind, it covers the axillary vessels and
brachial plexus. Its upper edge is attached to two-thirds
of the under surface of the clavicle, towards the scapula; in
front, this edge is free. The lower edge is also free. The
outer extremity is pointed, and forms the commencement
of its origin from the clavicle: the inner end is larger, and
terminates on the cartilage of the rib in front of the sulco-
clavicular ligament.
It will deprive the clavicle to the chef, and restore it
after it has been carried either forwards or backwards.
The clavicle being fixed, it may render firm the first rib.
SUBCONTRARY Position, in Geometry, is when two
similar triangles are so placed, as to have one common
angle, O, (Plate XV. Geometry, fig. 1.) at their vertex, and
yet their bases not parallel.
If the scalene cone A B L C K be so cut by the plane
DIEH, as that the angle at E = B, the cone is then said to be cut subcontrarily to its base B C; and in this
case the section DIEH will be a circle.
For, through the vertex A and centre of the base, let
the triangular section A B C be taken, so as to be at right angles to the planes of the base B K C L of the subcon-
trary section DIEH, and of the section F I G H taken
parallel to the base, and cutting the subcontrary section in
the line I O H; consequently, I O H is perpendicular to D E and F G, intersecting another one in O. The section
F I G H, parallel to the base of the cone, is a circle; therefore
F O \times O G = O I ^ { 2 } ; and the triangles G O E
and F O D having G E O = A B C = D F O, and
G O E = D O F, are similar; therefore E O : O G :: F D
: D O, and E O \times D O = F O \times O G = O I ^ { 2 } ; con-
sequently, O I is a mean proportional, either between FO
and O G, or D O and E O; and as the same would happen
wherever F G cuts D E, all the lines O I, both in the
sections F I G H, and D I E H, are lines in a circle; con-
sequently the section D I E H is a circle.
SUBCOSTAL, in Anatomy, a name given by Winflow
to the internal intercostal muscles. See Intercoastales.
SUBDARUPOUR, in Geography, a town of Hind-
doofan, in Bahar; 23 miles N. of Durbungah.
SUBDIVISION, in a general sense, denotes a second
division of any whole. In a military sense, a company is
said to form two subdivisions; whereas two companies
added together make a grand division; except the flank
companies, which of themselves constitute grand divisions.
SUBDOMINANTE, in Music, is a name given by M.
Rameau to the fourth note of the tone, because the domi-
nant is immediately above it, or rather because it has the
same interval of the tonic in descending, as the dominant
has in ascending.
SUBDUCTION, in Arithmetica, the same as subtraction.
3 H  SUBDU
SUBDUPLE RATIO, is when any number or quantity is contained in another twice. Thus 4, is said to be subduple of 2, as 8 is of 3. See RATIO.

SUBDUPPLICATE RATIO of any two quantities, is the ratio of their square roots.

SUBER, in Botany, the ancient Latin name of the Cork Tree, of obscure and doubtful derivation. (See Quercus, fp. 33.) It may not be amiss here to observe that in the famous Æneas, under fp. 37 and 55, Mount Athos is by accidental mistake put for Mount Atlas; and that the latter species, Q. Pseuda-cocceifera, is described and delineated in Labillardiere's Planta Syria, falc. 5. t. 6.

SUBER Montanum. See Cork, Foiil.

SUBERATES, in Chemistry, salts formed by the combination of any base with the fuberic acid. These salts may be generally described as possessing a bitter taste, and being decomposable by heat. The principal suberates are those of barytes, of potash, of lime, and of ammonia. The suberates, which are all volatile, are more or less soluble; some readily, and others with difficulty, crystallize. Some remain pulverulent, whilst others are deliquescent. The mineral acids decompose these salts, and precipitate from their solutions the fuberic acid, which separates in the crystallized form. None of these salts are yet come into use.

SUBERIC ACID, an acid prepared from cork by means of pitric acid. (See Acid of Cork.) It was discovered by Brugnatelli in the year 1787, and he gave it the name fuberic from fuber, the cork-tree. He has noticed, that this acid may be obtained in considerable quantities from paper, by treating it with nitric acid. Its taste is acid: it is generally seen in the state of powder, and is not crystallizable. Boiling water dissolves half its weight, but it is very insoluble in cold water. Parker's Chem. Catechism.

SUBETH, the word used by the Arabian writers to express a carus.

SUBETH Sabala, a term used by the Arabic writers to express a coma vigil.

SUBHAVATI, in Hindu Mythology, the name of the court or terrestrial paradise of the Hindu Neptune, who is called Varuna; which see. It is described in the Purana as situated far in the west; Varuna being guardian of that region.

SUBIACO, in Geography, a town of the Campagna di Roma; 28 miles E. of Rome.

SUBIANO, a town of Etruria; 7 miles N. of Arezzo.

SUBJECT, Subditus, a person under the rule and dominion of a sovereign prince or state.

Of subjects, some are by birth, others become so by aea of naturalization.

Anciently the lords called, abusively, those who held lands or fees of them, or owed them any homage, their subjects.

Subject, Subiectum, is also used for the matter of an art or science, or that which it considers, or on which it is employed. Thus, the human body is a subject of medicine.

In this sense anatomists call the body they are dissecting, and upon which they read lectures, their subject.

The subject of logic is thinking, or reasoning; but more particularly a syllogism, one of the terms of a proposition is called the subject, and the other the attribute.

In poetry, the subject is the matter treated of, or the event related, or set to view, and enriched with ornaments.

Subject also denotes the substance or matter to which an accident is added.

It is a maxim, that two contraries can never subsist in the same subject.

Subject, in Music, a series of notes at the beginning of a movement in the principal part, which serves as a text or theme, and which should not long be forgotten; as this first idea should give birth to all the rest. (See Design.) All the other parts require only art and labour in filling them up. But the principal melody depends on genius, and it is that alone which manifests invention. The principal subjects in music produce airs of many kinds. Canons, fugues, and imitations, are constructed on a few bases, and often on a few notes, which are so repeated after each other in the several parts, from the beginning to the end of the movement; in canons, rigorously in the same intervals; in free fugues, rigorously only at the beginning, in the answers; and imitations may be made in any intervals of notes that recall us of the passage to be imitated.

In writing upon canto fermo, and in elaborate counterpoint, the parts are frequently changed, and the subject, or canto fermo, sometimes given to one part and sometimetime to another, is called double counterpoint. (See Counterpoint.) These are very artful expedients for佟n coitus fugues. But the time for gaining fame and admiration in music by mere labour is over. Imagination has taken wing, and her flights and meanders, if accompanied by grace, are sure to be eagerly followed by every judge of the art; as these flights, if not too wild and capricious, need not preclude ingenuity and contrivance in the subordinate parts. A cold and barren composer, after having, with difficulty, found a mean and infipid subject, only transposes and repeats it in all the warrantsable keys; but a great master, full of fire and imagination, without suffering the subject to be forgotten, gives it, either by the accompaniment, or by some little change or grace, a new countenance every time he repeats it. And here we cannot in justice withhold our admiration at the ingenious and delightful manner in which Haydn and Mozart adhere to the spirit of their subiecta, without dull and monotonous iteration.

SUBJECTION, Subjectio, in Rhetoric. See Hyperbole.

SUBJECTION, Civil, in Law. See Civil Subjection.

SUBJECTIVE Part. See Part.

SUBINFEUDATION, in Law, was where the inferior lords, in imitation of their superiors, began to carve out and grant to other ministeri etates than their own, to be held of themselves, and were so proceeding downwards as infeudation, till the superior lords observed, that by this method of subinfeudation they lost all their feudal profots of wardships, marriages, and etfrates, which fell into the hands of these menfe or middle lords, who were the immediate superiors of the terre-tenant, or him who occupied the land. This occasioned the statute of quia empress. Bl. Com. vol. ii.

SUBINTRANTES FERRES, a term used by some medical writers to express those fever in which one fit begins before the other is perfect, or worn off.

SUBITO, Italy, immediately, without loss of time: as voli fubito, turn over quick

SUBJUNCTIVE, in Grammar, the fourth mood, or manner of conjugating verbs, thus called, because usually subjoined to some other verb, or at least to some other particle, as, if I loved: though this were true, &c.

The Greek is almost the only language that properly has any subjunctive mood; though the French, Spanish, and Italian,
Italian, have some show of it. In all other languages, the same inflections serve for the optative and the subjunctive moods; for which reason the subjunctive mood might be retrenched from the Latin, and those other grammars; because they are not the different ways of signifying, which may be very much multiplied, but the different inflections, that constitute the different moods. See Mood.

SUBLAPSARIAN, or Infralapsarian, in Theology, a term applied to faith as held that God, having foreseen and permitted the fall of Adam, and, in consequence of it, the loss of mankind, resolved to give a grace sufficient for salvation to some, and to refuse it to others.

Sublapsarian is used as synonymous with Infralapsarians, in opposition to Supralapsarian.

SUBLICIUS POMA, in Ancient Topography, one of the eight bridges over the Tiber at Rome. This was the first bridge that was built at Rome: it was constructed by Ancus Martius, entirely of oak wood; Ovid calls it Robornus. On this bridge the Roman Horatius Cocles kept at bay the whole army of the Tuufens, commanded by Porfenans; and from hence also the dead body of Heliogabalus was thrown into the Tiber. It crossed the Tiber from the foot of mount Aventine, to the spot here called prata Mutia, and led towards Etruria. A sudden inundation broke down this bridge, in lieu of which the pretor Emilius Lepidus built one of stone; when this was destroyed by the swelling of the water, the emperor Tiberius constructed another of stone; and when this was destroyed by the same means, the emperor Antonius Pius built a new one of marble, more lofty than the former. But this also has been demolished by the overflowing of the Tiber, so that only few remains of it are to be perceived, near the banks and under the water.

SUBLIMABLE BODIES, a term used by some of our chemical writers to express such substances as are capable of sublimation in a dry form.

SUBLIMATE, a chemical preparation, the basis of which is mercury or quicksilver. See Mercury.

SUBLIMATION, a chemical operation, by which volatile and solid substances are collected and obtained, and differs little from distillation, excepting that, in distillation only the fluid parts of bodies are raised; but in sublimation the solid and dry; and that the matter to be distilled may be either solid or fluid; but sublimation is concerned only about solid substances. There is also another difference, namely, that rarefaction, which is of very great use in distillation, has hardly any room in sublimation; for the substances which are to be sublimed, being solid, are incapable of rarefaction, and so it is only impulse that can raise them.

However, it may not be improper to inquire a little more nicely into the reason of such a diversity in the elevation of bodies; why some do ascend with a gentle heat, and others are not to be raised by the most vehement fire; and such an inquiry will more properly come in here, because this head contains all the business of volatility and fixation.

The cause of this elevation and ascent in the particles of bodies, is to be ascribed to the fire, not only on account of impulsion, but of another property the fire has, namely, to infuse itself into all the interstices of these bodies, and thereby break the cohesion of their parts, so that at last they become divided into very small parts, if not into the smallest that art can reduce them into.

Particles, thus separated and divided, lose much of their gravity. For the gravity of the same particle decreases in the same proportion as the cube of the diameter is lessened. Suppose, therefore, a body, whose diameter is 12; if, then, its diameter be made less by 1, viz. 11, the gravity of that body will be only 94, or thereabouts; a body, therefore, by being divided into very minute corpuscles, becomes easy to be sublimed.

And, indeed, that the surface of the body decreases in a very different manner from gravity, only as the square of the diameter is lessened. Where the gravity decreases in such a series, as is expressed by the numbers 12, 13, 1000, the diminution of the surface will observe this proportion; viz. 114, 121, 100; and when, upon reducing the diameter to 6, the gravity becomes less than 2, the surface will still amount to 36.

How much this contributes to a quick ascent, will appear from the sublimation of camphor, benzoin, and arsenic; whose particles, as they cohere but loosely, are, for this reason, diffused into a larger surface; upon which account they are the easiest to be sublimed of any; nay, these solid particles, upon account of their surface, will sooner ascend than many fluids.

So flower of sulphur rises sooner than oil, not only than that of vitriol, but any other, though ever so light.

By this contrivance of nature, viz. that the gravity of bodies decreases in a triplicate, but their surface in a duplicate proportion of their diameters, it comes to pass that bodies, which have a very different gravity, may be raised with the same force. Thus the salts of animals, as of hart-horn, human blood, that of vipers, &c. being composed of very minute corpuscles, as is found by experience, in diffusing them, do easily ascend, because the surface in them is not lessened so much as gravity is; and the salts of vegetables, as of tartar, bismuth, &c. which are of a more clese texture, by reason of their larger surfaces, are also without much difficulty raised.

The corpuscles also of minerals and metals, though very compact and heavy, do, in some measure, give way to the fire, and are capable of being sublimed. In all these instances, the breadth of the surface, which expouses the particles more to the impetus of the fire, is the reason why they are raised with so much ease as if their gravity had been diminished by diminishing their surface; so that particles, though ever so different in weight, may be equally raised by the same degree of heat, if the proportion of their gravity be reciprocal to that of their surfaces.

Sublimation is employed to separate volatile substances from
from others which are fixed or less volatile, to combine two volatile matters, as in the operation of the sublimates of mercury, and to collect some volatile sublimes, as leaded salt, sulphur, and all the preparations called flowers.

The apparatus for sublimation is very simple. This process is conducted sometimes in a crucible, with a cone of paper or another crucible inverted over it, in which the process is continued; and as in this case it is light and pungent, it was formerly named "flowers." A matras or small alembic is generally sufficient for the sublimation of small quantities of matter. But the vessels, and the method of managing the fire, vary according to the nature of the matters that are to be sublimed, and according to the form which the sublimate is to receive. When the matters to be sublimed are volatile, a high cucurbit, to which is adapted a capital, and even several capitals placed one upon another, are to be employed. The sublimation is performed in a sand-bath, with only the precise degree of heat requisite to raise the sublimate which is to be sublimed, and the capitals are to be guarded as much as possible from heat.

When along with the dry matter, which is to be collected in these sublimations, a certain quantity of some liquor is raised, as in the sublimation of leaded salt, and rectification of volatile concrete alkalies, a paffage and a receiver for these liquors must be provided, which is conveniently done by using the ordinary capital of the alembic, furnished with a beak and a receiver.

Some sublimates are required to be in as solid and compac safe as their nature will allow, as camphor, sal ammoniac, and all the sublimates of mercury. The most proper vessels for these sublimations are bottles or matrassefs, which are to be sunk more or less deeply in sand, according to the volatility and gravity of the matters that are to be sublimed. The art of conducting these sublimations consists in applying such a degree of heat, or in so disposing the sand, (i.e. making it cover more or less of the matrassefs,) that the heat in the upper part of the matrassefs shall be sufficient to make the sublimate adhere to the glass, and to give it such a degree of fusion as is necessary to render it compac, but not a heat so great as to force the sublimate through the neck of the matrassefs, and disrupt it.

Many sublimates may be reduced into flowers and sublimed, which cannot be sublimed in close vessels, but require a very great heat, with the access of free air, and even the contact of coals: such as moist foots or flowers of metals, and even some saline sublimes. The matters from which these sublimates are separated, must be placed among burning coals in open air, and the flowers are collected in the chimney of the furnace in which the operation is performed. This process is called sublimation in the manner of Geber. Of this kind of sublimates are the turity, calamine, or pompholix, gathered in the tops of furnaces in which ores are smelted. Macquer’s Dict. Chem. Eng. edit. art. Sublimation.

SUBLIME, in Dicouerfs, something extraordinary and surprizing, which strikes the foul, and makes a sentiment or composition ravish and transport.

This is what Longinus, who has written expressely on the subject, means by sublime. The definition, indeed, is not his, but M. Boileau’s; for the author, writing his book after another of Cecilius on the fame subiect, and employing himself almost wholly in fiewing what the sublime is, declined defining it, as supposing it well known.

By the definition it may appear, that the sublimate is a very different thing from what the orators call the Sublime Style; which see. See also Sublimity.

SUBLIMING GEOMETRY. See GEOMETRY.
SUBLIMITY.

Give me your weighty secrets to display,
From those black realms of darkness to the day.”

Pitt.

"Obscure they went; through dreary shades, that led
Along the waite dominions of the dead;
As wander travellers in woods by night,
By the moon’s doubtful and malignant light.”

Dryden.

Obscurity is not unfavourable to the sublime; for though it render the object indistinct, the impression, however, may be great; the imagination being strongly affected by objects of which we have no clear conception. Thus we see, that almost all the descriptions that are given us of the appearances of supernatural beings carry some sublime, though the conceptions they afford us be confused and indistinct. This sublimity arises from the ideas, which they always convey, of superior power and might, joined with an awful obscurity. (See Job, iv. 15.) Thus also, the picture which Lucretius has drawn of the dominion of superintuition over mankind, representing it as a portentous spectre sweeping its head from the clouds, and dismembering the whole human race with its countenance, together with the magnanimity of Epicurus in raising himself up against it, carries all the grandeur of a sublime, obscure, and awful image:

“I humanae ante oculos fade cum vitae jacet in terris, oppressa gravi sub religione, Quae caput a coeli regionibus offendebat, Horribilis super specus mortalibus infrans, Primum Graius homo mortales tollere contra Erit oculos auras.”

Lib. i.

In general, all objects that are greatly raised above us, or far removed from us, either in space or in time, are apt to strike us as great. Moreover, disorder, as well as obscurity, is very compatible with grandeur, and even frequently heightens it. Few things that are strictly regular and methodical appear sublime. In the freble attempts which human art can make towards producing grand objects, greatness of dimensions always constitutes a principal part. No pile of building can convey any idea of sublimity, unless it be ample and lofty. Thus, a Gothic cathedral raises ideas of grandeur in our minds, by its size, its height, its awful obscurity, its strength, its antiquity, and its durability.

The author, whose observations on this subject we are now citing, mentions another class of sublime objects, which may be called the moral, or sentimental sublime; arising from certain exertions of the human mind, from certain affections and actions of our fellow creatures. These may be referred to that class, which is distinguished by the appellation of magnanimity or heroism; and they produce an effect very similar to that which is produced by the view of grand objects in nature; filling the mind with admiration, and elevating it above itself. Of this sentimental sublime, we are furnished with instances in the famous contest between the Horatii and the Curati (see Curiaii); in the case of Porus and Alexander and all of Cesar, mentioned under the article Sublime Style. High virtue is the most natural and tender source of this moral sublimity. It has been a subject of enquiry, whether there be any one fundamental quality in which all the different objects above-mentioned, and others of a like kind, agree, and which is the cause of their producing an emotion of the same nature in our minds? The ingenious author of “A Philosophical Enquiry into the Origin of our Ideas of the Sublime and Beautiful,” has proposed a formal theory for the solution of this question. According to Mr. Burke, terror is the source of the sublime, and, in his opinion, no objects have this character but such as produce impressions of pain and danger. But Dr. Blair thinks, that, although many terrible objects are highly sublime, the author now mentioned has stretched his theory too far, when he represents the sublime as consisting wholly in modes of terror, or of pain. For the proper sensation of sublimity appears to be very distinguishable from the sensation of either of these; and on several occasions to be entirely separated from them. In many grand objects, there is no coincidence with terror at all; and in many painful and terrible objects, there is no sort of grandeur. Dr. Blair inclines to think, that mighty force or power, whether accompanied with terror or not, whether employed in protecting, or in alarming us, has a better title than any thing that has yet been mentioned to be the fundamental quality of the sublime, as no sublime object occurs to him, into the idea of which power, strength, and force, either enter indifferently or are not, at least, intimately associated with the idea, by leading our thoughts to some astonishing power, as concerned in the production of the object.

Before we close our account of sublimity, as it respects external objects and mental or moral qualities, we shall flow a few words on the difference between sublimity and beauty. The pleasure afforded by the contemplation of beauty appears to be a pure and unmixed pleasure, but it is less vivid than that which is produced by the sublime. As for the latter, often borders upon terror, it requires a greater exertion, and produces a stronger, though less durable sensation, than the beautiful. The sublime also differs from the beautiful, in being only conversant with great objects; and it differs from the pathetic, in affording a more tranquil pleasure.

Sublimity in discourse or writing, understood in its most extensive sense, is not merely that sublimity which exhibits great objects with a magnificent display of imagery and diction, but that force of composition, whatever it be, which excites the passions, and which expresses ideas at once with perplicivity and elevation, not licentious whether the language be plain or ornamented, refined or familiar. This is the sense in which Longinus uses the word; and he points out five sources of this sublimity; and of these, as we have already observed under the article Sublime Style, Dr. Blair allows only two to have any peculiar relation to the sublime. The sublime consists either in language or sentiment, or more frequently in an union of both, since they reciprocally affect each other, and since there is a necessary and indissoluble connection between them. The foundation of the sublime in composition must always be laid in the nature of the object described. Besides, the object must not only be sublime itself, but it must be so exhibited, as to give us a clear and full impression of it. For this purpose, it must be described with strength, conciseness, and simplicity. It is observed, that the early ages of the world, and the rude unimproved state of society, are peculiarly favorable to the strong emotions of sublimity; in such circumstances the genius of men is much turned to admiration and astonishment. Among ancient authors we are the most likely to find striking instances of the sublime; and more of these occur in the sacred scriptures than in any other writings, ancient or modern. In the preceding part of this article we have noticed the descriptions which they afford us of the Deity; descriptions that are wonderfully noble, both on account of the grandeur of the object, and the manner of repre-
reposing it. (See Piae xvi. 6, 8c. Habakkuk, iii. 6. 10. See also the passages cited by Longinus from Moses, Gen. i. 3, and Isaiah, xiv. 24, 27, 28.) Under this head we may mention another passage in Pl. lxxv. 1, "God filleth the noise of the seas, the noise of their waves, and the tumults of the people." For a variety of other passages that occur in the sacred writings, selected by the learned bishop Lowth as specimens of sublimity both of sentiment and language, we refer to his Lectures on the Sacred Poetry of the Hebrews. Homer has been admired in all ages, and by all critics, for sublimity, much of which he owes to that native and unassailable simplicity which characterizes his manner. His description of his hero, especially when he speaks, is a mere abstraction, the fire and rapidity, which he throws into his battles, present to every reader of the Iliad, frequent instances of sublime writing. His introduction of the gods tends often to heighten, in a high degree, the majesty of his warlike scenes. Hence Longinus bestows such high and just commendations on that passage, in the 15th book of the Iliad, where Neptune, when preparing to issue forth into the engagement, is described as flashing the mountains with his feet, and driving his chariot along the ocean. Minerva, arming herself for fight in the 5th book, and Apollo, in the 15th, leading on the Trojans, and flashing terror with his aegis on the face of the Greeks, are familiar instances of great sublimity added to the description of battles, by the appearances of those celestial beings. In the 20th book, where all the gods take part in the engagement, according as they severally favour either the Greeks or the Trojans, the poet's genius is signally displayed, and the description rises into the most awful magnificence. All nature is represented as in commotion: Jupiter thunders in the heavens; Neptune strikes the earth with his trident; the ships, the city, and the arms of the enemy, all tremble to its centre; Pluto flits from his throne, in dread lest the secrets of the infernal regions should be laid open to the view of mortals. The works of Offian also abound with instances of the sublime. From the various examples produced by Dr. Blair he is justified in maintaining, that simplicity, as opposed to studied and profuse ornament, and conciseness, as opposed to superfluous expression, are essential to sublime writing: and our author states the reason why a defect in either of these qualities is peculiarly hurtful to the sublime. The emotion which he says, that is occasioned in the mind by some great or noble object, raises it considerably above its ordinary pitch, and produces a sort of enthusiasm, which is very agreeable while it lasts, but from which the mind is tending every moment to fall down into its ordinary situation. When an author has brought us, or is attempting to bring us, into this state; if he multiplies words unnecessarily, if he decks the sublime object, which he presents to us, round and round with glittering ornaments; nay, if he throws in any one decoration that sinks in the leaf below the capital image, that moment he alters the key; he perplexes the tension of the mind; the strength of the feeling is emaculated; the beautiful may remain, but the sublime is gone. Hence our author concludes, that rhyme, in English verse, is unfavourable to the sublime, if not inconsistent with it. Homer's description of the nod of Jupiter, as flashing the heavens, has been admired in all ages, as highly sublime. Literally translated, it is as follows: "He spoke, and bending his fable brows, gave the awful nod; while he shook the celestial locks of his immortal head, all Olympus was shaken." Mr. Pope, in the subjoined translation, spoils the image, and attempts to beautify it; but, in reality, weakens it.

"He spake; and awful bends his fable brows,
Shakes his ambrosial curls, and gives the nod,
The stimp of fate, and sanction of a god.
High heaven with trembling the dread signal took,
And all Olympus to its centre shook."

Blank verse, by its boldness, freedom, and variety, is much more favourable than rhyme to all kinds of sublime poetry. Milton, whose genius led him eminently to the sublime, has fully proved this assertion. The whole first and second books of Paradise Lost are continued instances of it. As an example, we may cite the following description of Satan, after his fall, appearing at the head of the infernal host:

"He, above the reef,
In shape and gesture proudly eminent,
Stood like a tower: his form had not yet loft
All her original brightness, nor appeared
Less than archangel ruined; and the excess
Of glory obscured. As when the sun, new risen,
Looks through the horizontal misty air,
Shorn of his beams; or, from behind, the moon,
In dim eclipse, diffracted twilight sheds
On half the nations, and with fear of change
Perplexes monarchs. Darken'd fo, yet home
Above them all th' archangel."

Befide conciseness and simplicity, strength is another essential requisite of sublime writing. The strength of description arises, in a great measure, from a simple conciseness; and it also supposes a proper choice of circumstances in the description, so as to exhibit the object in its full and most striking point of view. A storm, or tempest, is a sublime object in nature; but to render it sublime in description, it must be painted with such circumstances as fill the mind with great and awful ideas; as Virgil has done in the following passage (Georg. i.), which we shall give in Dryden's translation:

"Ipse Pater, &c."

"The father of the gods his glory throngs,
Involv'd in tempests, and of clouds:
And from the middle darkness flashing out,
By fits he deals his fiery bolts about,
Earth feels the motions of her angry God,
Her entrails tremble, and her mountains nod,
And flying beasts in forests seek abode.
Great deeps seizes every human breath;
Their pride is humbled, and their fears confest;
While he, from high his rolling thunders throws,
And fires the mountains with repeated blows;
The rocks are from their old foundations rent,
The winds redouble, and the rains augment."

Every circumstance, says Blair, in this noble description, is the production of an imagination heated and enthralled with the grandeur of the object. The proper choice of circumstances in a sublime description has such a foundation in nature, that the least deviation from it is fatal. This is owing to the nature of the emotion aimed at by sublime description, which admits of no mediocrity, and cannot subsist in a middle state, but must either highly transport us, or, if unsuccessful in the execution, leave us greatly disgusted, and displeased. Thus, when Milton, in his battle of the angels, describes them as tearing up the mountains, and throwing them at one another; there is, in his description, as Mr. Addison has observed, no circumstances that are not properly sublime.

"From
**S U B**

« From their foundations loosing to and fro,
The planked the seated hills, with all their load,
Rocks, waters, woods; and by the flabby tops
Uplifting, bore them in their hands.»

If it be enquired, what are the proper sources of the sublime? the answer is, that they are to be looked for everywhere in nature. It is not by hunting after tropes, and figures, and rhetorical affinities, that we can expect to produce it. It must come unfought, if it come at all; and be the natural offspring of a strong imagination.

« Eft Deus in nobis; agitate calecitmus illo.»

In judging of any striking beauty in composition, whether it is, or is not, to be referred to this class, we must attend to the nature of the emotion which it raises; and only, if it be of that elevating, solemn, and awful kind, which distinguishes this feeling, we can pronounce it sublime. Hence, it follows, that it is an emotion which can never be long protracted. The utmost we can expect is, that this burst of imagination should sometimes flash upon us like lightning from heaven, and then disappear. In Homer and Milton, this effulgence of genius breaks forth more frequently, and with greater lustre than in most authors. Shakespeare also riffs often into the true sublime. But no author is sublime throughout. In a limited sense, however, there are some, who merit the name of continued sublime writers; and in this class we may justly place Democritus and Plato. In all good writing, the sublime lies in the thought, not in the words; and when the thought is truly noble, it will, for the most part, clothe itself in a native dignity of language. The main secret of being sublime is to say great things in few and plain words. The most sublime authors are the simplest in their style. If a writer affects more than ordinary pomp and parade of words, and endeavours to magnify his subject by epithets, you may immediately suspect, that, feeble in sentiment, he is struggling to support himself by mere expression. See **Sublime Style**.

**SUBLINGUAL.** In Anatomy, a branch of the lingual artery. (See Artery.)—Also, one of the salivary glands. See **Dilatation**.

**SUBLINGUAL.** Prim. See **Ranini**.

**SUBLUXATIO.** In Surgery, a violent sprain; also, an incomplete dislocation.

**SUBMARINE NAVIGATION.** See **Submarine Navigation**.

**SUBMISSION, Submersio.** See **Drowning**.

**SUBMULTIPLE.** In Geometry, &c. A submultiple number, or quantity, is that which is contained a certain number of times in another, and which, therefore, repeated a certain number of times, becomes exactly equal to it.

Thus, 3 is a submultiple of 21. In which case a submultiple coincides with an aliquot part.

**SUBMULTIPLE Ratio.** Is that between the quantity contained, and the quantity containing. Thus, the ratio of 3 to 21 is submultiple.

In both cases, submultiple is the reverse of multiple: 21, e. gr. being a multiple of 3, and the ratio of 21 to 3 a multiple ratio.

**SUBMULTIPLE Subhyperparticular.** See **Ratio**.

**SUBMULTIPLE Subsimplex.** See **Ratio**.

**SUBNORMAL, or Subperpendicular, in Geometry.** A line which determines the point in the axis of a curve, where a normal or perpendicular, raised from the point of contact of a tangent to the curve, cuts the axis.

Or, the subnormal is a line, which determines the point in which the axis is cut by a line falling perpendicularly on the tangent in the point of contact.

Thus, TM (Plate XV. Geometry, fig. 2.) being a tangent to a curve in M; and MR a normal or perpendicular to the tangent; the line PR, intercepted between the semidiameter PM and the normal MR, is called the subnormal.

Hence, 1. In a parabola, as AM, &c. the subnormal PR is to the semidiameter PM, as PM is to PT, and as MR to TM.

2. In a parabola, the subnormal PR is subduplicate the parameter; and consequently it is an invariable quantity: for

\[
PR = \frac{PM^2}{PT} = \frac{PM^2}{2AP} = \frac{\rho}{\alpha^2}
\]

In general, the subnormal may be found by dividing the square of the semidiameter by the sub-tangent.

**SUBOCCIPITAL, in Anatomy, the pair of nerves which run out between the occiput and atlas; they are the tenth pair of the head of some anatomists, but are now usually called the first cervical pair. See **Nerve**.

**SUBORBITAR, the foramen near the inferior edge of the orbit, and the artery and nerve which occupy that foramen. See **Canum, Artery, and Nerve**.

**SUBORDINATED, and Subordinating Affections.** See **Affections**.

**SUBORDINATION, a relative term, expressing the degree of inferiority between one thing and another.**

There is a series of subordinations running throughout all nature. In the church there are several degrees of subordination, as of deacons to priests, priests to prelates, &c. The like are observable in the secular state, in offices of war, justice, &c. And, even in the sciences, trigonometry is subordinate to geometry: and in the virtues, abstinence and chastity are subordinate to temperance: in music, some call the plagal tones subordi-

**NATION.**

**SUBORNATION, See Rape and Ravishment.**

**SUBORNATION, Subornation, a secret or under-hand preparing, influencing, or bringing in a false witness; or corrupting or alluring a person to do such a false act. Hence, the subornation of perjury, mentioned in the act of general pardon, 12 Car. II. c. 8. is the alluring or disposing to perjury.**

**SUBPERPENDICULAR.** See **Subnormal**.

**SUBPENA, in Law, a writ, by which any person, under the degree of peerage, is called to appear in chancery, in cases where the common law hath made no provision. See **Suit**.**

The name is taken from the words in the writ, which charge the party summoned to appear at the day and place assigned, ab puncto centum librarum, on the penalty of a hundred pounds.

The peers, in the like cases, are called by the lord chancellor's letter, giving notice of the suit intended against them, and requiring them to appear.

The writ of subprena, returnable into the court of chancery only, was devised by John Waltham, bishop of Salisbury, and chancellor to king Richard II., by a strained interpretation of the oath. Wefin, 2. in order to make the oath to use accountable to his confitique yuse, which process was afterwards extended to other matters wholly determinable at the common law, upon false and fictitious fugitives; for which, therefore, the chancellor himself is, by
7 Ric. II. c. 6. directed to give damages to the parties unjustly aggrieved. In the reigns of Henry IV. and V. the commons were repeatedly urgent to have the writ of subpoena entirely superseded as a novelty devised by the subtlety of chancellor Waltham, against the form of the common law; but though Henry IV. gave a palliating answer to their petitions, and actually passed the statute 4 Hen. IV. c. 25, by which judgments at law are declared irrevocable, unless by attainder or writ of error, yet his son put a negative at once upon their whole proceeding and, in Edward IV.'s time, the process by bill and subpoena was become the daily practice of the court. Bl. Com. book iii.

There is also a subpoena ad testificandum, for summoning of witnesses in other courts, as well as in chancery. See Evidence.

The subpoena dux tecum, is a writ of process of the same kind with the preceding, including a cause of bringing and produce books and papers, &c. in his hands, belonging to the parties, or such in which they are interested.

There is also a subpoena in the exchequer, as well in the court of equity there, as in the office of pleas.

SUBPRINCIPALIS, in some Latin writers of Music, is used for the note or chord called by the Greeks πεπρωμοσ, par-bopaste.

SUBPURGATION, Subpurgatio, a word used by some writers to express a gentle purgation.

SUBREGUA, in Geography, a town of Naples, in Abruzzo Ultra; 18 miles E. of Aquila.

SUBREPTIO, Subreptio, formed from sub, under, and repto, l creep, the act of obtaining a favour from a superior by surprize, or a false representation.

Subreption differs from subversion, in that the latter denotes a false expression of the quality of a thing, or fact, &c. And subreption, a want of expression, or a fraudulent reticency or concealment of a thing, which would have rendered the obtaining of the favour more difficult. See Sub垸ition.

SUBREPTITIOUS, or Subreptitious, a term applied to a letter, licence, patent, or other act, fraudulently obtained of a superior, by concealing some truth, which, had it been known, would have prevented the concession or grant.

The benefit of letters, licences, &c. is forfeited, when they are found contrary to the information given; they being then reputed subreptitious.

Papal bulls and signatures are null and subreptitious, when the true state of the benefice, the manner of the vacancy, and other necessary matters, are not justly and properly signified to the pope.

SUBROGATION, or Subrogation, in the Civil Law, the act of substituting a person in the place, and entitling him to the rights of another.

In its general sense, subrogation implies a succession of any kind, whether of a person to a person, or of a person to a thing.

There are two kinds of subrogation; the one conventional, the other legal.

Subrogation, Conventional, is a contract by which a creditor transfers his debt, with all its appurtenances, to the profit of a third person.

Subrogation, Legal, is that which the law makes in favour of a person, who discharges an antecedent creditor; in which case, there is a legal transtion of all rights of the ancient creditor to the person of the new one.

This the civilians more usually call subrogation, as being wholly the work of the law; and to distinguish it from the conventional subrogation, which they also call subrogation.

The verb is formed from the Latin, subrogatio, of the verb regare, which, among the ancient Romans, signified to ask, to interrogate; whence it was that they called the laws themselves regationes, in regard the people made them, upon being asked by the magistrates.

And, as laws made by the people could not be changed without their consent, and without being asked anew; if they thought good to have the law wholly abolished, lex abrogabatur; if only a part of it were to be abolished, lex derogabatur; and if any clause or amendment were added to it, lex subrogabatur.

The new magistrates were also subrogated in the place of the old ones; for, during the time of the republic, no magistrate could be, but by consent of the people, nor of consequence but by law, since whatever the people thought good was law.

This is what occasioned Salamanus to say, that subrogans and sublitura per legem, were reciprocals.

SUBSAGUR, in Geography, a town of Hindoostan, in Vissapour; 16 miles S. of Huttany.

SUBSCAPULAR, in Anatomy, the large branch of the axillary artery, which arises near the lower margin of the scapula. See Artery.

SUBSCRIPTION, the signature put at the bottom of a letter, writing, or instrument.

In church history we meet with instances of subscriptions in the life of Ignatius, written with the blood of Jesus. Nicetus, speaking of the subscriptions made at the council, in which that patriarch was deposed, says, they subscribed, not with common ink, but, what strikes a man with horror, with a pen dipped in the blood of Christ. The historian Theophanes tells us, that pope Theodore mixed the blood of Christ with ink; in which he wrote the deposition of Pyrrhus.

Subscription, in the English Commerce, is used for the share or interest which particular persons take in a public stock, or a trading company, by writing their names, and the shares they require, in the books or registers of it.

The French have likewise adopted the word subscription, using it in speaking of the actions of their India company.

A subscription differs from an action, in that the first is properly only an action begun, or an engagement, by making the first payment to acquit the rest in the time limited; and that the other is the whole action, performed in all its parts.

Subscription, in the Commerce of Books, signifies an engagement to take a certain number of copies of a book going to be printed; and a reciprocal obligation of the bookeller or publisher to deliver the said copies on certain terms. The usual conditions of these subscriptions are, on the part of the bookeller, to afford the books cheaper to a subscriber than to another, by one-third or one-fourth of the price; and on the part of the latter, to advance half the money in hand, and to pay the rest on the delivery of the copies; an agreement equally advantageous to the one and the other, as the bookeller is, by this means, furnish'd with money to carry on works, which would otherwise be above his stock; and the subscriber receives, as it were, interest for his money, by the moderate price the book stands him in.

Subscriptions had their rise in England, and it is but very lately that they have got into other countries. They were first
SUBSCRIPTION.

first set on foot in the middle of the last century, for the printing of Walton's Polyglot Bibles, which was the first book ever printed by way of subscription.

From England they passed a few years ago into Holland, and they have been since introduced into France.

In England they are become exceedingly frequent; and their frequency has rendered them liable to some abuses, which begin to discredit them.

Subscription to Articles of Faith (see Articles) is a written, solemn declaration of the subscriber's assent, and is governed, according to the statute of archdeacon Paley, by the same rule of interpretation with oaths—which rule is the "animus imponentis." The inquiry, therefore, concerning subscription will be, "qux impuluit, et quo animo." The bishop who receives the subscription, says this ingenious writer, is not the imposer, any more than the cryer of a court, who administers the oath to the jury and witnesses, is the person that imposes it; nor consequently is the private opinion or interpretation of the bishop of any significance to the subscriber, one way or other. The compilers of the 39 articles are not to be considered as the imposers of subscription, any more than the framers or drawers up of a law is the person that enacts it. The legislature of the 13th Eliz. is the imposer, whose intention the subscriber is bound to satisfy. They who contain, that nothing less can justify subscription to the 39 articles, than the actual belief of each and every separate proposition contained in them, must suppose, that the legislature expected the content of 10,000 men, in perpetual successio, not to one controverted proposition, but to many hundreds. It is difficult to conceive how this could be expected by any, who observed the incurable diversity of human opinion upon all subjects short of demonstration or oaths—which rule law did not intend this, what did they intend? Our author replies to this question, that they intended to exclude from offices in the church, 1. All abettors of Popery; 2. Anabaptists, who were at that time a powerful party on the continent; and 3. The Puritans, who were hostile to an episcopal constitution; and in general the members of such leading sects or foreign establishments, as threatened to overthrow our own. Whoever, he says, finds himself comprehended within these descriptions, ought not to subscribe. For the general reasons upon which he justifies the imposition of this test on the teachers of religion, we refer to the article Religion; where it will appear, that this excellent writer seems to intimate, that our articles of faith might be converted into articles of peace, and acknowledges, that subscriptions perpetuate the procreation of sects and tenets, from which any danger has long ceased to be apprehended. The cales in which subscription to the 39 articles is required are, those of clergy officiating in the church, and entitled to its preferments and emoluments, and of schoolmasters, of young men in the university of Oxford or Cambridge at the time of their matriculation; and at Cambridge all degrees in arts, law, phyic, music, and divinity, are guarded by subscription, nor are any admitted to their first degree of bachelor of arts without a bonâ fide subscription, i.e. "I, A.B., do declare that I am bonâ fide a member of the church of England as by law established." We must here, however, observe, that the three articles contained in the 36th canon, are those that are subcribed at Cambridge for a bachelor of divinity's degree, and for a doctor's in any faculty, divinity, law, or phyic. They include all the 39 articles, and are as follow:

1. That the king's majesty, under God, is the only supreme governor of the realm, and all other his highness's dominions and countries, as well in spiritual or ecclesiastical
SUBSCRIPTION.

Epioton." In queen Elizabeth's reign, 13 articles were let out by order of the metropolitans, and the rest of the bishops, "for the unity of doctrine, to be holden by all parsons, vicars, and curates, as well in tesionification of their common consent in the said doctrine, as to the stopping of the mouths of those, who go about to slander the ministers of the church for diversify of judgment." Some time after all of them were surveyed, and at length compiled within a system of 39 articles. These articles were again ratified by James I., according to the form commonly prefixed to the book of articles of queen Elizabeth; in which, among other things, are these words, "that the articles of the church of England (which have been allowed and authorized heretofore, and which our clergy have generally subscribed unto) do contain the true doctrine of the church of England, agreeable to God's word; which we do therefore ratify and confirm, requiring all our loving subjects to continue in the uniform profession thereof, and prohibiting the least difference from the said articles, &c." It is added, after an assertion "that we be supreme governor of the church of England," and the recital of some other particular obervations relating to these articles, "that no man hereafter shall either print or preach to draw the article and shall submit to it in the plain and full meaning thereof, and shall not put his own sense or comment to be the meaning of the articles, but shall take it in the literal and grammatical sense:"

"That if any public reader in either of our universities, or any head or master of a college, or any other person respectively in either of them, shall affix any sense to any article, or shall publicly read, determine, or hold any public disputation, or suffer any such to be held either way, in either the universities or colleges respectively; or if any divine in the land (who shall present or print any thing either way, other than is already established in convention with our royal assent; he or they the offenders shall be liable to our displeasure, and the churches cenpurchase in our commission ecclesiastical, as well as any other; and we will see there shall be due execution upon them."

By 13 Eliz. c. 12. none shall be admitted to the order of deacon, unless he shall first subscribe to the said articles.

And by the statute of 1786, no person shall be received into the ministry, nor by either by institution or collation admitted to any ecclesiastical living, nor suffered to preach, catechize, or to be a lecturer or reader of divinity in either university, or in any cathedral or collegiate church, chantry, or market-town, parish-church, chapel, or in any other place, except he shall first subscribe to this article following: viz. "That he alloweth the book of articles of religion agreed upon by the archbishops and bishops of both provinces, and the whole clergy in the convention holden at London, in the year of our Lord God one thousand five hundred fifty and two; and that he acknowledgeth all and every the articles therein contained, being in number nine and thirty, besides the ratification, to be agreeable to the word of God."

And by the statute of 13 Eliz. c. 12. no person shall be admitted to any benefice with cure, except he shall first have subscribed the said articles in the presence of the ordinary; and all admissions to benefits of any person contrary to this act, and all dispensations, qualifications, and licences to the contrary, shall be merely void in law, as if they never were.

The 13 & 14 Car. II. c. 4. require subscription to the 39 articles mentioned in the 13th Eliz. c. 12. and a declaration of unfeigned affent and consent unto, and approbation of them, under certain express penalties. It has been observed, however, that by the 13 Eliz. c. 12. subscription is enjoined to those articles which only concern the profession of the true Christian faith, and the doctrine of the sacraments; and that by 14 Car. II. the articles to be subscribed, are the articles mentioned in the preceding statute: the limiting clause, therefore, being still in force, there is no act of the legislature, imposing subscription to all the 39. Such is the opinion of Archdeacon Blackburne and Mr. Selden, but others are of a different opinion. We shall here merely remark, that the origin of the Act of Uniformity under Charles II. and various clausules in the act itself, suppose the reception of the disciplinarian, as well as the doctrinal and sacramental articles, and that the canons of the church do actually impose them all.

Can it be said, as some persons have argued, that a latitude of interpretation may be applied to articles which were framed to testify common consent, and which were designed to prevent a diversity of judgment? By those who are acquainted with the history of the times under consideration, and with the sentiments and character of the compilers and impensors of the articles, it must, as it has been conceived, be allowed, that the notion of diversity of judgment never entered into the minds of the English reformers: they supposed that the Scriptures had but one meaning, and with an excess of confidence imagined, that they were in possession of the truth. In confirmation of this it has been urged, that when the "Harmony of Confessions" was published, among those of other reformed churches, that of the church of England appeared. So that bishop Burnet, though disposed on other occasions to a liberality of interpretation, and though he left his dying testimony against the hard injunction of subscription, (Conclusion of his History, vol. ii. p. 634, fol. ed.) ingeniously confesses in his "History of the Reformation," (vol. ii. p. 169,) that the 39 articles were something more than articles of peace, and adds, "that the men who subscribed them, when they were first sent out, did either believe them to be true, or else they did greatly prevaricate." The bishop’s opinion seems to have remained unaltered; for when his Exposition was about to be published, bishop Williams strongly recommended that they might be considered only as articles of peace. Upon which the late judge Burnet, mentioning this incident in his father’s life, observes "that there might, perhaps, be reason to wish that they had been only imposed as such; but there was nothing in our constitution to warrant a supporter in giving that sense to them." Those who respect the opinion of these two able judges, the one of the original intention of the church, the other of the point of law, cannot confidently contend for the pacific sense of subscription. According to the intent of the first subscriptions, maintained by the bishop in his Hift. Reform. above-cited, he could no more give the subscribers of the present age the privilege of availing themselves of different grammatical terms, than he could allow them to consider the articles as articles of peace. Did not the royal declaration prefixed to them, to which we have already referred, and never invalidated by any act of the legislature, preclude a latitude of subscription? The articles
The subscription of young persons, at the age of 16, on occasion of their matriculation at one of our universities, and at the other on taking various degrees, has been lamented by many thoughtful and candid persons, both in and out of the established church: and whilst disputes about the sense and extent of subscription have remained undecided, and persons of literature and liberality enter the church, or continue in it, under this condition, it has been concluded by uninterested observers of their conduct, that subscription cannot afford any great security to any church of the foundresses of its ministers. While there is such a diversity of opinions concerning the very act which is required in order to prevent it, it is no wonder that many reflecting persons with to decline it, and more especially to see lay-subscription altogether abolished. Whatever may be our own private opinion on this subject, we feel the force of the objections that have been urged against it by enlightened and upright members of the church establishment; nor can we forbear expressing a wish, without the prospect or possibility of deriving any advantage from the event, that some other mode of theological or political orthodoxy could be devised, and that the church and the legislature would think themselves safe in adopting it. The honours and emoluments suspended upon this act, and either directly or remotely accruing from it, both in the church and state, present temptations which embarrass youthful integrity, and which in some instances have perplexed and dissuaded persons of mature years. Perhaps more relaxed terms of conformity would not be injurious either to the established church, against which liberal dissenters and Catholics have no hostility, or to lay-professions, for the exercise of which in various situations, and with peculiar honour and advantage, subscription is a preliminary condition.

Experience seems to have proved, that subscription to articles of faith and creeds of human compilation, may be relaxed and even abolished with great satisfaction to the parties immediately concerned, and without entailing any injury on the civil or ecclesiastical community.

When Protestant-different ministers, in the years 1772 and 1773, applied to the legislature for relief in the matter of subscription, they twice met with a repulse: at length, however, in 1779, relief was granted; and though it was not granted in the extent which was desired, what was the consequence? The consequence was, that so far from having been productive of any evil, it almost past unnoticed: the whole result was, that those dissenting ministers who could comply with the requisition demanded, were placed in a state of legal security, without the least hazard to the church. Some, indeed, have objected to any kind of subscription, even to the scriptures, as a condition of exercising the ministerial office: conceiving that it is not the province of the civil magistrate to interdict, or allow the exercise of a religious function. Every man, it has been said, who is thought capable of preaching, and whose real or imagined talents will induce any to hear him, has a right to employ his time and faculties in this way, provided that he be answerable with no overt act, that renders him legally amenable to the cognizance of the magistrate. See Toleration.

Subscriptions of Witnesses in Law. A will of lands must, by Stat. 29 Car. II. cap. 3, s. 5, be attested or subscribed by three credible witnesses at least; but for other conveyances, the actual subscription of the witnesses is not required by law, though it is prudent in them to do so, in order to affix their memory when living, and to supply their evidence when dead.

Subsequent, something that comes after another, particularly with regard to the order of time. See Posterior.
subsidized estates, after the nominal rate of 4s. in the pound for land, and 2s. for their goods; and for those of aliens in a double proportion. But this affront was made according to an ancient valuation, which was so low, that one subsidy of this fort did not amount to more than 70,000l.

It was anciently the rule never to grant more than one subsidy and two fifteenths, at a time; but this rule was broken through, for the first time, on occasion of the Spanish invasion in 1588, when the parliament gave queen Elizabeth two subsidies and four fifteenths. Afterwards, as money sunk in value, more subsidies were given; and we have an instance, in the first parliament of 1640, of the king's defining twelve subsidies of the commons, to be levied in three years.

The grant of scutages, tallages, and subsidies, by the commons, did not extend to spiritual preferments, those being usually taxed by the clergy themselves in convocation; which grants of the clergy were confirmed in parliament; otherwise they were illegal and not binding. A subsidy granted by the clergy was after the rate of 4s. in the pound, according to the valuation of their livings in the king's books, and amounted to about 20,000l.

Whilth this custom continued, convictions used to 8t as frequently as parliaments, but the last subsidies thus given by the clergy were those confirmed by flat. 15 Car. II. cap. 10. since which another mode of taxation has generally prevailed, which comprehends the clergy as well as the laity; in recompence for which the beneficed clergy have from that period been allowed to vote at the election of knights of the shire; and thenceforward also the practice of giving ecclesiastical subsidies has fallen into total disuse. The last instance of this kind of grant occurs in 1670. Blackett. Comm. book i. See Land-Tax.

In France the king alone, by his own authority, was accustomed to impose subsidies on his people, at his own discretion.

The term subsidy is applied to the pecuniary succour granted by a power that does not take part in a war, to another that is actually engaged in it. The term is also often used to signify a sum of money, paid annually from one sovereign to another, in return for a body of troops, furnished for his wars or kept ready for his service. The treaties for procuring such a resource are called "subsidy treaties." What Grotius says, that they who pay subsidies to other sovereigns, to engage them in their defence against powerful enemies, by fo doing acknowledge their own weaknesses, and that such an acknowledgment diminishes somewhat of their dignity; must be understood of such rates as are too weak to defend themselves, and who, in respect hereof, render themselves, in some measure, tributary; not of such as, subsisting by their own strength, give subsidies to their weaker neighbours, to prevent their being over-run by others.

Such, e.g. as the kings of England and France are, with regard to Sweden, and several other princes; to whom they generally grant subsidies in the treaties they conclude with them.

In the lift of English duties, or impositions, are divers kinds of subsidies: as the subsidyeward, or old subsidy, which is a duty composed of a tonnage and poundage duty; names arising from the different regulations by which it is imposed and levied: the new subsidy, which is to be raised, levied, and collected by the same rules and orders, and under the same penalties and forfeitures, as are signified in the several acts contained in the book of rates: the one-third subsidy, or the amount of one-third of the preceding subsidy; or of the net new subsidy of tonnage and poundage: the two-thirds subsidy, which is an additional subsidy of two third parts of the new subsidy, upon all goods liable to the said new subsidy, excepted in certain cases, excepted by acts of parliament, and contained in the book of rates: the subsidy of 1747, which over and above all subsidies, additional duties, impositions, &c. is a poundage duty of 1sd. in the pound, to be paid in ready money on goods and merchandize imported, except for tobacco, with respect to which it may be secured by bond; which duty is to be levied and collected by the same means, and under the same penalties, &c. as are directed for the old subsidy: subsidies on spirits: subsidy outwards, composed of a tonnage and poundage, and paid in ready money before shipping off, in order to exportation: subsidy granted in 1758-9, of poundage upon certain goods and merchandizes to be imported into this kingdom, &c. See Pothlertay's Díct. art. Subsidy. See Customs.

Subsistence, in the Military Art, is the money paid to the soldiers weekly, not amounting to their full pay, because their clothes, accoutrements, tents, bread, &c. are to be paid; it is likewise the money paid the officers upon account, till their accounts be made up, which is generally once a year, and then they are paid their arrears.

Subsistence, more generally, denotes either that species of subsistence which is found in the adjacent country, such as forage and corn; or that which is provided at a distance, and regularly supplied by a well-conducted commissariat, confiding chiefly of meat, bread, beer, &c. to which may be added wood or coals, and straw, which are always wanted in an army.

Substance, Subsanta, something that we conceive to subsist of itself, fabe, independently of any created being, or any particular mode or accident.

Thus a piece of wax is a subsistence; because we can conceive it as subsisting of itself, and of its own nature, without any dependence on any other created nature, or without any particular mode, form, colour, &c. See Mode.

It is a being, however, which is the subject of modes or accidents. Of substances, some are thinking or conscious beings, and others are extended and fold, or impenetrable. Of the former class is the human soul, and of the latter, philosophers consider matter only. If we exclude space out of our consideration, there will remain but these two sorts of substances, vis., matter and mind, or body and spirit; at least we have no ideas of any other subsistence but these. See Watts's Logic, chap. ii. sect. 2. and Phil. Eff. eff. ii.

Spinosa maintains, that there is but one subsistence in nature, of which all created things are so many different modifications; and thus he makes the soul of the same subsistence with the body. The whole universe, according to him, is but one subsistence; which subsistence he holds endowed with an infinity of attributes, in the number of which are thinking and extension. All bodies are modifications of this subsistence, considered as extended; and all spirits modifications of the same subsistence, considered as thinking. See Spinozism. See also Matter and Soul.

Mr. Locke's philosophy of substances is more just: our ideas of substances, that great author observes, are only such a combination of simple ideas as is taken to represent distinct things subsisting by themselves; and with the confused idea of substance is always the chief. Thus, the combination of the ideas of a certain figure, with the powers of motion, thought, and reasoning, joined to substance, make the ordinary idea of man: and thus the mind observing several simple ideas to coexist, together, which being preformed to belong to one thing, or to be united in one subject, are called by one name, which we are apt, afterwards, to talk of, and consider as one simple idea. See Idea.
We imagine these simple ideas do not subsist by themselves; but suppose some substratum, in which they subsist, which we call substance.

The idea of true substance is nothing but the supposed, yet unknown, support of those qualities which are capable of producing simple ideas in us.

The ideas of particular substances are composed out of this obscure and general idea of substance, together with such combinations of simple ideas as are observed to exist together, and are supposed to flow from the internal constitution and unknown essence of that substance.

Thus we come by the ideas of man, horse, gold, &c. Thus the sensible qualities of iron, or a diamond, make the complex idea of those substances, which a smith or a jeweller, commonly knows better than a philosopher.

The same happens concerning the operations of the mind, thinking, reasoning, &c. which we concluding not to subsist by themselves, nor apprehending how they can belong to body, or be produced by it, think them the actions of some other substance, which we call spirit; of whose substance or nature we have as clear a notion as that of body; the one being the supposed substratum of the simple ideas we have from without, as the other of those operations which we perform in ourselves, so altered in substance, so altered in our ideas, that the idea of corporeal substance in matter is as remote from our conceptions as that of spiritual substance.

Hence we may conclude, that he has the most perfect idea of any particular substance, who has collected most of those simple ideas which exist in it; among which we are to reckon its active powers, and passive capacities, though not strictly simple ideas.

Substances are generally distinguished by secondary qualities; for our senses fail us in the discovery of primary ones, as the bulk, figure, texture, &c. of the minute parts of bodies; the real essences and constitutions and differences depend, and secondary qualities are nothing but powers with relation to our senses.

The ideas that make our complex ones of corporeal substances, are of three sorts: 1. the ideas of primary qualities of things which are discovered by our senses; such as bulk, figure, motion, &c. 2. The sensible secondary qualities, which are nothing but powers to produce several ideas in us by our senses. 3. The abstracts we consider in any substance, to cause or receive such alterations in its primary qualities as are the influence of the senses and the mind should produce in us different ideas from what it did before.

Besides the complex ideas we have of material substances, by the simple ideas taken from the operations of our own minds, which we experience in ourselves, as thinking, understanding, willing, knowing, &c. co-existing in the same substance, we are able to frame the complex idea of a spirit; and this idea of an immaterial substance is as clear as that we have of a material one.

By joining the last with substance, of which we have no distinct idea, we have the idea of spirit; and by putting together the idea of coherent solid parts, and a power of being moved, joined with substance, of which, likewise, we have no positive idea, we have the idea of matter.

Farther, there are other ideas of substances, that may be called collective, which are made up of any particular substances, considered as united into one idea, as a troop, army, &c. which the mind does by its power of composition. These collective ideas are but the artificial draughts of the mind, bringing things remote and independent into one view, the better to contemplate the discourse of them united into one conception, and signified by one name. For there are no things to remote which the mind cannot, by this art of composition, bring into one idea, as is visible in that signified by the name universe.

Such is the generally received doctrine of substance; but Bishop Berkeley, in his Principles of Human Knowledge, and Mr. Collier, in his Clavis Universalis, have made great refinements on the subject.

Substances, Compound Earthy, for Plants, in Gardening, such compound earthy materials as are prepared and made use of in raising and cultivating particular sorts of plants of the finer flowers and other kinds. These confit of various kinds of sandy, peaty, dungy, animal, and other matters, mixed and put together in many different ways and proportions, according to the particular nature of the several plants and flowers to be grown in or upon them.

The earthy substances which are the most proper for these mixtures in many cases, and especially for the auricular plant kind, are, that which has been thrown up by the mole in dry, fine pasture-ground; that of fine maiden down-land, which is free from all sorts of stony matters; that of the surface spit of earth taken from strong yellow or hazel loams; and that of any good black, rather stiff, maiden mould land.

With two parts of the strong loam, or any other of these earthy matters, three of goose-dung soaked in bullock's blood, and of sugar-baked flour, may be mixed; in two parts of each of these two last matters, and the same proportion of night-foil; and two parts of the two former to four of the loam, soaked in night-foil and urine, with a small proportion of sea-fand. Also four parts of night-foil to two of cow-dung and loam, with a small proportion of sea-fand; and other still smaller proportions of these different substances, mixed and well blended together, may be made use of for this purpose. Several other mixtures of sandy, peaty, or bog-earthly, and other matters, are likewise necessary, in other cases, for raising and growing different plants and flowers. These different substances should be well mixed and incorporated together for a considerable length of time, after being first put together in that very early spring season, and being very often turned over during that time; as by such means they will become not only more intimately blended and united, but rendered more sweet and in better condition, as well as have the seeds of weeds, grubs, and insects, more perfectly destroyed. It will likewise be of great benefit to have these earthy substances exposed so as that they may have the influence of the sun and air; and it will be advantageous, too, to have them occasionally thrown out to the thickness of two or three feet, in order that they may be more fully acted upon by the powers of the sun during the summer, and be more equally affected by the frosts of the winter; and thereby be brought into a more fine, sweet, mellow state for the support of potted flower and other plants.

Plants are not so subject to rot and canker, it is said, where such substances have been turned over and exposed frequently, as every six weeks or two months, in preparing them, when they are employed in growing them; besides, they are raised much faster by them after they have been so managed.

In cases where insects, worms, or grubs prevail in substances of this nature, a little quicklime may be used, which not only tends to destroy them, but hardens the putrefaction and preparation of the materials for use, and which may be still more expedited by spreading them out.

Any of the above substances of this sort that contain sea-fand, will answer well for some other plants besides those of the auricular kind, as the more common sorts of polyanthus and primroses; but the finer kinds of these
SUB

It is supposed, the too rapid decomposition of the animal matter, and renders it very durable in its effects upon land.

Substances of the hair, woolen-rag, and feather kind, are all analogous, it is said, in composition, and that they principally consist of a substance similar to albumen, united to gelatine. This is shown to be the case, it is said, by the ingenious researches of the above-named inquirer; and that the theory of their operation is similar to that of bone and horn shavings.

Such manures as are formed from thee, as well as other animal substances, in general, require, it is thought, no chemical preparation to fit them for the soil or ground. The great object of the farmer should be to blend them with the earthy constituent matters in a proper state of division, and to prevent, as much as possible, their too rapid decomposition.

The use of bone-duft and horn-shavings has been found excellent on grass and mowing land. On a dairy farm, they have been employed for many years with very great success, in the quantity of from fifty to a hundred bushels an acre; which will constantly be sufficient, where the land is in any tolerable state, and will last for five or six years in great perfections. The advantage in carriage is very great, especially where the land lies at a distance, or through bad roads; as, at one load, sufficient may be drawn to manure an acre of ground. This, with their great durability, must, it is thought, recommend them to all such farmers as have the means of procuring them. It is now even, at the town of Sheffield, in Yorkshire, it is said, become a trade to grind bones for the use of the farmer, as a manure. If, however, bones be mixed in a heap with lime, they will, it is affeeted, in a short time be reduced to powder. The most proper season for applying these substances is in February or March; but they may be used at any other time of the year, the advantage of a wet day or two being always taken, as by that means they more readily settle into the ground. Very great swathes of hay and clover have been had, in some cases, by this means.

The writer of the Agricultural Report of Cornwall states, that a strip of land of fifteen yards width in that diocess, which had bone manure applied to it ten years ago, still shows the effect of it; and that so sweet is the herbage on it, that the cattle hang upon it as long as they can find a blade of grass. In this case, the quantity of boney matter laid on was about twenty-four Winchester bushels; and which had been previously covered with quick-lime, that the bones might be more easily broken; and, as soon as the lime became effete, they were picked out, which, though retaining their form, were readily reduced to powder by a hammer; and then, in this state, spread out thinly by the hand over the land.

Substances of the bony kind should, of course, be converted, as much as possible, to this use, in every situation where they can be had.

SUBSTANCES, Refining, for Common Salt, in Rural Economy, the several different matters employed in preparing, purifying, and clearing the liquor, or brine, in the making of this sort of salt. A great many substances are made use of in this way, and for this purpose; but the principal of them, and the most material effects which they produce, are thefe, as stated by Dr. Holland, in the Corrected Account of the Agriculture and rural Pratrices of Cheshire. Though there has been nothing exact or correct in the application of these substances, the chief additions which have been made use of in this view, at different times, are acids, animal jelly and gluten, vegetable mucilage, new or stale ale, wheat flour, resin, butter, and alum.

The first, it is said, has not been much used at any time in the above district; and it is extremely doubtful whether any good effects arise from their use; though the use of four whey, by the Dutch, was long supposed to produce a superiority in their fat; but which is believed to be solely owing to the gentle fires with which they carried on the evaporation, and not to the acid added to the brine. This addition is now never made at any works in the above county. The second fort of substances, or those of animal jelly and gluten, have been much used for clearing the brine, and promoting the separation of the earthy contents, and they seem to be very similar in point of action, when added to the brine, to those which they have on wine and fermented liquors. The substances of this kind which have been used are blood, whites of eggs, glue, and calves' or cows' feet. Blood has been long used as an addition to the brine, for the purpose of clarifying it, as is evident from Jackson's account of the making of salt; and it is still occasionally used at some works, and, when fresh, is found highly useful; but the difficulty of procuring it in the quantity wanted, and of keeping it without putrefaction, are objections to its use in general. Whites of eggs have been frequently added to the brine, for the same purpose as blood; and though they are not now much used, it is not supposed that they would not answer the purpose, but that the same objection is capable of being effected by means less expensive. Glue is frequently used for clearing the brine, and is found to answer the purpose perfectly well; and this is the only substance used at many works. Vegetable mucilage, as that of linseed, has been occasionally used for clearing the brine, and has been found to produce the same effect as animal jelly; but an inconvenience attends the use of it in the large way: it becomes putrid soon after it is put into the brine, and then loses its mucilaginous quality. It seems probable, too, that new ale or flate ale, which were long used as additions to the brine for clarifying it, could have effect only as they contained a certain proportion of vegetable mucilage; the acid contained being of little or no consequence. They are now never used. Wheat-flour and rein have each, it is said, been occasionally added to brine, where the manufacturer has wished to produce a fat of small grain. The mucilage extracted from the flour may have some effect, if separated from the oily parts of the flour, but it is probable that these additions act mechanically, and, by the interposition of their small particles between the minute crystals of salt, may prevent the cohesion of these, and thus prevent the grain from small. These additions are rarely made in the above district. Butter or some other oily substance is very generally used as an addition to brine, during the evaporating process, and after the clearing has been made, to assist the granulation of the salt, and to make the brine work more kindly; and though it has been thought to have no good effect, experience leaves little room for doubting that the addition of it enables the salt to crystallize more readily.

Salt-makers have long, it is said, been in the habit of adding alum to their brine, when they wished to procure a hard firm salt, of large grain; and though some may have objected to its use, it is thought that it does assist in promoting the crystallization of the salt in large grains; but in what manner its effects are produced is not ascertained, as not more than three or four pounds of alum are added to a quantity of brine capable of yielding as many tons of manure of soda. The action and operation of these substances may be seen more fully explained in the work alluded to above.

Substances destructive of insects infecting Fruit-Shrubs and Trees, in Gardening, such as are capable of destroying them, or of preventing their injurious ravages and effects on trees. Many different kinds of substances have been recommended for the purpose, at different times; but nothing perhaps has yet been found fully effective in this intention, in all cases. The substances and modes directed below have latterly been viewed as useful in this way, in different papers inserted in the Memoirs of the Caledonian Horticultural Society.

As a preventive against gooseberry caterpillars, which frequently infect and injure shrubs of that kind, Mr. Macmurray, a nurseryman, has found the substances mentioned below as very simple and efficacious. In the autumn season, he says, let a quantity of cow-urine be provided, and let a little be poured about the stem of each bush or shrub, just as much as merely suffices to moisten the ground about them. This simple expedient is said to have succeeded in an admirable manner, and that its preventive virtues have appeared to extend to two successive seasons or years. The bushes which were treated in this manner remained free from caterpillars, while those which were neglected, or intentionally passed by, in the same compartment, were wholly destroyed by the depredations of the insects.

Another mode of prevention is proposed, which, it is said, is equally simple and effectual; but the good effects of which only extend to the season immediately succeeding to that of the application.

This is, in situations near the sea, to collect as much drift or sea-weed from the beach, when occasion serves, as will be sufficient to cover the whole of the gooseberry compartment to the depth of four or five inches. It should be laid on in the autumn, and the whole covering remain untouched during the winter and early spring months; but as the fruiting season advances, be dug in. This method, it is said, has answered his most sanguine expectations; no caterpillars ever infecting the compartments which are treated in this manner.

Another method, which is said to have been found successful in the practice and experience of Mr. Elliott, in preventing or destroying caterpillars on the above fort of fruit-shrubs, is this: as the black currant and elder bushes, growing quite close to those of the gooseberry kind, were not attacked by this fort of vermin, it was conceived that an infusion of their leaves might be serviceable, especially when prepared with a little quick-time, in the manner directed below. Six pounds each of the two first forts of leaves are to be boiled in twelve gallons of soft water; then fourteen pounds of hot lime are to be put into twelve gallons of water, and, after being well incorporated with it, they are both to be mixed well together. With this mixture the infected gooseberry bushes or fruit-trees are to be well washed by the hand garden-engine; after which a little hot lime is to be taken and laid about the root of each bush or tree to wash, which completes the work.

Thus the caterpillars will be completely destroyed; it is said, without hurting the foliage of the bushes or trees in any way. A dull day is to be preferred for performing the work of washing, &c. As soon as all the foliage is dropped off from the bushes and trees, they are to be again washed over with the hand-engine, in order to clean them of all decayed leaves, and other matters; for which purpose any fort of water will answer. The surface of the earth, all about the roots of the bushes and trees, is then to be well flivered, and a little hot-lime again laid about them, to destroy the eggs or eggs of the insects.
This mode of management has never failed of success, it is said, in the course of six years' practice.

It is noticed, that the above quantity of prepared liquid will be sufficient for about two acres of ground in this sort of plantation, and cost but little in providing.

The use of about a gallon of a mixture of equal proportions of lime-water, chamber-ley, and soap-uds, with as much foot as will give it the colour and consistence of dung-hill drainings, to each bush in the rows, applied by means of the role of a watering-pot, immediately as the ground between them is dug over, and left as rough as possible, the whole being gone over in this way without treading or poaching the land, has also been found highly successful by others. The whole is then left in the above state until the winter frosts are fairly past, when the ground between the rows and bushes are levelled, and raked over in an even manner. By this means of practice, the bushes have been conflantly kept healthy, fruitful, and free from the annoyance of insects. The bushes are to be first pruned, and dunged where necessary.

A solution of soft soap, mixed with an infusion of tobow, has likewise been applied with great use in destroying caterpillars, by squirting it by the hand-syringe upon the bushes, while a little warm, twice in the day. But some think that the only safety is in picking them off the bushes, as they first appear, together with the lower leaves which are eaten into holes: also, the paring, digging over, and clearing the soil ground between the bushes, and treading and forcing such soil surface parts into the bottoms of the trenches.

Watering cherry trees with water prepared from quicklime, burrs, and common fods used in washing, in the proportion of a peck of the former and half a pound of the latter to a hogshead of water, has been found successful in destroying the green-fly and the black vermin which infect such trees.

The water should stand upon the land for twenty-four hours, and then drawn off by a cock placed in the caff, ten or twelve inches from the bottom, when the fods is to be put to it, being careful not to exceed the above proportion, as, from its acidity, it would otherwise be liable to destroy the foliage. Two or three times watering with this liquid, by means of a garden engine, will, it is said, destroy and remove the vermin.

The application of clay-paint, too, has been found of great utility in destroying the different insects, such as the coccus, thrips, and fly, which infect peach, nectarine, and other fine fruit-trees, on walls, and in hot-houses. This paint is prepared by taking a quantity of the most tenacious brown clay, and diffusing it in as much soft water as will bring it to the consistence of a thick cream or paint, passing it through a fine sieve or hair-sieve, so as that it may be rendered perfectly smooth, unadualous, and free from gritty particles.

As soon as the trees are pruned and nailed in, they are all to be carefully gone over with a painter's brush dipped in the above paint, especially the stems and large branches, as well as the young shoots, which leaves a coat or layer, that, when it becomes dry, forms a hard crust over the whole tree, which, by closely enveloping the insects, completely destroys them, without doing any injury to either the bark or buds. And by covering the trees with matto or canvas in wet seasons, it may be preferred on them as long as necessary. Where one drenching is not effectual, it may be repeated; and the second coating will mostly be sufficient. Where peach and nectarine trees are managed with this paint, they are, it is said, very rarely either hide-bound or attacked by insects.

This sort of paint is also useful in removing the mildew, with which these kinds of trees are often affected; as well as, with the use of the dew-syringe, in promoting the equal breaking of the eyes of vines, trained on the rafters of pine trees. See Syringe, Dew.

Watering the peach-tree borders with the urine of cattle, in the beginning of winter, and again in the early spring, has likewise been thought beneficial in destroying the insects which produce the above disease. Careful and proper cleaning and washing these trees, walls, and other places in contact with them, has, too, been found of great utility in preventing insects from accumulating on them.

SUBSTANCE, Colourings, for Chees, in Rural Economy, the material used in colouring cheese in some districts. It mostly consists of a portion of annatto, which is used by rubbing it upon a stone kept for the purpose, and then mixing it in the liquid flate with the milk. It is regulated in quantity by the shade of colour which is to be given, without any fixed rule. The quantity of an ounce is mostly the allowance for a hundred weight of cheese. Substances of this kind are most commonly used for the thinner sorts of cheese.

SUBSTANTIAL, in the Schools, something belonging to the nature of substance.

SUBSTANTIVE is also used in the same sense with essential, in opposition to accidental; in which relation it gives room for abundance of distinctions.

SUBSTANTIVE, in Grammar, is a quality ascribed to a noun or name, when the object it denotes is considered finally, and in itself, without reference to any other subject or idea. See Nouns.

Substantives, according to Mr. Harris, are all those principal words which are significant of substances, considered as substantives. See Speech.

Some of these are primary, or substantives properly so called, and have number and gender, and denominated nouns; and others are secondary, which are otherwise called pre-nouns. Hermes, ch. iv. and v.

Nouns substantive sometimes are used adjectively; and nouns adjectival also sometimes become substantives. See Nouns.

Indeed, custom does not allow us to use all adjectives indiscriminately, as substantives; nor all substantives as adjectives.

The laws observed in this respect are as follow:

All nouns either signify an individual, as Socrates, Alexander, &c.; or a species, as man, horse, &c.; or an essential quality, as rational, material, &c.; or an accidental one, as black, white, good, fair, &c.; or a dignity, office, art, &c.; as king, president, philosopher, &c.

Thus have we four kinds of nouns, of which the first is very rarely taken adjectively; for as they signify individuals, or particular beings, they can scarcely be applied to any thing but the thing they properly signify; yet we have sometimes known the name of Cato taken adjectively; as, This is to be Cato, indeed. Nor does Mallerbe scruple to say in French, Plus Marre que le Mars de la Thrace. Add, that proper names are sometimes converted into names of dignities, &c. as Caesar, Augustus, &c. In which case they may be considered, in the same light, as nouns of the fourth kind. Nouns of the second kind are also sometimes taken adjectively, as He is much a man, &c. The third kind are adjectives of themselves. For the fourth kind, all grammarians rank them among substantives, excepting F. Buxtorf, who will have them to be adjectives; or, to use his own
term, modificatives. Be that as it will, they are frequently used adjectively: *He is more a king, and more a philosopher, than any of his predecessors.*

Now, for adjectives taken substantively, 1. Participles passive are very rarely thus taken; though we sometimes say, *The loved are less happy than the lovers:* the taught have the advantage of the untaught: the befogged make a folly, &c. And, 2. Participles active are taken still more rarely for substantives. We scarcely ever, e.g., say, *the viewing, the reading; but* the lover, *the reader:* yet we say, *the fluent, the protestant, the tenant, the appellant, the opponent,* &c. 3. For nouns adjective, those applied to men are not only used substantively, but are even become substantives by use, whether they be such as regard religion, as Christian, pagan, Mahometan, &c.; or opinion, as Stoic, Peripatetic, Cynic, &c.; or country, as the English, French, Italian; or temperament, as the melancholy, phlegmatic, choleric, &c.

Under the same rule are likewise comprehended abundance of adjectives, signifying a number of people agreeing in some common attribute; as, *the learned, the great, the devout, the brave, the disinterested.* But use is here to be regarded; for we do not say the elegant, as we say the learned; but elegant writers, &c. Cullum, and the ear alone, are to decide these.

Again, adjectives taken substantively, for other things besides men, are either so used, to signify a number or sort of things that have some common quality; or to express an abstract quality. In both which, as in those men, there are some authorized by custom, and others formed every day on their model.

With regard to which last, use again, and the ear, are to decide. Here all the adjectives of colours are used substantively, as the white, black, green, &c. Some of those of qualities, as the cold, &c.; those of time, as the past, present, future; and many other matters, as the agreeable, the sublime, the principal, &c. Nor is it only in the positive, but also in the comparative and superlative degrees, that adjectives are used substantively; as the better of the two; the less of it, &c.

**SUBSTANTIVE VERB.** See **VERB.**

**SUBSTITUTE, SUBSTITUTE,** formed from sub, under, and statuo, *I appoint, or establish,* a person appointed to officiate for another, in case of absence, or other legal impediment.

A substitut in the militia is a person who voluntarily offers to serve in the room of another that has been chosen by ballot. But if he himself should be afterwards chosen by ballot, he is not exempted from serving again, as principals are, within certain restrictions. Substitutes may be provided for Quakers. Every substitute is liable to a penalty for not appearing to be sworn upon due notice being given; and every regularly enrolled soldier, who shall offer to serve as a substitute in the militia, is liable to forfeit $10; or to be imprisoned. Substitutes who defect are to serve the remainder of their time when taken.

**SUBSTITUTE, in Medicine, denotes a drug, or remedy, that may be used in lieu of another; or that supplies the place of another of like virtue, which is not to be had; called also succedaneum.**

**SUBSTITUTES, in Ship-Building.** For wood knees, that article of late being very scarce, many substiutes have been proposed and used. For instance, knees made of iron have been and are now much used in merchant-ships, particularly in East Indiamen. For hanging knees, and have been found to answer very well. But in king’s ships, wood and iron combined together, are used in more ways than one to connect the fids and beams together. One method was by an oak-chock at each end of the beam, sided as large as the beam at the upper end, and to taper to two-thirds of that size at the lower end, and moulded about two feet broad at the upper end, and one-third of that at the lower end, which reaches down six inches upon the spirit-kitting. Those chocks are fayed to the side, and close up to the under side of the beam, in such manner as to have a mortice, about one inch and a quarter by one inch and three-quarters deep, within and clear of the iron-plate knees. They are then bolted through the side with six bolts; the two upper bolts to be one inch and three-eighths; the two middle, one inch and a quarter; and the two lower ones, one inch and one-eighth. The beams are then secured to the chocks by iron-plate knees, five inches broad and one inch and an eighth thick: the arms along the beam and down the chock to be each four feet long, with a return or arm at the upper part against the side, about eighteen inches long each: the chock and beam-arm are connected by a diagonal brace, just to clear the front of the chock: before the plates are let in, iron keys are driven in the mortice at the head of the chock, which are sheathed with copper for that purpose. The iron-plate knees are then let in flush their thickness into the side of the beam and chock, one on the fore-side and one on the aft-side, the fluted and clotted through each other, with four bolts through the beam-arms, four through the chock-arms, and one through the middle of the brace of one inch and three-eighths, and two bolts through the side in each return or fore and aft arm, one of inch and three-eighths and one of inch and a quarter.

Observe, when any of the beams come over a port, they are to be knead at each end with one wood lodging and one wood or iron hanging knee, to cast clear of the side of the port.

At present, the fids are farther secured with a shelf, having a chock underneath, and an iron knee in front, under each beam. Thus the shelf is a piece of thick stuff of ten inches deep and about fourteen inches broad,ayed along the side and under-side of the beams all fore and aft, and scarfs one into the other, with a scarf fix six feet long, or in the round of the bow to have anchor-rock pieces fayed into the scarfs. The fore end of the shelf laps about four feet under the deck-hook, and douels thereto with two or more douls, and bolts upwards through the hook.

In the fids, the fids, the atf, and the clamps, with the arms, the arms, the facebook pieces to each side, and four douls in each scarf, and two douls upward into each beam and into the deck-transform; it is then set close, and bolted through the side with one inch and quarter bolts, about twenty inches and a half. The edges of the beams are next bolted through the shelf, with one bolt of an inch and a quarter, to clear the heads of the chocks, and one also through the water-ways.

Under each beam is fayed an oak-chock, close up under the shelf, ten inches sided, and moulded at the head to the breadth of the shelf, and at the heel not less than three inches, which reaches down to the spirit-kitting. In the front of each chock is fayed an iron knee, five inches broad and five inches thick at the shoulder, and one inch thick at the extremities, that is, the beam-arm to be three feet six inches long, and the arm on the chock to reach about six inches, or to take a bolt through the spirit-kitting; the beam-arm has four bolts, of one inch and three-eighths, driven upwards, and the chock-arm five bolts of one inch and three-eighths, except the two lower ones, which may be one-eighth less.

Sometimes these knees, instead of an arm along the beam, have a strap on each side, which claps the beam and bolts, with
with two bolts through the beam fore and aft, and one upwards at the shoulder or return.

Observe, that the foregoing given dimensions are for securing the gun-deck beams of a seventy-four gun ship, consequently the decks above are less in proportion, as likewise ships of a less rate.

SUBSTITUTION, in Grammar, the using of one word for another; or one mode, statue, person, or number, of a word for another. This the grammarians otherwise call a *fide commissa*.

SUBSTITUTION, in Civil Law, a disposition of a testator, by which he substitutes one heir to another, who has only the usufruit, and not the property of the thing left him.

Substitution is a kind of fiduciary inheritance, called also *fide commissa*, in regard the immediate inheritor has only the use or produce of the thing; the body of it being substituted and appropriated to certain persons, who are likewise to have the usufruit in their turns, but are never to have the property.

In some countries substitution is perpetual; in France it only holds to the fourth generation. Substitution answers to *remainder* in common law.

Among the Romans there was abundance of these fiduciary heirs, who enjoyed inheritances till they returned them into the hands of the right heir; and the reason why they did not likewise restore the fruits, or that the fruits were not deemed to make a part of the inheritance, but only of the thing, was, that the fiduciary or trustee was obliged to run the risk, and to hand the charge of the culture of the land.

SUBSTITUTION, in Algebra, &c. is the putting in the room of any quantity in an equation, some other quantity which is equal to it, but expressed by another manner. See *Reduction of Equations*.

SUBTRACTION, or Subtraction, in Arithmetic, the second rule, or rather operation, in arithmetic, by which we deduce a less number from a greater, to learn the precise difference.

Or, more jutly, subtraction is the finding of a certain number from two homogenous ones given, which with one of the given numbers, is equal to the other.

The doctrine of subtraction is reducible to what follows:

To Subtract a Less Number from a Greater. 1. Write the less number under the greater, in such manner, as that homogenous figures answer to homogenous, i.e. units to units, tens to tens, &c. as directed under Addition.

2. Under the two numbers draw a line. 3. Subtract, severally, the units from units, tens from tens, hundreds from hundreds; beginning at the right hand, and proceeding to the left: and write the several remainders in their correspondent places, under the line. 4. If a greater figure come to be subtracted from a less, borrow an unit from the next left-hand place; this is equivalent to 10, and, added to the less number, the subtraction is to be made from the sum; or if a cipher chance to be in the next left-hand place, borrow the unit from the next farther place.

By these rules any number may be subtracted out of another greater. For example:

If it be required, from 9800403459 To subtract 4743865263

The remainder will be found 505658196

For, beginning with the right-hand figure, and taking 3 from 9, there remain 6 units, to be written underneath the line: going then to the next place, 6, I find, cannot be taken from 5; wherefore, from the place of hundreds, 4. I borrow 1, which is equivalent to 10, in the place of tens; and from the sum of this 10 and 5, viz. 15, subtrahend 6, I find 9 tens remaining, to be put down under the line. Proceeding to the place of hundreds, 2, and the 1 borrowed at the left, make 3, which subtrahend from 4, leave 1.

Again, in the place of thousands, cannot be subtrahend from 3; for which reason, taking 1 from 4, in the place of hundreds of thousands, into the empty place of tens of thousands, the cipher is converted into 10 tens of thousands; whence one 10 being borrowed, and added to the 3, and from the sum 13 thousand, 5 thousand being subtrahend, we shall have 8 thousand to enter under the line; then subtrahend 6 tens of thousands from 9, there remain 3. Coming now to take 8 from 4; from the 8 farther on the left, I borrow 1, by means of which, the two ciphers will be turned each into 9. And after the like manner is the rest of the subtraction safely performed.

If heterogeneous numbers be to be subtracted from each other, the units borrowed are not to be equal to ten, but to so many as there go of units of the less kind, to constitute an unit of the greater: for example:

\[
\begin{array}{c|c|c|c}
 & \text{l.} & \text{r.} & \text{d.} \\
\hline
45 & 16 & 6 \\
27 & 19 & 9 \\
\hline
17 & 16 & 9
\end{array}
\]

For since 9 pence cannot be subtracted from 6 pence; of the 16 shillings, one is converted into 12 pence; by which means, for 6 we have 18 pence; whence 9 being subtrahend, there remain 9. In like manner, as 19 shillings cannot be subtracted from the remaining 16; one of the 45 pounds is converted into 20 shillings, from which, added to the 16, 19 being subtrahend, the remainder is 16 shillings. Lastly, 27 pounds subtracted from 44 pounds, there remains 17.

If a greater number be required to be subtracted from a less, it is evident the thing is impossible. The less number, therefore, in that case, is to be subtracted from the greater; and the defect to be noted by the negative character. E.g. If I am required to pay 2 pounds, and am only matter of 3, when the 3 are paid, there will remain 5 behind, which are to be noted, — 5.

Subtraction is to be proved by adding the remainder to the subtrahend, or number to be subtracted: for if the sum be equal to the number whence the other is to be subtracted, the subtraction is jutly performed. For example:

\[
\begin{array}{c|c|c|c|c|c}
& \text{l.} & \text{r.} & \text{d.} \\
\hline
9800403459 & 156 & 11 & 3 \\
4743865263 & 21 & 17 & 3 \\
\hline
505658196 & 134 & 14 & 0 \\
\hline
9800403459 & 156 & 11 & 3 \\
\end{array}
\]

Subtraction, in Algebra, is performed by connecting the quantities with all the signs of the subtrahend changed; and at the same time uniting such as may be united; as is done in addition; which fee.

Thus + 7 as subtracted from + 9 a, makes + 9 a — 7 a, or 2 a.

In the subtraction of compound algebraic quantities, the characters of the subtrahend are to be changed into the contrary ones, vis. + into —; and — into +.
As the addition of algebraic quantities includes three cases, viz. 1. The addition of like quantities with like signs, for which the rule is to add the co-efficients, to prefix the common sign to their sum, and to subjoin the common letter or letters: 2. The addition of quantities that are like with unlike signs, for which the rule is to substract the smaller co-efficient from the greater, to prefix the sign of the greater to the remainder, and to add to the common letter or letters: and 3. The addition of quantities that are unlike, for which they are made like by the signs or co-efficients prefixed: the general rule for substraction, comprehending all the cases that occur, is, change the signs of the quantity to be substracted into their contrary signs, and then add it to changed to the quantity from which it was to be substracted; the sum arising by this addition is the remainder, because, to substract any quantity, either positive or negative, is the same as to add the opposite kind.

From + 5 a
Substract + 3 a
Rem. 5 a - 3 a or 2 a.

From + 5 a
Substract - 3 a
Rem. + 5 a + 3 a = 8 a.

From - 5 a
Substract + 3 a
Rem. - 5 a - 3 a = - 8 a.

From - 5 a
Substract - 3 a
Rem. - 5 a + 3 a = - 2 a.

From 2 a - 3 x + 5 y - 6
Substract 6 a + 4 x + 5 y + 4
Rem. - 4 a - 7 x - 9 y - 10.

SUBTRACTION of Logarithms. See LOGARITHMS.
SUBTRACTION of Vulgar Fractions. See FRACTIONS.
SUBTRACTION of Decimals. See DECIMALS.

SUBTRACTION of Surds. See SUBTRACT.
SUBSTRENS, in Agriculture, a term sometimes used to signify the under stratum or bed of soils, or that which is interposed between the surface layer of materials, and the base or substructure upon which the whole is disposed or laid. See SOIL and STRATA.

SUBTRUCTION, in Building, denotes underpinning, ground-footing, &c. See Foundation.

SUBSTYLE, or SUBSTYLAN LINE, in Dialling, a right line, on which the style or gnomon of a dial is erected.

The angle included between this line and the style, is called the elevation or height of the style. See Style.

In polar, horizontal, meridional, and northern dials, the substyle line is the meridional line, or line of 12 o'clock; or intersection of a plane, on which the dial is delineated, with that of the meridian.

In all declining dials, the substyle makes an angle with the hour-line of XII, and this angle is called the distance of the substyle from the meridian.

In easterly and westerly dials, the substyle line is the line of 6 o'clock, or the intersection of the plane, on which the dial is delineated, with the prime vertical.

SUBSUPERPARTICULAR. See Ratio.

SUBSUPERPARTIENS. See SUBNORMAL.

SUBTANGENT of a Curve, the line that determines the intersection of a tangent with the axis; or that determines the point in which the tangent cuts the axis, prolonged.

Thus in the curve $AM$, &c. (Plate XIV. Analysis, fig. 5.), the line $TP$ intercepted between the semiordinate $PM$, and the tangent $TM$, is the subtangent. And $PR$ is to $PM$, as $PM$ to $PT$; and $PM$ to $PT$, as $MR$ to $TM$. See SUBNORMAL.

It is a rule in all equations, that if the value of the subtangent come out positive, the point of intersection of the tangent and axis falls on that side of the ordinate, where the vertex of the curve lies; as in the parabola and paraboloids. If it come out negative, the point of intersection will fall on the contrary side of the ordinate, in respect of the vertex or beginning of the absciss; as in the hyperbola and hyperboliform figures.

And universally, in all paraboliform and hyperboliform figures, the subtangent is equal to the exponent of the power of the ordinate, multiplied into the absciss: thus, in the common parabola, whose property is $t * = y y$, the subtangent is in length equal to $x$, the absciss, multiplied by $y$, the exponent of the power of $y y$, the square of the ordinate; that is, it is equal to twice the absciss: and by the former rule for paraboliform figures, it must be taken above the ordinate in the axis produced.

Thus, also, in one of the cubical paraboloids, where $p = x = y y$, the length of the subtangent will be $4 d s$ of the absciss: and in a parabola of any kind, the general equation being $a n = x a = y a +$, the subtangent is $= m + n$ or its ratio to the absciss is constantly that of $m + n$ or $n$. See Method of Tangents.

In the parabola, the subtangent $PT$ is double the absciss $AP$; and the subnormal $PR$ is subduple of the parameter.

SUBTENSE, formed from sub, under, and tendo, to stretch, in Geometry, a right line opposite to an angle, and presumed to be drawn between the two extremities of the arch which measures that angle.

The subtense of the angle coincides with the chord of the arc.

In every right-angled triangle, the square of the subtense of the right angle is equal to the squares of the subtenses of both the other angles, by the 47th prop. of Euclid. See HOMOTHETUS and TRIANGLE.

SUBTURGES, in Geography, a town of Hindoozian, in Oude; 22 miles E. of Luckow.

SUBTURMOOK, a river of Bengal, which runs into the bay of Bengal, N. lat. 21° 55'. E. long. 88° 30'.

SUBTERRANEUS, or SUBTERRANEAN, something under ground.

Naturalists talk much of subterranean fires, as the cause of volcanoes; and subterranean winds, as the cause of earthquakes.

Among the many places where subterranean fires are found, England is not wholly without them; though with us they appear only in the coal countries, and plainly feed on nothing but the upper stratum of the coal, called by the miners day-coal, unless where they have by accident been kindled.
kindled by actual fires at great depths, or fired downward, by being pent in for room. See VOLCANO.

We have an account in the Philosophical Transactions, of a subterranean town found at Portici, near Naples, in which many ancient statues, paintings, and other curiosities have been found. This subterranean town is probably the ancient city of Herculanum, which was swallowed up by an earthquake. See Phil. Trans. No 458. sect. 4, 5, and 6.

It is remarkable, that some of the ancient statues found there are as fresh and perfect, as if lately painted. Ibid. sect. 6. See Herculanum.

SUBTILE, in Physic, intimates a thing exceedingly small, fine, and delicate; such as the animal spirits, the effluvia of odorous bodies, &c. are supposed to be.

One kind of matter is only more subtile than another, in that, being divided into smaller parts, and those too more agitated; on the one hand, it makes less resistance to other bodies; and, on the other, inflates itself more easily into their pores. The Cartesians suppose a subtile matter for their first element. See CARTESIAN, and MATERIA SUBTILIS.

SUBTILIZATION, SUBTILIZATIO, the act of subtilizing, or rendering anything smaller and subtiler; particularly, the dissolving or changing of a mixt body into a pure liquor, or a fine powder, by separating the groarser parts from it.

SUBTRACTION. See SUBTRACTION.

Subtraction of Conjugal Rights, in Law, is where either the husband or wife lives separate from the other without sufficient reason; in which case the ecclesiastical jurisdiction, on a suit for restitution of conjugal rights, will compel them to come together again, if either party be weak enough to desire it, contrary to the inclination of the other.

Subtraction of Legacies, denotes the witholding or detaining of legacies, for which the spiritual court administrators redress, by compelling the executor to pay them. But in this case, the courts of equity exercise a concurrent jurisdiction with the ecclesiastical courts, as incident to some other species of relief prayed by the complainant; so to compel the executor to account to the testator's effects, or to the legacy, or the like.

Subtraction, with regard to real Property, is an injury which happens, when any person, who owes any suit, duty, custom, or service, to another, withholds or neglects to perform it. It differs from a diffe[m], (which see,) in that this is committed without any denial of the right, confining merely in non-performance; that strikes at the very title of the party injured, and amounts to an ouster or actual dispossession. (See OUSTER.) Subtraction, however, being a clearly an injury, is remediable by due course of law; but the remedy differs according to the nature of the services; whether they be due by virtue of any statute, or by custom only. (See Blackf. Comm. vol. iii.

Subtraction of Titles, is the witholding of titles from the parson or vicar, whether the former be a clergyman or a lay appropriator. (See TITLES.) In this case, luminary and expiatory affiance is given by the statutes of 27 Hen. VIII. cap. 20, and 32 Hen. VIII. cap. 7, which enact, that upon complaint of any contempt or misbehaviour to the ecclesiastical judge by the defendant in any suit for titles, any privy-counselor, or any two justices of the peace (or in case of disobedience to any definitive sentence, any two justices of the peace) may commit the party to prison without bail or mainprize, till he enters into a recognizance, with sufficient sureties, to give due obedience to the process and sentence of the court. Blackf. Comm. vol. iii.

SUBTRAY, or Meniere en Brenne, in Geography, a town of France, in the department of the Indre; 9 miles S. of Chartillon.

SUBTRIPLE RATIO. See Ratio.

SUBU, in Geography. See SIBBOO.

SUBVERSIO STOMACHI, a term used by some authors to express a violent vomiting, when what should pass through the intestines is voided constantly by the mouth.

SUBULARE FOLIUM, among Botanists. See LEAF.

Gen. Ch. Cal. Perianth inferior, of four, ovate, concave, spreading, deciduous leaves. Cor. cruciform, of four, obovate, undivided petals, rather larger than the calyx. Stam. Filaments fix, not so long as the corolla, the two shorter ones opposite; anthers minute. Fil. Germinfer superior, ovate; style shorter than the pouch; stigma obtuse. Peric. Pouch ovate, compressed, entire, tipped with the short style, of two cells; the partition contrary to its greater diameter; valves ovate; deeply concave. Seeds very small, roundish.

Eff. Ch. Pouch entire, elliptical, of two, deeply concave valves. Partition contrary to the greater diameter of the pouch. Style very short.

We have followed Wildenow in making this a species of Subularia, from Scopoli's description.

SUBULATED LEAF. See LEAF.

SUBULGUR, in Geography, a town of Hindoostan, in the circuit of Gohud; 20 miles S. of Kerowly.

SUBULO, a term used by Pliny for two years old. See FERULA.

SUBULO, in Natural History, a word used by the ancients to express a deer, or stag, at that time of its life when the horns first begin to appear.

Others have understood it as the name of the oryx, whose horn was narrow at the summit, and thence gradually larger toward the base; so that it resembled the figure of the fibulo. This is the fabulous creature called the unicorn, and described as a nimble and terrible animal. But it is certain that no such animal ever existed, as is called by this name, and it is thus described: the one-horned animal in the
the world is the rhinoceros, and this is an unwieldy heavy animal, not at all resembling the characters or figures we have of the fabulo, or oryx.

It is to be observed, that the fabulo of the most ancient writers was an instrument of iron, sharp at the point, used in the Rome-queries to break a way through large masts.

Suburbanus, Suburbanus, formed from sub, under, and urbs, city, an epithet given to those provinces of Italy, &c. which composed the ancient diocesi, or patriarchate of Rome. They were also sometimes called urbaria provinces.

Authors usually reckon ten of these suburbanus provinces; of which Italy, from the Po to the heel, made seven; and the isles of Sicily, Sardinia, and Corsica, the other three.

Yet Salamanus will have the suburbanus provinces confined to those four in the neighbourhood of Rome, to which the authority of the prefect of Rome extended; and these he makes the limits of the diocese of ancient Rome.

F. Sirmond takes the other extreme, and comprehends all the West under the name of suburbanus provinces.

Rufinus, who lived in the age of the council of Nice, explains the power ascribed to the pope, in the fifth canon of that council, by saying, that he had the care and superintendence of the suburbanus provinces. Hence the different sentiments of authors, with regard to the suburbanus provinces; some only conferring the pope as bishop of Rome; others as patriarch of the West, &c.

- Suburbs, buildings without the walls or compas of a city or town.

SUC Samhil, in Geography, a town of Peru, in Chusitan, 70 miles S. of Toifar.

SUC Aife, a town of Arabia, in Hedjas; 25 miles S. E. of Jambo.

SUCCADA, a town of Tripoli, in the gulf of Sidra; 45 miles S. E. of Medurada.

SUCCEADA, a town of the island of Borneo, and capital of a kingdom of the same name, at the mouth of a river. The chief products of the country are camphor and diamonds. S. lat. 6° 56'. E. long. 109° 56'.

Succesdaneum, formed from succeso, to succeed, in Pharmacy, a remedy substitutit in the place of another first prescribed, when the ingredients are wanting necessary for the composition of that other.

Substituta and sucedaneum are of equal import; unless with some authors we choose to use a substitute, where a simple of like virtue is put for another; and sucedaneum where a compound is used with the same intention for another compound.

Succenturiati Renes, in Anatomy, the renal capsules, as if they were subsidiary kidneys. (See Kidney.) The same epitaph is also given to the small additional spleens, when they occur.

Succenturiation, the act of substituting. See Substitution.

Success, in Geography, an uninhabited township of New Hampshire, in Grafton county, N. E. of the White mountains, on the E. line of the state, incorporated in 1773.

Success Bay, or Good Success Bay, a bay on the S. E. coast of Terra del Fuego, in the Straits of Le Maire. On the mountains inland of this bay, Mr. (now Sir Joseph) Banks and Dr. Solander found many new alpine plants, unknown in Europe; but the cold was so intense, that the latter had nearly fallen a sacrifice to its severity in the midst of summer. Dr. Solander, who had more than once crossed the mountains which divide Sweden from Norway, well knew that extreme cold, especially when joined with fatigue, produces a torpor and sleepiness that are almost irremediable: he therefore con- jured the company to keep moving, whatever pain it might cost them, and whatever relief they might be promised by an inclination to rest: whatever its downs, says he, will sleep; and who soever sleeps, will wake no more. Dr. Solander himself was the first who found the inclination, against which he had warned others, irremediable; and insinced upon being suffered to lie down. Mr. Banks intreated and re- monstrated in vain; down he lay upon the ground, though it was covered with snow, and it was with great difficulty that his friend kept him from sleeping. Richmond also, one of the black servants, began to linger, having suffered from the cold in the same manner as the doctor. Mr. Banks, there- fore, at first five of the company, one by one, Mr. Bed- chan, forward, to get a fire ready at the first convenient place they could find, and himself and four others remained with the doctor and Richmond, whom partly by persuasion and intreaty, and partly by force, they brought on, till they both declared they could go no farther. Mr. Banks had recourse to intreaty and expostulation, but they pro- duced no effect: when Richmond was told, that if he did not go now he would in a short time be frozen to death, he answered, that he defied nothing but to lie down and die. The doctor did not so explicitly renounce his life; he said he was willing to go on, but that he must first take some sleep, though he had before told the company that to sleep was to perish. Mr. Banks and the rest found it impossible to carry them, and there being no remedy, they were suffered to lie down, being partly supported by the buffets, and in a few minutes they fell into a profound sleep: soon after, some of the people who had been sent forward returned with the welcome news that a fire was kindled about a quarter of a mile farther on the way. Mr. Banks then endeavoured to wake Dr. Solander, and happily succeeded; but though he had not slept five minutes, he had almost lost the use of his limbs. Mr. Bed- chan, the muscles were so shrunk, that his shoes fell from his feet; he confessed to go forward, with such anattisance as could be given him, but no attempts to relieve poor Richmond were successful. Richmond, and a feaman sent to his relief, died. S. lat. 54° 50'. W. long. 65° 27'.

Cape Success in this bay at the point lies in S. lat. 55° 17'. W. long. 65° 27'.

Succession, Successio, in Philosophy, an idea which we get by reflecting on that train of ideas constantly following one another in our minds when awake.

The distance between any parts of this succession, is what we call duration (which see). When this succession of ideas occurs, we have no perception of time, or of was duration, but the moment we fall asleep, and that in which we awake, seem connected.

They who think we get the idea of succession from our observation of motion by our senses, will adopt Mr. Locke's sentiment above stated, when they consider that motion produces an idea of succession no otherwise than by producing a continual chain of dizziness ideas.

A man that looks on a body moving, perceives no motion, unless that motion produces a constant train of suc- cessive ideas. But wherever a man is, though all things be at rest about him, if he thinks, he will be conscious of succession.

Succession of the Signs, in Astronomy, is the order in which they follow each other, and according to which the sun enters, successively, into one, then into another; called, also, constantia. This
This order is expressed in the following technical terms:

"Sunt Aries, Taurus, Gemini, Cancer, Leo, Virgo, Libra, Scorpius, Arcitesens, Caper, Amphi, Pilces."

Or, in English:

"The Ram, the Bull, the heavenly Twins, And next the Crab, the Lion shines, The Virgin and the Scales; The Scorpion, Archer, and He-goat, The man that holds the watering pot, And Fifth with glittering tails."

When a planet is direct, it is said to go according to the order and succession of the signs, or in consecventia; that is, from Aries to Taurus, &c. When retrograde, it is said to go contrary to the succession of the signs, or in antecedentia, or from Taurus to Aries, &c.

Succession, in the Civil Law, implies a right to the whole effect left by a defunct.

Of this there are several kinds, ab-intestate, intestate, &c.

Succession ab-intestate, is that which a person has a right to by being next of kin, which is what we call, being next heir at law.

Succession intestate, is that in which all the effects are divided among the heirs, in equal parts. In such cases of intestate succession, the laws of the Roman law of succession ab intestate, the general rule of which succession was this:

1. The children, or lineal descendants, in equal parts. 2. In failure of these, the parents, or lineal descendants, and with them the brethren, or sisters of the whole blood; or, if the parents were dead, all the brethren and sisters, together with the representatives of a brother or sister deceased. 3. The next collateral relations in equal degree. 4. The husband or wife of the deceased.

Succession, Testamentary, is that in which a person comes by virtue of a will.

Succession in the direct Line, is that coming from ascendants, or descendants. See Line.

Succession, Collateral, is that coming by uncles, aunts, or other collaterals. See Collateral.

Succession, Adjacent, or Abandoned, is a burdenome or vexatious one, which no body will accept of. There is no real succession in benefices; for, here nobody inherits.

In effects that cannot be divided, as kingdom, &c., the succession falls on a single head; which is usually the eldest son of the deceased, as being the indivisible representative of his father.

In effects that are divided, all the children represent their father. It was on this principle, M. Courtin observes, that each of the sons of Jacob had his share assigned him in the Land of Promise. It is true, Manassieh and Ephraim, the two sons of Joseph, had likewise their shares; but this was because a double portion had been allotted their father, wherein he was treated as elder brother, in consideration of the great services he had done his father and brethren.

Succession to the Crown. See Crown.

Succession, in Agriculture, a term applied to the order in which crops, or what occupies the fields, whether arable, lays, or fallows, succeed each other in, in the different fields.

Succession of Crops and Cropping, in Agriculture and Gardening, such as are put in so as to come in due or proper succession. See Crops, Course of, and Rotation of Crops.

A very useful and advantageous succession of cropping, in garden culture, is stated, in a paper in the "Memoirs of the Caledonian Horticultural Society," to be that of beginning with celery, which is planted on poor run-out parts of the ground, formed into ridges seven feet in breadth, and five between them, allowing three on each side; the space of seven feet is then cast out in making them to the depth of a spading and the shovellings, the earth being laid equally on each side, and filling the ridges with good dung; the thickness of a foot; which, after it is smoothed, and well trodden in, is covered, in the whole, to about the depth of four inches, with the mouldy earth thrown out; the celery plants being carefully set out across the ridges, about fourteen inches row from row. The crop will thus, it is said, when fully earthened up, stand four or five feet from the top to the bottom of the ridge. These ridges are supposed to have several advantages over single rows, the mode usually practised, as by digging so deep, there is in the course of blanching a great quantity of new earth mixed with the old surface and dung; and the celery is kept more dry and free from rotting in the winter. The ridges may be planted at different times, so as to come in well for winter and spring crops.

The next season after this crop, the ground may be planted with cauliflower and red beet; in that which succeeds that, it may be sown with onions; and in the fourth year, the ground may be cropped with turnips. All these crops are capable of being raised with perfect success, in succession after the celery, without any further manuring.

SUCCESSIVE ACTIO, in Law. See Action.

SUCCESSOR, a person who holds a place which another held before him; whether he arrived at it by election, collation, inheritance, or otherwise.

The king of the Romans is presumptive successor to the empire.

The canonists say, a codjutor is a necessary successor to a prelature; a refugee to the refugite.

Civilians say, a titular usufructuary can do nothing to the prejudice of his successor.

SUCIFERA VARA, in Natural History, a name given by those who have written of the anatomy of plants, to those vessels which contain the juices, by way of distinction from those which only give passage to the air, and are called trachee.

Leeuwenhoek tells us that the microscope discovers the succiferous vessels of plants to be, in all respects, analogous to those of animals, and that they are of two kinds, veins and arteries; the latter receiving the juices from the root, and carrying them all over the plant; and the others receiving the juice from their extremities, and carrying it back again to the root, where it is again delivered to the arteries.

SUCCINATS, in Chemistry, salts formed by the combination of any base with the succinic acid.

SUCCINIC ACID, is an acid that rises during the dry distillation of Amber (which see), partly in the form of spicular crysftals, which attach themselves to the neck of the retort, and partly dissolved in the volatile oil, which rises at the same time. In this state the acid is of a dark yellowish-brown colour, being contaminated by the oil, and requires successive rectification before it can be obtained tolerably pure. Two methods have been practised of purifying the acid; the first is, to mix the brown concrete acid with lands, or which is still better, with dry unburnt white clay, free from calcareous earth, but properly to sublimation by a very gentle heat; the clay detains the mother of the oil, and the acid rises to the upper part of the vessel, where it forms light-brown needle-shaped crystals. The second, and more economical way, recommended by Pott, is first to wash the oil in warm water, in order to separate the acid held by it.
SUC

in solution; then, after pouring off the oil, to add the solid acid, and heat the water till the whole of it is dissolved: a filter of cotton wool moistened with oil of amber being now prepared, the hot solution is run through it; the oil is principally detained by the filter, and the fluid as it cools deposits long slender crystals of succinic acid, which may be rendered still purer by subsequent solution and filtration, or still more effectively, according to Löwitiz, by the following method: Make a saturated solution of the solid acid in hot water, and add a quantity of finely pulverized fresh burnt charcoal, equal to half the weight of the acid; strain the solution through a filter of charcoal powder, and as the liquor cools the acid will be deposited in long, clear, perfectly colourless crystals.

According to the German chemists, the proportion of acid yielded by amber is about one-thirtieth of its weight; the French, on the other hand, have not, in general, been able to obtain more than one-sixtieth.

Purified succinic acid is very acid to the taste, though not corrosive; in very cold water it is scarcely at all soluble, requiring from 24 to 30 times its weight of this fluid at 50° Fahr. for its solution; of boiling water, however, three parts are sufficient. The form of its crystals is that of truncated three-sided prisms, or, when prepared in the manner recommended by Lowitz, of thin four-sided tables.

A gentle heat is sufficient to volatilize this salt; it rises in white vapours like carbonated ammonia. It is neither efflorescent nor deliquescent when exposed to the air.

The bale of succinic acid is a compound combustible, one like the vegetable acids: it burns when exposed to the blow-pipe, detones with nitre, and when succinat of potash is heated in close vessels, a large quantity of carburetted hydrogen is given out, and carbonated potash, mixed with charcoal, is left behind.

Boiling alcohol dissolves succinic acid in the proportion of 117 grains to an ounce, which is almost wholly deposited as the liquor grows cold. If the impure acid is dissolved in alcohol, and 6 times the quantity of cold water is added, the mixture becomes turbid and milky, from the separation of the oil; and if in this state it is thrown upon a filter, a clear fluid holding the acid in solution passes through, and the oil remains behind on the filter.

Nitrice acid dissolves the succinic acid, but does not convert it into what was supposed by Wetzelt.

Potash combines readily with succinic acid, forming a neutral salt.

Succinat of potash, crystallizing in truncated tridreral prisms, which are somewhat deliquescent in the air, are readily soluble in water, have a bitterish saline taste, and decrепitate on hot coals. Its acid is destroyed by heat, leaving the alkali in a carbonated state.

Succinat of soda differs from the former salt, in being permanent in the air, and less soluble in water.

Succinat of ammonium forms needle-shaped crystals of a sharp saline bitter taste: it may be volatilized and sublimed without decomposition. The fixed alkalies disengage the ammonium, and unite with the acid.

Succinic acid with lime and barytes forms salts of difficult solution in water. It unites with magnesia in a gummy uncrystallizable mass.

The affinities of succinic acid have not been determined with any accuracy, on account of the difficulty of obtaining it pure, for any mixture of oil with the acid will greatly modify its action on other salts. According to Mureveau, barytes has the most powerful attraction for succinic acid, after which come lime, the fixed alkalies, ammonium, and magnesia.

Green arranges the affinities of succinic acid in the following manner: it decomposes in the moist way all the carbonated alkalies and earths.

All the earthy and alkaline succinates are decomposed by sulphuric acid.

The alkaline succinates are also decomposed by nitric, and muriatic, and florid acids, but nitrates, muriates, and fluorides of lime and barytes, are decomposed by succinic acid.

The boracic, benzoic, and acetic acids, are inferior in affinity to the succinic acid. Aitkin's Dict. of Chem. and Min. vol. i.

SUCCINUM. See Amber.

SUCCISA, in Botany, an old name for a common European species of Scania, (see that article,) whose root has the appearance of having been topped off at the bottom.

SUCCONEDE, in Geography. See Sukkonda.

SUCCOOT, a town of Nubia, on the Nile; 10 miles N. of Dongola. Lat. 22°. Long. 31° 40'.'

SUCCOREY, in Botany and Gardening. See Chichorium.

Succory, Gum. See Chondrella.

SUCCTORINE ALOES. See Aloes.

Succour, in the Military Art, denotes assistance for relieving a place, that is, raising the siege and forcing the enemy from it.

SUCCUBUS, or Succula, a term used by some visionary writers to signify a demon, or spirit, who assumes the shape of a woman, and, as such, lies with a man.

Some authors use incubus (which see) and succubus indiscriminately; but they ought to be distinguished: incubus being only properly used, where the demon is supposed to be in form of a man, and, as such, lies with a woman.

SUCCULATA, in Mechanics, an axis, or cylinder, with flares in it to move it round; but without any tympanum, or peritrochium.

SUCCULENT, in Agriculture, a term signifying rich, juicy, moist, &c. when applied to such plants and roots as are of that nature.

It has been remarked by Sir Humphrey Davy, that all green succulent plants contain fuchsine or mucilaginous matter, with woody fibre, and readily ferment. They cannot, therefore, it is supposed, if intended for manure, be used too soon after their death or destruction. When such green crops are to be converted to the purpose of enriching a soil, they should be turned into it, if possible, when they are just in flower, or at the time they are beginning to form and shew their flowers, as it is at this period that they contain the largest quantity of easily soluble matter, and their leaves are the most active in forming nutritive matter in such situations. These green crops, the weeds of ponds, the parings of dyke and ditch-fences, or the parts of any kind of fresh vegetable matter, require no preparation for fitting them for manure. The decomposition of them is thought to go on slowly beneath the soil; the soluble matters are gradually dissolved; and the flight fermentation that takes place being restrained by the want of a free communication of air, tends to render the woody fibre soluble, without occasioning the rapid diffraction of elastic matter.

In the case of breaking up old graves, and rendering it arable, the foil is not only enriched by the death and flow decay of the plants which have left soluble matters in the foil; but the leaves and roots of the grasse which are living at the time, and occupying a large part of the surface, afford, it is said, fuchsine, mucilaginous, and extractive matters, which become immediately the food of the crop, and the gradual decay and decomposition of which yield a supply for successive years.

The
The two former of these matters, when contained in a pretty full proportion in these kinds of plants and roots, render them highly nourishing also for food animals.

**Succumi,** in Geography, a town of Japan, in the island of Ximo; 25 miles S.W. of Fumai.

**Succunérah,** a town of Hindooftan, in the fubah of Agra; 46 miles S.E. of Etayah.

**Succus Pancreaticus.** See Pancreatic Juice.

**Succus Nervosus.** See Nervous Fluids, &c.

**Succusary,** in Geography, a town of New Jersey; 24 miles N.N.W. of New Brunswick.

**Sucharew,** a town of Ruflia, in the government of Upfa; 52 miles N. of Melznellik.

**Suchipila,** a town of Mexico, in the province of Guadaljara; 42 miles S. of Guadalajara.

**Suchitepec,** or St. Antonio de Suchitepec, a town of Mexico, in the province of Suconnce, on a river which runs into the Pacific ocean; 60 miles W.N.W. of Guatimala. S. lat. 14° 44'. W. long. 93° 36'.

**Suchona,** a river of Ruflia, which rises in lake Kubenicoon, and runs into the Dwinia, near Ufing.

**Suchotzko,** a town of Ruflia, in the government of Newwrood; 52 miles E.S.E. of Tschwien.

**Suchetein,** a town of France, in the department of the Roe; 21 miles N. of Juliers. N. lat. 51° 15'. E. long. 6° 14'.

**Suck,** a river of Ireland, which runs into the Shannon, about six miles S.E. from Balinafoe, separating the counties of Galway and Roscommon during a course of thirty miles.

**Suck creek,** a river of America, in Teneffee, which discharges itself into the Suck or Whirl, a few miles N. of the Georgia north line.

**Suckalton,** a town of Hindooftan, in the circe of Scharunpou; 21 miles E.N.E. of Merat.

**Sucksunny,** a town of America, in New Jersey; 12 miles W. of Morrittown.

**Sucker,** or Suck-Fish, in Ichthyology. See Remora.

'Sucker is also a name given to the lump-fish.

**Sucker, Bimaculated,** is a new species of sucker discovered near Weymouth, and described by Mr. Pennant. Its head is flat and acuminate on each side; the body taper; the pectoral fins placed unusually high; it has only one dorsal fin placed near the tail; the tail is even at the end; the colour of the head and body is a fine pink, that of the fins whitish; on each side of the belly is a round black spot.

**Sucker, Stone,** the English name of a genus of fish. See Patromyzon.

**Sucker, Unbauer.** See Liparis.

**Sucker, Goat,** in Ornithology. See Caprimulgus.

**Suckers,** in Gardening, such young offspring plants as arise immediately from the roots of older vegetables, and which, being generally furnished also with roots, when transplanted, readily grow, and become proper plants, similar to the mother ones. See Off-set and Sprouts.

The season for taking up or transplanting suckers of trees and shrubs, is almost any time, in open weather, from October till March, being careful to dig them up from the mother-plant with as much and many root-fibres as possible, and trimming them ready for planting, by shortening the long fraggling fibres, and cutting off any thick-nobbed part of the old root that may adhere to the bottom, leaving only the fibres arising from the young wood; though it is probable some will appear with hardly any fibres; but as the bottom part, having been under ground, and contiguous to the root of the main plant, is naturally disposed to send forth fibres for rooting; preparatory to planting them out, the items of the shrub and tree-suckers should likewise be trimmed occasionally, by cutting off all lower laterals; and any having long, slender, and weak tops, or such as are intended to assume a more dwarfish or bulbous growth, may be shortened at top in proportion, to form about half a foot to one or two feet in length, according to their nature or strength; and others that are more strong, or that are designed to run up with taller items, may have their tops left entire, or shortened but little: when thus taken up and trimmed, they should be planted out in rows in the nursery; the weak suckers separately in close rows; and also the shortened and stronger plants, each separately in wider rows; so that their rows may be from one to two feet asunder, in proportion to the size and strength of the suckers; and after being thus planted out, they should have the common nursery-culture of cleaning from weeds in summer, and digging the ground between the rows in winter, &c. and in from one to two or three years they will be of a proper size for planting out where they are to remain: and some kinds of trees, large shrubs, &c. produce suckers strong enough in one season to be fit for planting where they are to remain; as well as some forces of roes, and most kinds of other flowering shrubs; also some plants of the strong shooting gooseberries, currants, rafberries, and others of similar kinds.

It may generally be observed of such trees and shrubs as are naturally disposed to send up many suckers, that by whatsoever method they are propagated, whether by seeds, suckers, layers, cuttings, &c. they commonly still continue their natural tendency in this respect. When it is, therefore, required to have any sorts to produce as few suckers as possible, not to over-run the ground, or disfigure the plants, it is proper, both at the time of separating the suckers, or planting them off from the main plants, and at the time of their final removal from the nursery, to observe if at the bottom part they shew any tendency to emit suckers, by the appearance of prominent buds, which, if the case, should all be rubbed off as close as possible: as, however, many sorts of trees and shrubs are liable to throw out considerably more than may be wanted, they should always be cleared away annually at least, and in such as are not wanted for increasing, it is proper to eradicate them constantly, as they are produced in the spring and summer seasons.

Also numerous herbaceous and succulent plants are productive of bottom offset suckers from the roots, by which they may be increased.

In lifting and planting these sorts of offset suckers, the smaller ones should be planted in nursery-beds, pots, &c., according to the nature of growth and temperature of the different sorts, to have the advantage of one summer's advanced growth; and the larger ones be set at once, where they are to remain, in beds, borders, pots, &c., according to the different sorts or descriptions of them.

The suckers of many of the finer kinds of flower-plants, as in the auricula and others, may be separated or taken off from the parent plants any time between the months of February and that of August, as they may become of a proper size, or be wanted for increase; but if they be not wanted for this use, they should never be suffered to remain. They can often be clipped off by the fingers, or a sharp piece of wood, without removing much earth, or the plants from the pots; but when they are large, and cannot be thus separated with a sufficient number of fibres to their bottom parts, they may be taken out of the pots, and be removed by the knife without danger, which is perhaps the best way, as affording most fibres. The suckers of such old flower-plants, when they are wanted to blow strong, should
should always be taken off without disturbing the plants in the pots, especially when they are few. The suckers, in all cafes of this sort, should constantly be planted as soon as possible after they are fluffed, in proper small upright pots, giving a light watering at the time, with suitable temporary shade. They should be placed in proper situations out of the droppings of trees. They thus soon become strongly rooted. The suckers of such flower-plants must, however, never be removed after the latter of the above periods, as they have then done shootting, and are become inactive, and as the winter immediately succeeds, fiodo do well, especially without great care and trouble.

Timber-trees, in some cafes, as in the elm, may be beneficially propagated by suckers, as producing better and more found timber, than by raising them in other ways. The suckers, in such cafes, should be separated from the horizontal roots of the old trees at an early period, and be then planted out, when they will soon take firm root and become good trees.

SUCKEREE, in Geography, a town of Hindooftan, in Bundelcund; 8 miles S. of Pannah. See Pannah.

SUCKING PUMP. See pump.

SUCKLER, in Rural Economy, a term applied to a calf which is used for the purpose of sucking, or being made fat.

SUCKLING, a term applied to the art of fattening calves, lambs, &c. by means of milk. (See calf and lamb.) It also signifies a fort of white clover.

Sucking, Sir John, in Biography, an English poet, was born at Witham, Essex, in 1614, and is said to have possessed such natural talents, that he spoke Latin at the age of five years, and wrote it at nine. He chiefly devoted himself to music and poetry. Having finished his studies at home, he travelled abroad for farther improvement, and made a campaign under Gustavus Adolphus, in which he is said to have been present at five sieges, three battles, and some skirmishes. Upon his return to England, he appeared the accomplished gentleman and courtier, and excited admiration by his sprightliness and gallantry. Associating with wits and poets, he composed some dramatic pieces for the amusement of the court; and such was his prodigality, that when he brought his tragedy of "A Clandestine Marriage" on the stage, he expended four or five hundred pounds. Whilst he drew attention in the gay period of that reign by his poetical effusions and courtly manners, he affected to be indifferent to literary fame. When the troubles of this reign began, he evinced his loyalty by raising a troop of horse at the expense of 12,000L, placing himself at their head. On this occasion he incurred a disgrace which was trumpeted in ballads and squibs by his brother poets, and which is supposed to have tarnished his death in 1651, when he had arrived only at the 28th year of his age. Sucking has no claim to distinction among the British poets; though, if he had bestowed greater care and correctness on some of his fongs and ballads, they might have served as models of that class of compositions. His "Wedding Ballad" has always been popular; and the fancy and wit that sparkle in some of his amatory pieces attract notice. His plays, which are four in number, have long disappeared from the stage. His collected works, in prose and verse, have passed through several editions; the last appeared in 1774. 2 vols. 12mo. Life of Sucking, prefixed to his Works.

Sucking, Cape, in Geography, a cape on the N.W. part of North America, off which, and to the N.E. end of Kaye's island, is a muddy bottom with from 43 to 37 fathoms of water. The S.W. point of Kaye's island is in N. lat. 59° 40', and W. long. 143° 21'.

SUCKREE, a town of Hindooftan, in the circar of Ruttunpour; 8 miles N.W. of Ruttunpour.

SUCKRY, a town of Hindooftan, in Gurry Mundella; 10 miles S.E. of Gurrah.

SUCTION, in Physiology, the act of drawing into the mouth fluids and other substances by means of the preasure of the external air. When an infant is imbibing its food from the breast of the mother, its lips are applied closely to the nipple, so that no air can enter; but by enlarging the chest, the atmospheric preasure is removed from the surface of the nipple, while it still continues on the external surface of the breast; and thus forces the contents of the lactiferous tubes into the mouth. If the lips are immered in any fluid, and the chest expanded, the preasure of the external atmosphere will force it into the mouth. The act of suction, indeed, depending on this atmospheric preasure, is in all cafes essentially the same. See Lung.

Air is sucked through a pipe, in the same manner as with the naked mouth; it being here the same as if the mouth were extended through the length of the pipe. If a man apply his mouth to one end of an open tube, the other end of which is placed in water, the operation of sucking is performed in the following manner. By enlarging his chest, he rarifies the air, and of course diminishes its preasure on the liquor, which is immediately under the tube; in consequence of which, the preasure of the atmosphere on the surface of the surrounding liquor forces the liquor to ascend into the tube.

The suction of heavier liquors is performed after the same manner. e.g. Should one try to drink out of a spraying, &c. the lips are applied close to the surface of the water, so as to prevent any passage of the air between them; then the cavity of the abdomen, &c. being distended as before, the preasure of the air incumbent on the surface of the water, without the circumference of the mouth, prevailing over that upon the water within the same, the fluid is raised from the same principle as water in a pump.

In sucking a heavy liquor, as water, through a pipe, the longer the pipe is, the greater difficulty is found in the suction; and the bigger and diameter of the pipe makes a farther alteration therein. The suction of this arises from that great principle in hydrostatics, that fluids press in the compound ratio of the bales, and perpendicular altitudes.

From what we have said, it evidently enough appears, that what we call suction is not performed by any active faculty in the mouth, lungs, &c.; but by the mere impulse and preasure of the atmosphere.

A very curious and intelligent person distinguishes two different sorts of suction, performed after two quite different manners; a distinction which, however hitherto overlooked by authors, seems absolutely necessary.

Suction, then, according to him, is performed either, 1st, by the dilatation of the thorax; or, 2dly, by that of the cavity of the mouth.

In the former case, the lungs are kept continually distended; for if the breath be let go ever so little, the liquor in the tube will begin to subside.

On the contrary, when suction is performed by enlarging the cavity of the mouth, we may suck with our utmost force, and yet breathe freely through the mouth; so that this is the true proper suction; the other ought rather to be called sipping than sucking through a tube.

Note, the cavity of the mouth is enlarged by being a little...
SUCU, in Botany, a species of apple-tree, said to be frequent in the province of Canton, in China. The fruit is dried like figs to be kept all the year, and is brought into Europe. It is somewhat larger than our apple, almost round, and of a reddish colour, or sometimes green. When it is dry, it has a crust resembling honey or sugar.

SUCULA, in Maronitis. See Succula.

SUCY, in Geography, a town of France, in the department of the Seine and Oise; 10 miles N. of Corbeil.

SUCZAVA, or SUCHZOW, a town of Bukovina, on a river of the same name, formerly flourishing, and the capital of the country, in which were reckoned 60 churches, but now much declined from its former splendour; 84 miles N.W. of Jaffa. N. lat. 47° 57'. E. long. 25° 58'.

SUCZAVITA, a town of Bukovina; 30 miles W. of Suczava.

SUD, a river of Russia, which runs into the Schekha, 8 miles E. of Tcherepoeza, in the government of Novgorod.

SUD, Gulf of, a spacious natural harbour, one of the finest and safest of the Archipelago, lies to the south of a peninsula in the island of Crete. Its mouth is to the east, and its head runs to the W.N.W. It is not only sheltered by the angles and capes which the lands form, but also by the two islands of Suda; on one of which is situated a fort constructed by the Venetians, 8 miles E. of Canea, and which they preferred for a long time after the island was no longer in their possession. It was not till the reign of Achmet III. that the Turks made themselves masters of this fort, and thus became the tranquill possiessors of the whole island of Crete. The anchorage most frequented by the commanders of vessels, who with only to shelter themselves from a gale of wind, is to the S.S.W. of Cape Maleca, behind a small island known to mariners under the name of "Old Suda." Large ships of war anchor at all places, either at the entrance of the gulf, or by the side of the island just mentioned. Both of them go to the head of the gulf only, when they are to remain for a long time at the anchorage. The boats belonging to the country sometimes anchor between the two islands of Suda.

SUDAK, a sea-port of Russia, in the province of Tauris, on the coast of the Black sea; 20 miles S.W. of Theodosia.

SUDAMINA, little heat-pimply in the skin, like millet-grains, frequent in youth; especially those of a hot temperament, and that use much exercise.

SUDARIUM, in Ecclesiastical Writers, the name with Brandeum; which see.

SUDASEER BULGAR, in Geography, a town of Hindoostan, in Myrore; miles W.S.W. of Ferapatan.

SUDATORY, SUDATORIUM, a name given by the ancient Romans to their hot or sweating-rooms; sometimes also called laconica.

The sudatory was a species of their hypocausta or roves. See Hypocaustum. See also Sweating-House.

SUDBURY, in Geography, a borough-town of great antiquity, in the hundred of Baberg, and county of Suffolk, England, is situated on the south-western side of the river Stour, which is at this place navigable for barges, and over which there is a well-built stone bridge. Sudbury was at one period a place of much greater importance than at present. It comprehends three parishes, the population of which, in 1811, was estimated at 3471 inhabitants, dwelling in 589 houses. The name of this borough was originally Southburgh, to distinguish it from Norwich, then called Northburgh; and was one of the first places at which king Edward III. settled the Flemings, whom he invited to England to instruct his subjects in the woollen manufacture. This flourished here for some centuries, and afforded subsistence to many of the inhabitants of the town, who were employed in weaving of fays, coarse, and ship's flags. Sudbury has still a manufacture of fays, and a small one also of silk, which was established by the London mercers. In this town was born Simon de Sudbury, archbishop of Canterbury in 1375, who was beheaded by the populace, in the rebellion of Wat Tyler. He erected a part of St. Gregory's church, where he is interred, and also founded and endowed a college on the site of his father's house. Le-land remarks that this prelate, in conjunction with John de Chertley, founded here a priory of the order of St. Augus-
SUDE RWA LLE, a town of Germany, in the duchy of Verden; 6 miles N.E. of Verden.

SUDE TIC CHAIN, a range of mountains in Silesia, being a northern branch of the Carpathian mountains, extending from Jablunka S.E. to Friedberg in Upper Lusatia N.W., nearly 200 British miles in length. This chain has other more minute appellations, the north-west part towards Lusatia being called Rien, the middle part the Koniakow chain, and the south, the Moravian chain. Of this remarkable chain, not much noticed by geographers, the highest peak in the mountains of Rien, or of the giants, is the Schneekoppe, or snow head, in the Bohemian part, the Eule or Owl, and the Zottenberg, suppos'd by some to be the Aeciburghus of Ptolemy, the height of which is estimated at about 1210 Rhenish feet, and consisting entirely of serpentine, with some hornblende. The Moravian division divides into inferior branches, one of which forms a northern boundary of the principality of Troppau. Fabri computes the highest part of the Rien at 4930 Rhenish feet above the sea, and the Zottenberg at 1700.

SUDIS, Esox Sphyrena of Linnaeus, in Ichthyology, a name used by most authors for the sea-pike, a fish called by others lucius marinus, and Sphyrena.

It in some degree resembles the common river-pike, but is thinner in proportion to its length, and in some degree approaches to the acus, or tobacco-pipe-fish, in that particular. Its scales are small, and its nose long, and of a conic form, the under jaw running out a good way beyond the upper, and ending in a sharp point; its mouth is very wide, and yellow within; its tongue large and narrow, and armed with very sharp teeth; each of the jaws is furnished with a single row of large and sharp teeth, and in the middle of the lower jaw is one tooth longer than the rest, which has a hollow in the upper jaw for receiving it; it has two fins on the back, which are both very deeply forked. It is caught in the Mediterranean, and usually swims in shoals together. Its total length is ten or twelve inches; and it is esteemed a very well-tasted fish. Ray.

SUDKEULI, in Geography, a town of Bulgaria, on the Euxine sea; 60 miles E. of Byzantium.

SUDODHANA, the name of the mortal father of Boodh, the great reformer of India. The legends of the Cingalese of Ceylon agree with those of the north of India, in giving this name, or one very like it, to the father of Boodh, or Buddha.

SUDOGDA, in Geography, a town of Ruffia, in the government of Vladimir; 28 miles S.E. of Vladimir. N. lat. 55° 40'. E. long. 40° 54'.

SUDOR, in Medicine. See Sweat.

SUDORANGUINUS, the English Sweat. See Sweating Sicksex.

SUDORIFIC, in Medicine. See Diaphoretic.

SUDZA, in Geography, a town of Ruffia, in the government of Kurisk; 40 miles S.W. of Kurisk. N. lat. 51° 20'. E. long. 35° 14'.

SUE, LA, the appellation of Indians who inhabit the territory west of lake Superior, and the Misisipi. The number of warriors is reckoned at 10,000. Pike, in his recapitulation, states them at 3535, and the whole number at 21,675. See Sioux.

SUG, a river of Atrica, one of the branches of the Bembarogue, in Bengal.

SVEABORG, a fortress of Sweden, in the gulf of Finland, situated about 33 miles from Helingsborg, composed of seven rocky islands, which lie within the circumference of four miles. The principal of these islands is Warg-sa, or Wolf's island, which is 2400 feet in length, and 2000 in breadth,
broadth, and contains the governor's house. The project of surrounding these islands with fortifications was formed by general Ehrenwald, and the work begun in 1749. The works are said to be stupendous, and worthy of the ancient Romans. The walls are chiefly of hewn granite, covered with earth, from six to ten feet thick, and in a few places not less than forty-eight in height. The batteries, which commence on a level with the water, and rise in tiers one above another in all directions, commanding the only channel through which large vessels can fail to Hellingfors, render the possession of an enemy's fleet extremely dangerous, if not impracticable. In the island Wargön is a dry dock, capable of containing eleven or twelve frigates, hollowed in the solid rock, 500 feet long, 200 broad, and 14 deep. It is divided into three equal parts by two brick walls, running lengthways. Each part will contain four frigates, and may be closed with sluice-gates, so that each vessel lies separately from the others. The whole is covered with a wooden pent-houset roof, in order to preserve the frigates from the rain. This houset contains eleven frigates. At one extremity of this dock is a bafi, 200 feet square, closed at each end with sluice-gates, which serves for the entrance and exit of the frigates, and likewise for repair or building ships. At the other extremity is another bafi of the same dimensions for a man of war, which may likewise serve for the passage of the frigates, when the other is employed in repairing or building ships. The magazines for the stores and a battery are built on the edge of the water, which is of sufficient depth to admit each vessel close to the quay, to be equipped without trouble. There is an excellent port for seventy ships of the line, and a small harbour, no less secure, for ten frigates. For the purpose of building and refitting ships at Sveaborg, the Swedes procure oak from Gotland, part of the axe from Finland, hemp and masts from Riga. This fortres may not improperly be called, if completed, the Gibraltar of the north. Coxe's Travels.

SUEG, a town of Sweden, in Harjadal, on the Liufna; 86 miles W. of Sundfjord.

SVEGLIATO, in the Italian Myfic, is used for a brisk, lively, gay manner of fingering or playing. Thus they say, maniera svegliata.

SUEIRO da Coça, in Geography, a river of Africa, which runs into the Atlantic, N. lat. 5° 5'.

SUELDI, in Commerce, a money of account in some parts of Spain. At Alicante, accounts are kept in reals of 24 ducres, and also in libras of 20 soldos, subdivided into 12 ducres; the libra being valued at 32, 33d. silver. In Aragon, a soldo is divided into 8 quartos, or 16 ducres, and the libra is worth 20 soldos, or 42 3d. silver nearly. See Money.

SVELMOE, Geography, a small island of Denmark, near the S. coast of the island of Funen. N. lat. 55° 8'. E. long. 10° 20'.

SUEMEZ, Island of, an island in the Pacific ocean, at the entrance of Puerto de Bayilo Bucareli, about 25 miles circumference. N. lat. 55° 5'. E. long. 216° 59'.

SVENBORGH, a seaport town of Denmark, in the island of Funen, with the harbour in the island; in which are manufactures of wool and linen; 22 miles S. of odense. N. lat. 55° 5'. E. long. 10° 37'.

SUEN-HOA, a city of China, of the first rank, in Pe-tsche-li, near the great wall; 77 miles N. of Peking. N. lat. 40° 38'. E. long. 114° 39'.

SVENSKAHOGARNE, a small island in the Baltic, near the coast of Sweden. N. lat. 59° 28'. E. long. 19° 20'.

SVENTIUNGA, a town of Sweden, in West Gothland; 40 miles E.S.E. of Gothenburg.

SUEA. See MOGADOR.

SUERDFO, a town of Sweden, in Dalecarlia; 20 miles N. of Fahlun.

SUESANY, a town of Hungary; 8 miles W.N.W. of Rofenberg.

SUET, a flourishing village of America, in Massachusetts, the county of Barnstable, and township of Dennis, bordering on Harwich; containing about 36 dwelling-houses, the town of Dennis including 1739 inhabitants. Belonging to this village are five falls of fishermen, and four salt-works, which yield annually upwards of 600 bushels of marine salt, besides 2700 lbs. of Glauber salts.

SFIV, Securn, a kind of fat, found in deer, sheep, oxen, hogs, &c., which, melted down and clarified, makes what we call tallow, used in the making of candles.

The word is formed from the Latin, fistum, ficum, or sevum, which signifies the fame; and these a fust, faws, by reason of the fatness of that beast.

Mutton-fuet is the most conffient of real animal fats; it has some degree of brittleness, and requires a temperature of 127° Fahr. to melt it. In other respects it agrees with animal fats in general. Like thefe, it is emollient; it is sometimes boiled in milk in the proportion of 3J of the fat to 3j of milk, and a capital of the mixture is given occasionally in chronic diarrhoea, where there is much acidity of the contents of the bowels; but its principal use is to give conffidence to ointments and plasters. The "sevum praeparatum," or prepared fuet of the London Ph., is obtained by cutting the fuet in pieces, then melting it by a gentle heat, and pressing it through linen.

Another kind of fuet, which we shall mention in this connexion, is the "axungia porcina" of the Edinb. Ph., the "adesa sulvis" of Dub., the "adesa" of Lond. or the Stock-lard. The lard is chiefly obtained from the flank of the animal. It is freed from the membranes and velvets, by being cut in small pieces, then well washed in water till the water comes off colourless, and afterwards melted with a very gentle heat in a shallow vessel, kept on the fire till the water is wholly evaporated. While still liquid, it is poured into bladders, in which it concretes, and in this state it is brought to market.

Lard is inodorous, tafteless, and white; soft, and nearly semifluid. Exposed to a heat of 97° it melts, and concretes again when cooled. It is insoluble in water, alcohol, and ether: but is dissolved by the stronger acids, being at the same time decomposed; and, like the fixed oils, it combines with the alkalies and forms soap. It is oxidized, if when melted a little nitric acid be stirred into it; and assumes a greater degree of firmness, with a yellow colour. By destructive distillation it affords results very similar to those obtained from the analysis of fixed oil; and appears to be a compound of oxygen, hydrogen, and carbon, in unknown proportions. When lard is long exposed to a warm air, it becomes yellow, emits a fatty odour; and, owing to oxygen being attracted from the atmosphere, the folic acid is formed. This state of rancidity may, in some degree, be removed by washing it with very pure soft water; which during the operation becomes acid, and reddens litmus paper.

Lard is emollient, and on account of its softness and uncоoty, is preferable to fat as a friction, but seldom used for this purpose; and is chiefly employed in the formation of ointments. Its official preparation is the "adesa preparata," or prepared lard. That of the London Ph. is obtained by cutting the fat into small fragments, then
melting it by a gentle heat, and pressing it through linen. The "adeps nullius preparatus," or prepared hog's-lard of the Dub. Ph., is had by cutting fresh lard into small pieces, then melting it by a moderate heat, and straining it by pressing it through a linen cloth. Lard prepared by the dealers, and preferred with salt, is to be melted with twice its weight of boiling water, and well straining the mixture; it is then allowed to cool, when the lard may be separated. The lard in its liquid properties are intended for purging, fuel and lard; but in order to obtain them very pure, they should be washed in water till the water comes off colourless before they be melted. During the melting, the remaining water is evaporated; and that this is the case may be ascertained by throwing a little of the melted fat into the fire, when it will crackle if any water remain. The heat must not be raised above 97°, the melting point of fat; because otherwise the fat is decomposed, rendered acrid, and assumes a yellow colour. This purification is seldom attempted by the apothecaries; as both kinds of fat may be procured very well purified from the dealers. Keep the lard clean, and preserve it from the action of the air, it is, as we have already said, run into bladders in its liquid state. Thomson's Dif. See ADEPS, FAT, and ANIMAL OIL. See also CELLULAR SUBSTANCE.

F. le Compte mentions a tree in China, that bears a kind of fruit or tallow. See TALLOW-tree.

SUETIA, in Ichthyology, a name given by Bellonius, and some other writers, to the nactus, a species of cyprinus, according to the Aredian and Linnaean systems, and differing from the name of the cyprinus major, with the lower standing prominent, in form of a nose, and with fourteen rays in the pinna ani.

SUETONIUS TRANQUILLUS, CAUZ, in Biography, was the son of Suetonius Lensa, a tribune of a legion in the time of Otho, and born about the beginning of the reign of Vespasian, and died after A.D. 117. He is designated by Pliny the younger, as one of the "Scolastici." He was probably a teacher of grammar and rhetoric, composed fictitious pleadings, and perhaps sometimes pleaded real causes. With Pliny he was intimate, and was introduced to him for several purposes. His interest he obtained the dignity of military tribune, and also the "jus trium liberonum," granted to him by the emperor Trajan, though he was childless. He was afterwards sent to the emperor Adrian, though he left this office by his indifferently familiarity with the empress Sabina; an incident which occurred about the year 121, but how long, or in what condition he afterwards lived, no records inform us.

Suidas calls him a "grammatarian," and attributes to him several works; but all are lost, except his Lives of the Caesars, his Lives of eminent grammarians, and a small part of those of eminent rhetoricians. His work of the Lives of the first twelve emperors, down to Domitian inclusively, is one of the most interesting remains of ancient history; for without being distinguished by style or sentiment, it abounds with anecdotes relating to the manners, characters, and incidents of those times, which no where else occur. Some of the facts which he relates have been doubted; but his general character and mode of writing narrates, acquaint him of any intentional misrepresentation, though he indicates a propensity to pay undue attention to vulgar tales and turnip-store. His freedom in exposing the infamy of the Caesars may be politically vindicated on this general principle, "that history affords no leasons more instructive than the crimes and vices consequent upon debastic power." Suetonius's disreputable account of the Christs, whom he calls "genius hominum superfluis nova et malefic," a kind of people of a new and mischievous superstitition, can be attributed only to his ignorance of their doctrines and character. We have many editions of Suetonius; but among the best are reckoned Cufaboni a Boeclaro, 4to. Argent. 1647; Gravi, 4to. Tract. 1672, 1703; Pritca, 8vo. 2 vols. Trag. 1650, and 4to. 2 vols. Leard, 1714; Burmanni, 2 vols. 4to. Amst. 1720; Erati, 8vo. Lipl. 1748; Oudendorpi, 8vo. Lugd. Bat. 1751. Gen. Bioe.

SUEUR, EUSTACHIIUS LE, was born at Paris in 1617, the son of an obscure sculptor; who, upon discovering his son's inclination for painting, placed him as a pupil with Simon Vouet. From this school, the source of all that vitiated the style of art practised in France before the revolution, Le Sueur had the singular felicity of emerging with pure taste; and the firmness to pursue such studies as were most conducives to its improvement; while almost all his fellow students, seduced by the glitter and tinsel of art display, were led by their mangled and ably supported, indeed improved, by Le Brun, floated with the tide of fashion, and were lost in the abyss of frivolity and luxury of forms, and artificial combinations of effects. Had Vouet had many scholars like Le Sueur; or had the latter been duly estimated, and been longer preferred in existence, France might perhaps have justly boasted of her Raphael; and true taste have exalted the brilliancy of imagination so congenial to her children. But the luxurious court of Louis XIV. delighted too much in the pompous display of artifice, to relish the true simplicity of pure art; and too eager a desire for amusement and enjoyment, to feel gratification in those religious or pathetic emotions, which it was Le Sueur's delight to raise.

He appears to have drawn his taste from prints after the compositions of Raphael, as he never was out of his native country; and there were not many pictures of the Roman school at that time in France. It may be fairly said, that a portion of the spirit of Raphael had taken up its abode with him. The fame kind of subject introduced him, and above all he was actuated by the fame devoted to the subject of whatever he undertook. With him, as with Raphael, it led to the composition, and controlled his imagination in the execution of it; as is fully exemplified in his series of pictures on the life of St. Bruno. No work of his, however, places him, as the French writers have done, upon a complete parallel with his great prototype. He lacked the sweetness and fulness of the perfection he aspired to rival; both in drawing and execution, he fell far short of his own ideas; and of colouring, he scarcely caught a glimpse. But good sense and propriety governed his designs; and feeling and sentiment guided his hand; with colour sufficient to convey his ideas without offending; at least in his best works.

The brilliancy of Le Sueur's talents soon caustic their employment; and at the age of 23, (1640,) he was elected a member of the Royal Academy at Paris, and painted upon his admission a picture of St. Paul casting out a Devil. In 1649 he was engaged upon the great work in which his fame principally repose, viz. the Life of St. Bruno, which he painted in 22 pictures, for the conven of the Chartreux in Paris: they were afterwards purchased by the king of France, and now form part of the gallery at the Luxembourg. This celebrated series of compositions has suffered exceedingly by folly or malice, and by the hand of time; and still more, have so severely endured the untouched shallock of picture-cleaners and restorers, that we cannot now form a perfect judgment of their original beauty.
beauty. The compositions remain, but most of the faces of the figures have been re-touched, so that expression is weakened or destroyed; the original colouring, which happily was of necessity simple, has been disturbed; and it would be hard to attach to Le Sueur the defects of their present condition in this respect. There is, however, sufficient evidence in them of this ingenious artist's superior feeling and acquirements. He was only three years employed upon them; and when his youth is considered, they must be regarded as emanating from a mind of no common mould. His largest work is the Condemnation of St. Gervaise and St. Protas, now in the gallery of the Louvre; it was painted soon after thefuries above-mentioned; but is an attempt to combine somewhat of the talent of his master with his own, as if he were controlled by his employers. It is more confused in forms, and stronger and more varied in colour, than his pictures usually are; and is not the better for it. His picture of the Burning of the Magic Books at Ephesus, has infinitely more character and pathos; but is eminently defective in colour; in which quality the pictures of the Muses, painted by him, and in the Gallery also, are far his most perfect productions. He died in the early age of 38, in 1655.

SUEVRE, in Geography, a town of France, in the department of the Loire and Cher; 9 miles N.E. of Blois.

SUEZ, a town of Egypt, situated on a point of land, in the form of a peninsula, on the western coast of the Red Sea. As far back as the time of the ancients it was the ancient Arfinoe; but Volney thinks that Arfinoe was situated further north towards the bottom of the gulf. Browne says, that the ruins of Arfinoe may yet be recognised in a mount of rubbish in the neighbourhood of Suez; and that the spot is now called "Kolmum," and that remains extant of a stone-pipe for conveying water thither from Bir Naba. A rock, he says, on the African side of the gulf, furnishes petroleum, which is brought to Suez, and esteemed a cure for bruises, &c. In crossing the gulf junks before Suez, boats are used at high water, which comes in rapidly to the height of four feet; at other times camels, horses, and men ford it with safety. At Suez he observed, in the shallow parts of the adjacent sea, a species of weed, appearing in the fun-gline to be red coral; and he conjectures that if this was found in considerable quantities at a former period, it may have given its recent name to this sea: for this was the Arabian gulf of the ancients, whose name Erythraeum, or Red sea, was the Indian ocean. This weed may, perhaps, be the *Diothras* of the Hebrews, where it is written, יִשְׁלָמֶשׁ, that is, "Shelmish," their name for this sea. According to this traveller, Suez is a small town, built of burnt bricks, and contains 12 mosques, some of stone, and most of them mean building: there are also several coffee-houses. The houses are so close to one another, that there are only two piazzas into the city, that nearest the sea being open, and the other shut by a very insufficient gate. The only fold buildings are the khans. Scarcely any part now remains of the cattle, which the Turks built upon the ruins of the ancient Kolmum or Kolzoum, the "Clyma" of the Greeks, situated about 300 paces N. of Suez, on the bank of the sea opposite the fort, which leads to the frying of El-Naba. The sea near the town is very shallow; yet there is a small yard for ship-building. Its population is inconsiderable, consisting of a few Greeks and Copts, intermixed with Mahometans. Although the inhabitants are not numerous, here are four or five considerable resident merchants, who have their correspondents at Cairo, and in the towns of Arabia, and conduct the commerce between Egypt and India. These have a proportionable number of dependants, and persons who manage commercial affairs of a less considerable kind. Here are also ship-builders, and several other artisans; a large khan or shed where merchandize is lodged; some Greek Christians continually refiding here, Mahometan ecclesiastics, and others; and a number of fishermen and people more immediately connected with the sea. The population, however, is restrained by the difficulty of procuring water, scarcity of provisions, and other inconveniences, but invariably much exceeding the estimate given by Volney and others. Suez, according to Browne, is very modern, having been probably built within the last 300 years: and it is unknown to travellers of a more ancient date. At Suez, the chief article of trade is coffee. The sea here produces few fish: eels, indeed, and a few others of the shell kind, are seen; but the best fish come no higher than Coloph. Meat is scarce, bread of an inferior quality, and sometimes hardly eatable. Butter and milk are brought in small quantities by the Arabs. Water is brought from three several places: Bir-Naba, northward, affords the best; the other places are Aide-Mulga, and Bir-es-Suez. It is always bought in the skins at a considerable price; and in case of a war with the Arabs, none could be had.

Formerly the districts in the vicinity of Suez, says Volney, were covered with towns, which have disappeared with the waters of the Nile; the canals, which conveyed their waters, are destroyed, for in this shifting soil they are presently filled up, both by the hands driven by the winds, and by the cavalry of the Bedouin Arabs. At present, the commerce of Cairo with Suez is only carried on by means of caravans, which wait the arrival, and set out on the departure of the vessels, that is, towards the end of April, or the beginning of May, and in the course of the months of July and August. That which Volney accompanied in 1783, consisted of about 3000 camels, and 5000 or 6000 men. The merchandise consisted in wood, furs, and cordage for the ships at Suez; in some anchors, carried each of them by four camels, iron bars, carded wool, and lead; it likewise carried bales of cloth, and bundles of cochineal, corn, barley, and beans, Turkish paitres, Venetian sequins, and Imperial dollars. All these commodities were destined for Djededa, Mecca, and Moka, where they were to be bartered for Indian goods, and the coffee of Arabia, which forms the principal article of the return. There was besides a great number of pilgrims, who preferred the voyage by sea to a land journey; and it also carried the necessary provisions, such as rice, meat, wood, and even water, for no place in the world is more deftute of every necessary than Suez. From the tops of the hills, any eye, surveying the sandy plain to the N.W., the white rocks of Arabia to the E. or the sea, and the mountain Mokattam to the S., cannot discern even a sedge tree, or the smallest spot of verdure. Suez presents no prospect but extensive yellow sands, or a lake of green water; the ruinous condition of the houses heightens this melancholy scenery. The only water which can be drunk is brought from El-Naba, or the spring, situated at the distance of three hours journey on the Arabian shore; but it is so brackish that without a thorough distillation, it is impotable to Europeans. The sea might furnish a quantity of shell and other fish; but the Arabs seldom attempt fishing, at which they are far from expert; when the vessels are gone, therefore, nobody remains at Suez but the governor, who is a Mamlouk, and twelve or fourteen persons, who form his household, and the garrison.

The fortres is a defenceless heap of ruins, which the Arabs consider as a citadel, because it contains six brahs four-
four-pounders, and two Greek gunners, who turn their heads aside when they fire. The harbour is a wretched quay, where the smallest boats are unable to reach the shore, except at the height of the Red sea. There, however, the merchandize is embarked to convey it over the banks of fand, to the vessels which anchor in the road. This road, situated a league from the town, is separated from it by a shore, which is left dry at low water; it has no works for its defence, so that the vessels, which have been seen there to the number of 28 at a time, might be attacked without opposition, for the ships themselves are incapable of resistance, none having any other artillery than four rusty swivels.

Their number diminishes every year, since by continually coaling along a shore full of fand, one out of nine, at least, is shipwrecked. In 1783, one of them having anchored at El-Tor, to take in water, was surprized by the Arabs, while the crew were sleeping on shore. After plundering it of 1500 bags of coffee, they abandoned the vessel to the wind, which threw it on the coast. The dock at Suez is ill adapted to repair such damages; scarcely do they build a casaille in three years. Befides that the sea, which, from its flux and reflux, accumulates the sand upon that coast, will at last choak up the entrance, and the fame change will take place at Suez, which has already occurred at Kolzoum and Arfinne. Suez is 60 miles E.S.E. distant from Cairo. N. lat. 30°. E. long. 33°25'. Volney. Niebuhr. Browne.

**Suez, Jíbmu of.** that narrow neck of land which separates the Red sea from the Mediterranean. It has been a question much agitated in Europe, whether it would be practicable to cut through this Jíbmu, so that vessels might arrive at India by a shorter route than by the Cape of Good Hope. This space is not more than 16 or 19 ordinary leagues; nor is this interval interfected by mountains; nor can we discover, from the tops of the terraces at Suez, with any telescopes, a single obstacle on the nacked and barren plain to the N.W.; and hence may be inferred, that it is not the difference of levels which prevents the junction. Some, indeed, among the ancients were of opinion, that the Red sea was higher than the Mediterranean; and in fact, if we observe, that from the canal of Kolzoum to the sea, the Nile has a declivity, for the space of 30 leagues, this idea will not appear so ridiculous. The great difficulty of accomplishing this object arises from the nature of the corresponding coasts of the Mediterranean and Red sea, which are covered with shrubs, thorns and sandy soil, where the waters form lakes, fand, and morasses, so that vessels cannot approach within a considerable distance. It will therefore be found scarcely possible to dig a permanent canal among these shifting sands; not to mention that the shore is defile of harbours, which must be entirely the work of art. The country, besides, has not a drop of fresh water, and to supply the inhabitants, it must be brought as far as from the Nile.

The best and only method, therefore, of effecting this junction, is that which has been already successfully practiced at different times; which is by making the river itself the medium of communication, for which the ground is perfectly well calculated; for mount Mokattam suddenly terminating in the latitude of Cairo, forms only a low and semicircular mound, round which is a continued plain from the banks of the Nile, as far as the point of the Red sea. The ancients, who early understood the advantage to be derived from this situation, adopted the idea of joining the two seas by a canal connected with the river. Strabo (lib. xviii.) observes, that this first was executed under Seleucus, who reigned about the time of the Trojan war; and this work was so considerable as to occasion it to be remarked, "that it was 100 cubits (or 170 feet) wide, and deep enough for large vessels." After the Greeks conquered the country, it was restored by the Ptolemies, and again renewed by Trajan. In short, even the Arabs themselves followed these examples. "In the time of Omar-ebn-el-Katbar," says the historian El Makin, "the cities of Mecca and Medina suffering from famine, the caliph ordered Amrou, governor of Egypt, to cut a canal from the Nile to Kolzoum, that the contributions of corn and barley, appointed for Arabia, might be conveyed that way."

This canal is the same which runs at present to Cairo, and is used itself in the way to the N.E. of Berket-el-Hadji, or the Lake of the Pilgrims. Volney.

**SUFANGH ul Babri, a narrow island in the Red sea, near the coast of Egypt, about 7 miles in length. N. lat. 27°. E. long. 33°56'.**

**SUFEEDOON, a town of Hindooftan, in the subah of Delhi; 60 miles W. of Paniput.**

**SUFFA, a town of Candahar; 30 miles E.N.E. of Candahar. N. lat. 33° 10'. E. long. 66° 0'.**

**SUFFERANCE, in Ancient Customs, a delay or respite of time, which the lord granted his vassal, for the performance of fealty and homage, so as to secure him from any feudal feiseur.**

Sufferance, say the customs, is equivalent to fealty and homage, while it holds.

The word is also used for a delay which the lord grants his vassal, to quit themselves of fees or inheritances they have acquired, till they have paid the due of indemnity, &c.

**SUFFERANCE, Bill of. See BILL.**

**SUFFERANCE, EJFate au, in Lawo, is where one comes into possession of land by lawful title, but keeps it afterwards without any title at all. As if a man takes a lease for a year, and after the year is expired, continues to hold the premises without any fresh leave from the owner of the eftate. Or, if a man maketh a lease at will and dies, the eftate at will is thereby determined; but if the tenant continues possession, he is tenant at sufferance. This eftate, in the case of a subjek, may be destroyed, whenever the true owner shall make an actual entry on the land and oust the tenant; for, before entry, he cannot maintain an action of trespass against the tenant by sufferance, as he might against a stranger; because the tenant being once in by a lawful title, the law will suppose him to continue upon a title equally lawful; unless the owner of the land, by some public and avowed act, such as entry, will declare his continuance to be tortious or wrongful. Thus stands the law, with regard to tenant by sufferance; and landlors are obliged in those cases to make formal entries upon their lands, and recover possession by the legal processes of ejectment; and at the utmost by the common law, the tenant was bound to account for the profits of the land by him detained; but now by 4 Geo. II. c. 28. in case any tenant for life or years, or other person claiming under, or by collusion with such tenant, shall wilfully hold over after the determination of the term, and demand made in writing for recovering the possession of the premises, by him to whom the remainder or reversion of them shall belong; such person, if holding over, shall pay, for the time he continues, at the rate of double the yearly value of the lands so detained. This has also put an end to the practice of tenure by sufferance, unless with the tacit consent of the owner of the tenure. Bl. Com. vol. ii. See EJECTIONE Firma.**
SUFFERDA M, SUFFERDON, in Geography, a small fishing town of Hindoostan, on the coast of Concan; 15 miles S. of Choule.

SUFFETES. See Carthaginians.

SUFFIA, in Geography, a town of Bengal; 14 miles N.W. of Calcutta.

SUFFIBULUM, among the Romans a name given to the pretexta of the pontiffs, and palas of the Vestal virgins.

SUFFIELD, in Geography, a pleasant post-town of America, in Hartford county, Connecticut, with a handsome church and some respectable dwelling-houses, containing 2680 inhabitants. It lies on the W. bank of Connecticut river, on the great post-road from Boston to New York; 10 miles S. of Springfield.

SUFFEMENTA, Fumigation, in Pharmacy. See Perfumes.

SUFFINAGORE, in Geography, a town of Bengal; 14 miles N. of Ihalabad.

SUFFITION, Suffitto, among the Romans, a kind of Fration, practiced by persons who had attended a funeral; it was performed by walking over fire, and being sprinkled with water.

SUFFITUS, Suffiment, or Suffumigation, in Medicine, a thickish powder, prepared of odoriferous plants, gums, &c. which being thrown on coals, the vapours or fumes of them are received by smelling. See Perfumes.

SUFFOLATION, in Rural Economy, blown up with rich green food in different animals. See Blown and Hove.

SUFFOCATIO STRIUDA. See Croup.

SUFFOCATION, in Medicine, apoplexy, the destruction of life by impeding respiration.

The three ordinary modes of suffocation, or interruption of the breath, are hanging, drowning, or the respiration of fixed air, or carbonic acid gas. The fame result takes place from either of these causes, which is described at length under the article Drowning, and the same process is required for the resoration of breathing and animation in all these cases, except that, in the instance of suffocation by carbonic acid air, (whether arising from mines, lime-kilns, or vats of fermenting liquor,) the vital powers become more speedily and completely extinct, and the difficulty of resoration therefore greater. See Drowning.

SUFFOCATIVE CATARRH. See Catarrh.

SUFFOLK, in Geography, one of the maritime counties, or shires, on the eastern coast of England, is bounded by the German ocean on the east, by Essex on the south, from which it is divided by the river Stour; on the north by Norfolk, and on the west by Cambridgeshire. On Mr. Hodgkin's map of this county, may be measured an oblong of an almost unindented form, 47 miles long by 27 broad. This form comprehends a surface of about 812,160 acres, but Arthur Young is of opinion that the superficial contents of Suffolk do not exceed 800,000 acres.

General History.—Suffolk, so called from the Saxon appellation Sudulf, or southern people, in contradistinction to the Norulf, or northern people, constituted, at the time of the invasion of the Romans, part of the district belonging to the tribe whose conquerors determined Iceni, or Cenomani. In the Roman division of the island, it was comprehended in the province of Flavia Caerfensia. When the Romans, after a possession of four centuries, abandoned Britain, the Saxons, on the invitation of its puflanimous inhabitants, made themselves complete masters of the country, Suffolk constituted, with Norfolk and Cambridgeshire, one of the seven petty kingdoms (called East Anglia) into which these new masters parcelled out the island. To this state the German ocean formed a natural barrier on the east and north-east. The Stour divided it from the kingdom of the East Saxons, or Essex, on the south; and on the west and north-west it bordered upon the Mercian kingdom. The boundary on that side has not been accurately ascertained; but it is generally supposed that the infamous effort of human labour, known by the name of the Devil's Ditch, on Newmarket Heath, was formed as a line of demarcation and mutual defence. Abbot Floriciens fays, that "on the west part are a ditch and mound, like a lofty wall." By subsequent monastic writers it has been termed St. Edmund's ditch; and many antiquaries and historians have adopted this appellation.

When William the Conqueror had by his sword made good his claim to the English crown, the county of Suffolk was divided among his principal officers, in the following manner.

To Hugh de Abrincis, earl of Chester, his sister's son, he gave

To Robert, earl of Morton and Cornwall

To Odo of Champagne, earl of Albemarle and Holderness

To William Warren, earl of Surrey

To Eudo de Rye, reward of his household

To William Malet, lord of Eye in this county

To Robert de Todesc, a noble Norman

To Robert de Stafford

To Alberic de Vere, earl of Oxford

To Jeffery de Magniv, or Mandevil

To Richard de Tonebruge, or de Clare

To Roger Bigod, earl of Norfolk

To Ralph de Lim fiz

To Hugh de Grentmaisell

To Peter de Valoin

To Ralph Baineart

To Swene de Eslox

To Roger de Aubier

To Robert Bland, or Blunt

At the same time, Ralph Wafer, or Guader, was by the Conqueror constituted earl, or chief governor of the county, as well as Norfolk; but this nobleman, having conspired against the king, was obliged to quit the country, upon which his titles were conferred upon Roger Bigod.

About 1175, in the reign of Henry II., Suffolk was invaded, and its property greatly injured, by an army of Flemings, under the command of Robert, earl of Leicester. Meeting the royal troops at Burry, a battle ensued, and the former were repulsed with great slaughter. In the time of king John this county was again invaded, and subjugated by Louis, the dauphin of France, and his allies, the barons. During the reign of king Richard II. the populace of Suffolk, headed by John Wraw and John Ball, two priests, committed great excesses here, and among other persons, put to death the earl of Suffolk, then lord chief justice of England.

Nearly the whole of Suffolk is under the government and within the jurisdiction of the see of Norwich; it is divided into two archdeaconries, Sudbury and Suffolk; and these again into twenty-two deaneries.

Property.—The estate of property in this county may be considered beneficial in its division. The largest estate is supposed not to exceed 8500l. a year; there are three or four others which rise above 5000l., and about thirty others,
SUFFOLK.

Others, of 3000l. and upwards. Below this standard there are many of all sizes; but a circumstance which strongly indicates the prosperity of this portion of the kingdom, is the great number of yeomen, or farmers occupying their own lands, of a value rising from 100l. to 400l. a year. These, as Mr. Young emphatically remarks, are "a most valuable set of men, who having the means, and the most powerful inducements to good husbandry, carry agriculture to a high degree of perfection." The farms in Suffolk must, in a general light, be reckoned large; and to this circumstance chiefly may be attributed the good husbandry so generally found in the county. In the district of strong wet loam there are many small farms, from 20l. to 100l. a year; but these are intermixed with others, rising from 150l. to 300l. and even higher. In the sandy district they are much larger, from 300l. to 800l. or 900l. The usual terms for leases are seven, fourteen, and twenty-one years. Few counties have been more improved by the latter than Suffolk. By means of such leases, whole tracts in the sandy districts have been converted from warren and sheep-walks into productive enclosures. They have caused large tracts to be levelled; and occasioned an improved cultivation in almost every respect, which depended on the expenditure of larger sums than are laid out by farmers unable or unwilling to make such exertions.

Mr. Young gives the following estimate of the total rental of the county, founded upon the division of it according to the soil.

Buildings.—On a survey of the buildings in general of this county, the neglect of elegance and convenience in those of gentlemen of a certain property, as well as in farm-houses, cannot fail to strike the observer. The latter, indeed, are much improved within the last twenty or thirty years, but even at present they are too often built of lath and plaster, which decays in a short time, cause repairs to be so heavy a deduction from the receipts of an estate. The extent to which this evil operates in the eastern part of the kingdom is scarcely credible. Mr. Young informs us, that on one estate of about 1300l. a year, the repairs amounted in eleven years to above 4000l.

Though some individuals have most laudably distinguished themselves by building neat and comfortable cottages for the labouring poor, the small profit which the rent affords has prevented this practice from being frequent. The cottages of Suffolk in general are bad habitations, deficient in contrivance for warmth and convenience, the state of repair bad, and the want of gardens too common. The general rent of them is from two to three pounds, with or without a small garden.

Commerce and Manufactures.—The commerce and manufactures of Suffolk are incumbered; and those are, from various causes, upon the decline. The imports are the same as in all the other maritime counties; and corn and malt are the principal exports. Lowestoft is celebrated for its having a fishery, which was formerly more productive than at present. The principal employment of the poor of the county was, till lately, the spinning and combing of wool, which extended throughout the greater part of Suffolk, with the exception of the district in which the manufacture of hemp is exclusively carried on. In the year 1784, the woollen fabric was estimated by Mr. Oakes, of Bury, to employ 37,000 men, women, and children, whose earnings amounted, upon an average, to 150,000l. per annum. The Norwich manufacture alone employed nearly half of the above number. At present this fabric is far from being so flourishing in this county, having been chiefly transferred to Suffolk. At Sudbury there is a manufacture of fustian, and also a small silk manufacturing; and some calicoes are still made at Lavenham.

Agriculture.—The farmers of Suffolk have, for some years past, emulated the more celebrated agriculturalists of Norfolk. Among the implements peculiar to, or invented and first employed in the county, may be reckoned the Suffolk plow-plough; the horse-rake, for clearing of springcorn stubbles; the new drill-plough, invented by Mr. Henry Balding, of Mendham, who was ten years in bringing it to perfection; the → a considerable expense; threshing-mills, on the improved construction of Mr. Abbey of Blithborough; and the extirpator, or scalp-plough, a machine for destroying weeds, and clearing ploughed lands for seed, invented by Mr. Hayward, of Stoke-Att. A gentleman of this county has also contrived a moveable stage for building the upper parts of stacks of hay or corn, and which may be equally well applied to other useful purposes.

The agricultural societies, which in other parts of the kingdom have been productive of great and extensive benefits, Suffolk is perhaps less indebted than any other county: the only institution of the kind is the Mellford Society.

Suffolk was formerly noted for its hop-grounds, but not more than 200 acres, in the neighbourhood of Stow, are now appropriated to this plant. Bullein, in his "Bulwark of Defence," and in his "Government of Heath," speaks particularly of the hops of this county; and Tufford, in his "Five Hundred Points of good Husbandry," gives directions about the management of this crop in Suffolk. Carrots, cabbages, and saffron, are all cultivated in different parts of the county. Arthur Young states that at least 240,000 sheep were usually fed within Suffolk.

Suffolk is not less celebrated for its breed of horses, than for its cows: they are often fed on carrots, and are never permitted to remain in the stable at night, being turned out into a yard well littered with straw, and supplied with plenty of good sweet oat or barley straw to eat, but never clover or hay. With this treatment a horse never has swelled legs, and seldom any other ailment; he is kept in as fine condition, and will hold his work several years longer than one confined in the stable. With poultry this county is extremely well supplied, and especially with turkeys, for which it is almost as celebrated as Norfolk. Great quantities of pigeons are reared in the numerous pigeon-houses, in the open field part of the county bordering on Cambridgeshire. Suffolk contains many rabbit-warrens, especially in the western sandy district. One of them, near Brandon, is estimated to return above 40,000 rabbits in a year. Of late years, however, considerable tracts occupied by them have been ploughed up and converted into arable and pasture land. The quantity of butter computed to be sent from Suffolk to London annually, is about 40,000 firkins.

Wheat.—Though Suffolk must be reckoned among the earliest inclosed of the English counties, yet Mr. Young calculates the wafers to amount to nearly 100,000 acres, or an eighth of the whole, comprehended under the term sheep-walk, common, warren, &c. "None of these," adds 3 M
SUFFOLK.

that writer, "are, briefly speaking, absolutely wafte, if by that term is understood land yielding nothing. I include all lands uncultivated, which would admit of a very great improvement, not always profitable to the tenant, who may, on a small capital, make a great interest per cent. by a warren, for instance, but in every case to the public. Many farmers think sheep-walks necessary for their flocks, which is very questionable. They are undoubtedly useful, and if they are converted into inclosures, the number of flocks kept would on a farm might in a few cases decline, but good grazings adapted to the soil would be abundantly more productive for the flock. Whoever has viewed the immense waftes that fill almost the whole country from Newmarket to Thetford, and to Gaffrop Gate, and which are found between Woodbridge and Orford, and thence one way to Saxmundham, not to mention the numerous heaths that are scattered everywhere, must be convinced that their improvements for grazings would enable the county to carry many thousands of sheep more than it does at present."

Plains of the Poor.--The amount of money levied in this county in 1802, for the maintenance of the poor, was 149,646l. being at the rate of 4s. 10½d. in the pound, on the annual rental. The most singular circumstance relating to the poor in Suffolk, is the incorporation of various hundreds for erecting and supporting houses of industry. The local inconvenience and diffi culties arising from the number of poor, and the expense of maintaining them, occasioned many districts in the county to apply to parliament for the power of incorporating themselves, and of regulating the employment and maintenance of the poor, by certain rules not authorized by the existing poor laws. Several acts of parliament accordingly passed, incorporating those districts where the poor have since been governed and supported according to the power given by such acts. The result of an actual examination of these institutions by T. Ruggles, esq. is given by Mr. Young in the following terms.

"In the incorporated hundreds, the houses of industry strike one in a different light from the cottages of the poor. They are all built in as dry, healthy, and plesant situations as the nature of the country will admit. The offices, such as the kitchen, brew-houfe, bake-houfe, buttery, laundry, larder, cellars, are all large, convenient, and kept extremely neat; the work-rooms are large and well aired, and theexces kept apart, both in hours of work and recreation. The dormitories are also large, airy, and conveniently disfopied; separate rooms for children of each sex, adults and aged. The married have each a separate apartment for themselves; mothers with nurfe children are also by themselves. The infirmaries are large, convenient, airy, and comfortable; none without fire-places. All the houses have a proper room for the necessaries of the poor, and most of them a surgeon's room besides. The halls are in all large, convenient, well ventilated, with two or more fire-places, and calculated, with respect to room, for the reception of full as many as the other conveniences of the house can contain.

"The chapels are all sufficiently large, neat, and plain, several of them rather tending to grandeur and elegance. There were two houses which had no chapels; one of them made use of a room ample enough for the congregation properly fitted up, and kept very neat; the other attended the parish church. The apartments for the governor were in all the houses large and conveniently disfopied. In one or two of these apartments were rather more spacious and elegant than necessary. There are also convenient store-houses and ware-houses for keeping the manufactures of the house, the raw materials, clothing, &c. for the use of the inhabitants.

"The land belonging to the houses, and the gardens in particular, are calculated for producing a sufficient quantity of vegetable diet, so necessary to the health, as well as agreeable to the palate of the inhabitants."

Soil.—Although the greater portion of the surface of this county be sand, yet in many places this is combined with different loams. Near the S.W. side of the county, on a line from Wratting, to North cove, near Beccles, a strong loam, on clay-marle, prevails. Almost the whole of the maritime district consists of a sandy loam, and this is most profitably and successfully cultivated. Nearly the whole of the north-western side of the county presents a dreary sterile scene, and merely affords a few patches of vegetation scattered amongst sand. Some sheep and rabbits however are fed in this district. Beneath the sand is a subfratrum of chalk. A small part of this county is sanny, and in some places the peat-bog is found from one foot to two feet beneath the surface. A tract called Burnt-fen has lately been so much improved by the reparation of banks, that 12,000 acres of land have been drained and cultivated.

Division and Population.—The two grand divisions of Suffolk are the franchise, or liberty of Bury St. Edmund's, and the body of the county, or iugulable land, each of which furnishes a distinct grand jury for the county affixes. These are subdivided into 21 hundreds, comprehending 532 parishes.

The inhabited houses in 1801 were 39,353
By how many families occupied 43,481
Uninhabited houses 552
Perfons 210,431
Chiefly employed in agriculture 55,744
In trade, manufactures, or handcraft 34,004
In all other occupations 115,632

Rivers.—Suffolk is a well-watered county; its boundaries to the south and north are rivers, navigable to a considerable extent, and it is every where intersected with streams, which, if the practice of irrigation were more generally adopted, would be productive of great benefit.

The Stour rises on the west side of the county, on the borders of Cambridge-Norfolk and forms throughout its whole course the boundary between Suffolk and Essex. It passes by Sudbury, and after being joined by the Bret, and other smaller streams, receives the tide at Manningtree. Here increasing considerably in breadth, it presents a beautiful object at high water, to the fine flat and grounds of Mityl Thorn. It meets the Orwell from Ipswich, and their united waters, having formed the port of Harwich, discharge themselves into the German ocean, between that town and Langford fort.

The Gipping has its source in the centre of the county, near Stow-Market. Running in a south-east direction, it waters Ipswich, and affimes below that town the name of the Orwell. The banks of this river are in general picturesque, especially when it becomes an estuary below Ipswich, to which place it is navigable for ships of considerable burthen.

The Deben, which has its source near Debenham, takes a south-eastern direction, and passing by Woodbridge, falls into the German ocean.

The Alde rises near Framlingham, and runs south-west to Wolborough, where having approached to within a very small distance of the sea, it suddenly takes a southerly direction, and discharges itself below Orford into the German ocean.

The Blythe has its source near Saxfold, in the hundred of Hoxne, whence running east-north-east to Halffworth,
it then proceeds almost due east to Blythburgh and Southwold, where it falls into the sea.

The Lark rises in the south-western part of the county, pales Bury and Mildenhall, and joins the Great Ouse not far from the latter town.

The Waveney and Little Ouse have already been mentioned under the article NORFOLK. The former, after running fifty miles towards the sea, in an eastern direction, and approaching its very shores, is opposed by a rising ground, which gives it an abrupt direction almost due north. This leads it to the river Yare; and though its waters are sufficient to give name to a harbour of its own, it merely affects as a secondary river in deepening and enlarging the harbour of Yarmouth. The meadows through which it passes with an easy and gentile course, are suppos'd to be among the richest in England.

Roads and Canals.—The roads in every part of this county are excellent, the improvements made in them of late years being almost inconceivable; in most directions, indeed, the traveller finds crofs ones equal to turnpike roads.

SUFFOLK, a county of Upper Canada, bounded E. by the county of Norfolk, S. by lake Erie, until it meets the carrying-place from Point aux Pias unto the Thames, W. by the carrying-place or portage, and thence up the river Thames, until it meets the north-westernmost boundary of the county of Norfolk. Its boundaries were established by proclamation, July the 6th 1804. In conjunction with Effex, to give name to a harbour of its own, it merely affords as a secondary river in deepening and enlarging the harbour of Yarmouth. The meadows through which it passes with an easy and gentle course are supposed to be among the richest in England.

SUFFOLK, a county of America, in the state of Massachusetts, deriving its name from that of England, in which governor Winthrop lived, before his emigration to America.

It contains two towns, viz. Boston and Chelsea, besides several islands, in which are 34,381 inhabitants. It was constituted a county May the 10th, 1643.

SUFFOLK, a county of New York, comprising all that part of Naffau or Long Island, that lies eastward of Queen's county; bounded N. by Long Island Sound, E. and S. by the Atlantic ocean, and W. by Queens county. The whole area may be about 598 square miles, or 510,720 acres. It contains 21,113 inhabitants, of whom 413 are slaves, 2335 electors and sends three members to the house of assembly. This county was settled at an early period of the American history; and a considerable part of its first inhabitants came from New England. The inhabitants of this county are distinguished by their sobriety, temperance, and industry; and it is said that more domestic happiness and plain republican truth are not found anywhere than among the inhabitants of Long Island; which is.

SUFFOLK, a port-town of Virginia, in Nancemond county, on the E. side of the river Nancemond, containing a court-house, gaol, and about 40 houses. The river is navigable as far as this town for vessels of 250 tons, 28 miles W. by S. from Portsmouth. Allo, a port-town of Virginia, in Sussex county; 185 miles from Washington.

SUFFOLK Bay, or Tscrnaka Bay, a bay on the W. coast of St. Vincent; 1 mile N. of Cumberton bay.

SUFFOLK Farmer's Cott., in Agriculture; a convenient and useful sort of cart for farm purposes, which has lately been introduced from that county into Suffolk with great benefit and advantage.

SUFFOLK Grass, the common name given to the dwarf meadow-grass, which is said to be very commonly met with on all good loamy lands, and to be perhaps the best grass which we have for pastures, from the rapidity with which it propagates itself, and the fondness which cattle have for it. It is well known to be a very troublesome weed in garden grounds. See GRASS, and POA ANNUA.

SUFFOLK Powder, the name of a medicinal powder, good for the bite of a mad dog. It had its name from a country of Suffolk, who used to give it with great successe. It is still kept as a secret in some private families, but seems to be only the flavr of the earth, or the common buckthorn plantain dried and powdered, or the powder with some very trifling addition. This plant has been famous for its virtues in this case a great while among us, and Dr Grey, in his Complete Farrier, gives the method by which he cured dogs by it with great success. See Phil. Trans. No 450. p. 455.

SUFFRAGAN, suffraganus, in the Ecclesiastical Policy, a term applied (but not very properly) to a bishop, with respect to his archbishop, on whom he depends, and to whom appeals lie from the bishop's official.

In this sense, the archbishop of Canterbury has twenty-one suffragans, and the archbishop of York four. The term was never heard of before the eighth century. Some derive it hence, that the bishops are to help and assist the archbishop; quia archiepiscopus suffragani et subjectus tenuatur. Others say, it is because ecclesiastical matters are determined by their votes, or suffrages; et suffragium dicitur, quia cum suffragat causa ecclesiastica judecantur. Others hold they are called suffragans, because when called by a metropolitans to a synod, they have a right of suffrages, or of voting, or because they could not be consecrated without his suffrage.

Suffragan is more properly used for a choripcopos, or an assistant bishop, or coadjutor, who has a title in paribus sequilum, and assists another in the discharge of his function, or discharges itself in the absence of that other. They were consecrated, like other bishops, by the archbishop of the province, and appointed as titular bishops, to execute such power and authority, and to receive such profits as were limited in their commissions by the bishops or diocesan, whose suffragans they were, and whom they affiliated in duties merely episcopal; they conforming to orders, confirmation, and consecration of divers kinds. And in this respect, it is said, they differed from the coadjutors who affiliated their bishops in matters chiefly of jurisdiction, as in collating to benefices, granting institutions, dispensations, and the like, and who for these purposes need not have been episcopally ordained. This was the practice here in England especially: the two ends of orders, and of jurisdiction voluntary, in case of the inability of a bishop, were answer'd by two different persons; the first under the name of suffragan, and the second under that of coadjutor.

The suffragans are thus signified to be called episcopal bishops, by statute 26 Henry VIII. cap. 14. every archbishop or bishop, dispobed to have any suffragan, is allowed to name two proper persons, and to present them to the king, who was empowered to give one of them the title, style, and dignity of bishop and such of the fees as are mentioned in the statute, as he thought fit; and every such person should be called bishop suffragan of the same fee, and be consecrated accordingly. This act specifies the places for which such suffragans were to be appointed, and fixes the place of their respective residences. Their profits and jurisdiction were to be limited by the commission of the archbishop or bishop to whom they were suffragans, and the time of the exercise of their office was also limited by the same com-
mony: and they were forbord to exercise it otherwise than such communion directed, on pain of a premontré. Suffragans have now been discontinued for many years.

Du Cange observes, that the title suffragan has also been given to such priests as are subject to the visitation of the archdeacon; and suffragan of the pope, to the bishops of such dioceses as are immediately subject to the pope.

SUFFRAGE, SUFFRAGIUM, a voice or vote given in an assembly where something is deliberated on, or where a person is elected to an office or benefice.

The word is formed from the Latin, suffragium, which anciently signified money, as appears in the eighth novel of Juvenal: ut iudices sine suffragio sint; and the sixth novel, qui emerit presulatum per suffragium, episcopatus & ordine ecclesiasticus excitat.

Suffrages are sometimes given by word of mouth; and sometimes in writing, as at elections liable to a scrutiny. The president or chairman of the assembly usually collects the suffrages.

SUFFRAGES OF THE SAINTS, in the Remill Church, denote the prayers and intercessions which the saints are supposed to make to God in behalf of the faithful.

SUFFRAGE, in Geography, a name formerly given to a township of Ottego county, in New York, on the N. side of the Susquehanna, taken from Undalla, and incorporated in 1706; but its name has been since changed.

SUFFREIN'S BAY, a bay on the E. coast of Chineee Territory, so called by Perouze. N. lat. 47° 51'. E. long. 158° 47'.

SUFFERTRICUS PLANTS, in Gardening, a term applied to those sorts of luscious or somewhat woody vegetables, that are of a nature, in some degree, between that of the shrubby and the herbaceous, as exemplified in thyme, fage, hyssop, winter-favorvy, and many other such plants. The term properly signifies under-shrubby, and is consequently applied to plants of that kind.

SUFFUMIGATION, SUFFUMIGATIO, from sub, under, and fumus, smoke, in Medicine, a term applied to all remedies that are received into the body in form of fumes, i.e. of smoke, vapour, or perfume.

Suffumigations are composed of different matters, according to the nature of the disease. Their intentions are to soften sharp serous humours, to provoke or check the course of the menses, to raise a saltation in venereal evils, &c. See FUMIGATION and FUMIGATOR.

SUFFUSIO, the name given by Celsus to a cataract, or opacity of the crystalline lens.

SUFFUSION, SUFFUSIO, an overflowing of some humour, shewing itself in the skin; particularly that of the blood or bile.

That redness ordinarily arising from shame, is only a suffusion of blood appearing in the cheeks. See BLUSHING.

The jaundice is a suffusion of bile over the whole body. See JUNDICE.

SUIF, the Eastern name for a sect of poets, corresponding nearly to the Mystics of the West. See SOPHIS, and MYSTICAL POETRY.

SUGAHILA, in Geography, a town of Africa, in the country of Sulmulme; 6 miles S.S.E. of Sulmulme.

SUGAR, SACCARUM, a very sweet, agreeable saline juice, expressed from a kind of canes, or reeds, growing in great plenty in the East and West Indies. (See SUGAR-CANE.) Pure sugar is perfectly transparent and colourless, when crystallized; but when granular, of a pure gross of white, soluble in water and alcohol, without smell, and with a faintly sweet taste, having no other flavour.

It is a question not yet decided among botanists, &c.

whether the ancients were acquainted with this cane, and whether they knew how to express the juice from the fame? What can we gather from the arguments advanced on either side is, that if they knew the cane, and juice, they did not know the art of condensing, hardening, and whitening it; and of consequence, they knew nothing of our fugar.

Some ancient authors, indeed, seem to mention fugar under the name of Indian salt; but they add, that it oozed out of the cane itself, and there hardened like a gum; and was even friable between the teeth, like our common salt; whereas sugar is expreseed by a machine on purpose, and congealed by the fire.

Theirs, Salmainus (Pliniani Exercit. tom. i. p. 716. G.) tells us, was cooling and loofening; whereas ours, the fame author affirms, is hot, and excites thirst. Hence some have imagined, that the ancient and modern fugar plants were different: but Matthiolus in Dioecorides, c. 75, makes no doubt they were the same; and others are even of opinion, that ours has a laxative virtue, as well as that of the ancients, and that it purges puitia.

The generality of authors, however, agree, that the ancient fugar was much better than the modern; as confitting of only the finest and maturest parts, which made themselves a passage, and were condensed in the air. The interpreters of Avicenna and Serapion call fugar, Nudium; the Persians, tabasir; and the Indians, mbam. Salmainus (Contra de Sacchar. apud Plin. Exercit. vol. ii. p. 257, A.D. 1650) affirms us that the Arabs have used the art of making fugar, such as we now have it, above nine hundred years.

Others produce the following verses of P. Terentius Varro Atacinus, to prove that it was known before Jesus Christ:

"Indica non magna nimis arbo re crecit arundo; Illius e lentis premittur radicibus humor, Dulcia cui nequeant succo contendere melia."

Dr. William Douglas, in his Summary, &c. of the first planting of our American settlements, printed at Boston in 1751, and reprinted at London in 1755, affirms, that sugar was not known among the ancient Greeks and Romans, who used only honey for sweetening. Paulus Epigenes, he says, a noted compiler of medical history, and one of the last Greek writers on that subject, about anno 1635, is the first who expressly mentions sugar: it was at first called Mel arundiscaccum, i.e. reed or cane honey. He adds that it came originally from China, by way of the East Indies and Arabia, into Europe, and was formerly used only in syrups, conerves, and such Arabian medicinal compositions.

Lucas, enumerating the eastern auxiliaries of Pompey, describes a people who used the cane-juice as a common drink.

"Qui bibunt tenerà dulces ab arundine succos."

Another question among the naturalists is, whether the sugar-canels be originally of the West Indies, or whether they have been translated rather from the East?

The learned of these late ages have been much divided on the point; but Dr. Labat, a Dominican missionary, in a dissertation published in 1722, affirms, that the sugar-cane is natural to America, as India; and that the Spaniards and Portuguese first learned from the Orientals the art of expressing its juice, boiling it, and reducing it into fugar.

Those who adopt this opinion assert, that the sugar-cane was
SUGAR.

was found growing spontaneously in many parts of the new hemisphere, when first explored by the Spanish invaders. In support of this opinion, Labat quotes, among other authorities, that of Thomas Gage, an Englishman, who went to New Spain in 1625, and who enumerates sugar-canes among the fruits and provisions with which the Charibes of Guadaloupe supplied the crew of his ship. Labat further adds, that, besides the evidence of Francis Ximenes, who, in a treatise on American plants, printed at Mexico, affirms that the sugar-cane grows without cultivation, and to an extraordinary size, on the banks of the river Plata, we are assured by Jean de Lery, a Protestant minister, who, was chaplain in 1559, on the Dutch garrison in the fort of Coligny, on the river Janeiro, that he himself found sugar-canes in great abundance in many places on the banks of that river, and in situations never visited by the Portuguese. Father Hennenep, and other voyagers, bear testimony, in like manner, to the growth of the cane near the mouth of the Mississippi; and Jean de Laet to its spontaneous production in the island of St. Vincent. Hence it is concluded, that it is not for the plant itself, but for the secret of making sugar from it, that the West Indians are indebted to the Spaniards and Portuguese; and these to the nations of the East. Thus reflects Labat, and the first editions of his book is of opinion that his reasoning is incontrovertible; and it is also greatly confirmed by recent discoveries; the sugar-cane having been found in many of the islands of the Pacific ocean, by our late illustrious navigator captain Cook. In these accounts, says Mr. B. Edwards, there is no contradiction. The sugar-cane might have grown spontaneously in many parts of the new world; and Columbus, unprudently, of the circumstances, might likewise have carried some of the plants to Hispaniola; and this most probably was the fact.

However, the settlers applied to its cultivation, affords a wonderful contrast to the manners of the present inhabitants; since it appears, by the testimony of Oviedo, that no less than 30 ingenios, or sugar-mills, were established on that island to early as the year 1555.

Other writers, however, have maintained, that it was not known in America till the Europeans transplanted it thither. Its origin appears to have been from the inland continent of Asia, very probably as far east as China, where it abounds. As it grows in all quarters of the globe, it was first transplanted to Cyprus, and thence (according to various authors) into Sicily, where considerable quantities of it were produced about the year 1748, and thence, as some have asserted, was brought from India by the Saracens. Laftau conjectures, that the plant itself was unknown in Chrifdom, until the time of the Crusades. Its cultivation, and the method of preparing and purifying the juice, as practiced by the inhabitants of Acra and Tripoli, are described by Albertus Aquensis, a monkish writer, who observes, that the Christian soldiers in the Holy Land frequently derived refreshment and support, in a scarcity of provisions, by sucking the canes. It flourished also in the Morea, and in the islands of Rhodes and Malta, and from thence was transplanted into Sicily, but the time is not precisely ascertained. Laftau recites a donation of William, the second king of Sicily, to the monastery of St. Bennet, of a mill for grinding sugar-canes, with all its rights, members, and appurtenances. This happened in 1166. From Sicily it was transplanted by the Portuguese to Madeira about the year 1445, and from Sicily, or the Southern coast of Africa, to Egypt, that Province, through the efforts of the Hibertus, obissar, from Granada, which derived it from Valencia, whence it might have been transplanted by the Arabian Moors, it was brought to the Canaries; from the Canary islands to Brazil; where, indeed, some suppose sugar was originally and spontaneously produced. Others are of opinion, that the Portuguese, before they discovered, or at least planted in Brazil, being in possession of the coast of Angola in Africa, first transplanted the sugar-cane from Angola to Brazil. About the year 1506, sugar-canes were brought from Brazil and the Canaries, and planted in the island of Hispaniola, where many sugar-mills were gradually erected. It appears, however, by the testimony of Peter Martyr, in the third book of his first Decad, written during Columbus's second expedition, which began in 1493 and ended in 1495, that the sugar-cane was at that period sufficiently known in Hispaniola. The fact seems to have been, that Columbus himself carried it thither, among other articles and productions which he conveyed from Old Spain, and the Canary islands, where it grew, in his second voyage. In 1641, sugar-canes were transplanted from Brazil to Barbadoes, and thence to our other West India isles; as from Brazil they were also carried to the Spanish West India isles, and also the Spanish dominions in Mexico, Peru, and Chili; and lastly, to the French, Dutch, and Danish colonies.

The boiling and baking of sugars, says Dr. Heylin, in his Catalogography, the first edition of which was printed in 1624, as it is now used, is not above two hundred years old; and the refining of it more new than that, first found out by a Venetian in the days of our forefathers, who got one hundred thousand crowns by the invention. Before which art of boiling and refining it, our ancients made use of it rough as it came from the canes, but they most commonly used honey instead of it. The first account we have of sugar-refiners in England is in the year 1659. Anderson's Hist. of Com. vol. i. p. 82. 246. 331. 334. vol. ii. P. 79. 105.

SUGAR-Cane, in Botany. See Saccharum.

The root of this plant is jointed like those of the other sorts of canes and reeds, from which arise four, five, or more shoots, according to the age or strength of the root; these grow from eight to ten or twenty feet high, according to the richness of the ground; but those of middling growth are the best.

The canes are also jointed, and the length as well as the size of the joints depend upon the weather and the soil; when the joints are placed leaves, the cane is said to be open-branched; if the leaf on the cane to the next joint above their inferior, before they expand. The first joint, which comes out either at the third, fourth, or fifth month, according to the season and soil, always keeps in its first place near the earth; out of this comes the second, and out of the second a third, &c. each week producing its joint, or very nearly, and a corresponding leaf likewise drying and falling off nearly every week.

A cane of thirty-two joints, which is fit to be cut, has from five to twenty-eight of them which have lost their leaves, the next five or six still have their leaves, in a withered state, and ready to fall off; and the remaining joints, surrounded with green leaves, form the head, which is cut off after the last leaf is withered. In a cane, whole length is from seven or nine feet, and which grows in a new, or a very moist and favourable soil, the number of useful joints is between forty and fifty, the first above the ground generally appearing at the end of three months, or, with frequent showers, a fortnight sooner; and many canes in such a foil are found rotten, or almost dried up, at the end of thirteen months; and the fruit was exposed, well drained, and worked for a number of years, canes not shorter than four feet and a half have thirty-eight or forty joints, the first joint
SUGAR.

joint appearing about the fourth or middle of the third
month, and many canes that have been cut in such a foil at
the end of fourteen or fifteen months being found rotted or
dried; in a dry, but good foil, not manured, but well
worked, and seconded by the season, the canes have been
from three to four feet long, and have had from thirty to
thirty-four joints; the first joint coming out at the end of
four or four months and a half; and canes of this kind have
been found standing at the end of fifteen months, but very
dry, and sometimes a little changed; in a foil which is still
dried, and more parched, canes which have been about two
feet high have had from twenty-four to twenty-eight joints,
the first of which appears at the end of the fifth month, and
many of these canes have been dried at the end of fifteen
months. From these and similar observations on the growth
of canes in various kinds of foil, it has been inferred, that
if there be any in which they can exit till the fifteenth or
sixteenth month, they never grow to any kind of purpose
in any after the thirteenth, or even after the twelfth.
A deep foil and light land are most suitable to the fugar-cane;
and the rainy season is the proper time for planting it: the
sooner they are planted after the rains begin to fall, the
more time they have to get strength before the dry weather
sets in.

If the ground is proper for the fugar-canes, and they are
planted at a good distance from each other, and the land is
carefully managed by changing the crops to other species,
or allowing a fallow to rest and recover itself, the cane
plantation, says Mr. Miller, may be continued above twenty
years without replanting, and produce good crops the whole
life; whereas, in the common method, they are generally
replanted in five or seven years, and in some of the poor land
they are continued but two or three years. The canes are
propagated by cuttings or joints of proper lengths, from
fifteen to twenty inches, in proportion to the nearness of the
joints; which are generally taken from the tops of the canes,
just below the leaves; but Mr. Miller says, that if
they were chosen from the lower part, where they are less
cullulent and better ripened, they would not produce canes
so luxuriant, but their juice would be less crude, and con-
tain a greater quantity of fuls, which would be obtained by
less boiling than that of the commonly planted. However,
Mr. Cazaud, a late writer, and a planter of fugar-
canes, observes, that the upper part, commonly called the
head, is the best part that can be used for propagating
them; and he recommends to put the plant in the ground
as soon as it is cut. The distance which the canes are
usually allowed in planting is from three to four feet, row
from row; and the hills are about two feet alder in the
rows, in each of which hills they plant from four to seven
or eight cuttings; instead of which number, productive
often of blights, Mr. Miller is of opinion, that if one good
cutting were planted in each hill, or two at most, and if
both succeeded, the weakest were drawn out soon after they
had taken, blights would be prevented, and the quantity of
sugar would be full as great, and require little more than a
fourth part of the fuel to boil it. In the proper season
for planting, the ground should be marked out by a line, that
the rows of canes may be straight and at equal distances;
and the whole should be divided into pieces of sixty or se-
venty feet broad, leaving intervals between each of about
twenty feet, for the convenience of passage, and for the ad-
million of the sun and air between the canes.

The common method of planting the canes now practiced,
is to make a trench with the hoe, which is performed by
the hand; into this a negro drops the number of cuttings
intended to be planted, which are planted by other negroes,
and the earth drawn about the hills with the hoe, all which
is performed by the hand; but if the right use of the
plough was introduced, the work would be both better and
cheaper performed. If, therefore, instead of a trench
drawn by the hoe, a deep furrow is made with a plough,
and the cuttings properly planted therein, the ground being
deeper tilled, will be more favorable to the growth of
the canes. If the ground is afterward to be kept clear by the horse-
hoe, the rows of canes should be five feet asunder, and the
hills be two feet and a half distant; and but one cane left in
each hill. After they have made some shoots, the foamer
the horse-hoe is used, the more they will thrive, by keep-
ing the weeds under, and well tilling the land.

When the canes are from seven to ten feet high, and of
proportional size, the skin smooth, dry, and brittle; if
they are heavy, their pith grey or inclinable to brown,
the juice sweet and glutinous; they are esteemed in per-
fecction.

Mr. Cazaud observes, that the withering and fall of a
leaf is the only and a sufficient criterion of the maturity
of the joint to which it adhered; and that the eight left joints
of two canes, which are cut the same day, have exactly
the same age and the same degree of ripeness, notwithstanding
one of the canes may be fifteen, and the other only ten
months old: to which purpose he adds, that each joint of
the cane of a fuposed growth of ten months, contained the
same quantity of fugar as that of a cane of the fuposed
growth of fifteen months.

The time for cutting them is usually after twelve or fif-
ten months growth, but this varies according to the foil
and the season. Those which are cut toward the end of the
dry season, before the rains begin to fall, produce better
sugar than those cut in the rainy season, when they are
more replete with watery juice, and require a greater ex-
pense of fuel to boil it.

In those plantations where the number of negroes is
small, sugar is made in almost all feasons indifferently, and
consequently the canes are planted when the planter is best
prepared for his work, rather than at the most advantageous
time. The fystem of cultivation among planters, who are
better supplied in respect of labourers, consists in planting a
fourth or a fifth of their land in October, November, and
December; in digging very deep trenches, for the greater
nourishment of the root; in planting at great distances,
for the benefit of a freer circulation of the air; and in cutting
the canes in the four feint months, viz. February, March,
April, and May, because the sugar is then the finest, the
canes are cut with the leaf tops, and supply (as is fup-
posed) greater quantities of it. Those who adopt this
method, cut about three-fourths of their plantations, the
remaining being made up of young canes, to be cut the fol-
lowing year, and for new plants.

Mr. Cazaud, who has made many judicious observations
and experiments on the cultivation of the fugar-cane, has
adopted a new method. He employs the whole of the first
six months of the year in the buñilea of the crop, and in
May and June plants the canes which have been cut in
January. This course induces a necessity of cutting the
rattoons (or the canes proceeding from the old stumps) at
the end of the eleventh instead of the end of the twelfth
month, and the planted canes, which should stand fifteen
months, at the end of the year; so that the whole plant-
tation is cut every year; and he only plants a sixth part
of his land every year. He has largely illustrated the reasons
and advantages of this method; the fundamental principle
of which is the necessity of planting the canes in the only
season...
SUGAR.

season fitted to accelerate and preserve them: as in the Windward islands, the weather is commonly dry from the 15th of February to the 15th of May, and the rains are moderate till August, and copious the two or three following months, and afterwards decrease till February: and, therefore, the progression of the rain keeps pace, as it were, with that of the canes, when they are planted in May. With regard to the maturity of the cane, as far as it is of consequence to the sugar, this, he says, does not depend on the soil but on the season. In February, March, and April, all the canes, whatever be their age, are ripe as the nature of the soil ever allows them to be; and accordingly he never fails to make the greatest part of his sugar at this season. He observes, that the dryness of the weather, and not the age of the canes, which increases from January to April, is the cause, that in January four hundred gallons of juice commonly yield forty-eight gallons of sugar and molasses one with another; in February, from fifty to sixty; in March, from sixty to seventy-two; in April, sometimes eighty; after which period the sugar decreases, and when the rain is not very heavy, is at his business. The greatest relative maturity of his canes, he infers to be, when the juice of them was made up of four parts water, and one part of sugar and molasses; and in canes perfectly ripe, the quantity of sugar, he says, is equal to that of the molasses. After a trial of this plan for five years, he is convinced that there is a difference of above one-sixth in its favour. Miller's Gard. Dict. Phil. Trans. vol. i. part 1. art. xix. p. 207, &c.

The best soil, according to Mr. Edwards, which he has seen or heard of, for the production of sugar of the finest quality, and in the largest proportion, is the alluvial soil of St. Christopher's. Next to that is the soil, which in Jamaica is called the brick-mould, containing a due mixture of clay and sand. Plant-canes in this soil (which are those of the first growth) have been known, in very fine seaforns, to yield two tons and a half of sugar per acre. After this may be reckoned the black mould of several varieties. The beet is the deep black earth of Barbadoes, Antigua, and some other of the Windward islands; but there is a species of this mould in Jamaica, that is little if at all inferior to it, which abounds with lime and flint, on a substratum of foamy marl. We shall not enumerate the varieties of soil proper for this kind of culture; but content ourselves with mentioning a peculiar sort of land on the north side of Jamaica, chiefly in the parish of Trelawny, as few soils produce finer sugars, or such as answer so well in the pan, or which yield a greater return of refined sugar. This land is of a red colour, varying by different shades; but where every remarkable, when first turned up, for a glossy or shining surface, and, if wetted, for flaming the fingers like paint. This soil seems to consist of a native earth, or pure loam, with a mixture of clay and sand. It is easily wrought, and at the same time so tenacious, that a poasd dug in this soil in a proper situation, with no other bottom than its own natural texture, holds water like the finest clay. The system of husbandry in sugar plantations, which abound with this, chiefly depends on what are called root cane.

In most parts of the West Indies, it is usual to hole and plant a certain proportion of the cane-land (commonly one-third), in annual succession; and even the root of this land, on an average, is seven hopheads of 16 cwt. to ten acres, which are cut annually. In the cultivation of other lands, especially in Jamaica, the plough has been introduced of late years, and in some few cases to great advantage; but the use of the plough is not adapted to every soil or situation. The only advantageous system of ploughing in the Windward islands is to confine it to the simple operation of boling, which is much more easily and expeditiously performed by the plough than by the hoe, and which affords, in the case of stiff and dry soils, great relief to the negroes. The method of boling has been described. The proper season, generally speaking, for planting, is in the interval between August and the beginning of November. By having the advantage of the autumnal season, the young cane become sufficiently rooted before the severe dry weather sets in; thus the roots are kept cool, and the earth moist. By these means, they are ripe for the mill in the beginning of the second year, so as to enable the overseer or manager to finish his crop by the latter end of May. It has been justly remarked, that there is not a greater error in the system of plantings, than to make fugar, or plant canes, in improper seasons of the year; for by mismanagement of this kind, every succeding crop is put out of regular order. However, neither prudence in the management, nor favourable soils, nor seasonable weather, will secure the planter at all times from misfortune in the culture of his fugar canes. They are subject to a disease called the "blatt," which consists of many myriads of little insects of the aphus genus, said to be invisible to the unaided eye, whose proper food is the juice of the canes; in pursuit of which they wound the tender blades, and destroy the veins. The circulation is thus impeded, and the growth of the plant is checked, until it withers or dies in proportion to the degree of the ravage. In some of the Windward islands, the cane in dry weather is liable to be destroyed by a species of grub, called the "bovor." As Tobacco they have another destructive insect, called the "jump-fly." It is said that the "blatt" never attacks those plantations, where colonies have been introduced of the little animal, called the carnivorous ant; the "forina omnivora" of Linnaeus, and the "Raffles" ant of Jamaica.

The manure generally used in fugar-planting is a compound formed of the coal and vegetable ashes, drawn from the fires of the boiling and still-houses; feculences discharged from the still-houses, mixed with refuse of buildings, white lime, &c.; refuse, or field-trash, i.e. the decayed leaves and refuse of the canes, so called in opposition to the culture of his fugar canes. They are subject to a disease called the "blatt," which consists of many myriads of little insects of the aphus genus, said to be invisible to the unaided eye, whose proper food is the juice of the canes; in pursuit of which they wound the tender blades, and destroy the veins. When the rattoons or canes are ripe, as they ordinarily are in twelve or fifteen months, or, as Mr. Cazanu apprehends, in eleven or twelve months, they are cut, and carried in bundles to the mills. The mills consist of three wooden rollers, covered with steel or iron plates; and have their motion either from the water, the wind, cattle, or even the hands of slaves. These rollers or cylinders are from 30 to 40 inches in length, and from 20 to 35 inches in diameter; and the middle one, to which the moving power is applied, turns the other two by means of cogs. Between these rollers the canes, being previously cut, are twice compressed; for having paffed the firrt and second rollers, they are turned round the middle one by a circular piece of frame-work, or scree, called in Jamaica the "dumb-returner," and are forced back through the second and third; an operation which squeezes them completely dry, and sometimes even reduces them to powder. (For a farther account of sugar-mills, see the sequel of this article.) The juice from the mill ordinarily contains eight parts of pure water, one part of sugar, and one part made of gros oil and mucilaginous gum, with a portion of effusional oil. Some juice, however, has been so rich
SUGAR.

as to make a hoghead (16 cwt.) of sugar from 1300 gallons; and some so watery as to require more than double that quantity. A pound of sugar from a gallon of raw liquor is reckoned, in Jamaica, very good yielding.

SUGAR. Preparation of. The juice or liquor runs from the receiver to the boiling-house, along a wooden gutter lined with lead. In the boiling-house it is received (according to the modern improved system, which almost universally prevails in Jamaica) into one of the copper pans or cauldrons, called clarifiers. Of these, there are commonly three; and their dimensions are generally determined by the power of supplying them with liquor. There are water-mills that will grind, with great ease, canes sufficient for thirty hogheads of sugar in a week. On plantations thus happily provided, the means of quick boiling are indifferently requisite, or the cane-liquor will unavoidably become tainted before it can be exposed to the fire. The purest cane-juice will not remain twenty minutes in the receiver without fermenting. As cane-juice is so very liable to fermentation, it is necessary also that the canes should be ground as soon as possible after they are cut, and great care taken to keep and throw aside those which are tainted, which may afterwards be ground for the still-house. Clarifiers, therefore, are sometimes seen of one thousand gallons each. On elates that make on a medium, during crop-time, from fifteen to twenty hogheads of sugar a week, there are clarifiers of three or four hundred gallons each are sufficient. With pans of this size, the liquor, when clarified, may be drawn off at once; and there is leisure to cleanse the vessels every time they are used. Each clarifier is provided either with a fision or cock for drawing off the liquor. It has a flat bottom, and is hung to a separate fire, each chimney having an iron slider, which being shut, the fire goes out for want of air. These circumstances are indispensible, and the advantages of them will presently be shewn. The clarifiers are commonly placed in the middle or at one end of the boiling-house. If at one end, the boiler called the "teafire" is placed next the other, and several boilers (generally three) are ranged between them. The teafe is ordinarily from 70 to 100 gallons, and the boilers between the clarifiers and teafe is filled with the next the top of the boiling-house. On very large elates, this arrangement is found useful and necessary. The objection to so great a number is the expense of fuel; to obviate which, in some degrees, the three boilers on each side of the clarifiers are commonly hung to one fire.

The fire then from the receiver having filled the clarifier with fresh liquor, and the fire being lighted, the "temper," which is commonly Bristol white-lime in powder, is fired into it. One great intention of this is to neutralize the superabundant acid, to get proper rid of which, is the great difficulty in fugar-making. This is generally effected by the alkali or lime; part of which, at the same time, becomes the basis of the fugar. The quantity necessary for this purpose must, of course, vary with the quality of the lime used. On the lime butt of the cane boiler. Some planters allow a pint of Bristol lime to every hundred gallons of liquor; but this proportion is, Mr. Edwards believes, generally found too large. The lime is perceptible in the fugar, both to the smell and taste, and precipitates in the copper pans a black insoluble cacoa, which corrodes the bottom of the vessels, and is not detached without difficulty. Mr. Edwards is of opinion, therefore, that little more than half the quantity mentioned above is a better medium proportion; and, in order that lees of it may be precipitated to the bottom, an inconvenience attending the use of dry lime, Mr. Boulie's method of dissolving it in boiling water, previous to mixing it with the cane-juice, appears to him to be highly judicious. In some parts of Jamaica, where the cane-liquor was exceedingly rich, Mr. Boulie made very good fugar without a particle of temper. Too much temper is perceptible in the fugar, both to the smell and taste; it might be added, and also to the sight. It tingles the liquor first yellow, and, if in excess, turns it to a dark red. Too much temper likewise prevents the mellasses from separating from the fugar, when it is potted or put into the hoghead.

As the fire increases in force, and the liquor grows hot, a fcum is thrown up, which is formed of the mucilage or gummy matter of the cane, with some of the oil, and such impurities as the mucilage is capable of entailing. The heat is now suffered gradually to increase, until it rises to within a few degrees of the heat of boiling water. The liquor must by no means be suffered to boil; it is known to be sufficiently heated, when the fcum begins to rise into blisters, which break into white froth, and appear in general in about forty minutes. The damper is then applied, and the fire extinguished; after which, the liquor is suffered to remain a full hour, if circumstances will permit, undisturbed. During this interval, great part of the fecundities and impurities will attract each other, and rise in the fcum. The liquor is now carefully drawn off, either by a fision, which draws up a pure defected fream through the fcum, or by means of a cock at the bottom. In either case, the fcum sinks down unbroked as the liquor flows, its tenacity preventing any admixture. The liquor is received into a gutter or channel, which conveys it to the evaporating boiler, commonly called the "grand copper;" and, if originally produced from good and untainted canes, will now appear almost, if not perfectly, transparent. The merit of introducing into Jamaica the clarifiers at present in use with fisions and dampers, was claimed by Mr. Samuel Sainthill; and an exclusive patent, to secure his claim, was granted to him in 1778, by an act of the assembly.

The advantage of clarifying the liquor in this manner, instead of forcing an immediate ebullition, as practised formerly, is visible to the most inattentive observer. The labour which it saves in fscumming is wonderful. Neither can fscumming properly cleanse the subjekt; for when the liquor boils violently, the whole body of it circulates with such rapidity, as to carry down again the very impurities that had come up to the surface, and which with a less violent heat would have flated there.

In the grand or evaporating copper, which should be large enough to receive the net contents of one of the clarifiers, the liquor is suffered to boil; and as the fcum riseth, it is continually taken off by large fcummers, until the liquor grows finer and somewhat thicker. This labour is continued until, from the fscumming and evaporation, the subjekt is sufficiently reduced in quantity to be contained in the next or second copper, into which it is then laded. The liquor is now nearly of the colour of Madeira wine. In the second or second fcumming fscummers are continued; and if the subjekt is not so clean as is expected, lime-water is thrown into it. This addition is intended not merely to give more temper, but also to dilute the liquor, which sometimes thicken too fast to permit the fecundities to run together, and rise in the fcum. Liquor is said to have a good appearance in the second copper, when the froth in boiling arises in large bubbles, and is but little discoloured. When, from such fscumming and evaporation, the liquor is again sufficiently reduced to be contained in the third copper, it
SUGAR.

is laded into, and so on to the last copper, which is called the "teache," probably from the practice of trying by the touch. This arrangement supposes four boilers or copperns, exclusive of the three clarifiers.

In the teache the subject is still farther evaporated, till it is judged sufficiently boiled to be removed from the fire. This operation is usually called "striking," i.e., lading the liquor, now exceedingly thick, into the cooler.

The cooler, of which there are commonly six, is a shallow wooden vessel, about eleven inches deep, seven feet in length, and from five to six feet wide. A cooler of this size holds a hoghead of sugarc. Here the sugar grains; i.e., as it cools, it runs into a coarse irregular mass of imperfect semi-formed crystals, separating itself from the molasses. From the cooler it is carried to the curing-house, where the molasses drain from it. It may be proper in this place to observe, that, in order to obtain a large-grained sugarc, it must be suffered to cool slowly and gradually. If the coolers are too shallow, the grain is injured in a surpurring manner. Any person may be convinced of this, by pouring some of the hot syrup, when fit for striking, into a pewter plate; he will immediately find it will have a very small grain.

But, before we follow it into the curing-house, it may be proper to notice the rule for judging when the subject is sufficiently evaporated for "striking," or become fit for being laded from the teache to the cooler. Many of the negro boileurs guess solely by the eye, (which by long habit they do with great accuracy,) judging by the appearance of the grain on the back of the ladle; but the practice most in use is to judge by what is called the "touch," i.e., taking up with the thumb a small portion of the hot liquor from the ladle; and the heat diminishes, drawing with the forefinger the liquid into a thread. This thread will suddenly break, and shrink from the thumb to the suspended finger, in different lengths, according as the liquor is more or less boiled. The proper boiling height for strong mucovado sugarc is generally determined by a thread of a quarter of an inch long. It is evident, that certainty in this experiment can be attained only by long habit; and that no verbal precepts will furnish any degree of skill in a matter depending wholly on constant practice.

This method more certain and scientific was recommended some years ago, by John Proculeus Baker, esq., barrister at law, in the island of Jamaica, in a treatise published by him in 1775, entitled "An Essay on the Art of making Mucovado Sugar." It is as follows: "Provide a small thin pane of clear crown glass, set in a frame, which I would call a 'tryer;' on this drop two or three drops of the subject, one on the other, and carry your tryer out of the boiling-house into the air. Observe your subject, and more particularly whether it grains freely, and whether a small edge of melasses separates at the bottom. I am well satisfied that a little experience will enable you to judge what appearance the whole slip will put on, when cold, by this specimen, which is also cold. This method is used by chemists, to try evaporated solutions of all other salts; it may seem, therefore, somewhat strange, it has not been long adopted in the boiling-house."

The present improved systern of clarifying the cane-liquor, by means of vevels hung to separate fires, and provided with dampers to prevent ebullition, was first suggested, says Mr. Edwards, to Mr. Sainthill, (who three years afterwards claimed the merit of the invention,) by the practice in question.

The curing-house is a large airy building, provided with a capacious melasses cistern, the sides of which are sloped and lined with terras, or boards. Over this cistern is a frame of make joint-work, without boarding. On the joists of this frame, empty hogheads, without headings, are ranged. In the bottoms of these hogheads eight or ten holes are bored, through each of which the stalk of a plantain leaf is thrust, six or eight inches below the joists, and long enough to stand upright above the top of the hoghead. Into these hogheads the masts from the cooler is put, which is called "potting," and the melasses drain through the pongy stalk, and drop into the cistern, from whence it is occasionally taken for distillation. The sugarc, in about three weeks, grows tolerably dry and fair. It is then laid to be cured, and the process is finished. The curing-house should be close and warm, as warmth contributes to free the sugarc from the molasses.

Sugar, thus obtained, is called "mucovado," and is the raw material from which the British sugarc-bakers chiefly make their loaf, or refined lump. There is another fort, which was formerly much approved in Great Britain for domestic purposes, and was generally known by the name of Lisbon sugarc. It is fair, but of a soft texture, and in the West Indies is called "clayed sugarc." The process is conducted as follows: A quantity of sugarc is put into conical pots or pans, called by the French "formes," with the points downwards, having a hole about half an inch in diameter at the bottom, for the melasses to drain through, but which at first is closed with a plug. When the sugarc in these pots is cool, and become a fixed body, which is discoverable by the middle of the top falling in, (generally about twelve hours from the first potting of the hot sugarc,) the plug is taken out, and the pot placed over a large jar, intended to receive the syrup or molasses that drain from it. In this state it is left, as long as the melasses continue to drop, which it will do from twelve to twenty-four hours, when a stratum of clay is spread on the sugarc, and moistened with water, which oozing imperceptibly through the pores of the clay, unites intimately with, and dilutes the molasses; consequently more of it comes away than from sugarc cured in the hoghead, and the sugarc, of course, becomes too much the whiter and purer. The pots remain for twenty days in this situation, after which the sugarc is taken out, dried in the sun for some hours, and then taken to a large warm-room, where it is kept in a pretty airinglest for three weeks. The process, according to Sloane, was first discovered in Brazil, by accident. "A hen," says he, "having her feet dirty, going over a pot of sugarc, it was found under her tread to be whiter than elsewhere." The reason appointed for this process is not universally adopted in the British sugarc islands is this, that the water, which dilutes and carries away the melasses, dissolves and carries with it so much of the sugarc, that the difference in quality does not pay for the difference in quantity. The French planters probably think otherwise, upwards of four hundred of the plantations of St. Domingo having the necessary apparatus for claying, and actually carrying on the system. The loaf in weight by claying is about one-third; thus, a pot of 60 pounds is reduced to 40 pounds; but the melasses which are drawn off in this practice be reboiled, they will give nearly 40 per cent. of sugarc; so that the real loaf is little more than one-sixth; but the distillery, in that case, will suffer for want of the melasses; and, on the whole, Mr. Edwards believes that the usage of the English subscribers in shipping mucovado sugarc, and distilling the melasses, is more generally profitable than the system of claying.

The Cochinichine prepare a very excellent mollet sugarc, remarkably cheap, by a very simple process, similar to that of claying. The grained sugarc, after the gros syrup has drained from it, and it has become considerably solid, is placed
SUGAR.

placed in layers about an inch thick, under layers of the
tame dimensions of the herbaceous trunk of the plantain tree;
the watery juices, exuding from which, form like congealing,
and leave the sugar very white and porous, like a honey-
comb. This is puré enough to dissolve in water, without
any sediment.

F. Labat says several different kinds of sugars, pre-
pared in the Caribbees, viz. 
Crude sugar, or mufucado sugar;
strained, or brown sugar; earthen, or white sugar in powder;
refined sugar, either in powder or loaves; royal sugar; candi-
ded sugar; sugar of fine syrup; sugar of coarse syrup; sugar of
the gum.

SUGAR, Crude, or Mufucado, is that first drawn from
the juice of the cane; of which all the rest are composed. The
method of making it is that already described as for sugar
in the general.

SUGAR, Strained, or Brown, though somewhat whiter and
harder, does not differ much from the crude sugar; though
it is held a medium between this last and the earthen sugar
which is the white powder sugar.

The preparation of this is the same as that of the mufucado,
with this difference, that, to white it, they strain the
liquor through blankets, as it comes out of the first copper.
The invention of strained sugar is owing to the English, who
are more careful than their neighbours in the prepara-
tion of it: for they not only strain it, but, when boiled,
put it into square wooden forms, or moulds, of a pyramidal
figure; and when it has purified itself well, they cut it in
pieces, dry it in ovens, and barrel it up. See Refining of
SUGAR, infra.

SUGAR, Earthen, is that which is whitened by means of
earth laid on the top of the forms it is put in to purify itself.
See Refining of SUGAR.

SUGAR of the Scum. This is all made of the scum of the
two last copperers; those of the former being reserved for the
making of rum.

The scum defined to make sugar is kept in a vessel for
that purpose, and is boiled every morning in a copper set
apart for that use. With the scum, is put into the cooker
a fourth part of water, to retard the boiling, and give time
for its purifying; when it begins to boil, the usual ley is put
in, and it is carefully scummed; when almost enough boiled,
lime and alum-water are thrown in; and when it is ready
to be taken out, they sprinkle it with a little powdered
alum.

SUGAR of Syrup, or Treacle. There are three kinds of
syrups that run from sugar. The first, from the barrels of
raw sugar, which is the coarsest of all; the second, from the
forms, or moulds, after they are perforated, and before
they receive their earth; the third, that coming from the
forms after they have had their earth; which last is the
best.

The coarse syrups should only be used for rum, but sugar
being grown dear, endeavours have been used to make some
of them, and that with tolerable success. They are first
clarified with lime-water: and, when boiled, are put up in
barrels, with a sugar-cane in the middle, to make them purify
themselves. After twenty days, a quantity of coarse earth
is thrown in, to make them cast the remainder of their syrup,
and sit them to be returned into a crude sugar. The Dutch
and German refiners first taught the islanders how to turn
their syrups into sugar.

The second syrup is wrought somewhat differently: after
the copper it is to be boiled in is half full, eight or ten
quarters of lime-water are cast in; it is then boiled with a
brisk fire, and carefully scummed; some add a ley, and others
none. F. Labat takes the former method to be the better,
though it requires more trouble and attention. This sugar
may be earthed alone, or at least with the heads of loaves,
the dried tops, and such other kinds of sugars as may not
be mixed with the true earthed sugar, nor yet with the crude
sugar.

For the third syrup, after boiling and scumming it as the
former, they put it infantly into coolers, the bottoms of
which are covered half an inch thick with white sugar, very
dry and well pounded; and the whole is well stirred to incor-
porate the two together. This done, they throw the
syrup over with the same pound sugar, to the thickness
of one-fifth of an inch, this stiffening the sugar in forming its
grain. When setted, and the cruft gathered at the top, a
hole is made in the cruft five or six inches in diameter.

By this aperture they fill the cooler with a new syrup,
poured gently in, which insensibly raises up the former cruft.
When all the syrups are boiled, and the cooler is full, they
break all the crufts; and, after mixing them well, put them
up in forms or moulds.

The cruft is performed in the same manner as for the
earthen sugar, from which it only differs in that it falls short
of its gluts and brightenfs; being, in reality, sometimes
whiter and finer, though of a flatter and duller white. For
the use and management of the syrup of sugar, see Refining
of SUGAR.

SUGAR, Refined. Crude sugar, strained sugar, and the
heads or tops of loaves that have not whitened well, are the
bais, or ground, of this sugar. See Refining of SUGAR.

SUGAR, Royal. The bais of this sort ought to be the
purest refined sugar to be found. They melt with a
weak lime-water; and, sometimes, to make it the white, and
prevent the time from redining it, they add alum-water.

This they clarify three times, and pass as often through a
closet cloth, using the very best earth. When prepared with
these precautions it is whiter than snow, and so transparent,
that we see a finger touching it, even through the thickest
part of the loaf.

The curious in the whole art of sugar-making, or the
reducing vegetable juices to what we call sugar, by expres-
sion, decoction, clarification, graining, claying, and ery
Realization, will find farther accounts and directions, in the
several proclamations of this art, in Pocc'is Hill, in Anguilo's
Sala's Saccrologia; in Dr. Slate's Treatise on Sugars;
in Sir Hans Sloane's History of Jamaica; Baker's Essay,
above cited; and Edwards's History of the West Indies,
vol. ii. There are also several valuable papers in these sub-
jects in the Philosophical Transactions.

SUGAR, Refining of, is the art of purifying sugar, and of
giving it a superior degree of whitenefs and solidity. The
excellence of mufucado sugars, or such as have not been
refined by the planter, but are sent home in the most crude
state, conflifts in their whitenefs, dryness, or freeness, clean-
ness and sharpenfs, or strength. The judicious refiner de-
cides upon these several qualities by the eye, the touch, and
the taste.

The first operation in the process of refining is that of
clearing the pans; previously to which they are charged,
by throwing about six quarts of fresh bullock's blood (called
fpice) into each pan, and filling it with lime-water to about
half the height from the bottom to the part in which the
brace is fixed; and when these are well stirred together, the
pan is filled to the brim with raw sugar. This mass, with a
moderate fire, will in about two hours be brought to
the verge of boiling heat; but it should not be allowed
actually to boil; and in this time the earthy particles of the
sugar, and other adventitious impurities, will be separated
from it by the effect of the heat, and the cleansing quality
of
of the spice, and thrown to the surface. About two
quarts of spice are added to each pan, within the first hour
after the fires are lighted. The cumin thus produced, which
is usually from four to ten inches thick, is fit to be taken
off, when the surface appears black and dry, and not great;
and it is gently removed with a broad skimmer into a port-
able tub, and conveyed into the cumin-cistern. Having done
this, the panman stirs together a ladleful of spice (a gr.
about a quart), and a quantity of lime-water (a gr. one or
two gallons, as the case may require); and pours this mix-
ture into each pan. When the suger is again brought to a
falsing heat, it throws up a second cumin, not so foul as the
first, which is removed as before. He then adds a fresh
quantity of spice, but less than the former, and repeats this
operation, till the sugar casts up a clean milky froth, which
indicates that the impurity is wholly extracated. The suger
is also sometimes examined with a bright silver or metal
spoon, that any remaining fouleufs may be discovered. In
the making of double loaves, powder loaves, or very fine
single loaves, it is usual to heighten the natural colour of the
sugar by the addition of a little saffron, and to complete the
grain, and to complete the granulation. Upon this sugar.
operation much of the beauty and succefs of the manu-
facture depend; for if the sugars are not firred enough,
the grain of the refined sugare will be large and loose, and its
colour not sufficiently white; but if it be firred too much,
the grains will be broken, the sugre will be distributed in its
parts, and though close and smooth, without lustre; and it
will lose considerably of its due weight. When the third
skipping is boiled, and the coolers sufficiently fired, the
contents of the pans are removed to the coolers, as before;
and thus the first stage of refining for the day is completed.
The course of the other two firings is precisely the same.

The next operation in refining is conducted in that part
of the ground-floor of a sugare-house, which is denominated
the fill-house, because all the upper floors of the house are to
be filled from this; and this operation consists in filling the
moulds with the three skippings contained in the coolers.
The moulds, in the form of inverted cones, previously pre-
cared by coating and anointing them, and stopping their
apertures with wet linen rags, are placed side by side, and
in twos or three deep: their number is to suffice for the
quantity of liquar in the coolers, which is estimated by the
number of bafons which were skippag from the pans;
and they are propped up by other moulds (commonly such
as are broken) placed with the broad end downwards, in
front of the outward rank, by way of abatement: these are
called flagers. The sugar, being previously firred in the
coolers, in order thoroughly to mix each skippag, is ladled
out of the coolers in succession, and not all at once, (unless
the fillings are small, in loaves, and always in lumps,) into
bafons conveniently situated; and these are carried into the
fill-house, where as much of the sugar is poured into each
mould as will fill about one-third of its capacity; the same
quantity is again poured into each; and at the third time
they are filled to the brim.

The moulds being filled, the next operation, which is that
of filling the sugar in them, is cauled boaling, and is de-
signed to prevent an adhesion to the mould, and to lay the
grain of the mafs even and regular through all its parts.
In this business each man takes a tool, made of waincoat,
and called a knife, and in size proportioned to that of the mould
to be filled; with this tool, keeping his hand over the centre
of the mould, he farses the sugar from its sides by succes-
sive five strokes downwards, carried all round; and when two
revolutions are performed, the sugar is allowed to rest some
minutes, until it has acquired some firmness. The moulds,
SUGAR.

being fluffed round these or three or four times, according to the direction of the boiler, are no more disturbed till they are pulled up.

The proces already described relates to sugar once refined, called single loaves: double loaves are usually cleared with the whites of eggs instead of spices, (two hundred of which are necessary to each pan,) and with fresh water instead of lime-water. With respect to the proof, one rule only can be laid down; viz. the sugar must be boiled higher as the moulds which contain it are increased in size.

The order of refining is uniformly this: to begin the first day with the finest sugar intended to be wrought, and to proceed daily with sugar of a lower quality, and of course to begin with small loaf-moulds, and to use larger moulds progressively; so that the brownish sugar will be put into large lump-moulds; for this sugar works best in large masses, and it is likewise more in demand in England than the finer kind. The use of this distribution of a refining is to enable the boiler to make a more advantageous disposition of his syrups and scums. The order of the first twelve days is usually as follows: first day, double loaves; second and third days, powder loaves; fourth, fifth, and sixth, single loaves; seventh, Prussian lumps; eighth, Canary, or pattern lumps; ninth, tenth, eleventh, and twelfth days, large lumps. To these twelve days are added four or five more, in a part of the process called bafiard-boiling; and these fifteen or seventeen days constitute a complete series, denominated a complement, or refining.

From this digestion let us now return to the fill-houfe; where the second and third fillings having been boiled off, and passed from the coolers into the moulds, in the manner already described, the panman proceeds to make over the scum which was taken off the pans in the morning, in order to extract the remaining sugar from it; the method of doing this will be hereafter explained. When it is finished, the pans are loaded for the work of the following day. In the evening, when the new-made goods are cool, and fit for removal, without damage, they are pulled up into that floor of the house which is best suited for receiving them, and where a proper number of well-fortified pots are placed in ranks for this purpose. The up-stairs man plucks out from the point of every one the flopper or rag; and pricks them in the point with an awl, the size of which is proportioned to the mould; and they are then set upon the pots.

The contents of the moulds, cleared by the preceding operations of their earthy particles and water, comfit of the vegetable salt, and an oily matter, now called syrup, but which, after the final extraction of the fats, will be called molasses. For the separation of these there is required a series of operations, which may be distinguished by the name of filtering, or draining. In twenty-four hours after the loaves have been placed upon the pots, the quantity of syrup which will have exuded from the aperture of each, will fill more than half of the pot on which it stands. When the state of the loaves has been examined, by drawing one or two loaves of each filling out of their moulds, if the syrups are not in a digesting state, they are left unclayed for two or three days longer, and the warmth of the room in which they stand is somewhat increased; but if they manifest a proper appearance, they are prepared for receiving the first clay, which is laid on either the next or the third day.

The green new-made loaves are judged to bear a healthy and promising appearance, when the syrups have quitted the broad part of the loaf, and are evenly drawn together; and when the whole surface has a compact and smooth appearance, they are fit to receive clay. When the syrup hath scarcely descended from the top or face of the cone; when the head, i.e. the narrow and moist end, is not evenly drawn off to a line; it is concluded that the sugar is over-boiled, or of an ill quality; the syrups are not in a state of digestion, and time is given, and heat added, to make them fit to receive the clay. On the other hand, if the moisture is shrunk and settled, and of a pale colour just round the apex of the cone, there is reason to apprehend that the sugar is under-boiled, or too free; in which case the surface or coat will appear loofe, and want that smoothness which the well-boiled loaves exhibit. When this is the case, they must be lightly clayed, and care must be taken that the clay be not too thin or wet. Before the clay is laid on, the thin crust, which had been formed round the edge of the mould by the motion of the hauling knife, is scraped from each loaf into the receiving box, and by preffing the face of the loaf with that part of the hand which is nearest the wrift, a small concavity is made for receiving the first clay, as well as a proper solidity to the bed on which it is intended to rest.

The first or green syrup is now taken away, and poured into large earthen jars, called gathering-pots; and the empty pots are returned to receive the moulds which had been taken from them. When they are returned to their proper places, a small ladleful of wet clay is poured on the face of each loaf. This first or green clay dries up in five or six days, and forms a cake, which is taken off, and laid by for future use. When the clay is removed, the whole surface of the loaf will be found to have shrunk under it, and the loaf is become concave in the middle. With a tool, called a bottoming-trowel, the sugar which adheres to the sides of the mould is cut away by a horizontal movement: and a small quantity of scrapings, or of lumps broken down for this purpose, is added to the loose sugar which the trowel had cut; and they are piled down together on the surface, till the whole has been brought to a good level, and to a moderate degree of firmness for bearing the next clay.

On the following day the loaves are clayed a second time; and when this clay is dry, it is removed, like the former, and each loaf is drawn out of its mould, and carefully examined; and this part of the process is called overseeing. Double loaves, fine powder loaves, and fine single loaves, will sometimes, under this clay, be found neat, i.e. the redness or brownness will have quitted the loaf, and the head, though still moist, will appear perfectly free from discoloration. The workman, however, in order to be farther satisfied, cuts off the heads of two or three loaves with the trowel; and if he is satisfied, these loaves are to be clayed no more; but he proceeds to the operation of bruising-off, i.e. of scraping off the irregularities and impurities occasioned by the contact with the clay with an iron tool, called a bruising-book; and with one corner of this a number or letter is scratched upon the level face of the loaf. To those loaves which are not found neat, the workman gives a second clay; which is usually laid on in a thinner mass than the former. If his loaves are not yet quite finished, he puts a little fresh moisture on the back of the overseen clay, and thus effects his purpose.

The loaves being now rendered neat, and bruised off, must stand some days in the moulds to acquire face, or that spongy hardness of surface, which will enable them to stand firm, when they are turned down out of the moulds; and during this time they are once or twice loofed in the moulds by a gentle blow on a floor, or against a post; and thus the coats are improved by preventing adhesion to the moulds, and facilitating the precipitation of the remaining moisture. The windows
SUGAR.

windows are opened to let air in, if the weather be dry; and the points or noes are also examined, which will sometimes melt away, whilst the above operation is effecting. When these symptoms appear, the workman proceeds to turn down his loaves, by taking the moulds from the pots, covering the floor with clear brown paper, and turning each loaf down with its mould over it. They are usually turned down either upon the floor-head, or in some warm place, because by being left uncovered, and exposed to the air, the growth of moulds, the moisture remaining in the head will not descend into the body of the loaf, and be equally dispersed; but remaining in the head, would spoil and disfigure the loaf; partly by the syrup coagulating, and becoming unfit to descend between the fine interstices of the concrete body, and partly from the attrition of the solid particles. With these precautions, in twenty-four hours the moisture is apparently dispersed, and the cone aifies throughout an uniform appearance. The loaves are then taken off the floor, separately examined, and cleared of any discoloured spots with a small knife; and are either papered and set in the floor, or else are placed in the floor without paper, as the case may require. If any of them have still a remaining yellowness in the head, the point is cut off, and they are then called foot-loaves. They remain in the floor five, six, or seven days, till they are entirely dry, and are then fit for sale and use. The management above specified in the course of this one day's work is nearly the same, whether the fugar be fine or coarse.

Brown sugars, wrought in large moulds, require more clay than fine sugars in small moulds; nor is it necessary that lumps should be made neat; but it is the custom practice to cut off the wet head from every lump, so as to leave no remaining redens; these wet tips, called lump-headings, are received into a large mould, and placed upon a pot to drain, and when dry, are melted for making double loaves, or for improving powder loaves; or else they are bruised and mixed with brushings to bottom-up, i.e. to defend the face of loaves, or other goods, before they receive clay. Large lumps frequently need claying four times. And it may be observed in general, that sugars of every kind require more heat to bring them forward, as they sink in quality.

The materials for double-loaf boiling are made from refined sugar, and frequently from loaves or lumps bought for that purpose. But those who are most curious in this fabric, chuse to make lumps for this purpose, which are called melters: they are low boiled, and fired but little (though some boilers fir them much), in order to preserve the strength of the fugar unimpaired. Fine double loaves are kept in a room of the temperature of a common parlour; a little warmth is sufficient for powder loaves, and fine single loaves; inferior loaves, and lumps of a middling quality, require warmth; but the browneft lumps and boitards thrive in a glowing heat. Every fort of refined sugar will bear and require more heat in proportion as it is higher boiled; for the brown fyrup matter will not quit the denier, unless it be kept in a fluid state; and this can only be effectcd by the action of heat; and, moreover, the fluid parts of high-boiled goods must be more viscous than those of goods which have been left bound up by fire.

The fyrups, which are discharged from refined sugar during the operation of draining, exceed in bulk and weight the whole quantity of loaf or lump fugar, and are, therefore, of great importance in this manufactury; and upon the proper management of them much of its success depends. It will be proper, therefore, to pursue the enquiry relating to the use of fyrups, produced from a day’s work of fugar once refined in loaves. When the loaves are prepared to receive the first clay, the syrup is collected into gathering-pots, each of which contains from 50 to 60 pounds of fyrup; this is called green fyrup, on account of the new or green state of the loaves from which it runs; and the quantity of it is usually about 15 gathering-pots from each pan of goods. The next fyrup, called second runnings, is commonly collected when the second clay is removed, and amounts in quantity to about eight gathering-pots per pan. The third and last of the loaves, when the moulds are finally removed from the pots; it is called drippings, and is about five gathering-pots per pan. However, some workmen collect their fyrups oftener than thrice. The fyrups of every kind of refined fugar increase in fineness and value, the later they exude from the moulds. As for the appropriation of them, the green or low fyrups are boiled away on the days next after the conclusion of refining; they are taken into the pans without the addition of any fugar, and after a sufficient evaporation are poured into large moulds; and under the name of boitard fyrup, form a principal article in the fugar-trade. The finer fyrups are all incorporated with fugar, and a proportion of them is daily brought down through the fyrup-pipes into the ciltern, at the same time in which the fugar is first skimmed from the pans; the fyrup-pipe discharging its contents into the clarifying basket, so that the fyrup, as well as the fugar, falls through the blanket; and it is pumped back from the ciltern into the pans.

The following estimates exhibit the quantity of fyrup that may be allowed (ceteris paribus) to a given quantity of fugar, viz. for double loaves, six gathering-pots per pan; for powder loaves, 10 ditto; for fine single loaves, 15 ditto; for middling loaves, 20 ditto; for brown single loaves, and Canary lumps, 25 ditto; for lumps, 30 or 40 ditto.

With the necessary allowances for particular circumstances, the several sorts of fyrups may be duly appropriated in the following manner. Green fyrups of every kind may be mixed with raw fugar, or applied to the making of goods, two degrees in quality lower than those from which these fyrups were produced. Second runnings of every kind are fit to be incorporated with goods one degree below those from which they were produced. Drippings may be used with raw fugar, or with other proper materials, in making the same kind of goods from which they had been supplied. In other words, the green fyrup of double loaves would be used in making single loaves; the second runnings would go into the composition of powder loaves; and the drippings would enter into the subflance of other double loaves. Again, the green fyrup of large lumps would be boiled off in boitards; the second running would make pieces; and the dripping, added to proper fugar, would be united therewith in the production of other lumps.

Pieces are a better kind of baifard, which are either boiled from fyrups that are too good to make baifards, or are made of such fyrups, and a small portion of cheap and bad fugar, which is too poor to make lumps. In the latter case, they are called fugar-pieces; but in either, all the fyrup that comes from them is boiled again, either to make baifards or other pieces, according to its goodnec; whereas the fyrup that runs from baifards is always considered as a caput mortuum, and no efforts are made to obtain any fugar from it, but it is put into calks, and sold under the denomination of melaffes. It is, therefore, worth the boiler's attention to keep all the weight of fugar possible in his baifards; and for this purpose he boils them as high as he may venture, without incurring the danger of making flopped baifards, i.e. baifards from which the melaffa will
SUGAR.

will not run; which may be owing either to the ill quality of the materials, or to overboiling. But as the syrup of pieces is to be boiled again, a good workman never exhausts it by overboiling. The materials of which bahards and pieces are composed, not abounding with fats like those already treated of, have not an equal disposition to concretion; and, therefore, it is found necessary to give them some aid, in order to effect the necessary granulation; this is done by taking grain (which we shall presently explain) into the coolers. These inferior productions are stirred, neither in the coolers nor in the moulds, any more than by a small movement round the coolers, with an iron scraper, just sufficient to incorporate the grain with the hot fluid mass.

In order to illustrate the formation of this grain, we may observe, that the strong particles of sugar, which are capable of concretion, have evidently a greater degree of density than the oily or aequous. When the hot fluid is poured into a bahard or piece mould, these denser particles descend, and would pass into the pots if there were any passage for them; but the flopper is not taken out of the moulds of these goods until five, six, seven, or eight days after they have been pulled up; for they want time to harden, and cannot safely be left unstopped. Having reached the lower part of the mould, they are formed into small very fine frustums of the nature of candy, and when the floppers are withdrawn, these small thines remain near the point of the mould, and are properly called *bathard* or *piece*, as already explained.

Bahards and pieces are usually clayed but twice, and when dry enough, are knocked out of the moulds, their wet heads being cut off into a large mould placed to receive them, and they are called *bathard-boading* or *smear*; in another mould is preserved the grain, which usually forms a stratum about two inches broad, beginning about four inches from the point of the mould. The bahards and pieces are then put into the store, and in five, six, or seven days, will be found dry enough; for they must not, like lumps and loaves, be rendered perfectly dry. They are then taken out and piled in a room, as near as may be possible, and ground all together; or the brown tip is cut off, and the other two parts, called the middle and face, are ground together: or sometimes the bahard or piece is divided into three parts, which are ground separately, and sold at different prices.

We shall now close this article with a short account of the method of making over *scums*, and the application of their produce. The refineextracts from the scum of his sugar, every particle of sugar which it is in his power to obtain; and after he has reduced the scum to such a rate that it appears to be a mere earth, resembling garden mould, he sells it to a scum-boiler, who again tries it over the fire, and extracts a small quantity of sweet liquor out of it.

The scum of fine treble or double loaves is often put into the pans again without any procès, and mixed with raw sugar, for the production of inferior goods: but, in general, the scum of each day's work is made over in the same day after the boiling of the sugar is finished. The method is this; the panman, having put about three quarts of spicce into his pan, draws lime-water until the pan be four-fifths full without the pan-brace; to this he adds about four tubs of the scum, each tub containing about three-fourths of a hundred-weight. Having flurred the liquor well, he makes a moderate fire, and the scum will separate from the fluid and float upon the top of it; with a small iron scraper he prevents any foulness from adhering to the bottom of the pans; and then suffers the fire to increase, and the liquid, upon the verge of boiling, is seen through the openings of the dirty surface. Having kept it simmering for several hours, and having provided a cooler or receiver, over which is placed a strong wooden frame, and upon this a balket, to which a coarse bag, called the *fum-bag*, is fitted, he pours the contents of his pan into this balket and bag; and then the mouth of the bag is drawn up, and well twisted together, and a strong board, called a *fum-board*, is laid upon the bags, with several weights upon the board, to press down the fum. In the space of an hour, or an hour and a half, the bag should be twisted and prefixed; and the liquor, which oozes plentifully through the bag, is usually taken into the pans the next morning: its thinnes renders it useful in clearing the pans, and if any groat matter hath passed through the bags, it is drawn off with the rest of the scum of the fugar when cleared. The fum, as it is taken from the pan, is called *fum*, and the liquid matter drawn from it bears the same appellation; in contradistinction to the poor meagre liquor which is exprized from the same fum when they are made over a second time, by an operation much like the former. After prefilling and draining, the exhausted remains, under the name of *rubish fum*, are either burnt in the cockell, or delivered to the scum-boiler at a very low rate. The produce of over-made scums must be used immediately, or it must be shortened, *i.e.*, boiled thick; otherwise it will turn four and do great harm; for acidity is a confant enemy and destroyer of sugar.

The liquor drawn from these scums is commonly used in bathard boailing, or in the brownet lumps. There is a large proportion of the fat fum usually left of every refining, to be made over during the bathard boailing; it is common to let by the first or grossest fum for this purpose, and to keep separate the finer and later scums, which are made over day by day in the manner already described: the liquor thus obtained from the fat scums, being full of sugar, is very useful to the bathards, fortifying the syrups, and promoting their strength and adhesion. The editor is indebted for the materials which have supplied this article, and those on the manufacture of sugar-candy, and the construction of a sugar-boufe, to the kind communication of Mr. Griffin, an eminent sugar-refiner in London.

Of the improvements that have been made in the processes for refining of sugar, we shall give an account according to the order of time in which the patents were granted. In October 1812, Edward Charles Howard, esq. of Welfbourn Green, in the county of Middlesex, obtained a patent, the specification of which informs us, that he has established and adopted the following operations. In the first instance, he submits raw or muscovado sugar to a primary operation, by well mixing, as expeditiously as possible, the laied sugar with such a quantity of water as will, at the common temperature of the atmosphere, bring it to a magma of the confluence of well-worked mortar: having left it at rest for the space of an hour or more, he heats it to a moderate temperature, *e.g.* from 190° to 200° Fahr., which is most conveniently effected in a vessel surrounded by boiling-water or steam, under the common pressure of the atmosphere; he then adds more sugar, or a thicker magma, to make up the mass and to fill it with the water-bath; and when it is become cold in the moulds, he takes the flopper out of the mould, and suffers the melleas to drain from it. When the drain-
SUGAR.

cold water, till the magma acquires a consistency, which will not allow it to readily cloe behind the fixar; and then replaces it, in that condition, upon the uniform and firm surface before prepared; and as soon as the magma becomes moderately dry, he pours upon it, with the intervention of a float or similar guard, a cold saturated solution of fine sugar in cold water, about half an inch deep; or, he takes off the said magma down to the surface of the lump, loaf, or mafs, left after the first paring, and remixes the fame with water to a thinner consistency than last-mentioned, and again replaces it as aforesaid; and he repeats the said operations by this magma, or with a cold saturated solution of finer sugar than that which he intends to refine, to the increased purity and quality. He farther declares, that when the sugar proves extremely cloe-grained, and the surface extremely hard, an unsaturated solution of sugar, or even water itself, may be poured on it, without running in; but this process requires too much nicety for general practice. When the sugar proves open-grained, the finer the sugar, the better, because the moisture thereon is thereby prevented from descending too fast or unequally into the loaf. It is not necessary, that the sugar taken from the surface of the loaf should be used as magma or syrup upon it.

The fit time for terminating this primary operation is ascertained either by drawing from time to time one of the lumps, loaves, or mafs so prepared, or by observing the greater or less freedom with which a new moisture is admitted, and the colour of the mafles dripping out. It is farther declared, that it is most beneficial in conducting this process, to leave the temperature of the place or apartment in which the mafles are placed, previously to their being crested with the magma, to about 60°, and again to raise the same to about 75° wherewith the surface of the loaf becomes dry for the last time. It will be necessary, in every case of the percolation of mafles or syrup, to pierce, perforate, or break the dry surface of the mafs of sugar in the mafles, when it is become so solid or iced over as to prevent the access or escape of the air into or out of the sugar, and thus to impede or prevent the flow of the mafles or syrup.

This primary operation being finished, the operator does in the usual manner break or draw out the lumps, loaves, or mafs, and separate the neat or good sugar from that which retains mafles, referring the latter to be mixed up with raw sugar, for a subsequent preparatory operation, such as has been already described. The former is then refined by pouring upon it, in any convenient vessel, 6 lbs. of water (boiling-hot) to every 5 lbs. of sugar, deducting about 6 per cent. for the moisture previously contained in it; and having infused a perfect diffusion of the sugar, by farring, the impurities are allowed to subside, and then the solution is drawn off from the said impurities into another clean suitable vessel; and in order farther to clarify and separate impurities and colouring matters, the ordinary finings are added. These finings are prepared by making well-burned lime with boiling water, so as to obtain a cream of lime; to this is added about an equal bulk of water, and the mixture is boiled for some minutes, until the lime assumes the appearance of fine curd; the extraneous matters or lumps, always contained in lime, are separated by washing over, or, as the chemists term it, by the procès of elucion; and that this may be done effectually, the lime and liquor so washed over, are made to pass through a fine anneal sieve as will admit the passage of the finest curds. The next part of this process is to diffuse about 24 lbs. of alum for every cwt. of solid sugar that is to be refined in about 16 times its weight of water, and to add to this solution about 70 or 80 grains of whiting for each pound of alum; and after farring up the mixture till the effervescence ceases, the suspended finitures are allowed to subside, and the solution is drawn off from the precipitated matters, and then are put into it the prepared lime-curds, shook up with the water they retain (the whole being agitated during the effusion) in such quantity of the curds, so that paper stained with turmeric shall barely change its colour by immersion in the mixture, and shall recover its former yellowness when dry, and shall, by immersion in the clear supernatant liquor, after subduction, be scarcely changed at all. The finings, thus duly prepared, are suffered to settle to the bottom of the containing vessel; and after draining off the supernatant liquor, the said finings are placed upon blankets, supported in the manner of a filter, and the moisture is drained off till the mafs begins to contract, and separate by cracks in it; and in this last state the said finings are fit for the clarification of the sugar last drawn off, as above described.

Such a quantity of that solution, or of any other similar solution of sugar, is added by degrees, and with farring, as will bring them to an uniform creamy state. This mixture is then poured into the whole quantity of the said solution of sugar prepared or intended for clarification as aforesaid, with sufficient agitation for diffusing the finings equally.

The refined or clarified sugar is then suffered to remain, either during the night, or for about six hours, and the bright liquor drawn off from the finings, in the usual methods; and an evaporation is commenced and carried on at the temperature of about 200°, which is best effected by the heat of flame, or water under the common pressure of the atmosphere, until the hot liquor shall have acquired a specific gravity of about 1.37 (tan. of water being 1.00); and in this state the same is transferred to any convenient vessel, and thinted frequently, until it assume the proper granular consistence to fill the moulds, and accordingly the moulds are filled with it. The fillers are then taken out from the moulds as soon as they become cold, and the syrup naturally contained in the lump, loaf, or mafs, is allowed to run off from it in the usual manner: during the farring operation, and when the farring has left the upper surface of the lump, loaf, or mafs, the farrings is pared down, before described; and if the farring appear sufficiently fine, then, in the intermediate consumption, or market, it is taken out of the mould, after it ceases to drip, in the usual manner, the smaller end of the loaf not clear of syrup being cut off; and it is then dried in the ordinary mode. But if the lump or loaf be not sufficiently white, the farring before pared off the surface is mixed up to a magma with water, as in the primary operation. If the loaf, as above prepared, be not sufficiently dense or cloe in its grain to satisfy the consumer, the loaf, previously to drying, is remoulded, according to the usual practice, by flamping the grains into a metallic or other mould, which will immediately redivide the farring. If it be required to retain the point of the lump, loaf, or mafs, without returning the syrup contained in that point upon its body, this derivatatum is effected by the appendage of a pipe, applied and fixed to moulds of the usual construction, having the aperture enlarged to one inch at the leaf, or to form part of a new mould, which is to be fabricated on purpose; then the lower portion of the farring is taken off, which will be contained in the said pipe, along with the redundant syrup, instead of taking off the point as usual.

To the first of the liquors left in the two great or other vessels which contain the insoluble impurities, is added about its bulk of boiling water, and it is then passed through a cloth
SUGAR.

a cloth sufficiently close in its texture for retaining the gross impurities; and the second liquor, containing the above-described finings, is added, abstracting from them, by washing and subduing, all the sweet they contain; which sweet liquor is used for magma. The syrups, which drain from the magma which have been subjected to the action of finings, may be evaporated without any addition, provided the boiling temperature be avoided by means of the flame or water-bath above-mentioned; and such syrups will, by such treatment, afford strong crystals a second, third, or even fourth time. Or, otherwise, sugar remaining from top-parings, cut-off points, or any other remnants, may be melted in them, upon the water-bath, to bring the flame up to their crystallizing densitv or granular consistence; and the inferior syrups may be advantageously mixed with mucovado sugar instead of water, in the manner stated in the account of the primary operation.

The lumps, loaves, or maffes of sugar which have been refined by the use of the ordinary or common finings, or any other sugars in a forward state of refinement, may be further refined by the application of further finings, prepared in the following manner: by diffusing about three pounds and a half of alum for every hundred weight of solid sugar, in about sixteen times its weight of boiling-hot water, and adding to such solution about seventy or eighty grains of whiting for each pound of alum; and after stirring up such mixture till the effervescence ceases, allowing the suspended substanaces to subside, and drawing off the solution, pouring into it (instead of the lime-curls in the ordinary finings) a concentrated solution or ley of caustic soda, until the agitated mixture shall produce a very slight film upon turmeric paper; and then adding to it the fairest water, wafching the precipitate by alternate diffusing of any-bulk charcoal, &c. and afterwards reduced into smaller pieces or powder. 3dly. Bituminous earths, commonly called coals, either in the state in which they are mined, or articles of their products after fusion, and reduced, as before-mentioned. 3dly. Certain argillaceous earths, known by the name of ochres. 4thly. The vegetable charcoal, usually called lamp-black. The first-mentioned articles, however, are preferred in the processes of refining and clarifying sugar; which renders the sugar so clarified much whiter than by the heretofore common methods of clarifying sugar. The following is the most convenient process of refining sugar, from which one of the above-mentioned finings is preferred. We charge, say the patentees, or fill our boilers or pans with sugar and water, or lime-water, as in the common and well-known methods of refining sugar, only sometimes preferring to add a little more water or lime-water than in the common mode of refining, as it generally more easily and effectually separates the animal charcoal, or other substanaces, from the liquid sugar. And we also add to the above sugar and water in the boiler the substanaces before-mentioned, in any quantity, according to the quality of the sugar to be refined or clarified; though we generally prefer from two to five pounds of charcoal or earths before-mentioned, to and for every hundred weight of sugar to be refined or clarified. And, farther, we pour into the boiler the usual finings of eggs, blood, or other albuminous matter, in rather larger quantities than in the usual mode of refining, in order, in some degree, to coagulate and combine the animal charcoal, or other substanaces, with the dirt contained in the sugar. We now well stir up and agitate the liquor in the boiler, in order that the animal charcoal, and other substanaces, may have the greater effect in blanching the liquor. And after the coagulated albumen has completely risen in the form of scum by the application of heat, in the usual way, we either skim it off, as in the common processes, or we pour the whole of the liquid sugar and scum into and upon the
the usual or any other known filter, when this clarified liquor is completely separated from the albuminous matter, as well as from the animal charcoal, or other substances employed; taking care to return back into the filter the first runnings of the said liquor, if not quite separated from the above substance used. And, further, we proceed in the usual manner to evaporate, granulate, and refine the said refined sugar. And further, we boil over and filter our liquor in the usual manner. We further declare, that the sugar so clarified and refined is preferable to sugar refined in the heretofore common mode, inasmuch as it is purer and whiter. And we further declare, that the syrups obtained by these processes have not that tendency to ferment which the syrups have which are produced in the heretofore usual method.

A patent, dated June 29th, 1815, was granted to John Taylor of Stratford, in the county of Essex, manufacturing chemist, for a method or methods of purifying and refining sugar. The patentee, in his specification, declares that his invention is applicable to the purification and improvement of raw sugars, if employed in the original manufacture in the West Indies; or that the said raw sugars, as now commonly imported into this country, may thereby be improved in quality here, so as to render the subsequent operations of refining less complex and expensive than when raw sugar not so purified is employed. The patentee states the nature of his invention to be as follows: "I have found that the melasses and other soluble impurities contained in raw sugar may be separated therefrom by mechanical means, without the use of heat; and that, by abstraining these from the raw sugars, the injury caused by their mixture with the refined sugar in crystallization is avoided. For purifying raw sugar according to my invention, it must first be brought to a moist state; and if the process be employed in the original manufacture in the West Indies, the degree of moisture at which the sugar will be upon draining a short time after it is taken from the coolers in which it is crystallized, will be sufficient. But if my said invention be practiced in this country on sugars as dry as they are usually imported, they will require to be mixed with a certain proportion of cold water, or lime-water. This proportion may be varied according to the opinion of the operator and the quality of the sugar, and will readily be determined by trial, as no exact rule can be laid down for each case;—in general, the proportion of water may be from one-eighth to one-tenth of the weight of the sugar. The sugar and water are to be well mixed in any proper vessel, and the whole is then to be subjected to preasure, carried to such a degree as to express all the fluid part therefrom, which will be found to contain the melasses and soluble impurities, and a certain quantity of sugar in solution; and the sugar, if the preasure be sufficient, will be rendered dry, and much improved in colour and appearance.

"I further declare, that though my invention may be carried into effect in a variety of ways, by using preasses of various construction, and by exposing the sugar to preasure in a variety of modes, yet that the following operation is the one which by preference I adopt. After the sugar has been mixed with water, or otherwise moistened, I inclose it in strong linen or woollen cloths, each of which is cut about thirty inches square, and being laid over a wooden box twelve inches square and two inches deep, some of the moistened sugar may be pressed in, and the cloth folded round it so as to form a square cake. A press is to be constructed with a platform, capable of containing at least four piles of these cakes, which may be arranged so as to stand at a certain height, and may then receive a degree of preasure, which will cause the fluid part to flow out, and which is to be received in a copper pan, fixed upon the platform of the press, and furnished with a spout, to convey the expressed syrup into a receiving vessel. While these cakes are preassing, another set is to be got ready, and the first having been hardened with preasure, may be adjusted so as to keep the piles upright, and the fresh cakes let upon them, and so exposed to preasure. In this way a considerable quantity of sugar may be got into a press, and, after having been moderately hardened, the whole should be taken down, and again set up, and exposed to a higher degree of preasure, which will render the whole dry, and of uniform good colour and appearance.

"I further declare, that any machine or apparatus is capable of applying preasure to sugar, either vertically or horizontally, and whether the sugar be inclosed in cloths, as I have described, or in bags, or in cases, frames of wood, metal, or other materials, may be used for the purpose of my invention; but that I prefer the mode I have herein pointed out; and that I have found the hydrostatic presses, and commonly known by the name of Bramah's presses, most convenient for the purpose.

"And I further declare, that the sugar prepared and purified in the way I have described is much improved, and may be refined into lump-sugar by any of the processes for that purpose, and with less expense and trouble, and in less time, than is required for raw sugar not so purified. And further, that if my said invention be applied to the original manufacture of sugar in the West Indies, the sugar so prepared will be fit for immediate shipment, as all the time required for draining and drying will be saved, and all danger of fermentation prevented.

"And I do further declare, that the sugar contained in the expressed syrups may be obtained therefrom by the usual processes of evaporation, and from its not being injured by the usual application of heat, is capable of being made into an inferior sort of refined sugar."

Sugar. Barley, Saccharum borde tum, is a sugar boiled till it be brittle, and then cast on a stone anointed with oil of sweet almonds, and formed into twisted sticks, about the length of the hand, and the thickness of a finger. It should be boiled up with a decoction of barley, whence it takes its name; but, in lieu of it, they now generally use common water, to make the sugar the finer. To give it the brighter amber colour, they sometimes cast sugar from it. It is found very good for the cure of colds and rheums.

Sugar-Candy, Saccharum candum, or Crystallinum, is sugar depurated and crystallized, and differs from common sugar in being much harder and transparent. See CANDY. The sugar to be used in this process is first diffused in a weak lime-water, then clarified, scummed, strained through a cloth, and boiled, and put in forms or moulds, that are traversed with little rods, to retain the sugar as it crystallizes. These forms are suspended in a hot floe, with a pot underneath, to receive the syrup that drops out at the hole in the bottom, which is half-stopped, that the filtration may be the gentler. When the forms are full, the floe is shut up, and the fire made very vehement.

Upon this, the sugar fastens to the sticks that cross the forms, and there hangs in little splinters of crystal. When the sugar is quite dry, the forms are broken, and the sugar is taken out candied. Red sugar-candy they make, by casting into the vessel, where the sugar is boiling, a little juice of the Indian fig; and if it is desired to have it perfumed, they cast a drop of some essence in, when the sugar is putting into the forms.

Vol. XXXIV.
SUGAR.

This method of making sugar-candy is that of F. Labat, practiced in the Caribbees.

The method among our manufacturers is as follows. A fove is set apart for this purpose; the entrance into which is in the ground-floor, and as near as possible to the pans; and the top is usually from ten to fourteen feet above the ground, and covered like the top or crown of an oven. Beams are fastened into the walls, at the distance of about twenty-six inches from each other, and sufficient to bear a large weight; upon which strong planks are laid when they are wanted, and upon the planks the candy-pots are set; when the fove of candy is finished, the planks are removed. The pots are usually made of thin copper, without feet, and with an iron rim round the top, to strengthen them; the bottoms are hammered into the mof perfec flatlets, that they may stand firm and steady: they are perforated in rows on two sides with holes about one-tenth of an inch in diameter. According to the old method of piercing, the holes were very close laterally, and the candy of each firing united with that of the next, and the whole formed a strong cake; but according to the improved method, the holes are kept at a proper distance apart, i.e. at the distance of one inch and a half in the upper rows, and widening downwards to two inches; and the candy is formed in different bars, more convenient for package and sale, and much more beautiful than the former.

When a fove of candy is intended to be made, the cockell should be moderately heated, at least twenty-four hours before the operation begins; and the candy-pots are filled. i.e. a coarse white thread is drawn by a needle through the first hole of the bottom row, and the end being fastened there, the thread is led across the infide of the pot to the opposite hole, and continued from side to side, till that row is finished; the next row above it is then filled in the same manner, &c. till every row is finished. The pots, being all filled (viz., about forty to each pan of sugar), must be pasted, i.e. the holes must be stopped either by pasting papers over them on the outside, or by brushing any glutinous matter over the outside. When the foves and pots are ready, the workman places five pots upon the pavement, beginning either at the right or the left-hand corner of the fove opposite to the cockell.

The management of the pans is nearly the same as has been described under Refining of Sugar, with some small differences. The fugar intended for candy should be cleared with lea water and otheroods; the lime-water for brown candy should be of the greatest strength; and the workman endeavours to extract the scum as soon as possible, because it is imagined that the strength of the sugar may be impaired if it be suffered to lie too long discolored. No scum is ever incorporated with the fugar intended for candy; indeed four or six gathering-pots to a pan are sometimes taken; but it is apprehended, that it would be better to omit even this. The fugar melted for candy should be the strongest that can be obtained.

When these precautions have been observed, let us imagine the fugar cleared off and skimped into the cittern. The panman pumps back about the usual quantity: the boiler carries the evaporation to the point he judges proper; and it is immediately skimmed off into bafons, which are carried directly to the fove; and the pots are then filled in the following manner. The full-house man receives the first bafon, and pours its contents into No. 1, proceeds to No. 2, and so on, till he has reached No. 5; and then proceeds to fill No. 5, 4, 3, 2, and 1. When this is filled, the full-house man goes on till he has covered the whole pavement; he then lays two planks upon the lowest beams, and places a series of pots upon the farther one, standing upon the other to fill them; he then lays down another strong plank, and covers that on which he stood, and so proceeds to build up row after row, till the whole is filled. In the whole process of this business he moves slowly and cautiously, and causes all the doors to be shut, so that no currents of air may approach him; as skillless is of the greatest consequence, and the least confluence of the air is sufficient to disturb and break the crystallization. When the pots are filled, the fove-door is fastened up, and covered with a blanket, or dropped with wet clay. The cockell is foked to such a degree, that the candy may stand in a blood-heat; at the end of five or seven days, the crystallization of brown candy will be complete. The pots are then removed from the planks and the floor, and the operation commences, which is called ferring, or breaking-up a fove of candy. Each pot is brought to the side of a cooler, upon which, over a frame, a clean basket is laid, into which all the sugar that has not crystallized is poured off, and along with it the currif, which is a cast of candy, that had formed itself upon the surface; the fypur or uncrystallized fugar runs through the basket into the cooler, but the crust remains in the basket, in which it is washed and dried, and afterwards packed for sale with the candy. As soon as the fypur is poured off, the pot is brought to the side of a clean water, blood-warm, are poured in till it be nearly filled; the pot is then smartly shook round, and the water is returned into the pan. The candy being thus worked, the boiler examines it. If it be strong and good, it presents a beautiful appearance; the sides of the pot are everywhere covered with a coat about half an inch thick, the front of which is cut in fancy forms, reflecting the light in various directions; and upon every line the crystals fall in the most varied and capricious forms. If the pots were pierced, as they formerly were, so that the fringes might lie but an inch asunder, the candy of each line would then run into the next, their sides become united, and the whole form a strong cake, not to be separated without force; but the modern improved pots are so pierced, that the crystals are suspended upon every thread in different bars, without either lateral or perpendicular cohesion.

The washing above described is necessary to cleanse from the face of the crystals every particle of fypur matter, which would otherwise occasion a clamminess in the candy, and obscure its luster. After washing, each pot is turned down into a cooler or other receiver, and when they are washed and drained, they are again put into the fove to be dried; for this purpose they are placed in the fove aflant, resting against the wall, or against each other, with the mouth downwards; and under each pot is placed a small earthen pan, called a candy-bafon, to receive the remaining moisture which will drip from them: the fove is again fastened up, and the cockell foked, so as to produce a fierce fire, which must be well kept up for three days: at the end of which time the candy will be dry enough to quit the pot; they are therefore taken out of the fove, and turned down upon the floor, previously covered with clean paper; and with a little flaking, or a gentle blow, the whole mass of candy quits the pot, retaining the form of it complete: and then the candy is returned to the fove for the third and last time, where in three or four days, with a good fire, it will become perfectly dry, and fit for sale. It is generally packed in boxes of about fifty-five pounds each; at the bottom of the box is a layer of the bottoms of the pots, which have the least beauty or fineness; then a course of bars of candy, upon that a stratum of crust, and so on to the top of the box, finishing with bars of the bandfomest candy.
SUGAR.

candy, nearly laid with the face upwards. At the bottom of the candy there are often found masses of sugar which hath not yet crystallized, but is become concreted in small round grains, of a lighter colour than the candy; this is called fool, and is either sold at a lower rate, under the name of candy-foot, or melted with other sugar, for the making of lump and loaves. The syrup of candy is fit to be taken copiously with raw sugar in lump-boiling. The washings and the drips from the bafon are applicable to the same use.

White-candy is made like the former, but from fine lump or loaf sugar, cleared as for double loaves. It is boiled to lower proof; stands in a milder warmth; forms in three days instead of seven; and the value depending upon the whiteness, it must be managed with the utmost delicacy in every stage of the process.

The brown froth crystallizes as regularly as the white, but becomes clammy and deliquescenit in a damp air, whereas the white candy remains always dry. On account of its superior hardiness, it is less easily soluble than the loaf-sugar, and would be excellently calculated for preparing all vegetable food, if the price was lower. The sole difference between the white candy and the finest loaf appears to be in the form, which in the candy is the natural flake form of sugar, but in the loaf is granular, owing to the agitation given to it for this express purpose whilst cooling. The most common form of the regular crystals of sugur-candy is an oblique four-sided prism, terminated by dihedral summits. White sugar-candy, and also sugar, are used as ingredients to render water a vehicle for colours in miniature-painting. The intention of using them is to prevent the colours from cracking when mixed with gum-arabic, and also to make the gum-water work more kindly with the pencil. See Starch.

Sugar-Houses, is a brick or stone building, constructed for a sugar-refining manufactory. A house intended to contain one or two pans should be square, or nearly square: but a house of larger dimensions ought to be of an oblong form; as it may be conveniently heated, by placing the chimney of the stove and of the pans at opposite angles. A house to contain one pan should consist of fix floors besides the ground-floor; the dimension about twenty-seven feet square; a two-pan house about thirty-six feet by forty feet; a house of four pans, about forty feet by sixty or sixty-five feet. The stove is a brick building from eight to fourteen feet square, usually placed in one corner of the building. The height of the several stories should be as follows; the fill-hose, or ground-floor, nine feet below the girders; the next floor above it, called the ware-house, of the same height; and every other floor upwards, fix feet at most between the girders and the floor. In every floor must be left an aperture, through which a rope is fastened upon a brafe pulley upon the uppermost floor for drawing up the sugars: and provided due attention be given to the strength of the building, and to the exclusion of dams and a cold air, a sugar-house cannot be rendered too light. The utensils necessary to a sugar-house are of copper, lead, iron, carpentry, back-maker’s work, wicker-work, pottery, &c. The copper utensils are the pans, coolers, cisterns, syrup-pipes, bafons, ladles, skimmers, and, in some cases, candy-pots, &c.

The pans are usually made of a conical form, from five to fix feet diameter at the top, decreasing to a diameter of about two feet fix inches, or three feet. The coolers are vessels of thin copper, of fix feet in diameter, and about twenty inches high: the number of pans and coolers is usually the fame. The clarifying cistern is a large receiver, either of copper or lead, placed as near as possible to the sides of the pans, and capable of containing at least one-third more than the contents of all the pans collectively. The syrup-pipes are tubes of four inches diameter, made of thin copper, or tin-plates, and suspended perpendicularly over the clarifying cistern, from the upper floor through the whole building. The bafons are vessels containing from four to fix gallons each, in which the boiled sugar is carried from the pans to the coolers, and from the coolers to the moulds. The ladles are of several sizes. Skimmers are of fourteen inches diameter, pierced with holes like a clynder; and likewise a small one of the same kind. Cullenders are of eighteen inches diameter, and fourteen inches deep, through which the clay is to be strained; and there is also another, which is smaller, for the purpose of straining spice.

The leaden utensils and plumbers’ ware, are such as follow: the bench is a shed about one foot broad, running before the pans, and rising in front, by which it is capable of receiving the sugar which is spilled before the pans. The clem-cistern is a wooden receiver, usually lined with lead, and nearly as large as the clarifying cistern.

The sugar-pipes are a pewter or hard metal pipe from the lime-cistern to the pans, and leaden pipes for the conveyance of common water or liquor to the pans, and to the lime-cisterns. The pumps are a copper pump fixed in the clarifying cistern, and a spare pump of the same kind.

The iron-founder supplies bars of a triangular form, to be laid under the pans, and the cockell, which is an iron trunk, used to dry the goods in the stove; and also iron doors, stove-doors, and pan-doors, &c.

The carpenter raises the frame-vent over the pans, which is a hood of thin board, so formed as to conduct the flames to the two brick funnels, which are led up on either side of the pan-chimney to the top. He also furnishes the racks of the stove, a trough to convey the sugar from the pans to the cistern, and another to return it from the cistern to the pans, syrup-froths, blocks, cooler oars, &c.

The back-makers supply two or more tubs or backs for lime-water, which are round, oval, or square, and whose capacity varies from thirty to two hundred barrels. The high-chimney, is any vessel large enough to hold a considerable quantity of common water. The mould-cistern is a large oblong vessel, in which the moulds are foaked before they are used: it is usually about four feet fix inches deep, and should be capable of containing at once as many moulds as are used in one day’s refining.

The clay-cisterns are supplied either by the back-maker or carpenter, and also the clay-bar, which is made of oak or elm, its club end being flueck full of iron-points: its use is to macerate and fine the clay.

The wicker-work consists of refining-basket, clem-baskets, pulling-up baskets, coal and clay-baskets, &c.

The sugar-mill is one of the most simple machines of the kind: the runner is sometimes made of cast-iron and sometimes of stone: the former is preferable, because a larger diameter and a broader surface may be had with the same weight. The runner and the centre post should have a brafe collet within them, for the iron spindle to turn upon. The mill should stand on a solid foundation; either on the earth, or on the centre of a brick or stone arch. The veeels of pottery are of various sizes, and of two different forms and denominations, six, pots and moulds.

The construction of the pan-chimney requires peculiar attention; it should be placed on iron beds, and the horizontal bars on which it rests must be wrought in the walls of the building, and clenched down on the outside. But the setting of the pans is the most difficult work; for it is necessary that they should be so fixed, as that the flames, which
SUGAR.

which burn away under them three or four times in a year, should be taken out and replaced, without pulling down the whole work.

After all, a principal consideration in the construction of a sugar-house, is the obtaining a sufficient degree of heat. Various degrees of heat are required for different sorts of goods, and occasionally for the same sort: accordingly each floor may be made more or less warm, as the cafe requires. The heat is introduced through the pan-chimney, the stove-chimney, and sometimes through iron or brick flues raised on purpose. It is communicated from the chimneys by fluttering the register-plates; after the fires are extingushed, or when they are nearly out, and the remaining ashes are perfectly clear. After fluttering the register-plates, the small iron doors (one of which is fixed in the chimneys both of the cockell and the pans upon every floor) are opened, to convey heat where it is wanted.

Labourers in sugar-houses are very subject to dysenteries: the visnum animonis cercatum is an effectual remedy in these cafes.

Sugar-Mill, a machine used in the West Indies to press out the juice from the sugar-cane, as briefly described under our article Sugar, sapra. The sugar-mill is a very simple machine, consisting only of three vertical rollers mounted in a frame. The power is applied to the centre one to turn it round, and all the three are made to turn together by means of cog-wheels. The canes are introduced between these rollers, which as they turn round draw in the canes and give them a very violent pressure, which is sufficient to extract the juice and leave the canes dry.

Sugar-mills are worked by cattle, wind, or streams of water; and since the improved steam-engines of Mr. Watt have become general, many steam sugar-mills have been sent out to the West India plantations. In situations where a fall of water cannot be obtained, those are preferable to catttle-mills or wind-mills; for if cattle are used, an extra flock should be kept on purpose, because the regular cattle of the plantation are fully employed at the seafon of cutting the canes. The operations of the mill should be carried on constantly in a regular manner, until the whole crop is finished, or there will be danger of the juice fermenting in the canes, if the machinery is not sufficiently powerful to extract the juice from the canes as fast as they are brought in from the field in bundles. For this reason wind-mills are very objectionable, as no dependence can be placed upon them for fulfilling their allotted task in the required season. In many wind-millers levers are provided, to which mules or oxen can be harnessed, to work the mill when the wind fails, the machinery of the faiIs being then detached. But this expedient takes off the cattle from their regular field employment. A water-mill, or steam-engine, is free from these objections; and if it is sufficiently powerful, the whole produce of a plantation can be pressed, and the juice obtained ready for the boiling-house, in a short a time that the juice will be quite fresh. There are some water-mills in Jamaica, sufficiently powerful to grind as many canes in a week as will make thirty hogheads of sugar.

Plate Sugar-Mill contains two views of a sugar-mill to be worked by steam. K represents the axis of the crank of the steam-engine, and L the fly-wheel; I is a pinion, fixed upon the end of the axis K, and turning the large cog-wheel ZI, which is fastened upon the extremity of the horizontal shaft G, which supports the pivots of the two latter wheels, are built into a wall, which may be considered as the wall of the house in which the steam-engine is placed. At the opposite end of the horizontal shaft, G, is fixed the bevelled cog-wheel F, which gives motion to the horizontal bevelled wheel E, fixed upon the top of the axis, D, of the middle roller B. The other rollers, A and C, are placed on each side of it, and all three are made to turn round together by a cog-wheel, S S S, at the upper end of the rollers mounted in an iron frame, consisting of two horizontal frames, P P, Q Q, furnished by uprights O, O, and the openings of the frames P Q, contain the brafs bearings for the pivots of the three rollers, which brafs are adjustable by means of cros keys, and wedges driven through openings in the frames, so as to force the rollers towards each other, and retain them at a regular and invariable distance. The surfaces of the rollers are fluted, as is shown in the figure, with grooves of a small depth. These make the rollers take a firmer hold of the canes to draw them in, and also facilitate the running down of the juice from the canes into a pan or ciferon, which is formed round them at the lower part Q Q, by a plate of iron upon the frame Q, turned up all round at the sides; and at one end there is a spout, Q, to carry off the juice into a pipe, which leads to the boiling-house. This receptacle for the juice forms a small circular channel or gutter round the lower edge of each roller, to receive the juice which runs down the surface of the rollers; but a small raised rim is carried round the centre part or pivot of each roller, the edge of which is higher than the surface of the liquor in the pan, to prevent the juice flowing down into the bearings of the lower pivot. The weight of each roller, which is considerable, is supported in a brass step or bearing beneath the frame Q, as is shown by the dotted lines in fig. 1, and in some cases friction-rollers are applied beneath. The rollers are made of cast-iron, and hollow within; the external surfaces are truly turned.

The operation of the sugar-mill is extremely simple: the canes are made to pass twice under the pressure, first between the rollers B, C, and then between B and A. For this purpose, the negro who attends and feeds the machine, takes the canes in a handful, and applying their ends between the rollers B and C, the motion will draw the canes in between them, and they thus receive a first preasure. Another person, who stands behind the mill, and is called the returner, bends the ends of the canes as they come through, and holds them in contact with the surface of the centre roller B, so that it will carry them round by its motion, and introduce them again between the rollers A, B, where they will come out again in front, pressed dry from their juices. The second pair of rollers, A, B, are adjusted by the wedges of their bearings, so as to be rather nearer together than the first pair, because the canes are flattened and crushed by the first preasure between the rollers B, C, and require a still greater degree of preasure the second time. The space between the rollers is very small in either case, for the canes are of a very frit substance, and they are squeezed excessively hard in passing between them. In the most complete mills they employ what is called a dumb returner, instead of having a person behind the mill to return the canes. This is a circular piece of frame-work, or kind of screen, which is fixed fast to the frames P and Q, and is made to encompass the middle roller at the back. It receives the canes as they come through the first time, and holds them in contact with the middle roller, till the ends return between the other pair of rollers. It effects this much more completely than the most active of returners can do. The canes which have passed through the mill are squeezed completely dry, and are sometimes even reduced to powder. This refuse is called cane-trash, and is used as fuel in the boiling-house.

Sugar.
SUGAR.

Sugar-mills were formerly made of wood in the framing, and the rollers were made of hard wood; afterwards they were covered with an iron cladding. The belt mills are now made wholly of iron, which is a better material, because it will not suffer the rollers to yield, and the canes which are presented cannot escape the full force of the pre累累 to which it is intended to subject them. When the sugar-mill is turned by cattle, the axis, D, of the middle roller has a long lever, E, and cross rod, F, in place of the wheel E: the arms of the lever extend on each side at least eighteen feet from the centre for the cattle to draw from; and to render the arms firm, the axis L is carried up to a considerable height above E, and oblique braces of wood are extended from the extremities of each of the arms, by which the horses or mules draw, to the top of the vertical axis, thus forming a triangle. Two mules are harnessed to each arm for the common small mills; but for a mill such as is represented in the drawing, four arms must be provided, to admit of six or eight mules to turn it.

Some sugar-mills have been made within these few years of an improved structure: the rollers are placed horizontally, and the centres of the three are arranged in a triangle, two rollers being below and one above them, so that the upper roller, to which the power is applied, touches the other two: in fact it rests upon them, and the returner is rendered unnecessary, because the two lower rollers are so near together, that the canes pass from one to the other. This is not a new invention, as we find a drawing of it in Mr. Smellie's MS. papers entitled "sugar-mill, designed for Mr. Grey in 1754," and sent by him to Jamaica, but not then executed." This mill, which is on a large scale, and has two sets of rollers, is worked by an over-shot water-wheel, the axis of which forms the upper of the three rollers at each end, and is for that purpose caged with a cylinder of iron: the other two rollers at each end of the wheel are placed beneath the axis, so that it will rest upon them. The upper roller, therefore, answers to the middle roller of the common sugar-mill, and the two lower ones to the outside rollers; but the centres being arranged in a triangle, instead of a straight line, the two outside rollers are brought as near together as they can be to touch, which must not be, because their surfaces move in opposite directions. The two lower rollers are contained in a small cistern, which is to receive the juice; and if the level of the water-wheel renders this cistern too low for the juice to run off to the boiling-house, a small pump is applied to lift it into a proper trough. This pump is worked by a lever and a pin, projecting from the shaft of the water-wheel. The two lower rollers are turned round by means of a cog-wheel upon the end of each, working in cog-wheels upon the axis of the water-wheel and upper roller; but it is necessary to have two separate cog-wheels upon this axis, because as the two lower rollers are placed so near together, the cogs of their wheels would touch; and as this cannot be, because the adjacent surfaces of the two lower rollers must move in contrary directions, the cog-wheels upon the two lower rollers are therefore placed in different planes, so that they will fall side by side, and will not meet each other. The teeth of the cog-wheel upon the upper roller or axis of the water-wheel is made of double breadth, or has two separate rings of cogs, one giving motion to each of the rollers. By this means the three rollers are all turned round in the same direction, as in the common vertical mill. This occasions the two adjacent fides of the two lower rollers to move in contrary directions.

The advantages of placing the rollers horizontal are considerable. The weight of the water-wheel, as well as its power of rotation, tend to keep down the upper roller upon its work. The feeding of the mill is rendered much more regular and easy, and the canes are returned through a second pre累累, without the aid of the returner.

For the convenience of feeding the mill, a board or bench is placed in a sloping direction, leading to the space between the first of the lower rollers and the upper roller: upon this bench the canes are spread in a regular and even layer, which is pushed forwards and backwards, and other canes are introduced between the rollers, in the same manner as a threshing-mill is supplied. The canes as they pass through are prised against the surface of the back lower roller, because the space between the two is not sufficient for the canes to fall through; and the motion of the back roller raises up the canes, and introduces them between the back roller and the upper roller. This second pre累累 deprives the canes of all their juices, and they are received on an inclined board, which slopes from the rollers sufficiently to carry down the cane-trafi into a heap, from which it can occasionally be carried away. A mill of this kind will do much more work than a vertical mill, for the negro must lose time in feeding the canes between the vertical rolls, because he can only present as many as he can hold between his hands; but with a horizontal feeding board he spreads out a sufficient quantity of canes, and by pushing them forwards, presents them to the mill as fast as it will take them in, and that at the same time without choking, because he can arrange them in a layer. There is no advantage in placing the rollers vertically, which was originally done only with a view of making the most convenient application of the power of the water. When a water-wheel is used, or a steam-engine, the horizontal rolls are the most convenient as well as the most effective. When a water-wheel is applied to turn the common sugar-mill, the wheel, E, at the top of the axis of the middle roller, is made twice or three times as large as represented in the figure, and its teeth downwards; then a wheel, similar to the wheel F, gives it motion; this latter wheel is fixed upon the end of the axis of the water-wheel, but it is then placed beneath the wheel E, instead of above it.

Sugar, in Agriculture, is a material that is found to be present in many substances which are employed as the food of domestic animals, and upon which their power of nourishing and rendering them fat, in a great measure, depends. It is ascertained to exist, in a pretty large proportion, in a great number of plants and substances that are used in this way; and its feeding or fattening properties in such cases have lately been put to the test and more fully proved, in consequence of the markets of this country having been so much overstocked with this substance in its prepared state, from our possessions in the West Indies. Various hints, proposals, and attempts, for bringing it into use in this intention, have been made; and different limited trials have fully decided that it is capable of being employed for this purpose with success; but hitherto the want of proper regulations in regard to the duties that have been laid upon it in this country, have put a bar to any considerable trials or undertakings in this way. Most forts of the above description of animals are fond of this substance, as well as the other matters which contain it; and it is found to support and keep them in condition in an equal manner to most kinds of grain, or other matter of that kind; but from the smallness of the quantity employed, some sort of deft material is constantly necessary, such as hay, cut straw, chaff, or some other similar bulky substance, in order to fill and digest the stomach in a proper manner. See SACCHARINE Matter.

It is observed on the same authority, that besides the crystallized
SUGAR.

crystallized and solid sugars, there appears to be a fugar which cannot be separated from water, and which exists only in a fluid form; and that it is this which constitutes a principal part of melasses or treacle, which has also been employed with success in fattening animals of the cattle kinds, in mixture with some sort of diffusing substaninces. See SROLL—SROLLING, and TREACLE.

SUGAR, in Chemistry and Medicine, denotes a crystallizable effuential salt, of a sweet agreeable taste, contained more or less plentifully in many kinds of vegetables, as well as in the fugar-cane, which furnishes the greatest quantity of it.

Sugar, according to the experimental trials of some, contains carbon, oxygen, and hydrogen, nearly in the proportions of three of the first, four of the second, and eight of the last. And the estimates of others give the same elementary parts, as in substances of the gum kind; as eleven of carbon, ten of oxygen, and twenty of hydrogen.

M. Marggraf has obtained fugar from the roots of several plants, as from carrots, parsnips, white and red beets. Among all the vegetables indigenous to the middle and north of Europe, which are fermentable saccharine, the beet-root is found to exceed them all in the quantity of fugar which it contains: this was ascertained by M. Marggraf, in his experiments for discovering some native fugar that might serve as a substitute for foreign fugar. (Mem. de l'Acad. de Berlin, for 1747.) See BERTA. Two methods were pursued by this accurate chemist. One was to dry a given portion of the vegetable, to boil it in rectified alcohol, and then keep the alcoholic solution at rest for a time, by which the fugar will separate in crystalline grains. This mode, however, is much too expensive to be pursued in manufacture, but it serves as an useful indication of the comparative proportions of fugar in different vegetables, though the actual quantity obtainable by the usual mode of manufacture appears to fall far short of what is yielded by treatment with alcohol.

The other method was to imitate in the small way the process performed on the fugar-cane juice, which also was attended with a certain degree of success. The experiments of this celebrated chemist are the following: three roots were selected, the white beet, the red beet, and the skirret, all of which gave evident indications of abounding in fugar, for when cut in slices, and dried, their taste is very sweet, and the microscope shews a number of crystalline grains of fugar dispersed through their substance.

Some slices of white beet thoroughly dried, but not burnt, were powdered coarsely, and 8 oz. of this powder, again dried, were put into a bottle with 16 oz. of highly rectified alcohol, and being loosely stopped, the liquor was slowly brought to boil on a sand-bath, with frequent shaking. The vessel was then removed, the solution filtered, and the powder pressed strongly, to squeeze out all the liquor. This clear solution was then put into a bottle which was corked, and set by in a cool place. A crystallized salt deposited gradually in the course of some weeks, which was hard and tolerably pure fugar. This was redissolved and again crystallized in the same way, by which a very pure fugar was obtained. In this way, 8 oz. of the white beet-root gave half an ounce, or ½ of fugar; 8 oz. of skirret-root, equally dried, gave 3 drachms, or about ½ of fugar; and the same quantity of the red beet gave only 2½ drachms, or about ½ of fugar. The solution, however, still contained a quantity of fugar mixed with the refined part of the root, and if it is evaporated to dryness, a sweetish uncrystalized extract remains.

The skirret-root was then treated in the following man-

ner without alcohol, with a view of extracting the fugar. A quantity of it was chopped small, bruised in a mortar, and the juice expressed through a cloth bag, and the pulp was again moistened with water, and expressed, to get out all the saccharine liquor. The whole liquor was then kept at rest for 48 hours in a tortilla collar, by which most of the feculence subsided, and the clear liquor was carefully drawn off. The author lays much stress on this part of the process, which, if it is not done properly, considerably hinders the subsequent production of the fugar. The clear liquor was then heated in a copper pan, clarified with white of egg, and boiled down to the constipate of thick syrup, and kept in this state for about six months in a warm place, by which it concreted into a semi-fluid crystalline mass, composed of impure crystals of fugar and a good deal of syrup. The whole mass was then a little warmed, to give the syrup a little more fluidity, and poured into a funnel-shaped vessel of tinued iron, with holes at the sides and bottom, and let by in a warm place; by which, after a considerable time, the impure uncoagulable syrup slowly filtered to the bottom, leaving the purer saccharine part in the form of a brown granular mass. The latter was then re-dissolved in water, again clarified with white of egg, strained, boiled with a little lime, again strained, and then evaporated to a thick consistence, and stirred till cold. A fugar yield not quite pure than the last was thus obtained, which, on being kept for a week in a funnel-shaped pot, with a single hole at bottom, plugged up, congealed into a grained fugar equal to good mufcovado, from which a syrup separated and dropped through when the plug was withdrawn.

Such is the process of this chemist to obtain a fugar from the skirret-root, and he proceeded in the same manner with the white and red beet-root, and with the same success. He further observes, that he rinsed the beet-roots, being harder than the skirret; that the mucilaginous deposit from the beets was browner and less copious than from the skirret; the fugar from the white beet was the most abundant and the purest, and that from the red beet was the least so. The mucilage or sediment from the skirret, washed with cold water and purified, yielded a very good white farina.

All these roots are very watery. The white beet loses by gentle, but entire, defecation, full three-quarters of its weight, and the red beet seven-eighths.

For an account of the experiments of Achard, and other chemists, see BERTA.

It is also presumed, that much fugar may be obtained from other vegetables, as from green peas, cabbage, green farinaceous grains, as barley, (see MALT,) ripe fruit of grape, date, and fig, and the root of parsnip, &c. and from several trees, as the fycamore and birch trees. Green maize (see MAIZE) contains a liquor from which the American fayages are paid to extract fugar. It may also be extracted from the asclepias cand e r E T E F E C T I C A C N I E N N O N, and from any flowers collected while the morning dew is upon them. But the vegetable which yields the largest quantity of fugar, next to the fugar-cane, is the fugar-maple. (See MAPLE.) The methods employed for extracting fugar from this tree in Canada are related by M. Gautier, in the Memoirs des Scav. Etrang., tom. ii. and by M. Kalm, in the Swedish Mem. for 1757. (See MAPLE Sugar.) The season for tapping the tree is from February to April, for about six weeks, during which time a tree of moderate size will yield from 20 to 30 gallons of sap, from which may be made about five or six pounds of pretty good fugar. The tree does not seem to sustain any injury from this operation, for the juice is more savoury from the trees that have been
been already tapped, than from those that are fresh. This juice, which is clear, and of a pleasant taste, is made into fugar by the farmers in the country, with a simple apparatus. It is usually clarified with lime and white of egg (or milk) boiled down, grained, and clayed, like the canec-juice. Sometimes the quantity of liquid is reduced by freezing at the proper season, which is preferred to evaporation. This substance might, it is supposed, be made into loaf-fugar, as well as the framec-juice. It is commonly kept in a half-purified state, like the common moist fugar. The juice will also furnish a pleasant wine by fermentation, and a good vinegar.

By discovering a menstrum that would dissolve the fugar, and not the slimy substance, the saccharine and mucilaginous parts of plants might be separated from one another with advantage. Sugar is scarcely, if at all, contained in any part of the animal kingdom, (honey certainly belonging to the vegetable,) except in milk, and in the urine, during the singular disease called "diabetes mellitus."

Pure fugar appears either in a regularly crystallized form, or in thinning white crystallized grains. Both in candy and loaf it is hard and brittle, inodorous and sweet. If hard loaf-fugar be rubbed in the dark, it is very luminous. With the nitric acid it is convertible chiefly into the oxalic acid. It is very soluble both in water and alcohol. Mafles, which are constituted chiefly of the uncrytallisizable parts of the juice of the fugar-cane, and which Prouit has denominated liquid fugar, are more soluble in alcohol than fugar. Sugar requires only its own weight of water at 49° for its solution; and when united at a higher temperature with a smaller quantity, it remains dissoled and forms a syrup. The watery solution, mixed with mucilaginous, farinaceous, or other matters, readily enters into the vinous fermentation; whence it is inferred, by considering that the strength of the liquor and quantity of alcohol produced depend on the quantity of fugar, that the most essential part of the process of vinous fermentation is the conversion of fugar into alcohol. Four parts of boiling alcohol dissolve one part of fugar; but a moiety of fugar again separates by reft in crystals. Oils readily combine with fugar, and the mixture is miscible with water. Lime and the fixed alkalies unite with fugar, and form compounds, without any sweet taste. The concentrated strong acids dissolve and decompose fugar, but the weaker simply dissolve it; and the alkaline and earthy hydro-sulphurte, sulphures, and phosphures, decompose it, and resolve it into a vitrifica resembling gum. Its ultimate constituent parts, according to Lavosier, are 64 of oxygen, 38 of carbon, and 8 of hydrogen, in 100 parts.

Sugar melts at a heat considerably above that of boiling water, and forms a blood-red viscid fluid, which, cooked, has a flavour of emperyums, not ungrateful, mixed with the natural sweetness. When melted, it takes fire from a lighted substance, and burns with a strong flame, and a penetrating odour, which excites coughing, and is owing to the production of an acid.

If fugar be distilled per se from a glass retort with a heat gradually increased to redness, and the proddebs be carefully collected, they will be found to be, first, a coloured liquor, strongly acid and punget, called the "pyromucous." A large quantity of gas comes over at the same time, which is hydro-carbonat mixed with a little carbonic acid; and a very pure charcoal is left behind, which burns away in the open air without leaving any residue. Neither azot, ammonia, nor lime, nor any other substance, is obtained in this process, whence it appears that fugar is one of the purest hydro-carbonous oxydes known.

SUGAR.

The actual chemical differences between mucilage and fugar, as stated by Mr. Cruikshank, are the following: fugar is soluble both in water and alcohol, and crystallizable from either solution; but mucilage is insoluble in alcohol, and refuses to crystallize from its watery solution: 480 grains of fugar yielded by distillation 130 grains of charcoal, 270 grains of liquid pyromucous acid, 41 ounce-measures of carbonic acid gas, and 119 ounce-measures of hydro-carbonat gas. The same quantity of gum arabic yields 75 grains of charcoal, 210 grains of pyromucous acid, 95 ounce-measures of carbonic acid, and 180 of hydro-carbonat. It also gave about 10 grains of lime, and the acid, when saturated with lime, gave out a little ammonia; and hence it appears, that linde and azot are substances that belong to mucilage, and not to fugar. The habitus of each substance with nitric acid differ also considerably. When gum arabic (e. g.) is heated with nitric acid only till nitrous gas begins to be digested, a quantity of white insoluble matter precipitates, which is the "mucous" acid, and the residue is "malic" acid, which a farther addition of the nitric converts into oxalic. But fugar is changed into oxalic, or malic and oxalic acid, without the production of any mucous acid. The quantity of oxalic acid produced from a given weight of fugar with nitric acid also exceeds that yielded by the same weight of mucilage with the same proportion of acid. In the spontaneous changes, also, fugar and mucilage differ essentially: fugar being the essential material of the vinous fermentation; but mucilage is incapable of this process, when pure, and appears to contribute little to the generation of alcohol, when in combination with fermenting materials.

From the known properties of fugar, it is supposed to unite the unctuous part of the food with the animal juices; hence some have concluded, that it is nutritive to animals, and increaseth copulence; others have ascribed to it a contrary effect, as it is said to prevent the separation of the oily matter, which forms fat, from the blood; and others, again, have charged it with rendering the juices thicker and more sluggish, retarding circulation, obstructing the natural secretions, and thus occasioning or aggravating scrofulatic, cathartic, hypochoonidrical, and other disorders. However, experience seems to shew, that the moderate use of it is at least innocent.

Professor Murray, who has treated this subject very elaborately, thinks that by the fermentation which fugar undergoes in the stomach, and by its relaxing salutary faponaceous qualities, as well as by the acid which it contains, it rather tends to emaciate than to fatten the body; and in this opinion he observes that he has the authority of Borehove, who says, if this sweet be taken in large quantities it produces emaciation, by disolving too much of the animal oil. He is therefore much furthered, that Mr. John Hunter should lately recommend fugar and honey as the best restoratives to those suffering from great debility by a long course of mercury. What may be the effects of fugar in this respect in its refined state may be difficult to determine; but in its crude state there can be no doubt of its affording a considerable share of nourishment, both as combined in various vegetable matters, and as separated by art. Those animals which wholly feed upon it in the fugar islands, become remarkably corpulent; and the negro children, whose diet happens sometimes for a season to be confined to mafles, are easily distinguished from others by their superior bulk; they are, however, more disposed to suffer from worms, and are likewise less active and healthy.

Sugar however appears, by the experiments of several writers, to prove deleterious to various kinds of worms, either
either by immersing them in a solution of sugar, or sprinkling it upon their bodies; and twenty grains of lump-sugar forced into the stomach of a frog, produced immediate torpor and death, which followed in the course of an hour; it also proved fatal to pigeons, and to the galline kind, but not to sparrows; and with sheep and dogs it had no other effect than that of a cathartic.

Sugar may certainly be taken into the stomach in pretty large quantities, without producing any bad consequences; though proofs are not wanting of its miscible effects, in which, by its attenuating and dissolving the fluids, and relaxing the Bowels, debility and Difease are said to have been produced. Stark for many days took from four ounces of sugar, to eight, ten, fifteen, and even twenty, with bread and water, by which naufca, Satus, ulceration in the mouth, with redness and tumefaction of the gums, oppression, purging, pain, and redness of the right nostril, bleeding at the nose, and livid fleas over the right scapula, were produced. We are told that a boy, who was much affected by acidity of the stomach, in a short time greedily ate a large quantity of lump-sugar; soon afterwards he was taken ill, and the next morning found dead in his bed. Upon examining his body, red spots, and other marks of a diffused state of the blood, were discovered. What degree of credit ought to be given to these and other tales of the like kind, we leave to the judgment of our readers; but that the liberal use of sugar to many stomachs has greatly impaired the digestive powers, and laid a foundation for various complaints, is highly probable. At the same time we must admit, that several indulge largely in this article, if not with advantage, at least with impunity.

As a medicine, sugar cannot be considered to possess much power. Dr. Cullen classes it with the attenuantia; and Bergius states it to be febrifuge, ediscurans, relaxans, pecfortalis, vulneraria, antifeptica, nutrimens. In catacular affections, both sugar and honey are frequently employed; it has also been advantageously used in calculous complaints; and from its know power in preserving animal and vegetable substances from putrefaction, it has been given with a view to its antifeptic effects. The candy, by dissolving slowly in the mouth, is well suited to relieve tickling coughs and hoarseness. The use of sugar in various medical compositions is too obvious to require being particularly pointed out.

Raw sugar and maflasses, by virtue of their oily or treacly matter, prove emollient and gently laxative. The crystals or candy are most difficult of solution, and hence are most proper where this soft lubricating sweet is wanted to dissolve slowly in the mouth, as in tickling coughs and hoarseness. Refined sugar, externally applied, is elciharotic.

Coarse sugar, in which there is more oil than in refined sugar, is recommended as a good medicine in collyria for discharging ulcers of the cornea, in which affringents are hurtful. Aikin. Lewis. Woodville.

Sugar, Acid of. See Oxalic Acid.

Sugar, Empergeromastic Acid of. See Sugar, jupra, and Pyromusius Acid.

Sugar, Caff or Cheese of. See Cask and Chest.

Sugar of Lead. See Lead, and Saccharum Saturni.

Sugar, Maple. See Acer, Maple Sugar, and Sugar maple.

Sugar of Milk. See Milk.

Sugar of Raff, succharum refatum, is white sugar clarified, and boiled into a confection in rofe-water; when boiled, they form it into lozenges, sometimes into little grains, of the fize of peas, by keeping it furring till it be cold and dry. It is reputed good to soften and alay scrofulous, &c. of the breast. See Rose.

Sugar. Spirit, a name given by our distillers to a spirit made in England, Holland, and other places, from the washings, fermentations, drofts, and waife of a fugar-baker's refining-house. The manner of preparing it is the fame with that ufed for the malt and maflasses spirts. The refue of the fugar is fermented with water in the ufual manner, then distilled into what is called low wines, and afterwards rectified, without any addition, into proof-spirit.

When the operation is well performed, and no foul, fetid, or foreign matter has got in among the wash, this is a tolerably clean spirit. We commonly make it thus, but in Holland it is ufually made very yellow and difagreeable; though capable, by an easy rectification, familiar with us, but not much known abroad, of being brought to a fine and clean spirit. With us this sugar-spirit is ufed to mix with, and adulterate brandy, rum, and arrack, which will receive a large dofe of it without its being at all difcoverable; but the Dutch, who have it very coarse, can only adulterate rum with it, and even that will bear but a small proportion, without being betrayed by its nauseousness.

This sugar-spirit, reduced to alcohol, makes one of the purest spirits we are acquainted with, much superior to that of maflasses, and much more to that of malt. Shaw's Essay on Distillery.

We have in the Philosophical Transactions, an account of a volatile and pungent spirit of sugar, which was made from what the fugar-bakers call sugar-water; which is so other than the water in which the aprons, moulds, and other utensils, employed in the refining of sugar, are washed. This was fo extremely pungent, that a man could not smell to a large quantity of it without danger of suffocation; and fo volatile, that no Ropping it would preserve its spirit for any length of time. Phil. Trans. No 130.

Sugar Scum, in Agriculture, the surface scummy material which is taken off from the boilers of the fugar-bakers, and which in some places is made considerable use of as a manure. It consists principally, according to Sir H. Davy, of bullock's blood, which has been employed for the purpose of separating the impurities of common brown sugar, by means of the coagulation of its albuminous matter by the heat of the boiler. It is of course of an animal nature, and must be most useful on lands in which there are subfiances of the muddy kind, on which it can readily operate and produce a beneficial effect.

SUGAR-Leaf Point, a cape on the W. coast of Eheimomauhee, the northern island of New Zealand.
S. lat. 29° 3'.
W. long. 185° 8'.
SUGENHEIM, a town of Germany, belonging to the marginve of Anpach, insulated by the bishopric of Bamberg; 20 miles N. of Anpfacht. N. lat. 45° 4' E.
long. 10° 31'.
SUGER, in Biography, abbot of St. Denis, and prime minister of France under Louis the Young, was born in the year 1082. He was employed by Louis le Gros, who conferred on him the abbey of St. Denis, and employed him in a variety of concerns of a very different nature from those of his ecclesiastical appointment, so that he adopted the manners and appearance of a statesman, more than those of an abbot. At length, by the exhortations of St. Bernard, he determined to reform both his monastery and his own conduct. Accordingly he had resolved on confining himself to his cloister, when Louis the Young, successor to Louis le Gros, setting out on a crusade to the Holy Land in 1147, nominated Suger regent of the kingdom. In this high station he acted with wisdom and integrity, and adopted measures for supplying the king with money, without burdening his subjects. After the king's return he continued to place confidence in Suger, who prevailed with him not to divorce his queen Eleanor of Guinevere; but unfortunately for the kingdom, this great minister died in 1152, at the age of 70. He was magnificently interred at St. Denis, the monks expressing a due sense of his fame, by merely inscribing on his tomb the words, "Here lies the abbot Suger." His works were a "Life of Louis le Gros," "Memoirs of his Administration at the Abbey of St. Denis," &c. "Epitaphs," &c. which Du Chene has published in the collection of French historians. Moreri.
SUGGESTION, Suggestio, the act of hinting, or furnishing another with a thought or design, or of intimating it artfully into his mind.
In the French law, a testament is said to be made by suggestion, when it is made by surprize, and contrary to the intention of the testator.
If suggestion be proved, the testament becomes null. Articles of suggestion are not admissible against a testament written with the testator's own hand, which is never suspected.
SUGGESTION for Prohibition, in Law. See Prohibition.
SUGGESTION, Prosecution by Information or. See Information.
SUGGESTUS, among the Romans, a place in the Campus Martius raised higher than the rest, where every magistrate, according to his rank, was allowed to harangue the people; but private persons could not, unless they first obtained leave from some magistrate to do it.
SUGGUNDARIUM, among the Romans, a place where infants, not exceeding forty days old, were buried; it being unlawful to burn them.

SVIBOVETY, a town of Croatia; 40 miles E. of Agram.
SUIERUS, (Schweitzer,) John Caspar, in Biography, a learned divinity, was born in Switzerland in 1619, studied divinity at Saumur and Montauban, and became professor of sacred literature at Zurich. His study of the Greek fathers produced several works, the principal of which cost him 20 years' labour, and was entitled "Thefaurus Ecclesiasticus, e Patribus Graecis, ordine Alphabetico exhibens quaequeFragmenta, Ritus, Dogmata, Heresies, et hujusmodi alia humanae," Amst. 2 vols. fol.; and in a much enlarged edition, Amst. 1758. Among his other works were "Observations Sacros," Tigrur. 1665; 4to, and "Miscellanea," containing several extracts of the Greek fathers, with a Latin version, Tigrur. 1681, and a "Greek and Latin Lexicon." Moreri.
His son, Henry Suierius, was also a professor at Zurich and at Heidelberg, and the author of some literary works. He died in 1705, the same year with his father.
SUCIDE, in a general sense, and according to the etymo-logy
SUICIDE.

logy of the term, derived from s and cedo, is self-murder. The only question in the argument concerning this subject, says archdeacon Paley, is no other than this,—May every man who pleases to destroy his life, innocently do so? Shall we say, that we are then only at liberty to commit suicide, when we find our continuance in life become uuelefs to mankind? Any man may, if he pleases, render himself uuelefs; and perfous of a melancholy disposition are prone to regard themselves as uuelefs, when this in the judgment of others is not actually the case. But if a law were promulgated, allowing any person to destroy another, when he judged him to be uuelefs, would not the latitude of such a rule be universally condemned? And would it not amount to a permission to commit murder at pleasure? A similar rule, regulating the right to dispose of our own lives, would be capable of the same extension. Besides, no one can be pronounced uuelefs, for the purpose of this plea, who has not lost every capacity and opportunity of being useful, and also the possibility of recovering either; and this supposes a state of such complete destitution and despair, as cannot be predicated, it is presumed, of any man living. Shall it be said, that it is only lawful for those who leave none to lament their death, to depart voluntarily out of life? Here it should be considered, not whether there are any to feel sorrow for us, but whether their sorrow for our death will exceed that which we should suffer by continuing to live? In this view of the question, the judgment that is formed will depend on much of the state of the spirits, or the pressure of any present anxiety, as to very little in hypochondriacal constitutions from an unqualified licence to commit suicide, whenever the diffidences fancied or feared, or actually endured, rose high enough to overcome the pain and dread of death.

Men are never tempted to destroy themselves, uuelefs they are oppressed by some grievous uneasinesses; and to these cases the restriction of the rule ought to apply. But what effect can we look for from a rule, which proposes to weigh our own pain against that of another; the misery that is felt, against that which is merely conceived; and in such an insufficient balance as the party’s own deterred imagination? Any other rule that can be assigned will ultimately bring us to an indiscriminate toleration of suicide, in all cases that involve the danger of its being committed.

It therefore becomes a subject of inquiry, what would be the effects of such a toleration? They must evidently be the loss of many lives to the community, of which some might be useful or important; the affliction of many families, and the confusion of all; for mankind must live in continual alarm for the fate of their friends and dear relatives, when the restraints of religion and morality are withdrawn; when every difficulty, which is powerful enough to tempt men to suicide, shall be deemed sufficient to justify it; and when the follies and vices, as well as the inevitable calamities of human life, so often make existence a burden.

A second consideration, and perfectly distinct from the former, is this. By continuing in the world, and in the exercise of those virtues which remain within our power, we retain the opportunity of mitigating our condition in a future state. This argument, it is true, does not stand, in a case where uuelefs prove suicide to be a crime; but if it supply a motive to dissuade us from committing it, it amounts to much the same thing. Now there is no condition in human life which is not capable of some virtue, active or passive. Even pietty and resignation under the sufferings to which we are called, testify a virtue and acquiescence in the divine counsels more acceptable, perhaps, than the most prostrate devotion; afford an edifying example to all who observe them, and may hope for a recompense among the moit arduous of human virtues. These qualities are always in the power of the miserable; indeed of none but the miserable.

Besides the general reasons already stated, and applicable to all cases of suicide, each case has some aggravations peculiar to itself; such as the duties that are deserted; the claims that are defrauded; the (obra, affliction, or disgrace which our death, or the manner of it, causes to our family or friends; the occasion thus given to many for suspecting the sincerity of our moral and religious professions, and those of all others, as well as our own; the reproach we entail upon our order, calling, or sect, &c. &c. Here we might add, that suicide implies a want of reverence for God, and renunciation to his will, who has assigned to every man his part in life to be maintained till the Lord of life and death disposes him from it; that it argues a dishonourable weakness of mind, want of fortitude, in not being able to endure the calamities of life; and the want of a due regard to that future state of existence to which the person chargeable with suicide passes by an act displeasing to God, and admitting of no repentance.

Should it be said, that we do not come into life by our own consent, as a follower does into an army, the answer is obvious, that God, as our creator and the preserver of life, has a much greater right to our humble obedience, than a general can have to that of a follower, how willingly soever he may have enlisted himself into his service. If we consult Scripture in reference to this subject, we find there the same general principles, that may, by construction and implication, be applicable to this subject. Here we find, in a variety of passages, that human life is represented as a term assigned or preferred to us; and, therefore, we are not at liberty to determine for ourselves the duration of our lives. We learn also that Christ and his apostles inculcate upon their followers, both by doctrine and example, no virtue so frequently and so earnestly as patience under affliction; and that the conduct of the apostles, and of the Christians of the apostolical age, affords no obscure intimation of their sentiments upon this point. In this world they experienced every extremity of outward injury and distress; and the change which death brought with it was, in their expectation, infinitely beneficial. Yet it never entered into their minds to hasten this change by an act of suicide; and this affords a very strong presumption that they apprehended some unlawfulness in the expedient.

In defence of suicide, many arguments have been urged, and particularly this following; that if we deny to the individual a right over his own life, it seems impossible to reconcile with the law of nature that right which the state claims and exercises over the lives of its subjects, when it ordains or inflicts capital punishments. It is also said that it will be equally difficult to account for the power of the state to commit its subjects to the dangers of war, and to expose their lives without scruple in the field of battle. This reasoning we observe, is founded on an erroneous principle, viz. that the state acquires its right over the life of the subject from his own consent; but the truth is, that the state derives this right, neither from the consent of the subject, nor through the medium of that consent, but immediately from the donation of the Deity.

No writer has discussed the subject of suicide more amply than Mad. de Stael, in her “Reflections sur le Suicide,” printed at London in 1819. Although it must be admitted that every act by which a man voluntarily causes his own death is not criminal, yet all such acts are suicide. Circumstances occur in which it is a duty to perform acts of which a man’s own death is the necessary result. This is the
the cafe in all the operations of war. Besides these suicides of duty, there are other cases of the hazard or sacrifice of life, which are considered as acts of virtue, requiring singular magnanimity, and justly distinguished by the most splendid reputation. Codrus and Decius present themselves to the recollection of every reader. Volunteers for the most perilous services are easily found; such are mounting a battery, or boarding a ship. They are arraigned on a charge of superstition, their death being neither demanded by duty, or performed for the preservation of a community or an individual, are yet generally considered as acts which, whether they be strictly moral or not, can only be performed by minds of the most magnanimous virtue. The suicide of Cato is of this kind. The merit of Regulus's return to Carthage was enhanced, in the opinion of one of the most sensible and moderate of moralists, principally by his certain knowledge of the death which his barbarous tormentors had prepared for him. Every cafe in which a man prefers death to guilt is a suicide of duty. Of this nature is all martyrdom, where life is to be saved only by false pretensions, or by compliances which the conscience of the martyr deems still more criminal. Among the early Christians there prevailed a fort of ambition of martyrdom, which the fathers of the church condemned as the fruit of misguided zeal, but which the people considered with reverence. Dying men deplored the natural death which robbed them of the honours of martyrdom. Another form of suicide was allowed by the most illustrious Christian teachers. They allowed a woman to kill herself in order to prevent an involuntary, and therefore an imaginary, pollution of the body, when the mind remained perfectly spotless. They did not, indeed, with Lucretia, claim this privilege from the flame of past violation; but they permitted it, for the prevention of that which was to come. It is needless to observe, that this opinion can be justified by no principle; but it is evidently an excrescence from the principle of a suicide of duty, and proceeds partly from the confusion of guilt with disgrace, and partly also from the abusive application of moral terms to physical things.

Opposed to the voluntary deaths, which are enjoined or applauded, are two classes of culpable suicide, which are termed the criminal and the vicious. A criminal suicide is that by which a man, under the influence of selfish impatience or apprehension, withdraws himself from the performance of evident, urgent, and important duties. This is that kind of selfish suicide which argues, at least, the vicious purpose of withdrawing from the practice of virtue, and destroying the power of rendering service to mankind. For these purposes, life is to be endured when it is miserable, as well as sacrificed when it is most happy. And it must be acknowledged as an indubitable truth, that it is a more excellent habit to regard life as an instrument of serving others, than as a source of gratification to ourselves. Whatever theoretical principles are adopted, it is evident that it can never be praiseworthy, or even lawful, to sacrifice life, but in the observance of duty, or in the practice of virtue; that suicide, to be moral, must be for others; and that if there be a few beings so eminently useful, as well as removable, that their early approaches to an exception, they are to be viewed with that mercy, which is the first virtue of religious creatures, and without which we are unable to contemplate perfection.

Mad. de Stael calls the suicides of duty and virtue by the names of devotion and sacrifice; and they are thus distinguished from the suicides of selfishness. This ingenious female writer discards the vulgar notion, that suicide is a proof of cowardice. To suffer well, it is said, is a proof of patience, of fortitude, and of firmness; but boldly to seek the means of deliverance from suffering, is represented as the office of courage. Patience endures the gangrened limb; courage encounters the terrors of amputation; and it is alleged, that words are distorted from their natural sense, to call that man a coward, who has completely conquered the fear of death. But the question still recurs, whether death is not a lesser evil in the view and estimation of persons disposed to suicide, and under the influence of the principles and feelings that agitate their minds at the moment of reflection and anticipation, than the disgrace or diflire, or other evils, which they would thus endeavour to prevent or escape: accordingly, though a man, generally speaking, cannot be denominated a coward who has vanquished the fear of death, yet he is mere a coward, or at least polluted in a lower degree of virtuous fortune, than a person who has overcome the dread of greater evils, and who has resolution to live in order to encounter them with patience and resignation, till Providence orders his discharge.

Among the most remarkable persons who have contended for the innocence, and even for the merit of some suicides, are two eminent English divines of the 17th century, whose writings have long since sunk into almost total oblivion. The first was the celebrated Dr. Donne, who was probably driven to the contemplation of this question by his own sufferings; and who, during the period of his calamities, wrote a book entitled **Breviary**, and who afterwards bade it "both the presb and the fire," desiring it to be remembered that it was written by Jack Donne, not by Dr. Donne.** This book, which is ingenious but paradoxical, was published many years after his death by his son, a disaffected young man, tempted by his necessities to forget his father's prohibition. (See the biographical article **Dorne**.) Henry Dodwell also, the learned non-juror, maintained the innocence of suicide in some cases, in an apology for the philosophical writings of Cicero, prefixed to a translation of "Cicero de Finibus," by his brother non-juror, the noted Jeremy Collier, a writer remarkable for vulgar threwness and coarse vigour. (See **DODWELL AND COLLIER.** Befides the writers on this subject to whom we have already referred, we may mention Watts against Self-Murther, and Clarke on Nat. and Rev. Religion.

In the East, suicide is in some instances not only legal, but esteemed to be even meritorious; and this is laid to be on the authority of the sacred books of the Hindoos. We are informed by Mr. Colebrooke (At. Ref. vol. viii.,) that legal suicide was formerly common among the Hindoos, and is not now very rare. Widows burning with the corpse of their husbands may be reckoned of this class of self-murder. It is called Sati; and under **Sutter** in this work, a copious account will be found of this horrid sacrifice. Among men, drowning themselves in holy rivers, is often referred to of late than burning. The junction of two rivers is mystically contemplated by the enthusiastic Hindoos, and all acts in themselves good, are rendered vastly better if performed at such a spot. (See **Junctions and Triumphs.** At such junctions, called **Sangam,** enthusiastic Hindoos sometimes drown themselves, or cut their throats. Burning, is, however, occasionally, though rarely, referred to by men. We may here advert to the early instance given of this by Calanus, the Brahman, in the presence of Alexander and his army. (See **Calaun.** His name probably was **Kala.** Some Hindoo poems of great celebrity and beauty describe very pathetically the burning of the aged and blind parents of a small Anchorite, accidentally slain by
one of the monarchs of antiquity, named Daifartha, the
mortal father of the incarnated hero Rama. (See Rama:
and of Daifartha, see something under Sani.) This story
is beautifully told in the Ramayana, and in other poems;
and a text of law is quoted by the commentator to prove
in such cases the legality of suicide. A particular and
very meritorious method of personal combustion, consisting
of fanning the body all over with cow-dung, and setting
it on fire, is called Kari/bagni; which fee. And under the
article Sankaracharya will be seen an instance of its
application on the person of the celebrated and elegant
scholar of that name. Perious afflicted with loathsome,
and incurable diseases, have not unfrequently casued them-
selves to be buried alive. Among the lowest tribes of
the inhabitants of Berar and Gondiwalla, suicide is occasionally
vowed by such persons in return for boons solicited from
idols; and is fulfilled by the successful votary throwing
himself from a precipice situated in the mountains between
the Tapto and Nirmada rivers. The annual fair held near
that spot at the commencement of spring, usually witnessed,
it is reported, eight or ten victims of this superstitious.

In the Mahratta country, in Benares, and probably in
other parts of India, there is a particular tribe, which fur-
ishes individuals ready to devote or sacrifice themselves for
the attainment of any object earnestly desired, either by
the individual or the family; or, it is said, even by strangers.
The recovery of a debt is sometimes effected by these
means; and an old woman is usually the medium. Revenge,
as well as money, is bought by this process. The old lady
places herself conspicuously before the door of the debtor,
threatening self-destruction in default of satisfaction; her
blood refting on the head of the uncomplying party. See
Ruskea and Surabhi.

We may conclude, that instances of self-murder on these
occasions rarely occur. Sometimes the creditor, or seeker
of redress, will carry a cow or a calf before the door of the
defendant, or offending person, threatening, in the event of
refusal or delayed satisfaction, to kill it; the fin refting on
the uncomplying party. In these ufages we see how inad-
quate the law is found to be in securing the property of in-
dividuals, and to what shifts they are reduced in seeking the
justice that, under enlightened governments, is fo promptly
afforded.

In the Ayin Akhery is said, that the Hindoo reckon
different modes of suicide to be legal, and free to be preferable
to others. These are, 1. Starvation. 2. Being covered
with cow-dung, and consumed by fire. This is the mode
called Kar/bagni. 3. Being buried in snow. 4. Going
into the sea at the mouth of the Ganges, (the junction of
the holy river and the sea,) there praying and confessing
sins, until the alligators devour the penitent. 5. Cutting
one's throat at Allahabad, at the junction of the Ganges
and Jamna.

Among the various methods of legal or meritorious su-
icide, said to be in practice with the Hindoes, we should have
expected to find that concerning which we have lately heard
so much, viz. being crushed under the wheels of the ponde-
rous car of the god of Jagnath, and other idols. (See Ja-
ganath.) But we are inclined to think, that the victims of
superstitious, thus self-immolated, are not by any means so
numerous as might be supposwed from some recent publica-
tions. Dr. Buchanan, in his interesting tract, entitled "Chri-
stinian Recherches in Asia," describes his visit to Jaga-

he was present on the grand days of the procession, at the
most crowded seafon, and attended closely at the wheels of
the car. Among the many thousands of pilgrims that re-

bort to Jaganath at the annual fair,—so many thousands,
that a hundred thousand, more or less, are scarcely, it is
said, observable,—it might be reasonably expected that some
individuals would be mad or euthaustic enough to throw
themselves before the chariot-wheels, and be crushed to
death. This, we think, is likely to happen occasionally;
but we believe it is not common. The writer of this article
has attended, in different parts of India, the procession of
the ponderous cars, on which the idols of Hindoo worship
are annually exhibited to the admiring populace; but he
never saw an instance of immolation; nor did he ever know
any one, and he has inquired of many persons, who had seen
such. All have frequently heard of them. The story is
handled from one to another, and believed by most.
The language and practice of the Hindoes, however, seem
to familiarize the terms of legal suicide and veinal falsethood.
See Saraswatj.

SUIDAS, in Biography, the author of a Greek Lexicon,
of whom so little is known, that some have doubted whether
a person of this name ever existed. But his name is actually
found in all the MSS. of his lexicon, and is often mentioned
by Rufinus in his Commentary upon Homer. Croesus
and some others suppose that he lived under Constantius,
the son of Leo, emperor of the East, who began his reign
in 912; and others say, that he lived at a later period than
the year 1180. Bentley says of him, that he has brought
down a point of chronology to the death of the emperor
Zimicces, i.e. to the year of Christ 973; so that he seems
to have written his Lexicon between that time and the death
of the succeeding emperor, which was in 1035. The
Lexicon is a compilation from various authors, made some-
times with, and sometimes without, judgment and diligence.
Notwithstanding its errors and imperfections, it is an useful
book, and a storehouse of all sorts of erudition. It fur-
nishes an account of poets, orators, historians, &c. with
many excellent passages of ancient authors, whose works are
lost. It was first published at Milan in 1499, in Greek,
and has been twice printed with a Latin version; but the
best edition is that of Kuller, printed at Cambridge, with
a Latin version and notes, in 1705, in 3 vols. fol. On this
edition Touph has bestowed much pains. Fabricius has
a large alphabetical index of the authors mentioned by Suidas
in his Lexicon.

SUIEN-PIN, in Geography, a town of China, of the
third rank, in Tche-kiang; 25 miles N.W. of Tchau-
tcheou.

SUJERMA, a town of Hindoostan, in the cirkar of
Gohud; 25 miles W. of Gohud.

SVIJAGA, a river of Russia, which runs into the
Volga, near Sviatz, in the government of Simbirk.

SVIJAJSK, a town of Russia, in the government of
Kajan, at the union of the river Sviagha with the Volga;
20 miles W. of Kazan. N. lat. 55° 45'. E. long. 48° 34'.

SUI-KEOU, a town of China, of the third rank, in
Chen-fi; 20 miles S. of Tai-yuen.

SUILEKEM, a town of the island of Bommelvaert;
5 miles W. of Bommel.

SUILLEAT, a river of England, in the county of
Oxonfer, which runs into the Avon, near Tewkesbury.

SULLUS, in Botany, a name given by Micheli to a
kind of Fungus, called Foricum in Italian, either because
it is the favourite food of hogs, or only fit for those animals
to eat. There are, however, some wholesome species,
which, with the noxious ones, are now referred to the Boletus of Linnæus, Perforo, &c.

SULLY, in Geography, a small island in the Bristol Channel, near the coast of South Wales. N. lat. 51° 23'. W. long. 2° 11'.

SVINOE, one of the Faroe islands, in the North Atlantic ocean. N. lat. 61° 56'. W. long. 6°.

SUPPES, a town of France, in the department of the Marne, and chief place of a canton, in the district of Châlons-sur-Marne, on a river of the same name; 15 miles W. of St. Mesenhouse. The place contains 2165, and the canton 6649 inhabitants, on a territory of 327¼ square miles, in 16 communes. Alto, a river of France, which runs into the Aisne, 6 miles N.E. of Rouay, in the department of the Aisne.

SVIR, a river of Russia, which forms a communication between the lakes Ladoga and Onizeloe.

SUIRE, or Siva, a river in Ireland, which rises in the western parts of Slieveblom, but chiefly from the lofty eminence of that mountain called Ben-dagh, i.e. the black hill, on the confines of the King's county and Upper Ormond. This river falls from four miles through a very fertile part of the county of Tipperary, watering the towns of Thurles, Holy Cross, and Cashel; and continues nearly in the same direction until obstructed by the Waterford mountains, where it is compelled to take a northerly course through Clonmel, and thence to Carrick-on-Suir. Here it leaves the county of Tipperary, and flows easterly, forming the boundary between the counties of Waterford and Kilkenny. It next passes the city of Waterford, and, about eight miles lower, forms a fine confluence with the Barrow, already augmented by the Nore. These united rivers flow together several miles, until they fall into St. George's Channel, at the beautiful bay of Waterford. They are called the Three Sifters, as having their sources in the same mountain, and, after widely separating, thus meet before they come to the sea.

The Suir is navigable for ships of large burden as far as Waterford, and for smaller vessels to Clonmel. It is about 100 miles in length, and its banks, in many parts, are remarkable for rich and romantic scenery. There are several bridges to cross this river; but the largest is that at Waterford, which is about 800 feet across. The tide rises here from nine to twelve feet, and is perceptible many miles higher. The water, in these parts, occasionally exhibits a phosphoric appearance, which varies at different times of the year, but is chiefly remarkable at the high or spring tides in autumn. See Barrow, Nore, and Slieblom.

SUIRDFORD. See Schweinfurt.

SUISOPOUR, a town of Hindoostan, in the cirque of Rantapour; 36 miles S.E. of Rantapour. N. lat. 26° 41'. E. long. 77° 15'.

SUIT, SUTE, SEISE, in Law, (from the French suite, a following another,) is used in divers senses. As, suit in law, which is of two kinds, real and personal; the same with what we call real and personal actions; from which also proceed mixed actions. See Action.

Suit in Equity or Chancery, commences by preferring a bill to the lord chancellor in the style of a petition, praying relief at his hands, and also proceeds of subpoena against the defendant; perhaps by this or that action. The suit in equity is also prayed, commanding the defendant to cease. The bill must call all necessary parties before the court, otherwise no decree can be made to bind them, and must be signed by counsel, as a certificate of its decency and propriety. When the bill is filed in the office of the fix clerks, if an injunction be prayed therein, it must be at various stages of the cause, according to the circumstances of the case. But, upon common bills, as soon as they are filed, process of the subpoena is taken out; which is a writ commanding the defendant to appear and answer to the bill, on pain of 100£. And if the defendant, on service of the subpoena, does not appear within the time limited by the rules of the court, and plead, demur, or answer to the bill, he is said to be in contempt, and is liable first to attachment, then to an attachment with proclamation, next to committal of rebellion, afterwards to the search of a terjeant at arms, and, lastly, to a sequestration. After an order for sequestration issues, the plaintiff's bill is to be taken pro confesso, and a decree to be made accordingly. But if the defendant is taken upon any of this process, he is to be committed to prizon till he puts in his appearance or answer, and performs what this process is designed to enforce, and clears his contempt by paying the charges.

The process against a body corporate is by distinguishing, to detach them by their goods and chattels and process, till they shall obey the summons of the court. And for the process against a peer and member of the house of commons, see Letter Misse.

If the defendant appears regularly, and takes a copy of the bill, he is next to demur, plead, or answer. See Daumier and Pello.

The most usual defence that is made to the plaintiff's bill is an answer given in upon oath, or the honour of a peer or peers; but where there are amicable defendants, their answer is usually taken without oath, by consent of the plaintiff. If the defendant lives within twenty miles of London, he must be sworn before one of the masters of the court; if farther off, there must be a domicil potestate in his answer in the country, where the commissioners administer to him the usual oath; and then, the answer being sealed up, either one of the commissioners carries it up to the court, or it is sent by a messenger, whorawer he received it from one of the commissioners, and that the same has not been opened or altered since he received it. An answer must be signed by counsel, and must either deny or confess all the material parts of the bill; or it may confess and avoid, i.e. justify or palliate the facts. If one of these is not done, the answer may be excepted to for insufficiency, and the defendant be compelled to give another. A defendant cannot pray any thing in this his answer, but to be dismissed the court; if he has any relief to pray against the plaintiff, he must do it by cross-bill.

After answer put in, the plaintiff, upon payment of costs, may amend his bill, either by adding new parties or new matter, or both, and the defendant is obliged to answer afresh to such amended bill. But this must be before the plaintiff has replied to the defendant's answer, by which the cause is at issue; for afterwards, if new matter arises, which did not exist before, he must set it forth by a supplementary bill. There may be also a bill of revoir, and likewright a bill of interpleader, where a person who owes a debt or rent to one of the parties in suit, but, till the determination of it, he knows not to which, desires that he may interplead, that he may be safe in the payments. In this case, it is usual to order the money to be paid into court, for the benefit of such of the parties, to whom, upon hearing, the court shall decree it to be due.

If the plaintiff finds sufficient matter confessed in the defendant's answer to ground a decree upon, he may proceed to the hearing of the cause upon bill and answer only;
in which case, he must take the defendant’s answer to be true in every point. Otherwise the court is for the plaintiff to reply generally to the answer, averring the bill to be true, certain, and sufficient, and the defendant's answer to be directly the reverse, which he is ready to prove as the court shall award; upon which the defendant rejoins, averring the like on his side, which is rejoining ifue upon the facts in dispute. These are proved by examination of witnesses, and taking their depositions in writing. For the purpose of examining witnesses in or near London, there is an Examiner’s office, and elsewhere it is done by commissio. When the depositions of witnesses are taken, they are transmitted to the court with the same care that the answer of a defendant is sent. When they are all examined, the depositions may be published, by a rule to pass publication; after which they are open to the inspection of all the parties, and copies may be taken of them. The cause is then ripe to be set down for hearing, which may be done at the procurement of the plaintiff or defendant before either the lord chancellor or the master of the rolls, according to the discretion of the clerk in court, regulated by the nature and importance of the suit, and the arraignment of causes depending before each of them respectively. Either party may be summoned to hear judgment on the day fixed for the hearing; and then if the plaintiff does not attend, his bill is dismissed with costs; or if the defendant makes default, a decree will be made against him, which will be final, unless he pays the plaintiff's costs of attendance, and gives good caue to the contrary on a day appointed by the court. A plaintiff's bill may also at any time be dismissed for want of prosecution, which is in the nature of a nonsuit at law, if he suffers three terms to elapse without moving forward in the cause. For the method of hearing causes, see Hearing.

The chancellor's decree is either interlocutory or final. If any matter of fact is strongly controverted, it is referred to a jury upon a feigned issue.

If a question of mere law arises in the course of a cause, it is referred to the opinion of the judges of the court of king’s bench, upon a caue flated for that purpose. Another thing also retards the completion of decrees. Frequently long accounts are to be settled, incumbrances and debts are to be inquired into, and a hundred little facts to be cleared up, before a decree can do full and sufficient justice. These matters are always by the decree on the first hearing referred to a master in chancery to examine, which examinations frequently last for years, and then he is to report the facts, as it appears to him, to the court. This report may be excepted to, disproved, and overthrown, or otherwise confirmed, and made absolute by order of the court.

When all ifues are tried and settled, and all references to the matter ended, the cause is again brought to hearing upon the matters of equity referred; and a final decree is made, the performance of which is enforced (if necessary) by commitment of the peron, or sequestration of the party's estate. And if by this decree either party thinks himself aggrieved, he may petition the chancellor for a rehearing. But unless a rehearing be defined, the decree signed by the chancellor, and enrolled of course. (3 Geo. II. c. 30.) However, a bill of review may be had on sufficient cause alleged: and from this court the dernier resort is a petition of appeal to the house of lords. Bl. Com. vol. iii.

Suit of Court, or Suit of Service, an attendance which the tenant owes the court of his lord. See Secta and Service.

Suit Covenant, when your ancestor hath covenanted with nine to fuc to his court.
much as in them lies; and if individuals refuse, it is the
bounden duty of the legislature, on a general scale, to do
any thing, and every thing in its power, towards the re-
moval of grievances, which may and ought to be removed,
and to which nothing can be objected, but the pride and
caprice of a few individuals; justice being no further con-
cerned than in pecuniary compensation. The crown has lately
fet a high example, by the sale of many, if not most of its
claims of this nature, at a fixed and moderate rate; an ex-
ample, which it is very defirable may be enforced on all
inferior lords, who indeed themselves, it must be presumed,
in fact and law, held only of the crown.

SUITÉ, Fr., a suit, fet, or feries of movements, in
Musice. At the beginning of the last century, there were
two kinds of fonatas and concertos in Itale; the one was
called fonate et concerti da chiesa; and the other, fonate et con-
certi da camera. The compositions da chiesa, for the church,
were more grave, studied, and rich in harmony. While
those da camera, or private concertos, were composed of a
set of light dancing air, as an allemanda, corrente, minuetto,
fandango, gavotta, and giga, or jig. Those the French
call fait; and Handel calls his two first books of leffons,
Suites des Pieces. The first and third fet of Corellis fonatas
were composed for the church; the second and fourth for the
chamber. And his first eight concertos are concerti da chiesa,
and the last two concerti da camera. And as it was very
common in Italy, on great fes, for the principal violin
to play foles between the several parts of the masses, or be-
tween the motetto fongs by great vocal performers, we be-
thieve that the first fes of Corelli were composed for and played in the church; and the fix last for the chamber.

SVITEI, in Geography, a town of Sclavonia, on the
Save; 23 miles E.S.E. of Posega.
SUK el Harf, a town of Arabia, in the country of
Yemen; 28 miles S.E. of Saade.
SUKAKO, a town of Sweden, in the government
Ulea; 12 miles from Braheild.
SUKAIS, a town of Sweden, in the government
Abo; 23 miles N. of Bornoneborg.
SUKAN, or SUKAN, a town of the desert of Syria,
neat Charid; a warm sulphurous spring; 140 miles S.S.E.
of Aleppo.
SUKASERAY, a town of Hindooftan, in the cir-
car of Chandere; 15 miles S.W. of Seronge.
SUKASSA, a town of Africa, in the Vled de Nune.
N. lat. 27° 23' 11" W. long. 10° 10' 11".
SUKERRABA, a town of Arabia, in Yemen; 4 miles
S.S.E. of Othama.
SUKE-SHUE, SHUKESHY, or Shububu. See SHU-
HUHU.
SUKI, a town of Asiatic Turkey, in Natolia, governed
by an aga; 12 miles N.E. of Milet.
SUKKONDA, a town of Africa, on the Gold Coaf, in
district of Anta; where the trade in gold is very
considerable, and where the English, French, and Dutch,
have factories and forts.
SUKOR, or SUNKAR, a town of Hindooftan, in
Sehwan, on the Indus; 5 miles W. of Behker.
SUKOS, a town of Bengal; 18 miles N.E. of Nat-
tore.
SUKOTYO, in Zoology, a genus of the class and
derder Mammalia Bruta. Horn on each side near the eyes.
There is only one

Species.

INNUSUS. This species has an upright mane, which is
short, narrow, reaching from the top of the head to the
rump. This animal is described by Dr. Shaw. "This," ac-

ording to Niewhoff, its only describer, and who has
figured it in his Travels to the East Indies, "is a quadruped
of a very singular shape. Its size is that of a large ox;
the snout like that of a hog; the ears long and rough, and
the tail thick and bushy; the eyes are placed upright in the
head, quite differently from those of other quadrupeds.
On each side the head, next to the eyes, stand the horns, or
rather the teeth, not quite so thick as those of an elephant.
This animal feeds on herbage, and is seldom taken. It is
a native of Java, and is called by the Chinese Sukotyo." Niewhoff was a Dutch traveller, who visited the East
Indies about the year 1563, and continued his peregrinations
for several years.

SUKPORAH, in Geography, a town of Hindooftan,
in Bahar; 4 miles N.E. of Bahar.
SUKRIA, a town of Peria, in the province of Irak;
42 miles N. of Hamadan.
SUKTUESKOI, a fortress of Russia, in the govern-
ments of Irkutki; 128 miles S.S.E. of Nertchink.
SUKULSDERAI, a town of Hindooftan, in Oude; 18
miles W.N.W. of Luckow.
SULA, a river of Russia, which runs into the Vitchegea
near Uf Sifolke.—Allo, a river of Russia, which runs into
the Dnieper, 16 miles N.W. of Gorodische, in the govern-
ment of Kiev.
SUL, in Ornithology, a name given by Hoier, and some
others, to a bird, described as a distinct species of the web-
footed water-fowl, but seeming to be no other than the
anfer breonis, or island goos.
SULAK, in Geography, a river of Russia, which runs
into the Caspian sea, 8 miles N. of Atrachane.
SULAPOUR, a town of Hindoostan, in Dowlatabad;
15 miles S. of Naldourouk.
SULASSA, a town of Persia, in Khorasan; 350 miles
N.N.E. of Herat.
SULAT, a town on the E. coast of Sumur. N. lat.
12° 5', E. long. 125° 30' 0'.
SULAU, or ZULAU, a town of Silezia, which gives
name to a lordship, in the principality of Oels; 17 miles
N.W. of Oels. N. lat. 51° 6', E. long. 17° 10'.
SULAW, a town of Germany, in the Middle Mark of
Brandenburg; 4 miles S.W. of Zoeilen.
SULBEEK, a small island of Prussia, in the Curich
Haft, at the mouth of the Ruf.
SULCATED LEAF, among Botanists. See LEAF.
SULDINGEN, in Geography, a river of the country of
Hoya, which runs into the Wefer, 4 miles S. of Bahren-
burg.
SULDORF, a town of Westphalia, in the duchy of
Magdeburg; 8 miles S.S.W. of Magdeburg.
SULÉC, a town of the duchy of Warnaf; 45 miles
N.E. of Geneva.
SULEHIE, a town of Egypt, on the right bank of
the Nile; 8 miles S.S.E. of Aina.
SULEJOW, a town of Poland, in the palatinate of
Sirdia; 50 miles E. of Sirdia.
SULÉN, a river of the duchy of Berg, which runs into
the Rhine, 7 miles above Cologne. SULEN ISLANDS, a clifer of small islands in the North
sea, near the coast of Norway, N. lat. 61° 5', E. long.
4° 41'.
SULENDORF, a town of the principality of Lune-
burg-Zelle; 9 miles E. of Ulten.
SULGEN, a town of Switzerland, in the canton of
Zurich; 15 miles N. of Zurich.
SUL

SÜLEN, or Suling, a town of Austrian Swabia; 21 miles N.E. of Salamanfweiler.

SÜLG, or Sylg, a river of the Tyrol, which runs into the Adige, near Glurnez.

SÜLIAGO, or Suliago, a chain of small islands in the Pacific ocean, about 90 miles in length, and 12 in breadth. N. lat. 9° 24′ to 10° 33′. E. long. 125° 27′ to 128° 36′.

Süliago, an island in the Pacific ocean, about 20 miles in circumference, and 20 miles distant from the north-east coast of Mindanao; which gives name to the above-mentioned cluster. N. lat. 9° 27′. E. long. 126° 27′.

SÜLIAO, or Suriago, a town of the north coast of Mindanao, in a bay between two protecting capes. N. lat. 9° 45′. E. long. 126° 31′.

SULIPACHA, a town of South America, in the province of Tucuman; 130 miles N. of St. Salvador de Junjú.

SÜLISKAR, or Bora, a small island in the North sea, about 45 miles from the north-west part of Scotland. N. lat. 58° 44′. W. long. 5° 53′.

SÜLITELMA, the highest of all the mountains of Lapland, and which the natives have long regarded with a kind of awe, is situated in N. lat. 67° 10′, near the margin of a lake that communicates with the Western ocean. It forms three peaks, which have the several elevations of 5520, 5620, and 5910 feet. These peaks are covered with an accumulation of eternal snow, compressed into an extremely hard substance, of the depth perhaps of 100 feet. The sides of the mountain, at the altitude of about 2500 feet, exhibit real glaciers, consisting of icy vaults, sometimes 300 feet high, clutered with sharp-pointed pyramids of solid ice, which is perfectly clear and colourless; but its clefts appear blue. Near the base of this mountain the lake Lomeniari, with an elevation of only 2265 feet above the level of the sea, has a great quantity of snow lying on its banks through the whole year. Half a degree farther north, the Virjari, at an altitude of 1900 feet, is covered with ice in the middle of summer. These observations agree very well with theory, which gives from 2232 to 2236 feet for the height of the mean boundary of congelation in these latitudes. A little below this limit we may place the ordinary clefts of the glaciers, which seem to owe their formation to the alternate influence of thaw and frost, in changing, by degrees, the lower zone of snow into an icy wall. The beautiful and fantastic groups which these glaciers often present are, by the simplicity of the northern tribes, ascribed to the invisible powers of magic. They are hence called "Jegna" in Lapland, and "Jöckel" in Iceland, and "Gyckel" in some parts of Norway, from the Gothic verb "gyckla," the same as the German "gaukela," to trick or bewitch the eye.

The term "Sulitelma," and "Ben-la-di." the name of a remarkable mountain in Pershtireh, have the same origin; meaning, in the Lapland and Gaelic languages, "the hill of God!! the rude inhabitants of both countries being accustomed anciently, at certain feasts, to perform religious rites on their summits.

SULKAVA, a town of Sweden, in the province of Tavastland; 1158 miles E.N.E. of Tavathus.

SüLENKAI, or Suling, a town of Hinder Pomerania; 10 miles W.N.W. of New Stettin.

SÜLKUZA, a town of European Turkey, in Bessarabia; 16 miles S. of Bender.

SÜL, in Agriculture, a term applied sometimes to a plough. (See Flough.) It is the name of the old plough, especially that of Devonshire.

SUL-Paddle, a term applied to a plough-paddle; the name of the paddle by which old ploughs were cleaned from the earth which hung about them.

SÜLLAGE, in Rural Economy, a term applied to a drain of filth, or the dirt cleaned up from the streets.

SÜLLANE, in Geography, a river of Ireland, in the county of Cork, which runs into the Lee, 15 miles W. of Cork.

SÜLFELD, a town of the duchy of Holstein; 10 miles S.S.W. of Segeborg.

SÜLLIVAN, a post-township of America, in New York, at the north extremity of Madison county, bounded north on Oneida lake, east by Lenox, south by Cazenovia and Smithfield, and west by Onondaga county; about 14 miles from north to south, and 54 from east to west. Sullivan was first erected in 1803, then in Chenango county; and in 1809, the eastern and largest part was erected into the town of Lenox. The settlements commenced about 1798. The population of this town is 1774. The southern part is hilly, but the northern and largest part is quite level. The Canaseraga and Chittenango creeks furnish good mills in abundance. Here are eight school-houses and a meeting-house. It furnishes iron-ore, but its chief mineral is gypsum. — Allo, a county of New York, ereched in March, 1803, from Ulster county; so called in honour of General Sullivan, an officer in the revolutionary army. Its form is irregular, and the whole area may be computed at 625,000 acres. It is bounded north by Delaware county, east by Ulster county, south by Orange county, and west by the Delaware river, or the state of Pennsylvania; situated between 41° 24′ and 42° N. lat., and 71′ and 7° 68′ W. long. from New York. It contains, besides Thompson the capital, Bethel, including 737; Liberty, having 410; Lumberland, with 525; Mamakating, with 1865; Navinlock, having 935; and Rockland, including 309 inhabitants; the whole population consisting of 6108, and the number of electors being 466. This county is distant 80 miles, in a right line, about S.W. from Albany, and about the same distance N.W. from New York, and 41 miles W. from the Hudson. A large proportion of the county is mountainous, though the vales and plains are extensive and fertile. It has several streams, besides the Delaware river, that forms its well boundary; and several small ponds and lakes, the principal of which are White lake, Black lake, and Great lake, or lake Superior. In 1810 this county had 1597 spinning wheels, 259 looms, 1252 sheep, and 48,923 yards of cloth produced from household industry. Ulster and the county fend four members to the house of assembly. — Allo, a township of Chemehug county, in New Hampshire, containing 516 inhabitants. — Allo, a post-town of Maine, in Hancock county, in Frenchman's bay; 23 miles N.W. of Goldsborough; containing 711 inhabitants. — Allo, a county of East Tennesee, in Washington district, containing 6647 inhabitants, of whom 773 are slaves. At the court-house there is a post-office.

SÜLLIVAN'S ISLAND, one of the three islands which form the north part of Charleston harbour, in South Carolina; about 7 miles S.E. of Charleston. — Allo, an island in the Mergui Archipelago; about 35 miles in extent from north to south. N. lat. 10° 48′ to 11° 21′.

SÜLSONIACE, in Ancient Geography, a station of Britain, in the second iter or route of Antonine, placed between Verolamium or St. Alban's and London; 9 miles from the former, and 12 from the latter; which all our antiquaries agree to have been at Buckleigh hill, where many Roman antiquities have been found. Mr. Baxter, and
SULLY, MAXIMILIAN DE BETHUNE, DUKE OF, in Biography, marshal of France, and prime minister under Henry IV., was born at Rofni in 1559, and educated by his father, who had sprung from an illustrious family of the ancient counts of Flanders, in the reformed religion, to which he hedged his son, even in his tender years, through life. At the age of eleven he was presented to the queen of Navarre, and her son Henry, whom he followed to Paris, where he pursued his studies. Here he lay concealed for three days, during the horrible massacre of St. Bartholomew's in 1572, and thus, by favour of the principal of the college of Burgundy, he escaped the fate to which all the Huguenots were condemned. At this time Sully entered into the service of the king of Navarre; taking leasons in history and mathematics from the young king's preceptors; and, in some years, he entered into the army. After the death of Charles IX., Henry of Navarre quitted the court, and placed himself at the head of the Huguenot party; and on this occasion Sully entered into the ministry of a volunteer. In his youth he manifested more valour than military skill; but he possessed another very important and useful quality, which was economy, and which enabled him to maintain his own expenses a company of cavaliers: and it was by the exhibition of this quality that he gained the friendship and confidence of Henry. In 1580, the king conferred upon him the office of counsellor of Navarre, and that of his own chamberlain. During the time which he spent in the service of the duke of Anjou, brother to Henry III., and in which he entered for the purpose of regaining some property that belonged to his family, he attended that prince in his visit to the English court; but when he found that the bigotry of the duke led him to treat his Protestant followers with coldness and indifference, he abandoned his service, and returned to that of the king of Navarre. Henry willing at this time for a confidential person, whom he could employ at the court of France to watch and penetrate the design of the League, sent Rofni thither for this purpose in 1583. During his residence there he married, at the beginning of 1584, Anne de Courtenay, descended from an illustrious family of that name. In the following year he was summoned by Henry to assist in the approaching war with the League; and having joined him without hesitation, he presented him with a sum of money which he had amassed, and which was honourably employed in various sieges and battles. In 1586 he concluded a treaty with the deputies of Switzerland, by which they stipulated to furnish 20,000 men for the royal cause. In the battles of Coutras and Ivry he acquitted himself so well, that his fidelity and bravery were signalized by the approbation and applause of Henry. Having lost his wife, he married again in 1592, and for some time lived in retirement. But being neglected by Henry, who was now lawful king of France, he zeal in his service was somewhat abated; however, when his presence and assistance became necessary, his affection for his master induced him to forget any apparent or real flight, to which he had been treated, and to aid him again with his counsel. Henry, being a Protestant, found it difficult to maintain, without very hazardous struggles, his tenure of the throne; and began seriously to think of reconciling himself to the Catholic faith. But one of his chief objections was an apprehension that he should thus offend his former faithful friends, and reduce himself to the necessity of fighting against them. Rofni, more consistently perhaps to principles of policy than to those of truth and integrity,

Vol. XXXIV.

persuaded him to adopt the measure, to which his interest more than the conviction of his judgment led him to incline. His arguments prevailed; and Sully himself was employed to negotiate with the Catholic chiefs on the ground of Henry's abjuration of Protestantism. Sully, however, never sacrificed his own conscience or professions; but he acted in this instance with a firmness, that religion was a matter of little importance to Henry himself, and that the question, whether he was to be denounced Calvinist or Catholic, was of trivial consideration compared to that, whether there were to be peace or war in France. Such temporizing measures, however, cannot be said to reflect honour either on the counsel of Sully or the character of Henry; nor did they immediately produce the effect which might have been expected. The League, supported by Spain, continued to oppose Henry's tranquil possession of his crown; and for this purpose the talents of Sully, both in the cabinet and the field, were found to be very important and useful. Accordingly they were called forth into vigorous exertion; and in the progress of his promotions, he was made secretary of state in 1594, member of the council of finance in 1596, and superintendent of the finances in 1598; and, moreover, he was employed in many interesting negotiations, one of which was that for the king's second marriage to Mary de Medicis. Another of Sully's diplomatic missions was that which produced a confidential interview, in 1601, with Queen Elizabeth at Dover. The accession of James I. to the throne of England, in 1603, afforded occasion to another mission of Sully to that island, where, by his reputation and dexterity of management, he succeeded in renewing the treaties subsisting between the courts of France and Great Britain. As a finance minister, Sully contrived to improve the royal revenues, and to lighten the burdens of the people; but our limits will not allow us to detail the measures which he adopted for this purpose. He was no less firm than wise in his conduct on this occasion. While he was refitting applications for oppressive edicts, to which the king, who was always disposed to listen to the requests of his favourites and mistresses, inclined, his mistresses, d'Entraigues, the marchionesses de Verney, hautly paid to him, "To whom would you have the king to grant favours, if not to his relations, courtiers, and mistresses?"—"Madam," he replied, "you would be in the right, if his majesty took the money out of his own purse; but is it reasonable that he should take it from these of the traders, the artisans, the labourers, and peasants? These people, who maintain him and all of us, find one matter sufficient, and has no need of so many courtiers, princes, and mistresses." The conduct of Sully increased the calumny and abuse of those court minions, whose selfish and ambitious views make them heedless of an extravagance by which they profit, however oppressive it may be to the great body of a nation: but Henry approved it, and regarded his minister as entitled to increasing confidence. The spirit of his administration was that of order, regularity, and economy, joined with that forbearance of manners which he derived from the reformed religion. As an enemy to luxury, he did not encourage the introduction of those arts and manufactures which minister to refined gratification; but agriculture, as the basis of national prosperity, he laboured to promote.

The picture of Sully's own life is thus exhibited by one of his biographers, and it is curious and interesting. "He rose every day at four in the morning, and employed his two first hours in reading and dispatching the memorials which lay upon his desk. At seven he went to the council;
and he passed the rest of the morning with the king, who
gave him orders relative to the different offices which he
held. He dined at noon, and afterwards gave a regular
audience, to which perons of all ranks were admitted.
The ecclesiastics of both religions were first heard; then
came the turn of villagers, and perons of inferior condi-
tion; perons of quality were referred till the last. When
this was concluded, he usually refused his labours till
supper-time, when he caufed his doors to be shut, and lay-
ing aside all business, indulged himself in society with a few
friends. He commonly went to rest at ten; but if any
thing extraordinary had deranged the operation of the day,
he borrowed some hours of the night. His table was
simple and frugal; and when he was reproached with its
plainness, he would reply with Socrates, that if his guests
were wise, they would be satisfied; if not, he did not wish
their company." What would be your majesty's treasury,"
was the reply. Sully was firmly attached to his religion, nor
was any temptation that could be
performed sufficient to pervert his mind, and seduce him
from it. The pope even addressed him with a letter of
eulogy on his administration, and closed it by expressing a
wish, that he would enter into the right faith. In his reply
he said, that it was wise to pray God for the holiness of
his conversion." The faithful services of this
excellent minifter were further rewarded by the post of
governor of Poitou, and grand-maister of the ports and
havens in France; and also, in 1606, by the dignity of a
peer, on which occasion he chose to take his title from his
estate of Sully-sur-Loire. He continued at the
head of affairs till the affaffation of Henry, in 1610. He
was then dismissed from court, with a gratuity of 100,000
crowns, and afterwards lived chiefly in retirement. When
he appeared at the levee, it was in his old-fashioned dress,
with a gold chain about his neck, to which was appended a
large medal with the effigy of his deceased mother. It is
said, that when he was once sent for by the young king
Louis XIII., to give his advice on some important affair,
his uncouth figure excited the mirth of some young courtiers.
Sully, perceiving it, and turning to the king, said, "Sire,
when your father, of glorious memory, did me the honour
to call me to his presence, to consult me in state affairs, he
previously sent away the buffoons." Louis felt the rebuke,
and remained alone with Sully. In 1634 he received the
staff of marshal of France, in exchange for his post of
grand-maister of the ordnance. He died in 1641, at the
age of 83 years. A statue was erected to this great man
by Louis XVI., and his eulogy was made a prize-subject
by the French Academy. The "Memoires de Sully,"
entitled by the author, "Oeconomies Royales," were
written without order or connection, and in a very fimple
fyle. They have been several times printed; and the Abbé
de l'Ecluse gave an edition of them in 1745, which were
arranged in better order, and the language was rendered
more correct. They have always been held in high eifen,
on account of their biological and political information,
and the interesting anecdotes of the perfons and court of

SULLY, in Geography, a town of France, in the department of the Loiret, and chief place of a canton, in the district of Gien, situated on the Loire; 12 miles N.W. of Gien. The place contains 2109, and the canton 6180 inhabitants, on a territory of 345 kilometres, in 10 communes.—Alfo, a town of France, in the department of the Saone and Loire; 7 miles E.N.E. of Autun.

SULM, or Sulmach, a river of Wurtzberg, which runs into the Neckar, near Neckar's Ulm.

SULMGAN, a river of Wurtzberg, which rises near Murhard, and runs into the Neckar at Neckar's Ulm.

SULMONA, anciently called "Sulmo," the place of
Orid's nativity, a town of Naples, in Abrazzo Citra, the
seat of a bishop, containing 11 churches and 12 convents;
21 miles S. of Civita Chieti. N. lat. 42° 3'. E. long.
13° 50'.

SULOW, a town of Poland, in the palatinate of San-
domirz; 8 miles N.W. of Malogocz.

SULPHATES, in Chemistry and Mineralogy, a name
given to crystallizable salts, formed by the combination of
any base with the sulphuric acid; alumine requiring the pre-
ence of potash or ammonia in order to crystallization. The
sulphates are scarcely decomposable by heat alone, but when
infused in contact with charcoal, or any carbonaceous matter,
they are converted more or less completely into sulphures;
which fee. In pure alcohol they are all infusible. All the
folutions of these salts are decomposed by the other salts of
barytes entirely, and nearly so by the salts of lime, the acid
forming a precipitate with these earths. A fimilar decom-
position takes place when any sulphate is added to the soluble
salts of lead, silver, and other metals, whose sulphates are
little soluble. None of the sulphaes are entirely decom-
posed at a moderate temperature by any other acid; the
sulphur being the highest in the order of affinity, with
very few exceptions. But some of the acids partially de-
compose the sulphates, and by taking part of their base,
they reduce the remainder to the state of acid-sulphates.
The nitric and muriatic acids are of this kind, and the tar-
aceous, with regard to the sulphate of potash. But the
acids that are fixed in the fire, such as the boracic, phos-
phoric, and arsenic, decompose the sulphaes totally, in a
red heat long continued.

SULPHATE of ALUMINE, is a ternary compound of argil
or alumine, potash and sulphuric acid. The sulphate of
alumine is made by dissolving pure alumine in equally pure
sulphuric acid, at a boiling heat, evaporating the solution
to complete dryness, and then redissolving the residue in water.
Vauquelin distinguishes seven different kinds of sulphate of
alumine. He has shown, that if a few drops of solution of
potash, or of sulphate of potash, be added to an uncrystal-
lizable solution of sulphate of alumine, the crystalliza-
tion will immediately commence. Sulphate of alumine is
insufible in any heat; but when strongly urged in the fire, it
parts with its acid altogether. (See ALUM and ALUMINE.)
Alum is well known as an article of the materia medica, and
is used as an internal and external remedy for restraining
violent hemorrhages. It is also administered in cases of ob-
ininate diarrhoea, diabetes, and flour albus; though Dr.
Cullen says that it is not to be depended upon in the two latter
diseases. In internments it has been recommended as an
auxiliary to cinchona, and also in confluent small-pox, when
the pulses are bloody; and Dr. Percival regarded it as a
prophylactic in colica pictonum, and a cure for lighter
causes. It is used locally in gargles, and as the basis of in-
fusions in cases of gleet and leucorrhoea, and of colliria in
chronic ophthalmia. The dose in hemorrhages is from
grams 5 to 10, repeated every hour or two, till the bleeding
abates. It is sometimes administered diffused in the serum of
milk, in the form of whey, prepared by boiling 31 of powdered
alum in a pint of milk, and straining. The dose of the whey is
1/2 of or 1/3 of. The official preparations of alum are as
follow; vis. alumen extractum, or dried alum of the Lond.
Ph., prepared by melting alum in an earthen vessel over the
fire,
SULPHATE.

fire, and increasing the heat until the ebullition cease; or, \textit{fulvus aluminis nigricans}, olim, \textit{alumen ybun}, dried sulphate of alumine, formerly burnt alum, of the Edinb. Ph., obtained by melting sulphate of alumine in an earthen or iron vessel, and kept over the fire until it cease to boil; or, \textit{alumen ybun}, burnt alum of the Dub. Ph., prepared by exposing any quantity of alum to the heat of a strong fire in an earthen vessel until it cease to boil. This dried alum has a more astringent taste than the crystallized salt; it is obtained in the form of a light, opaque, white, spongy, friable mass, 100 parts of which contain 36.25 acid, and 63.75 alumine. It is chiefly used as an astringent, to deflux fungus in ulcers, and has been also given internally to the amount of 2 or 3 for a dose in cases of colic.

The \textit{liquor aluminis compositus}, or compound solution of alumine of the Lond. Ph., is prepared by dissolving alum and sulphate of zinc, of each half an ounce, in two pints of boiling water, and filtering the solution. This is astringent and detergent, and is employed as a lotion for cleansing ulcers, and in some cases of cutaneous eruptions. Properly diluted, it is a useful collirium in ophthalmia, and an injection in gleet, and in flor albus, when the discharge proceeds only from the vagina.

\textit{Pulvis fulvus aluminis compositus}, is described under Powders.

\textit{Solutio fulvus aluminis composita}, or compound solution of sulphate of copper of the Edinb. Ph., is prepared by boiling fulvate of copper, sulphate of alumine, of each 3 oz., in 2 lbs. of water, in order to diffuse them, and then adding to the liquor filtered through paper, \textit{\textdegree} oz. of sulphuric acid. This is sometimes used as a lotion for hæmorrhages; and, largely diluted, as a lotion in ophthalmia, and for the treatment of the purulent ophthalmia of infants.

\textit{Sulphate of Ammonia}. See \textit{Sal Ammoniacs}, and \textit{Salts}.

This saline sublimate promotes vegetation; but, according to lord Dunonald, it is not to be had in such quantities as to render it an article of much importance to agriculture.

Sir Humphrey Davy found in some trials, that the effects of this sulphate, as well as those of some others, were, in a certain degree, injurious to barley and grass growing on a light sandy soil, in all cafes, when used in a proportion which equalled one-thirtieth part of the weight of the water in which they were diffused, but less so in this than some others. But that when the proportion was one three-hundredth part, the effect was different. The plants watered with a solution of it of this strength grew in exactly the same manner as similar plants watered with rainwater.

\textit{Sulphate of Barites}. See \textit{Barites}, and \textit{Salts}.

\textit{Sulphate of Copper}. (See Copper.) This salt, as an article of the materia medica, is emetic, astringent, and tonic, when taken internally. As an emetic, it has been given in the early stage of phthisis, and where laudanum has been taken as a poison; and as an astringent and tonic, in alvine hæmorrhages, intermittent fever, epilepsy, and some other specific affections; but other remedies, equally powerful and less injurious, should be employed, and the use of this discontinued. Externally it is employed as an astringent, to confine fungus, and in solution as a stimulant to foul obstinate ulcers. It forms the basis of a very unchemical preparation, Bate’s “\textit{aqua camphorata},” which Mr. Ware recommends, diluted with 16 parts of water, in the purulent ophthalmia of infants. As an emetic, the dose is from gr. i to vi, in f 3 of water; but as a tonic, it should be given in the form of pill, beginning with gr. i, and increasing the dose to gr. i; the official preparations are, \textit{fulvus aluminis sulphatis comp.} of the Edinb. Ph., and cuprum ammonium of Lond., Edinb., and Dub. Ph. For the preparation of the former, see \textit{Sulphate of Aluminis}, fuscus.

The latter, or ammoniated copper of the Lond. Ph., is prepared by boiling together in a glastra mortar \textit{\textdegree} oz. of sulphate of copper, and six drachms of subcarbonate of ammonia, until the effervescence ceases; then wrapping up the ammoniated copper in a lubulose paper, and drying it with a gentle heat. The Edinb. Ph. directs it to be prepared by rubbing thoroughly together in a glastra mortar two parts of pure sulphate of copper with three parts of subcarbonate of ammonia, till the effervescence terminates, and they unite in a violet-coloured mass, which is to be wrapped up in a lubulose paper, and dried, first on a chalk-stone, and afterwards with a gentle heat. It is preferred in a well-flapped glastra phial. According to the Dub. Ph. it is obtained by rubbing 1 oz. of sulphate of copper and \textit{\textdegree} oz. of carbonate of ammonia in an earthenware mortar, till the effervescence ceases, and they unite into a mass, which is to be dried, wrapped up in a lubulose paper, and preferred in a phial closed with a glastra stopper. This preparation has the odour of ammonia, a hot, fleshy, metallic taste, and a rich blue colour. The blue colour is lost by exposure to the air, and the salt acquires a greenish hue. It is tonic and antiphlogistic; and has been principally employed in epilepsy, for which it was first proposed as a remedy by Dr. Cullen; who recommends it not to be continued for more than a month at a time. The dose is gr. i, increased gradually to gr. v, given twice a day, either in pills made with crumb of bread, or combined with valerian.

\textit{Sulphate of Iron}. (See Iron.) This salt, known in commerce by the name of green vitriol, is, with regard to its medicinal properties, tonic, emmenagogue, and antiphlogistic; it has been given with advantage in dysentery, in the latter stage of phthisis, and in amenorrhea, depending on a weakened action of the blood-venulae. The dose is from gr. i to vi, combined with ammoniacum, rubarb, myrrh, or bitter extracts. It has lately been used diffused in water, as a lotion to cancerous and phagedenic ulcers. Its official preparation is \textit{tinctura ferri muriatis}. See \textit{Tincture} and \textit{Iron}.

In reference to Agriculture, sulphate of iron is formed naturally in many places in great abundance, according to lord Dunonald, by the spewage of oxygenation, from the phosphorus or pyritic subfusates. These matters are generally found accompanying the coal flata, as well as coal itself; particularly in such coals as are phlogiferous. This salt is very soluble in water, and is in a high degree injurious to vegetation, when it abounds in soils containing clay and siliceous matter, without any admixture of vegetable or calcareous subfusates. It is decomposed by alkaline salts, forming with them vitriolated tartrar, Glauber salts, vitriolic ammonia, gypsum, and Epsom salt. When added to soils containing calcareous matter, and a due proportion of animal and vegetable subfusates, it has been found, when not used in too great quantities, to have produced beneficial effects in promoting the growth of plants; but experiments have not as yet been made fully to ascertain its effects on arable land.

It may be further noticed, that some very interesting observations have been lately made on this subfusate, as contained in peat of Tintgrith-moor, Bedfordshire, by Dr. George Pearn, in a communication prefaced to the Board of Agriculture. And it is stated, in answer to several queries put
SULPHATE.

by him to J. W. Willaume, ecf. that, in answering them, he shall divide the subject into three articles; first, the peat considered as an object of fuel; secondly, the ashes; thirdly, the salt of peat, or dust: the two last are objects of manure.

I. Peat.—The peat which is found after the removal of the root or exterior surface, to about a spade’s depth, has long been known as an article of fuel. It is, however, used only by cottagers, who burn it on a brick-hearth; it has been discarded from the parlour, the kitchen, the brew-house, &c. as being injurious to grates, and to all sorts of vessels put on it. It cannot be employed in the roasting of meat, as it will impart a disagreeable taste; and it is destructive of all sorts of furniture by the effluvia which it emits, or by the dust or ashes which may chance to be blown from it. If these disagreeable consequences could be obviated, it might be made an article of general consumption, as a substitute for coal, much to the advantage of the fellar and conserver: it is dug out in the form of a brick to a certain depth, well known to the common labourer. This depth must be carefully attended to, lest you should cut out the staple, in which case it could not be retrieved; but this circumstance being attended to, it will grow again to its former state in the space of fifteen years. Thus the whole moor is divided into proper portions, and periodically once in fifteen years.

II. Ashes.—The turf, or surface, and such parts of the peat as do not appear to be of the best quality, are laid up in considerable heaps, and reduced to ashes by the action of fire. The ashes are red.

Answers to Queries.—1. The ashes have been long known as a manure, and the demand is on the increase.
2. The quantity usually laid on an acre, by spreading or fowing it, is fifty buchells, either on grass or arable land.
3. It is laid on hot land. By hot land, we understand sandy, gravelly, chalky soils of a dry nature, such as are burnt up in a long continuance of hot weather. It is most commonly used for grasses; but it is in considerable esteem as a manure for oats or barley, on land of the nature above-mentioned.
4. The vegetable effect is surprising, inasmuch as it will double or treble a crop of any new-lown grafs, such as trefoil, &c.
5. He has seen the benefits arising from it on old pature-land overgrown with moss, which it effectually destroys, and produces in its stead white or Dutch clover. You may, it is laid, trace to an inch the effusion and recommencement of this manure. It is observable, that near the fire-heaps, as far as the wind can carry the lighter parts of the ashes, the production of clover is sure to be abundant; it is equally favourable to the growth of barley and oats.
6. The ashes are bought by a lot of biglers, who carry them in bags loaded on asles to a considerable distance, where they are known to be in great repute: they must come excessively dear to the consumer by this mode of conveyance. The farmers in the vicinity fend for them in waggon, particularly Mr. Brumby, near Sundon, in Bedfordshire, a considerable and intelligent farmer, who increases his consumption every year, both for his grass and arable land.

III. The Salt of Peat, or Dust.—1. The dust or grey saline substance is produced by heating the earth containing this salt to a powder; it is found in particular spots, not universally, the earth not being equally impregnated with it in all places: it has not been known as a manure above fix years; but on trial, greatly increases, it is laid, in reputation and demand.
2. Fifty buchells are the proper quantity per acre. This should not be exceeded, for if it be laid on in too great an abundance, it may prove extremely deleterious.
3. It is used for cold lands. By cold lands are understood clayey or wet grounds.
4. It will much improve the vegetation of fawn grasses, and old pasture, and is equally favourable to the production of corn; the ground, whether grass or arable, being of a cold nature.
5. It is not mixed with lime, or any other substance.
6. The dust is likewise bought by the biglers, and carried to great distances. The nearer farmers likewise fend for the dust in waggon, particularly Mr. Antie, of Dunstable-Houghton, and Mr. Smith, of Sundon, who hold this manure in great esteem.

The following are the experimental hints and remarks of Dr.Pearson on the substance called salt of peat, or dust; which are,
1. That it is a blackish-grey, coarse, and rather heavy powder; has no smell; tastes strongly phytic; readily dissolves in the mouth; did not deliquece on exposure to the air.
2. That it dissolves in four times its weight of water at the temperature of sixty degrees of Fahrenheit, and in twice its weight of boiling-hot water, giving a pale-green coloured solution, with a trifling sediment, which is insoluble in nitric acid.
3. To dissolve (a) he added a little liquid proffix of vegetable alkali, in a perfectly neutral state, which occasioned immediately a most abundant precipitation of proffix of iron; and this stuff was added gradually, till no further precipitation took place.
4. Into the decanted and filtrated fluid (3) was poured liquid, caustic, volatile alkali, but without inducing any change.
5. Into the same fluid (3) was poured liquid carbonate of vegetable alkali, which produced a scarcely perceptible cloudy appearance.
6. Into the solution (3) was dropped the aqueous solution of muriate of barytes, which occasioned immediately a milky appearance.
7. To the solution (3) he added the oxalic acid, and turbidness ensued.
8. A little of the powdery substance called the salt of peat, with concentrated sulphuric acid, produced no emission of fumes or smell.
9. The solution (3) with muriate of barytes, immediately grew thick and white as cream.
10. The solution (3) with carbonate of potash deposited a very copious greenish sediment; and the same effect ensued with caustic volatile alkali.
11. The solution (3) with oxalic acid gave instantly a very turbid, blue-green precipitation.

The preceding experiments, he says, manifest that the melt-salt consists of sulphate of iron, vulgarly called green vitriol of iron, mixed with a very minute proportion of silicious earth and of lime, united either to sulphuric acid, or to carbonic acid. But the presence of the earths, magnesia and argil; the uncombined alkalis, the uncombined acids, are by these experiments excluded. In short, the salt of peat is almost pure sulphate of iron.

Remarks.—1. The salt of peat is, he apprehends, deposited by evaporations which run over the moors where it is found; and hence he should expect many of such waters to be
SULPHATE.

be strongly impregnated with it, and in many parts the soil to be tinged red and yellow by ochre. Very likely, on inquiry, much iron pyrites will be found on or near the moors.

This is, says Mr. Willaume, exactly the fact. This sulphate of iron, the salt of peat, during the heat of summer is frequently found in a crystallized state, white, and cracking under the feet; but is deliquescent in that form, and turns to its former dark colour when the air becomes moist.—Note by Mr. J. W. Willaume.

2. The quantity spread on land is said to be fifty bushels per acre, which he estimates at 2250 pounds avoirdupois: this will give nearly seven ounces and a half per square yard. If a larger quantity be applied, it is observed it will prove extremely deleterious. This is true also of every other substance, such as lime, alkaline salts, marine salts, nay of the dung of animals; for if they be used in certain quantities, they poison plants instead of promoting their growth. This is equally true in the animal kingdom; for there is not an article taken as food, or as seasoning, which is not a poison, if taken in certain quantities. A human creature may be poisoned, or intoxicated, by beef or pudding, according to the quantity of them taken into the stomach. He may be poisoned, or have digestion greatly affected, by salt, or pepper, according to the quantity. In fact, the vulgar notion of the term poison is erroneous; for by it is conceived that substances so called are in their nature positively destructive of life; but the truth is, that the most virulent poisons are, in all reason and fact, only deleterious according to the quantity applied. White arsenic swallowed in the quantity of ten grains or less, will destroy life; but in the quantity of one sixteenth of a grain, it is as harmless as a glass of wine; and further, in that dose it is a remedy for invertebrate agues. It is concluded from these considerations, that there is no admittable contradictory evidence to the testimonies for the fertilizing effect of sulphate of iron, unless by such contradicting evidence the quantity stated to be used exceeds fifty bushels per acre; it being an established fact, that in certain proportions this metallic salt is a poison to plants.

Further, it is supposed that this discovery will give new light, so as to explain fully the rationale of the improvement of land by the burnt earth and ashes from peat-bog and burning. It is usual to account for the effects of these processes, by referring to supposed alkaline or other effects; but of these there is no evidence, nay, on trial, he has not detected them, or at least not in any efficient quantity; but this he knows that such earths and ashes contain oxidy of iron, and as such are used in the manufacture of manures. This communication of Mr. Willaume affords evidence, he thinks, of the truth of this conjecture, for the ashes of the peat which affords the salt “have been long known as a manure, and the demand is on the increase;” of course these ashes contain an unusual quantity of oxidy of iron. A consequence of this reasoning is, that the burnt earths of field are, he supposed, containing oxidy of iron in proportion to the oxidy of iron it contains. Accordingly the ashes of the peat, says Mr. Willaume, have a surprising effect; they will double or treble a crop of any new-founo crops, such as trefoil, &c.; and are fo beneficial, that in spite of the expense, they are carried in bags by biglers to a great distance. The doctor concludes by asserting, that the more he contemplates the facts in Mr. Willaume’s letter, the more evidence he perceives for the truth, that metallic salts, and metal oxides in general, and salts and oxides of iron in particular, are manures, if applied in proper doses. He is zealous that it may be understood, that he considers the salt of peat, and the ashes of peat, as operating in promoting vegetation, analogous to sea-soiling, or condiments, taken with food of animals; that is, analogous to mustard, cinnamon, ginger, &c. which are not of themselves at all or scarcely nutritious, but contribute to render other things nutritious, by exciting the action of the stomach and other organs of digestion and assimilation. He has no doubt of the truth of the proposition, that no living thing, neither plant nor animal, can grow and live in a state of visible action without constant supplies of matter which has been alive; in other words, living animals and vegetables can only live on dead animals and dead vegetables. No plant or animal has ever been known by experience, nor in the nature of things does it seem reasonable that they can be nourished by mere water and pure air, as some persons have affirmed.

Also on the other two substances the doctor thus remarks:

2. The Peat.—It is a dense mass of vegetable matter for a certain depth, partly in a dead and partly in a living state, with which is mixed more or less earth; and in burning, it affords so much empirical oil, as to give a disagreeable taste to roasted provisions; hence, as we are told, it has been rejected from the kitchen. The fuel affords a vast quantity of what the chemists call lignic acid; hence it is rejected also from the parlour, as very destructive to grates. He begs to suggest that this lignic acid might be faved in burning the peat as fuel, and be used for various purposes in manufactures; and the charred peat may be used in place of charcoal of wood. Probably, too, other useful products will be found, on examining the matters more accurately which are afforded by distillation.

3. After.—If the peat were mere vegetable matter, the ashes afforded by it would be as trifling as those of wood; but some parts of the moor contain so much earth and oxidy of iron, as to leave behind, on burning, a considerable quantity of incombustible matter; and such kind of peat, we are told, is not used as fuel; but, after burning, the refuse matter is an efficacious manure, much more so than is commonly afforded by paring and burning. The ashes are more red and more fertilizing than ashes of common turf, because they contain more iron.

The spontaneous springing up of white clover in land manured with these ashes, is similar to the spontaneous growth of this plant on heath-land, which has been covered with lime to destroy all its present vegetation; and this fact shows that probably these ashes are buried in the earth for ages, which yet remain alive, but are not set free until exposed to the influence of air, water, carbonic, and lives the animal or vegetable matter. And other facts discovered by respectable chemists are added, which serve to show that other facts, beside sulphate of iron and certain earths, may be employed advantageously as manures, although, like iron, they have been esteemed deleterious to plants.

1. Ashes of pit-coal are a good manure for græs. It is stated in the fourth volume of Nicholson’s Journal, that he much valued friend, the Rev. William Gregor of Grampound, on examination of the ashes which are sold in Liverpool, found them to contain both sulphate of magnesia and sulphate of lime, especially the former salt. He apprehends that these ashes also contain oxidy of iron, or perhaps sulphate of iron. These ashes, says Mr. Gregor, “advanced” over græs, apparently produced good effects, notwithstanding the sulphate of magnesia, which he was well assured they contained. On this it is remarked, that from this observation of Mr. Gregor, it seems he is aware of the prevailing popular opinion, that sulphate of magnesia is not favourable to vegetation; and to reconcile his facts with the unfriendly nature of magnesia to plants, as discovered by Mr. Tennant, he observes,
SULPHATE.

observes, that the effects of sulphate of magnesia may be very different from those of magnesia and carbonate of magnesia. He apprehends it is the magnesia (calcined till urine, as to which this learned chemist found it harmful to vegetables, as the discovery was made on the examination of Notting-ly lime, which the farmers near Doncaster employ as a manure, while they reject the lime of their own neighbourhood. In the latter Mr. Tennant met with magnesia, and in the former none. See LIME.

2. The earth from ashes, called cinia, is a durable and efficacious manure. It is observed, that professor Mitchell, of New York, in a letter addressed to Dr. Pearlion on cinia, says, that he found in the ashes of wood, a plant, remarks, that the ashes of wood contain very commonly sulphate of potash, also phosphoric acid, besides other well-known facts; but after these facts are separated by lixiviation, there remains a peculiar earth, and a small proportion of iron. This earth differs from lime, barites, magnesia, fiesontain, and very other known species of earth. He would call it cinia, for plenti-ful, common, and important as it is, science has not digni-fied it with a name. To judge of the excellence of this earth as a manure, after all the facts are extracted from foap-boat ashes, the earth falls for ten cents the bushel; and notwithstanding this high price, it is not unusual for the farmer to pay for the article twelve months before-hand. When ploughed into fertile ground, at twelve loads per acre, it produces great crops of wheat, clover, and other forts of grass and grain, and its fertilizing operation will last twenty years. Although some of the other ingredients of the ashes left after lixiviation may prove beneficial, yet the effects are chiefly from the cinia, or new-named earth.

This earth, which is so prized in America as a manure, was, it is said, esteemed of old in Asia, as an ingredient in a cement among the ancient Syriants, it was one of the materials forming the plaster of their walls; and as it holds an intermediate place between lime and potash, it can easily be conceived how it may act both as a cement and a manure. It is to be hoped chemists will turn their attention to this important subject. See vol. vii. of Tilloch's Philosophical Magazine.

4. Sulphate of iron in the pest of Ruffia. This was found by professor Robison. And it is observed, that sometimes the pest of vegetable matter is necessary to form peat or black mould of vegetable matter, but the peat is different from that of vegetable matter. Peat-ashes, says the professor, always contain a very great proportion of iron: he has seen three places in Ruffia where there is superficial peat-mofs, and in all of them the vitriol is so abundant as to effloresce. In particular, on a moor near St. Peterburgh, the clods threw the vitriol (sulphate of iron) every morning when the dew has evaporated. According to this learned professor's observations, the sulphate of iron in peat-coal may be accounted for in the following manner: peat-mofs form very regular strata, lying indeed on the surface; but if any operation of nature should cover this with a deep load of other matter, it would be compressed and rendered very solid; and remaining for ages in that situation, might ripen into a sublimate very like peat-coal. See Medical and Chirurgical Review for November 1803.

5. Use of peat-dui and peat-ashes. In answer to a letter from Dr. Pearlion, requesting to know what experiments Mr. A., had made from the turf-dui taken from The same moor he affords the testimony of having made use of the ashes and duii near thirty years, and frequently laying on from eighty to a hundred bushels per acre. Our land, says he, is dry and very thin-flapped, owing to the chalk-rock lying very near the surface: it encourages vegetation in moist warm weather, but when hot and dry, the reverse. We never mix any other manure with it. It costs about four cents per bushel, including all expenses. We chiefly spread it over feed, grass, clover, &c.

In addition to these useful and interesting statements, it may be noticed, that the able writer of a late work on Agricultural Chemistry, has witnessed the fertilizing effects of a ferruginous water used for irrigating a graft meadow made by the duke of Manchester at Priesty Beg, near Woburn, in Bedfordshire, an account of the produce of which has been recorded in some of the Publications of the Board of Agriculture. It is not doubted that, in this case, the peat-flat noticed, also, that vitriolic water acted chiefly by produc- ing the sulphate of lime, or a sublimate of that nature. It is observed, that the soils on which both are efficacious, are those of the calcareous kind, and that sulphate of iron is decomposed by the carbonate of lime in such soils; that the sulphate of iron confits of sulphuric acid and oxtyd of iron, and is an acid and very soluble salt; that when a solution of it is mixed with carbonate of lime, the sulphuric acid quite the oxtyd of iron to unite with the lime; and that the compounds produced are infelid, and comparatively infelid.

Some of the depots from the ferruginous water on the soil of the above meadow was collected, and it was found that it consisted of sulphate of lime, or a sublimate of that fort, carbonate of iron, and infelid sulphate of iron. The principal grafts in the above meadow are, it is said, the iron, fox-tail, cock's-foot, meadow fescue, heroine, and sweet-infelid vernal grafts. The ashes of three of these grafts, as the meadow fox-tail, cock's-foot, and hor, have been examined, and found to contain a considerable proportion of sulphate of lime, or a sublimate of that kind.

This knowledge of the nature, formation, and use of this sublimate, may lead to many useful improvements in soils which contain it, or the matters of which it is composed, as well as to more suitable and proper appli-cations for them in the way of manure, and to better and more advantageous methods of using and applying them.

SULPHATE OF IRON, DRIED, of the Edinb. Ph. is prepared by heating any quantity of sulphate of iron in a close glass vessel, until it becomes white, and perfectly dry. The process is nearly the same in the Dub. Ph. The degree of heat in these processes should not exceed 212° of Fahrenheit. Its official proportion is the "red oxtyd of iron," which is rarely used, except as a pharmaceutical agent. See IRON.

SULPHATE OF KALI. See SULPHATE OF Potash.

SULPHATE OF Lime. See Gypsum, Sulphate of Lime, and Salts.

According to lord Dundonald, sulphate of lime exists in great abundance in many soild. It is produced by the decomposition of aluminous schist, containing a due proportion of calcareous matter; with which the sulphuric acid will join, as it is formed, in preference to the earth of alum or clay. It is likewise formed by the decom-posion of pyrites in such soild as contain a sufficiency of calcareous matter for the sulphuric acid to combine with, in preference to the earth of iron, the other constituent part of pyrites.
SULPHATE.

Sulphate: and it is found in immense quantities, constituting not only the soil, but the subsoil, in some countries, to a great depth. It is to be decomposed by alkaline salts; the sulphuric acid forming with them sulphate of potash and sulphate of soda, according to the alkali used. It is a salt very insoluble, requiring upwards of five hundred times its weight of water to dissolve it; hence, supposing it equally deleterious to vegetation, as alum hath been considered, which is soluble in only fifteen times its weight of water, it must, he says, prove less injurious, from its greater degree of insolubility; but this substance, far from being hurtful to vegetation, when applied to certain soils, promotes it in a very high degree, as is evinced by the use of it in some parts of the continents of Europe and America; and it is further proved by the chemical analysis of vegetables, whereof ashes are found to contain a certain portion of the component parts of it.

Sir Humphrey Davy, in his work on "Agricultural Chemistry," observes, that calcareous matter, besides being used in the forms of lime and carbamate of lime, is applied for the purposes of agriculture in other combinations; one of which is the compound substance which is that of sulphate of lime. That was material composed of sulphiure of lime and the same body that exists combined with water in oil of vitriol and lime; and that when dry, it is composed of fifty-five parts of lime, and seven-five parts of sulphuric acid. That common sulphate of lime, or feline, such as that which is found at Shotover-hill, near Oxford, contains, besides sulphuric acid and lime, a considerable quantity of water; and the composition of which may be expressed and explained somewhat in this manner. Sulphuric acid one proportion, seventy-five; lime one proportion, fifty-five; and water two proportions, thirty-four.

The nature of this sulphate is, it is said, easily demonstrat'd; when oil of vitriol is added to quick-lime, there is a violent heat produced; and when the mixture is ignited, water is given off, and this sulphate alone is the result, if the acid has been used in sufficient quantity; and this sulphate mixed with quick-lime, if the quantity has been deficient. This substance, free from water, is sometimes, it is said, found in nature, in which case it is called by hydrous feline. It is distinguished from the common sulphate, by giving off water when heated. When this sulphate, free from water, or deprived of it by heat, is made into a paste by the same fluid, it rapidly sets, it is said, by combining with that liquid. Plaster of Paris, it is observed, is powdered dry sulphate of lime; and that its property as a cement, and in its use in making casts, depends upon its solidifying a certain quantity of water, and forming with it a coherent mass. Sulphate of lime is soluble in about five hundred times its weight of cold water, and is still more soluble in that which is hot; so that when water has been boiled in contact with this sulphate, crystals of it are deposited as the water cools. Sulphate of lime, too, is easily distinguished, it is said, by its properties of affording precipitates to solutions of oxalates, and of barytie salts.

There has long been much difference of opinion prevailing among farmers and agriculturists in respect to the use of this substance on land. It is said to have been had recourse to with much advantage and in some few districts of this country; and a variety of strong testimonies in favour of its power and efficacy, when laid on land, has been brought to the notice of the Board of Agriculture by Mr. Smith. In America, too, it is stated to have been employed with signal success, especially in some provinces; but in many other counties of this kingdom, it is said to have failed, though tried in various ways, and upon different kinds of crops. It is remarked, that very discordant notions have been formed as to the manner in which this substance operates. Some have supposed it to act by its power of attracting moisture from the air; but this agency, it is thought, must be comparatively insignificant. When combined with water, it retains that fluid too powerfully to yield and supply it properly to the roots of the plants; and its adhesive attraction for moisture is inconsiderable: the small quantity in which it is used, is likewise, it is supposed, a circumstance hostile to this idea. It has been said, too, that this substance afflicts the putrefaction of animal matters, and the decomposition of manure; but some experimental trials have been made on this subject, which are in contradiction to the notion. On some minced veal being mixed with about one-fourth of its weight of this sulphate, (some veal without the sulphate being exposed at the same time and under the same circumstances,) there was no difference, it is said, in the time in which they began to putrefy; but the results appeared to be more rapid in the case in which there was no sulphate present. Other similar mixtures were made, in which in some cases larger, in others smaller, quantities of sulphate were employed; and in one instance, pigeon's dung was used instead of flesh, and with precisely similar results. It certainly, in no case, it is said, increased the rapidity of putrefaction.

A series of experiments, it is said, has been carried on for a great length of time in this country, upon the operation of this sulphate as a manure, though it has not been generally known; as the Berkshire and Wiltshire peat-ashes contain a considerable portion of this substance. In the Newbury fort, from one-fourth to one-third of this sulphate has been found, and a still larger quantity in some from the neighbourhood of Stockbridge, besides other constituent matters. These very substances are much in use for top-dressing cultivated grasses, particularly fai-fains and clover. In examining the ashes of these two, and those of rye-grafs, it was found that they afforded considerable quantities of this sulphate, and that this substance, probably, is intimately combined as a necessary part of their woody fibre. If this be allowed, it is suppoed easy to explain the reason why it operates in such small quantities; for the whole of a clover, or of a fai-faine, on an acre, would it be said, on the average which has been made, only afford, by incineration, three or four bushels of this sulphate. In examining the soil of a field near the above town, which was taken from below a foot path, where this sulphate could not have been artificially furnished, not any of this sulphate could be detected it; yet at the very time the soil was collected, the peat-ashes were applied to the clover in the field. The reason why this sulphate is not generally efficacious is, probably, it is suppoed, because most cultivated soils contain it in sufficient quantities for the use of the grasses. In the ordinary course of cultivation, this substance is, it is said, furnished in the manure; as it is contained in flabile dung, and in the dung of all cattle and animals feeds on grass; but it is not taken up in corn crops, or those of peas and beans, and in only very small quantities in turnip crops; however, where lands are exclusively devoted to paiturage and hay, it will, it is said, be continually consumed.

Four different foils cultivated under a series of common course of crop, have, it is said, been examined for this sulphate: of which, one was a light sand from the county of Norfolk; another a clay, bearing a good wheat, from that of Middlesex; the third, a sand from Suffolk; and the
the fourth, a clay from Essex. In all of them this sulphate is rated to have been found; and that in the soil from Middlesex it amounted to nearly one per cent. The writer, too, has been informed by Lord Dandans, that, having tried this sulphate on two of his estates in Yorkshire without any benefit, he was induced to have the foils of them examined for this sub stance, in the manner directed in speaking of foils, in both of which this sulphate was found. See Soil.

It is thought, that if these reasoning and statements should have the confirmation of future inquiries, a practical inference of some value may be derived from them; which is, that it is possible in March, in which have ceased to bear good crops of clover, or other artificial forage, may be restored by being manured with this sulphate.

It may be noticed, that, in addition to the place already mentioned where this substance is found, it also abounds pretty much, it is said, in many other parts of this country; as in Gloucestershire, Somersetshire, Derbyshire, Yorkshire, and some others, and only stands in need of pulverization, in order to prepare and fit it for being applied to the land.

It may be remarked, that although the ashes of certain peas, as seen above, afford sulphate of lime, it is not, it is said, to be concluded from that that all peas agree with them, as some which have been examined contained no quantity that could be useful; and abounded with injurious matters. Vitriolic matter is, however, usually formed in peas; and where the soil or substratum is calcareous, the ultimate result is the production of this sulphate. In general, when a recent ash of this sort emit, when acted upon by vinegar, a strong smell, like that of rotten eggs, it will, it is said, furnish this sulphate.

In Oxfordshire, in some cases, this substance has been found over clover in March, in which have ceased to bear good crops of clover, or other artificial forage, may be restored by being manured with this sulphate. In general, when a recent ash of this sort emit, when acted upon by vinegar, a strong smell, like that of rotten eggs, it will, it is said, furnish this sulphate.

In Kent, when found over a large part of a field of lucern, and a part left without any, the superiority of the part found with it was very great. In Suffolk, it has been found on portions of natural grasses, beans, potatoes, peas, barley, wheat, red clover, and tares, in moist weather, at about eight bushels, and in the above quantity to the acre, on sandy loam, and open, without any perceptible effect, where the same or the following year, being produced by it. This would seem to show that this land, in so many instances, is so much impregnated with it as to stand in need of no more for giving luxuriance to the plants upon it.

**Sulphate of Magnesia.** See Magnesia, Epsom Salt, Salt, and Salts.

By Dr. Home's experiments, sulphate of magnesia has been found in a very high degree to promote vegetation. He states, that it made the garden-mould be used for his experiments produce one-fourth more grain.

Sir Humphrey Davy, however, thinks, that though this substance has been flattered by some inquirers to have been found useful as a manure, it is not met with in nature in sufficient abundance, or capable of being made artificially in a sufficiently cheap manner, to be of useful application in the common course of husbandry and management of land. See Magnesia, in Agriculture.

**Sulphate, Ammonio-Magnesian,** a triple salt, compounded of sulphuric acid, magnesia, and ammonia, by adding pure ammonia to sulphate of magnesia, in which case a great part of the earth is precipitated, and the rest remaining in solution, the salt is formed by evaporation. It is also procured more speedily, and with less loss, by adding to a solution of sulphate of magnesia one of sulphate of ammonia, each somewhat concentrated. An abundant deposition of regular, transparent, thinning crystals takes place immediately, which are the triple salt in question: its form is generally octahedral; its taste is salt and bitter. When heated, it first melts in its own water of crystallization, after which it is decomposed, ammonia is first given out, then acidulous sulphate of ammonia rises, and simple sulphate of magnesia remains.

This triple salt is much less soluble in water than either of the sulphates of which it is formed, as is obvious by its precipitating on the addition of the two solutions. According to Potters, it is saturated in per cent. of sulphate of magnesia, and 1% of sulphate of ammonia.

**Sulphate of Potash.** See Salts.

This saline substance has been found by Dr. Home to promote vegetation in an extraordinary manner. The garden-mould on which his experiments were made, produced an increase of one-fourth more grain, in consequence of the application of this salt. It is to be had from most vegetable matters by combustion; it forms at least one-third of the saline matter obtained by the lixiviation of their vegetation. This is sufficiently, it is said, a proof, independent of Dr. Home's experiments, that vitriolated tarter is beneficial to vegetation. This substance is a refuse article in some branches of manufacture; but the quantity produced is a mere trifle, in comparison to the quantity that might, it is thought, be advantageously applied to the purposes of agriculture.

This sulphate, which is found in the ashes of some peas, as those of Berkshire, is certainly an useful substance as manure, though the results of Dr. Home's trials have been questioned by Mr. Nasmith, in his elementary work on agriculture; who has pointed out experiments which he considers as hostile to the doctor's opinions and conclusions, and as unfavourable to the power and efficacy of any sort of substance of this kind.

Sir Humphrey Davy has found the effects of this sulphate to be much the same on the growth of plants of the grain and grass kind, when employed in large and small proportions, as those of the sulphate of ammonia: which would seem to shew, that the effects are different according to the quantities made use of, and that large quantities are unfavourable.

**Sulphate of Soda.** See Salts and Soda.

From experiments, sulphate of soda has been proved to promote vegetation in a very high degree. It is procured in small quantities, in the processes for making the muriatic acid, and muriate of ammonia, or sal ammoniac. The high price at present of this article precludes the use of it; but could it be made and sold at a cheap rate, it would, as Lord Dundonald thinks, prove a most valuable acquisition to agriculture. Sir Humphrey Davy has found that the effects which it produces, when used in different proportions for plants of barley and grass, are much the same as those of sulphate of ammonia.

**Sulphate of Strontian.,** a salt without taste and smell; nearly insoluble in water; not decomposed by any single acid; but barytes, alone or in combination, abstracts its acid, with which barytes has the greater affinity. It is also decomposed by the carbonate fixed alkalies, and with much more ease in the moist way than the sulphate of barytes. Sulphate of strontian, like the barytic sulphate, is readily soluble in sulphuric acid, and precipitable thence by dilution with water. This salt is decomposed by fusion with charcoal into a sulphuret. For the analysis of the native sulphate, see Strontian.

**SUL-**
SULPHITE.

SULPHITES, salts formed by the combination of any base with the sulphurous acid. N.B. All salts that are composed with acids whose names end in -ite, terminate in -ite, instead of ate. These salts have always a disagreeable sulphurous taste; they are decomposed by the nitric, muriatic, and some other acids, which do not affect "salts": if exposed to fire, they yield sulphur, and become sulphates; and even by mere exposure to the action of the atmosphere, they are converted into sulphates. The principal of these salts are the following: viz.

Sulphite of Alumine, formed from pure alumine. It is in the state of a white soft powder; sweetish to the taste, and then sulphurous; insoluble in water, but taken up by an excess of acid; not crystallizable. It is decomposed, according to Dr. Thomson, of

but applicable to no use. See ALUMINE.

Sulphite of Ammonia, prepared by faturating a solution of caustic ammonia with gaseous sulphurous acid. See AMMONIA, AND SALTS.

Sulphite of Barites, may be prepared with either pure barites, or the carbonate reduced to a fine powder; or it may be obtained, by compound affinity, from a mixture of an alkaline sulphite with muriate of barites. It is in the form of a white powder, tafteafte, and insoluble in water. By long exposure to the air, it is converted into sulphate of barites. When strongly heated, sulphur is diffused, and the residue becomes sulphate. This salt may be dissolved in liquid sulphurous acid, and by slow evaporation, may be obtained in needle-formed crystals, or truncated tetrahedrons. These crystals are sometimes transparent, but often opaque; nearly infinid, and leaving on the palate a sulphurous flavour; sparingly soluble in water; and the solution is advantageously employed for purifying the sulphites from any mixture of sulphate. According to Fourcroy, the crystallized sulphite consists of

It is decomposed by the sulphates; by the alkaline phosphates; by the nitrate and muriate of flourian; and by the alkaline carbonates. See BARITES.

Sulphite of Lime. See LIME.

Sulphite of Magnesia, is prepared with carbonated magnesia, diffused in twice its weight of water; it is in the form of powder, but by an additional portion of sulphurous acid, readily diffores; and by gradual evaporation, is deposed in the form of transparent, deprived, tetrahedral pyramids. To the taste it is at first sweetish and earthy, and afterwards sulphurous; exposed to the air it becomes opaque, and is slowly converted into a sulphate. It is soluble in twenty parts of water at the common temperature; boiling water takes up an additional portion, which it deposits in crystals on cooling. When exposed to a dry heat, it cools, and assumes the consistence of a vitific gum, and at length dries, having lost 45 per cent., which is nearly pure water; at a higher heat the sulphurous acid rises unaltered, and the earth remains behind. From this mode of analysis it appears, according to Fourcroy, to consist of

It is decomposed by the alkaline and earthy-alkaline carbonates; by the sulphates of alumine and zircon; by the earthy nitrates; by the phosphates of the alkalies, and of lime, glycine, alumine, and zircon; and the alkaline borates. It is not applied to any use. See MANGENIA.

Sulphite, Ammonico-Magnesian, a salt formed, according to Fourcroy, by mixing magnesia with sulphite of ammonia, or ammonia with sulphite of magnesia, or by adding together the two sulphites. It occurs in the state of small transparent indeterminate crystals; it is lees soluble in water than either of the two sulphites separately, of which it is composed. Exposed to air it changes into the triple sulphate of ammonia and magnesia. When heated, it first gives out sulphurous acid, then acridulous sulphite of ammonia sublimes, and pure magnesia remains behind. The proportion of its constituent parts has not been ascertained. It is decomposed by barites, flourian, lime, and the fixed alkalies. It is not used.

Sulphite of Potash, is most conveniently prepared by connecting a retort, charged with sulphuric acid and mercury, with a Woulfe's apparatus of two bottles, the former of them containing a little water, and the latter about two-thirds filled with a solution of crystallized carbonate of potash, in thrice its weight of water. The retort being heated, sulphuric acid gas is produced, which passing through the water in the first bottle, is thereby purified from any contamination of sulphuric acid, and then enters the alkaline solution in the next bottle, by which it is rapidly absorbed, carbonic acid gas escaping in bubbles at the same time. When the effervescence has ceased, and the sulphurous acid is no longer taken up by the liquor, the procés is finished, and the liquor, as it cools, generally deposita crystals, if the above proportions of alkali and water have been observed.

Sulphite of potash, thus prepared, is a transparent salt sometimes colourless, but often with a slight yellowish tinge. It crystallizes either in the form of lengthened rhomboidal plates, or divergent needles. To the taste it is pungent and sulphurous; its specific gravity is 1.58; it is readily soluble in its own weight of water, at the common temperature, and in a much smaller quantity of boiling water. If this solution be exposed to the air, it will be covered in a short time with a crystalline pellicle; when this falls to the bottom, it is succeeded by another, and so on, till the whole is converted into sulphate of potash. By an exposure to a temperature of about 300° Fahr. sulphite of potash loses about 22 per cent.; of which 15 are sulphurous acid gas, 5 are sulphur, and 2 water: the salt that remains being sulphate of potash, with a slight excess of alkali. If it be rapidly ignited in a platina crucible, when the decr iptation ceases, a blue flame makes its appearance, occasioned by the combustion of the alkali, after which the salt is found to have lost 22 per cent. as before. The component parts
SULPHUR.

parts of this salt, according to Dr. Thomson's analysis, are

This, as well as other sulphites, is most conveniently analyzed in the following manner: first, alay the solution with sulphite of barytes, to ascertain whether any mixture of sulphate is present, and having thus got rid of the sulphuric acid, add nitrate of lead as long as any precipitate falls down. The sulphite of lead, thus obtained, confits, according to Dr. Thomson, of 25 per cent. sulphurous acid, and 75 yellow oxyd of lead.

Nitric acid converts this salt into sulphate of potash: oxynuratic acid produces a similiar effect, driving off at the same time a portion of sulphurous acid, so that the resulting sulphur is mixed with a little muriate. It is also converted into sulphate by the oxys of gold, silver, mercury, the red oxyd of lead, and the black oxyd of manganese. It is decomposed, by compound affinity, by all the earthy and alkaline sulphates, except sulphate of barytes; by the nitrates, with the exception of nitrate of ammonia; by the muriates, except muriate of alumine; by the phosphates of soda, ammonia, alumine, and glycine; by the fluorites of soda, ammonium, barytes, frontian, and magnesia; by carbonate of soda, and by all metallic salts except the carbonates. It has not been applied to any use.

SULPHITE of Soda, is prepared from carbonate of soda, in the same manner as sulphite of potash is from carbonated potash. At first it is a confusedly crystallized mass, and this, by subsequent solution in hot water, affords, on cooling, very regular distinct crystals, in the form of compressed tetrahedral prisms, with dithedral summits. Its specific gravity is 2.95. Its taste cooling and sulphurous. It is soluble in four times its weight of water, and in less than its own weight of boiling water. It effloresces on exposure to the air, and becomes covered with a white crust, but does not fall into powder as sulphate of soda does. When heated, it first melts in its water of crystallization, and on increasing the temperature, undergoes changes analogous to those described in the preceding article. According to Dr. Thomson, it is composed of:

It is decomposed by the alkaline and earthy sulphates, with the exception of the sulphates of barytes and soda; by the earthy nitrates; by the ammoniacal earthy muriates, phosphates, and fluorites; by the borate and carbonate of potash; and by most of the metallic salts. It has not yet been applied to any use. Akin.

SULPHUR, in Mineralogy, an inflammable mineral, which burns with a blue flame and a peculiar suffocating odour, and has almost always a yellow colour. By these characters it may be easily distinguished from every other mineral. Sulphur has been considered as the product of volcanic fires, and the greatest part of the sulphur of commerce is obtained from the vicinity of volcanoes; but sulphur, either pure or combined with oxygen, enters largely into the composition of numerous metallic and earthy minerals, and may be said to form a component part of the globe itself. Sulphur, combined with iron or iron pyrites, is widely and abundantly distributed through many of the strata. (See PYRITES and STRATA.) Sulphur, combined with oxygen or sulphuric acid, unites with lime and forms gypsum, which exists in beds and strata of considerable extent. (See GYPSUM.) In almost all metallic veins we meet with combinations of sulphur, and in beds of coal, and in bituminous wood. Pure native sulphur is emitted in great quantities from volcanoes, and hence we may infer that this mineral exists abundantly in the interior of the earth. It exists also in a gaseous state combined with hydrogen, and is absorbed by water, giving to it peculiar properties. See WATERS, Mineral.

Native sulphur is divided by Werner into two kinds, common sulphur and volcanic sulphur. They are principally distinguished by the different situations in which they occur, being essentially the same. The colour of common sulphur is yellow, which sometimes inclines to greenish or grey. It occurs in nodular masses, and crystallized, in acute double four-sided pyramids, forming octohedrons, and also in double fix-sided pyramids. The crystals present several varieties by truncation of the points or edges. The octohedron, according to Hauy, is the primitive form of the crystal. The crystals are rarely perfect (those from Sicily are the best, and are sometimes five inches in length); they are translucent and sometimes transparent, and polishes in a remarkable degree the property of double refraction; they are soft, brittle, and easily broken; the lustre is more or less shining, between resinous and adamantine. Native sulphur is negatively electric by friction; its specific gravity is 1.99. It melts easily, and burns with a blue flame. If sulphur be suffered to cool slowly after melting, and a part of it be poured off, the remaining solid part will be found covered with minute capillary crystals of no determinate form, having no analogy with the form of the native crystal.

Massive native sulphur is both opaque and translucent, and has sometimes a rough and sometimes a conchoidal fracture, and generally a shining lustre.

Native sulphur is also disseminated in small fragments in different stones; it sometimes forms a powdery incrustation over other minerals. Native sulphur occurs both in primary and secondary rocks, but more abundantly in the latter. Sulphur very frequently accompanies rock-fault and gypsum, and may be considered as more particularly associated with them than with any other minerals that are not volcanic. It often forms beds in the marie and shale which cover or alternate with gypsum. Native crystallized sulphur has been found on the under surface of coal beds, near whin-lykes, in the county of Durham. Sulphur occurs in the torm of powder in the strata subjacent to coal in Derbyshire, and has sometimes been found massive in Anglesea.

Native sulphur also occurs in veins which traverse some of the mountains in Hungary, composed of giesis and mica-flate. M. Humboldt mentions as an extraordinary fact, the existence of sulphur in a bed composed of quartz, passing into hornstone, and traversing a mountain of mica-flate, in the great mountain of sulphur in Quito, between Alausi and Tician, and describes two other repositories of sulphur in primitive porphyry. Sulphur is found on the surface of the ground in beds of considerable thickness, deposited by waters holding sulphuretted hydrogen gas in solution. These repositories of sulphur, according to Pallas, are very common in Siberia; some of them furnish a sufficient quantity to be worked with advantage as sulphur-pits. The fame naturalist says, that on the north of the Caspian sea, and
SULPHUR.

to the south of Saporiva, in Siberia, there are marbles and even rocks which deposit great quantities of sulphur, with some carbonate of lime. Other waters, such as the warm springs of Aix-la-Chapelle and Tivoli, deposit sulphur; and we have seen a similar deposition from the mineral springs near Llandegley, in Radnorshire. The sulphur forms a white pellicle on the water, and is deposited on the stones at the bottom and sides of the spring. It has been discovered in cressets, horse-radish, and several other vegetables. It is also evolved from animal subfusces, during their putrefaction, in combination with hydrogen.

Volcanic sulphur is far more abundant than common sulphur; its colours are various shades of yellow, inclining to orange and red. It is found sulfured in small crystals in beds, or in a state of powder in the cavities of lava, contiguously to the craters of volcanoes. It is sometimes mixed with decomposed lava. Sulphur is the product of all active volcanoes; but the most remarkable sulphuriferous, or sulphuriferous reporitories, in Europe, are in Italy, Sicily, the Lipari islands, and Iceland. Solfataras, near Pozzuoli, in the kingdom of Naples, is an oval plain about two hundred yards in diameter, surrounded by steep rocks on all sides, which are perpetually decomposing and falling down in ruins. The plain is elevated about two hundred and fifty yards above the level of the sea, and is regarded as the crater of an ancient volcano. The plain is feebly hotter than the atmosphere in the warmest days of summer, and burns the feet through the shoes. Vapour and steam rise from almost every part of the plain to a considerable height. This vapour has the odour of sulphur, and it forms on the sides, and in the crevices of the rock, large masses of mafrous sulphur. In the middle of the plain there is a kind of basin, three feet lower than the rest of the surface, which forms hollow when any person walks over it, as if there was a great cavern beneath. Further on is a small lake, called Agrano, the temperature of which is below that of boiling, but it is in a state of constant ebullition, from subterranean vapours which rise through the water. Beyond this lake are the excavations from whence the earth is dug which furnishes the sulphur; it is light and tender. From the crevices in this part, the vapour which exhales is accompanied with a noise. The workmen always dig into the plain for the earth, and neglect the sulphur, which is formed on the surface in considerable quantities, and of a bright yellow colour. They say the latter has lost its nature, and does not make sulphur of so good a quality as that which is procured from the soft stone under the surface.

Ever since the days of Pliny, the Solfataras has supplied a considerable part of the sulphur of commerce in Europe. According to M. Breislak, the sulphur is formed by the decomposition of sulphureted hydrogen gas, which is plentifully diffused in this place. See SOLFATARAS.
The sulphur is extracted from the earth with which it is mixed by sublimation. The earth containing it is put into earthen pots, placed in two rows in a long furnace. These communicate with other pots of a similar kind, placed on the outside of the furnace, by an earthen tube: the outer pots have an aperture at the bottom stopped by a peg, and a smaller aperture at the top, to let out the vapour. The sulphur in melting passes with a hissing noise into the second vessel; under this is placed a bucket filled with water, into which the melted sulphur flows when the peg is withdrawn, and instantly becomes solid. It is melted again, and cast into wooden cylindrical moulds, forming roll-sulphur. Volcanic sulphur occurs also in other parts of Italy, in Sicily, the Lipari islands, and in Iceland. It is found indeed in all volcanic countries and islands. The West Indian islands in which it is obtained, are St. Domingo, St. Lucia, Martinique, Guadaloupe, and St. Vincent's. The volcanic sulphur in the Cordilleras of Quito is abundant, and of the purest quality.

Volcanic sulphur is purer than the sulphur obtained from pyrites; the latter is almost invariably mixed with arsenic and other metallic matters, on which account the sulphuric acid made from it is improper for many manufactures, particularly for the preparation of the bleaching liquid.

Mr. Sylvestre has collected small specimens of crystallized sulphur, formed by sublimation, at Bradley, near Wolverhampton. At that place a bed of coal has been for many years on fire. This heat has had the effect of subliming sulphur from the iron pyrites, which condenising among the cinder and other refuse on the surface, is found in an efflorescent form of a bright yellow colour. Muriates of ammonia is frequently found in the same situation in a sulfured form.

Sulphur is obtained in large quantities, at a small expense, from the pyrrhotine copper-ores during the roasting which this undergoes previous to the process of fusing. At the celebrated Pyres mine in Anglesea, works for this purpose are constructed on a large scale. At the foot of a low but steep ridge of rock, are constructed maffles of masonry, not unlike high blast-furnaces, except that the top is capped with a dome of brick-work, from which proceeds a horizontal flue, about the size of a common chimney, which terminates in a square or oblong brick chamber, built at the top of the rock. Some lighted fuel is introduced by means of a door in the dome of this roasting furnace, and a few basketfuls of ore, broken into moderately small pieces, are thrown on it, fresh parcels of ore being added from time to time, as the preceding parcels get lighted; a sufficiency of air for the slow combustion required in this process, is lent by means of a door at the bottom of the kiln, which also serves to take out the ore by when properly roasted: that part of the sulphur which escapes combustion rises in vapour, and collects in the dome (the door of which is only opened to admit fresh charges of ore), whence it passes through the flue into the chamber, where it presently concretes, lining the sides and roof; each chamber has a door, by means of which about once in five weeks, it is cleared of the sulphur. This rough sulphur is in fuffy pulvulent crusts, of a dirty greyish-yellow colour. For its purification it is melted in a boiler, the impurities are got rid of by scumming and subfusces, and the fluid mass is then laded into cylindrical moulds, to form the common roll-sulphur or brimrose, or into cones about two feet high, forming the loaves of sulphur. The impure drags are also sold in the shops under the name of sulphur visum.

Besides the common sulphur, there are two other forms in which this substance appears in commerce, namely, the sulfured, or flowers of sulphur; and the precipitated, or magallery of sulphur.

Flowers of sulphur are prepared in the laboratory, by heating in a land-bath an earthen cucurbit charged with roll-sulphur, and surmounted by a jet of aludels; at a gentle heat the sulphur frits melts, then rises in vapour, and concretes within the aludels in the form of a glittering yellow powder, which, when examined by a microscope, appears to be composed of minute crystals. Flowers of sulphur are made in the large way by conducting the vapour of melted sulphur into close chambers instead of aludels, and being prepared with less care, it is often inferior in purity to that obtained by the former method. Flowers of sulphur, however prepared, are more or less seidulous from a mixture of 3 R 2 sulphurous.
SULPHUR.

fulphurous acid, on which account, an infusion of them in water reddens tincture of litmus; this acid, however, may easily be got rid of by washing the powder first with a warm and very dilute solution of pearl-ash, and then with two or three successive parcels of warm water.

Magpyery of sulphur is prepared by decomposing by the fulphuric or any other acid a solution of alkaline sulphuret; a proper bleed precipitate falls down, which is to be thoroughly edulcorated with successive parcels of warm water. Sulphur in this state has a dull earthy appearance, owing to its extremely minute flake of division; it is of a yellowish-white colour, is smooth and almost incipient to the touch; by exposure to light it acquires a yellow colour. It is generally looked upon as the purest form of sulphur, yet from some of its properties, and the mode in which it is prepared, there is some reason for supposing that a portion of hydrogen enters into its composition.

The sulphur that is procured in the roasting of ores, especially those of copper, is apt to contain, besides earthy impurities, a very notable proportion of arsenic, while on the other hand the volcanic sulphur in general, and that of Sicily in particular, is entirely free from this contamination. This is the cause of the universal preference given by the manufacturers of fulphuric acid to Sicilian, over English sulphur; and hence it is a matter of some consequence to be able to ascertain, in a compendious and satisfactory manner, the purity of any particular sample of this substance. The following method will, we believe, be found to answer every practical purpose. Having rubbed to fine powder in an earthenware mortar some of the sulphur to be examined, take 100 grains, and put them into a Florence flask with five ounce-measures of the beet oil of turpentine; heat the mixture gently over a lamp, or a pan of charcoal, till it has boiled for about a minute, then pour the clear hot solution into a fix or eight-ounce vial, fill it with a cork, and shake it till the liquor has cooled down to the temperature of the hand; it will now be quite turbid with sulphur that has separated from the oil during its cooling, and being run through a glass funnel very lightly plugged with fine tow, will pass out clear, leaving the sulphur behind. The oil is now to be again transferred to the sulphur remaining in the flask, and to be a second time boiled, cooled, and filtered as before. By repeating this process four or five times, there will be left only a brownish-orange residue, on which the oil will refuse to act any longer. This residue being laid on a piece of earthenware, is to be exposed to a heat not higher than that of melting lead, till it ceases to exhale any fulphurous vapours; being then rubbed up with a little powdered charcoal and pressed into the bowl of a tobacco-pipe, or any other convenient vessel; it is to be heated nearly red, upon which a white vapour will arise, and shew itself to be arsenic, by its peculiar garlic odour. The fulphur precipitated from the oil of turpentine may be entirely freed from this latter by exposure to the air and light for a day or two; it will then be of a beautiful sparkling yellow colour (far superior to that of the common flowers of sulphur) and entirely inodorous. The common English brimstone or roll-sulphur sometimes contains a full fifteenth of insoluble residue, chiefly opiminent; the best Sicilian sulphur in small rolls, contains hardly more than three per cent. of residue which appears to be little else than earth, as it affords no arseneical odour when heated with charcoal. Aikin.

SULPHUR, in Chemistry, is a simple body, and susceptible of combustion. It is of a yellow colour, with a shade of green. It is very fragrant, and easily powdered. It has a peculiar taint, if we may so call that girtine has which distinguishes it from all other bodies, and also smell, especially when rubbed. At the common temperature it is inodorous, unless when rubbed; but if a roll of sulphur be held for a minute in a moist warm hand, it breaks across with a sharp cracking, not unlike the snapping from the discharge of an electric spark, the hand acquiring a peculiar disagreeable odour, which lasts some minutes. It is a nonconductor of electricity and becomes suddenly electrified by rubbing with the hand. Its specific gravity is 1.99, water being 1. Dr. Wollaston has ascertained, that it refracts light more than water, their powers being as .201 to 1.336. Its specific heat is said to be 1.83, water being 1. It fuses at about the temperature of 200° or 224° Fahr., when it melts into a transparent brownish-red fluid. By an increase of heat, the fluidity diminishes, and the sulphur begins to sublime in visible vapours. When it somewhat exceeds the temperature of 300° Fahr., its confidence will be like that of treacle, and the vapour will take fire, the inflammation spreading instantly to the whole mass. If kept some time in fusion, it becomes thick and viscous. When sulphur has become viscous by heat, its fluidity may be restored merely by lowering its temperature: and if, after having been kept in this state for a few minutes, it be poured, without previous cooling, into warm water, it does not become hard and brittle, as in its natural state, but remains soft, like wax, and of a reddish or brown colour. In this state it is employed to receive impressions from seals and medallions, which afterwards hardening, become permanent, and are known in the arts by the name of sulphur casts. This substance has been fupposed to be an oxvd of sulphur by some, but it is doubted by others.

When sulphur is heated in a close vessel beyond its fusing point, it ultimately assumes the elastic form, and may be sublimed or distilled into a separate vessel. It adheres to the sides of the receiver in an efflorescent form, in which state it is known by the name of flowers of sulphur. At the temperature of 500°, when atmospheric air is present, it burns with a blue flame, giving out suffocating fumes, as experienced in lighting the common brimstone-match. This arises from its combination with oxygen, a compound to be yet treated of. The atom of sulphur is 15, oxygen being 7.5: and hydrogen 1.

Sulphur combines with the metals, and all the other inflammable bodies perhaps, with the exception of azote. Its combination with the metals, and the earths and alkalies, are treated of under those bodies respectively, and are termed fulphurets, which see.

Sulphur combines with oxyquiriatric acid, forming a peculiar compound. This substance was discovered by Dr. Thomson, who considered it, at the time, as a compound of muriatic acid and oxvd of sulphur, and called it fulphuritted muriatic acid. Under the consideration of the oxyquiriatric acid being a simple body, this compound has been called sulphuranse by sir Humphrey Davy, and chloride of sulphur by Dr. Thomson. It is formed by passing chlorine gas over flowers of sulphur, or by heating sulphur in a retort filled with the same gas. The result of this union is a liquid of a red colour, when viewed by reflected light; but by transmitted light, it is of a yellowish-green colour. It smokes when exposed to the air, and its fumes irritate the eyes. It has a strong smell, resembling that of sea-weed. Its specific gravity is 1.6. It does not appear, in a pure state, to possess acid properties. It does not red-den litmus, when perfectly dry. When water is added, the mixture becomes cloudy, sir Humphrey Davy fays, by the deposition of sulphur: he further observes, that the mixture
SULPHUR.

mixtume becomes strongly acid, and that it is found to contain oil of vitriol. According to the original experiments of Dr. Thomson upon this substance, the proportion of chlorine to the sulphur was about 35 to 51, which would give nearly twice as much of sulphur.

Sir Humphrey Davy's experiments shew their proportions to be from 10 grains of sulphur to 30 cubic inches of chlorine, which give their proportions 1 to 2.38, which is very nearly 1 atom of sulphur, 15 acid, and an atom of chlorine 33. If the last account be correct as to the proportions, when the compound is added to water, two atoms of muriatic acid and an atom of sulphuric acid ought to be produced. But sir Humphrey rates, that free sulphur was seen, and that oil of vitriol was found in the mixture. It appears unlikely, that in a situation where sufficient oxygen was present to convert all the sulphur into sulphurous acid, there would be free sulphur and sulphuric acid.

Some accurate experiments on the combination of chlorine with sulphur and phosphorus would be highly useful in the present state of chemical science.

Sulphur combines with phosphorus (see Phosphorus), and also with carbon (see Carbon), forming a liquid compound, which has been thought to be a compound of hydrogen and sulphur, and has been long known by the name of alcohol of sulphur.

This substance is considered by Sir Humphrey Davy as a compound of sulphur and hydrogen, with more sulphur than the last sulphuret. This opinion cannot be founded upon the process he gives for its preparation. He says it may be formed by palling sulphur over charcoal ignited in a porcelain tube: the experiment must be made with the exclusion of air. This point has been settled by Berzelius and Dr. Marcet, in a paper by these gentlemen, read to the Royal Society on the 29th of April, 1813, where it is clearly made out to be a compound of sulphur and carbon.

They obtained it by subliming sulphur through ignited charcoal in a porcelain tube. The first product is a liquid of a yellowish colour, which colour is owing to the presence of a little sulphur. By distillation in a glass retort a colourless product is obtained, which is the pure sulphuret of carbon.

Its taste is exceedingly pungent and disagreeable, and its smell stronger than sulphuret of hydrogen. It boils at the temperature of 110° or 115°. The elasticity of its vapour at 53°, is such as to support 7.25 inches of mercury. Water at the same temperature supports 433, alcohol 1.2, and ether 11 inches. It produces by its evaporation greater cold than ether, and advantage has been already taken of this to freeze mercury. It may be cooled down to 50°, without congealing. It readily dissolves sulphur; but if to the solution be added ether or alcohol, the excess of sulphur is precipitated, and the two liquids combine.

Mercury and potassium undergo no change when heated in this liquid: but when potassium is heated in a vessel exhausted of air, and filled with the vapour of sulphuret of carbon, it burns with a red flame. The combustion is the result of the sulphur combining with the potassium. A black matter is produced; and if water be added, a common sulphuret of potassium is formed, mixed with the carbon which was separated. The authors of these experiments, in order to ascertain whether the sulphuret of carbon contained hydrogen, mixed some of its vapour with oxygen gas, and exploded it by the electric spark, but no water was obtained, which would have been the case, if hydrogen had been present. They did not obtain the slightest trace of muriatic acid, by treating this gas with chlorine. These, and several other sensible tests, were used without hydrogen being detected.

In other experiments they found, that when it was burnt with oxygen, sulphurous and carbonic acids were obtained, and in the residue carbonic oxide; but they found nothing to indicate the presence of any other element in this compound, than sulphur and carbon.

The last enquiry was to ascertain the proportions in which these elementary bodies existed in this compound. By passing its vapour slowly through a red-hot tube filled with red oxide of iron, the oxygen combined with carbon, forming carbonic acid, and perhaps carbonic oxide. The sulphur combined with the iron. In order to ascertain the proportion of sulphur, the iron containing it was dissolved in nitric acid. This converted the sulphur into sulphuric acid, which was then precipitated by barytes, and from that it fell the weight of the sulphur could be estimated. The result of this analysis gave

100.

Berzelius has found that this substance combines with ammonia and lime, forming peculiar compounds. It will probably be found to combine with some of the other oxides.

The combinations of sulphur with oxygen are supposed to be three, but two only are at present known. These are sulphurous and sulphuric acids.

Sulphur, in fine powder, is sparingly soluble by digestion in highly rectified alcohol, but a more concentrated solution is made by precipitating each to the other in the state of gas; for this purpose, put some sulphur into a crucible, and suspend within the flame a vial filled with alcohol, then lute on a head and proper apparatus, and proceed to distillation; both the sulphur and alcohol are volatilized, and meeting with each other in the upper part of the vial, combine readily together, and condense in the receiver into a yellowish strongly smelling fluid, from which nearly the whole of the sulphur may be again precipitated by the addition of water.

Oil of turpentine and the other effluvial oils dissolve a considerable proportion of sulphur when hot, the greatest part of which they again deposit in crystals if cooled slowly. The fat oils unite with sulphur by boiling, and acquire a deep yellowish-brown colour, and a strong fetid odour; the combination is generally called balasam of sulphur. By long reposing in a cool place, it deposits small octahedral crystals of sulphur.

The order of affinities for this substance, according to Bergman, is fixed alkali, iron, copper, tin, lead, silver, bismuth, antimony, mercury, arsenic, and molybdena.

The uses of sulphur are very important. It is employed in medicine; it enters into the composition of sulphuric acid, of gunpowder, and of the common composition for paying the bottoms of ships. Its fumes, when burning, are employed for bleaching of silk and wool, and checking the progress of vinous fermentation. Common matches, which
SULPHUR are in daily use for lighting of fires, derive their principal utility from being tipped with sulphur. SULPHUR is of Antimony, Golden. See Antimony.

SULPHUR, in the Medecin de Plante, is laxative, and a stimulating diaphoretic. Its operation is gentle, and on this account it is one of the best means for keeping the bowels loose in hemorrhoidal affections; and the diaphoresis, which it excites, renders it serviceable in chronic rheumatism and catarrh, and in aconit, root, rickets, asthma, and other phlegmonic affections unattended with acute inflammation. It is supposed to combine with hydrogen in the stomach. It manifestly transpires through the skin, perhaps in the state of sulferated hydrogen; and this may be the cause of silver's being blackened in the pockets of those who take sulphur. It is specific in phlegm and some other catarrhal affections, in which it is applied externally, and taken internally at the same time. The dose may be from 3 j to 3 j, mixed into a solution with syrup or tussar, or in milk. Its purgative power may be increased by combining it with super-tartrate of potash; and in haemorrhoidal cases with magnesia. Its official preparations are as follows:

Sulphur lotum, or washed sulphur. That of the Russian. Ph. is obtained by pouring upon a pound of sublimed sulphur boiling water, the liquid being drawn off from time to time, washed away, and then drying it. The sulphur sublimatum lotum, or washed sublimed sulphur of the Edinb. Ph., is prepared by boiling a pound of sublimed sulphur for a short time in four pounds of water, then pouring off this water, by repeated affusions of cold water, washing away all the acid, and, lastly, drying the sulphur. The Dubl. Ph. directs warm water to be poured upon sublimed sulphur, and the washing to be repeated as long as the water employed shall appear acid, which is known by means of a test paper; and then dry the sulphur on cellophane paper. Sulphur precipitatum, or precipitated sulphur of the Lond. Ph., is prepared by boiling a pound of sublimed sulphur, and three pounds of fresh burnt lime, together in water; then filtering the liquor through paper, and dropping into it as much astringic as may be sufficient to precipitate the sulphur; and finally washing this with repeated affusions of water, until it becomes tafetaf. The precipitated sulphur is white, with a very light greenish tinge; its whiteness being owing to the presence of a little water. It differs in no respect from sublimed sulphur.

Oleum sulphuratum, or sulphurated oil of the Lond. Ph., is obtained by adding four ounces of washed sulphur gradually to a pint of olive-oil, heated in a very large iron-pot, and stirring the mixture after each addition till they have united. Or, according to the Edinb. Ph., by boiling eight ounces of olive-oil and one ounce of sublimed sulphur with a gentle heat in a large iron vessel, stirring constantly until they unite. N.B. Care should be taken to prevent the mixture from boiling over, and the iron-pot should be sufficient to contain the bulk of the ingredients. The odour of this solution is fetid, and the tafeta acid; its colour is a brownish-red; its consistence thick; and when heated, it emits sulphurated hydrogen; when much concentrated, the sulphur crystallizes in octoehedrons. This oil is stimulant, and externally detergent. It was formerly regarded as a balsamic, and recommended in catarrh, asthma, and phlegmatic affections; but its internal use is now properly exploded. When employed, its dose was from 1/2 to 1/4 of an ounce. It is sometimes externally applied for cleansing foul ulcers. The official preparations are:

* Emplastrum ammoniacum cum hydrosypry, and emplastrum hydrosypry. (See Emplastrum.) Unguentum sulphuris, and unguentum sulphuris compositum. (See Unguet.)

SULPHUR CRUDE, in Geography, a branch of Green river, in Kentucky.

SULPHUR ISLAND, an island in the North Pacific ocean, discovered by Captain Gore in the year 1790, about five miles long, in a N.N.E. and S.S.W. direction. The S. point is a high barren hill, flat-topped at top, and when seen from the W.S.W., it presents an evident volcanic crater. Its surface exhibited a variety of colours, and a considerable part of it was conjectured to be sulphur, both from its appearance and smell. N. lat. 24° 49'. E. long. 149° 12'.

SULPHUR MOUNT, a mountain of Guadaloupe, famous for the exhalation of sulphur and athes.

SULPHURATED IRON. See Iron.

SULPHURATED SILVER. See Silver.

SULPHURATED WINE. See Wine.

SULPHURES, or SULPHURETS, are combinations of alkalies, earths, or metals, with sulphur; and hence a suffusion is said to be "sulphurated," when it is combined with sulphur.

The several combinations, to which we now refer, are:

sulphurated hydrogen, and the hydro-sulphurates (see each article); the sulphurets as above defined (see Sulphur, and the articles infra); the super-sulphurated hydrogen, or sulphurated hydrogen, with a considerable, but in general an uniform, excess of sulphur; and the sulphurated hydrogen, or combinations of sulphur, sulphurated hydrogen, and the alkaline or earthy bases.

SULPHURET OF HYDROGEN is a gaseous compound of sulphur and hydrogen. It constitutes a portion of the atmosphere, but is most abundant where animal matter is undergoing decomposition. Its presence is easily detected by a plate of polished silver, which it first turns yellow, and ultimately a bluish-black. This gas was formerly denominated "heptic acid;" by Berthelot and other French chemists it is called "gas hidrogene sulfuric;" and by some German authors "hydrothionic acid;"

The best way of procuring sulphuret of hydrogen is from a sulphuret of iron, which is prepared as follows:

Heat a bar of iron to a bright red heat; then apply to it a roll of brimstone; the sulphuret will be formed, and drop off in the liquid form. These limbs must be collected and kept in a close-flapped bottle.

To one part of this sulphuret in a glass bottle, add two parts of water and one part of sulphuric acid. The addition of the acid causes the immediate evaporation of the gas, which, for nice purposes, should be collected over mercury, since water absorbs a considerable portion of it.

This gas, like hydrogen, takes fire, and burns with a pale blue flame. It is rather heavier than common air, in the proportion, according to Kirwan, of 10000 to 9053; so that 100 cubic inches of it weigh about 33 grains. When moderately diluted, it may be breathed for a short time without danger.

It has a fetid and disagreeable smell, which owing to its presence, we perceive in rotten eggs; and when water is added to the residuum of inflamed gunpowder, it changes vegetable blues red, and has some other properties common to acids.

Water absorbs its own volume of this gas, to which it gives a disagreeable smell and taste, as is evinced in the water at Harrowgate, and many other natural springs. It blackens some of the white metals, and all their solutions, particularly lead, silver, and mercury, and precipitates several metals from their solutions; and it combines copiously with the alkaline, earthy, and metallic bases, saturating them like an acid.
SULPHURET.

It is constituted by one atom of sulphur 15, and one of hydrogen 2; the hydrogen gas not changing its volume. Hence its atom and specific gravity are each equal to 16, hydrogen being 1. This result is confirmed in the decomposition of this gas by electricity. The sulphur is deposited till the hydrogen remains pure, without any change of volume. See Sulphuretted Hydrogen and Gas.

This gas combines with an equal volume of ammonia, forming a substance having all the characters of a salt. It also combines with the alkalies, earths, and other oxides, forming salts. This is a sufficient proof of its acid characters.

Gay Lussac has on this account called it the hydrofulphuric acid, and its compounds with oxide, hydrofulphates. These have been formerly called hydrofulphurates. If the idea becomes finally adopted, that acids may exist without oxygen, Gay Lussac's nomenclature is the most correct. This ingenious chemist supposes that sulphur, carbon, and azote, may act the part of oxygen; and that chlorine and iodine are of the same class; and that all of them, except oxygen, have a double property of acting as the base and the acidifying principle. In sulphuric acid, for instance, the oxygen is the acidifying principle; but in the gaseous body of which we are treating, the hydrogen may be considered the base of the acid, and the sulphur the acidifying principle. The same thing may be observed of chlorine and iodine. See Simple Bodies.

Sulphuretted hydrogen exercises a very strong action on some metals in subsistence, and on many more metallic faults. The metals that are not precipitated from their solutions by it, are iron, cobalt, nickel, manganese, and in some cases antimony and arsenic. These solutions, however, are deeply coloured by the sulphuret; that of iron becoming black; of antimony, orange; of arsenic, yellow, &c.; but either no precipitate forms, or if formed, it is redissolved by an excess of acid. Thus, if sulphuretted hydrogen is added to a solution of the red sulphate of iron, the metal is immediately brought to the state of the green, or lefs oxygenated sulphate, but no precipitate is formed, unless the sulphuretted hydrogen be in great excess, as the red sulphate has naturally an excess of acid. On this principle is founded an useful test to distinguish iron from lead in wine or any other liquor; for by adding hydro-sulphuretted water, and a slight excess of dilute muriatic, or any other weak acid, if iron only be present, the liquor will assume a deep red, but will remain transparent, whereas lead will give a black muddy sediment. Often, too, this test is useful for separating one metal from another in the same solution, both where a precipitable and a non-precipitable metal are present, and where there are metals more or less easily precipitable. Thus, if manganese, zinc, tin, and copper, are in the same solution, the first addition of hydro-sulphuretted water will separate the tin, after which the copper will fall, and then the zinc, while the manganese remains in solution.

In all the above circumstances, it is the simple his hydro-sulphuretted water which is meant, and not the alkaline hydro-sulphurets; for though the action of the latter is in general very similar to that of the simple hydro-sulphurets, there are some important differences; and in particular, the alkaline hydro-sulphurets precipitate all the metallic solutions without exception.

For an account of the alkaline and earthy hydro-sulphurets, we refer to the article Sulphuretted Hydrogen; supplying here the deficiencies of that article. For the hydro-sulphuret of barytes, see Barytes. The hydro-sulphuret of strontian is formed like that of barytes; and the gas which it gives out, when decomposed by acids, burns with a red flame, like the other faults of frontian. (See Strontian.) An hydro-sulphuret of magnesia is formed by diffusing pure magnesia through water, and passing through it sulphuretted hydrogen, and thus effecting a solution. (See Magnesia.) For the hydro-sulphuret of lime, see Lime.

The hydro-sulphuret of ammonia of the Edinb. Ph. is prepared by expelling four ounces of water of ammonia in a chemical apparatus, to a current of gas arising from four ounces of sulphuret of iron, and eight ounces of muriatic acid, previously diluted with two pounds and a half of water. The sulphuret of iron for this purpose may be conveniently made from purified rust of iron, three parts, sublimed sulphur, one part, mixed together, and exposed in a covered crucible to a moderate fire, until they cobere in a mafs.

The hydro-sulphuret of ammonia of the Dub. Ph. is obtained by putting four ounces of sulphuret of iron in coarse powder into a matrix, and pouring gradually over it seven fluid-ounces of muriatic acid, diluted with two pints of water; and in a proper apparatus transmitting the gas evolved from it through four ounces of water of caustic ammonia. Toward the close of the operation apply a moderate heat to the matrix.

This hydro-sulphuret is of a dark-green colour, has a very fetid odour, and an acrid disagreeable taste. It is decomposed by the acids. This preparation is a powerful purge, relieving the action of the stomach, and of the arterial system, in a remarkable degree; and even in moderate doses producing sicknes, vomiting, and vertigo. It was first proposed as a remedy by Mr. Cruikshank, with the view of diminishing the morbid appetite and powerful action of the digestive organs, which attend those laboursing under diabetes mellitus; and its subsequent use has been confined to the treatment of that disease. The dose to an adult should not at first exceed m v, or m vj, given in a large tumbler of water, three or four times a day; and the number of drops should be gradually increased, until a flight degree of godliness takes place, when any further increase must be stopped.

SULPHURETS of Heparis, or Liver of Sulphur. See Liver of Sulphur.

When sulphur is melted with an alkali, a brown uniform mass is produced, which, as long as it continues dry, is a simple combination of sulphur and alkali. But while dissolving in water, a certain quantity of sulphuretted hydrogen is immediately generated, which remains in the solution and unites with the sulphur and alkali, but may be expelled by the addition of an acid, which at the same time precipitates the greater part of the sulphur in a state of purity. The liquid sulphurets therefore contain sulphur, alkali or alkaline earth, and sulphuretted hydrogen, so that they differ from the hydro-sulphurets of the same bales in containing a large excess of sulphur, and therefore give with acids a copious precipitate of sulphur, which the simple hydro-sulphurets do not.

SULPHURET of Lime. See Lime.

SULPHURET of Potasb, or the common Liver of Sulphur; which see. See also Salts.

The sulphuret of potas of the Lond. Ph. is prepared by rubbing together an ounce of washed sulphur and five ounces of subcarbonate of potas, and placing the mixture over the fire in a covered crucible until they unite.

The Edinb. Ph. directs to take carbonate of potas and sublimed sulphur, of each eight ounces; rub them together, and put them into a large crucible, to which a cover is adapted, and apply the fire cautiously till they melt.

The sulphuret of kali of the Dub. Ph. is prepared by mixing
mixing together subcarbonate of kali and sublimed sulphur, of each two ounces; and exposing them in a crucible, with an adapted cover, to a fire gradually raised till they unite. Well prepared sulphuret of potash is inodorous while dry; but when moistened or dissolved in water, it emits the fetid odour of sulphuretted hydrogen. Its taste is bitter and acrid; it changes the vegetable blues into green; it is hard and brittle; breaks with a glassy fracture; is of a liver-brown colour, and stains the skin brown. On being exposed to the air it attracts moisture; its colour changes to a pale green; the fetid odour is emitted, and it is gradually converted into hydrogurgetted sulphuret of potash, combined with a small portion of sulphate of potash. It is also decomposed by acids; and in a violent heat the sulphur sublimes, leaving behind the potash. It is expectorat and diaphoretic. It has been frequently given in chronic asthma and chronic catarrh, without much benefit; but has been found useful in arthritis, rheumatic, and herpetic affections; and in combination with cicutia, as a palliative in cancerous cases. From a theory founded on its chemical action on metallic salts out of the body, it has been strongly recommended as an antidote against arlenical, saturee, and mercurial preparations, when these have been taken in doses sufficient to produce deleterious effects; but it has hitherto been too seldom employed to ascertain its real value in these cases. The usual dose is grs. iij. or grs. iv., combined with soap, in the form of pills, for the first-mentioned cases; or from grs. v. to grs. xx., as an adjunct to cicutia in cancer, given several times a day.

Sulphurets of Barites and Strontian, Liquid, may be obtained either by boiling the pure earth with sulphur and water, or by calcining the sulphates of these earths with charcoal, to convert them into sulphurets, and dissolving the latter out from any remaining undecomposed sulphate.

Sulphuret of Ammonia, Boyle's fuming liquor, or volatile liver of sulphur, is a combination of sulphur with ammonia, which cannot take place except in the liquid form, and in this case with difficulty, and only through the medium of dilatation. The process for obtaining it, being an improvement of that of Beaumé, is as follows: Mix together in a mortar, and put into a retort, 3 lbs. of flaked lime, 1 lb. of sal ammoniac, 8 oz. of flowers of sulphur; and add to this, when in the retort, 6 oz. of water. Adapt a tubulated receiver, and proceed to dilatation with a gentle heat. The first drops that fall are nearly watery, but those that follow are yellow; and when about 6 oz. of liquor have distilled over, a vast quantity of white elastic vapour arises, which fills the receiver, and would burst it, if it had not vent, and of which only a portion is condensed, and with great difficulty. The fire is then to be kept up steadily for an hour or more, till the bottom of the retort becomes brightly red, during which about six or eight ounces more of liquid are obtained.

The product of this dilatation is a yellow, pungent liquid, smelling strongly both of ammonia and of sulphuretted hydrogen, and giving out abundance of white fumes the moment it is uncorked. It is the liquid sulphuret of ammonia. In this process the ammonia, expelled from the sal ammoniac by means of the lime, acts upon the sulphur in the moment of its formation, dissolves the sulphur, and, together with the water present, rises in vapour, and condenses in the receiver. Though only fix ounces of water are added to the mixture, full double the quantity is obtained, the whole being expelled from the flaked lime by the heat. If less water is added, the product is still more fuming, and there is a still greater waste of incenerable vapour. This waste, however, was only incurred before the invention of Woulfe's apparatus; for by its adoption the whole of the vapour may be condensed, either in water, or in an alkaline solution, at pleasure.

Berthollet instituted a course of experiments to ascertain the precise nature of this fuming liquor, for an account of which we refer to Aikin's Dictionary.

Sulphuret of Water. (See Antimony.) The prepared sulphuret of antimony of the Edinb. and Dub. Ph. is an inodorous, infipid, blackish or deep leaden-grey dull powder, which stains the fingers, and is insoluble in water. It is inert, except where it meets with acid in the stomach, in which case it usually operates either as a diaphoretic or mild cathartic; but occasionally produces expectoration and purging; so that the stomach and bowels should be evacuated previously to its use. It has been found efficacious in cirsitis, chronic rheumatism, and herpetic eruptions. The dose is from grs. v. to 3j.; mixed with honey or any convenient vehicle. The official preparations are, oxydum antimonii, oxydum antimonii cum sulphure vitriificatum, antimonii sulphuraturn precipitatum, and pulvis antimonialis. See Antimony.

The precipitated sulphuret of antimony of the London Ph. is prepared, by mixing 2 lbs. of sulphuret of antimony in powder, four pints of solution of potash, and three pints of distilled water; and boil the mixture over a gentle fire for three hours, stirring it constantly, and occasionally adding distilled water, so that the same measure may be kept up. Strain the solution through a double linen cloth, and while it is hot, drop in gradually as much sulphuric acid as may be necessary for precipitating the powder; then wash away the sulphate of potash with hot water, dry the precipitated sulphuret of antimony, and rub it into powder. The Edinb. Ph. directs to boil 4 lbs. of solution of potash, 3 lbs. of water, and 2 lbs. of prepared sulphuret of antimony, in a covered iron-pot, over a gentle fire for three hours, stirring often with an iron spatula, and adding water as may be necessary. Strain the hot liquor through a double linen cloth, and add to it as much diluted sulphuric acid as may be required for precipitating the sulphuret, which must be well washed with warm water. The "brown antimonized sulphur" of the Dub. Ph. is obtained by mixing subcarbonate of kali, and prepared sulphuret of antimony, of each 1 oz.; melting the mixture in a crucible, and when cold, reducing it into a powder. Put it into a mortar with four pints of water, and boil for a quarter of an hour; then remove the vessel from the fire, and cover it when the liquor becomes liverpied after setting, decant it cautiously from the sediment. The antimonized sulphur will partly separate as the liquor cools; add as much diluted sulpiuric acid as will precipitate the whole of it, which takes place with an excess of acid; then agitate the mixture, that the latter precipitate (of an orange colour) may be mixed with the rest; and when it has subsided, pour off the liquor from the sediment, which is to be washed with cold water as long as it emits indius indicates the presence of acid in the effused fluid: finally, dry it upon tibulous paper. The refult of these different formulæ is the same, viz., a sulphuretated hydro-sulphuret of oxyd of antimony. In the Dublin procés, the precipitate thrown down whilst the decanted liquor cools is a powder of a brick-red colour, the well-known kermis mental, which is the oxyd of antimony in union with such portions of sulphur and sulphuretted hydrogen only as it can attract; while the precipitate, afterwards thrown down by the acid, is the old sulphuret of antimony, or a hydro-sulphuret of antimony with an excess of sulphur, but not enough to form a compound, or intermediate product, is obtained, which is the sulphuretated hydro-sulphuret of the oxyd, as in the former
SULPHURIC ACID.

former cases. According to Theard, the oxide in these two powders is in a different state of oxidization; an opinion, however, which is at least very problematical. The following are the proportions of their constituents given by him: Kerneous mineral consists of 72-760 parts of brown oxide of antimony, 20-308 of sulphurated hydrogen, 4-156 of sulphur, and 2-786 of water and loof; golden sulphur of antimony contains 68-30 of orange oxide of antimony, 87-90 of sulphurated hydrogen, 2-130 of sulphur, and 1-823 of water and loof—in 100 parts. But the real difference appears to consist in the larger portion of sulphur thrown down with the golden sulphur; the base being the same in both as stated by Tammendorff.

The precipitated sulphuret of antimony, as it is called, is an orange-coloured powder, slightly fussy to the taste, inodorous, and insoluble in water. It readily catches fire, and burns with a blue and greenish flame, excites the odour of sulphurous acid, and leaves the metal, after the combustion, in the form of a greyish-white oxide.

This preparation of antimony is diaphoretic and expectorant. It was formerly much employed in asthma, and in catarrhal affections; but it is uncertain in its operation, often producing vomiting in very small doses, and is not much employed in modern practice. It is, however, when combined with mercurials, a useful alterative in herpetic eruptions.

SULPHURET of Iron. (See Iron.) The sulphuret of iron of the Dub. Ph. is obtained by mixing six ounces of filings of iron, and two ounces of sublimed sulphur, and exposing them in a covered crucible to a gentle heat till they unite.

SULPHURET of Mercury, Black, or Ethiopic mineral. See MERCURY.

SULPHURET of Mercury, Red. See MERCURY.

SULPHURETTED Sulphur, Super, Hydrogenated Sulphur of Chenevix, Soufre Hydrogiante, is a very curious combination discovered by Berthollet, and consisting simply of sulphuretted hydrogen, with a large excess of sulphur, and without any alkaline or other base. It is prepared by mixing at once a large proportion of muriatic acid with liquid sulphuret of potash, or better, by pouring the sulphuret in small portions into the acid, during which most of the sulphur is precipitated as fusible, but very little effervescence takes place, and the sulphuretted hydrogen, instead of escaping in a gaseous form, does with a portion of the liquid hydrogen, and so the compound is thrown down into a liquid of the appearance of oil, which gradually collects at the bottom of the vessel in which the mixture is made. This substance was first noticed by Scheele.

When this sulphur is kept in a phial with water, on the surface of which it swells, it is constantly in a state of ebullition, and if the phial is uncorked, the whole of the sulphuretted hydrogen escapes, and the sulphur returns to its original state, and falls to the bottom of the water. Also, if a little of this liquid is taken in the mouth, it gives a pungent, bitter, hydro-sulphuretted taste, which soon goes off, leaving nothing in the mouth but solid sulphur, sticking to the teeth.

When a solution of potash is added to super-sulphuretted hydrogen, a small portion of sulphuretted hydrogen escapes, and the remaining unites with the potash, forming a solution, which resembles in every respect the common liquid sulphuret of potash.

SULPHURIC ACID, Vitriolic Acid, or Oil of Vitriol, is formed by oxygen and sulphur; but it is also found that water is essential to the existence of this acid.

In the most concentrated state in which sulphuric acid can exist, it is a transparent, colourless, dense liquid, of an oily consistence, and greatly to the touch. Its taste is very caustic, and so extremely sour, that a few drops only will render a pint of water too sour to drink. It has no smell, except when it is contaminated with animal or vegetable matter, the smallest quantity of which discolours it. When exposed to these influences it destroys their texture, and leaves a black mark. It changes most vegetable blues to red, and manifests other qualities of acids in a very eminent degree.

The fixity of sulphuric acid is very considerable; when in the state of common oil of vitriol, it requires nearly a red heat for its vaporization; and though when diluted with water it will boil at a considerable lower temperature, yet little else than water is driven off, and the acid becoming more and more concentrated, requires a continually increasing heat to keep up its ebullition, till it arrives at the degree necessary for the volatilization of the acid itself.

Sulphuric acid freezes or cryallizes by exposure to cold, and it appears to coagulate with more ease when moderately concentrated than when it is dilute; this remarkable circumstance was first pointed out by the duc d'Ayen, who was then confirmed by Moreau, and has since been treated at large, and in a very satisfactory manner, by Mr. Keir. (Phil. Trans. for 1787, p. 267.) This accurate observer found sulphuric acid of the specific gravity of 1.738, contained at about 40° Fehr; but that if the density is either increased or diminished, a greater cold is required for its congellation. Proceeding from the above density in each direction, he found that sulphuric acid at the specific gravities of 1.730 and 1.775, or at any intermediate density, freezes when exposed to the cold of melting snow; that if the energy of the freezing mixture be increased by the addition of common salt, it will cause sulphuric acid at the specific gravities of 1.841 and 1.75; or at any intermediate density; but that acids at the specific gravities of 1.815 on the one hand, and 1.745 on the other, continue fluid. Sulphuric acid while freezing contains considerably in its dimensions; sometimes it forms a congealed mass, but often shrinks into large regular crystals in the form of oblique truncated octahedrons, or compressed hexagonal prisms, terminated by hexagonal pyramids.

Sulphuric acid attracts water with great avidity, and accumulates in bulk. This takes place even in a flopped bottle, if the flopper does not fit very tight. If some of the sulphuric acid at the usual density of 1.85 be mixed with one-fourth of its weight of water, the temperature of the mass instantly rises to near 500° Fehr, and a mutual penetration takes place, the density of the compound being greater than the mean density of its ingredients. If even four parts of sulphuric acid and one of ice, both at the temperature of 30°, be mixed together, the heat of the mass will rise to 212°; but if the proportion of ice be increased considerably, the caloric necessary to the liquid state of the mixture will exceed that which is extracted during the combination of the ingredients, and cold will be produced; thus, if four parts of ice and one of acid at 30° be mixed together, the temperature of the mass will be cooled down to − 4°. But in all cases where concentrated sulphuric acid is employed in the composition of freezing mixtures, there is at the moment of their combination, as Beaumé has well observed, a very sensible production of heat, which must materially diminish the friability of the ice; thus, according to the able chemist last mentioned, (Chem. Exper. i. p. 219.) if one part of sulphuric acid at the temperature, and four parts of ice, be mixed together, the effect is to raise the thermometer in an
SULPHURIC ACID.

an instant to 94° Fhr., from which it sinks as speedily to 34°. But if the acid has been previously diluted with water, the temperature sinks on the addition of ice to 5° Fhr., without any previous heat having been excited. So powerful is the affinity of sulphuric acid for water, that it will absorb moisture with great rapidity from the air, so as in a very few days to double or treble its weight. Even a boiling temperature, when the acid is moderately concentrated, will not counterbalance this strong tendency; hence it is that sulphuric acid cannot by boiling in an open vessel, be concentrated nearly so much as by distillation in a close apparatus.

The specific gravity of this acid varies from 1.85 to the most dilute acid, depending upon the water it contains.

The following table of the specific gravities of sulphuric acid of different strengths, is taken from Mr. Dalton’s New System of Chemical Philosophy.

The acid at 100°, at the head of the column, is the real acid, or that which combines with different bases, to form the salts called sulphates. It is difficult to say whether it does really exist in a separate state. Mr. Dalton says it is formed when nitrous gas, oxygen, and sulphurous acid, are mixed together, and appears in shining crystals, like hoar frost. On the other hand, sir Humphrey Davy affirms, that when nitrous acids, and sulphurous acid, are mixed, in a glass globe, and the gases perfectly free from moisture, no sulphuric acid is formed. But if a drop of water be introduced, there will be an immediate condensation, and a beautiful white crystalline solid will line the interior of the vessel; whereas, if the globe contain plenty of water, nitrous gas will be given off with great violence, and the water will be found to be a solution of oil of vitriol. We should feel some delicacy in doubting the accuracy of either of these authorities, but it is nevertheless certain, that one of them has been deceived. The experiments were certainly a little different. Mr. Dalton employed nitrous gas and oxygen, which we should imagine could not give a result different from sir Humphrey’s, who employed the nitrous acid ready formed. Both these chemists seem to agree, that the acid of the specific gravity 1.85 contains an atom of water. This acid is the strongest that can be made by concentration, for at its boiling point, which is 620°, the acid and water rife together.

It will be perceived from the table, that the specific gravity varies very little with the first portions of water; and hence it is a very uncertain test of the value of very strong acids. We have generally observed, that those who keep an hydrometer for the purpose of asfaying the oil of vitriol, hardly ever complain of its want of specific weight.

Mr. Dalton recommends the boiling point of strong acids as a better test of their strength. The table shews, that when the quantity of real acid varies one per cent, the specific gravity is only changed in the third decimal place; but the boiling point varies as much as 15°. This points out a simple method of asfaying sulphuric acid with much greater precision than by the hydrometer. An instrument might easily be constructed for this purpose. It should consist of a small platina cup, capable of holding as much sulphuric acid as will cover the bulb of a mercurial thermometer. An upper part may be attached to this cup, to contain the item of the thermometer, and at the same time to guard it from the heat of the fire on which the cup is placed.

The cup of platina, being filled with the acid to be tried, may be placed on a small charcoal fire, or a sand-bath, or indeed a clear common fire, till the acid boils, when it will shew the strength of the acid, by degrees marked upon the scale of platina: the degrees being expreessions of the specific gravity, instead of degrees of temperature. The firft column in the table gives the relative number of atoms of water and acid for different strengths. The way in which the acid mixes with water as well as with the solutons of salts, seems to favour the idea of their proportions being indefinite. But this is merely an apparent anomaly. The acid may combine with one, with two, with three, and perhaps a greater number of atoms of water, but this number may still be limited. An acid weaker than the limited number of atoms of water would give, is constituted by the limited compound becoming equally disperfed through a mass of water, the excess of water not being combined but merely mixed. Such may also be the case with solutons of salts.

That the acid and the water are combined chemically, the condensation of volume, and change of temperature, clearly prove; and in the present state of chemistry, it is not less clear that the proportions of compounds are limited.

Sulphuric acid is constituted by one atom of sulphur 15, and three atoms of oxygen 22.5, making its atom 37.5. The strongest liquid acid, as will be seen by the table, will consist of an atom each of acid and water, which will be 37.5 + 8.5 = 46: the specific gravity of this is 1.85. Acids of this strength, down to 1.8, have the name of oil of vitriol, from the circumstance of this acid being formerly distilled from green vitriol. That the component parts of sulphuric acid are sulphur and oxygen, may be demonstrated either by analysis or synthesis; thus, if sulphur be digested.
SULPHURIC ACID.

Digested with nitric acid, nitrous gas will be given out from the decomposition of the acid, while the oxygen, the other element, will combine with the sulphur, and form with it sulphuric acid; on the other hand, if sulphate of soda be mixed with charcoal and exposed to a red heat, the sulphuric acid is deoxygenated by the superior affinity of the charcoal; carbonic acid and carbonous oxide are produced, and the sulphate of soda is found to be converted into sulphuret of soda, from which the sulphur may readily be procured by solution in water, and the addition of an acid.

But though the elements of sulphuric acid are ascertained, much doubt still exists with regard to their relative proportion.

Several methods have been employed for ascertaining these proportions. Lavoisier, for this purpose, placed a given weight of purified sulphur in a receiver, with a little water to absorb the acid produced; then setting fire to the sulphur, he supplied it with oxygen gas of known purity, till the combustion ceased: then by ascertaining the weight of sulphur burnt, and of oxygen gas consumed, he inferred that sulphuric acid was composed of 57 parts of sulphur and 20 parts of oxygen. Berthollet, having ascertained that nitre and sulphur, in the proportion of four parts of the former to one of the latter, when heated in a retort, reacted on each other quietly and without explosion, mixed together 288 grains of nitre, and 73 grains of sulphur, and heated the mixture in a glass retort till the emission of nitrous gas entirely ceased. During the process, 12 grains of sulphur had sublimed unaltered, and 228 grains of sulphate of potash were produced by the combination of the alkaline base of the decomposed nitre with the newly produced sulphuric acid. Now, according to Kirwan, sulphate of potash is composed of 45.2 sulphuric acid, and 54.8 potash; therefore, out of the 228 grains of sulphate of potash, 103 grains were sulphuric acid, composed of 72 - 12 = 60 grains of sulphur, and 43 grains of oxygen; hence 100 parts of sulphuric acid consist of

Muriatic acid gas combines readily, and in abundance, with sulphuric acid; and the compound acquires a brownish tinge, and, when exposed to the air, emits dense white fumes of muriatic acid gas, probably mixed with a little sulphuric acid, as their odour is more pungent and suffocating than that of simple muriatic acid. The nitric and sulphuric acids unite readily together, either by direct mixture, or by adding a little nitre to sulphuric acid. This compound is of considerable use for recovering the silver from clippings and other refuse of the manufactories of silver-plate. Sulphuric acid absorbs, by agitation, a considerable quantity of red nitrous vapour, and in consequence acquires a light blue colour. The mixture, when exposed to the air, gives off a white vapour. If water is added, the great heat that is thereby generated causes a very rapid and copious emission of the nitrous vapour, and sulphuric acid and water alone remain behind. Sulphuric acid, thus impregnated with nitrous vapour, after a time becomes nearly colourless, and then concretes into solid crystals.

In this state, when dropped into water, it acquires a green colour, and both the crystals and water sparkle with the spontaneous and copious production of nitrous gas. When the crystals are simply exposed to heat, they melt, emit a dense red fume, and, after the nitrous vapour is thus driven off, the residue is common sulphuric acid.

Concentrated sulphuric acid, even when cold, acts in a very striking manner on most kinds of vegetable and animal matter. If a piece of paper or straw, for example, be immersed in sulphuric acid, the texture of the straw is speedily broken down, it acquires a deep black colour, and is diffused through the acid in a state of half solution. This phenomenon, however, does not take place, as is generally supposed, on account of the reaction of the sulphuric acid on the carbon and hydrogen, producing sulphurous acid, but from the strong affinity of the acid for water; in consequence of which, the oxygen and hydrogen of the vegetable matter combine together into water, while the carbon is precipitated.

Sulphuric acid combines with all the metallic oxides, with the alkalies, and all the earths except flaxes, forming an important genus of salts, called in the reformed nomenclature sulphates; which see.

The following is the order of the affinities of sulphuric acid: barytes, bontian, potash, soda, lime, magnesia, ammonia, glycine, yttria, alumine, zircon, metallic oxide.

When sulphur is burnt in oxygen, whether in the pure gas or in the atmosphere, it forms only sulphurous and not sulphuric acid; but if the sulphurous acid be absorbed by water, and exposed to the air for some time, the latter absorbs oxygen, and is converted into sulphuric acid. Hence sulphuric acid cannot be formed by the mere combustion of sulphur; a circumstance which renders the process of manufacture much less simple than it otherwise might be.

\[ \text{Sulphuric} \]
SULPHURIC ACID.

Sulphuric acid is at present formed by mixing together one part of nitre and seven parts of sulphur. This mixture is placed in a chamber, lined with lead. When these materials are set on fire, the nitre facilitates the burning of the sulphur; but it does not furnish sufficient to convert the sulphur into sulphuric acid. The 7 parts of sulphur will require 10.5 of oxygen for that purpose, but the nitre employed with it can furnish no more than .225, supposing the nitric acid to be reduced to the state of nitrous gas. This is so small a portion of the whole, that some other source must be explored, which is doubtless the atmosphere.

The combustion of the sulphur, which is facilitated by the presence of the nitre, first converts the sulphur into fulphurous acid; which, from its gaseous form, would soon be dispersed, if it were not condensed by its conversion into sulphuric acid. When a portion of the nitric acid of the nitre is decomposed by the sulphur, nitrous gas is evolved; but in its ascent, it meets with the oxygen in the chamber, and is converted into nitrous acid gas, which appears in red flames. The new-formed substance can now disperse of an atom of oxygen, which the sulphurous acid is wanting to convert it into sulphuric acid. The bottom of the leaden chamber is covered with water to the depth of two or three inches. This water seems to answer a double purpose; in first facilitating the action of the nitrous acid gas upon the sulphurous acid, and then dissolving the sulphuric acid as it is formed. When the nitrous acid gas has dispersed of its atom of oxygen, it returns to the state of nitric gas; and in rioting, unites with more oxygen, which it again gives to sulphuric acid; thus continuing its receiving and giving office, till it is accidentally dispersed through the same aperture which admitted the common air. A necessary connection between the chamber and the atmosphere will appear obvious. Atmospheric air must be admitted for the combustion of the sulphur, and to afford oxygen to the sulphurous acid; and through the flame, or some other opening, the residual azote must be returned into the open air. Some nitrous gas, and probably nitrous acid gas, will escape at the same time. If the latter were not the case, a constant decomposition of nitre by the sulphur would not be necessary. The theory of this process has been given by the French chemists, Chemist and Deformeur. Sir Humphry Davy objects to it in some degree. He holds, that the union of the oxygen of the nitrous acid with the sulphurous acid does not take place till they come in contact with water; the latter, according to his opinion, being essential to the constitution of the sulphuric acid. If the above theory be correct, a simpler mode of manufacture might be pointed out. The combustion of the sulphur might be so managed, as to furnish the sulphurous acid without loss, but mixed with azote.

From another source nitrous gas and atmospheric air may be furnished. These with the other products meeting where water is present, ought to form sulphuric acid in a very small space compared with the large chamber at present employed. The gases, by this means, might be furnished in proportions so exact, that nothing but azote would escape.

The acid and water which cover the floor of the chamber now only arrive at a certain strength, which is very far short of that required. At that strength it is drawn off, and not taken by evaporation. This used to be performed in glass retorts, which are very liable to break. If this is not performed in a retort from which there is but a small opening, the acid would not part with so much of its water, and its concentration would be limited at a very inferior strength to that used for most purposes. Dr. Wallotta has introduced vessels for the concentration of oil of vitriol made of platina: they are very expensive, but answer the purpose admirably. Some manufacturers use leaden vessels for this purpose.

Sulphuric acid is employed extensively in bleaching, with the oxyammoniacal acid, and in dyeing. It is the cheapest and most useful acid for cleaning the surface of plates of silver, copper, and iron, by dissolving their oxyds.

The sulphuric acid is said to have been found by Balassari, in a concrete state, lining a grotto in mount St. Amiato, in Tuscan: it also occurs in the crevices of volcanic mountains, and dissolved in some mineral waters. But the sulphuric acid of commerce is obtained either from the distillation of sulphate of iron, or from the combustion of sulphur. We shall here subjoin a brief account of both methods, referring to Aikin's Dictionary of Mineralogy, &c. for farther particulars.

Sulphate of iron, or green vitriol, consists of sulphuric acid, water, and oxyd of iron: by proper methods, the acid may be separated from the other ingredients of the salt; and this continued to be the only origin of sulphuric acid in the great way, till the discovery, by the manufacturers of English chemicals, of the art of preparing it by the combustion of sulphur. As this latter discovery has not, however, as yet entirely superseded the former, we shall give an account of both, beginning with the most ancient.

Sulphuric acid is thus prepared at Bleyl, in Bohemia. A long horizontal furnace or gallery of brick-work is constructed, capable of receiving a number of retorts: the retorts themselves are pear-shaped vessels, with a slightly curved neck, by which they fit into earthen receivers ready of the form of common retorts. The whole apparatus being prepared, each retort is charged with three pounds of sulphate of iron, previously calcined at a full red heat, and the fire is lighted. The first effect of the heat is to drive off the moisture absorbed by the vitriol in the interval between its calcination and distillation: this phlegm, being only very slightly acridious, is allowed to escape; and when it ceases to come over, the receiver with a little water in it is luted on to the retort. The fire is now raised, and kept up for 34 hours, during which time the acid rises in the form of dense white vapours, which fill the receiver, and are then absorbed by the water, and the fumes being at a high temperature, soon render the receiver very hot: hence the workmen judge of the termination of the process, by the receiver becoming cool, in conformance of the vapour ceasing to rise. The red oxyd of iron, or colcothar, is now taken out of the retort, and its place is supplied with a fresh charge of calcined vitriol: the distillation then takes place as already described, except that the former produce of acid is not emptied out of the receiver, and, therefore, there is no occasion to add any water. If the retort is well made, and carefully lubricated over, it will last for three successive distillations, and the quantity of acid obtained is nearly equal to half the weight of the calcined sulphate.

If the acid be examined at different periods of the distillation, it will be found to be more and more dense, according to the violence of the fire required for its extraction: the latter portion, if received in a separate vessel, will generally congeal upon cooling; hence it is called glacial sulphuric acid.

This acid used to be, and perhaps in still, prepared at Nordhausen, in Saxony: it is of a dark brown colour, and exhalates, when exposed to the air, abundance of dense, white, suffocating vapours; its usual specific gravity is \( \approx 1.95 \). For other properties, see Aikin, \( \text{aki} \) supra.
SULPHURIC ACID.

From the facts which he has recited it seems probable, that the essential difference between the common and glacial acid is, that the latter, from the mode in which it is prepared, contains a smaller portion of water than the former, and that to this is owing both its volatility and property of congealing. It is incidentally mixed with sulphurous acid, but the presence or absence of this does not appear to be of any material importance.

The sulphates of copper and zinc have occasionally been employed, instead of the sulphate of iron, but with a manifest disadvantage, both because they are dearer than the latter salt, and because they require a higher and longer continued heat to drive off the whole of the acid.

The following is the usual method of manufacturing sulphuric acid from the combustion of sulphur. A chamber is constructed of frame-work, and lined with strong sheet-lead; the only aperture is a small door, made to shut very close, the bottom of which is a little higher than the floor of the chamber. Water is poured into this chamber, till it rises to the height of an inch or two upon the floor, and a flame is introduced, on which is placed an earthen pot containing a few pounds of sulphur and nitre, in the proportion of from eight to ten of the former to one of the latter. This mixture is set fire to by means of a red-hot iron, and the door is immediately closed. At the expiration of about six hours, a second charge of sulphur and nitre is introduced, which after a similar interval is replaced by a third, and so on without interruption for a fortnight or three weeks. At the end of this period, the water in the chamber is sufficiently acidulated; it is accordingly transferred to a leaden boiler, where the greater part of the water is evaporated. In proportion, however, as the acid becomes more concentratated, it is more disposed to corrode and dissolve the lead of the boiler; therefore, before this degree of concentration takes place, the liquor is transferred into large green glass retorts, where a degree of heat is applied sufficient to drive off almost the whole of the water. As the acid becomes stronger, it also becomes clearer and less coloured, in consequence of a portion of acid re-acting on the impurities with which it is tinged, and thus destroying them. When the acid is thus brought to the required density and clearness, it is poured out of the retorts into large globular glass bottles, surrounded with wicker-work stuffed with straw, called carboys, and is then brought into the market, under the name of oil of vitriol.

The sulphuric acid obtained from the distillation of green vitriol exists ready formed in the falt; its extraction is a perfectly simple process, and the only impurities that it can possibly contain are sulphurous acid, and a very minute portion of oxvd of iron, and of the earth of the retort. When loaded with sulphuric acid, it has a suffocating odour, and, when exposed to the air, gives out a white vapour like strong muriatic acid. It need formerly to be sold in this state by the name of fuming oil of vitriol, and was further distinguished by its property of congealing into a soft ice, and a very moderate degree of cold. By dilution with a little water, and subsequence boiling for a few minutes in a glass vessel, the sulphuric acid is driven off, and the residual fluid is common sulphuric acid in a state of very considerable purity.

When the method of producing sulphuric acid by the combustion of sulphur and nitre was first discovered, the apparatus employed was a series of very large glass balloons, set at the bottom of each of which was a little water to condense the vapour; only a small quantity of the mixture could be burnt at once, and constant superintendence was necessary to supply the balloons with fresh charges of the materials. In order to save much of this manual labour, and the heavy loss arising from the frequent fracture of the vessels, leaden chambers were made use of, which, besides requiring less attendance, and being upon the whole cheaper, rendered it easier for the manufacturer to extend his establishment to any required magnitude. These chambers are of various construction: the most simple and in most general use are furnished only with two apertures, one small door, by which the water and the sulphur and nitre are introduced, and a leaden pipe with a stop-cock, by which the water, when acidulated, is drawn off: other chambers have besides a few small apertures, for the introduction of atmospheric air during the combustion, and a steam-pipe connected with a boiler, it being found that if the water is introduced in the state of steam, a much more rapid condensation of the acid ensues than in the usual way of proceeding. In some of the beetle contrived chambers, the combustion of the nitre and sulphur is effected in a separate flow, and the acid vapour thus produced is poured by means of a pipe into the condensing chamber.

There is a good deal of difference among the manufacturers as to the proportion of nitre employed: by some it is made equal to one-fifth of the sulphur, while by others it is not allowed to exceed one-tenth. This, however, appears to be satisfactorily established, that within the above limits the greater the proportion is of nitre, the more easily and more perfectly the acid is condensed. The less the nitre, the less the fume; and the less fume, the less the yield of acid. The nitre exceeding one-fifth of the sulphur, the combustion will be so rapid as to drive into the chamber a considerable proportion of sulphur unaltered. It would conduct much to the purity of sulphuric acid, and might probably be found even to be an economical plan, to line the chamber with glass instead of sheet-lead: the general appearance of the chamber would then resemble a green-house, and all the work-work should be faced internally with glass. A composition of wax, malein, and fine sand, would form a strong cement for the glass, and little liable to be acted on by acid vapours. More especially if the interfaces filled up with it were dunted with powdered glass, or very fine sand, while the cement was yet warm and adhesive. Such a chamber would have the additional advantage of allowing the operator to see what was passing within, without the necessity of opening the door.

The common English sulphur is unfit for the preparation of sulphuric acid, on account of a yellowish-brown colour which it gives to the fluid, and which it is not easy to get rid of. For this reason, the refined Sicilian sulphur is the only kind that is employed in this manufacture, at least in Britain.

Common sulphuric acid may be freed from the sulphates of lead and potash, which it generally contains, by distillation. This, however, though apparently a very simple process, is rather a nice matter to manage, according to the usual method. Sulphuric acid is not capable of being distilled at less than a red heat: when, therefore, the dense hot vapour first comes in contact with the necks of the retort and receiver, it is apt to break them, unless the precaution has been taken of thoroughly heating them by means of a pan of charcoal placed beneath, a minute or two before the distillation commences. All this risk, however, may be avoided, and in some laboratories it actually is so, by connecting the glass body, in which the acid is boiled, with the receiver, by means of a tube of platinum. Boiling sulphuric acid has not the least action on this metal, and the vapour, in its passage through, becomes so far cooled and condensed, that it flows into the receiver in drops.
SULPHURIC ACID.

Sulphuric Acid, in the Materia Medica, is a valuable tonic, astringent, and antiseptic. Its official preparations are the following: \textit{vis. Acidum sulphuricum dilutum; acidum sulphuricum aromadictum; acid. citricum; acid. muriaticum; acid. nitricum; aqua super-carbonatis potassii; fulphans potassii; pectina; soda; muriaria; antimonii; ferri fulgur; hydrazoammonitum; fulphants hydrazoammonitum; zinci fulphas; and other sulphuricos.}

The \textit{acidum sulphuricum dilutum}, or diluted sulphuric acid of the Lond. Ph., is obtained by adding a fluid-ounce and a half of sulphuric acid gradually to 14 fluid-ounces and a half of distilled water, and mixing. The Edinb. Ph. directs one part of sulphuric acid to be mixed with two parts of water. The Dubh. Ph. orders 2 oz. by weight of sulphuric acid to be mixed gradually with 14 oz. by weight of distilled water, and the mixture to be set aside to cool; then the clear liquor to be poured off. The fp. gr. of this acid is to that of water as 1900 to 1000. The tonic and anti- septic powers of this acid render it extremely serviceable in low typhoid fevers, dyspeptic affections, diabetes, convulsions, and in cutaneous eruptions. It restrains the colliquative sweats which attend hectic; locally applied, it is a common and useful adjunct to gargles in coryza, and to check catarrh; and as a refrigerant, it is given with certain benefit in phthisic hemoptyses, from whatever part they may arise. In the first-mentioned cases the diluted acid may be combined with infusions of cinchona or other vegetable bitters, and aromatics; and in the latter, with infusion of roes, mucilage, or simple water sweetened with syrup. The usual dose is from \textit{m}, x to \textit{m}, xxx, but in malignant erysipelas, with a tendency to hemorrhagy, it has been given to the amount of \textit{f} in twenty-four hours; and it has also been given with evident advantage, says Thomson, to the same amount, in violent uterine hemorrages.

The \textit{acidum sulphuricum aromadictum}, or aromatic sulphuric acid of the Edinb. Ph., is prepared by dropping 6 oz. of sulphuric acid gradually into 2 lbs. of alcohol; digelling the mixture in a covered vessel with a very gentle heat for three days; then adding of cinnamon bark, bruised, \textit{f}, oz. and ginger root, bruised, 1 oz.; digelling again in a clove vessel for six days, and filtering through papers placed in a glass funnel. The colour of this oil, which is generally regarded as an imperfect ether, is peculiar and aromatic, and its taste grateful and pleasant (\textit{f}); it is limpid, and of a brownish colour. This is an agreeable mode of exhibiting sulphuric acid in dysepsia, chronic asthma, and most of the complaints for which the diluted acid has been found serviceable. The dose may be from \textit{m}, x to \textit{m}, xxx in bitter infusions, or any convenient fluid vehicle, given three or four times a day.

The \textit{acidum citricum}, or citric acid of the London Ph., is obtained by taking of lemon juice a pint, sparked chalk an ounce, or a quantity sufficient to faturate the juice, and nine fluid-ounces of diluted sulphuric acid: add the chalk by degrees to the lemon juice heated, and mix them; then pour off the liquor. Wash the citrate of lime which remains in repeated portions of water, and then dry it. On the dried powder pour the diluted sulphuric acid, and boil for ten minutes; express the liquor strongly through a linen cloth, and filter it through paper. Evaporate the filtered liquor with a gentle heat, so that crysals may form as it cools. To obtain the crysals pure, dilute them in water a second and a third time; filter each solution, boil it down, and put it apart to crystallize. (\textit{See Citric Acid.}) The solution of this acid in water, in the proportion of \textit{f}, of the crysals to \textit{m}, of water, answers nearly all the purposes of recent lemon juice, and is even preferable for forming the common effervescing draught with subcarbonate of potassa. A solution of \textit{f}, in \textit{m}, of water, sweetened with sugar that has been rubbed on fresh lemon-peel, forms a grateful refrigerant beverage, resembling lemonade, and equally useful in febrile and inflammatory complaints. It is probable that the crysallized acid may be equally useful in scurvy as the fresh juice of the fruit; but we have not heard whether this point has yet been ascertained.

\textit{Acidum muriaticum}, or muriatic acid of the London Ph., is prepared by taking of muriate of soda dried, 2 lbs.; \textit{f}, lb. of sulphuric acid; and 1 pt. of distilled water; first mixing the acid with half a pint of the water in a glass retort; and when the mixture is cold, adding to it the muriate of soda; pouring the remainder of the water into the receiver; and, having fitted to it the retort placed in a sand-bath, distilling over the muriatic acid into this water, with a heat gradually raised until the retort becomes red-hot. The specific gravity of muriatic acid is to that of distilled water, as 1.170 to 1.000. The Edinb. Ph. directs to take of muriate of soda, 2 lbs.; of sulphuric acid, 16 oz.; and 1 lb. of water: first expose the muriate of soda in a pot to a red heat for a short time, and when it is cold, put it into a retort; then pour the acid, mixed with the water and cooled, upon the muriate of soda; and, finally, distill from a sand-bath with a moderate fire as long as any acid comes over. The Dubh. Ph. directs to take of muriate of soda, dried, sulphuric acid, and water, of each fix pounds; to dilute the acid with the water, and after it is cold, to add it gradually to the muriate put into a glass retort; then to distil the liquor until the residuum becomes dry. (See \textit{Muriatic Acid.}) This acid is tonic and antiseptic. It has been efficaciously used in typhus fevers, and in some cutaneous eruptions. It is a common and useful adjunct to gargles, in the proportion of from \textit{f}, to \textit{f}, in \textit{f}, of any fluid, in ulcerated fore- throats, and cancerous oes; and, in a very highly diluted state, \textit{f}, in \textit{f}, of water, it has been recommended as an injection in gonorrhoea.

This acid has even been regarded as an antitoxin in general phthisical affections; but the observations of Mr. Pearson have shewed this opinion to be erroneous; yet, by its salutary effects on the stomach and general health, "it is a medicine capable of ameliorating the appearance of venereal ulcers, and of restraining for a time the progress of the disease," where it is desirable to "gain a little time, previously to the entering on a mercurial course." The dose is from \textit{f}, to \textit{f}, in \textit{f}, of a sufficient quantity of water.

A very important property of muriatic acid, in the state of gas, is the power it possesses of neutralizing putrid miasms, discovered by Moreau in 1773. It is, therefore, used as an agent for destroying infection in sick rooms and hospitals, dilengaged by pouring sulphuric acid on common salt.

\textit{Acidum nitricum.} (See \textit{Nitric Acid.}) For the other articles above enumerated, see \textit{Antimony, Iron, Mercury, Potassium, Salts, Sulphate, &c.}

For an account of the \textit{ether sulphuricos}, or sulphuric ether, see \textit{Spirit.}

The ethereal oil of the Lond. Ph. is prepared in the following manner. After the distillation of sulphuric ether, distill again the remaining liquor with a gentle heat, until a black froth swells up; then immediately remove the retort from the fire. To the liquor in the retort add water sufficient, that the oil may float upon it. Let this be scummed off, and as much lime-water be added to the retort as will raise any acid it may contain; and shake them together. Lastly, take off the ethereal oil after it is separated. The oily ethereal liquor of the Dubh. Ph. is obtained by taking what remains in the retort after the distillation.
SULPHURIZED MURIATIC ACID, a fagicular compound resulting from the incomplete oxygenation of the sulphur when exposed to the long continued action of oxymuriatic acid, by which it is converted into sulphuric acid; the properties of which have been only examined by Dr. Thomson. It is thus prepared: Char a retort with common salt and oxys of manganese; to it a Woulfe's apparatus, with two or three bottles; put some dry leaves of sulphur into the first bottle, and into the next some bexomated potash, to absorb the superfusible acid: then pour into the retort some concentrated sulphuric acid, and oxymuriatic acid gas will be immediately liberated. After the sulphur has been for some time in contact with this gas, it will become moist and doughy, its colour will change to orange, by degrees it will become more and more soft, and at length will be resolved into a red fluid: so soon as this is effected, the process must be stopped.

The liquid thus obtained is perfectly clear, of a colour between scarlet and crimson, by reflected, and green by transmitted light; its specific gravity is 1.63, and its weight is more than twice that of the sulphur employed. When first exposed to the air it smokes like the distilled muriate of tin, but after a time its fumes are not more copious than those from strong muriatic acid. It is very volatile at a moderate temperature. Its odour resembles that of sea-weed, but is much stronger, and it affects the eyes in the same manner as wood-smoke does. Its taste is acid, hot, and bitter. It changes paper stained with vegetable blues to red, but not very rapidly, unless water is added.

This fagicular substance has not yet been very exactly analysed; nor does it appear to be uniform in its composition; in one specimen Dr. Thomson found the relative proportions of muriatic acid and oxys of sulphur to be as 44 of the latter to 35 of the former. In another specimen the proportions were 47.1 muriatic acid, 35.5 oxys of sulphur, and 4 sulphuric acid. The oxys of sulphur appears to be composed of 53.6 sulphur, and 6.2 oxygen. Aikin.

SULPHUROUS or SULPHUROUS, is formed when sulphur is burnt in the open air. At the common temperature it exists in the gaseous form. It is the peculiar fagocating effects of this gas that we feel when the sulphur burns. The first chemist who seems to have examined this acid with any attention was Stahl, who named it "phlogiilicated vitiolic acid." Our knowledge of it was enlarged by Scheele, Priestley, Berthollet, Vaquelin, and Fourcroy; but we are indebted to Dr. Thomson for the best analyses of it that has yet appeared, and for the discovery of various interesting facts, which had been either overlooked or obscurely stated by preceding inquirers. The most simple way of obtaining this gas is by heating sulphuric acid with mercury, or bits of copper, in a glass retort. If the neck of the retort be placed under a receiver filled with mercury, in a mercurial bath, the gas will be obtained.

It is elastic and colourless, like air. Its smell is pungent and fufing, it is insoluble in water, it is inflammable, and supports combustion or animal life. It first reddens vegetable blues, but ultimately destroys their colour. It is employed for destroying the colour of silk, wool, and hair. These bodies are exposed to the fumes of burning brimstone, which is the cheapest way of forming this gas. This process is called flowery. Accordingly these forms are employed to discharge the natural yellow tinge from white woolen cloth, and to refine silk that has become yellow by long wearing, to its original whiteine; it is also used to check the fermentation of vinous liquors. Its specific gravity is easily known, when we learn that oxygen is converted into sulphurous acid without changing its volume, and it takes up its own weight of sulphur. Hence the specific gravity of oxygen is doubled, and the specific gravity of sulphurous acid gas is to that of hydrogen, as 1 to 30, which agrees with experiment, or about twice as great as that of atmospheric air. (See Gas.) Water absorbs about 30, or, as others say, 20 times its bulk of this gas, to which it communicates a disagreeable taste and the smell of the gas. The gas is expelled by heat; but if they remain for some time exposed to the air, the smell vanishes from the absorption of oxygen, which converts the sulphurous into sulphuric acid.

It does not appear susceptible of any change by heat; but, according to an experiment made by Monge and Cloutet, if exposed at the same time to great prelure, and a cold equal to 31° of Fahrenheit, it looses its elasticity, and assumes a liquid state. Water, it is said, by simple exposure to this gas, without agitation or extraordinary prelure, absorbs, according to Priestley, about 44 times its bulk, or 4/5 of its weight; and, according to Thomson, at 51° Fahr., 33 times its bulk, or 4/5 of its weight; but if water be saturated by this gas, by means of a Woulfe's apparatus, the bottles of which are surrounded with ice, it will be found to have taken up, according to Vaquelin, about 4/5 of its weight. The specific gravity of this liquid acid is flated by Berthollet at 1.04, and by Vaquelin at 1.03; by Thomson at 1.05 at 68°.

We may learn from what has been observed, that this acid is constitute by one atom of sulphur 15, and two atoms of oxygen 15; the weight of its atom being 30.

From Dr. Thomson's analysis it appears that 82 parts of sulphuric acid, and 18 of sulphur, constitute 100 of sulphurous acid; according to which (if the analysis of sulphuric acid by Chenex be assumed the most authentic) this acid consists of

The order of the affinities of sulphurous acid, as far as it has been ascertained, is the following: barytes, lime, potash, foda, magnesia, ammonia, and alumine. It is separable in the form of gas from its earthly and alkaline bates, by the sulphuric, muriatic, phosphoric, and tartaric acids. Oxigenous gas seems to have no effect on sulphurous acid gas, when both ingredients are dry; but if to a mixture of one part of the former and two of the latter, a little water be added, a sudden diminution of bulk will at first take place, on account of the absorption of part of the acid gas by the water; after which a gradual absorption occurs, in consequence of the process of an actual combination between the two gases, by which sulphuric acid is formed, and part of the oxygen gas disappears. Oxymuriatic acid gas is readily decomposed by sulphuric acid; the vessel is filled with white vapours, and a mixture of sulphuric and muriatic acids is the result.

Hydrogen gas and sulphuric acid exercise no action on each other at the common temperature, but if a mixture of three
SUL
three parts, by bulk, of the former, and one of the latter, is
made to pass through a red-hot glass tube, the sulpheric
acid is totally decomposed, and the products are sulphar,
water, and sometimes a little sulphuretted hydrogen.
Phosphorus, even when strongly heated in a glass tube,
appears to have no action on sulpheric acid gas. Phos-
phuretted hydrogen, on the contrary, even at the ordinary
temperature, readily decomposes this acid; the mixture
looses its state of elastic fluidity, a white vapour makes its
appearance, and the fides of the vessel are lined with a mixture
of sulphur and phosphorus. Sulphuretted hydrogen has a
similar effect to phosphuretted hydrogen, and sulphur is pro-
duced from the decomposition both of the acid and of the
inflammable gas.
Charcoal, at the common temperature, imbibes a con-
siderable quantity of sulpheric acid gas, but appears to
produce no material change upon it; at a red heat, however,
the gas is decomposed, sulphar is deposited, and phos-
phuretted hydrogen is produced; the hydrogen, doublets, or
originating from the water, either of the acid gas or of the
charcoal.

White camphor, sulpheric acid combines readily, and
the result is a liquid, the properties of which have been but
little investigated; this compound, when dropped into
water, precipitates again the camphor, which appears to have
undergone scarcely any alteration.

Sulphuric acid, especially at a low temperature, absorbs
a large proportion of sulpheric acid gas; the combination
soon becomes solid, and in this state it has but little odour;
but if a portion be laid on a piece of glass, and exposed to
the air, it presently resolves into a liquid, at the same time
dissolving, with a very visible effervescence, the greatest
part of the sulpheric gas. Strong and colourless nitrte
acid, by being impregnated with sulpheric acid gas, ac-
quires a deep orange tinge, and nitrous gas is disengaged;
the sulpheric being at the same time converted into sul-
phuric acid.

Water, when saturated with sulpheric gas, forms the
liquid sulpheric acid; it is best prepared in a Woulfe's ap-
paratus, with two or more bottles, into the first of which
should be put a little water, to take up the sulpheric acid,
which the gas is generally more or less mixed, while the
purified sulpheric acid is absorbed by the water in the se-
cond and succeeding bottles. This liquid acid absorbs oxy-
gen from the air, and is gradually converted into sulpheric
acid. But if a little of it is confined in a glass tube, her-
metically sealed, and exposed to the common heat of a sand-
bath for a few weeks, the inside of the tube will be observed
to be lined by degrees with minute crystals; after a time the
deposition of crystals will cease; if then the end of the tube
be broken off under mercury, this latter fluid will rise
in the tube, showing that a portion of the air has disappeared,
and the residue, on examination, will be found to be wholly
deprived of oxygen; the liquid, which was pure sulpheric
acid, will be converted, for the most part, into sulphar,
and the crystals are sulphar. Hence it appears, that by
the long continuance of heat, the oxygen of the liquid sul-
pharic acid quits one part of its base in order to form sul-
phuric acid with the remainder.

Sulphuric acid combines, either directly or by com-
posed affinity, with the different saltifiable bases, forming
the genus of salts, which have obtained the name of
salts.

Those metals whose affinity for oxygen is weak, as lead,
mercury, and copper, are not acted upon by sulpheric
acid. Some metallic oxides simply combine with the acid
into a sulphate; others, as the black oxide of manganese,
give out a portion of oxygen to the acid, converting it
totally, or in part, to sulpheric. Hence there is produced a
sulphate, either mixed or not with a sulphite.

SULPHURWORT, MEADOW, in Agricola, the
common name of a plant of the grass kind, often met with
in meadows of the more moist description. See Hy-
Fennel.

SULPICIUS-SEVERUS, an ecclesiastical histori-
on, and prebiter of the fifth century, who is placed by
Cassius about the year 401, and who is supposed to have died
about the year 430. He was a native of Gaul, educated for the
bar, and became eminent for his eloquence. He acquired
wealth and married. After the death of his
wife, he took orders, and devoted himself to a religious
life, first under the discipline of Phebeanus, bishop of Ages,
and afterwards under that of St. Martin, bishop of Tours.
Paulinus, bishop of Nola, with whom he was intimate, makes
honourable mention of him in his letters. He died in
some time at Touloufes, and afterwards at Eauze, in Galla
Carsonnenses. Censorius says, that in his old age he em-
braced Pelagianism; but being convinced of his error, me-
nifested his repentance by perpetual silence afterwards; this
is, as some suppose, by writing no more books. It appear
from his own works, as well as from the testimony of
Jeron, that he imbued some of the notions of the Millenarians.
Du pin says that he was very credulous with regard to
 miracles; but Tillenouf believes every word. It is recorded,
much to his praise, that he was adverse to every kind of
persecution, and that he disapproved of the interposition of
miracles in the province of religion. His testimony in the
books of the New Testament is very explicit, and he con
firms many of the historical facts recorded in them. His ge-
neral division of the sacred writings is into the law, the
prophets, the gospels, and the apostles;—the law and the
apostles;—the Old and New Testament. He was the au-
thor of many works, the principal of which is his "Sacred
History," in two books, written in a neat and elegant Latin
style, bearing a comparison with that of the best classical
writers, and containing a full array of events in the affairs
of the Jews, and of the church, from the beginning of the
world to the confilhip of Stilicho and Aurelian, A.D. 400.
This history, after the period of the evangelical writings, is to
short, and even defective; the author having wholly omitted
the reign of the emperor Julian, and, as Dupin says, having
committed many faults against the truth of history, especi-
ally the ecclesiastical. He has also given an account of St. Martin,
bishop of Tours, and three letters on the death and virtues
of that saint, in which he has intermixed fables with many
peculiar curiosities. His most entertaining work is one of
his dialogues, which relates the mode of life of the cistercian
monks, and affords an instructive delineation of the state of
monachism at that period. Some epistles to his father and
other persons are also preferred. His works have been fe-
reral times republished. The best editions are those of Le
Clerc, Lipl. 1709, 8vo, and of Hieron. a Prato, Vern.

SULS.

SULTAN, or Soldan, a title or appellation given to the emperor of the Turks.

Baron de Tott says that it is a title given to the Polish princes, born while their fathers were in possession of the throne, and to those of the Gungushian family. It is bestowed, however, on the person who enjoys the rights of succession; and this, by the Turfik law, belongs to the eldest of the family, born while the father possesses the throne. But the baron is certainly mistaken when he affirms, that in Turkey or Tartary the title sultan conveys no idea of sovereign authority. The legend on the coin of the Turkish emperors, which begins with these words “Soultan el Beren,” sovereign of the earth, evinces the contrary.

It had its rise under Mahmoud, son of Sebecstehgin, the first emperor of the dynasty of the Gaznovers, toward the close of the fourth century of the era of the Hegira; when that prince going to Segesst to reduce Kalaf, governor of that province, who affected the sovereignty; Kalaf was no sooner advertised of his coming, than he went out to meet him, delivered the keys of his fortresses, and owned him his sultan; that is, his lord or commander. The title pleased Mahmoud so well, that he assumed it ever afterwards; and from him it passed to his descendants, and to other Mahometan princes.

Vatter will have the word Turfik, and to signify king of kings; adding, that it was first given the Turkish Agios, oxen and sheep; others will have it originally Persian, allying, in proof of it, an ancient medal of Cofcoe; others derive it from foldanum, quafo fial dominus; others from the Hebrew סלע, סכלא, to rule, reign.

In the Roman ceremonial, we also find mention made of a foldan, or marshal, who is to attend the pope when he marches in state. He is also to apprehend malefactors.

SULTANS, Epocha of the. See Gledaan Epocha.

SULTAN Flower, Cyanus, in Botany, a species of Centaurea, which see.

Sultana-Schrijf. See Schrijf.

SULTANA, the wife of a sultan.

Travellers, it is observed, have improperly called sultans the wives of the grand vizier; as this name is given in Turkey only to the princesses of the blood, daughters of a sultan, or to the mother of him who occupies the throne. The daughters of the sultans no longer bear any other name but that of "Kanoom-sultan." The grand vizier, either from pride or political motives, must not marry his subjects; he thinks himself too exalted above the rest of mankind to involve himself with a woman by the ties of marriage, and place her, in some measure, in the same rank as himself. He has an indeterminate number of female slaves destined to his pleasures, and to give him succourers. But among this great number, seven of them only, after having enjoyed more or less the favours of the sultans, are raised to a rank above the others; they become his favourites; they participate most commonly in his pleasures; and sometimes acquire no small degree of influence over public affairs. They are distinguished by the name of "Kadum." The slave who becomes the mother of a boy, or the favourite sultan, is called at Hahasti-sultan, i.e., the private sultana.

(See Arsh.) She has a hose and flaves; she obtains a distinguished rank; she is treated with the greatest respect; she enjoys a fort of liberty in the interior of the harem; and in a word, she approaches the sultan as often as she wishes, and is reckoned the emperor's chief wife, if this term may be used.

Vol. XXXIV.

SUL

She is likewise allowed a large revenue, and acknowledged in the seraglio as queen, by every expression of duty and respect. The other women (though they may have issue) are not called queens; but they are called sultanas, because they have had carnal commerce with the king; but they are not so honoured with the title of queen, who is the mother of the first begotten son, heir to the empire. If this son should die, the mother returns among the "Kadums," if he be not heir to the old seraglio, called "Eckli-sera," constructed by Mahomet II. (See SERAIL.) If another of the sultanas should have a second son; then her son being to succeed the deceased heir, she is immediately made queen, and the former shall remain a sultana only, and be deprived of her revenue and royalty; and thus the title of queen is transferred from one sultana to another, by virtue of the son's succession.

The mother of the new sultan, or reigning emperor, is called "Valadi or Valada sultana," has her liberty, a palace, and revenues. Greaves's Works, vol. ii. p. 648, &c. For an account of the condition and treatment of these slaves that are not selected among the favourites, see ODALITES.

SULTANA also denotes a strong Turkish vessel of war.

SULTANABAD, in Geography, an old city of Persia, in Khorasan. See TARSHISH.

SULTANABAD, a circuit of Bengal, bounded on the N. by Rajemal and Anmore, on the E. by Raujehy, on the S. by Birboom, and on the W. by Birboom and Hendosa; about 25 miles long, and 18 broad.

SULTANABAD, a large town of Persia, in the province of Kerman, situated at the foot of a pass on the banks of a fine river, and surrounded with gardens and cultivated lands. In its vicinity grows a tree, which produces a fruit, resembling in flavour the quince, but in appearance the coffee-berry.

SULTANGUNE, a town of Bengal; 14 miles W. of Boghipour.—Alfo, a town of Hindostan, in Oude; 40 miles W. of Lucknow.

SULTAN-HISAR, a town of Asiatic Turkey, in Natalia, once a strong place, a part of the citie of the ancient Tralles; taken in 1403 by Timur Bee; 52 miles S.E. of Miletas. N. lat. 37° 51'. E. long., 28° 4'.

SULTANI. See BJORE.

SULTANIA, or SULTANEE, an old city of Persia, in the province of Irak, said to have been built in the 13th century, on the ruins of the ancient Tigranocerta; the residence of many of the Persian kings, and one of the largest cities of Asia. It was taken and pillaged by Timur Bee, who nevertheless suffered the edifices consecrated to religion to remain. It is situated in a pleasant and fertile plain, where the king usually encamps during the summer months, in order to avoid the hot and unhealthy climate of Teksm. This city, which is 70 miles from Caffewen, and 300 from Meana, was the capital of the descendants of Holaku; but is now an entire mass of ruins; occupied by about 20 poor families, who live in wretched hovels, in the vicinity of the tomb of sultan Hodabunda, the founder. This is a large and beautiful structure, built of brick, and covered with a cupola, ninety feet high, that would do honour to the most scientific architect in Europe. The latitude of Sultanien was ascertained by several observations, whilst the millstone was encamped with the king in June 1810. The mean of these observations was 35° 52' 30" N. The longitude is said to be 48° 26'. E.

SULTANIA, or TURKISH SIAUN. See SIAUN.

SULTANPOUR, in Geography, a town of Hindostan, in the country of Lahore; 61 miles S.E. of Lahore. 3 T

N. lat.
N. lat. 50° 25'. E. long. 73° 30'.—Alfo, a town of Bengal; 53 miles S. of Calcutta.—Alfo, a town of Hindostan, in Gujarat; 30 miles S. of Goa.—Alfo, a town of Hindostan, in Oude; 50 miles N. of Allahabad. N. lat. 24° 13'. E. long. 82° 28'.

SULTE, or Sule, a town of Mecklenburg, containing some salt-works and boiling-houses; 23 miles E. of Rostock. N. lat. 54° 8'. E. long. 13° 40'.

Sultz, a town of France, in the department of the Upper Rhine, with a medicinal spring; 12 miles S.W. of Colmar.—Alfo, a river which rises in the county of Cilley, and runs into the river Save, 7 miles E. of Rein.

Sulz, or Sulz. See Sulz.

SULTZBACH, a town of France, in the department of the Upper Rhine; 6 miles S.W. of Colmar.—Alfo, a town of the duchy of Wurzburg; 9 miles S.E. of Lauingen.

SULTZBURG, a town of the duchy of Baden, celebrated for its wine; 20 miles N.E. of Bale.

SULTZDORF, a town of the duchy of Wurzburg; 4 miles S.E. of Konigshofen in the Grabfeld.

SULTZHEIM, a town of the duchy of Wurzburg; 2 miles N.N.W. of Gerothalm.

SULTZMACT, a town of France, in the department of the Upper Rhine; 9 miles S.W. of Colmar.

SULZEN, a river of European Turkey, which runs into the sea, 6 miles S. of Italic.

SULZ, a town of Germany, in the margravate of Anspach, on a river of the same name; 13 miles W. of Anspach.—Alfo, a river of Bavaria, which runs into the Altmahl, near Beringen.—Alfo, a river of Anspach, which runs into the Wormitz at Waffertudingen.—Alfo, a river of Helfe, which runs into the Fulda, two miles N. of Hursfeld.—Alfo, a town of Wirtemberg, near the Neckar, with ample salt-works; 12 miles N. of Rothweil. N. lat. 48° 18'. E. long. 8° 40'.

SULZA, a town of Saxony, in the principality of Weimar, on the river Ilm, near which are some silver-mines belonging to the prince of Saxe-Coburg; 14 miles N.E. of Weimar. N. lat. 51° 5'. E. long. 11° 42'.

SULZANO, a town of Italy, in the department of the Mela; 12 miles N.N.W. of Brescia.

SULZBACH, an imperial village of Germany, in the circle of the Lower Rhine, given in 1802, among the indemnities to the prince of Nassau-Ulimen.—Alfo, a town of Germany, in the lordship of Limburg; 5 miles E.S.E. of Galdorf.—Alfo, a river of Wurzburg, which runs into the Kirch, near Denkendorf.—Alfo, a town of Bavaria, and capital of a principality to which it gives name, united with Neuburg. It contains churches for the Luthers and Roman Catholics, and about 500 houses. In the neighbourhood is an iron-mine. The tax to the chamber of Westfals was 48 m. dollars 51 kreutzert; 48 miles N.N.E. of Ingolstadt. N. lat. 46° 50'. E. long. 11° 45'.

—Alfo, a town of France, in the department of Mont Touerere; 3 miles N.W. of Latereck.

SULZBURG, a town of Bavaria, lately belonging to the abbey of Kempten; 6 miles S. of Kempten. N. lat. 46° 51'. E. long. 11° 47'.

SULZBURG, Obir, a town and citadel of Bavaria, and capital of a lordship to which it gives name, united with Pyrbaum; 29 miles W.N.W. of Ratibon. N. lat. 49° 8'. E. long. 11° 20'.

SULZER, JOHN-GEORGE, in Biography, was born in 1720 at Winterthur, in the canton of Zurich, and being the youngest of twenty-five children, and having loft both his parents in the same day in the year 1734, his patrimony was scarcely sufficient for defraying the expense of his education. In 1736, however, he was sent to the gymnasium of Zurich, where he was principally indebted for instruction to John Gellner, and also to Bournier and Breitinger, who formed and directed his taste. At this time his attention was divided between the study of the Hebrew language, Wolff's philosophy, and the system of Linnæus. In 1739 he was licensed to preach by the synod of Zurich. His first publication was entitled "Moral Considerations on the Works of Nature;' and his account of a tour which he made in 1742 into the neighbouring part of the Alps was printed. In 1745 he visited Berlin, and there gained the friendship of Euler and Maupertuis; but during his previous residence at Magdeburg he edited a translation of "Schlocher's Itinera Alpina," and wrote his "Treatise on the Education and Instruction of Youth." On the recommendation of Sack and Euler of Berlin, he was appointed professor of mathematics in the Joachimsthal college at Berlin. Having obtained leave from the king in 1750 to visit Switzerland, he married a lady to whom he had formed an attachment at Magdeburg. He then accompanied Klopfrock to Zurich, and on his return to Berlin in the same year, he was made a member of the Royal Academy of Sciences, to the philosophical clafs of which he contributed various psychological essays, which were afterwards translated into German, and published in a separate volume. In the year 1760 he had the misfortune to lose his wife, after which event he never entirely recovered his strength and spirits. In order to dispense his grief, he was allowed, in 1765, to revisit his native country, where he employed his time in completing his "Theory of the Fine Arts." In 1765, on his return to Berlin, he obtained the king's consent to resign his professorial chair, and resolved to retire with his two daughters, not yet of age, to the vicinity of Zurich, and there calmly to wait the approach of death. But the king retained him at Berlin, and granted him a pension, with a professor's chair in the Knights' academy, then newly established. He also granted him a piece of ground on the banks of the Spree, near the city, where he might erect a house, and amuse himself with gardening, of which he was exceedingly fond. In this spot he spent the happiest period of his life, from the year 1765 till his death. His employment, besides that of writing, was the superintendence and occasional inspection of schools and gymnasia in the king's dominions. In 1768 he published, for the use of schools, "Exercises to excite Attention and Reflection," and "Observations on the reciprocal Influence of Reasons in Language, and of Language on Reason." In the next year he committed to the press his excellent "Dictionary of the Fine Arts:" the first part of this work appeared in 1771. In the same year Sulzer made an attempt in dramatic writing, and prepared Mercier's "Defensor," the Berlin theatre: he also endeavoured to convert Shakspere's "Cymbeline" into a regular piece for the same purpose; but his talents did not appear suited to this kind of composition. In 1771 he was invited by the duke of Courland to Mihen to establish a new gymnasium, which proposal his bad health obliged him to decline, though he drew up the plan of the establishment, and made efforts for procuring able professors. In 1772 the state of his health prevented the discharge of his professional duty in the military school. In order to obtain relief in his malady, he undertook, by the advice of Haller, a tour to Nice, an interesting journal of which has been printed. In the course of this journey he received the last proof of the effem of his sovereign, in the intelligence that he was appointed director of the philosophical clafs of the academy. The mild climate of Italy proved a
SUM

first favourable; but in the autumn of 1776 his complaints increased; and in 1777, after his return, he had an interview with the king. On the day before his death he was very cheerful, and conversed freely with his friends; and when one of them said that he hoped to see him again, he replied, with much composure; “Yes, I hope to too; without this hope, life would be a miserable dream.” He expired, as if falling asleep, in the month of February 1779.

SULZFIELD, in Geography, a town of the duchy of Wurzburg; 5 miles S.S.W. of Kitzingen. N. lat. 49° 43'. E. long. 8° 30'.

SULZHEIM, a town of the duchy of Wurzburg; 7 miles S.E. of Schweinfurt.

SUM, SUMMA, in Mathematics, signifies the quantity that arise from the addition of two or more magnitudes, numbers, or quantities, together.

This is sometimes called the aggregate; and, in algebra, it is sometimes denoted by the letter Z, which stands for summa or sume; and at other times by the letter S.

Sums of an Equation is when the absolute number being brought over to the other side, with a contrary sign, the whole becomes equal to 0: this Descartes calls the sum of the equation proposed.

SUMA, a name given by some of the chemical writers to tartar.

SUMACH, in Botany. See RHUS.

The ancients used sumach, instead of salt, for seasoning their meat; whence the Latins call the tree ribes obovatum; and from its use in dressing of leather, it has been called ribes coriaria.

SUMACH, Myrtle-leaved. See CORIARIA.

SUMADA, in Geography, a town of Switzerland, in the Upper Engadine; 8 miles S.W. of Zulm.

SUMAGA, a town of Italy, in the Friuli; 3 miles W. of Concordia.

SUMAGE, SUMAGHUM, or Sumagham, in our Old Writers, toll for carriage on horseback. “Pro uno equo portante summagium per dimidium ann. abolum.” Chart. de Foresta. 215.

SUMAN, in Geography, a town of Hindoozab, in the Dooob; 10 miles N.N.E. of Esfah.

SUMANSTOWN, a village of Pennsylvania, in Montgomery county; 37 miles N.W. by N. from Philadelphia.

SUMARA, a mountain of Arabia, in Yemen; 6 miles S.W. of Jerim.

SUMAR, in Mythology, a sort of flute with two pipes, one of which, the shorter, is used for playing airs, and the longer, in a continued blast; just like the long pipe in the Bulgarian bagpipe. In Egypt they have a bagpipe, called “Sumara el Kurb;” but this is not equal to the Bulgarian bagpipe, which affords the finest music ever heard by Niebuhr in Turkey.

SUMAS, in Geography, a town of New Mexico; 390 miles S.S.E. of Santa Fé. N. lat. 30° 50'. W. long. 105° 36'.

SUMASINTA, a town of Mexico, in the province of Tabasco, on a river of the same name; 115 miles S. of Campeachy. Also, a river of Mexico, which rises about 200 miles S. of Zacualpa, in the province of Chiapas, and runs into the bay of Campeachy, N. lat. 18° 30'. W. long. 90° 40'.

SUMATI, in Hindu Mythology, is the name of a beautiful damsel, espoused by Sagara; the latter being, like Samadra, a personification of the seas. She is said to be the father of Supern, the animal half eagle half man, on which the god Vehu rides. A most extravagant legend, in which, perhaps, is buried some historical or physical fact, is related of this damsel in the Ramayana, and in other Hindoo venerated books.

Being childless, she and her husband engaged, as is usual, in a course of sacred austerities, and was rewarded by a choice given her by the gods, of having one or sixty thousand sons. She preferred the latter, and brought forth a gourd (capsa his lagernaria), whence issued that number of male children, who were carefully brought up by their nurses in jars of butter. This will suffice to all the monstrous legends of Hindoo romance. Some something farther of this story, on which hinges a great deal of incident, probably historical, highly embellished by poetical exaggeration, is noticed under our article SUPERS.

SUMATRA, in Geography, an island in the East Indian seas, the most weedy of those demilitarily Sunda islands, and constituting, on that side, the boundary of the Eastern Archipelago. Its general direction is nearly N.W. and S.E. It is divided by the equator into almost equal parts, one extremity being in 5° 33' N. and the other in 5° 36' S. lat.

Fort Marlborough, on the point of land called “Ooong Carrang,” in S. lat. 3° 46', the only place whose latitude has been determined by actual observation, is found to lie 102° E. of Greenwich; but the situation of Acheen Head is also pretty accurately fixed by computation at 95° 34'; and the longitudes in the fratries of Sunda are well ascertained by the short runs from Batavia, which city has the advantage of an observatory. Sumatra lies exposed on the S.W. side to the Great Indian ocean; the N. point stretches into the bay of Bentara; to the N.E. it is divided from the Malay Peninsula by the fratries of Malaca; to the E. by the fratries of Banca, from the island of that name; to the S.E. by the commencement of the Chinifea seas; and on the S. it is bounded by the fratries of Sunda, which separate it from the island of Java.

Some traditions report that Sumatra was anciently a part of the continent of Asia. John De Barros speaks of it as the Aurea Chersonesus of the ancients, conceiving it to be a continuation of the continent; and another writer describes the fratries of Malaca as a large river. This large island seems to have been utterly unknown to the Greek or Roman geographers, whose discoveries, or rather conjectures, extended no farther than Ceylon, which was probably their “Taprobane.” The idea that Sumatra was the country of Solomon’s Opheir, is too vague to merit discussion. (See OPHEIR.) The Arab travellers, who, about the year 1173, penetrated into India and China, mention an island, which they call “Ramni,” with which the situation and productions of Sumatra tolerably coincide. Marco Polo, whose writings published in 1299, though condemned as fabulous, bear many signatures of authenticity, describes an island called “Java Minor,” which was probably Sumatra. The name of Sumatra is not much known; the orthography of it is various, is of uncertain etymology. The appellation Samader, given to this island, has some resemblance to Sumatra; but the Nubian geographer, Edrisi, describes it as lying near to the river Ganges. M. d’Anville is confident, that the “Jabaddi infula” of Poloemy is Sumatra, though usually supposed to represent Java. The commentators of Arrian assert that this is the island meant by the “Infula Simundii,” or “Palesimundii,” of that writer, in his “Periplus Mani Erethret.” A friar named Odoricus, who in 1311 visited some of the Indian islands, speaks of Java and “Symolza,” which perhaps may suggest the true etymology of Sumatra. Reland thinks, that Sumatra owes its name to “Samadra,” supposing him to signify, in the language of the country, “magna forma,” from the large
ants which abound in that country; but as there is no remarkable hill that bears the appellation which he mentions, this etymology is not probably correct. The name, whatever be its origin, seems to have been acquired by the Portuguese on the coast of Malabar, where they made their first establishments, and obtained a knowledge of the more eastern countries.

Sumatra, according to Mr. Marfiden's statement, is one of the largest islands in the world; resembling Great Britain more perhaps in size than in shape, though, like Great Britain, it is broadest at the southern extremity, and narrows gradually towards the north. A chain of mountains runs through its whole extent, in some parts double, and in others treble; but situated, in general, more to the western than the opposite coast, and being on the former seldom so much as 20 miles from the sea. The height of these mountains, though very great, is not sufficient to allow their being covered with snow, during any part of the year, which is the case with those of South America, between the tropics. (See Ophir.) Between the ridges of these mountains are extensive plains, elevated, however, considerably above the surface of the maritime coasts, where the air is cool, and affording the most eligible situation for inhabitants, who are here the most numerous, and spots the moat cleared of woods, which in other parts of the island cover the hills and plains with a perpetual shade. Here are also many large and beautiful lakes, that extend at intervals through the whole country, forming a communication between the different parts, and furnishing most of the larger rivers, those especially that discharge themselves to the eastward. Waterfalls and cascades are also not uncommon. The country is everywhere well watered, and abounds with springs; and on the western coast the rivers are innumerable, but too small and rapid for the purposes of navigation. The heat of the air is less intense than might be expected, in a country occupying the middle of the torrid zone; the thermometer, at the most sultry hour, or about two in the afternoon, generally fluctuating between 83 and 85 degrees. At full tide it is usually as low as 76; but in the off season it is much more perceptible than usual, a temperature would seem to indicate. Inland, as the country ascends, the degree of heat decreases rapidly, requires the warmth of fires, and checks the vegetation of the cocoa-nut tree. The temperature of this island is not unreasonably ascribed to its narrow form. Frost, snow, and hail, are totally unknown to the inhabitants. The atmosphere, however, is in common more cloudy than that of Europe; and between the hills, a fog, called "caboot" by the natives, is dense to a surp passing degree; it rises in the morning, and is seldom dispersed till about three hours after sun-rise. The water-spout is a phenomenon that frequently occurs; and thunder and lightning are very common; and during the north-west monsoon, the explosions are extremely violent. On the west coast of Sumatra, the south-east monsoon, or dry seaon, begins about May, and slackens in September; the north-west monsoon begins about November, and the profuse rains cease about March. The monsoons, for the most part, commence and subside gradually there; the months of April and May, October and November, generally affording weather and winds variable and uncertain. The soil of Sumatra may be represented generally as a stiff, reddish clay, covered with a stratum or layer of black mould, of no considerable depth. Its population being thin, it happens that at least three parts in four of the island, and towards the south much a greater proportion, remains an impervious forest. Along the western coast swamps abound, and have a considerable extent, and surround spots of land, which become so many islands and peninsulas, of various elevation. This unevenness of surface has been ascribed to various causes; but Mr. Marfiden inclines to trace its origin to the springs of water with which these parts of the island abound, and which are themselves owing to the loftiness of the ranges of mountains that occupy the interior country, and interrupt and collect the floating vapours. The earth is rich in mineral and fossil productions. It affords, even in its present exhausted state, a considerable quantity of gold, copper-mines of very rich ore, iron-ore, tin, sulphur, salt petre, coal, and rock-crystal. Mineral and hot springs have been discovered in many districts; and also earth-oil, soft rock, called "nappal," and polishing the qualities of the steatite. The mountain fone is a species of granite. Many curious fossils are discovered in cliffs, occasioned by the encroachments of the sea, such as petrified wood, and sea-shells of various sorts. Here are also various kinds of coloured earths.

In this, as well as all the other islands of the eastern Archipelago, there is a number of volcanic mountains, and earthquakes frequently occur. The convulsions which attend them, and the gradual recedes of the sea, produce new land; while its encroachments on other parts occasion beds of sand, and the overflow of the dry earth. The chain of islands that lie parallel with the west coast of Sumatra may probably have been a part of the main, and separated from it, either by some violent effect of nature, or the gradual attraction of the sea. The coast, however, where the shore is flat and shelving, is defended from the attack of the sea by a reef or ledge of coral rock, against which the surf (a term erroneously laid by Mr. Marfiden not to occur in our dictionaries) exerts its violence, without any great effect. (See Surf.) The spring-tides on the west coast of Sumatra are attimated to rise in general no more than four feet; it is always high water there when the moon is in the horizon, and consequently at fix o'clock nearly, or the days of conjunction between the year, in parts not far remote from the equator. This, according to the Newtonian theory, is about three hours later than the uninterrupted course of nature; and is owing to the impediment which the waters meet with in revolving from the eastward.

The inhabitants of Sumatra may generally be divided into three classes: one comprehending the Mahomedan inhabitants of the sea-coast, and the other the Pagan of the inland country; and if we descend to the principal subdivisions, we may distinguish the empire of Menangchow, not Menangchow (which feee), and the Malays; the Aboro; the Battas; the Rejangs; and the Lampoons. The Rejangs, though inconsiderable in the political scale of the island, are placed by Mr. Marfiden in a kind of central situation, not geographically, but with regard to the encroachments of foreign manners and opinions, introduced by the Malays from the north, and the Javans from the south. Their form of government and laws extend, with little variation, over a considerable part of the island, and especially over that portion principally connected with the English. These people, formerly of more extensive diffusion, have a proper language, and a perfect written character, that is generally used in remote districts. The country of the Rejangs is divided, to the north-west, from the kingdom of Anac Boongey, of which Muco Muco is the capital, by the small river Oori, near that of Cattows; which last, with the district of Laboon on its banks, bounds it on the north or inland side. The country of Muoco, where Palembang river rises, forms its limits to the east. Bencoolen river confines it on the south-east; though the inhabitants
inhabitants of the district called Lemba, extending from thence to Silebar, are entirely the same people in manner and language. The principal rivers, besides those already mentioned, are Laye, Pallay, and Soongeylamo; in all which the English have factories, the resident or chief being stationed at Laye. The persons of the inhabitants of the island, though differing considerably in district remote from one another, may be comprehended in general under the following description; except the Achenees, whose complexion with the Moors of the west of India has distinguished them from the other Sumatrans. They are rather below the middle stature; their bulk corresponds; their limbs are for the most part short, but well-shaped, and particularly small at the wrists and ankles. Upon the whole, says Mr. Mariden, they are gracefully formed; and among the natives there is scarcely one deformed person to be seen. The women, however, have the preposhous custom of flattening the noses and compressing the heads of children newly born, which, as the skull is cartilaginous, increases their natural tendency to that shape. A similar practice prevails at Uletsia. They likewise pull out the ears of infants, in order to make them stand erect from the head. Their eyes are uniformly dark and clear; their hair is strong and of a shining black colour, improved in this respect by the constant and early use of cocoa-nut oil. The men wear their hair short, but that of the women is long, reaching in some instances to the ground. The men are bearded, but the Malay priests display a little tuft, which is sufficient to show that nature has not witheld from them this token of manhood. It is the same with respect to other parts of the body, in both sexes; and this mode of attention to their persons is esteemed a point of delicacy, and the contrary an unpardonable neglect. The boys, as they approach puberty, rub their chins, upper lips, and those parts of the body that are subject to superfluous hair, with chunnam (quick-lime), especially of shells, which destroys the roots of the incipient beard. The few pigs that afterwards remain are eaten out with twinges, which they constantly carry with them for this purpose. Their complexion is yellow, and that of the superior clafs, and especially of women of rank, approaching to a great degree of fairness. Most of the females are disgusting ugly, but some of them exhibit an appearance that is strikingly beautiful. Perons of superior rank encourage the growth of their hand-nails, particularly those of the fore and little fingers, to an extraordinary length; occasionally tingling them red, with the expressed juice of a shrub, called eeni, as they do also the nails of the feet, which are always uncovered. The natives of the hills, through the whole island, are subject to those monstrous wens from the throat, of which instances occur in Europe. (See Goitre.) The inhabitants of the country are superior to the Malays of the coast in respect of size and strength, and fairness of complexion. The inhabitants of Pahsummah are also described as being more robust in their features than the planters of the low country.

The original clothing of the Sumatrans is the same with that found among the inhabitants of the South Sea islands, and is mostly, in the habitation cloth. The men consist of a clofe waffcoat, without sleeves, having a neck like a shirt, buttoned close up to the top with buttons, often of gold filagree. This is peculiar to the Malays. Over this they wear the "badjoo," which resembles a morning gown, open at the neck, but fastened close at the wrists and half way up the arm, with nine buttons to each sleeve; usually made of blue or white cotton-cloth; for the better fort of chints, and for great men of flowered fikls. The "cayen-farrong" is not unlike a Scots highlander's plaid, being a piece of parti-coloured cloth, six or eight feet long, and three or four wide, fewed together at the ends, forming, as some have described it, a wide fack without a bottom. This is sometimes gathered up, and flung over the shoulder like a fash, or folded and tucked about the waist and hips; and in full dress, boused on by the belt of the creefe (dagger), which is of crimson silk, and wraps several times round the body, with a loop at the end, in which hangs the sheath of the creefe. They wear short drawers, reaching half way down the thigh, generally of red or yellow taffeta. They have no covering to their legs or feet. Round their heads they fasten a kind of turban, which is a fine coloured handkerchief; the country people usually twifling a piece of white or blue cloth for this purpose. The crown of the head remains uncovered, except on journeys, when they wear a "toodong," or umbrella hat, completely screening them from the weather. The women have a kind of bodice, or rather short waffcoat, that defends the breasts, and reaches to the hips. The cayen-farrong comes up as high as the arm-pits, and extends to the feet, being folded and tucked over at the breast; except when the "talies-pending" or zone, is worn about the waist. This is usually of embroidered cloth, sometimes fastened with a plate of gold or silver, about inches broad, and in front with a clasp of filagree work, with four kinds of precious stones. The women, however, have the "salendang," or piece of fine, blue, thin cotton-cloth, five feet long, and wrought or fringed at each end, is thrown across the back of the neck, and hangs down before, serving as a veil to women of rank, when they walk abroad.

They have different modes of dressing the hair; they wear no covering, except ornaments of flowers, which are fancifully arranged. Among the country people, particularly in the southern mountains, the virgins (orang-guddeo, or goddeefes, as it is usually pronounced) are distinguished by a fillet, which goes across the front of the hair, and fastens behind. This is commonly a thin plate of silver, about an inch broad; those of the first rank have it of gold, and those of the inferior clafs ufe the leaf of the neepah tree. Befides this peculiar ornament, their flate of pucelage is denoted by their having rings or bracelets of silver or gold on their wrists. Strings of coins are universally worn by children, and the females, before they are of an age to be clothed; and they have a kind of modesty-piece, which is a plate of silver in the shape of a heart, hung before by a chain of the same metal, or ringed round the waist. Both sexes have the extraordinary custom of filing and otherwise disfiguring their teeth, which are naturally very white and beautiful. At the age of about eight or nine they bore the ears of the female children, a ceremony which must precede their marriage. Their ear-rings are mostly of gold filagree, fastening, not with a clasp, but in the manner of fluds.

The houfes of the Sumatrans are not only permanent, but convenient, and are built in the vicinity of each other; that they may enjoy the pleasure and benefit of society. Their suburbs, or "downdens," are always fruited by the banks of a river or lake, for the convenience of bathing, and of transporting goods; and an eminence, difficult of access, is generally chosen for security. The rows of houfes commonly form a quadrangle, with passageways or lanes between the buildings, occupied in the more considerable villages, by the lower clafs of inhabitants, and where their padde-houfes or granaries are erected. It is in the middle of the square stands the "balii," or town-hall, which is a room about

50
SUMATRA.

50 to 750 feet long, and 20 or 30 wide, without division, and open at the sides, except when on particular occasions it is hung with mats or chintz. In their buildings, they never use stone, brick, or clay; but the frames of their houses are of wood, the under-plate resting on pillars of about six or eight feet in height, which have a sort of capital, but no base, and are wider at top than at bottom. For their flooring, they lay whole bamboo, four or five inches in diameter, close to each other, and fasten them at the ends to the timbers. Across these are laid laths of split bamboo, about an inch wide, and of the length of the room, which are tied down with filaments of the rattan, and over these are usually spread mats of different kinds. The sides of the houses are generally closed with bamboo half-split, or with the bark of some kinds of trees. The most general covering of their houses is the leaf of a species of palm called neepal. The mode of ascent to the houses is by a piece of timber, or stout bamboo cut in notches, their buildings being raised to different elevations, in order to secure themselves from the attacks of wild beasts. In the buildings of the doorways, where the most respectable families reside, the wood-work in front is carved, in the style of bas-relief, into a variety of uncouth ornaments and grotesque figures, not much unlike the Egyptian hieroglyphics, but certainly without any mystic or historical allusion. The furniture of their houses is as simple as the buildings; their bed is a mat, usually of fine texture, and manufactured for the purpose, with a number of pillows worked at the ends, and adorned with a shining substance that resembles foil: over the head hangs a sort of canopy or valance. Instead of tables, they have somewhat that resembles large wooden falters, round each of which three or four persons dipose themselves; and on these are laid large wasters, which hold the cups that contain their curry, and plantain leaves, or moties or leaflets, filled with rice. Their mode of fitting is either on the hamsches, or on the left side, supported by the left hand, with the legs tucked in on the right side; leaving that hand at liberty, which they always, from motives of delicacy, scrupulously eat with: the left being reserved for lefs cleanly offices. They employ neither knives, spoons, nor any substitutes for them; they take up the rice and other victuals between their thumb and fingers, and dexterously throw it into the mouth by the action of the thumb, dipping frequently their hands in water as they eat. In cooking they employ an iron vessel, with a wide rim and narrow bottom; they have some coarse china, and a species of earthen pipkins, used in their cooking, mostly imported from Bantam; and in smaller number in the island, particularly in Lampoon, where they give them a sort of glazing: but the original Sumatran vessel for boiling rice, is the bamboo, which the fire almozt wholly destroys before the rice is drenched. They have occasion for fire, chiefly in cooking their victuals; but their houses have no chimneys, and their fire-places are merely temporary contrivances of a few loose bricks or stones: their fuel is wood: flint and flake for striking fire are unknown, but they are chiefly used in traveling, when they take up their habitations in the woods or deserted houses. They frequently kindle fire by the friction of two sticks; seizing a piece of dry, porous wood, and cutting smooth a spot of it, and they then apply a smaller piece of a harder substance, with a blunt point, in a perpendicular position, the other lying horizontally, and turn it quickly round, between the hands, as chocolate is milled, pressing it downwards at the same time. By this motion a hole is soon formed, and before it has penetrated far, the larger piece takes fire. The food of the Sumatrans is chiefly vegetable; but in their entertainments, they admit the flesh of the buffalo, goat, and fowls. Their dishes are allSOO prepared in that mode of dishing called "curry," but whatever be the quantity or variety of their meat, the principal article of their food is rice. Their meat is drenched immediately after the animal is killed, except when they preserve it in the mode called "drying:" this is done by cutting the flesh of the buffalo into small thin flakes, and exposing them to the heat of the sun, generally on the thatch of their houses, till the meat becomes so dry and hard, as to resist purification, without the use of salt. Fifth is also preferred in the same manner.

The most important article of cultivation in Sumatra is rice, which serves both for the food of the inhabitants and for commerce. The next important object of culture is the cocoanut tree, which is applied to a variety of purposes. To thefe we may add the "penang," or betel-nut tree, of which the natives make large plantations. The island also is richly strewed with vegetables of other kinds for domestic use. Their fruits and flowers, as well as medicinal shrubs and herbs, are too numerous to be recounted in this place. Their beasts, birds, reptiles, and insects, are too various for recital. Of those productions of Sumatra, which are regarded as articles of commerce, the most important and abundant is pepper, of which the natives distinguish three species, which are called in different places by different names. Among other commodities of the island, a conspicuous place belongs to the camphire, to which we might add the benjamin or beouzoin, the cassia, rattans, and canes, cotton, coffee, turpentine, and gums. As varieties of wood, we may enumerate the ebony, pine, fad extends, teak, manchineel, iron-wood, and the banyan-tree. Besides these articles of trade afforded by the vegetable kingdom, Sumatra produces many others, and among the chief of these is gold; it affords also tin, copper, and iron, sulphur, arsenic, and salt. The manufacture of wax, ivory, and birds’-nefs. The general articles of import trade are the following: from the coast of Coromandel, salt; long cloth, blue and white; chintz, and a variety of other cotton goods; from Bengal, opium and taffetas; from China, coarse porcelain, tobacco, iron pans, and a number of small miscellaneous commodities; from the Eastern islands, Buggelias clouting, a coarse, striped, cotton manufacture, much worn; guns, called zantakers, creeses, and other weapons; fillers creese-belts, toodongs or hats, salt of a large grain, and sometimes rice, especially from the island of Bally; from Europe, silver, iron, lead, cutlery, and other hardware, brass-wire, and flaxen cloth. Among the manufactures of Sumatra, we may mention the flax, (which see), the forging, &c. of iron, the carpenter’s work, carving in wood and ivory, cane and basket work, and the manufacture of mats, of silk and cotton cloths, and different kinds of earthenware, of gunpowder, of sugar, and of salt. The skill of the Sumatrans in the sciences is very limited. They are fond of music; but most of their instruments are borrowed from the Chinese. The Malay language is universally spoken along the coast of Sumatra, it is practised in Java and the Moluccas, and it is the mediate dependencies, and is understood almost in every part of the island. This language has been much and justly celebrated for the smoothness and sweetness of its sound, infonch that it has been called the Italian of the East: this is owing to the prevalence of liquids and vowels in the words, and the infrequency of any harsh combination of mute consonants: and these qualities render it peculiarly adapted to poetry, to which the Malays are passionately addicted. The character used by the Malays in writing is the Arabic; their books are, for the most part, either transcripts from the Koran, or legendary tales, of little merit as compositions.
compositions. Besides the Malay, many other languages are spoken in Sumatra, the principal of which are the Rejang and the Batta. Their writings are executed with ink, on the inner bark of a tree, cut into narrow strips of considerable length, or folded together in squares, each square or fold answering for a page. On occasions they write on the outer covering of a joint of bamboo, with the point of their creese or other weapon, which serves the purpose of a stylus. None of these languages are so agreeable as the Malay. The Malay and native Sumatran differ more in the features of their mind than in those of their person. The Malay, it is observed, may be compared to the buffalo and tiger. In his domestic state, he is indolent, stubborn, and volupptuous as the former, and in his adventurous life, he is infectious, blood-thirsty, and rapacious as the latter. The original Sumatran is mild, peaceable, and forbearing; but when his resentment is roused, he is implacable. He is temperate and sober, being equally abstemious in meat and drink. Hospitality is carried to the extreme among the Sumatrans: their manners are simple, generally devoid of the Malay cunning and chicane, and yet quick of apprehension, and endowed with a considerable share of penetration and sagacity. In respect to women, without being inoffensive, they are remarkably continent; they are modest, guarded in their expressions, courteous in their behaviour, grave in their deportment, being afraid not to laugh, and to a great degree patient. On the other hand, they are licentious, indolent, addicted to gaming, diffident in their dealings with strangers, fulsome, regardless of truth, mean in their transgressions, servile, cleanly in their persons but dirty in their apparel, which they never wash: impoverished of the future, as their wants are few, and easily supplied. Of their government, laws, customs, and manners, we can only give a hasty and imperfect sketch. The inhabitants of the Rejang country live in villages or doofoons, under the government of a magistrate, called "dupatty." His dependants seldom exceed 100. A certain number of the dupatties belonging to each river, are chosen to sit in a legislative or judicial capacity, at the quaioc or river's mouth; and over the whole presides the pangaran, or prince of the country. All the governments throughout the island are a mixture of the patriarchal and feudal. The foundation of right to government among these people seems to be the general consent; and if a chief excites an undue authority, they conceive themselves at liberty to relinquish their allegiance. The powers of the pangaran, though he claims delphic sway, are very limited, and he is seldom able to punish a turbulent subject, otherwise than by private assassination. He levies no tax, nor has any revenue. Appeals in all cases lie to him, and none of the inferior courts are competent to pronounce sentence of death. All punishments and cauks are by the laws of the country commutable for fines, and appeals, being expensive, seldom occur. Although the rank of dupatty is not strictly hereditary, the fon generally succeeds the father at his decease.

The Rejangs are distinguished into tribes, the descendants of a different ancestor. Of these tribes there are four principal ones, which are said to derive their origin from four brothers, who have been united from time immemorial in a league, offensive and defensive: there are several inferior tribes. The system of government among the people near the sea-coast, who, towards the southern extreme of the island, are planters of pepper, is much influenced by the Europeans, who are lords paramount. Pafsummah, which nearly borders upon Rejang to the S.W., is an extensive and comparatively populous country, bounded on the N.W. by that of Lassattang, and on the S.E. by that of Lempoo, and distinguished into the broad Pafsummah, which lies inland, and extends within a day's journey of Palembang river; and Pafsummah on the W. side of the range of hills, whether the inhabitants are said to have mostly removed, in order to avoid the government of the Dutch. Pafsummah is governed by four independent pangerans, who acknowledge a kind of sovereignty in the sultan of Palembang; and in almost every doofoon there is an inferior pangeran.

Among the Rejans, there is not any perfous or clafs of persons regularly invested with a legislative power. In all their duties they are governed by traditional customs, the authority of which is founded on usage and general consent. All causes, both civil and criminal, are determined by the several chiefs of the district, assembled together, at stated times, for the purpose of distributing justice. They settle litigations with respect to property by a kind of arbitration. The Rejang laws have not long ago (in 1770) been collected into a code, and committed to writing. The modes of marriage, according to the original institutions of the Sumatrans, are by joojoo, ambel-ana, and femundo: the first is a certain sum of money, given by one man to another, as a consideration for the person of his daughter, whose situation differs little from that of a slave to the man she marries, and his family. Chastity is a prevalent virtue in Sumatra. In the country, prostitution for hire is unknown, and is confined to the Malay bazaars at the sea-ports. Adultery is punishable by fine, but the crime is rare. In the second mode of marriage, by ambohana, the mother of a virgin makes choice of some young man for her husband, generally from an inferior family, and he is taken into the house of his father-in-law, who kills a buffalo on the occasion, and receives 20 dollars from the fon's relations. In this case, the bridegroom becomes wholly, as it were, the property of the family with which he connects himself; all his interests are vested in that family and dependent upon it, and he has in himself so property. The third mode of marriage, called femundo, has been adopted from the Malays. It is a regular sham between the parties, on the footing of equality. The nature of marriage consists simply in joining the hands of the parties, and pronouncing them man and wife, without much ceremony, except the entertainment given on the occasion; and a little apparent courtship precedes marriage. The customs of the Sumatrans permit their having as many wives by joojoo as they can afford to purchase and maintain; but they have seldom more than one. A man married by femundo cannot take a second wife, without repudiating the first.

Among the amusements of the Sumatrans, gaming is very prevalent: accordingly they gamble with dice. They adduce themselves to cock-fighting, and to quail-fighting. Fencing is a common diversion; so is the diversion of toffing a ball. Smoking of opium is a common practice, and the use of it is general and pernicious. (See Amook.) Betel and tobacco are also much used. The Sumatran females bear children at an early age, wise, before 15, and they are generally past it at 30, and grey-headed and thinned, at 40. The country people being totally ignorant of chronology, can seldom give an account of their age. The children among the Rejangs have generally a name given them by their parents, soon after their birth; and another name, sometimes title, is bestowed at a subsequent, but not determinate period. The father is sometimes named from his first child; the women never change the name given them at their birth. A Sumatran frantically abstains from pronouncing his own name. The boys are circumcised, where Mahometanism prevails, between the sixth and tenth year. At their funerals,
funerals, the corpse is carried to the place of interment on a
broad plank, which is kept for the public service of the
doorsom, and lasts for many generations; it is constantly
rubbed with lime, either to preserve it from decay, or
to keep it pure. No coffin is used, the body being simply
wrapped in white cloth: round the grave are fixed white
flags or „reamers; a shrub, bearing a white flower, and
sometimes wild marjoram. The women who attend the
funeral make a hideous howl, like the Iri. Burying
places are held in extraordinary reverence.

The Rejangs are said to be totally without religion, nor
can they be denominated Pagans, if that appellation con-
veys the idea of mistaken worship. They worship neither
God, devil, nor idol. Nevertheless, they have some con-
fused notion of superior beings, who may render themselves
visible or invisible at pleasure; but they have no name for
the Deity. The superstition that has the greatest influence
on the minds of the Sumatrans, and which approaches
nearest to a species of religion, is that which leads them to
venerate, almost to adoration, the toms and manes of their
deceased ancestors. The Sumatrans have an imperfect
notion of a metempsychosia; and in some parts, chiefly
southeastward, they superstitiously believe that certain trees,
particularly those like the banyan, of venerable appearance,
are the parts of the mortal frame of spirits of the woods, a
notion resembling that of the dryadse and hamadryades
among the ancients. The inland people are paid to pay a
kind of adoration to the sea, and to make it an offering
of cakes and sweetmeats on their first beholding it, deprecating
its power of doing them mischief.

The account which we have already given of the manners
and customs of the Rejangs may serve in general for the inhabi-
tants of other districts of Sumatra: but where any very
remarkable dissimilitude occurs, it will be found noticed in the
sequel of this, or in the general account of the Lampoon country, as
Lampon; of the Malay government and Menangcbow; see Malaoca
and Menangcbow. The country of the Rejangs may be con-
sidered in general as bounded to the N. by that of Aceh, and
to the S. by Paffamman and the independent district of
Ou or Aru; or more precisely, as extending from the great
river of Sinkell to that of Taboocoy, on the coast, and
inland, as far S. as Ayer Bongey, at the back of which the
Ou people commence. The country is populous, and the
majority of the people reside at a distance from the sea, in the
central parts of the interior plains; but more than one
ridge of hills, on the borders of a great lake; where the
soil is fertile and much cultivated. This country is divided
into a number of districts, of which the principal are as fol-
low: viz. Ancola, Padambola, Mendeeding, Toba, Selendo-
gang, and Sinkell. The inhabitants are subdivided into
tribes, of which Ancola has five, Mendeeding three, and
Toba five; the others are not ascertained. The English
settlements in this part of the island are at Natal and Tappa-
nooey. See NATAI and TAPPANOOLY.

The province of the Rejangs is rich in precious stones of
camphire, gum ben-
jamin, cafias, cotton, and indigo. The domestic animals are
horses, cows, buffaloes, goats, hogs, and dogs of the cur
kind; with the wild ones that are common to all parts of
Sumatra.

The Battas are in their persons below the stature of the
Malays, and their complexions are fair. Their dress is
commonly of a species of cotton-cloth, which they them-
selves manufacture; this they adorn with fringes of beads;
and the covering of the head is usually the bark of a tree. The
young women wear rings of tin in their ears, often to
the number of fifty in each. The food of the lower people

is maize and sweet potatoes: the rajals and persons of in-
ferior rank indulge themselves with rice; and on public
occasions they kill cattle for food. Their horses they clothe
the most luxurious food. Their houses are constructed
with frames of wood, and boarded; and their roofs are covered
with a species of vegetable, that resembles coarse horsecab.
Their towns seldom consist of more than twenty houses;
and in each of these is a kind of town-hall, for the transacti-
of public business, festivities, and the reception of strangers,
whom they entertain freely and hospitably. At the end of
this is a building, from which are seen the spectacles of leas-
ing and dancing, and below it is a kind of orchestra for
music. The men are allowed to marry as many wives as a
civil place, each of whom has her own apartment; the parents of the younger woman receive a valuable consideration
from the husband, and this is returned when a divorce
takes place against the man's inclination. The condition
of the women appears little better than that of slaves:
besides their domestic duties, they work in the rice planta-
tions, whilst the men lead an idle inactive life, passing the
day in playing on a kind of flute, crowned with garlands of
flowers. Their music is preferable to that of the other Se-
matrans. They are much addicted to gaming, which they
pursue to such an excess, that when a portion loses more than
he can pay, he is compelled the Mapilias and Malabar one.
Horse-racing is a favourite diversion. The Battas have a language and
written character peculiar to themselves.

Dr. Leyden (see Asiatic Researches, vol. 1) confers
the Batta language as the most ancient language of Suma-
tra, and as having considerable claims to originality; though it
is not only connected with that of the Malays, but also with
the Bugis and Bima languages. In point of constructi
it is equally simple as the Malay, but its most intimate
connection is with the Bugis, which may be reckoned in
the original language of the Ifam has her two letters, ap,
with twenty-two letters, varied by the six vocalic fonds,
a, e, i, o, u, u. The Batta language is said to be the chief
source of that diversity of dialect which is discoverable in
the languages of Sumatra. The Rejang dialect is formed by
the mixture of the Batta and Malay; of the Lampung or
Lampon, by mixing Malay and Batta with a proportion of
the Javanese. The Karrwos, who are subject to Ach or Achi,
use only a slight variation of the Batta language, while in
the language of Ach or Achi proper consists of a mixture of Malay and
Batta, with all the jargons used by the Moçems of the East.
The Achines are divided into a number of tribes, each of which is
able to fix vocalic founding, like the Buggis. The Batta cha-
acter is written neither from right to left, nor from left
to right, nor from top to bottom; but in a manner directly
opposite to that of the Chinefes, from the bottom to the top
of the line, as the Mexicans are said to have arranged their
hieroglyphics. The material for writing is a bamboo, or
the branch of a tree, and the instrument with which they work
is the point of a kris or creafe. The Battas sometimes use
their bamboo horizontally instead of perpendicularly, as in
the Chinefes and Japanese do their books, but the Chinefes
consider the correct mode of reading to be from the top to the
bottom.
SUMBAWA, SUMBAVA, or Sumbawa, one of the Celebesian islands, opposite to Bouton (which lies), consists of several petty states, viz. Bima, Dompo, Tambora, Sangar, Papakat, and Sumbawa, independent of each other, but united together by a defensive alliance, as far as regards their possessions in this island. Bima lies at the east end of Sumbawa, about 45 leagues S. of the W. point of Celebes; it is in the same flat, under whose jurisdiction are comprehended the islands of Sasa, the whole of Mangery at the W. point of the island of Endé, childishly demoted to the early Portuguese navigators, and also by succeeding voyagers and geographers, and the island Goenong-api, which last lies a little to the N. of Bima. The Bima language, which is used in the independent states of Bima, extends also over the greater part of the island Endé. It is in some respects related to Bugis and Javanese, and on the coast is mixed with Malay; nevertheless it has strong pretensions to originality in its pronouns, verbal auxiliaries, and simple names of objects. The dialect of Bima is of Obi, and all the inhabitants of the islands are called Obi, almost always pronounced Bali. Hence it is not improbable that Herodotus refers to the ancient Batta.

The government of the country is divided into a number of chiefships, the heads of which, called rajahs, are seldom dependent upon any superior power; but they enter into associations with each other, particularly those of the same tribe, for mutual defence and security against any common enemy. The more powerful rajahs assume authority over the lives of their subjects. The revenues of the chief arise principally from fiefs, paid to them in justice; and while their fiefs are settled by a magistrate, appointed for that purpose; and from him there is no appeal to the rajah. Notwithstanding the independent spirit of the Batta, they pay great respect to the sultan of Menangcob. With regard to war, they are in a state of perpetual hostility, and they are always prepared for attack and defence. Their campan of towns are fortified with large ramparts of earth, half-way up which they plant brushwood; and without the rampart there is a ditch, on each side of which is a palisade of carrion timber, and beyond this a hedge of prickly bamboo. At each corner of the fortress, instead of a tower or watch-houses, they contrive to have a tall tree, which they ascend to reconnoitre, and from which they fire. The standard in war is a horse's head, from which hangs a long mane or tail of hair. Their arms are matchlock guns, bamboo lances, and a fide-weapon, like a sword or large knife. They carry no creese, like the Malays. They have machines, curiously carved, for holding their bullets, and others for the reserve of gunpowder, which they manufacture for themselves. In trade, the natives of the island exchange their camphire and camphire for iron, steel, brass-wire, and salt. They barter again with the more inland inhabitants, for the products and manufactures of the country.
SUM

SUMEN, a word used by some anatomical writers to express the hypogastrium.

SUMENE, in Geography, a town of France, in the department of the Gard; 4 miles E. of Le Vigan.

SUMI, a town of Russia, in the government of Charkov; 68 miles N.N.W. of Charkov. N. lat. 50° 54'. E. long. 35° 4'.

SUMIDOIRO, a river of Brazil, in the capitania of Matto Groppo, which runs for some distance under ground, and thence derives its name. It empties itself on the S. side into the Amazon; and as its source is at a short distance from that of the Guayouba, a large western branch of the Paraguay, there is an easy communication from the one to the other.

SUMISSOR, a town of Napaal; 70 miles from Moscow.

SUMISWALD, a town of Switzerland, in the canton of Berne; 12 miles W. of Berne.

SUMITRA, in Hindoo Mythology, was the mother of Lakhshman, half-brother to the heroic Ramachandra; Dahartha being the mortal father of both. Both, however, are stated to be in fact of divine origin, Rama being an incarnation of Vishnu, and Lakshman of Siva, the mighty many-headed serpent, on which Vishnu reposeth, in his paradise called Vaikuntha.

SUMMAH, in Geography, a town of Algiers; 12 miles S.S.E. of Constanina.

SUMMARO, a small island in the Baltic, S.E. of Aland. N. lat. 50° 58'. E. long. 20° 5'.

SUMMARY, an abridgment, containing the sum and substance of a thing in a few words.

The summary, placed at the head of a book, a chapter, a law, or the like, is very useful to the reader, to facilitate the understanding of them.

A recapitulation is to contain a summary of the whole preceding discourse.

SUMMARY Conviction, in Law. See Conviction.

SUMMATORIUS CALCULUS, the method of summing differential quantities; that is, from any differential given, to find the quantity, from whole differencing the given differential results.

This method we more usually call the **inversion method** of **summation**; and foreigners, **integrals calculus**. See **CALCULUS and FRACTION**.

SUMMEI-KIEUM, in Geography, a town of the Birman empire, on the Irrawaddy, in which is a manufacture of saltpetre and of gunpowder; 60 miles S.S.W. of Ava.

SUMMEIMTOH, a town of Birmah, on the Irrawaddy; 6 miles N. of Deneebow.

SUMMER, a small river of Brabant, which runs into the Deme near Hasselt.

SUMMER, one of the seasons of the year, commencing in these northern regions, on the day the sun enters Cancer, and ending when he quits Virgo.

Or, more literally and universally, the summer begins on the day when the sun's meridian distance from the zenith is the least. It ends on the day when his distance is a mean between the greatest and smallest.

The end of summer coincides with the beginning of winter.

It is said, that a frosty winter produces a dry summer; and a mild winter a wet summer. It often happens so, in fact; but why it should be so, is perhaps a question difficult to determine. The curious may, on this subject, consult the Philosophical Transactions, No. 458, sect. 10.

SUMMER-CLAIR, in Rural Economy, a provincial term applied to the undulating state of the air seen in a hot, calm day near the surface of the ground, appearing to rise as from hot embers, in which case it is said the **summer-clair** rides.

SUMMER-Crepuscul, in Botany. See CHERNOPHYTUM.

SUMMER-Edén, in Agriculture, a provincial word signifying to make use of as a pasture at that season, or to summer-feed.

SUMMER Frost-Marking, for Shepherds, in Rural Economy, the practice of milking ewes for the purpose of converting their milk into cheese. This custom or practice was some time ago much on the decline, in consequence of the injury done to the sheep, but has more lately been somewhat revived, on account of the increasing demand and value of the cheese thus produced.

The summer ewe-milking for this use, formerly commenced, is said by the writer of the Agricultural Report of the County of Peebles, 'there about the latter end of June, the lambs being weaned early, is the order that the more cheese might be made: it now, however, seldom takes place until the beginning or middle of the following month; continuing in some places for nine weeks, but more commonly confined to about six. The sheep-farmer not unfrequently needs additional female-servants for performing the buffeting of ewe-milking.'

A ewe is a female serving, or ewer. Seven or more of these are often allotted to each milker: consequently but little time can be allowed for sleep during the night, especially as the ewes must be milked over night, when confined to the fold, and again in the morning, before putting them out to pasture: besides, the time of detaining them in the fold is shortened as much as possible, that they may have more time to feed through the day.

The fold for milking the ewes is a sort of inclosure of the fold-like kind, with walls inserted below the coping-folds, in order to prevent the ewes from breaking or leaping over it; and value of the cheese, thus produced. The summer ewe-milking for this use is but little time can be allowed for sleep during the night, especially as the ewes must be milked over night, when confined to the fold, and again in the morning, before putting them out to pasture: besides, the time of detaining them in the fold is shortened as much as possible, that they may have more time to feed through the day. The fold for milking the ewes is a sort of inclosure of the fold-like kind, with walls inserted below the coping-folds, in order to prevent the ewes from breaking or leaping over it; and value of the cheese, thus produced. The summer ewe-milking for this use is but little time can be allowed for sleep during the night, especially as the ewes must be milked over night, when confined to the fold, and again in the morning, before putting them out to pasture: besides, the time of detaining them in the fold is shortened as much as possible, that they may have more time to feed through the day. The fold for milking the ewes is a sort of inclosure of the fold-like kind, with walls inserted below the coping-folds, in order to prevent the ewes from breaking or leaping over it; and value of the cheese, thus produced. The summer ewe-milking for this use is but little time can be allowed for sleep during the night, especially as the ewes must be milked over night, when confined to the fold, and again in the morning, before putting them out to pasture: besides, the time of detaining them in the fold is shortened as much as possible, that they may have more time to feed through the day.
high price, on account of its scarcity; but which may be remedied, it is thought, as the cost of it becomes so high as to render it beneficial for the sheep-farmer to sacrifice the advantage of the animals to the increase of their cheese.

The cheese, when become old, is, it is said, accounted one of the best stomachics that can be used as food. It is said of late to have fetched an enormous price, which is recalling the practice of ewe-milking and making of cheese.

The wages of ewe-milking unusually amount, it is said, to above half-a-crown a week, with board; each milker being allowed, besides, a piece of coarse cloth, which is called an ewe-milkers' brat, in order to cover her before, and prevent her clothes from being spoiled by the tar and other filth adhering to the wool of the sheep.

SUMMER-FALLOW, in Agriculture, a name sometimes given to a naked fallow. See FALLOWING OF LAND.

SUMMER-FALLOWING, a term often applied to the process or practice of frequently ploughing and working over arable land at this season, with the view of ameliorating and rendering it clear of weeds. It is chiefly had recourse to for crops of the wheat kinds, but sometimes for those of the barley, turnip, and some other sorts, which require a fine mouldy clean state of the more superficial parts of the soil. The author of a late work on "Agricultural Chemistry," has supposed that the chemical theory of summer-fallowing is very simple. It affords, it is said, no new source of riches to the soil or land; it merely tends to produce an accumulation of decaying matter, which, in the common course of crops, would be employed as it is formed; and that it is scarcely possible to imagine a single instance of a cultivated soil, which can be supposed to remain in summer-fallow for a year with advantage to the farmer. The only cases where this practice can be beneficial, it is said, seem to be those in which it may be used for the destruction of weeds, and for cleaning such soils as are in a foul condition.

In this ancient practice, which is still extensively made use of, the soil or surface mouldy earth is much exposed to the air, and submitted to different procedures, which are purely of a mechanical nature. It is thought that the benefits arising from fallows, or fallowing, have been much overstated; that a summer-fallow, fallowing, or a clean fallow, may sometimes be necessary on lands overgrown with weeds, especially if they be fends which cannot be pared and burnt with advantage; but that it is certainly unprofitable as a part of a general system in husbandry or management of land.

It has been supposed, it is said, by some writers, that certain principles necessary to fertility are derived from the atmosphere, which are exhausted by a succession of crops; and that these are again supplied during the repose of the land, and the exposure of the pulverized or broken-down parts of the soil to the influence of the air; but that this, in truth, is not the case. The earths commonly found in soils cannot, it is said, be combined with more oxygen; some of them unite with azote; and such of them as are capable of attracting carbonic acid, are always saturated with it in those soils on which the practice of summer-fallowing is employed.

The vague ancient opinion of the use of nitre, and of nitrous salts in vegetation, seems, it is said, to have been one of the principal speculative reasons for the defence of summer-fallow, or fallowing. Nitrous salts are produced, it is said, during the exposure of soils containing vegetable and animal remains, and in the greatest abundance in hot weather; but that it is probably by the combination of azote from these remains with oxygen in the atmosphere, that the acid is formed; and at the expense of an element which otherwise would have formed ammonia; the compounds of which are evidently much more efficacious than the nitrous compounds in afflicting vegetation.

It is further noticed on the subject, that when weeds are buried in the soil, by their gradual decomposition, they furnish a certain quantity of soluble matter; but that it may be doubted whether there is as much useful manure in the land at the end of a clean fallow, or fallowing, as at the time the vegetables clothing the surface were first ploughed in. Carbonic acid gas is formed during the whole time by the action of the vegetable matter upon the oxygen of the air, and the greater part of it is lost to the soil in which it was formed, being dissipated in the atmosphere.

The action of the sun, too, upon the surface of the soil or land, tends, it is said, to dilate the gaseous and the volatile fluid matters that it contains; and heat increases the rapidity of fermentation; and in the summer-fallow or fallowing, nourishment is rapidly produced, at a time when no vegetables are present capable of absorbing or drinking it up, by which much wants is the consequence.

It is justly concluded that land, when it is not employed in preparing food for animals, should be applied to the purpose of the preparation of manure for plants; which is effected by means of green crops, in consequence of the absorption of carbonaceous matter in the carbonic acid of the atmosphere. But that in a farmer's fallow or fallowing, a period is constantly lost, in which vegetables may be raised, either as food for animals, or as nourishment for the next crop; and that the texture of the soil or land is not so much improved by its exposure then as in the winter season, when the expansive powers of frost and ice, the gradual diffusion of snows, and the alternations from wet to dry, tend to pulverize and reduce it, and to blend its different parts together more fully.

From these facts and circumstances, it is clearly evident that the practice of summer-fallowing should be had recourse to as little as possible by the farmer, as there is obviously much wants and loss by it in other ways than by the length of time the land lies idle and unproductive.

SUMMER Flowers. See Flowers.

SUMMER Fruits. See Fruits.

SUMMER Land, in Agriculture, a term signifying the fallowing of land in the summer.

SUMMER Management of Flowers, in Gardening, is that which confits in the proper cleaning, watering, directing their growth, and exhibiting them when necessary. See SUMMER Stage.

SUMMER Polities. See SOLASTIC.

SUMMER Stage for Flowers, in Gardening, that which is constructed for the purpose of exhibiting different sorts of flowers at this season. These stages, for the auricula and other similar plants in pots, should be built with deal, or some other light wood not liable to warp by the heat of the sun; the back parts of them may, and the sides should always be fo formed as to have a sort of flutters for sliding up and down occasionally, in order to admit air and light when necessary. Light frames should also be made and raised in the fronts and other parts of the stages, for training canvas, sheets, or mats over, for defending and protecting the flowers from cold winds, flight night-sheets, and too great funny heats, which not unfrequently happen, to some kinds, before as well as when they are in full bloom. The shelves on which the flowers are to be placed in the pots or otherwise, should be made something in the manner of flairs, about six inches in width, and raised two or three inches, or more, one above the other. The roof or covering part may be
be formed of light wood, of the fame kinds as above, being made rather lofty in the front, as from about seven to eleven and a half feet, or rather higher, if thought proper. It should be close, rather thick, and durable, in order to prevent the heat of the sun from penetrating too much through it, which would draw up the flower-frames of the plants too much, and render them weak, as well as be injurious to the wood. The lowest shelf, in such frames, should be about three feet from the ground, and the whole confit of not more than fix in number, in order that the flowers may be within easy reach. The whole length of such frames in the front may be different according to circumstances, but about nine feet in the clear is an useful length; in which case, each shelf may contain about fifteen pots of the largest plants; and a frame, when completely full, holds from about eighty to ninety such pots of flowers, which are mostly sufficient. Such show-frames have, in some instances, looking-glasses fixed up in them at one end, so as to give a reflection of the flower-plants, which has often a fine effect. The insides, as well as the outsides of such frame-frames, should be painted with some dark suitable colour, in the former to serve as a back-ground to the flowers; those of the dark-green, black, or chocolate kind, as giving the best contrast, are probably the most proper, by rendering their appearance the most lively and beautiful.

The proper aspects for such frames, are such as best suit the particular sorts of flowers. For the auricula, they may often front a full northern exposure with advantage. See AURICULA.

SUMMER-First, and SUMMER-Working, in Agriculture, terms applied to summer-fallowing.

SUMMER Tatt. See TAT.

SUMMER Tatt, in Ornithology, the name of a bird, the smallest of all the duck-kind, called by Gmelin the annas circus. See also under DUCK, and Tatt.

SUMMER WHEAT, in Agriculture, the triticum e全民um of botanical writers. See SPRING WHEAT.

SUMMER, formed from the French soumet, which signifies the same thing, in Architecture, is a large stone, the first that is laid over columns and piazzas, beginning to make a cross vault; or it is a stone, which being laid over a pedistool, or column, is hollowed to receive the first haunch of a plinth.

SUMMER, in Carpentry, is a large piece of timber, which, being fastened on to two stone piers, or posts, serves as a lintel to a door, window, &c.

There are also summers used in various engines, &c. serving to sustain the weight, &c.

SUMMER-TREE, denotes a beam into which the ends of joists are fastened, and to which the girders are framed.

See BREST-SUMMER, and GIRDER.

SUMMER of an Organ. See SOUND-BOARD.

SUMMERS ISLANDS, in Geography. See BERMUDA.

SUMMILY, in Agriculture, a term popularly signifying a tump fallow, autumn or naked fallow.

SUMMIT, formed from the French sommet, which signifies the same, the vertex or point of any body or figure; as of a triangle, a pyramid, a pediment, &c.

SUMMIT LEVEL, the highest pound of a canal.

SUMMITS OF FLOWERS, the same with the anthers, or tops of the stamens. See FLOWER.

SUMMONER, SUMMONITOR, an appraiser, or petty officer, who is to cite persons to appear at a certain time and place, to answer to the charges exhibited against them. See APPRAISER, and SUMMONS.

SUMMONS, SUMMONITIO, in Law, a citing or calling a person to any court, to answer a complaint, or even to give in his evidence. This is the same with the vocatio in jus, or the cientis, of the civilians; hence also our old word somner, or sumner.

SUMMONS in terra petita, is that made on the land which the party, at whose suit the summons is sent out, seeks to have. This warning on the land is given, in real actions, by erecting a white fitch, or wand, on the defendant's grounds (which fitch, or wand, among the northern nations, is called the baculus nuntiatorio); and by flat. 51 Eliz. c. 3, it must also be proclaimed on some Sunday before the door of the parish church.

SUMMONS ad Warranuntandum is a process, by which the vouches in a common recovery is called.

SUMMONS to Parliament. See PARLIAMENT.

SUMMONS, in War. To summon a place, is to feed a drum, or trumpet, to command the governor to surrender; or, in case of refusal, to protest to make an assault, and to lay all in fire and blood. See CAPITULATION, and CHAMADE.

SUMMULGUR, in Geography, a town of Bengal; 8 miles E.N.E. of Burdwan. N. lat. 23° 31'. E. long. 88° 20'.

SUMMUM BONUM, in Ethics. See Chief Good.

SUMMUM GENUS. See GENUS.

SUMNAUT, in Geography. See PUTTAN-SUMNAUT.

SUMNER, a town of America, in the district of Maine, and county of Oxford, containing 611 inhabitants.

SUMNER, a county of West Tennessee, bounded N. by Kentucky, E. and S. by the Indian lands, and W. by Davidson county, watered by Cumberland river, and very fertile. It contains 13,792 inhabitants, of whom 773 are slaves. This county has a Presbyterian, Baptist, and two Methodist churches.

SUMNUM, a rich district of Persia, in the province of Khorasan, bounded on the N. by mount Elberus, and S. by the Great Salt Desert. It contains 50 villages; and Sumnum, the capital, is a small town, 23 furlongs from Tehran. "Damgan," 12 furlongs from Sumnum, is supposed to be the ancient Hecatompolis, for some time the metropolis of the Parthian empire. This is the chief town of a district of the same name, situated in a spacious plain, famous for a victory gained by Nadir Shah over the Afghans. "The town of "Bifran," called also Shaver, yields, with its dependencies, a revenue of 19,695 tomans.

SUMOOKGUR, a port of Bengal; 11 miles N. of Calcutta.

SUMOOM, HAM, in Meteorology, a perilous wind of Persia. See Great Sandy Desert.

SUMOROKOF, ALEXANDER, in Biography, the founder of the Ruffian theatre, was the son of Peter Sumoroko, a Ruffian nobleman, and born at Molcow in the year 1777. From his father's house, where he acquired the elements of literature, he was removed to the seminary of cadets at Peterburgh, where he displayed a peculiar genius for poetry, as well as great zeal in the profecution of literary improvement. The early productions of his muse were of the amorous clafs; they soon attracted notice; and under the patronage of count Ivan Shuvelof, he was introduced to the empress Elizabeth, and taken under her special protection. Having much admired the books of Racine, he was led to turn his attention to the drama; and at the age of 29 he composed his first tragedy, intituled "Koval." This was exhibited at the court-theatre, and the applause it obtained induced the writer to proceed in the same career, and to have produced nine tragedies, several comedies, and some operas. In his tragedies, Racine was his model; and though
though he fell short of the perfections of his exemplar, he was in many instances a successful imitator of his excellencies. His comedies possessed humour, but were deficient in purity. Sumorokoff, having so far succeeded in his dramatic performances, made attempts in every species of poetry, except the epic. He wrote love songs, idylls, fables, satires, anacreontics, elegies, versions of the Psalms, and Pindaric odes. In the latter species of composition he was far inferior to his contemporary Lomonosoff, being deficient in that elevation and fire which characterize those of the latter; but the tenderness of his elegies, and the natural simplicity of his pastorals, are much admired, and his fables will bear a comparison with those of La Fontaine. Our poet also wrote some historical pieces in prose, which are commended for periclisey of style, though they abound too much in ornament. Sumorokoff enforced the favour of his female sovereigns. Elizabeth raised him to the rank of brigadier, appointed him director of the Russian theatre, and settled upon him a pension of 400l. per annum. Catherine II. created him counsellor of state, honoured him with the order of St. Anne, and distinguished him by her munificence. He died at Moscow in October, 1777, in the 51st year of his age. "In his private character," says one of his biographers, "he exhibited the virtues and the faults of exquisit felicity; equally alive to benefits and injuries, open and unostentuous; polite when treated with respect, but opposing pride by haughtiness; irascible and inconsiderate." With Lomonosoff he contributed to diffuse a taste for poetry and elegant literature among his countrymen, and they have produced a numerous class of followers. Coxe's Travels in Russia.

SUMP, in Metallurgy, a round pit of stone, lined with clay within, for receiving the metal on its first fusion from the ore.

SUM, in Mines, denotes a pit sunk down in the bottom of the mine, to cut or prove the lode still deeper than before; and when the lowest level of that lode is arrived at, it is called a sump. From this pit they lay a pipe, through which, when the sea is in, the water runs into a well adjoining to the sump, and from this well they pump it into troughs, through which it is carried to their cisterns, in order to be ready to supply the pans. See SALt.

SUMPH, in Mining, denotes a pit sunk down in the bottom of the mine, to cut or prove the lode still deeper than before; and when the lowest level of that lode is arrived at, it is called a sump. From this pit they lay a pipe, through which, when the sea is in, the water runs into a well adjoining to the sump, and from this well they pump it into troughs, through which it is carried to their cisterns, in order to be ready to supply the pans. See SALT.

SUMPTER, or SUMTER, in Geography, a district of South Carolina, containing 19,054 inhabitants, of whom 11,638 are slaves.

SUMPTER-HORSE, is a horse that carries provisions and necessaries for a journey, Ruft.

SUMPTERSVILLE, in Geography, a town of South Carolina, in Clermont county; 519 miles from Washington.

SUMPTUARY LAWS, Leges Sumptuarie, are laws made to restrain excess in apparel, costly furniture, eating, 

Most ages and nations have had their sumptuary laws; and some retain them still. But it is observed, that no laws are worse executed than sumptuary laws.

Political writers have been much divided in opinion with respect to the utility of these laws to a state. Baron Montesquieu observes, that luxury is extremely proper for monarchies, and that under this kind of government there should be no sumptuary laws; and it is also necessary in despotic states; but ruinous to democracies. With regard to England, whose government is compounded of both species, it may fill be a dubious question, says judge Blackstone, how far private luxury is a public evil; and as such cognizable by public laws. See LUXURY.

A government, says Montesquieu, may make sumptuary laws with a view to frugality; and this is the spirit of such laws in republics. In general, the purer a state is, the more it is ruined by its relative luxury, and consequently the greater occasion has it for relative sumptuary laws. The richer a state is, the more it thrives by its relative luxury; for which reason it must take care not to make any relative sumptuary laws.

Sumptuary laws may, under some governments, be necessary for particular reasons. The people, says the same writer, by the influence of the climate, may grow to numbers, and the means of subsistence may be so uncertain, as to render an universal application to agriculture extremely necessary. As luxury in those countries is dangerous, their sumptuary laws should be very severe. In order, therefore, to be able to judge whether luxury ought to be encouraged or proscribed, we should examine first what relations there is between the number of people and the facility they have of procuring subsistence. In England the soil produces more than is necessary for the maintenance of those who cultivate the land, and of those who are employed in the woollen manufactures. This country may be therefore allowed to have some trifling arts, and consequently luxury. In France likewise there is corn enough for the support of the husbandman, and of the manufacturer. Besides, a foreign trade may bring in so many necessaries in return for toys, that there is no danger to be apprehended from luxury.

On the contrary, in China the women are so prolific, and the human species multiplies so fast, that the lands, though ever so much cultivated, are scarcely sufficient to support the inhabitants. Here therefore luxury is pernicious, and the spirit of industry and economy is as requisite, as in any republic. They are obliged to pursue the necessary arts, and to shun those of luxury and pleasure.

The sumptuary laws of that ancient Locrian legislator Zaleucus, are famous: by thee it was ordained, that no woman should go attended with more than one maid in the street, except the were drunk: that the should not go out of the city in the night, unless the went to commit fornication; that the should not wear any gold or precious apparel, unless the proposed to be a common harpum: and that men should not wear rings, or tiptoes, except when they went a whoring, 

The English have had their share of sumptuary laws, chiefly made in the reigns of Edw. III. Edw. IV. and Hen. VIII. against picked shoes, short doublets, and long coats; though all repealed by statute 1 Jac. I. c. 85. As to excess in diet, there remains still one law unrepealed. Ste Diet.

Under king Henry IV. Camden tells us, pride was got so much into the foot, that it was proclaimed that no man should wear shoes above six inches broad at the toes. And their other garments were so short, that it was enacted, 25 Edw. IV. that no person, under the condition of a lord, should, from that time, wear any mantle or gown, unless of such length, that, standing upright, it might cover his privy members and buttock.

Among the Romans, the sumptuary and cibary laws were very numerous: by the lex Orcha, the number of guests at feasts was limited, though without limitation of the charges of them. By the Fannian law, made twenty-two years afterwards,
SUN

wards, it was enacted, that more than ten ares should not be spent at any ordinary feast; for the solemn feasts, as the Saturnalia, &c. an hundred ares were allowed; ten of which, Gellius informs us, was the price of a sheep, and a hundred, of an ox.

By the Didian law, which was preferred eighteen years after, it was decreed that the former sumptuary laws should be of force, not only in Rome, but throughout all Italy; and that, for every transgression, not only the master of the feast, but all the guests too, should be liable to the penalty.

SUMRAH, in Geography, a town of Syria, in the pachalic of Tripoli, anciently called Simypha, or Taximra; 18 miles N. of Tripoli.

SUMSERAH, a town of Bengal; 53 miles S. of Dacca.

SUMSERNAGUR, a town of Hindooistan, in Bahar; 52 miles S.W. of Patna.

SUMSKOI, a town of Ruffia, in the government of Oolnitz; 16 miles S. of Kemi.

SUMULPOUR, a town of Hindooistan, in Orissa; 18 miles S.W. of Cuttack.

SUN, SOL, in Astronomy, the great luminary which enlightens the world, and by his presence constitutes day. For his real apparent diameter, density, and distance, see those articles. See also PLANET and SOLAR SYSTEM.

The sun, which, in the infancy of astronomy, was reckoned among the planets, should rather be numbered among the fixed stars. It appears bright and large in comparison with them, because we keep constantly near the sun, whereas we are at an immense distance from the stars. For a spectator, placed as near to any star as we are to the sun, would see that star a body as large and bright as the sun appears to us; and a spectator, as far distant from the sun as we are from the stars, would see the sun as small as we see a star, diversified of all its circulating planets; and would reckon it one of the stars in numbering them.

The sun agrees with the fixed stars in the property of emitting light continually, and in retaining constantly its relative situation, with very little variation; and it has probably many properties in common with them. The stars, as well as the sun, possess gravitation, and the other general properties of matter; they are supposed, like the sun, to emit heat as well as light; and it has been conjectured with great reason, that they serve to cherish the inhabitants of a multitude of planetary bodies revolving round them. See STAR.

According to the Copernican hypothesis, which is now generally received, and which has even demonstration on its side, the sun is the centre of the whole planetary and cometary system; round which all the planets and comets, and our earth among the rest, revolve, in different periods, and in elliptical orbits, according to their different distances from the sun, which is supposed to be placed in the lower focus of all the planetary orbits. Strictly speaking, however, if we consider the focus of Mercury’s orbit to be in the Sun’s centre, the focus of Venus’s orbit will be in the common centre of gravity of the Sun and Mercury; the focus of the Earth’s orbit in the common centre of gravity of the Sun, Mercury, and Venus; the focus of the orbit of Mars in the common centre of gravity of the Sun, Mercury, Venus, and the Earth; and so of the rest. Nevertheless, the focules of the orbits of all the planets, except those of Saturn and the Georgium Sidus, will not be sensibly removed from the centre of the sun; nor will the foculi of these orbits recede sensibly from the common centre of gravity of the Sun and Jupiter. See this motion illustrated and demonstrated under EARTH and PLANET.

SUN, Motion of the. The sun, though thus placed of that prodigious motion, by which the ancients imagined him to revolve daily round our earth, yet is not a perfectly quiescent body.

From the phenomena of his maculae or spots, it evidently appears, that he has a rotation round his axis; like that of the earth, by which the natural day is measured; only slower.

Some of these spots have made their first appearance near the edge or margin of the sun, and have been seen some time after on the opposite edge; whence, after a stay of about fourteen days, they have reappeared in their first place, and taken the same course over again; finishing their entire circuit in 27$^2$ 20th: which is hence deduced to be the period of the sun’s rotation round his axis; and, therefore, the periodical time of the sun’s revolution to a fixed star is 25$^2$ 15th 10th; because in 27$^2$ 20th of the month of May, when the observations on which this calculation is founded were made, the earth describes, according to the elder Calini, an angle about the sun’s centre of 26° 22'; and, therefore, as the angular motion of 365$^2$ + 25° 32' is to 360', so is 27$^2$ 20th to 25° 15th 10th. Others fix the period of the sun’s rotation on his axis, with respect to the fixed stars, at 25$^2$ 10th; and they observe, that this axis is directed towards a point about half way between the pole star and Lyra, the plane of rotation being inclined a little more than 7° to that in which the earth revolves.

This motion of the spots is from west to east; whence we conclude that of the sun, to which the other is owing, to be from east to west. For the various appearances of the four spots, their cause, &c. see MACULAE and SPOTS.

Under the articles to which we have referred, a brief account is given of Dr. Herchel’s hypothesis with regard to the physical construction of the sun and the spots observed on his surface: we shall here present our readers with a more detailed account of this hypothesis. Dr. Herchel has found it convenient to lay aside the old names of spots, nuclei, James, faculae, and lucubi, because they are figurative expressions that may lead to error. Instead of these, he adopts the expressions of openings, shallow, ridges, nodules, corrugations, indentations, and pores.

Openings, he says, are those places where, by the accidental removal of the luminous clouds of the sun, its solid body may be seen; and this not being lucid, the openings through which we see it may, by a common telescope, be mistaken for mere black spots, or their nuclei.

Shallow are extensive and level depressions of the luminous solar clouds, generally surrounding the openings to a considerable distance. As they are less luminous than the rest of the sun, they seem to have some diffuseness, though imperfect, resemblance to penumbrae; which might occasion their having been called so formerly.

Ridges are bright elevations of luminous matter, extended in rows of an irregular arrangement.

Nodules are also bright elevations of luminous matter, but confined to a small space. These nodules, and ridges, as account of their being brighter than the general surface of the sun, and also differing a little from it in colour, have been called faculae, and luculi.

Corrugations, he calls that very particular and remarkable unevenness, ruggedness, or asperity, which is peculiar to the luminous solar clouds, and extends all over the surface of the globe of the sun. As the depressed parts of the corrugations are less luminous than the elevated ones, the disk of the sun has an appearance which may be called mottled.

Indentations are the depressed or low parts of the corrugations; they also extend over the whole surface of the luminous solar clouds.

Pra
The appearances, which have been called spots in the sun, are real openings in the luminous clouds of the solar atmosphere, he evinces by a number of observations. His next series of observations is added to prove, that the appearances which have been called penumbrae, are real depresions, or hollows. These are followed by others, also of the same kind as before, that ridges are produced above the general surface of the luminous clouds of the sun; that nodules are small, but highly elevated, luminous places; that corrugations confine elevations and depressions; that the dark places of corrugations are indentations; and that the lower places of indentations are pores. Hence he infers, that the several phenomena above enumerated could not appear, if the shining matter of the sun were a liquid; since by the laws of hydraulics, the openings, hollows, indentations, and pores would instantly be filled up, and that ridges and nodules could not preserve their elevation for a single moment. Whereas, many openings have been known to last for a whole revolution of the sun, and extensive elevations have remained supported for several days. Much less, he says, can it be an elastic fluid of an atmospheric nature, because this would be fill more readily to fill up the lower places, and expand itself to a level at the top. It remains, therefore, to allow this shining matter to exist in the manner of empyreal, luminous, or phosphoric clouds, residing in the higher regions of the solar atmosphere. This opinion is illustrated and confirmed by a variety of observations. From these observations, it is inferred that the corrugations are caused by a double stratum of clouds; the under stratum, or that which is next to the sun, consisting of clouds less bright than those which compose the upper stratum, and probably not unlike those of our planet. These double regions of clouds are thought to afford us sufficient proof of the existence of a solar atmosphere; which atmosphere is of great density, and, like our's, subject to considerable agitation. These agitations indicate, that there is some clear atmospheric space, between the solid body of the sun and the lower region of the clouds. It also appears, that the gases of the solar atmosphere are transparent; because our author's observations prove his being able to see the reflected light of the corrugations from their indentations, and of the self-luminous regions in general, from the hollows which they surroun and illuminate. In order to explain the generation of hollows, it is presumed from actual observation, that a transparent elastic gas comes up through the openings, by forcing itself a passage through the planetary clouds. This elastic gas is constantly formed, and ascends everywhere, by a specific gravity less than that of the general solar atmospheric gas contained in the lower regions. When it goes up in moderate quantities, it makes for itself small passages among the lower regions of clouds, which are called pores. When this gas, denominated empyreal, has reached the higher regions of the sun's atmosphere, it mixes with other gases, which, from their specific gravity, reside there, and occasional decompositions which produce the appearance of corrugations, the elevated parts of which are small self-luminous nodules, or broken ridges. Between the interfaces of these self-luminous clouds, which are ascertained not to be closely connected, the light reflected from the lower clouds will be plainly visible, and being much less intense than the direct illumination from the upper regions, will occasion the faint appearance called indentations. The mixed light, partly reflected from these indentations, and partly emitted directly from the higher parts of the corrugations, will resemble a mottled surface.

When a quantity of empyreal gas, more than what produces only pores in ascending, is formed, it will make for itself small openings; or, meeting perhaps with some resistance in passing upwards, it may exert its action in the production of ridges and nodules; and lastly, if still further an uncommon quantity of this gas should be formed, it will burst through the planetary regions of clouds, and thus will produce great openings; then spreading itself above them, it will occasion large spaces and, mixing afterwards gradually with other superior gases, it will promote the increase, and afford the maintenance of the general luminous phenomena.

If this account of the solar appearances should be well founded, we shall have no difficulty in ascertaining the actual state of the sun, with regard to its energy in giving light and heat to our globe; and nothing will now remain, but to decide the question, which will naturally occur, whether there be actually any considerable difference in the intensity of light and heat emitted from the sun at different times.

From other observations, which we cannot detail without far exceeding our prescribed limits, Dr. Herschel is induced to suppose, that the appearance of copious spots indicates the approach of warm seasons on the surface of the earth; and he has endeavoured to maintain this opinion by historical evidence; connecting the varying temperature of our atmosphere with the appearance and disappearance of the solar spots. The spots or hollows, which our author considers as parts of an inferior stratum consisting of opaque clouds, are, as he thinks, capable of protecting the immediate surface of the sun from the excessive heat produced by combustion in the superior stratum, and perhaps of rendering it habitable to animated beings. But if stars are suns, and suns are habitable, a very extensive field of examination is thus opened to our view. Dr. Herschel's hypothesis, however ingenious and consonant to the observations by which he supports it, is liable to some objections. If we inquire into the intensity of the heat, which must necessarily exist, wherever the above-mentioned combustion is performed, we cannot avoid the conviction, that no clouds, however dense, could impede its rapid transmission to the parts below. Besides, the diameter of the sun is 111 times as great as that of the earth; and at its surface, a heavy body would fall through no less than 450 feet in a single second; so that if every other circumstance permitted human beings to reside upon it, their own weight would prevent an insuperable difficulty, since it would become nearly thirty times as great as that upon the surface of the earth, and a man of moderate size would weigh above two tons. Some of the most celebrated astronomers have imagined, from the comparative light of different parts of the sun's disc, or apparent surface, that he is surrounded by a considerably denser and extensive atmosphere, imperfectly transparent; conceiving that, without such an atmosphere, the marginal parts, which are seen most obliquely, must appear considerably the brightest; but this opinion, says Sir William Young, is wholly erroneous, and the inferences that have been drawn from it, respecting the sun's atmosphere, are consequently without foundation. See ZODIALCAL LIGHT.

Those who have maintained that the substance of the sun is fire, argue in the following manner: the sun flames, and his rays, collected by concave mirrors, or convex leaves, burn, consume, and melt, the most solid bodies; or else convert them to ashes, or glafs; wherefore, as the force of the solar rays is diminished, by their divergency, in a duplicate ratio of the distances reciprocally taken; it is evident, their force and effect are the same, when collected by a burning
SUN.

ing lens, or mirror, as if we were at such distance from the fun, where they were equally dense. The fun’s rays, therefore, in the neighbourhood of the fun, produce the same effects, as might be expected from the most vehement fire: consequently, the fun is of a fiery substantiae.

Hence it follows, that its surface is everywhere fluid, that being the condition of flame.

Indeed, whether the whole body of the fun be fluid, as some think; or solid, as others; they do not presume to determine: but as there are no other marks, by which to distinguish fire from other bodies, but light, heat, a power of burning, consumming, melting, calcining, and vitrifying; they do not see what should hinder, but that the fun may be a globe of fire, like our’s, invested with flame; and supposing that the maçule are formed out of the solar exhalations, they infer that the fun is not pure fire; but that there are heterogeneous particles mixed along with it.

Philosophers have been much divided in opinion with respect to the nature of fire, light, and heat, and the causes that produce them: and they have given very different accounts of the agency of the fun, with which, whether we consider them as substantiae or qualities, they are intimately connected, and on which they seem primarily to depend. Some, among whom we may reckon Sir Isaac Newton, consider the rays of light as composed of small particles, which are emitted from shining bodies, and move with uniform velocities in uniform mediums, but with variable velocities in mediums of variable densitie. These particles, they say, act upon the minute constituent parts of bodies, not by impact, but at some indefinitely small distance; they attract and are attracted; and in being reflected or refracted, they excite a vibratory motion in the component particles. Others, as Boerhaave, represent fire as a substantia fuis generis, unalterable in its nature, and incapable of being produced or destroyed; naturally existing in equal quantities in all places, imperceptible to our senses, and only discoverable by its effects, when, by various causes, it is collected for a time into a less space than that which, from its tendency to an universal and equable diffusion, it would otherwise occupy. This matter of the fun is not supposed to be derived from the fun in any wise: the solar rays, whether direct or reflected, are of use only as they impel the particles of fire in parallel directions: that parallelism being destroyed, by intercepting the solar rays, the fire instantly assumes its natural state of uniform diffusio. According to this explanation, which attributes heat to the matter of fire, when driven in parallel directions, a much greater must be given, when the quantity so collected is amassed into a focus; and yet the focus of the largest luminary does not heat the air or medium in which it is found, but only bodies of densitie different from that medium.

M. de Luc, in his Lettres Physiques, is of opinion, that the solar rays are the principal caufe of heat; but that they only heat such bodies as do not allow them a free passage. In this remark he agrees with Newton; but then he differs totally from him, as well as from Boerhaave, concerning the nature of the rays of the fun. He does not admit the emanation of any luminous corpuscles from the fun, or rather self-luminous substantiae, but supposes all space to be filled with an ether of great elasticity and small densitie; and that light confints in the vibrations of this ether, as found confits in the vibrations of the air. Upon Newton’s supposition, says an excellent writer, the caufe by which particles of light, and the corpuscles constituting other bodies, are mutually attracted and repelled, is uncertain. The reason of the uniform diffusio of fire, of its vibration, and repercussion, as stated in Boerhaave’s opinion, is equally inexplicable; and in the last-mentioned hypothesis, we add to the other difficulties attending the supposition of an universal ether, the want of a first mover to make the fun vibrate. Of these several opinions concerning elementary fire, it may be said, as Cicero remarked concerning the opinions of philosophers concerning the nature of the soul: “Harum inintellectualium qua vera sit, Deus aliquis viderit; quae veridimilius, magna queso elius.” Watson’s Chem. Eff. vol. i. p. 154.

For a farther account of these opinions, see Fire, Heat, and Light. Dr. Herchel’s opinion has been stated at large in this article, and also under Macule, &c.

The figure of the fun is a sphericoid, higher under its equator than about the poles. This we prove thus: the fun has a motion about its own axis; and therefore the solar matter will have an endeavour to recede from the centres of the circles in which it moves; and that with the greater force, as the peripheries of the circles are greater: but the equator is the greatest circle; and the extent towards the poles, continually decrease; therefore the solar matter, though at first in a spherical form, will endeavour to recede from the centre of the equator farther than from the centres of the parallels.

Consequently, since the gravity by which it is retained in its place, is supposed to be uniform throughout the whole fun; it will really recede from the centre more under the equator than under any of the parallels; and hence the fun’s diameter, drawn through the equator, will be greater than that passing through the poles, i.e. the fun’s figure is not perfectly spherical, but spheroidal.

Befides the fun’s rotation about its axis, ascertained by the spots on its surface, it has another motion, which is a kind of agitation round the centre of gravity of the sytem, occasioning a change of place, and dependent on the motions of the planetary bodies that surround it. This kind of motion was long ago inferred from theory only, but it has been actually demonstrated by modern observations. Supposing all the planets to be in conjunction, or nearly in the same direction from the fun, the common centre of the sun’s revolution round the common centre of gravity of the sytem must be undisturbed by any reciprocal actions or revolutions of the bodies composing it, the fun must describe an irregular orbit round this centre, its great distance from it being equal to its own diameter. We may form an idea of the magnitude of this orbit by a comparison with the orbit of the moon: a body revolving round the fun, in contact with its surface, must be nearly twice as remote from its centre as the moon is from the earth, and the sun’s revolution round the common centre of gravity of the sytem must therefore be, where it is most remote, at four times the distance of the moon from the earth.

The fun, like many other stars, has probably a progressive motion, which is supposed, from a comparison of the apparent motions of a great number of the stars, to be directed towards the constellation Hercules. It is beyond doubt that many of the stars have motions peculiar to themselves, and it is not certain that any of them are without such motions; it is, therefore, in itself, highly probable that the fun may have such a motion. But Dr. Herchel has confirmed this conjecture by arguments almost demonstrative. He observes, that the apparent proper motions of forty-four stars out of fifty-six are very nearly in the direction which would be the result of such a real motion of the solar sytem: and that the bright stars Acrurus and Sirius, which are probably the nearest to us, have, as they ought to have, the greatest apparent motions. Besides, the stars...
SUN

SUN

Ctllor appears, when viewed with a telescope, to consist of two stars, of nearly equal magnitude; and though they have both a considerable apparent motion, they have never been found to change their distance a finger second; a circumstance which is easily understood, if both their apparent motions are ascribed to a real motion of the sun, but which is much less probable, on the supposition of two separate and independent motions. See Star.

Ros folis is recommended by some as a great cordial, and good for consumptions, convulsions, and the plague. Formerly a cordial wine, in which this herb, with several spices, as a principal ingredient, was in great repute, under the name of rogefola, though now almost out of date. Miller’s Bot. Off.

Sun-Fish, Mola, the Tetrodon mola of Linnaeus, and a species of ophicephalus in the Arctedent Sytem, in Ichthyology, a fish of a very singular figure. Its body is broad and short, and its hinder extremity is terminated by a circular fin, which serves it for a tail; so that it looks like the head of a large fish ferried from its body; it is frequently of two feet in length, and sometimes very much exceeds that size, growing even to two hundred weight. It has no scales, but is covered with a hard, hardish, and rough skin. Its back is black, and its belly white; the sides are of a middle colour between both. Its back and belly both terminate in a narrow edge. Its mouth is very small for the size of the fish, and, when open, is round. Its jaws are hard, and edged like a knife within; externally they are rough, as if befiled with several rows of small teeth. The head does not at all project from the rest of the body. The eyes are very small. The gills are only two elliptic holes, covered with their proper membranes. Its flesh is very soft, and its bones are all grizzled and tender. The skin tacks very firmly to the flesh, and is not easily taken off. It is caught in the Mediterranea, and sometimes in the British seas. Willoughby’s Hist. Pisc. p. 151.

Mr. Pennant describes the sun-fish of Mount’s Bay, under the title of the oblong didon. In form, he says, it resembles a blunt, or spool-shaped fish cut off in the middle; the mouth is very small, and contains in each jaw two broad teeth with sharp edges; the eyes are little, having before each a small semilunar aperture; the pectoral fins are very small, and placed behind them; the dorsal fin, and the anal fin, are high, and placed at the extremity of the body; the tail-fin is narrow, and fills all the abrupt space between those two fins; the colour of the back is darkly and dappled; the belly silvery; between the eyes and the pectoral fins are

freaks pointing downwards; the skin is free from scales; the meat of the fish is uncommonly rank; it feeds on shellfish. Care, says Mr. Pennant, must be taken not to confound this fish with the sun-fish of the Irish, which in all respects differs from it. The former, or tetrodon mola of Linnaeus, which he calls short didon, differs from the latter in being shorter and deeper; the back and anal fins are higher, and the aperture to the gills not semilunar, but oval; the situation of the fins is the same in both.

One of these fishes, of five hundred weight, was taken in 1754, near Plymouth; and on boiling a piece of the flesh, to try how it would take, (as some authors have described it as a fine fish for the table,) it was found, instead of a firm mass, to be all converted, in a few minutes, into a perfect jelly, so that it could not be taken out otherwise than with a spoon. In colour and consistence this jelly resembled boiled flesh when cold, and had little or nothing of a fishy flavour, but a very agreeable taste; it stuck firmly to the lips, however, and to the fingers, appearing very remarkably glutineous: and as the ancients had no other glue than one made of fish, this jelly was tried, as to its flocking quality, on leather, and on paper, and was found to answear as well as common pate; but by some accident it was not tried upon wood.

It will be extremely worth while, on some other opportunity, to try whether a true ichthyocolla may not be prepared by boiling down its jelly. Philos. Tran. N. 456. P. 143. Abr. vol. ix. p. 73. &c.

Sun-Fish is also a name sometimes given to the hussing shark.

Sun-Flower, in Botany. See Helianthus.

Sun-Flower, in Agriculture, a well-known annual plant of large growth, and considerable produce, which has lately been introduced into field culture with utility and advantage, in several different views. It is the helianthus annus of botanical writers, and supposed to be a native of Mexico, in South America; though it would seem to be indigenous to many different parts of the world. It is said to be very wild, though of small growth, in the southern districts of Africa; be not unknown in China, and to be extremely common in the East Indies, where it is designated the sooroa mao-ky, or sun-flower.

Soil and Situation.—The plant, which is of a hardy nature, thrives well, and, raised by seed, admits of considerable latitude in regard to the nature or quality of soil, on which it may be grown with advantage, where there is sufficient depth, strength, and moisture, for the plants to derive proper support and nourishment from them.

The situations in which they are grown should consistantly be open, and exposed as much as possible to the warmth of the sun; as the crops in such not only ripen and fill the seed better, but the plants are of a considerably larger growth than in those which are close and confined. In preparing the ground for this sort of crop, it should not be rendered light by too much ploughing, but be in a rather firm state of mould in the more superficial parts; being always, however, as clean and free from all sorts of weeds as possible. Where manure can be spared, it may be ploughed in, or prepared in the land by furrows near to the time of sowing the seed as may be convenient.

In choosing seed for this crop, as in most other cases, the hardest, finest, fullest, and plumpest, and that which has been the best ripened, should always be preferred as much as possible; as it is from such that the best and most perfect crops are raised. The seed for this purpose, too, should constantly have been kept and preserved in a dry, airy situation or place, so as not to have had any tendency to throw

out
SUN

out things or sprouts. And the practice of swimming it, before it is put into the ground, is proper and beneficial, in order to remove any light and imperfect seeds that may be present.

Three or four quarts of seed, but mostly the first quantity, will be sufficient for an acre of land, if double dibbled, which is not the produce of more than half a score plants. In seeding the plants, the finest and thickest of which are in the most open exposures should be chosen for the purpose, letting them remain until they are perfectly well ripened, and chiefly making use of the large principal heads only; the seeds, when threshed out, being safely kept out of the way of moisture.

The time of sowing the feed must, in some measure, be regulated by circumstances; but the more early, in general, the feed can be got into the ground in February, or the succeeding month, the better, as the crops will become ripe and ready the sooner in the latter end of the summer, or the beginning of the autumn, which is of much importance in securing them.

There are different methods of sowing. It is probable that, in many cases, it might be most conveniently sown in flight drills, made at the distance of about a foot, or eighteen inches, according to the nature or quality of the soil, by an implement constructed for the purpose, so as to form the drills, and drop two or three seeds only, at such different spaces, into them, covering them by a following chain or light roller, as practised for turnip seed. Or they might be let by the dibble, as practised for wheat, at such distances apart; or in the quinquex order, as some have proposed, which, it is said, augments the distance of the plants near a foot, but is not so convenient in cleaning the crops. But others think, that the seed should be dibbled in after the manner of beans, the ground being previously levelled by means of a light barley-roller, and one, or perhaps two, seeds being then dropped into each hole; then the roller should be again passed over the ground, in order to close the holes in upon the feed, and prevent its being disturbed by the harrow, which should afterwards follow and conclude the busines.

Any mode which is capable of affording the means of placing the feed at equal, regular depth and distance, and of covering it well from being destroyed in any way, as ensuring a more regular, perfect, and certain growth in the plants, and promoting their more equal ripening, would be of advantage, as the plants would thereby be made to ripen more uniformly together; be sooner dry in the sheaf or bundle, and the work of threshing out the feed be more perfectly, easily, and readily performed. Such a contrivance could require little difficulty, trouble, or expense, and might answer for some other purposes of plants of this sort, which, though they do not transplant or remove well without balls of earth about their roots, may still be raised from seed in small beds only, or be thinned out from the general crops, in that way, for supplying and filling up any breaks or defects that may arise or take place from the failure of feed, or any other cause. This sort of work must, however, in all cases, be carefully done; and in such water be given at the same time, and for some days afterwards, if the weather be not moist.

The plants being supposed to arise, either at large intervals in rows at one foot apart, or at twelve-inch intervals with three feet distances in the row, would take about 14,520 to an acre of land.

In the culture of crops of this sort, the land between the plants is, from the first, to be kept quite clear from all sorts of weeds, but especially while they are in their infant state of growth. And as soon as they are ripe sufficiently above the surface of the land, the supernumerary plants should all be well thinned out by the hoe, where they are not waited for filling up any vacancies that may have occurred in the crops; but where this is the case, it should be done by a small spud, or garden-trowel with a long handle, so as to preserve the mould about their roots as much as possible, as they do not transplant well without this. In all cases where there are proper distances or spaces preferred between the rows, the work of after-culture may be readily accomplished by means of a single horse-hoe plough, contrived for the purpose, so as to cut up the weeds, lift the mould well, and lay it up a little to the roots of the plants. The parts between the plants in the rows, where necessary, may be cleared and cleaned by a small, light hand-hoe. Where, from the nature and quality of the land, the plants rise to a great height, they may be pruned, and some of the lower branches may often be taken of early, with great advantage to the crops in their growth, and the production of seed.

As to the best mode of harvesting these crops of this sort, some have thought that pulling up the stalks by the roots, in dry weather, is a better practice than that of reaping or cutting them over by the surface of the land, not only on account of their woody nature, but as preventing the lodging of the feed, especially where they are not grown upon a very stiff bound soil. The roots are to be well cleaned from all dirt, before threshing the feed out, for the sake of the sample. As the seeds readily quit the heads when perfectly dry, they can be easily threshed out.

After being pulled or cut, they may probably remain out until quite dry, but it is not so convenient in cleaning of materially injuring them. They may be bound up together with tarred twine, and be put up in small packs or parcels, in sheaves of small sizes; the heads being made to incline inward, in order that they may sooner become dry. As soon as they are become perfectly dry and well cured, they are, in large crops, either to be stacked up somewhat in the manner of other grain, or, in cases where they are only of small extent, to be headed and collected gradually, from time to time, as the flowers or heads become ripe, and a fork, proper basket, or other contrivance; depthing the heads, where necessary, upon a fort of hurdles or racks, arranged in tiers one above another for the purpose, and placing them under large, open, airy shed-buildings; or, in some instances, they may be strung on proper small comb, by means of holes made through the middle of each head; being thus suspended in the open air and sun, so as to have the full drying influence of the atmosphere.

When well cured and sufficiently dry, the seed may be threshed out, and put by for future use; being preferred in a similar manner to corn, either in granaries, or other convenient dry places. Where the heads are cut into half, they may be safely houset with little or no loss of feed. Crops of this kind may stand out in the field, in case of necessity, until late in the autumn, without much danger.

The gradual taking off the heads, too, as they become ripe, where that method is practised, often greatly prevents the depredations of birds, and other vermin, as well as the shedding and dropping of the feed upon the ground, by which great loss may sometimes be sustained. Crops of this kind are not much exposed to diseases, such as blight, mildew, or others of a similar sort; but are, for the most part, in a blooming healthy state. And though some infects may fix and shelter themselves on the flowers or heads, they cannot, from the close compact state of the feed in them, lodge in their intercepts; consequently the tom-tits, which are per-
The sun's greatest enemies are those crops, may not only seek the insects as their food, but at the same time plunder the seed of the flowers; as it is certain, and well known, that they not unfrequently work it out of the heads, even before it gets fully ripe. The capability which these birds possess of suspending their bodies in a backward direction upon the flowers, also tends to facilitate their getting out the seeds from the heads. Such birds are not, however, numerous in any situation. Rats and mice, too, often commit great depredations on these crops, separating the infusible of the seeds from the outer coats of them, in somewhat the same manner as squirrels do nuts, consuming the inner parts, and rejecting the hulls; they shou'd, therefore, be well secured from them.

The expense of these crops cannot be very great, either in the preparation and culture of the land, or in the management and securing of the produce afterwards. As to the produce of this sort of crop, it must be very different, according to the seafon, the nature of the culture which is made use of in raising it, the care that is taken in its growth and after-management, and the kinds of the plants that are employed for the purpose, as well as some other circumstances of less importance. But when grown with care, in a suitably open manner, and in good seafons, the produce will mostly be very abundant. Some have stated it so high as upwards of fifty bushels the acre, supposing each plant, on the average, to afford nearly the quantity of a pint of seed; but taking it at half this quantity, which is probably near the mark, when properly cultivated, the produce will be sufficient to fully repay the farmer, and leave him a very ample profit.

This is a sort of crop which is capable of being used and applied for many different purposes; as for feeding and fattening many forts of animals, in different ways, for drawing and forming a fine oil from, for the use of the clothier, the printer, and others; for the use of the fibrous and other parts, in the making of pack-thread, paper, and other manufacturing purposes; for the purpose of fuel in the roots, naked items, and some other parts; and probably for some other uses and purposes, to which it has not yet been much applied.

In the feeding of animals, the feed, being of a farinaceous, oily quality, may be given as a cheap, substantial, and nourishing food to near cattle, horses, sheep, pigs, rabbits, and poultry of all sorts.

In the feeding of near cattle with it, it may be used either in the reduced mealy state, or that of cake, after it has been expressed or manufactured for oil. This crop is said sometimes to be cultivated in America, as green food for cattle.

For horses it may be used as their usual food, either in the natural, or bruised, broken, and reduced states; which latter is probably the best, not only as digesting more readily, and going much further, but as improving the table, and rendering the substance more agreeable to the animals. It may be mixed with a little bran at first. There can be no doubt of the utility and advantage of this sort of provender for all sorts of working animals of this kind.

As to sheep, they must have this sort of food given to them in the mealy state, or that of the hulky matter, they being mixed with suitable quantities of wheat-bran or pollard. In this way it may feed such animals very well, and with some advantage.

For pigs or swine, too, it should always be given in the coarse, reduced, mealy state, either in the solid form, or in that of soup or wash.

For rabbits this sort of food may be made use of in different states, but it is probably best employed in the state of feed or meal, in mixture with bran or pollard, as the animals are very fond of it in these ways. The bulky chaffy material may likewise be used in the same way, as a dry food, in some cases, with great benefit. While using such food, the animals are said to look extremely sleek and well in their coats, and to frisk about and drum the floor with their hinder feet, which are the true signs of health and condition.

Poultry of most forts soon become fond of this food in its feed state, and it supports and keeps them very well; but it may probably be given to them with more advantage in the state of coarse meal, in mixture with mashed potatoes or soaked bran.

Pheasants, in the domestic state, are said also to have been often fed with this sort of food; as well as tame pigeons, in some cases, and partridges, and some other birds, with complete successe, and in a superior manner to most sorts of corn feeding.

The refuse plants may be employed as the foundations in littering of farm-yards, as well as for some other purposes about them, as wattled defences, divisions, fences, and covering for the sides of sheds, &c.

The flowers, too, afford considerable supplies of honey and wax to bees, which may be of great importance in many situations.

There is an oil capable of being prepared from these seeds, which is said to be of the fine almond kind, and which may be applied to different purposes in the arts. In the East Indies, eight quarts of this fine transparent oil is said to have been produced from about eighty pounds of the clean feed, which had been grown and ripened in a suitable situation. There is a sort of oil, from the process of making it, which may be made use of as noticed above.

The manufacturing of this oil has also been already practiced in some parts of this country; and the plant is said to have been actually cultivated in the field, in France, in this intention. There can, therefore, be little doubt of its utility in this way.

At the above rate, the produce of oil on the acre would be very great indeed, as that space would afford upwards of two hundred bushels feed, two of which would be more than the weight then stated; but supposing it to yield one-third, or even a half less, the produce in oil would be fully sufficient to encourage the cultivation of these crops; and the refuse, or cake, would amply repay the expenses incurred in the process of milling.

The oil is applicable to the uses of the clothier, in softening and preparing the wool for the card and the loom. It is equal in value, for this use, to the rancid and spoiled Florence or tallow oil; the animal oils being unfit for this purpose. It is, of course, worth four or more shillings the gallon, in this application. But it is capable of other more valuable uses, as for book-printing, burning in lamps, where pureness and brilliancy are required, and some other purposes in the arts, where the finer sorts of oil are necessary. It has been found to be particularly well adapted to the printing bruna of the American printers.

The strong fibrous and some other parts of the plant may be useful for the purpose of manufacturing into pack-thread, instead of hemp; and for the making of paper, in which intention the white, shining, silver, fibrous substance, which is contained in a large proportion, is more desirable at the attention of the manufacturer than any other part.

The large roots, naked items, and some other waste parts, may, in many places, be converted with advantage to the purposes of fuel. They may be made use of in the billet or
other forms, for drying malt, and other familiar uses, in some places; and be used in this and other ways as common fuel, and be sublimated as chips for lighting of fires, in the dried state, near large towns.

It is not improbable but that this sort of crop may be applicable to some other purposes, to which it has not yet been thought capable of being applied. It may, therefore, be concluded, that this plant may now not only be cultivated for the purpose of ornament, but for a variety of economical uses and applications of the farmer and the manufacturer, as well as some domestic purposes. It may also be found useful and beneficial with hemp, in the cultivation and improvements of land and marsh kinds, as drinking up and throwing off a large quantity of moisture. It may consequently hereafter be found a plant of great utility and consideration to the farmer and manufacturer, as well as to the gardener.

**Sunflower, Baffard.** See Helianthus. Sunflower, Dwarf, Helianthemum, or Cissus. See Helianthemum and Cistus.

The root of helianthemum, taken internally, is esteemed good against the bites of serpents: and the tops are effectual for the same purpose. The plant is astringent, and a good demulcent, in the form of a decoction, particularly in diarrhœa, hemorrhois, and ulcers of the fauces. J. Bauhin says, it is good in all disorders attended with a flux of any kind.

**Sunflower, Dwarf American.** See Rudbeckia.

**Sun Flower, Tick-seed.** See Corokia. **Sun-Plant of Hindooeifan.** See Son.

Sun-Starched, a term used by our Gardeners, in some parts of England, to express a deftremation of fruit-trees, owing to the sun's affecting them too forcibly and too suddenly; the consequence of which is the loss and withering of the fruit. Such trees only are subject to this as are planted in places sheltered from the burning sun, and only open to the sunner's, and it may always be cured by proper waterings.

**Sun-Spurry, in Botany.** See Euphorbia.

**SunAMOOKY, in Geography, a town of Bengal; 12 miles N. of Bihilpore.**

SUNAPEE, a lake and mountain of America, in Cheshire county, New Hampshire. The lake is about 8 or 9 miles long and 3 broad; and communicates by Sugar river, to the Merrimac, at the distance of 14 miles W. The mountain is situated at the S. end of the lake.

SUNBURSAH, a town of Hindooefan, in Bahar; 58 miles E.S.E. of Hajipur.

SUNBURY, a county of New Brunswick, on the river St. John, at the head of the Bay of Fundy, containing eight townships, viz. Conway, Gagetown, Barton, Sunbury, St. Anne's, Wilwot, Newton, and Mangerville. The three last were settled from Massachusetts, Connecticut, &c. The lands are generally level, tolerably fertile, and abounding with timber. Alto, the chief town of Northumberland county, Pennsylvania, situated on the E. side of Susquehannah river, just below the junction of the E. and W. branches of that river, in N. lat. about 40° 52'. The town is regularly laid out, and contains a court-houe, brick jail, a Presbyterian and German Lutheran church, and 700 inhabitants; about 76 miles above Reading. Alto, a township of Delaware county, is the district of Ohio, containing 656 inhabitants. Alto, a port-town and port of entry in Georgia, pleasantly situated in Liberty county, at the head of St. Catherine's Sound, on the main, between Medina and Newport rivers, about 15 miles S. of Great Ogeechee river. The town and harbour are defended from the fury of

the sea by the N. and S. points of St. Helens and St. Catherine's Island; between them is the bar and entrance into the Sound; the harbour is capacious and safe, and has ample anchorage for ships of great burden. It is an agreeable and healthy town, and the resort of the planters from the adjacent country during the sickly season. It has been rebuilt since the war, when it was destroyed by fire. An academy was established here in 1788; 40 miles S. of Savannah.

SUNBUY, a town of Hindooefan, in Bahar; 12 miles S. of Patna.

SUNCHEULI, a mountain of Peru, in the jurisdiction of Larcazes, in which is a gold-mine.

SUNCOOK, a town of America, in Oxford county and district of Maine, now called Lovell; containing 365 inhabitants. Alto, a river of New Hampshire, which runs into the Merrimack, N. lat. 43° 51'. W. long. 71° 26'.

SUNCOPULLY, in Natural History, a name given by the people of the East Indies to a kind of sparry substance of a whitish colour, which they calcine, and afterwards give in aces, and other intermittent cafes.

It is erroneously by some supposed to be a species of arsenic; for it has none of its qualities.

SUND, in Geography, a town of Sweden, in Est Gotland; 40 miles S. of Linnemer; Alto, a town of Sweden, in the province of Varmeland; 26 miles N. of Carlshad.

SUNDA, a town of Hindooefan, in Ouide; 30 miles N.N.E. of Kairabad.

SUNDA Jlanda, a group of islands in the East Indian sea, the largest of which are Borneo, Java, and Sumatra.

SUNDA, Straits of, an arm of the East Indian sea, which runs between Java and Sumatra. The length of this channel on the Sumatra side, taken from the Flat Point to Vaban, or Hog Point, is 15 German miles; and on the Java side, from the first point or Java head, to the point of Bustain, full 20. In the mouth of this strait lies Prince's Island, which lies.

The entrance of the strait on this side affords an uncommonly pleasing prospect over the Sumatran shore; and the Flat Point, being low and covered with trees, and behind it the majestic mountains of Sumatra, rising with a gradual ascent, reaching to the clouds; further the Keizers, or Emperor's island, lying in the middle of the channel, and hence called "Drum in den Weg," i.e. "Thwart the Way," or "Middle Isle." On either side of this island a strong current runs during the whole year. Ships passing out through the Straits of Sunda often anchor in the bay of Anjer. The Dutch East India Company claims an absolute sovereignty over the Straits of Sunda.

SUNDAEV, a fortres of Ruffia, on the Ural; 60 miles S. of Uralk.

SUNDAL, a town of Norway, in the government of Dromhein, on the Driva; 66 miles S.S.W. of Dresden.

SUNDAMINUM, a town of Hindooefan, in Myajo; 25 miles E. of Rydroog.

SUNDANA. See Sandel Befia.

SUNDAY,
SUNDAY, a town of Persia, in the province of Segesta or Seistan; 66 miles S. of Kin.

SUNDAY, the first day of the week, thus called by our idolatrous ancestors, because set apart for the worship of the sun.

It is now more properly called the Lord's day, die Dominica, because kept as a feast in memory of our Lord's resurrection on this day; and Sabbath-day, because substituted under the new law in the place of the sabbath in the old law.

The appellation of "Lord's day" was adopted by the earliest Christian writers. At the time when St. John wrote the book of his revelation, the first day of the week had obtained this name (Rev. i. 10.) and this same, together with St. John's use of it, sufficiently denotes the appropriation of this day to the service of religion; and that this appropriation was perfectly known to the churches of Asia. We have reason to believe, that by the "Lord's day," was meant the "first" day of the week; because we find no trace of any lattice of the days which could entitle another to that appellation; accordingly this appellation was used both by the Greek and Latin churches. So it is styled by Clemens Alexandrinus, by Ignatius, by Dionysius, bishop of Corinth, by an African synod, and by Tertullian. Sometimes, indeed, it is simply called 

The reason why they observed this day with so much joy and gladness is said to have been, that they might gratefully commemorate the glorious resurrection of their Redeemer, which happened on that day. Accordingly St. Barnabas says, "we keep the eighth day with gladness, on which Christ arose from the dead;" and Ignatius also says, "let us keep the Lord's day, on which Christ arose from death." Justin further relates, that "on Sunday the Christians assembled together, because it was the first day of the week, on which God out of the confused chaos made the world, and Jesus Christ our Saviour arose from the dead; for on Friday he was crucified, and on Sunday he appeared to his apostles and disciples, and taught them those things which the Christians now believe." To the same purpose, Origen advises his auditors to pray unto Almighty God, "especially on the Lord's day, which is a commemoration of Christ's passion; for the resurrection of Christ is not only celebrated once a year, but every seven days." But it has been observed, that although it is not improbable that the first day of the week was thus distinguished in commemoration of our Lord's resurrection, we have no evidence in scripture that this was the case, or that it was instituted for this purpose. That this day was denominated "Sunday" at a very early period, is evinced by a variety of testimonies, which it is needless to cite. Justin Martyr and Tertullian in particular use this appellation. But though they so far complied with the Heathens as to call this day Sunday, yet they do not seem to have so far indulged the Jews as to call it the "Sabbath-day," for through all their writings they violently declaim against sabbatizing, or keeping the Sabbath-day, that is the Jewish observance of the seventh day, which we must always understand by the word "Sabbath" in the writings of the ancients, not the observance of the first day, or the Lord's day; for that was constantly celebrated: and by those who condemn the observance of the Sabbath-day, the sanctification of the Lord's day is approved and recommended, as by Justin Martyr and Tertullian, and also by Ignatius, who says in one place, "let us no longer sabbatize," and in another, "instead of sabbatizing, let every Christian keep the Lord's day, the day on which Christ rose again; the queen of days, on which our life arose, and death was conquered by Christ." The Eastern churches, however, in compliance with the Jewish converts, who were numerous in those parts, performed on the seventh day the same public religious services that they did on the first day, observing both the one and the other as a festival. Whence Origen enumerates Saturday as one of the four fasts solemnized in his time; though, on the contrary, some of the Western churches, that they might not seem to Judaize, fasted on Saturday. If it be inquired, what duties were appointed for the Jewish Sabbath, and under what penalties, and in what manner it was observed among the Jews, we are informed by the fourth commandment, a specific law from God; from work was enjoined not only upon Jews by birth, or religious profession, but upon all who resided within the limits of the Jewish state; that the same was to be permitted to their slaves and their cattle, and that this rest was not to be violated under pain of death. (Exod. xxxi. 14.) Befides, the seventh day was to be solemnized by double sacrifices in the temple. (Num. xxix. 9, 10.) Accordingly, we find in the sequel of the history of the Jews, that the Sabbath was in fact observed amongst them, by a scrupulous abstinence from every thing which, by any possible construction, could be deemed labour; as from dicing meats, from traveling beyond a Sabbath-day's journey, or about a sabbath mile. In the Maccabear war, they suffered 1000 of their number to be slain, rather than do any thing in their own defence on the Sabbath-day. In the final siege of Jerusalem, after they had so far overcome their persecutors, as to defend their persons when attacked, they refused any operation on the Sabbath-day, by which they might have interrupted the enemy in filling up the trenches. After the establishment of synagogues, it was the custom to assemble in them on the Sabbath-day, for the purport of learning the laws and explaining, and probably for the exercise of public devotion. According to the Jewish computation, the Sabbath held from 6 o'clock on the Friday evening to 6 o'clock on Saturday evening.

It has been a question of considerable interest, whether the command by which the Jewish Sabbath was instituted, extend to Christians? Some, in the discussion of this question, have supposed that the transmigration of the wilder-

ness, recorded in the 16th chapter of Exodus, was the first actual institution of the Sabbath, and that it was afterwards established with great solemnity by the fourth commandment. Whilom others contend that the Sabbath was instituted at the time of the creation, as related in the second chapter of Genesis. The principal arguments pertaining to this question, have been briefly stated under the article Sabbath. Archdeacon Paley, who adopts the opinion of those who maintain that the institution of the Jewish Sabbath first took place in the wilderness, considers, as they do, the blessing and sanctification, i.e. the religious dis-
tinction and appropriation of the seventh day, mentioned in the book of Genesis, as not having been made till many ages afterwards. He argues, that the words do not assert, that God then "blessecd" and "sanctified" the seventh day, but that he blessed and sanctified it, because he had on that day retired from the work of creation, and for that reason: and it if is asked, why the Sabbath, or sanctification of the seventh
SUNDAY.

Seventh day, was then mentioned, if it was not then appo-
inted, our author replies, that the order of connection,
and not of time, introduced the mention of the sabbath in
the history of the subject which it was ordained to com-
memorate. This interpretation, he says, is strongly sup-
ported by a passage in the prophecy of Ezekiel, where the
sabbath is plainly spoken of as a sabbath, or, as the expression
is supposed to mean, as sabbath instilled, in the wilderness.
(Ezek. xx. 10, 11, 12.) Nehemiah also accounts the pro-
mulgation of the sabbatic law amongst the transvagions in
the wilderness, and this circumstance is considered as afford-
ing another important argument in favour of the same
opinion. (Nehem. ix. 14.) If the divine command, by
which the sabbath was instituted, was actually delivered at
the creation, as many learned writers have maintained, it
was without doubt addressed to the whole human species
alone, and continues, unless repealed by some subsequent
revelation, obligatory upon all who have the knowledge of it.
But if the command was published for the first time in
the wilderness, then it was immediately directed to the Jewish
people alone, and the sabbath ought to be regarded as part of
the peculiar law of the Jewish policy. In further sup-
pport of this latter opinion, it is alleged, that the sabbath is
described as a sign between God and the people of Israel
(Exod. xxxi. 16, 17. Ezek. xx. 16.) and that it does not
seem easy to understand, how the sabbath could be a
sign between God and the Gentiles, if there were no speci-
fic regulations as to the observance of it. The reference
was peculiar to that people, and designed to be so. The
distinction of the sabbath is, in its nature, as much a positive ceremonial institution, as that of many
other sabbaths which were appointed by the Levitical law
to be kept holy, and to be observed by a distinct rest: such
were the first and seventh days of unleavened bread;
the feast of pentecost; the feast of tabernacles; and in the 23d
chapter of Exodus, the sabbath and thefe are recited
together. It is further argued, that the observance of
the sabbath was not one of the articles enjoined by the apostles
in the 15th chapter of Acts, upon them "which, from
among the Gentiles, were turned unto God." St. Paul
evidently appears to have considered the sabbath as part of
the Jewish ritual, and not binding upon Christians as such.
Col. ii. 16, 17.

To the objection, that the reason assigned in the fourth
commandment for hallowing the seventh day, viz., "because
God rested on the seventh day from the work of the cre-
tation," pertains to all mankind, it is replied, that although
in Exodus the commandment is founded upon God's rest
from the creation, in Deuteronomy (chap. v. 13-15.) the
commandment is repeated with a reference to a different
event. If it be objected, that inasmuch as the other nine
commandments in the decalogue are confessedly of moral
and universal obligation, it may be reasonably presumed
that this is of the same, the answer is, that this argument
will have less weight, when it is considered, that the dif-
tinction between positive and natural duties, like other
distinctions of modern ethics, was unknown to the simplici-
ty of ancient language; and that there are various passages in
Scripture, which give it in a general or ceremonial, and not
positive nature, and confessedly of partial obligation, are
enumerated, and without any mark of discrimination, along
with others which are natural and universal. See Ezek.
xxviii. 5-9; and Acts, xx. 28, 39.

If the law by which the sabbath was instituted be con-
idered as a law only to the Jews, it becomes an important
inquiry, whether the founder of Christianity delivered any
new command upon the subject; or, if that should not
appear to be the case, whether any day was appropriated
to the service of religion, by the authority or example of
his apostles? The practice of holding religious assemb-
lines upon the first day of the week was so early and general in
the Christian church, that we derive from hence considerable
proof of its having originated from some precept of Christ,
or of his apostles, though no such precept be now extant.
It was on the first day of the week that the disciples were
assembled, when Christ appeared to them for the first time
after his resurrection. (John, xx. 19.) If we allow that
this might have been accidental, yet we read in the 25th
verse of the same chapter, "that after eight days," that is,
on the first day of the week following, "again the disciples
were within," which second meeting upon the same day
of the week seems like an appointment and design to meet
on that particular day. The same custom seems also to
have been observed in a Christian church at a great distance
from Jerusalem. (Acts, xx. 7.) The practice men-
tioned in this passage seems now to have been familiar and
established. (See also I Cor. xvi. 2.) From these pas-
fages we deduce ample evidence, that the Christians held
and frequented religious assemblies upon the first day of
the week. Nevertheless, a cessation upon that day from labour,
beyond the time of attendance upon public worship, is not
intimated in any passage of the New Testament; nor did
Christ or his apostles deliver, as Paley supposes, any com-
mand to their disciples for a discontinuance upon that day of
the public observance of the sabbath. They cannot be
condemned as a defect in the Christian institution by
any who consider, that in the primitive condition of Chris-
tianity, the observation of a new sabbath would have been
useless, or inconvenient, or impracticable. During Christ's
personal ministry, his religion was preached to the Jew
alone. They already had a sabbath, which, as subjects of
that economy, they were obliged to keep, and did keep.
It was not, therefore, probable that Christ would enjoin
another day of rest in conjunction with this.

Archdeacon Paley deduces from his whole inquiry in
this subject the following conclusion; viz., that the ob-
serveing upon the first day of the week for the purpose of
public worship and religious instruction, is a law of Chris-
tianity, of divine appointment; and that the resting on
the day from our employments longer than we are detained
from them by an attendance upon these assemblies, is to Christians
an ordinance of human institution; binding, nevertheless,
on the conscience of every individual of a country in
which a weekly sabbath is established, for the sake of
the beneficial purposes, which the public and regular observ-
ance of it promotes; and recompen-sating, perhaps, in some degree,
to the divine approbation, by the resemblance it bears to
what God was pleased to make a solemn part of the law
which he delivered to the people of Israel, and by its su-
fervency to many of the same uses.

We may observe, in general, that if the design of a reli-
gious assembly require that it be held frequently, it is not
expedient that it should return at fixed intervals; and that
the same sabbaths should be observed throughout the country.
That part of the religious distinction of feasts, which
originates in a political or ceremonial, and burdens
during times set apart for the exercise of public worship,
is founded in the reasons which make public worship itself
a duty. But as the celebration of divine service never oc-
cupies the whole day, the other interval of Sunday, is not
spent at church, must be considered as a mere rest
from the ordinary occupations of civil life; and he, who
Paley, who would defend the institution, as it is required
to be observed in Christian countries, unless he can produce
a command for a "Christian sabbath," must point out the
uses
SUNDAY.

uses of it in that view. 1st, that interval of relaxation which Sunday affords to the laborious class of mankind contributes, in a great degree, to the comfort and satisfaction of their lives, both as it refreshes them for the time, and as it relieves their six days' labour by the prospect of a day of rest always approaching. In this view of the institution, whatever may be its origin, it must appear to be highly useful; nor is anything loftier to the community by the intermission of public industry one day in the week; for in countries tolerably advanced in population, and the arts of civil life, there is always more than enough of human labour.

2ndly, Sunday, by suspending many public diversions, and the ordinary rotation of employment, leaves to men of every rank and profession sufficient leisure, and not more than sufficient, both for the external offices of Christianity, and the actual, but equally necessary, duties of religious meditation and inquiry. And thirdly, they whose humanity embraces the whole sensitive creation, will esteem it no inconsiderable recommendation of a weekly return of public rest, that it affords a respite to the toil of brutes. Having fixed the obligation of Christians to comply with the religious observations of Sunday, as it arises from the public uses of the institution, and the authority of the apostolic practice, it follows of course that the manner of observing it ought to be that which best fulfills these uses, and conforms the nearest to this practice. The uses of this institution are to facilitate attendance upon public worship, or to mollify the condition of the laborious classes of mankind, and by a general suspension of business and amusement, to invite and enable persons of every description to apply their time and thoughts to subjects pertaining to their salvation. The duty of the day must, therefore, be violated; 1st, by all such employments or engagements as hinder our attendance upon public worship, or occupy so much of our time as not to afford sufficient leisure for religious reflection; such are travelling, visiting during the whole day, or employing the time at home in any kind of business that bears no relation to religion. Secondly, by unnecessary encroachments upon the rest and liberty which Sunday grants to afford to the inferior orders of the community. Thirdly, by such recreations as are unhealthily forborne, out of respect to the day; as hunting, shooting, fishing, public diversions, frequenting taverns, and playing at cards or dice.

It was Constantine the Great who first made a law for the proper observance of Sunday; and who, according to Eusebius, appointed it should be regularly celebrated throughout the Roman empire. Before him, and even in his time, they observed the Jewish Sabbath, as well as Sunday; both to satisfy the law of Moses, and to imitate the apostles, who used to meet together on the first day.

By Constantine's laws, made in 321, it was decreed, that for the future, the Sunday should be kept a day of rest in all cities and towns, but he allowed the country people to follow their work. In 358, the council of Origen prohibited this country labour; but because there were still many Jews in the Gauls, and the people gave into a good many superstitious usages in the celebration of the new sabbath, like those of the Jews among that of the old; the council declares, that to hold it unlawful to travel with horses, cattle, and carriages, to prepare foods, or to do any thing necessary to the cleanliness and decency of houses or persons, savours more of Judaism than Christianity.

It is well observed by judge Blackstone (book iv.), that besides the notorious indecency and scandal of permitting any secular business to be publicly transacted on this day, in a country professing Christianity, and the corruption of morals which usually follows the profanation of it; the keeping one day in seven holy, as a time of relaxation and refreshment, as well as for public worship, is of admirable service to a state, considered merely as a civil institution. It humanizes, by the help of conversation and society, the manners of the lower classes, which would otherwise degenerate into a forbid ferocity and savage selfishness of spirit; it enforces in the industrious workman a habit of going to church in the ensuing week with health and cheerfulness; it impresses on the minds of the people the sense of their duty to God, to necessitate them to make good citizens; but which would be worn out and defaced by an unremitting continuance of labour, without any stated times of recalling them to the worship of their Maker. Accordingly, the laws of king Athelian (c. 24.) forbade all merchandizing on the Lord's day, under very severe penalties. And by 27 Hen. VI. c. 5, no fair or market shall be held on the principal festivals, Good Friday, or any holidays, except the four Sundays in harvest; a pain of forfeiting the goods exposed to sale. Moreover, by 1 Jac. c. 22, no shoemaker is to expose to sale any shoes, &c. on pain of 5s. 4d. a pair; and by 2 Car. I. c. 1, no persons shall assemble out of their own parishes, for any sport whatsoever, upon this day; nor, in their parishes, shall use any bull or bear-baiting, interludes, plays, or other unlawful exercises or pastimes, on pain that every offender shall pay 5s. 4d. to the poor. By 26 Car. II. c. 7, no person is allowed to work on the Lord's day, or use any boat or barge, (unless allowed by a justice of the peace, or ferry watermen permitted to ply on the Thames, &c. 16 W. c. 21.), or expose any goods to sale; except meat in public houses, milk and milkcarrs at certain hours (10 & 21 W. c. 24.), and works of necessity or charity, or forreheit of 5%. Or if any butcher, by himself, or any other for him by his privy or content, shall kill or fell any victuals on the said day, he shall forfeit 6s. 8d. Nor shall any drayman, carrier, or the like, travel upon that day, under pain of 50s. (3 Car. c. 1.) Fifth-carriages (for the supply chiefly of the markets within London and Westminster) shall be allowed to ply on Sundays or holidays, whether laden or returning empty. No arrest can be made nor process served upon a Sunday, except for treason, felony, or breach of the peace: nor can any proceedings be had, nor judgment given, nor suppofed to be given, on a Sunday: nor shall any hundred be answerable for a robbery committed on that day.

By 9 Ann. c. 23, it shall be lawful for any licensed hackney-coachman, or his driver, or any chairman, to ply and stand with their coaches and chairs, and to drive and carry the same respectively on the Lord's day, within the limits of the bills of mortality.

By 31 Geo. III. c. 49, it is enacted, that every house, room, or other place, which shall be opened or used for public amusement, or for public debate, or any such other purpose, upon any part of the Lord's day called Sunday, and to which persons shall be admitted by the payment of money, or by tickets sold for money, directly or indirectly, shall be deemed a disorderly house or place; and the keeper of it shall forfeit 100l. for every Sunday the same shall be so used, and be otherwise punishable as the law directs in cases of disorderly houses; and the person managing the same, or acting as master of the ceremonies, or as moderator, president, or chairman, in any such debate, shall forfeit 100l., and the door-keeper, or other person delivering out tickets, 50l.; and any person advertising such amusement shall forfeit 50l. For the penalty of killing game on Sunday, see Game. For the penalty of not attending public worship on Sunday, see Nonconformists.
SUN

By 24 Geo. III. c. 65, it is enacted, that no baker carrying on his business in the city of London, or within twelve miles of it, shall make and expose to sale any bread or rolls, or bake any meat puddings, pies, or tarts, or in any other manner exercise his trade or calling, except in the manner allowed by that act, which permits the selling of bread, and the baking of meat puddings or pies only, on the Lord's day, between the hours of 9 o'clock in the forenoon and 1 o'clock in the afternoon, so as the person requiring the bread or meat of the baker or feme to and from the place where such meat pudding or pie is baked, the penalty is 10s., and professions are to commence within six days after the offence is committed.

By 48 Geo. III. c. 70, which principally adjusts the penalties annexed to offences, any mauler or mistrefb baker is allowed within the limits of the weekly bills of mortality, and within ten miles of the Royal Exchange, to deliver to customers on the Lord's day bakings, until half an hour past one in the afternoon of that day.

In the brevity, or other offices, we meet with Sundays of the first and second class. Those of the first class are, Palm, Easter, Ascension, and Whitsunday, those of Quasquimode and Quadragesima; each of which see under its proper article. Those of the second class are the common Sundays.

Anciently each Sunday in the year had its particular name, which was taken from the introit of the day; which custom has only been continued to some few in Lent: as Reminiscere, Oculi, Lector, Judica.

SUNDAY, QUASAMODEMA. See QUASAMODEMA.
SUNDAY, TRINITY. See TRINITY.
SUNDAY, LETTER. See DOMINICAL LETTER.
SUNDAY RIVER, in Geography, a river of Southern Africa, on the south coast of the Cape Colony, which falls into Algoa, or Zwart Kop's bay, opposite to the island of Saint Croix. It rises in the midst of the Snowy mountains, and contains a permanently flowing stream, broad and shallow in the middle part of its course, and narrow and deep towards the mouth, which, like the other rivers, is choked with a bed of sand. This, as well as the other rivers of the colony, is well stocked with perch, eels, and small turtle, and, to a certain degree, from the sea-coast, abounds with almost every kind of fish-fish peculiar to this part of the world.

SUNDAY SALT. See SALT.
SUNDBACH, or LANDMAT, in Geography, a river of Switzerland, which runs into the Linth, near Weinfen.
SUNDBORN, a town of Sweden, in Dalecarlia; 5 miles N.E. of Falun.
SUNDEH, a town of Sweden, in Dalecarlia; 5 miles N.E. of Falun.
SUNDEEP, or SUNDEE, an island at the mouth of the river Merga, or Burhampooter, about 100 miles in circumference; anciently belonging to Aracan. The Portuguese, in 1602, finding it naturally strong, took it from the Mogols; but the king of Aracan, jealous of their growing power, compelled them in the next year to retire. N. lat. 22° 29'. E. long. 91° 33'.
SUNDER, Ta, in Agriculture, a provincial term, signifying to air and expel to the fun and wind, as hay that has been cocked up without being fully dry, and is repressed out.
SUNDERAGODA, in Geography, a town of Hindoostan, in the circular of Cisacole; 5 miles S.E. of Kemedy.
SUNDERGOP. See SUNDERBORG.
SUNDERBUNDS. See DELTA OF THE GANGES.
SUNDERDOO, or MELUNDY, a fortified island in the Indian sea, near the W. coast of Hindoostan, 10 miles to the N.E. by. N. of Vingoda rocks, and reduced by commodore James in 1765. N. lat. 5° 53' 50'. E. long. 75° 16' 30'.

SUNDERREN, a town of the duchy of Weilphala; 25 miles W. of Brlon.
SUNDERGAT, a town of Bengal; 28 miles S. of Calcutta.
SUNDERHAM. See SODERHAM.
SUNDERKIOPEI. See SODERKIOPEI.
SUNDERLAND, a borough-town in the north division of Easington ward, and county-palatine of Durham, England, is seated on the south-west bank of the river Wear, and on the high road which branches from thence to Durham, Stockton, Newcaith, and Shields. In the reign of Henry VIII., Sunderland first began to assume a separate municipal importance; at that time the conservatorship of the river belonged to the crown; but since that period separate commissioners have been appointed. Bishop Morton, in 1624, incorporated the inhabitants by the title of "Mayor, aldermen, and commonalty of the borough of Sunderland." This charter, in the unquiet times which succeeded, was suffered to expire. At the restoration of Charles II., letters patent were issued for the erection of a light-house and piers, and for the preparation of the harbour; for which purpose, various acts of parliament had already passed, since the reign of Henry VIII. Till the year 1719, this town was comprised within the parish of Bishop's-Wearmouth (see WEARMOUTH), but the population having then increased greatly, an act of parliament was procured for making the town and township of Sunderland a distinct parish; upon which a church was erected here, as a part of one of the common fields. Sunderland harbour is formed by two piers, on the north and south sides of the river; on the former of which a circular light-house was erected in 1802. The trade of Sunderland has been long in a state of progressive increase; but during the latter part of the last century has been yet more rapid. The exports are coal, lime, glai, glas-bottles, grind-stones, and copperas. The principal trade, the principal inhabitants, employs about 500 ships, exclusive of 492 keels, which convey the coal from the staiths to the large vessels. This coal is chiefly directed to the metropolis; although great quantities are sent to the Baltic, to France, and Holland; making the whole quantity annually exported from Sunderland about 315,000 Newcastle chaldrons. The number of persons employed in this trade some time since was supposed to be 36,000, or the Wear only. A good deal of linen is annually sent to Yorkshire and Scotland. Many of the inhabitants of the town are employed in the manufacture of patent rope, bottles, and broad glas, copperas, and white and brown earthenware. There are also various free-rose quarries in the neighbourhood of Sunderland. The principal buildings here are the parish-church, a chapel of ease, which has been erected on account of the increased population; meeting-houses belonging to the various sects of dissenters; the barrack; the theatre, and the assembly-room. The town also contains several charitable institutions, among which are a humane society, a dispensary, and two schools. The municipal government is vested in a mayor, aldermen, &c. Here are two annual fairs, with a weekly market on Friday. The population of Sunderland consisted, in 1811, of 12,829 persons, occupying 1684 houses. At the extremity of the town, towards Bishop's-Wearmouth, is the celebrated iron bridge over the Wear, for a particular description of which, see the article BRIDGE. (See also WEARMOUTH.)
SUN

SUNDERLAND, a township of America, in the state of Vermont and county of Bennington; 16 miles N.E. of Bennington; containing 575 inhabitants, and a lead-mine. — Allo, a township of Maitlandshire, in Hampshire county, on the east side of Connecticut river, about 40 miles N. of Hadley; containing a handsome congregation church, and 551 inhabitants, and incorporated in 1718.

SUNDERLAND FOR, a fort of the island of Barbadoes; 1 mile N. of Speights Town.

SUNDERLAND POINT, a cape of England, in the county of Lancaster, at the mouth of the river Lune; 5 miles S.S.W. of Lancaster.—Allo, a cape on the E. coast of England, and county of Northumberland, in the German Sea. N. lat. 52° 37'. W. long. 1° 44'.

SUNDERSHAUSEN. See Sondershausen.

SUNDGAW, formerly a district of Germany, on the left side of the Rhine, but now the southern part of the department of the Lower Rhine.

SUNDI, a province of Africa, in the kingdom of Congo, on the borders of the river Zaire. Its chief town has the same name.

SUNDIVA. See Sundrep.

SUNDSIO, a town of Sweden, in the province of Jamtland, on a branch of lake Storforo; 10 miles S.S.E. of Offerfors.

SUNDSTAD, a sea-port town of Sweden, in the province of Medelpad, on the W. side of the gulf of Bothnia. The harbour, about a league in length, is very convenient. The chief articles of trade are tar, bark of birch-trees, deals, linen, &c.; 20 miles S. of Herland. N. lat. 62° 47'. E. long. 17° 5'.

SUNEKOS, a river which rises in Bootan, and runs into the Burhampoteer, a little below Rangamatty, in Bengal.

SUNERAMPOUR, a town of Bengal; 40 miles N.E. of Dacca. N. lat. 24° 2'. E. long. 91° 9'.

SUNERONG, SUNNERGAUM, or SUNERGAUM, a town of Hindooftan, in the country of Bengal, formerly a considerable city, and celebrated for its manufacture of cotton; situated on one of the branches of the Burhampoteer; 14 miles S.E. of Dacca.

SUNGRA, a town of Peria, in the province of Seilkan or Segeltan; 50 miles W. of Meemend.

SUNSEEL, a town of the duchy of Warfaw; 27 miles S. of Petrograd.

SUNGRA, a town of Bengal; 26 miles S. of Ghor-dore.

SUNGUMNERE, a town of Hindooftan, in Baglan; 35 miles W. of Bahbelgong.

SUNGWAH, a town of Hindooftan, in Baglan; 14 miles N. of Amednagur.

SUNHERETE, a town of France, in the department of the Lower Pyrenées; 7 miles S. of Mauléon.

SU-NIM, a town of China, of the third rank, in Petchch-li; 27 miles S.E. of Puo-tsing.

SUNISA, a town of Afghan Turkey, in Natalia; 25 miles N. of Tocat.

SUNK ISLAND, an island on the river Humber, about two miles in length, and a mile and a half in breadth, of an oblong form, and about nine miles in circumference; separated from the coast of Yorkshire by a channel two miles broad, which is almost dry at low water. On this island are some thousand acres in cultivation, and a few inhabitants to take care of the banks; 10 miles N.W. of Spurn Head.

Vol. XXXIV.
the females; in regard it was required, that the victims were perfect, and without any defect; sullus, or sulus, in the language of the Ojib, signifying integer, entire. See AMBARVALIA.

SUPARABU, in Geography, a small island in the Atlantic, near the coast of Brazil. S. lat. 25° 37'.

SUPAY Ucco, or Driell's Hill, a remarkable eminence in Quito, in Peru, between the valleys of Chugui-pata, and that of Paece. It has its name from a fabulous story of enchantment, propagated by a superstitious Spaniard. It is thought to contain rich mines.

SUPERACUTE, in the Old Mufic, were such high sounds as exceeded E la, the highest note in the scale of Guido, before the term alti, or in alto, came into use. It has long been proverbial to say, in speaking of any thing in excess, alluding to the high notes in music, that a man's pride, vanity, or inflection, goes a note above E la. See ALT, SCALE, and DIAGRAM.

SUPERBIPARTIENS. See RATIO.

SUPERBUS MUSCULUS, in Anatomy, the superior straight muscle of the eye. See EYE.

SUPERCARGO, an officer charged with the accounts of the cargo, and all other commercial affairs in a merchant-ship.

SUPERCIILIARY, in Anatomy, an epithet of certain parts about the eye-brow. The superciliary arch or ridge is the bony superior margin of the orbit. The foramen or notch of the same name is placed in that arch, and gives passage to the superciliary artery and nerve.

SUPERCIILII CORRUGATOR, a small muscle of the eye-brow. See EYE.

SUPERCILIUM, in the Ancient Architecture, denotes the uppermost member of the cornice; called by the moderns corona, crowns, or lambry.

Mr. Evelyn conceives, it should rather have been called fullicium, or drip; to denote its office of sheltering the order from rain. &c.

SUPERCIILUM is also used for a square member under the upper tole, in some pedestals.

Some authors confound it with the tore itself.

SUPERCIILUM Terrae. See ADIANTUM.

SUPEREROGATION, in Theology, what a man does beyond his duty, or more than he was commanded to do.

The Romanists stand up fireniously for works of supernerogation; and maintain, that the observance of evangelical counsels is such. By means of these, a rock of merit is laid up, which the church has the disposif of, and which she distributes in indulgences to such as need.

This monstrous and absurd doctrine was first invented towards the close of the 12th century, and modified and embellished by St. Thomas in the 13th; according to which it was pretended, that there actually existed an immense treasure of merit, composed of the pious deeds and virtuous actions, which the saints had performed beyond what was necessary for their own salvation, and which were, therefore, applicable to the benefit of others; that the guardian and dispenser of this precious treasure was the Roman pontiff; and that, of consequence, he was empowered to assign to such as he thought proper a portion of this inexhaustible source of merit, suitable to their respective guilt, and sufficient to deliver them from the punishment due to their crimes.

The reformed church do not allow of any work of supernerogation; but hold with the apostles, that when we have done our best, we are but unprofitable servants.

SUPERFETATION, in Physiology, the formation of another child, in consequence of a second impregnation, in a female already pregnant. The possibility of such an occurrence has been doubted; and reasons are assigned in the article GENERATION, under the head of Physiology of the female organs, which justify that doubt. The following has been since published, under the title of "A case of superfetation," by Dr. Maton, in the fourth volume of the Transactions of the College of Physicians, p. 161. A lady, who had previously borne children, had, on the 1st of Nov. 1807, another male child, which was brought forth under circumstances peculiarly distressing; being drop on a bundle of straw at midnight in an uninhabited room. Though this infant had every appearance of health at the time of birth, he lived about nine days only. On the 2d of February, 1808, (not quite three months from the former accouchement,) it was delivered of another male infant completely formed, and apparently in perfect health. This child died in about three months of measles.

SUPERFICIAL CONTENT. See SUPERFICIAL, ELM, and MEASURING.

SUPERFICIAL FOURNEMENT, in Fortification, the same with caisson, which is a wooden chest, or box, with three, four, five, or six bombs in it. Sometimes it is filled only with powder, and used in sieges, by being buried under ground, with a train to it, to blow up any lodgment that the enemy may make.

SUPERFICIAL Hollow Earth-Drain, in Agriculture, such a drain as is formed with earthy materials, at no great depth. This sort of drain may be found useful and effective, according to Mr. Marshall, "where a basis of firm clay or strong loam, is situated beneath an absorbent subsoil, and at a convenient depth, as from twenty to thirty inches beneath the surface, being grooved out of the base, and formed with earth alone, at a comparatively small expense, even where stones or bricks are plentiful. They may be employed with effect, either to collect water from the surface, or to receive rising waters through the perforations of their basins. In forming them, a wider trench having been sunk through the soil and the subsoil, if any, a narrower groove is, it said, formed in the base, leaving a flat even shoulder, or shelf, on either side of it. On these shoulders the inverted turf, raised at the top of the trench, or collected in making surface-drains on old graps lands, and cut five or five inches thick, is laid as a cover to the groove; and upon this the excavated mould of the trench is returned." And in regard to the dimensions of a drain of this sort, they may be three; the bottom of the trench ten or twelve inches wide; the top of the groove five or six inches, narrowing to three or four inches at the bottom; its depth five or six inches. As the turf decays, the middle of the cover moulds down, and forms an arched roof to the open drain, which thus acquires an oval form. It is added, that if, in forming a drain of this construction, the bottom of it could or touch upon a vein, or a stratum, of loose earth, so that in the water more particularly lodges, it is necessary to line the pipe or operative part of the drain with turf, to prevent the sides from hollowing into, and thereby choking up the channel. If the difficult part of the operation, the wider trench is to be continued down to the bottom of the drain; and if this also require to be strengthened, a few inches lower, to receive a floor of turf. On this floor, ten or twelve inches wide, two lines of sods are set on edge, and leaning somewhat outward, so as to answer the form of the groove; and are firmly fixed in their places by the covering turfs. The joints on every side are to be left sufficiently open, to permit the waters to pass freely into the trenchlet or pipe of the drain, and close enough.
enough to prevent any gritty matter from entering it, and thereby filling it up.

Supercial Horizontal-Draining Angles, that kind of tool of the auger fort, which is employed in boring in horizontally into the land, in pits, quarries, and other similar places, at no great depth from the surface. See Spring-Draining Angle.

Superficies, or Surface, in Geometry, a magnitude, considered as having two dimensions; or extended in length and breadth, but without thickness or depth.

A surface is not a body of the least sensible magnitude, as some have imagined, but it is the termination, or boundary of a body; neither is a line to be considered as the surface of the least sensible breadth, but as a termination or limit of a surface; nor is a point to be considered as the least sensible line, but as the termination of a line; and in this sense it is plain that a point cannot be conceived to have parts, or magnitude. (See Magnitude.) See also Macaulay’s Fluxions, vol. i. p. 245; and Mr. John Bernouilli’s Letter to Monfier Coursat, concerning his Comment on the Analyse des Infiniment petits. Jo. Bernoull. Opera. vol. iv. p. 160, seq.

In bodies, the superficies is all that presents itself to the eye. A superficies is chiefly considered as the external part of a solid; when we speak of a surface simply, and without any regard to body, we usually call it figure.

Superficies, Rectilinea, is that comprehended between right lines.

Superficies, Curvilinea, that comprehended between curve lines.

Superficies, Planes, is that which has no inequality, but lies evenly between its bounding lines.

Superficies, Convexa, is the exterior part of a spherical or spheroidal body.

Superficies, Concava, is the interior part of an orbicular or spheroidal body.

The measure or quantity of a surface is called its area; which see.

The finding of this measure, or area, is called its quadrature; which see.

To measure the surfaces of the several kinds of bodies, as spheres, cubes, parallelepipeds, pyramids, prisms, cones, &c. see AREA and SPHERE, CUBE, &c.

In order to evince the use of fluxions in finding the superficies of solid bodies, let $F A F$ (Plate XIV. Analysis, fig. 6.) represent a solid generated by the revolution of any given curve $A F$ about its axis $A H$; also, let a circle, whose diameter is the variable line (or ordinate) $R B R$, be conceived to move uniformly from $A$ towards $F F$, and to dilate itself so, on all sides, at the same time, as to generate, by its periphery, the proposed superficies $R A R$; then, the length of that periphery, or the generating line, being expressed by $3.141592 	imes R R = 2 \pi R R$, and the celerity with which it moves by $\dot{z}$, the fluxion of the superficies $R A R$, or the space that would be uniformly generated in the time of describing $\dot{z}$, will therefore be truly represented by $2 \pi R R \dot{z}$.

Hence, if $w$ be taken to represent the whole surface $R A R$, generated from the beginning, we shall have $w = 2 \pi R R \dot{z} = \pi \dot{z} + \pi \dot{z}$; whence $w$ itself may be found as in the following examples.

1. To determine the convex superficies of a cone. The semi-diameter of the base $D C$ or $D C$ (fig. 7.) being put $= \ell$, the slanting line, or hypotenuse, $A C = c$, and $F G$ parallel to $D C = y$, and $c$, we shall, from the similarity of the triangles $A D C$ and $G m g$, have $b = c \cdot \frac{c}{b}$; whence $\dot{w} = \frac{2 \pi c}{y} \dot{y}$; and consequently $\dot{w} = \frac{2 \pi c}{y} \dot{y}$. This, when $y = \ell$, becomes equal $\frac{2 \pi c}{y} \dot{y} = \frac{2 \pi c}{y} \dot{y} = \frac{2 \pi c}{y} \dot{y} = \frac{2 \pi c}{y} \dot{y} = \frac{2 \pi c}{y} \dot{y}$.

For the superficies of a coneoid, &c. see CONOID.

2. To find the superficies of a sphere $A E B H$ (fig. 8.) In this case, putting the radius $O H = a$, $A E = x$, $H m = y$, &c. we shall (by reason of the similar triangles $O H F$ and $H m b$) have $y = (F H) : a (O H) = x (H m)$.

$x (H b) = \frac{a x}{y}$; therefore $\dot{w} = \frac{2 \pi a x}{y} = \frac{2 \pi a x}{y} = \frac{2 \pi a x}{y} = \frac{2 \pi a x}{y} = \frac{2 \pi a x}{y}$.

And consequently the superficies ($w$) itself is $2 \pi a x = A F \times$ periphery $A E B H$; which, if the whole sphere be taken, will become $A B \times$ periph. $A E B H = 4$ times the area $B E A H$.

Hence the superficies of a sphere is equal to four times the area of its greatest circle: and the convex superficies of any segment of it, is to that of the whole, as the axis (or thickness) of the segment to the diameter of the sphere. This, as we have already shown, is $\frac{a^2}{3} + \frac{c^2}{3}$, and consequently its ($w$) (when $c = b$) $\sqrt{a^2 - b^2}$, and consequently $\dot{z} \left( = \sqrt{a^2 + b^2} \right) = \sqrt{a^2 - b^2}$; therefore, in this case, $\dot{w} = \frac{2 \pi a x}{y}$.
which being to \( \frac{2 \rho b c x}{aa} \times \sqrt{a^2 - x^2} \), the fluxion before found, in the constant ratio of \( 1 \) to \( \frac{2 \rho b c x}{a^2} \), their fluents must, therefore, be in the same ratio; and so the latter expressing the superficies \( C \times F \times D \), will conseqently be \( \frac{2 \rho b c x}{aa} \times B \times E \times F \times H = \frac{2 \rho}{a} \times \frac{FH}{HS} \times B \times E \times F \).

This solution, it may be observed, obtains only in case of an oblong spheroid, generated by the rotation of the ellipsis about its greater axis; for in an oblate spheroid, generated about the lesser axis, the value of \( \sqrt{a^2 - c^2} \) will be impossible; hence, in this case, \( H \times F \) is greater than \( H \times A \).

But if we, here, put \( b = \sqrt{a^2 - c^2} \), and \( d = \frac{a^2}{b} \), the value \( \tilde{s} \) (found above) will become \( \frac{2 \rho b c x}{a^4} \sqrt{a^2 + x^2} \).

\[
\sqrt{a^2 + x^2} = \frac{2 \rho b c x}{d^2} \times \frac{d x}{d^2} \times \sqrt{a^2 + x^2};
\]

whence the following may be brought out by the help of a table of logarithms: for, let the variable part \( \sqrt{d^2 + x^2} \) be transformed to \( \left( \frac{\sqrt{d^2 + x^2}}{\sqrt{d^2 + x^2}} = \frac{d^2 + x^2}{d^2 + x^2} = \frac{d^2 x^2 + x^2}{d^2 x^2 + x^2} = \right) \frac{1}{\sqrt{d^2 x^2 + x^2}} + \frac{1}{\sqrt{d^2 x^2 + x^2}} \), so that the numerator of the form \( \frac{\sqrt{d^2 x^2 + x^2}}{\sqrt{d^2 x^2 + x^2}} \) (now in a given ratio to the fluxion of the quantity under the radical sign) may be had by the common rule; by which means we get \( \frac{1}{\sqrt{d^2 x^2 + x^2}} \), for the true fluent of the said term; to which adding the fluent of the other term \( \frac{1}{\sqrt{d^2 x^2 + x^2}} \), or \( \frac{\sqrt{d^2 x^2 + x^2}}{\sqrt{d^2 x^2 + x^2}} \), there arises \( \frac{1}{\sqrt{d^2 x^2 + x^2}} + \frac{1}{\sqrt{d^2 x^2 + x^2}} \times \text{hyp. log.} \) \( x + \sqrt{d^2 + x^2} \), for the fluent of \( \sqrt{d^2 + x^2} \); and this corrected and multiplied by \( \frac{2 \rho c x}{d} \) gives \( \frac{2 \rho c x}{d} \times \sqrt{d^2 + x^2} + \text{hyp. log.} \) \( x + \sqrt{d^2 + x^2} \), for the superficies in this case, where the proposed spheroid is an oblate one. Simpson's Fluxions, vol. i. p. 187, &c.

Superiorities, Line of, a line usually found on the sectar, and Gunter's scale. The description and use of this, see under Sectar and Gunter's Scale.

Superiorities of the Earth, Internal, a term used by Tull, and others, to express that part of the earth which affords the pabulum, or what is called the 

The internal superficies of the earth, which is the pasture of plants, is not like the external surface, which is the pasture of animals, in that it cannot be enlarged without the addition of more surface taken from land adjoining to it, by enlarging its bounds or limits; but the internal superficies, or artificial pasture of land, may be enlarged without addition, or more land, only by division of the same earth; and this artificial pasture may be increased in proportion to the division of the parts of the earth, of which it is the superficies.

The "cube of earth of one foot" has but six square feet of superficies, but divide this cube into cubical inches, and then its superficies will be increased twelve times, that is, it will be forty-two superficial feet. Divide these cubes into such others, as bear the same proportion to inch that an inch does to a foot; and then the same quantity of earth, which had at first only six feet superficies, will have a superficies of eight hundred and sixty-four feet of natural pasture; and in the same manner is the foil divided, and consequently this pasture increasable ad infinitum.

Poor land does not afford an internal superficies to well stocked with these fruitful particles as rich land does, but this we may compensate by dividing it more, and then what it wants in quality may be made up in quantity.
SUP

The common method of dividing the foil is by dung, or by tillage, or by both; and none of the natural pastures is ever lost, or injured by the use of the artificial means, but, on the contrary, it is meared by such means, a free communication being made by them between pore and pore. Tull's Horaeoing Husbandry, p. 18.

SUPERFINE, in the Manufactory, a term used to express the superfine fineness of a stuff. Thus a cloth, camblet, &c. are said to be superfine, when made of the finest wool, &c., or when they are the finest that can be made.

The term is particularly used, among gold wire-drawers, for the gold or silver wire, which, after being drawn through an infinite number of holes, each less and less, is at length brought to be no bigger than a hair.

SUPERFLUOUS INTERVAL, in Music, is one that exceeds a true diatonic interval by a femitonic minor. See INTERVAL. Thus the

Superfluous Second, or Tone, contains a femitonic minor more than a tone, in practice found, and will therefore be expressed by $\frac{5}{4} \times \frac{4}{4} = \frac{20}{16} = \frac{5}{4}$. The root of these expressions is a tone minor, and a femitonic minor; since $x \times \frac{5}{4} = \frac{5}{4} \times x$; and the other is a tone major, and femitonic minor; for $x \times \frac{4}{4} = \frac{4}{4}$. This last occurs in practice, and is one of the intervals of the chromaticum tonizium. See CHROMATIC and SECOND.

In the temperate scales these two superfine tones coincide. Thus from $B\flat$ to $C$ sharp, or from $F$ to $G$ sharpened, are superfine tones.

Superfluous Third is greater than the third minor by a femitonic minor, and will therefore be expressed by $\frac{5}{4} \times \frac{4}{4} = \frac{20}{16} = \frac{5}{4}$. It is not in use. It forms a fourth on our harphichords. Thus from $B\flat$ to $D$ sharp is properly speaking, a superfine third; but $D$ sharp and $E\flat$ being confounded, it fails for a fourth.

Superfluous Fourth. This interval is expressed by $\frac{5}{4} = \frac{5}{4} \times \frac{4}{4}$. It is by practitioners, and in temperate scales, confounded with the tritonus. See INTERVAL.

Superfluous Fifth is expressed by $\frac{5}{4} = \frac{5}{4} \times \frac{4}{4}$. This is equal to two thirds major, for $\frac{4}{4} \times \frac{4}{4} = \frac{4}{4}$. The superfine fifth occurs in the same way as from $C$ to $G$ sharpened.

Superfluous Sixth. This interval is of two kinds; being the respective complements of the two diminished thirds to the octave. One only, strictly speaking, answers to the general definition of a superfine interval, which is that interval which exceeds the fifth minor by a femitonic minor, and is therefore expressed by $\frac{5}{4} = \frac{5}{4} \times \frac{4}{4}$. But the other interval, which is a comma more than the former, and is two femitonic major less than the octave, is chiefly used in harmony, as between $B\flat$ and $A$, where it has a fine effect. It is expressed by $\frac{5}{4} = \frac{5}{4} \times \frac{4}{4} = \frac{20}{16} = \frac{5}{4}$. See INTERVAL and Diminished Third.

Superfluous Seventh is expressed by $\frac{5}{4} \times \frac{4}{4} = \frac{20}{16}$. This is a dissonant less than the octave. See INTERVAL.

Superfluous Octave is a femitonic minor more than the octave, as from $C$ to $E$ sharpened. It sometimes occurs in the basses of instrumental pieces.

SUPERINCESSION RABENS. See SILING.

SUPERINCESSION FOLIERS. See ROLLING.

SUPERINSTITUTION, SUPRINSTITUTION, denotes one upon another. As if A, be admitted and instituted to a benefice upon one title, and B, be admitted, instituted, &c. by the presentation of another.

SUPERINTENDENT, in the French Customs, an officer who has the prime management and direction of the finances or revenues of the king.

The term is also used for the first officer in the queen's household, who has the chief administration of it.

They have also a superintendent of the buildings, answering to the surveyor of the works among us.

The cardinal de Richelieu made himself superintendent of commerce.

Superintendent also denotes an ecclesiastical superior in several reformed churches where episcopacy is not admitted; particularly among the Lutherans in Germany, and the Calvinists in some other places.

The superintendent is, in effect, little other than a bishop; only his power is somewhat more restrained than that of our diocesan bishops.

He is the chief pastor, and has the direction of all the inferior pastors within his district or diocese.

In Germany they had formerly superintendents general, who were superior to the ordinary superintendents. These in reality were archbishops; but the dignity is sunk into dioceses; and at present, none but the superintendent of Wittenberg assumes the quality of superintendent general.

Superior, or Superior, something raised above another, or that has a right to command another. Thus an abbot is called the superior of an abbey, and a prior the superior of a convent.

The canonists hold, that a perpetual superiority constitutes a title; but a superior may be continued by those who constituted him such, yet without the superiority's being rendered by that means perpetual.

The church of France formerly allowed the superiority and primacy of the pope, and his infallibility to all the other Roman churches do. See PAPAL, AMBASSADOR, AND PRIEST.

Superior Auris, in Anatomy, a muscle of the external ear. See EAR.

Superior Oculus Retini et Obliqueus, two muscles of the eye. See EYE.

Superior Serratus Pectoralis. See SERRATUS.

Superior Courts of Record. See COURT.

Superior, Lake, or Upper Lake, so called from its northern situation, in Geography, the largest and most magnificent body of water on the continent of North America, and said to be the most extensive in the known world, being computed at 400 miles in length, and 1800 miles in circumference. According to Mackenzie, its greatest breadth is 120 miles, and its circumference, including the bays, 1300. The water of this lake is clear and pellucid, of great depth, and abounding with a great variety of fish, which are the most excellent of their kind. Here are troops of three kinds, weighing from five to fifty pounds,urgeon, perch, chub, pike, red and white carp, black bass, herrings, &c. &c. and the left and right of all, the "tiamang," or white fish, which weigh from four to sixteen pounds, and is of a superior quality in these waters. This lake may be denominated the grand resort of the river St. Lawrence. The principal rivers that discharge themselves into it are the St. Louis, the Nipigon, the Pic, and the Michipicoten. Although it receives ample supplies, it is said that not a tenth part of its waters pass off by the streams mentioned below. Hence it appears that by evaporation this large inland sea furnishes the interior parts of the country with vapours, without which they must, like the interior parts of Africa, be a desert. This lake, and also Michigan and Huron, form one large inland sea, which might be called the sea of Canada, or that of Huron; and this part of the said sea opens into the lake Huron by the straits of St. Mary, about 40 miles in length, and in some places only one or two in breadth,
breath, with a rapidity towards the N.W. extremity, which, however, may be defended by canoes. The prospects are here delightful. The forenoon on this large expanse of water are of less danger than those on the ocean, the waves breaking as suddenly, and running nearly as high. In this lake are several islands, one of which, called "Minong," or "Tile Royale," is about 100 miles in length, and in many places 40 broad: they are surrounded by the lavers or bays as residences of the Great Spirit. This vast collection of water, says Mackenzie, is often covered with fog, particularly when the wind is from the E., which drives against the high barren rocks on the N. and W. shore, diluting the air with torrents of rain. It is very generally said that the shores of this lake are denoted by a smell on the preceding day; but the phenomenon does not seem to be regular, as the smell often frequently suffocated without any subsequent wind. Along the surrounding rocks of this immense lake, evident marks appear or the decrease of its water, by the lines observable upon them. The interval, however, between the highest and the lowest is not to great as in the smaller lakes, as it does not amount to more than six feet, the former being very few. In the year 1658, when the six millionaires visited the south of this lake, they found the country full of inhabitants. About this time a band of the Nezinsauges, who were converted, are said to have emigrated to the Nipigon country, which lies to the N. of Lake Superior. Few of their descendants are now remaining, and not a trace of the religion communicated to them is to be discovered. The inhabitants now found along the coast of this water are all of the Algonquin nation, but in their whole amount they do not exceed 150 families. These people live chiefly on fish, the country, for want of shelter, affording few other animals. The rocks appear to have been overrun by fire, and the flinted timber, which once grew there, is frequently seen lying along their surface. Indeed, as there is little appearance of foil, vegetation to any great degree cannot be expected. Between the fallen trees there are briars, with gooseberry-bushes, raspberries, &c. which invite the bears in greater or less numbers, as they are a favourite of such animals. Beyond the rocky banks are found a few moose and fawn-deer. The waters alone are abundantly inhabited. The water at the Grand Portage, some years ago precipitately withdrew, the fall being equal to four perpendicular feet, and then rushed back with great velocity above the common mark. It continued thus falling and riling for several hours, gradually decreasing, till it settled at its usual height. Here is frequently an irregular flux and deflux, which does not exceed ten inches, and is attributed to the wind. The bottom of the bay, which forms an amphitheatre, is clear and inclosed; and on the left corner of it, beneath a hill, 500 or 400 feet in height, and crowned by others of a greater altitude, is the fort, pincered in with cedar palisades, and inclosing hovels constructed of wood, and covered with shingles. These are calculated for every convenience of trade, and the accommodation of the proprietors and clerks during their short residence there. The soil bordering on the lake has been favourable only to the cultivation of potatoes, which circumstance is ascribed to the cold damp foams of the lake, and the moisture of the ground from the springs that illude from beneath the hills. In the vicinity are meadows that yield abundance of hay for the cattle; but agriculture has not hitherto been an object of consideration. N. lat. 45° 4' to 48° 45'. W. long. 84° 40' to 91° 55'.

Superioris Labii Lectoris, in Anatomy, a muscle of the upper lip. See Delegation.

Superiority, in Agriculture, a fort of tenure, in some places, as in some parts of Scotland. It is that kind of tenure, or nominal fort of security is land, which the lord or superior had, in early times, given to a tenant upon him, and which still exists, in some degree, in some parts of the more northern districts of the island. The writer of the account of the State of the Agriculture of the County of Peebles states, that superiority is merely that nominal title to land, which confers the right of franchises. That as 400l valuation of superiority gives the right of franchises, and that as, in the above county, superiority may be retained, when the property of the land is conveyed away, and that this superiority may also be feebly conveyed in any given portions, it is evident that, in creating votes, the superiority of the whole valuation, 51,927l. Scots, would, if paid, give one hundred and twenty-nine voters at the county election; as, however, the number commonly upon the roll of freethinkers does not exceed thirty or thirty-five, it may be readily inferred, that the county has not been much disturbed by the anomalies of political contest.

Such forts of nominal tenure should, however, now be done away; since circumstances have so much changed the nature of property in land.

Superiority, in Mufs., in early days of counterpart, signified the treble or half height part.

Superlativic, in Grammar, an inflexion of noun adjective, serving to augment and heighten their signification, and shew the quality of the thing denoted to be the highest degree.

In English, the superlativic is usually formed by the addition of of, as richest, holiest, &c. rarely by the addition of siffus, as generalissimo; more frequently by the prefix of, as most honourable, most amiable, &c.

The French are generally forced to form their superlatives by prefixing of le plus, sometimes of tres, and sometimes of fort.

The Italians and Spaniards have great advantages over them in this respect; their language abounding with magnificent words, for exaggerating things with auxiliary particles; yet the Hebrews are more poor than the French in this respect, as having neither comparatives, nor superlatives. They express these degrees by the particles and, and that; sometimes by the preposition bin, and sometimes by redoubling the word; of which we find frequent instances in the Bible.

Superana, in Hindoo Mythology, is a name of great celebrity in the legends of the East, usually employed to carry the person of the god Vishnu. The Hindoo deities have different animals assigned as their vehicles, when journeying. These are called in Sanskrit vamas, or vaham; which see. One of the commonest names of Superana is Garuda, sometimes pronounced Gauro, by which a large species of falcons, well known in all parts of India, is also once had. The English usual style is the Brahmany kite; it being held in veneration by many Hindoos, who very much dislike having it killed. In this there is utility, as well as superstition; for the bird in question is very useful, in concert with the vulture, in devouring carrion, and performing the office of scavenger. It is well when
SUP

when superstitition promotes, as is not unfrequent, the purposes of utility.

The mythological Garuda is seen variously portrayed in pictures, as a man with the beak and wings of an eagle, painted red, green, or blue. He is also frequently seen in carvings, and is sculptured in the cavern temple at Elephanta, with Vihnu, seated fire-walking, rather ridiculously in our eyes, on his shoulders; Garuda holding by both hands on Vihnu’s ankles. Wherever he appears in this cave, his projecting nose or beak has been broken off, as it is said, and with reason, by the iconoclastic fury of the Portuguese, while Bombay and its contiguous islands, including that called by us Elephanta, were in their possession; a bigotry to be regretted in a thousand instances, and no where more than in Elephanta cave, which still exhibits, though sadly defaced, some of the most extraordinary and curious sculptures in existence.

Garuda is a very important personage in Hindoo mythology; and his birth, life, and exploits, are constantly referred to in Hindoo writings. One of the Puranas is called, after him, Garuda Purana, and contains his history. Vihnu being the sun, Garuda seems, as his apparent vehicle, and in some points of family and character, to be a personification of the sky. His younger brother is named Aruna, and is the driver or precurser of the glorious car of Surya, or the sun; hence corresponding perhaps with the Aurora, or dawn, of western fable; as well as carrying Vihnu, and his comfort Lakshmi. Garuda is seen also flying through the air with Rama and Sita, and sometimes with Kriiti, on his back. But there are representations by feasters of these several gods, who, each adoring the incarnation as the deity, array the object of their adoration in the attributes of the archetype. See Krishna, and Sects of Hindus.

Garuda is a fabled to have married a beautiful woman: her name or parentage does not occur to our recollection, nor in our memoranda. The tribe of serpents, alarmed at this marriage, left the offspring thereof inherit the propensities of the fire, waged fierce war against him; but he destroyed them all, save one, which he placed in an ornament about his neck. In several parts of the Elephanta cave, Garuda is seen with this appendage; and on very ancient Hindoo coins and medals, he has snakes and elephants in his talons and beaks: for he is sometimes spread and double-headed, like the eagle of Propheta. A legend connected with the parentage and exploits of the hero of this article is noticed under our article Kusa. Garuda had a son of some note, named Sumabha; and a daughter of surpassing beauty, named Su-mati, who was espoused by Sagara, or the sea. When we recollect the furnishes that Garuda, or Sumeru, as the vehicle of Vihnu, a type of the aqueous element, is a personification of the sky or visible firmament, we may discover some connexion in the allegory of an alliance between his descendant and the sea. The beautiful maiden, (the meaning of her name, Su-mati, which see,) thus allied, became wonderfully prolific; the brought forth (if the Hindoo romantic language be rightly construed) a gourd, whence ensued 60,000 male children.

The author of the Hindoo Pantheon, in his account of Garuda, notices the extensive prevalence of serpentine forms in the mythological machinery of Egypt and Greece, as well as in India. In many instances, the bird of Jove is brought to our minds by the fables related of this Indian eagle. The story of Prometheus is also found to have a near relation to some of them.

SUPERNATANT Part of the Ship, that part which, when afloat, is above the water.

SUPERNATURAL Grace. See Grace.

SUPERNATURAL theoP. See Theology.

SUPERNUMERARY, in the latter times of the Roman empire, soldiers added to the legions after it was completed. These were the same with those in former times called Accensi.

SUPERNUMERARY, something over and above a fixed number. In several of the offices are supernumerary clerks, to be ready on extraordinary occasions.

There are also supernumerary surveyors of the excise, to be ready to supply vacancies, when they fall: these have but half-pay.

SUPERNUMERARY, in Ancient Music. Proslambanomenos, the lowest found in the Greek scales, said to have been added by Pythagoras to complete the octave, was termed supernumerary, as it implies additional, or addition. It answers to Ars, the second note in the first hexachord of the Guido scale, who still added another note, Gambut, to the Greek scale.

SUPERNUMERARY Bones of the Head. Anatomists distinguish this appendage several bony pieces found in some skulls, chiefly between the parietal and occipital bones. They form breaks in the lamboidal future, and are joined by the futures to the bones already mentioned.

Their figure, number, and size, vary extremely: sometimes they are triangular, or approaching to that form, but oftener they are of no determinate figure: in some subjects they incroach on the occipital bone, and in others on the parietal bones; and sometimes they extend themselves in every way. They are commonly indented, and broader on the outside of the skull than on the inside, in which they have no visible indentations; and sometimes, when they are small on the outside, are hardly at all to be seen within. They have by some been termed keys, a name used by joiners for the pieces which serve to strengthen the joints of boards; but this can agree to them only in respect to their situation, not in respect to their uses with regard to the other bones of the head. Some such bones have also been found in the joints, between the bones of the head and face; and between those of the bones of the face with each other. Winflow. See Cranium.

SUPERONERATIONE Pastule. See Surcharge.

SUPERPARTICULAR. See Ratio.

Ptolemy, in his Harmonics, seems to lay a great stress on superparticular ratios, beyond the superpartient in music. He does not call the intervals which may be expressed by the former ratios, excepting 2 : 3 and 3 : 4, dissonants, as the Pythagoreans did, but consonants, as if they were of a middle nature between consonant and dissonant. But all the doctrine of superparticular ratios is a precarious hypothesis. The two thirds, major and minor, expressed by 5 : 4 and 6 : 5, are superparticular, and concords. Their octaves, 5 : 2 and 12 : 5, are superparticular, and concords also. Ptolemy also refutes the Pythagoreans for excluding the diapason dissonant, expressed by 8 : 3, from the number of concords, because its proportions were superpartient; yet his own doctrine is equally precarious. Vide Euler, Tentam. Nov. Theor. Music. p. 65, 64.

SUPERPARTIENT RATIO. See Ratio.

SUPER-PREROGATIVA Ratis, a writ which formerly lay against the king’s widow for marrying without the suitor’s licence.

SUPER-
SUP.

SUPERPURGATION, Hypercatharsis, in Medicina, an excessive, over-violent purging.

SUPERQUADRIPARTITIUS. See Ratio.

SUPER-SALTUS, in Chymistry, faits with an excess of acid, as super-tartrate of potash. See SALTUS.

SUPER-GAUPLARIS, Superior and Inferior, in Anatomy, old names for the muscles of the fascia, commonly known under the terms supera or infra, spina; which see.

SUPERSEDEAS, in Law, a writ suffused in divers cases, importing, in general, a command to stay or forbear some ordinary proceedings in law, which, in appearance, ought to be done, or purged, were it not for the cause on which this writ is granted.

Thus, a man regularly is to have a surety of peace against him of whom he will swear he is afraid; and the justice required hereunto cannot deny it him; yet, if the party be formally bound to the peace, either in chancery, or elsewhere, this writ lies to stay the justice from doing that, which otherwise he ought not to deny.

SUPERSEDEAS, Clerk of the. See Clerk.

SUPERSEDEAS, a Commission of Bankrupt. If such a commission ifues, and there is sufficient to pay all the creditors, and the charges, and satisfaction is made to all the creditors, the commission may be superseded. A commission is also sometimes superseded, when the creditors agree with the bankrupt, and consent to a supersedeas.

SUPER-STATUTO, 1 Ed. III. c. 12, 13, is a writ that lay against the king's tenants holding in chief, who aliened the king's land without his licence.

SUPER-STATUTO de articulis Cleri, cap. 6, a writ lying against the sheriff, or other officers, that distrains in the king's highway, or in the lands anciently belonging to the church.

SUPER-STATUTO facta pour Sanechial & Marshal de Roy, &c. a writ that lies against the warder or marshal for holding plea in his court, or for trespasses or contracts not made, and arising within the king's household.

SUPER-STATUTO versus Servantes et Laboratores, a writ which lies against him who keeps any servants, departed out of the service of another contrary to law.

SUPERSTITION, extravagant devotion, or religion wrongly directed, or conducted.

Superstitition consists in false and abject notions of the Deity, in the gloomy and groundless fear of invisible beings, and in the absurd rites which these notions and fears naturally produce; and, generally speaking, it is the effect of ignorance, or of a judgment perverted by a four and splanetic temper.

The author of the article Fanaticism in the Diction. Encyclopaedia, Paris, defines fanaticism as a blind and passionate zeal, which arises from superstitious opinions, and leads its votaries to commit ridiculous, unjust, and cruel actions, not only without shame, but even with certain internal feelings of joy and comfort; from which he concludes that fanaticism is really nothing more than superstitition fret in motion.

The difference between true religion and superstition seems to be this: that the former is the exercise of the understanding and affections, and the regulation of the conduct, founded on just notions of God, and of the method of averting his displeasure and securing his favour; and the latter is the result of fancy and passion un directed and un governed, and originating either in the delusive hope of pleasing God by some opinion or practice entirely distinct from, and contrary to, those notions, or the diftressing fear that he will not be pleased with the addition of something which such notions neither require nor justify.

Superstition, says Dr. Hartley (Obl. on Man. p. 290.), may be defined a mistaken opinion, concerning the severity and punishments of God, magnifying these in respect of ourselves or others. It may arise from a sense of guilt, from bodily indisposition, from erroneous reasoning, &c. That which arises from the first cause, has a tendency to remove itself by regulating the person's behaviour, and consequently lessening his sense of guilt; the other kinds often increase for a time, come to their height at last, and then decline again. They do also, in some causes, increase without limits during life. All kinds of superstition have been productive of great absurdities in divine worship, both among Pagans, as well as Jews and Christians; and they have all a great tendency to form the mind, to check natural benevolence and compassion, and to generate a bitter persecuting spirit. These effects are much augmented, where superstition and enthusiasm pass alternately into each other at intervals, which is no uncommon case.

Superstition has been often used, especially by the ancients, for an excess of religion, agreeably to that verse of Aulus Gellius, lib. iv. cap. 9.

"Religentem effe operoet; religiosem nefas."

It was a piece of superstition in the ancient Romans, to observe the flight of birds, the entrails of victual, &c. It has been observed by some excellent critics, that the Greek word ἡσυχασμος, which occurs in the New Testament, though it is often used in a bad sense, has also a good, or at least an innocent, meaning. Accordingly they think that it should be rendered religious, and not superstition, in Acts, xxv. 19., alleging, that it cannot be supposed Feltus would speak contemptuously to Agrrippa of the Jewish, that is, of Agrippa's own religion, when Agrippa was come to Cesare, with his filter Berenice, to him, Thus also it is apprehended that the word ἡσυχασμος, Acts, xxv. 23., should be translated devout, or exceedingly addicted to the worship of invisible powers, and not too superstitious. The word in the former sense, it is urged, would give no offence at Athens; it was the peculiar character of the Athenians, and conveyed an encomium which they were fond of above any other. The latter harsh sense of the word is inconsistent with the whole design of St. Paul's argument. Lard. Cred. vol. i. p. 489. note s. Duddr. in loc.

Monti. Thiers has an express treatise "Des superstitious populaires." Women, he observes, are naturally more inclined to superstition than impiety. Plutarch has endeavoured to shew, that superstition is worse than atheism. The punishment allotted, by several councils, for the superstitious, is, to fast a month in prison.

SUPERSTITIOUS MAGIC. See Magic.

SUPERSTITIOUS Usus, in Law. See Mortmain.

SUPER-SULPHATE of Potash. See SALT.

SUPERVISOR signifies a surveyor or overseer; it was formerly, and still remains, a custom among some, especially of the better sort, to make a supervisor of wills, to overlook the execution, and fee their wills truly performed: but it is little purpose, as being now so carefully executed.

SUPINATION, in Anatomy, that motion of the upper extremity, by which the palm of the hand and the corresponding surface of the fore-arm are turned upwards or forwards. See Extremities.

SUPINATOR, the name of two muscles of the fore-arm, which have the effect of bringing that part and the hand into the supine attitude.

The supinator radii longus (humero-fus-radialis) is a narrow but
SUP

but very elongated muscle, placed superficially on the anterior part of the radial edge of the fore-arm, and extending from the inferior part of the humerus to the carpal end of the radius. It is flattened laterally in its upper fourth, and transversely in the lower three-fourths. Its anterior side is covered by the fascia of the fore-arm and the skin; the posterior is fixed above to the external ridge of the humerus, while it covers, below the suspensory brevis, the extensor carpi radialis longus, the pronator teres, the flexor carpi radialis, flexor digitorum sublimis, flexor longus pollicis, the radial artery and nerve. The outer side is unattached, and offers nothing remarkable; the inner covers the brachialis internus, and the radial nerve above, and has no particular relations of importance below. The upper extremity of this muscle is thin and pointed; and attached to the outer edge of the humerus below the passage of the radial nerve. Thence the muscle descends, at first a little obliquely forwards, and afterwards straight, or in a line parallel to the radius. The thickness and breadth increase as far as the elbow, from which they decrease again to the inferior extremity. The latter is attached to the anterior edge of the lower end of the radius at the base of its styloid process. The suspensory longus arises by short aponeurotic fibres from the humerus and the inter-muscular aponeuroses; its slightly fibrous tendinous, below in a thick flattened tendon, which forms about the lower third of the muscle. It will bring the radius and hand either from the flat pronation or supination, and pass into the middle between these attitudes; and then will it bend the elbow joint.

SUPINATOR RADII BREVIS (epi-condylo-radial), is a short flattened muscle, with curved fibres, placed at the outer part of the fore-arm near the elbow, where it closely surrounds the head of the radius, extending from the back of the external condyle of the humerus, and the neighbouring outer edge of the ulna, to the anterior part of the radius. The external surface is convex, and covered towards the front by the pronator teres, the radial artery and nerve, and the suspensory longus. The middle of the muscle is covered by the extensors radialis; and the back part by the extensor digitorum communis, extensor carpi ulnaris, and anconeus. The internal surface covers the capsule and external lateral ligament of the elbow, and adheres closely to these parts; it is then inserted in the upper third of the posterior and external surfaces of the radius. The posterior edge is attached to the external condyle, and to a longitudinal ridge of the ulna. The anterior is fixed to the radius, at the root of the occipital tuberosity, and for about two inches farther on the bone, terminating where the tendon of the pronator teres commands its insertion. This anterior edge is partly covered by the pronator teres. The attachment to the condyle and the ulna takes place by means of a strong tendon: the muscular fibres arising from this bend spirally round the head of the radius, passing from above downwards, and from behind forwards to the radius, in which they are implanted. The suspensory brevis rotates the radius on its axis, so as to turn the hand supinum; it will then extend the elbow.

SUPINE, in the Latin Grammar, a part of the conjugation of verbs, to indicate either the infinitive mood.

There are two kinds of supines: the one in um, whose signification is active, and marks a motion, as dare nupsum; the other in u, having a passive signification, as hordrem cadit, &c. The supines have neither number nor person.

They have their name, says Probus; and after him Volus, quod ad infar fupinorum et tesisforum bominum omnium habet confusa; or, according to Priscian, quod nuptatur a participio passivorum, quae supina appellata est; quis in primo loco sit, totum conjugationis modum suffizient.

Vol. XXXIV.

SUPINO, in Geography, a town of Naples, in the county of Molise, formerly the see of a bishop, removed to Boiano; 13 miles S.S.E. of Molise.

SUPITZBACH, a river of Saxony, which runs into the Elbe, near Torgau.

SUPOUR, a town of Hindoostan, in Allahabad; 27 miles E.S. of Ghazipore.

SUPPING, in Rural Economy, a term applied to the beverage afforded to servants, labourers, and cottagers, by the dairies in some districts, such as whey, milkings, and butter-milk, which is given to them instead of being converted to the use of pigs, as is usually the case, by which some lofs may probably be sustained by the farmer.

SUPPLANTALIA, or SUPP Ramp, among Physicians, plasters, or other medicaments, applied to the soles of the feet; generally made of leaven, mustard, horse-radish, falls soap, gunpowder, &c.

SUPPLE. To supple a horse in the manage, is to make him bend his neck, shoulders, and sides, and to render all the parts of his body more pliable.

SUPPLEMENT of an Arc, in Geometry, or Trigonometry, is the number of degrees that it wants of being an entire semicircle: as complement signifies what an arc wants of being a quadrant.

SUPPLEMENT, in Matters of Literature, an appendage to a book, to supply what is wanting in it.

Freinhenius has written divers supplements, to restore the blemishes of several antiquities, and to remove which had been lost. The French have also used the word supplement for a kind of tax, or after-payment, charged on lands, offices, &c. that are pretended to have been sold beneath their value.

SUPPLEMENTAL BILL, in Law. See Suit in Equity.

SUPPLETORY OATH. When there is only one witness (the civil law universally requiring the testimony of two) to make up the necessary complement of two, the civil courts admit the party himself (plaintiff or defendant) to be examined in his own behalf; and administer to him what is called the suppletory oath; and if his evidence happens to be in his own favour, this immediately converts the half proof into a whole one. Blackst. Com. vol. iii.

SUPPLICATION, SUPPLICATIO, in Antiquity, a religious solemnity observed on account of some remarkable successes against an enemy; and especially when the army had conferred the title of imperator on their general, in whose name the senate ordered the temples to be opened for the reception of the people, and thanks to be rendered to the gods.

On such an occasion the emperor sent messengers crowned with laurel with letters to the senate, which were likewise adorned with laurel, to demand of them the title of imperator, and the honour of a supplication. This solemnity consisted in sacrificing and feasting in the temples, with giving thanks to the gods for successes obtained, and praying for the continuance of their affluence. At first there were only a few days taken up in such festivals; but afterwards they were increased gradually, till they came to no less than fifty. On subduing the Sabines, in the year of the city 305, a solemnization of one day only was ordained; on the taking of Veii, Camillus had a supplication of four days decreed him; Pompey had twelve on putting an end to the Mithraic war; Caesar had fifteen, and afterwards twenty, for reducing Gaul; Octavianus and Pansa had fifty days of supplication for delivering the colony of Mutina.

SUPPLICAVIT, in Law, a writ, influing out of the court of king's bench, or chancery, for taking surety of the peace when one is in danger of being hurt in his body by another.
It is directed to the justice of the peace, and sheriff of the county; and is grounded on the statute 1 Ed. III. which appoints, that certain persons shall be assigned by the lord chancellor to take care of the peace. See Good-keeping.

SUPPLIES, called also aids and subventions, are extraordinary grants made by the commons of Great Britain, in parliament assembled; who, when they have voted a supply to his majesty, and settled the quantum of that supply, usually resolve themselves into what is called a committee of ways and means, to consider of the means and means of raising the supply so voted. And in this committee every member (though it is looked upon as the peculiar province of the chancellor of the exchequer) may propound such schemes of taxation as he thinks will be least detrimental to the public. The resolutions of this committee (when approved by a vote of the house) are in general esteemed to be (as it were) final and conclusive. For though the supply cannot be actually raised upon the subject till directed by an act of the whole parliament, yet no man may say he will not subscribe to the advancement of the government in case of ready cash, on the credit of the whole house of commons, though no law be yet passed to establish it; and which requires the assent of the other two branches of the legislature. The general reason given for this exclusive privilege of the house of commons, is that the supplies are raised upon the body of the people, and, therefore, it is proper that they alone should have the right of taxing themselves. This reason, says judge Blackstone, would be unanswerable, if the commons taxed none but themselves; but it is notorious, that a very large share of property is in the house of lords, which is equally taxed with the property of the commons; and, therefore, he says, the commons not being the sole persons taxed, this cannot be the reason of their having the sole right of raising and modelling the supply. The true reason, arising from the spirit of our constitution, he apprehends to be this. The lords being a permanent hereditary body, created at pleasure by the king, are suppos'd more liable to be influenced by the crown, and with less influence to continue so, more than the commons, who are a temporary elective body, freely nominated by the people. It would, therefore, be extremely dangerous to give the lords any power of framing new taxes for the subject. It is sufficient that they have a power of rejecting, if they think the commons too lavish or improvident in their grants. See PARLIAMENT and MONEY-BILLS. Blacklt. Com. vol. i.

SUPPLY, in Sea Language, a fresh recruit of provisions or stores sent to a ship or fleet.

SUPPLY and Consumption of Agricultural Produce, the quantity of this sort of produce which is necessary for the supply and consumption of the country by its population, and in some other ways connected with it, in a greater or less degree. It is a subject which is obviously involved in much difficulty, and on which, any calculations that may be offered to the public, can only be supposed to approximate, in some measure, towards the actual truth. At several different periods and times, calculations have however been furnished by different individuals on this very interesting matter; and those which have more lately been brought forward by the able calculator and writer of the Corrected Account of the Agriculture of the County of Middlesex, so far as they go, seem the most deserving of attention, not only as entering more fully into the business, but as laying down more data for proceeding upon, than any others which have fallen under our notice and examination.

The writer begins by stating, on the authority of the parliamentary reports, that the excess of the imports over the exports of corn, shows clearly, that the annual consumption of this country in that article has been greater than its produce, on an average of five years, ending at Christmas 1794, by quarters of

Wheat and flour - - - - - - - - - 184,821
Barley and malt - - - - - - - - - 66,445
Oats and oatmeal - - - - - - - - - 83,681
Rye - - - - - - - - - - - - - - - 36,799
Pease and beans - - - - - - - - - 41,848

The whole of the annual average imports exceeded the exports by

1,145,584

And that the same for five years, ending at Christmas 1799, was

Wheat and flour - - - - - - - - - 469,956
Barley and malt - - - - - - - - - 33,831
Oats and oatmeal - - - - - - - - - 618,041
Rye - - - - - - - - - - - - - - - 44,199
Pease and beans - - - - - - - - - 23,777

The whole of the annual average imports exceeded the exports by

1,191,131

The average of the said ten years was an annual deficiency of 1,168,361 qrs. of grain; to which, if we add that of the year 1800, which amounted to 2,269,344 qrs. of corn, we shall discover, it is said, that the average of the eleven years was annually 1,268,452. This quantity is equal to the broad-corn of nearly as many persons, or to the entire produce of (in acres of land) - 413,000

Proportion of fallow, one-fourth of the land - 105,500
Clover and root crops ditto - 105,500
Land to support the requisite number of labouring cattle to till the deficiency of arable, and to produce food, both in corn and hay, for their own support; one horse to every 20 acres, and allowing them to require four acres each, is in acres - 136,000
Hedge-rows, site of buildings, yards, roads, ponds, gravel-pits, &c. Together - 790,000
Allow for inferiority of quality between commons and old inclosures; one-fifth of 790,000 is 158,000; but say only - 150,000

1,010,000

The average quantity and price of all sorts of grain may be found thus:

<table>
<thead>
<tr>
<th>Acres.</th>

Dividing 17 2/3 qrs. by 6 acres, gives a bare 3 qrs. per acre; and dividing 26l. 10s. 6d. by 17 2/3 qrs. gives a bare 30s. per quarter, that is, 3 qrs. at 30s. is a full average of the corn, exclusive of the straw, feed, and walking. The proportion which the number of acres bears in each fort of grain, will be seen below.
SUPPLY.

It is further noticed, that the whole deficiency during the said 11 years, was not less annually than all that could be grown by cultivating our commons, to the extent of 1,000,000 acres. The miserable consequence of which was, that, notwithstanding we imported food from any country where it could be obtained, the death became so great as to occasion the death of about 100,000 inhabitants. The present system of passing local acts, every session of parliament, for enclosing a few thousand acres of waste land, is altogether, it is thought, unequal to the task of warding off the return of death, or to keep down the price of provisions; owing to human beings increasing in a much greater proportion than such additional cultivation.

It is also said, that Mr. Claud Scott, the most eminent corn merchant that perhaps ever lived, laid an account before a committee of the house of lords early in the year 1797, by which it appeared, that for three years, ending the 5th of January in that year, there were paid to foreign nations for grain imported into this kingdom the following sums; namely,

<table>
<thead>
<tr>
<th>Year</th>
<th>Amount</th>

</tr>
</tbody>
</table>

In the three years was paid £7,446,012

Average annually £2,482,000

The writer's opinion therefore, he says, perfectly accords with the language of lord Carrington, who, on quitting the chair of the Board of Agriculture, in March 1803, said, "if, after the experience of more than 20,000,000Sterling having been sent to foreign countries for the purchase of grain, within the short period of a very few years, the legislature still can condemn millions of acres, which are capable of every kind of produce, to remain obnoxious to the little that can be of infatuation."

After this statement, the ingenious writer and calculator attempts to estimate the quantity of land in South Britain, or what is commonly called England and Wales, which is occupied with each sort of field crops; the probable number of horses and sheep, which are kept and made use of; the quantity of animal food; and the various other products of the soil which are raised, together with the weight and value of wool; and the total amount of all sorts of agricultural produce.

It is said, that the returns then lately made to parliament prove, that there were about 9,000,000 of inhabitants in the above extent of South Britain; and that the best opinion appears to be, that all those who eat wheat bread, consume annually eight Winchester bushels of wheat; which include puddings, pies, confectionary, and every other application of wheat in the article of food. This quantity of wheat is about equal, it is thought, to the average produce of half an acre of land; that is, after deducting feed, loss by vermin, accidents, &c. from the gross produce, the remaining net quantity is 76 bushels per acre.

That those persons who eat bread made from spring-corn and rye, will in like manner require the net product of half an acre; as the flour of this sort of grain is so much deficient in quantity, weight, and nourishment, as fully to balance the greater number of bushels per acre in the produce; therefore, as half an acre supplies bread for one person, it is said, that

1st. Nine million inhabitants consume the corn which grows on

2dly. Beer.—A family of six persons, of all ages, requires 24 bushels of malt annually; which, at the usual proportion of nine to eight, is rather more than three bushels and a half of barley to each person; but as there are many who do not drink malt liquor at all, this would be too large an allowance for all England and Wales: therefore it may be estimated at three bushels each, which, for the whole population, is 27,000,000 bushels, or 5,375,000 quarters of barley; and that, at the average crop of three quarters per acre, after allowing four for feed, &c. is, in acres

Distilleries.—In the whole of Great Britain, rather upwards of 500,000 quarters of barley are, it is said, used in this manufactory, which, divided by 3, reduces them into 165,000 acres; from that number deduct 15,000 for Scotland, and the remainder for England and Wales is about

Beer and spirits exported, the produce of

Starch, hair-powder, and other manufactures

Corn consumed by oxen, sheep, hogs, poultry, rabbits, &c. the produce of

Horses consume, it is said, corn to the amount of the produce of from one and a half to three acres each, or on the average two acres.

Arable land employs about one horse to every 15 acres, which on 15,000,000

Grass land employs one horse to every 100 acres, which, on 20,000,000, is

Number of horses used in agriculture

Horses kept for pleasure, and taxed

Post-chaise horses, mail-coach horses, stage-coach horses, hackney-coach horses, &c. supposed to be about

Horses used in waggon and cart, in mills, canals, and navigable rivers, in caravans, and for all the other purposes of draught, not before described

Cavalry of all the various descriptions

Number of horses not used in agriculture proper

Total number of horses

Which, at two acres each, will consume the produce of arable land
Land cropped with turnips, carrots, parsnips, cabbages, and potatoes, coriander-feed for the brewers, and

dragglets, canary-feeds for birds, and with dyers', physical and culinary herbs; cultivated by the
plough
Clovers, rye-grasfs, &c. one year's lay, in the proportion of one-tenth
Fallow, in the proportion of two-tenths

The consumption of the country requires, in aration,
But we import corn, proportionate to the produce, of upwards of

Which, deducted from the foregoing number, leaves the quantity of arable land in South Britain, rather under

* This estimate would seem to be too low by nearly one-third or fourth, or probably more.

It is said, that in order to discover the quantity of land cropped with each species of grain, the writer adopts the following hypothesis, founded on his own observations, made in most of the counties in England, namely, that, including the common arable fields, six-tenths of all the arable land in South Britain is cultivated under the old system of wheat, spring-corn, fallow: three-tenths are in something like the rotation of wheat, turnips, spring-corn, clover; and the remaining one-tenth is in a course of oats, roots, clover.

First position, 6-10ths divided by 3, gives us for
fallow 2, wheat 2, oats and beans 2, together

Second position, 3-10ths divided by 3, gives us that the wheat is 0.75, the barley and rye 0.75,
the roots 0.75, and the clover 0.75, together

Third position, 1-10th divided by 3, produces for oats and beans 0.5, roots 0.25, and clover 0.25, together

General proportion, fallow 2, wheat 2 7/5, oats
and beans 2 5/7, barley and rye 0.75, roots 1,
clover 1, together

According to this statement, it is concluded that every 10,000,000 acres of arable land, are cropped in the following proportions; namely,

<table>
<thead>
<tr>
<th>Grain</th>
<th>Acres</th>
</tr>
</thead>
<tbody>
<tr>
<td>Wheat</td>
<td>2,750,000</td>
</tr>
<tr>
<td>Oats and beans</td>
<td>2,500,000</td>
</tr>
<tr>
<td>Barley and rye</td>
<td>750,000</td>
</tr>
<tr>
<td>Roots</td>
<td>1,000,000</td>
</tr>
<tr>
<td>Clover</td>
<td>1,000,000</td>
</tr>
<tr>
<td>Fallow</td>
<td>2,000,000</td>
</tr>
</tbody>
</table>

Total 10,000,000

By which also it appears, it is said, that the corn-crops, including beans, are in the proportion of fix to ten; the green crops in that of two to ten; and the fallow, of two to ten.

It is noticed, that having before shewn, that there is at most 15,000,000 acres of land in aration in South Britain, it is only necessary to increase the said numbers one-half, and the produce will shew, that the soil of England and Wales is annually cropped with the following quantities of each kind of grain, &c: thus,

<table>
<thead>
<tr>
<th>Grain</th>
<th>Acres</th>
</tr>
</thead>
<tbody>
<tr>
<td>Wheat</td>
<td>4,125,000</td>
</tr>
<tr>
<td>Barley and rye</td>
<td>1,125,000</td>
</tr>
<tr>
<td>Oats and beans</td>
<td>3,750,000</td>
</tr>
</tbody>
</table>

Carry forward 9,000,000

* This estimate would seem to be a good deal too high, as perhaps one-third or fourth, or more.

Brought forward 15,000,000

Clover, rye-grafls, &c. one year's lay
Turnips and other roots, as aforesaid,
The arable land, producing at least one crop annually, is
Fallow, as aforesaid,

Together 15,000,000

Hop-grounds.—The produce of the two years 1772 and 1773, was, it is said, nearly 8000 tons annually; therefore we may call that the consumption at that period. The next clearing year was 1787, being a period of 14 years; and the average produce of the 14 years was 8937½ tons, and there never was remembered a greater scarcity than at the coming in of the growth of 1788, so that the consumption from September 1774, to September 1788, must have increased from 8000 tons to 9875 tons, otherwise the average product of 8937½ tons could not have been confirmed. The average produce of 13 years, ending with the year 1800, has been 9668 tons; therefore the consumption in this latter period must have decreased 209 tons, and they are now much more on the decline, as drugs are used for the purpose of curing beer, in lieu of hops.

Nursery grounds about 10,000
Fruit and kitchen gardens cultivated by the spade 50,000
Pleasure-grounds, the drested and unprofitable parts only; the rest being either pastured by cattle, or mown for hay; plantations, belts, and clumps 35,000
Land depastured by cattle; lays of more than one year; meadow of natural grasses, meadow of fawn grasses, and water-meadow and orchards on grafsland, which includes the cider counties * 20,000,000

This quantity of grafs-land, it is said, includes parks, paddocks, and pleasure-grounds, whether mown for hay, or grazed by cattle.

Carry forward 35,120,000

* This estimate would seem to be a good deal too high, as perhaps one-third or fourth, or more.

| Acre. | £
|-------|-------
| 35,120,000 | 1,980,000 |
| 2,000,000 | 39,100,000 |
| 1,980,000 | 7,816,000 |
| 46,916,000 | 22,121,000 |

which taken from 46,916,000 acres, the quantity of land in England and Wales, leaves 24,795,000, whereof the produce is consumed by human beings, in the proportion of 2½ acres each. By attending to the preceding part of this account, it will appear that it is divided in the following proportions; namely, for bread, half an acre; for liquids, one-eighth of an acre; for animal food, near two acres; and for roots, greens, and fruit, &c. one-eighth of an acre.

No peron will, it is supposed, expect any of these quantities to be mathematically true, or correct; particularly as we have no maps of England that can be depended on, for the purpose of ascertaining the quantity of land, not even, perhaps, nearer than eight in ten of the actual quantity. This fort of calculation is only meant to furnish the mind with some general ideas respecting England and Wales.

Animal Food.—There are, it is said, annually sold at Smithfield market, about 100,000 bullocks, and 700,000 sheep. There are many also sold at several of the towns and large villages near the metropolis, of which no account is taken, perhaps equal to the supply of Southwark, and all the places out of this county that lie within five or ten miles of town; consequently the inhabitants of this county consume nearly as much animal food as is sold at Smithfield.

For Middlesex, 100,000 beasts, at 100 ft. of 8 lbs. each, is—
700,000 sheep, at 10 ft. each, is—
Lams 24, calves 24, hogs and pigs 2, together—
Poultry, game, and fish, ¼ lbs.; dairy, ¼ lls;—

Total—

| Stone. | £
|-------|-------
| 10,000,000 | 4,350,000 |
| 7,000,000 | 2,100,000 |
| 7,000,000 | 330,000 |
| 1,100,000 | 6,680,000 |

which divided amongst 818,129 inhabitants, is 30 ft. 5 lbs. or 24½ lbs., which cost upwards of 8½. 5s. each person.

For England and Wales 1,000,000 bullocks, at 90 ft. each, is—
9,000,000 sheep, at 9 ft. each—
Lams 8, calves 8, swine, fish, poultry, game and dairy, 24; together—

Total—

| Stone. | £
|-------|-------
| 90,000,000 | 81,000,000 |
| 40,000,000 | 211,000,000 |

which, at 4½. 6d. a stone (offal included in the price, but not in the weight), amounts to 47,145,000ls. sterling per annum; which being divided among 9,000,000 of inhabitants, is 23 ft. 3½ lbs. or 187½ lbs.; and being priced in the same manner, amounts to 5½. 5s. 5d. per head, the meat nearly to 3 lb. 10 oz. per week for each person.

Wool and Mutton.—It is stated that it was given in evidence, on passing the last wool bill, that the clip of England and Wales amounted annually to about 600,000 packs, of 240 lbs. each, or 144,000,000 lbs., which fell at 10d. per pound, and produce 6,000,000l. sterling. That the mills and machinery employed in the woollen manufactory are supposed to have cost 6,000,000l. sterling, and the manufactured goods produced from the wool are said to be worth 18,000,000l. whereas are exported annually to the amount of 6,000,000l. The average yield of each sheep is taken to be a small fraction more than 4 lbs., by which divide the whole quantity of wool, and it will be seen that we have of stock sheep 35,000,000. It is apprehended that they consist nearly of

12,000,000 breeding ewes, which bring as many lambs. The former are killed off at an average of five years old, or annually—
25,000,000 other sheep, which are killed off at an average of three years, or annually—
35,000,000 Total number of sheep. Of which are killed annually—

Lams slaughtered—
Lams and sheep die in, from the rot, one in twenty-five of the last two numbers—
Yearly increase and decrease—

The mutton, taken at 9 ft. per sheep, and the lambs at 5 ft. gives 100,000,000 ft. as the yearly consumption.

Annual
SUPPLY.

Annual Produce of the Agricultural Capital of England and Wales.—This is stated as follows:

* It is noticed, that this part of the account might be varied, by stating the amount of animal food at 40,000,000. 

The wool, as | 6,000,000 |

The tallow, skin, bones, &c. | 10,000,000 |

Fed by horses, &c. | 5,000,000 |

The produce of animals | 61,000,000 which is the same amount as above.

It is noticed in conclusion on this, that if the manufacturing and commercial parts of Great Britain were to be tried by this rule, namely, of sharing less than one-fourth part of their real gains, as appears to be the case with the agricultural branch of the community, they could not exist an hour under what they would term such severe oppression.

But as the increase of the population of South Britain, since the above calculation was made, is supposed to be about one million, it will be necessary to add a tenth to the above number of acres, which will give the amount which is required for the supply and consumption of the present time, and makes the whole

And although the quantities of land which are taken up by each foot of crops; the number of horses and sheep which are made use of and kept, or the amount of animal food and other products of the land, and wool-bearing animals, with the whole of the agricultural produce, as above, of the other different parts of the kingdom, known under the names of Scotland and Ireland, cannot be well ascertained and calculated for want of sufficient grounds and data to proceed upon, (though they may probably approach those of the first part or division in some degree) yet the supply and consumption of their population may be thrown, when estimated on the same principles as the above, to require as below.

<table>
<thead>
<tr>
<th>Acres</th>
<th>£</th>
</tr>
</thead>
<tbody>
<tr>
<td>27,274,500</td>
<td>Brought forward 27,274,500</td>
</tr>
</tbody>
</table>

The former having, it is supposed, a population of 1,805,000, will, for its supply and support, stand in need of about the produce of | 4,975,000 |

The latter, as containing, it is believed, a population of about 5,500,000, will demand for their supply and consumption the produce of | 15,150,000 |

These two being added to the quantity requisite for the supply and consumption of the first part of the kingdom, will give the amount of the acres which are necessary for supplying the whole of the population of the united kingdom with this sort of produce, which are | 47,400,000 |

As, however, the supply and consumption in these last cases may be somewhat less abundant than in the other, the number of acres here stated may perhaps be rather too large.

The number of cultivated acres of land necessary for the supply, subsistence, and support of the population of the united kingdom being thus extensive, every endeavour should be made to keep up with it as much as possible, by the better and more perfect culture of those lands which are already in that state, and by promoting the enclosure and cultivation of those in the condition of waste, as by those and other suitable means, an almost unlimited increase of agricultural produce may be drawn from the earth, and the nation be ultimately rendered independent of foreign supply.

Supply.
SUPPLY'S Passage, in Geography, a channel of the South Pacific ocean, between Sirius island and Queen Charlotte's island, so named by Lieut. Ball, who commanded the Supply shore-ship, in 1792.

SUPPORTED, in Heraldry, a term applied to the uppermost quarter of a shield, when divided into several quarters; these seeming, as it were, supported or sustained by those below.

The chief is also said to be supported when it is of two colours, and the upper colour takes up two-thirds of it: in this case it is supported by the colour underneath.

SUPPORTERS, figures standing on the scroll, and placed by the side of the escutcheon, and seeming to support or hold up the same. SUPPORTERS are, chiefly, figures of beasts: figures of human creatures, used for the like purpose, are more properly called tenants.

Some make another difference between tenant and supporter: when the shield is borne by a single animal, it is called tenant; when by two, they are called supporters.

The figures of things inanimate, sometimes placed aside of escutcheons, but not touching or seeming to bear them, though sometimes called supporters, are more properly called colts.

Supporters have formerly been taken from such animals as are borne in the shields; and sometimes they have been chosen as bearing some allusion to the names of those whose arms they are made to support. F. Menefriar traces their origin to the ancient tournaments, in which the knights caused their shields to be carried by servants or pages under the disguise of lions, bears, griffins, blackamoors, who also held and guarded the escutcheons, which the knights were obliged to expose to public view some time before the lists were opened. But Sir G. Mackenzie says, that the first origin and use of them are derived from the custom of leading such as are invested with any great honour, to the prince who confers it, and of his being supported by two of the quality, when he receives the symbols of such honour: and in remembrance of that solemnity, his arms were afterwards supported by any two creatures which he chose.

The supporters of the English arms are a lion, and an unicorn; some of the former kings have had a leopard, and an unicorn; others, griffins; others, eagles. See Arms.

The supporters of the French arms are angels; which are said to have been first introduced by Philip VI., his device being an angel overthrowing a dragon, the dragon being, at that time, the device of the kings of England.

Those of the prince of Monaco are Augustine monks; those of the family of the Ursini, bears; in allusion to their names.

In England, supporters are the prerogative, first, of those called nobles majores, viz. dukes, marquises, earls, viscounts, and barons; secondly, of all knights of the garter, though they should be under the degree of barons; thirdly, of knights of the Bath, who both receive on their creation a grant of supporters: and lastly, of such knights as the king chooses to honor in this manner. Supporters are not hereditary, except to the elder branches of some knights of the garter, whose ancestors had this honour granted them; and to the eldest sons of peers above the degree of a baron, who bear their father's arms and supporters, with a label, &c. See Crown.

The Germans permit none but princes and noblemen of rank to bear them: among the French, the use of them is more prominent.

Supporters, in Ship-Building, are the knees placed under the catheads, for their security and support. They formerly partook of the curve of the middle rail of the head, but lately the arm at the side stands plumb, or perpendicular.

SUPPOSTITIOUS BIRTHS. See Bastards.

SUPPOSITORY, a preparation of salt, honey, &c. which is introduced into the rectum, in order to procure it. Medicinal compositions are also thus applied, with a view of driving out local diseases of the bowels.

SUPPRESSION, formed from sub and prono, I press under, in Law, the extinction or annihilation of an office, right, rent, or the like.

SUPPRESSION, in Grammar, denotes an omission of certain words in a sentence, which yet are necessary to a full and perfect construction. As, "I come from my father's;" that is, "from my father's house.

Suppression is a figure of speech very frequent in our language; chiefly used for brevity and elegance. Some rules relating to it are as follow:

1. Whenever a word comes to be repeated in a sentence oftener than once, it is to be suppressed. Thus we say, "This is my master's horse," not, "This horse is my master's horse."

2. Words that are necessarily implied may be suppressed.

And, 3. All words that use and custom suppress in other languages, are to be suppressed in English; unless there be particular reasons to the contrary.

SUPPRESSION, in Medicine, is applied to the humours that are retained in the body by some obstruction or stoppage of the usual outlet.

We
SUPP

We lay, a suppuration of urine, of the menesfs, &c. See ISCHURIA, URINE, MENSES, &c.

SUPPRESSION of Urine. There are commemorated in the Philosophical Transactions three cases of an actual and total suppuration of urine, supposing to proceed from a stone lodged in the neck of the bladder; but in all which, on introducing the catheter, it was found that there was no stone there, nor any urine in the bladder. In all these cases the same remedy was used; that is, a great quantity of acid diluted largely with water, and in conformance of this, the urinary secretion was immediately restored, and the patient soon voided it in a proper manner, and was restored to health without any further use of medicines. Philos. Trans. No 253.

A suppuration of urine sometimes happens to women with child, by the womb falling down, and preffing on the urethra.

It is also occasioned by an inflammation of the bladder, a swelling of the hemorrhoidal veins, hard lumps formed in the rectum, a stone in the bladder, excrescences in the urethra, pain from a pain of the bladder, hysterical affections, &c., of which cases requires a particular treatment. It may be observed, in general, that in all of them, mild and gentle applications are the safest; as strong diuretic medicines, or things of an irritating nature, generally increase the danger. See Retention of Urine.

SUPPRESSION, Fire of, in Chemistry. See FIRE.

SUPPURATION, in Surgery, denotes the processes by which purulent matter is formed in cases of abscesses, ulcers, wounds, &c.

When, notwithstanding the means usually employed for the relief of inflammation, this affection becomes attended with more severe pain, a much harder tumefaction, and a conical prominence in its centre, suppuration is likely to ensue. When the patient is seized with reiterated shiverings; when the fever, and all the symptoms of inflammation, suddenly cease, without any perceptible reason; when the patient experiences a heavy, cold, dull uneasiness, instead of acute pain in the part affected; when the most elevated part of the tumour appears soft and white, while the red has its redness increased; and when, at the same time, the face changes from a livid to a blood-red, the suppuration of a fluid; matter is undoubtedly already formed.

We shall not here dwell upon the symptoms which attend suppuration, as they are considered in other surgical articles of this dictionary. See Abscesses, &c.

With respect to the theory of suppuration, it may be observed, that the exposure of the internal surfaces and structure of the body, continued for a certain time, necessarily occasions suppuration. Here the influence of the air is not the cause; for, were a wound to be made into a cavity naturally closed, pus would be formed after a certain time, even in a vacuum. When matter forms in circumcised cavities, without a wound, the air cannot be supposed as a cause; nor does the air, in emphysematous cavities, excite suppuration. The sympathetic fever, attendant on inflammation, has been considered an essential step to suppuration; but with little foundation. Is there not a regular secretion of pus from the most indolent ulcers? Is there not the same process on every blistered surface? In such cases, is there not oftentimes a total absence of fever? That dead animal matter cannot be converted into pus, is proved by the roughness of the cellular membrane, tendons, fasciae, &c. remaining unchanged a considerable time in abscesses, and by dead bone lying unaltered in pus for many months. Whatever diminution of these substances may happen under such circumstances, occurs only on that side which is next to the living solids; and it can be satisfactorily accounted for on the principle of absorption.

The idea, that fermentation contributes to the formation of pus, is quite defective of foundation. The discharge of pus from secreting surfaces, without any loss of substance; the stationary state of many abscesses; the backwardness of matter to become putrid, while unexposed to the air; sufficiently evince that no fermenting power is present.

The opinion, that extravasated blood may in time change into pus, is equally erroneous. When suppuration is about to take place in the cellular substance, or membranes of circumcised cavities, the vessels alter their mode of action, so as to make pus. The change happens gradually. Hence, pus and coagulating lymph are often found blended together in the same abscess.

The fact, that pus may be formed without a breach in the folds, or dilatation of parts, was first noticed by the celebrated Dr. William Hunter, in the year 1749 or 1750. The example of the breast of a fatted duck, who died of empyema. M. Quefniy has also alluded to, in the Memoirs of the French Academy of Surgery, which fell under the observation of M. Peyronie, in which there was a very copious suppuration of the brain. The patient died, and the head was examined. The propensities of brain wanting was so trivial, compared with the quantity of pus which had been produced, that Peyronie justly concluded, that the matter had not been formed from the blood, but from the fluids of the part. See Remarques sur la Plaisir du Cerveau, tom. ii. p. 165, edit. in 1808.

The modern doctrine of suppuration is, that the pus is separated from the blood by the inexplicable operation of the secreting arteries, just as ordinary secretion takes place; and that the peculiar mode of action in the arteries is the reason why pus should be separated from the circulation, rather than coagulating lymph, mucus, &c. It is further believed, that the fluids never suffer any dilatation, so as to enter into the composition of pus; but that the deficiency, frequently apparent in them, arises from absorption. The arteries, in producing pus, a fluid diffuse from blood, and of which the diffusible fluids of the blood, are looked upon, considered as a new combination, seem to assume all the power of glandular secretion. Cooper's First Lines of Surgery, chap. p. 53 edit.

SUPPURATIVES, or SUPPURATING Medicines, are ripeners, or medicines that promote suppuration.

Suppuratives are all hot; by which means, increasing the warmth of the part, they resolve the humour into a pus. Such are mallows, meillot, lily-roots, diaphyson, pelargon, figs, aromatic gums, meals, &c.

SUPPUTATION. See COMPUTATION.

SUPRA, in Myth. See EPI and HYPER.

SUPRACOSTALES, in Anatomy, the levatores costarum muscles. See INTERCOSTAL Muscles.

SUPRACOMPOSITE, in Botany and Vegetable Phystiology, is a term applied to a leaf, or a panicle, which is more than twice compound or subdivided. See Leaf, Inflorescence, and Panicula.

SUPRALAPSARIANS, in theology, persons who hold that God, without any regard to the good or evil works of men, has resolved, by an eternal decree, fut faciam, antecedently to any knowledge of the fall of Adam, and independently of it, to save some; and does others; or, in other words, that God intended to glorify his justice in the condemnation of some, as well as his mercy in the salvation.
Supremacy, in the *English Policy*, the superiority of the king over the Church of England, as well as of the state of England, of which he is established head. See *King*.

The king’s supremacy was first established by the Church, or, as others say, recovered, by king Henry VIII. in 1534, after breaking with the pope. *Stat. 24 Hen. VIII. c. 12. 25 Hen. VIII. c. 21. 26 Hen. VIII. c. 1. 35 Hen. VIII. c. 3. 1 Ed. VI. c. 12. 1 Eliz. c. 1. It is since confirmed by several canons, as well as by the articles of the church of England; and is passed into an oath, which is required as a necessary qualification for all offices and employments, both in church and state; from persons to be ordained, from the members of both houses of parliament, &c. See *Oath and Coronation Oath*.

The oath was finally established by 1 W. c. 8. as Vol. XXXIV.
plain, before Alexander joined it to the shore by a mole, very manifest, since it is plain that the sea, by covering this mole while land, has enlarged it by successive accumulations, and formed the present isthmus. The village of Sour is situated at the junction of this isthmus with the ancient island, of which it does not cover above one-third. The point to the north is occupied by a bafoon, which was a port evidently formed by art, but is at present so chocked up that children pass it without being wet above the middle. The opening at the point is defended by two towers, opposite each other, between which formerly passed a chain fifty or sixty feet long, to shut the harbour. From these towers began the walls, which, after surrounding the bay enclosed the whole island: but at present we can only follow their traces by the foundations which run along the shore, except in the vicinity of the port, where the Motouallis made some repairs twenty years ago, but these are again fallen to decay.

Further on in the sea, to the north-west of the point, at the distance of about three hundred paces, is a ridge of rocks, which rise to the surface of the water. The space which separates them from the main land in front, forms a fort of road, where vessels may anchor with much safety than elsewhere; but a free from danger, for they are exposed to the north-west winds, and the bottom injures the cables. That part of the island which lies between the village and the sea, that is, the western side, is open; and this ground the inhabitants have laid out in gardens: but such is their sloth, that they contain far more weeds than useful plants. The southern side is rocky, and more covered with rubbish. The whole island contains only fifty or sixty poor families, which live but indifferently on the produce of their little grounds, and a trifling fisheries. The houses they own are no longer, as in the time of Strabo, edifices of three or four stories high, but wretched huts, ready to crumble to pieces. Formerly they were defended towards the land, but the Motouallis, who possessed themselves of this place in 1766, enclosed it with a wall of twenty feet height, which still subsists. The most remarkable building is a ruin at the south-east corner. This was a Christian church, built probably by the Crusaders; a part of the choir only is remaining: close to which, amid heaps of stones, lie two beautiful columns, which were found by a kind of chance in ruins, and Djezzar, who has stripped all this country to ornament his mosque at Acre, wished to carry them away, but his engineers were not able even to move them.

Leaving the village, on the side of the isthmus, at a hundred paces from the gate, we come to a ruined tower, in which is a well, where the women go to fetch water. This well is fifteen or sixteen feet deep; but the depth of the water is not more than two or three feet. Better water is not to be found upon the coast. From some unknown cause, it becomes troubled in September, and continues some days full of a reddish clay. This seasoan is observed as a kind of festival by the inhabitants, who then come in crowds to the well, and pour into it a bucket of sea-water, which, according to them, has the virtue of restoring the clearness of the spring. As we proceed along the isthmus, towards the continent, we perceive, at equal distances, the ruins of arcades, which lead in a right line to an eminence, the only one in the plain. This hill is not fictitious, like those of the desert, but a natural rock of about one hundred and fifty feet in circumference, by forty or fifty high; nothing is to be discovered above but ruins, and the tomb of a sultan or sultaness, remarkable for the white dome at the top. The distance of this rock from Sour is about a quarter of an hour's walk. As we approach it, the arcades become more numerous, and are not so high; they terminate by a considerable bend, and, at the foot of the rock, form suddenly a right angle to the plain, and proceed obliquely towards the sea: we may follow their direction for above an hour's walk at a horse's pace, till at length, we distinctly perceive, by the channel on the arched, that this is no other than an aqueduct. This channel is three feet wide, by two and a half deep; and is formed of cement harder than the stones themselves. At last we arrive at the well where it terminates, or rather from which it begins. This is what some travellers have called the well of Solomon, but, among the inhabitants of the country, it is known only by the name of Ras-el-Gen, or head of the spring. They reckon one principal, two lesser, and several small ones; the whole forming a piece of masonry which is neither of hewn nor rough stones, but of cement mixed with sea-pebbles. To the south, this stone-work rises about eighteen feet from the ground, and fifteen to the northward. On this side is a slope, wide and gradual enough to permit carts to ascend to the top, at which when we arrive we discover what is very surprising: for, instead of finding the water low, or no higher than the ground level, it reaches to the top; that is, to a height of more than thirty feet higher than the ground. Beyond this, the water is not calm, but bubbles up with violence, and rushes through channels contrived at the surface of the well. It is abundant as to drive three mills which are near it, and form a little rivulet before it reaches the sea, which is only four hundred paces distant. The mouth of the principal well is an octagon, each side of which is twenty-three feet three inches, the diameter, therefore, must be sixty-one feet. It has been said that this well has no bottom; but La Roche affirms that he found it at six and thirty fathoms. It is remarkable, that the motion of the water at the surface has corroded the interior lining of the well, so that its edge refts almost upon nothing, and forms a half arch, suspended over the water; among the channels which branch out from it, is a principal one, which joins that of the arches above-mentioned: by means of these arches, the water was formerly conveyed to the rock, and from the rock, by the isthmus, to the tower, whence the water was drawn. The adjacent country is a plain of about two leagues wide, far and nearly level; to the east it is crossed by a kind of marsh, which stretches from Kafmio to Cape Bianco. The soil is a black earth, on which a small quantity of corn and cotton are successfully cultivated.

Sour has now no other trade besides the exportation of a few sacks of corn and raw cotton, nor any merchant but a single Greek factor in the service of the French of Saide, who scarcely makes sufficient profit to maintain his family; 18 miles S.S.W. of Saide. N. lat. 35° 13'. E. long. 35° 13'. Volney's Travels in Egypt and Syria, vol. ii. For the history of ancient Tyre, see Tyre.

Sura. See Taor.

Sura, the name of a drink used in the East Indies, and made of the juice that flows from the cocoa-tree.

This juice being evaporated, and exposed to the sun, forms a sugar, but it is little esteemed.

Sura, in Anatomy, the calf of the leg.

Sura, in Geography, a town of Asia Minor, in the province of Dierbekir, on the Ephesates; 55 miles S. of Kaliahbe.—Alfo, a town of the Arabian Trak, on the Ephesates; 150 miles N. N.W. of Baffora. Alfo, a town of Ephesates, in Watermann, column 15; 15 miles N. of Stroemthas. Alfo, a river of Norway, in the province of Drombog, which runs into the North sea, opposite to Christianland.
SUR

—Alfoo, a river of Ruffia, which runs into the Volga, near Vefil, in the government of Ninigorod.

SURA, the name of a race of genii, or good angels, of whom mention is perpetually made in the mythological writings of the Hindoos. They are sometimes called Soor, or Soors, by European writers. Auroa, or Alfoo, is the name of a malevolent race, opposed to the Suras; the initial letter being changed in the Sanscrit tongue, and Sura meaning good. It seems to be a generic term, comprising several species of benevolent genii; such as Gandharvas, Kinnara, Dunhudi, Puhipha-vrihti, Sinara, Uparsa, &c, who appear to be celestial choristers, dancers, mountain nymphs, flower-flowers, nereids, &c. Among the Auras may be classed the Daitayas, (offspring of Diti and Kasyapa,) Raksha, Yaksha, Pitri, Danava, (offspring of Danu,) &c.

The Suras, it is suggested, are stars of the northern hemisphere, and the Auras of the southern. The Hindu writings abound in allusions to their state of continued warfare, and it seems probable, so prone are the Suras to physical as well as moral pertonification, that such fables are of an altronic nature, and relate to the rising and setting, and other phenomena, of stars in the two, or supposed light and dark, hemispheres.

Sura appears alfo to mean fermented liquors, or spirituous liquors, and Auroa such as reject them. This has not lutherho been explained. The first book of the Ramayana contains the well-known and popular allegory of chivalry in the ocean, so beautifully translated by Mr. Wilkins in that curious work the Bhagavat Gita. Among the precious things produced by this process was Sura, there said to be wine or Suraderi, goddess of wine. (See Suradevi.) Sura is likewise a name of Surya, the regent, or a personification of the sun. (See Surya.) Hence has arisen some apparent confusion in alluding to Sura the regency of both wine and wealth, and in regard to the latter, of intellectual wealth; for the Veda is represented to be the true wealth and wine of the devout. The word Sura, indeed, in Sanscrit, means both wine and wisdom, or intellectual wealth. The Veda abounds in praises of the sun, or as mystics say of the sun or soul, of the universe; or, in other words, of the Deity: but in these points we must refer to the articles Maya, Mystical Poetry, O'um, and Veda.

SURABHI, in Hindu Mythological Romances, is the name of an all-yielding cow, of whom many marvellous stories are related, and to which reference is frequently made in the writings and conviction of the Hindoos. Her origin is of course equally miraculous with her deeds. She is said to have arisen from the sea, when churned by the gods and demons, as related in our article Kurma-vatara; in which article reference is made to this, and in which a typographical error occurs, that we here take the opportunity of correcting. Speaking of Surabhi, for a "similarly beautiful," read "similarly bountiful." An instance of her bounty may be seen in our article Jamadagni. A Hindoo poet having occasion to mention the wealth or munificence of an individual of ancient days, is very likely to express this by saying, that "Indra had entrusted him with Surabhi, the cow yielding all that the heart can desire," as we find paid of the munificent prince Jamadagni. Indra, the regent of the firmament, is the supposed possessor of the boon-granting cow, and is hence, probably, called lord of wealth. See Indra.

Among a pastoral people, whose local food is of so much consequence, it is natural to expect that great regard will be paid to kine. A milch cow is in India an object of great importance and veneration. It is common for Brahman and others to feed a cow before they take their own breakfast, offering ejaculations of a pious and benevolent tendency.

The Hindoos hope to obtain the favour of the boon-granting cow, by shewing kindness to her offspring; and adoration of a cow is not uncommon, such as presenting flowers to her, washing her feet, &c. Travellers have noticed many instances of affectionate tenderness for cows and calves, on the parts especially of individuals of the feds of Brahmans and Bania. See Suṣra of Hindoos.

In marriage ceremonies, a cow, as a representative of Surabhi, the granter of desires, the emblem of fruitfulness, is one of the actors. The hospitable rites are concluded by letting loose a cow at the intersection of a gueft. A barber, who attends for that purpose, exclaims "The cow! the cow!" upon which the gueft pronounces this text: "Re- lease the cow from the fetters of Varuna. May the sabda my foe; may the deystray the enemies of both him (the host) and me. Dismise the cow, that the may eat grass and drink water." When the cow has been released, the gueft thus addresses her: "I have earnestly entreated this prudent perfon; saging, kill not the innocent harmless cow, who is mother of Rudras, daughter of Vafus, fifter of Adityas, the source of Urmita, or Ambrosia, &c." Mr. Cobilepko, in his "Eflay on the Religious Ceremonies of the Hindoos," A.R. Ref. vol. vii. remarks on the above passage, that "the guefts' intercession evidently imply a prayer, now become obsolete, of flaying a cow for the purposes of hospitality."

A cow, the reader will perceive, is no unimportant mythological personage; nor is the bull; the latter we have spoken of in another place, as the vehicle of the Hindoo god Siva, and the symbol of divine justice (See Siva.) These superstitions are not confined to India, though they probably originated there. Similar honours were paid to the symbollical bull by the Egyptians, as sufficiently noticed under our article Apis. In the Edda, too, some relations remind us of the Surabhi of the Brahmanas; for the northern nations strove a most proficuous cow, yielding rivers of milk from her teats, and legions of men from her body. See Edda.

The time is not, perhaps, very remote, when the original inhabitants of India had left abhorrence of killing kine than many sects now feel on that point. Ancient books profess the flaying of kine, as well as other animals. It must be allowed, however, that the very ancient code of laws called the Institutes of Menu, (See Menu,) lays down very severe penalties for flaying a cow, even without malice. These are in chap. xi. of that curious work, verfe 100 and following. The extreme utility of the cow and bullock in well-peopled and agricultural countries, will almost necessarily give rise to a repugnance at flaying them, which will, in no time, grow to stronger prohibitory feelings, and at length be flamed with the fanchion of holiness. Here we see, what we in many cases suppose, that mythology and religion inculcate principles grounded originally on the conveniences and wants of mankind. Of this, the reverence paid to the ichneumon hy the Egyptians is an example. (See Zeus.) And the sacredness of the falces, called by the English the Brahmany kites, in India, is another. See Superna.

SURACA, in Geography, a town of the island of Samos; 4 miles S.W. of Cora.

SURADEVI, in Hindu Mythology, is the name of the goddess of wine, or of strong drinks; but however often she may be sacrificed to, she is very rarely heard of, and her same rarely occurs in Hindu writings. Her origin...
from the sea, when churned by gods and demons to obtain certain precious articles, is noticed under our article Kurn-

mavatara. See also Sur.

SURADSJE, in Geography, a town of Arabia, in the
province of Yemen; 16 miles E.S.E. of Doran.

SURAES, or KURJAN SURAES, a name given in
Perfia to buildings constructed for the accommodation of
travellers. They are more commodious than the "choulties"
on the Coromandel coast, containing a variety of apartments.
They generally form a square, with a range of rooms on
each side, behind which are sometimes excellent stables.
It is customary for the muleteers to collect all the dirt which
has been made, and on his leaving the furnace, to set it on
fire, so that the stables are kept tolerably clean.

SURAJABAD, in Geography, a town of Bengal; 16
miles S. of Dacca.

SURAJEESIJUNN, a town of Hindooftan, in the cir
car of Elichpour; 12 miles W. of Elichpour.

SURAJPOUR, a town of Hindooftan, in Oude, on
the Gogra; 17 miles S. of Gooracour.-Allo, a town in
the circur of Schaurinpur; 25 miles S. of Merat.-Allo,
a town in Oude; 15 miles E. of Corah.-Allo, a town of
Oude, on the Ganges; 25 miles N.N.W. of Furruckabab.

SURAJPUTTY, a town of Hindooftan, in Bahar;
15 miles W. of Durbunngah.

SURAJGURAH, a town of Hindooftan, in Bahar;
15 miles S.W. of Mangbir.

SURALES MUSCULI, in Anatomy, the gastrocnemius
and soleus, which make up the chief bulk of the calf.

SURA, in Geography, a town of the principality of
Georgia, on the frontiers of Imiretta, anciently a city of
Colchis, and called Surium by Pliny; 50 miles W.N.W.
of Telif.

SURAMI, a town and fortress of Georgia, in the
province of Carduel; 24 miles W.S.W. of Gori.

SURAN, a town of Perfia, in the province of Khorasan;
45 miles N. of Maras.-Allo, a river of Perfia, which runs
into the Vatka; 32 miles N.E. of Slobozskoi, in the go-

derno of Viatka.-Allo, a town of Hungary, formerly
strong, but now defenced; 4 miles N.E. of Neuheuvel.

SURANUH, in Mythology, the wife of Surya, the
Hindoo Phoebus, a regent of the sun. She is fabled as
the daughter of Twiskha, the engineer of the gods, who is
found to correspond in many points with the Vulcan of the
Greeks. See Twashta, and Surya.

SURA, in Geography, a town of Austrian Poland; 15
miles N. of Lublin.

SURAT, a city of Hindooftan, in the province of
Gusserat, situated in a large and fertile plain on the left or
south bank of a considerable river, named "Tappi,"
which fee. It is encircled by two brick walls, that divide
it into the inner and outer town. The inner wall, which
is much decayed, is about two hours' walk in circumference,
and the outerwall, which is in tolerable good condition,
and which incloses both the inner town and the suburbs,
requires almost three hours to walk round it. The citadel
stands within the inner wall, on the inner side of the Tappi, and
is divided by trenches from the town. The outer wall is
within about twelve feet, and without more than twenty
feet high, and seven or eight feet in thicknees, and which,
at the height of eight feet, is reduced to about half its
thicknees, for the construction of a parapet to accommodate
those who defend the wall with small arms, the upper part
serving as a breast-work, and having loop-holes, through
which are fired the fuljets. It is, as Stavirinus says, almost
the only defence which the place possesses; the semi-circular
bastions butting out from the walls, and planted with a few
cannon, and the bulwarks, or foonces, projecting from the
wall, and placed at intervals round the town, at the distance
of five or six hundred feet from each, contribute little to the
security of the town; that, however, should be excepted
which is situated near the Naffry-gate, and which the
English have caused to be rebuilt in a stronger manner.
The inner town has twelve gates, two towards the river, and
ten towards the country; and opposite to these there is a
many in the outer wall. One of the gates, leading to the
river, and situated just below the castle, is called the
"Chiap-gate," because all the goods imported and ex-
ported must be carried through this gate, in order that the
custums may not be defrauded. Close to the inner wall are
several high and narrow spires, round which are balconies,
called by the Turks minarets, and serving for the purport
of calling the Mahometan to prayer. Although Surat has
been long under the dominion of the Mahometan Mogul,
it has no handsome mosque with towers, such as often occur
among the Turks and Arabians. The space included be-
tween the two walls has few houses, as it is chiefly covered by
gardens, which are extensive, by tracts of arable land, and
numerous lime and brick-kills. Few good houset are ten
either in the inner towns or the suburbs; but spite is
made of bamboo and plastered with mud, often occur.
If one division or ward, indeed, leading to the Delhi-gate, there
stands a building, which have a tolerably handsome
appearance. The larger houset are flat-roofed, and have
 courto before them; but the houset of the common people
are high-roofed. The squares of the city are spacious;
but the streets are, in general, unpaved, narrow, and ir-
regular, with projecting corners and shops. In dry weather
the dust of the unpaved streets is insufferable; and in the
rainy season they are very dirty, and much neglected
point of cleanliness by the native inhabitants, who throw
every kind of filth into the middle of the road, and fellon
or ever remove the accumulating dung-hills. Each street
has its own gates, which are shut up in times of turbulence;
and thefe, says Niebuhr, are as frequent here as at Cairo.
The principal edifice belonging to the city is the citadel or
castle, which was erected by the Mogul, on the corner of
Gusserat. It is a strong building, constructed of hewn
stone, and well provided with artillery. It has been
improved, with regard to strength and defence, by the English.
The court, or palace, where the nabob resides, is called the
"Durbar;" it lies to the S.W., about 200 paces from the
castle. The mint, where the silver which is imported is
 coined into rupees, is a large pile of buildings, surrounded
by a high wall. The lodges, or factories, of foreign nations,
especially the Portuguese, French, English, and Dutch,
are situated in the inner town; and each have what they call
a sharif in the suburb. Surat has two caravanseras, but it
had formerly a greater number, which were liberally sup-
ported. Its mosques scarcely deserve to be mentioned.
Its bazaars, or market-places, are numerous, and much
 frequented; and it has also a great number of retail shops.
The "Meidan," called the Cattle-gram, on account of the
proximity to the castle, is a large open plain. S. of the
castle, where both the Dutch and English companies have
large tents, or awnings, surrounded by palings of bamboo.
The bales of piece-goods are lodged here till they are
chipped and shipped off; and at a small distance is a
"latty," or warehouse, hastily constructed of wood, and
closet with mats of palm-leaves, in which private goods
were formerly houset.

At Surat provisions are plentiful and cheap; but though
it is built on the banks of a river, the inhabitants would
want water, that of the river before the town being al-

brackish,
brackish; if this inconvenience were not remedied by a number of deep wells, lined with brick, from which water is brought by oxen in leathern bags. Notwithstanding the warmth of the climate, the air of this city is wholesome. Fahrenheit’s thermometer has been observed at 98° in the month of March, while the wind blew from the N.; and at Bombay, 25° farther to the S., it snowed, in the month of May, at 93°.

The trade of Surat finds obstructions from the harbours, which lie too far out to enter, before the Tapshee is full of sand-banks. In the dry season the river is too low; and in that of the rains, it swells too suddenly, so as to overflow all the neighbourhood. If the river were confined by dikes, the stream, which, during the rains, often rises twenty-eight feet above its ordinary level, would carry away all the sand, and thus clearing the channel, would admit of the access of ships to the walls. But the despotic governments of Afla are impediments to all improvements for the general good.

General toleration and unqualified liberty are here granted to persons of all religious professions; and its inhabitants are accordingly very numerous. The Europeans residing here estimate the population of the city at a million of souls. Others have not allowed them to be much more than half this number; and Niebuhr is of opinion that this calculation exceeds the truth by two-thirds.

It is a curious circumstance, that though Surat furnishes no hospital for human beings, it has an extensive establishment of this nature for sick or maimed animals. When the Europeans turn out an old horse, or any other domestic animal, to perish as useless, the Indians voluntarily assume the care of it, and place it in this house, which is full of infirm, decrepit cows, sheep, rabbits, hens, pigeons, &c. Niebuhr says, that he saw there a blind and helpless tortoise, of a large size, which was reported to be 125 years old. The charitable Indians keep a physician on purpose for these animals. This hospital is said to contain 25 acres in extent; and its revenues amounted yearly to 6,000 rupees.

The country round Surat is very fertile, and so industrious are the inhabitants, that a piece of uncultivated ground is rarely to be seen any spot that does not yield some useful production. The soil is a reddish clay, and is seldom manured; except that they sometimes burn the dry stubble or refuse of the fields, the ashes of which serve, in some measure, to supply the wants of other manure. The cow and horse dung is either used for fuel, or for other purposes. The chief productions of the fields are wheat, nolis, or a grain serving the purpose of rice, and growing in bundles like maize; rice, allo a shrub, yielding a fruit from which is expressed an oil that is used for lamps, and the stalks of which, rolled in water, and separated into threads, serve for flax and hemp, and also tobacco. The chief article of trade which this country affords is cotton-cloth, and chiefly coarse and coloured cottons. No forests are met with in the vicinity of Surat; but besides the low and small underwood, there occasionally occur large shady trees, many of which are esteemed holy by the Goentoos, and under the shade of which they therefore build their pagodas or temples. Culinary vegetables are plentiful here. Beef is good and fat, and so are mutton and venison; but poultry are scarce. Butter and milk are good, and not very dear. Of wild animals, the tiger is, besides snakes, the only one to be feared. The houres swarm with bugs.

In surveying the vicinity of Surat, we must not omit the gardens, which are the property either of Europeans or of natives of the country. The finest of these is that belonging to the Dutch East India company, which presents a rich and charming aspect. The garden, formed by a late nabob, at the expense of 500,000 rupees, is very extensive; but laid out without much taste. Among the buildings of this garden is one of uncommonly large dimensions, having bath and fountains, and ornamented with Indian magnificence. The other buildings are harem for the nabob’s wives, entirely separate from each other, in each of which is one good apartment, the others being narrow chambers appropriated to the slaves. The passages from one suite of rooms to another, are so narrow, so winding, so blocked up by doors, as to afford a striking instance of the difficulty with which the unfortunate great in despotic countries regard all about them. The burial-places of the Dutch and of the Portuguese are situated in the suburbs. In the former, there is scarcely a tomb without lofty spires, and the meanest has a grave-flone with a sculptured epitaph. These burial-places are surrounded by a high wall, and covered, as Stavorinus estimates them, 100 roods of ground. The burying-place of the English is without the suburb walls. The principal inhabitants of Surat are Mahometans, and mostly strangers, although employed in the service of the government. They are as zealous in the observance of their law, as the Turks and Arabians. Although of the sect of the Sunnites, they tolerate the Shiites, and even permit them to celebrate the festival of Hassen. They make no scruple of drinking wine publicly, or of lending money upon interest. All people of distinction in Surat, and through the rest of India, speak and write the Persian language. Hence has this language been received at the courts, and the knowledge of it is very useful for the dispatch of business. In trade, corrupt Portuguese is the language used; and this is in India what the Lingua Franca is in the Levant. The Mussulmans of Surat bring about them many fakers of their own religion from the interior parts of the country. (See FAIR.) The Hindoos, the aboriginal inhabitants of the country, compose the most considerable part of the population of Surat. They are almost all of the cast of the Banians; and hence their skill and dexterity in matters of calculation and economy often raise them to places of considerable trust, in the collection of the taxes and customs for the Mahometans. These Banians, being born to trade, have engrossed the commerce of India to such a degree, that all foreign nations are obliged to employ them as brokers; in which employment they give better satisfaction than the Jews in Turkey. Europeans have never found reason to repent the entrusting even of their whole fortune to the Banians, who continue to give astonishing proofs of their probity and fidelity. Some of them are very rich, but all live in a style of moderate simplicity, wearing for drees only a plain robe of white cotton. At Surat are numbers of Percees, or Perians, who are skillful merchants, industrious artisans, and good servants. (See Parsees.) The same city are also Armenians, Georgians, and Jews, but not in considerable numbers. The Indian Catholics, commonly called Portuguese, from their speaking the Indian dialect of the Portuguese language, are numerous. The principal disorders to which the inhabitants are subject, are burning fevers, and the dysentery. Few of the natives of the country attain to any very advanced age. At Surat, the day is reckoned from funet to funet, and is divided, not into twenty-four hours, but into sixty gannes. Here are no clocks: the progress of the day is measured by different means. In a conspicuous situation, a man stands to put a cup of copper, pierced with a hole in the bottom, from time to time under water; every time the cup sinks, a garri is counted, and the man announces its lapse, by striking the number which it makes upon a plate of metal, that sounds like
SURAT.

like a clock. Each garri consists of 24 of our minutes.
In the bouses of the great too, where clocks and watches are not wanting, this old fashion of measuring time is still kept up.

The coins current at Surat are those of gold, silver, and copper. The gold coin of the country is the mahur (which see.) The silver rupee is the standard coin. (See Rupee.) The only copper coin is the pice (which see.) Almonds are also paid to pass for money at Surat, which are brought from Persia, and they are called "badams." The comparative value, at the lowest medium of exchange, is variable: sometimes 60p. bitter almonds have been the current rate of a pice. No other money is current here; all foreign coins being taken according to their weight and affray. The weights are very various here, and are regulated according to the nature of the commodities to be weighed. The maund is the general standard weight. (See Maund.) The yard, as a measure of length, is known to the natives by the same name as in England, and with them is one gia, and 8 teefoo, the gia being 24 teefoo: the standard gia of Surat is 1 1/4 Dutch ell. Distances are reckoned by cada (which see.) The carriages most common here, as well as in other parts of India, are the hackeries or kakkris, which are drawn by oxen, and run upon two wheels; the oxen being on particular occasions much ornamented. At Surat the citizens display their taste for magnificence to a great degree in their palanquins, which are a sort of couches upholstered from a bamboo, and borne by four men; one of these carriages, ornamented with silver, covered with rich stuffs, and upholstered upon a handiome bamboo, properly bent, will cost above 200l. sterling.

Surat, and the great distress of which it is the capital, belonged, for a long time, to the Great Mogul, who, to keep his distant province the more effectually in obedience, put it under the government of two nabobs, independent of one another. The one reigned in the city, and was properly the governor of the province; the other had the command of the citadel, and enjoyed the title of admiral, with a small revenue, appropriate to the maintenance of a small fleet, for the defence of the coast against pirates. After Shah Nadir's expedition into Hindoostan, the diffant nabobs of this vast empire aimed all at independence, and left the Mogul nothing but a shadow of authority; asking him only for form's sake to confirm, them in their places. Teg Beg Khan, nabob of Surat, a rich and powerful man, followed this example, and procured his brother to be declared nabob of the citadel. The two brothers then looked upon the whole province as their patrimony, and acquired immense wealth. Teg Beg Khan, dying in 1746, without children, left his fortune to his relations, by which several of them were railed to a condition which enabled them to aspire to the government of the city. His brother died in the following year; and his widow, a woman extremely rich and ambitious,rove to make her son-in-law nabob at once of the town and citadel. The contetl of the different competitors for the supreme authority produced a civil war in the town of Surat. Each of the rivals raised as many troops as he possibly could: with these he cantoned and entrenched himself in his houuse and gardens, and, from time to time, endeavoured to surprize or drive away his opponents. During these houfe operations, which were not attended with great slaughter, the inhabitants were content with fluctuating the gates nearest to the scene of action, and continued to go about their ordinary affairs without fear of being pillaged. Nay, they were sure of receiving compensation whenever any casual injury was done to any person, through means of the disturbances. Hence trade suffered no interruption. Some of the rival candidates impenetrably called in the Mahrrattas; and they, without doing anything for any party, made the victors pay for their alliance, although they had, apparently, favoured the vanquished. Since that time, the Mahrrattas have enjoyed a third part of the revenue amount of the customs of Surat; and one of the officers constantly attends to receive this tribute. The English and Dutch had always kept their factories in a state of defence, and on the occasion of the disturbances, they increased their military preparations. The nabobs of the country then had recourse to those powerful states. Each of the two European nations took part with one of the competitors, furnished him with ammunition, entrenched themselves in their factories, and fought against each other, although not openly at war. The nabob, protected by the English, was at last expelled from the city. But, in 1748, he returned, and his mother-in-law, the rich widow above-mentioned, made so good an ufe of her treasures, that the nabob, for whom he had been expelled, was obliged to ride to him the government of the city. When the English saw the city in the hands of their creature, they began to think seriously of gaining possession of the citadel. The court of Bombay, in 1759, sent Mr. Spencer, one of their members, a man of ability, and beloved by the Indians, to Surat, with a considerable force. The nabob opened the gates of the city to the English, and allowed them to lay siege to the citadel undisturbed. It was taken in a few days. To avoid giving offence to the Indians, the English declared, that they made the conquest in the name of the Great Mogul, and waved his flag from the walls of the citadel. This expedition thus accomplished, Mr. Spencer sent a long representation to the court of Delhi, in which he stated the reasons which had induced the merchants of Surat to put themselves under the protection of the English, and to expel the usurping nabob from the citadel. He added, that those petty tyrants had suffered the fleet necessary for the protection of trade to fall into a state of decay, so that none but the English could restore it. He offered, at the same time, that if the Mogul would grant to the Company the post of admiral, with the revenues annexed to it, they would maintain a fleet which should give full security to trade. These facts were attended, and the proposal seconded by the principal inhabitants of Surat, who signed the memorial. The Great Mogul, who in his state of weakness durst not send a governor to the province, but considered it as lost, readily granted the Company's request: and a member of the council of Bombay now discharged the office of nabob and admiral at Surat. Upon this title, the Company enjoy a third of the revenue from the customs of this city, with other funds of income still more considerable, which enables them to keep on foot a body of troops, with some ships of war. The English are the actual possessors of Surat. They keep the nabob of the city in a state of absolute dependence, allowing him only an income on which he may live suitable to his dignity. The Indians are in pet content with their new masters. The merchants are no longer in danger of the avaricious extortions of the nabobs, and they complain of the selfish spirit of their masters. The Indians dare not fail without a passport from the admiral. The great trade carried on at Surat renders this city the flor of the most productive of Hindoostan. Hither is brought from the interior parts of the empire an immense quantity of goods, which the merchants carry in their ships to the Arabia gulf, the Persian gulf, the coast of Malabar, the coast of Coromandel, and even to China. The provinces near this city are full of manufactures of all sorts. Ship-building is a branch of the business carried on here, for which
which they are furnished, at a low price, with the excellent timber called "teak." Of foreign nations, the Dutch have next after the English the most considerable establishment at Surat: they have here a director, several merchants, a number of writers and servants, and a few soldiers: their trade has, however, declined, till it has become trifling. The affairs of the French are in worse state. This nation is here in no estimation, but what is paid to their capuchin friars, who are generally beloved and respected at Surat. These good regular clergy have done essential service to the public, by keeping a register of all events that have happened in Hindostan, from 1676 to the present time. Such, nearly, is also the condition of the Portuguese in India. Although they were the first Europeans who established themselves here, they are, at present, the least in power and respect. In all appearance, the English must shortly engross the whole trade of this city. Being at once sovereigns and rich merchants, they have every means in their power, by which foreign nations can be excluded, or the Indians restrained from this source of opulence.

Surat, with respect to the English, is subordinate to the presidency of Bombay, which sends one of its members either, under the denomination of chief, who has a council, by which all matters occurring at his factory are settled, subjeet, however, to the approbation of the governor and council of Bombay; 112 miles S. of Amedabat. N. lat. 21° 10' 50" E. long. 73° 50'.

Surat Pengee, a narrow channel of the East Indian sea, between the north point of Sumatra, and a small island called Stony island. N. lat. 5° 32'.

Suraz, a town of Ruffia, in the government of Polotik; 80 miles E. of Polotik. N. lat. 55° 18'. E. long. 25° 34'.

Surazsk, a town of Ruffia, in the government of Novgorod Sieverkoi; 72 miles N.W. of Novgorod Sieverkoi. N. lat. 54°. E. long. 42° 22'.

Surb Grigor, a town of Turkmeh Armenia; 5 miles N.E. of Erzerum.

Surbach, a river of France, which runs into the Rhine, 5 miles below Fort Vauban.

Surbating, in Heaven, is a term used to signify when the soul is worn out, bruised, or spoiled by any accident, as by bad shoeing, especially when the shoes lie flat on the feet; or when the horse goes too long barefoot; as also by travelling on hard roads, or among dry, hot sand, in hot weather, which dries the hoof, whereby the sole becoming hard, presses upon the soft parts beneath it. If a horse be furiously or bad shoeing, the part that is affected may be known by the swells of the sole, where it presses most; and therefore it ought to be pared deeply in that part, before another is put on; but if the foot is not the fault, it may be known that he is furiously or by his continual hitching and moving; but by feeling his hoofs, you may observe them both very hot and dry. According to some the cure is very easy, before it becomes attended with other accidents, and may be performed only by Roping up the feet with cow's-dung and vinegar. Some use only hog's grease hot, thickened with bran; and others make use of vinegar and foot balm, together; but nothing will be more efficacious, in case it be troublesome, than first soothing the sole with the application of soothing things, and after that, pouring a mixture of warm pitch and tar upon the sole of the foot.

Surbilsah, in Geography, a town of Hindooftan, in the circar of Bilbah; 15 miles S.E. of Bilbah.

Surcharge, in the Forest, is when a commoner puts more beaks in the forest than he has a right to. See Forest.
SURD.

numbers, or in fractions, any exact root of such number proposed.

And as whenever this happens, it is usual, in mathematics, to mark the required root of such number or quantity, by prefixing before it the proper mark of radicality, which is \( \sqrt{} \), and placing above the radical sign the number that denominates what kind of root is required. Thus \( \sqrt{2} \) signifies the square root of 2, and \( \sqrt{16} \) signifies the cubic root of 16: which roots, because they are impossible to be expressed in numbers exactly (for no effable number, either integer or fraction, multiplied into itself, can ever produce 2; or, being multiplied cubically, can ever produce 16), are properly called surd roots.

There is also another way of notation, now much in use, by which roots are expressed without the radical signs, by their indices: thus, \( n, \sqrt{n}, \sqrt[n]{n} \), &c. signify the square, cube, and fifth power of \( x \); \( \sqrt{5}, x^\frac{1}{5}, x^\frac{1}{5} \), signify the square root, cube root, &c. of \( n \).

The reason of which is plain enough; for since \( \sqrt{x} \) is a geometrical mean proportional between 1 and \( n \), \( \sqrt[3]{n} \) is an arithmetical mean proportional between 0 and 1; and therefore \( \sqrt[5]{x} \) is the index of the square of \( \sqrt[5]{n} \), which is the proper index of its square root, &c.

Observe also, that, for convenience, or brevity's sake, quantities or numbers, which are not surds, are often expressed in the form of surd roots. Thus, \( \sqrt[4]{2}, \sqrt[4]{4}, \sqrt[4]{7} \), &c. signify \( 2, 4, 7 \), &c. But though these surd roots (when truly such) are inexpressible in numbers, they are yet capable of arithmetical operations (such as addition, subtraction, multiplication, division, &c.); how readily to perform which the algebraist ought not to be ignorant.

For the method of performing these operations, see the sequel of this article.

Surdts are either simple or compound.

Surdts, Simple, are those which are expressed by one single term, as \( \sqrt{c} \).

The surds \( \sqrt{2}, \sqrt{3}, \sqrt{5} \), &c. though they are themselves incommensurable with unit, according to the definition, are commensurable in power with it, because their powers are integers, i.e. multiples of unit. They may be also sometimes commensurable with one another; as the \( \sqrt{8} \) and the \( \sqrt{2} \), because they are to one another as 2 to 1. These incommensurables are called by some communicable: and when they have a common measure, as \( \sqrt{3} \) is the common measure of both, then their ratio is reduced to an expression in the least terms, by dividing them by their greatest common measure. This common measure is found as in commensurable quantities, only the root of the common measure is to be made their common divisor.

Thus, \( \sqrt[3]{8} = \sqrt[3]{2} = 2 \), and \( \sqrt[3]{18} \) = \( \sqrt[3]{2} \).

Surdts, Compound, are those formed by the addition or subtraction of simple surdts: as \( \sqrt{5} + \sqrt{2}, \sqrt{5} - \sqrt{2} \), or \( \sqrt{7} + \sqrt{2} \); which last is called an unscorable root, and signifies the cubic root of that number, which is the result of adding \( 7 \) to the square root of \( 2 \).

1. To reduce rational Quantities to the Form of any surd Roots assigned.—Involve the rational quantity according to the index of the power of the surd, and then prefix before it the radical sign of the surd proposed. Thus, \( a = \sqrt[n]{a^n} \).

\[ \sqrt{a^2} = \sqrt{a^2} = \sqrt{a}; \quad \text{and} \quad 4 = \sqrt{16} = \sqrt{64} = \sqrt{256} = \sqrt{4}. \]

And by this way may a simple furd fraction, whose radical sign refers only to one of its terms, be changed into another, which shall respect both numerator and denominator. Thus, \( \frac{\sqrt{a}}{5} \) is reduced to \( \frac{\sqrt{a}}{5} \), and \( \frac{\sqrt{a}}{25} \) to \( \frac{\sqrt{a}}{25} \):

\[ \frac{\sqrt{2}}{4} \]

also \( a \) reduced to the form of \( a^n \) is \( a^n \).

And roots with rational co-efficients may thus be reduced so as to be wholly affected by the radical sign. Thus, \( a \times \sqrt[3]{a} = a \sqrt[3]{a^2} \).

2. To reduce simple Surdts, having different rational Sps (which are called heterogeneous Surdts), to others that may have one common radical Sign, or which are homogeneous: or to reduce Roots of different Names into those of the fame Name.—Inolve the powers reciprocally according to each other’s indices, for new powers; and let the product of the indices be the common index. Otherwise, as surdts may be considered as powers with fractional exponents, reduce these fractional exponents to fractions having the same value, and a common denominator. Thus, by either rule, \( \sqrt[n]{a} \) or \( a^n \), and \( \sqrt[n]{n} \) or \( n^n \), will be \( \sqrt[n]{n} \) or \( n^n \), and \( \sqrt[n]{n} \) or \( n^n \), and \( \sqrt[n]{n} \) or \( n^n \).

Also \( \sqrt[3]{3} \) and \( \sqrt[2]{2} \) are reduced to other equal surds \( \sqrt[27]{27} \) and \( \sqrt[4]{4} \) having a common radical sign.

3. To reduce Surdts to their most simple Expressions, or to its lowest Terms possible.—Divide the furd by the greatest power denoted by the index, which you can discover, and multiply it, and will make it without any remainder; and then prefix the root of that power before the quotient or furd is divided; this will produce a new surd of the fame value with the former, but in more simple terms. Thus, \( \sqrt[16]{4} \) by dividing by 16 \( 4 \), and prefixing the root \( 4 \), will be reduced to this, \( 4 \sqrt[4]{4} \), and \( \sqrt[12]{4} \) will be deprefred to \( \sqrt[2]{3} \).

Also \( \sqrt[3]{b} \) will be brought down to \( b \sqrt[3]{c} \).

To reduce \( a^n \) to its lowest term: suppose \( n \) the greatest power, that will divide \( a \) without a remainder; and let \( y = \frac{a}{n} \) then will \( a \) \[ a = n \times y \]; for \( a = x \).

therefore \( a = \left( n \times y \right) = n \times y \), \[ a \times y \]

Also \( \sqrt[75]{75} \) or \( \sqrt[75]{5} \) = \( 5 \times 3 \), or \( 5 \times 3 \) and \( \sqrt[81]{81} \) = \( 27 \times 3 \), or \( 27 \times 3 \) = \( 3 \times 3 \).

This reduction is of great use, whenever it can be performed; but if no such square, cube, biquadrate, &c. can be found for a divisor, find out all the divisors of the power of the furd proposed; and then see whether any of them is a square, cube, &c. or such a power as the radical sign denotes; and if any furd can be found, let that be used in the fame manner as above, to free the furd quantity in part from the radical sign. Thus if \( \sqrt{288} \) be propred, among its divisors will be found the squares, 4, 9, 16, 36, and 144: by which, if 288 be divided, there will result the quotients 72, 32, 16, 9, and 2; wherefore, instead of \( \sqrt[288]{288} \).
Surd.

\[ \sqrt[n]{288} \text{ you may put } 2 \sqrt[3]{72}, \text{ or } 3 \sqrt[3]{32}, \text{ or } 4 \sqrt[6]{18} \text{ or } 6 \sqrt[6]{8}, \text{ or, lastly, } 12 \sqrt[3]{2}; \text{ and the same may be done in species.} \]

By the two last problems we may determine, whether any two roots are commensurable one to another; and also find their ratio. For after reduction into the lowest terms, and the same name, if the powers are equal, the roots are commensurable, and their ratio is equal to that of the rational co-efficients. Thus, \( \sqrt[3]{75} \) and \( \sqrt[3]{27} \) reduced, will be \( 5 \sqrt[3]{3}, \) and \( 3 \sqrt[3]{3}, \) which are commensurable; and \( 5 \sqrt[3]{3} : 3 \sqrt[3]{3} :: 5 : 3. \)

4. To add and subtract Surds. — When they are reduced to their lowest terms, if they have the same irrational part, add or subtract their rational co-efficients, and prefix the sum or difference to the common irrational part. Thus,

\[ \sqrt[3]{75} + \sqrt[3]{48} = 5 \sqrt[3]{3} + 4 \sqrt[3]{3} = 9 \sqrt[3]{3}; \] \[ \sqrt[3]{a^2} + \sqrt[3]{b^2} = a + b \text{ and } \sqrt[3]{a^2} - b = a \sqrt[3]{a} - b \sqrt[3]{a}. \]

And \( \sqrt{150} - \sqrt{34} = 5 \sqrt{6} - 3 \sqrt{6} = 2 \sqrt{6}. \) If they have not the same irrational part, they can only be connected by the sign + or −.

Hence it appears, that the sum or difference of any two square roots is equal to the square root of the sum or difference of the sum of the powers, and twice the product of their roots.

E.g., \( \sqrt[3]{75} + \sqrt[3]{48} = \sqrt[3]{75 + 48} + \sqrt[3]{2 \times 5 \times 3} = \sqrt[3]{123} = 9 \sqrt[3]{3}. \)

For if \( \sqrt[3]{a^2} \) and \( \sqrt[3]{e^2} \) be any given quantities, it is plain that \( a \sqrt[3]{a} \pm e \sqrt[3]{e} = a \pm e = \sqrt[3]{a^2} + 2 ae + 2 \sqrt[3]{a}. \)

5. To multiply and divide Surds. — If they have the same rational quantity, they are multiplied by adding their indices, and divided by subtracting them. Thus, \( \sqrt[3]{a} \times \sqrt[3]{a} = a^{\frac{3}{6}} = a^{\frac{1}{2}} = \sqrt[3]{a}. \) and

\[ \sqrt[3]{2} \times \sqrt[3]{2} = \sqrt[3]{2^2} = \sqrt[3]{3}. \] \[ \text{Also, } \frac{\sqrt[3]{a}}{\sqrt[3]{a}} = a^{\frac{3}{6}} = a^{\frac{1}{2}} = \sqrt[3]{a}. \]

If they have different rational quantities, and the same sign, multiply these rational quantities into one another, or divide them by one another, and let the common radical sign over their product: thus, \( \sqrt[3]{a^2} \times \sqrt[3]{b^3} = \sqrt[3]{a^2 b^3} \) and \( \sqrt[3]{a^2} \div \sqrt[3]{b^3} = a^{\frac{1}{2}} \div b^{\frac{1}{3}} \) and \( \sqrt[3]{a^2} \div \sqrt[3]{b^3} = \sqrt[3]{a^{\frac{1}{2}} b^{\frac{1}{3}}}. \) \[ \text{and } \sqrt[3]{5} \div \sqrt[3]{3} = \sqrt[3]{5 \div 3} \] \[ = \frac{\sqrt[3]{5}}{\sqrt[3]{3}}. \]

If the Surds have not the same radical sign, reduce them (by prob. 2.) to such as shall have the same radical sign, and proceed as before. Thus, \( \sqrt[3]{a} \times \sqrt[3]{b} = \sqrt[3]{a b}; \) and \( \sqrt[3]{2} \times \sqrt[3]{4} = 2 \sqrt[3]{2} \times 4 = 2 \sqrt[3]{2^3}. \) \[ 4 \div 2 = \sqrt[3]{2^2} \div \sqrt[3]{2} = \sqrt[3]{2}. \] \[ 4 \div 2 = \sqrt[3]{2}. \] \[ \text{If the Surds have any rational co-efficients, their product or quotient must be prefixed.} \]

Thus, \( 2 \sqrt[3]{3} \times 5 \sqrt[3]{6} = 10 \sqrt[3]{18} \) and \( \frac{8 \sqrt[3]{5}}{2 \sqrt[3]{6}} = \) \[ \frac{\sqrt[3]{5}}{3}. \]

6. Evolution and Evolution of Surds.—The powers of Surds are found by multiplying their indices by the index of the power required. Thus, the square of \( \sqrt[3]{2} \) is \( \sqrt[3]{2^2} = 2 \sqrt[3]{2} \) and \( \sqrt[3]{2} \) of \( \sqrt[3]{3} \) is \( \sqrt[3]{3^2} = 3 \sqrt[3]{3}. \) \[ \text{And } \sqrt[3]{3} \div \sqrt[3]{3} = \sqrt[3]{3 \div 3} = \sqrt[3]{1} = 1. \]

Evolution is performed by dividing the fraction which is the index of the Surd, by the name of the root required. Thus, the square root of \( \sqrt[3]{a^2} \) is \( \sqrt[3]{a^2} \) or \( \sqrt[3]{a^3}. \)

Simple Surds are commensurable in power, and by being multiplied into themselves, give, at length, rational quantities. But compound Surds, multiplied into themselves, commonly give irrational products. Yet, in this case, when any compound Surd is proposed, there is another compound Surd, which, multiplied into it, gives a rational product. Thus, \( \sqrt[3]{a^2 + \sqrt[3]{a^3}} \) or \( \sqrt[3]{a^2 + \sqrt[3]{b^3}} \) or \( \sqrt[3]{a^2} \) of \( \sqrt[3]{b^3} \), the product will be \( a - b. \)

The investigation of that Surd, which multiplied into the proposed Surd, gives a rational product, is made easy by three theorems, delivered by Mr. Maclaurin, in his Algebra, p. 109, eq. to which we refer the curious. This operation is of use in reducing Surd expressions to more simple forms. Thus: suppose a binomial Surd divided by another, as \( a \sqrt[3]{20} \div a \sqrt[3]{12} \) by \( b \sqrt[3]{5} \div b \sqrt[3]{3} \) the quotient might be expressed by \( \frac{2 \sqrt[3]{20} + 2 \sqrt[3]{12}}{2 \sqrt[3]{5} - 2 \sqrt[3]{3}} \). But this might be expressed in a more simple form, by multiplying both numerator and denominator by that Surd, which multiplied into the denominator, gives a rational product: thus, \( \sqrt[3]{20} + \sqrt[3]{12} \div \sqrt[3]{5} = \sqrt[3]{20} + \sqrt[3]{12} \div \sqrt[3]{5} = \sqrt[3]{20} + \sqrt[3]{12} \div \sqrt[3]{5} = \sqrt[3]{20} \div \sqrt[3]{5} + \sqrt[3]{12} \div \sqrt[3]{5} = \sqrt[3]{100} + \sqrt[3]{60} + \sqrt[3]{60} = 8 + 2 \sqrt[3]{15}. \)

To do this generally, see Maclaurin, lib. cit. p. 115.

When the square root of a Surd is required, it may be found,
found, nearly, by extracting the root of a rational quantity that approximates to its value. Thus, to find the square root of $3 + 2\sqrt{2}$, first calculate $\sqrt{2} = 1.41421$. Hence, $3 + 2\sqrt{2} = 5.82842$, the root of which is found to be nearly $2.41421$.

In like manner we may proceed with any other proposed root. And if the index of the root, proposed to be extracted, be great, a table of logarithms may be used.

Thus, $\sqrt[5]{5 + \sqrt{17}}$ may be most conveniently found by logarithms.

Take the logarithm of 17, divide it by 13; find the number corresponding to the quotient; add this number to 5; find the logarithm of the sum, and divide it by 7, and the number corresponding to this quotient will be nearly equal to $\sqrt[5]{5 + \sqrt{17}}$.

But it is sometimes requisite to express the roots of surds exactly by other surds. Thus, in the first example, the square root of $3 + 2\sqrt{2}$ is $1 + \sqrt{2}$.

For the method of performing this, the curious may consult Mr. Maclaurin's Algebra, p. 115, seq. where also rules for trinomials, &c. may be found.

For extracting the higher roots of a binomial, whose two members are squares or commensurable numbers, we have a rule in Sir Isaac Newton's Arithmetica Universalis, p. 59, but without demonstration. This is supplied by Mr. Maclaurin, in his Algebra, p. 120, seq. as also by S. Graveland, in his Matheseos Universalis Element. p. 211, seq.

It sometimes happens, in the resolution of cubic equations, that binomials of this form $a + b\sqrt{-9}$ occur, the cube roots of which must be found. To these Sir Isaac's rule cannot always be applied, because of the imaginary, or impossible factor $\sqrt{-9}$; yet if the root be expressible in rational numbers, the rule will often lead to it in a short way, not merely tentative, the trials being confined to known limits. See Maclaur. loc. cit. p. 127, seq.

It may be further observed, that such roots, whether expressible in rational numbers, or not, may be found by evolving the binomial $a + b\sqrt{-9}$, by the Newtonian theorem, and summing up the alternate terms. Maclaur. loc. cit. p. 150.

Those who are desirous of a general and elegant solution of the problem, to extract any root of an impossible binomial $a + \sqrt{-b}$, or of a possible binomial $a + \sqrt{b}$, may have recourse to M. de Moivre's Letter to Dr. Saunderson, inferred by way of Appendix to his Algebra, and to the Philosophical Transactions, No. 455; or to Dr. Marty's Abridgment, vol. viii. p. 1, seq. See also on the management of surds, Kerley's Algebra. Ward's Mathem. part ii. cap. 4. Jones's Synopsis. Palm. Math. part i. &c. 3. cap. 6. Saunderson's Algebra, vol. ii. Bonnycastle's Algebra, &c. &c.

SURDS, Commensurable. See Commensurable.

SURDS, Heterogeneous. See Heterogeneous.

SURDS, Homogeneous. See Homogeneous.

SURDAH, in Geography, a town of Hindoostan, in Bengal; 15 miles S.W. of Natore.—Allo, a town of Hindoostan, in the cirec of Ruttunpour; 18 miles N.E. of Dundah.—Allo, a town of Bengal; 10 miles S.E. of Baulacah.

SURDE, or SURDY (Sourê). See Schech Souré.

This island, situated in the Red sea, nearly east of Nobhure (Faloor), appears at first sight like a two-masted vessel. It is not far from Sheikh Shaib, called by d'Anville Bafheeb, which is one of the largest islands in the gulf, and inhabited.

SURDESOLID. See Surdesolid.

SUREAU, in Geography, a river of Louisiana, which runs into the Missour, N. lat. 38° 54', W. long. 92° 47'.

SUREN, a river of Switzerland, which runs from the lake of Sempach into the Aar, 2 miles N.E. of Arau.

SURENHSUS, WILLIAM, in Biography, a celebrated Hebrew scholar in the university of Amsterdam, well known for his edition of the Mishcach, with notes and a Latin version, which he began to publish in 1698, and completed in 1703, in 3 vols. fol. It contains also the commentaries of the rabbins, Maimonides and Barthenofa.

SURETY, in Law, a bail that undertakes for another man in a criminal case, or action of trespass, &c. See Fire-Juffer.

SURETY of the Peace, an act by which a person in danger of hurt from another, is forsworn by a bond, or recognizance acknowledged by the other to the king, and bound with him, for keeping the peace. See Securitas Pactic.

This security a justice of the peace may command, either as a minister, when commanded thereto by higher authority; or, as a judge, when he doth it of his own power, derived from his commission.

It differs from jury of good abearing, in that whereas the peace is not broken without an affray, or such like: the jury de bono gesta may be broken by the number of 10 men, or by his or their weapon, or harm.

See Peace, and Good Abearing.

SURF, in Agriculture, a term sometimes, in draining, applied to a fough, which is the conduit or bottom part of a drain, when formed with brick or stones. See Drainage.

SURF of the Sea, the swell of the sea, which breaks upon the shore, or any rock lying near the surface of the sea; and which renders such places dangerous.

The surf forms sometimes but a single range along the shore; at other times there is a succession of two, three, four, or more, behind each other, extending perhaps half a mile out to sea; the number of ranges being generally a proportion to the height and violence of the surf. The force of the surf is very great. In some places the surfs are usually greater at high, and in others at low water; but they are said to be uniformly more violent during the spring-tides. Mr. Mardin, in his History of Sumatra, has made some ingenious observations on the cause of surf in general, and particularly on the phenomena of the same which occur on the coast of that island.

When a wave is at its height, it defends the force of gravity, and the momentum acquired in defeding impels the neighbouring particles, which, in their turn, rise and impel others, and thus form a furzification of wave. This is the case in the open sea; but when the swell approaches the shore, and the depth of water is not in proportion to the size of the swell, the furzification waves, instead of preying on a body of water, which might rise in equal quantity, preys on the ground, whose reaction causes it to rush on in the manner which we call a surf. Some have stated, that in forming a surf, the body of water has no actual progressive motion.
Mr. Marsten denies this fact, and says, that the only real progression of the water is occasioned by the perpendicular fall, after the breaking of the surf: when, from its weight, it flows on to a greater or less distance, in proportion to the height from which it fell, and the slope of the shore. That the surfs are not, like common waves, the immediate effect of the wind, is evident from this circumstance, that the highest and moft violent often happen when there is the least wind, and vice versa; and sometimes the surfs will continue with an equal degree of violence during a variety of weather. On the west coast of Sumatra, the highest surfs are experienced during the south-east monfoon, which is never attended with such gales of wind as the north-west. The motion of the surf is not observed to follow the course of the wind, but often the contrary; and when it blows hard from the land, the spray of the sea may be seen to fly in a direction opposite to the body of it, though the wind has been for many hours in the same point. The surfs do general in the tropical latitudes are, as our author apprehends, the consequence of the trade or perpetual winds which prevail, at a distance from shore, between the parallels of 30° N. and S., whose influence on the ocean causes a long and constant swell, which exists even in the calmest weather, about the line, towards which its direction tends from either side. This swell, when a squall happens, or the wind freshens up, will, for the time, have other subsidiary waves on the extent of its surface, breaking often in a direction contrary to it, and which will again subside as a calm returns, without having produced on it any perceptible effect. For further observations on this subject, we refer to Mr. Marsten's Hist. of Sumatra, p. 52, &c.

**SURFACE.** In Geometry, see SUPERFICE.

**Surface,** in Ornamental Gardening, that part of natural, easy, agreeable, and tasteful connection of the different parts of the surface of ornamented grounds, which constitutes and affords beauty, variety, and ornamental effect in them. It has been observed by Mr. Loudon, in his work on forming, improving, and managing country residences, that connection is essentially requisite to the formation of character in such situations; and that nothing in ground is so disagreeable as its interruption, and the want of suitable, neat, natural connection in its several superficial parts. It is well and truly said, that the most beautiful mound formally placed upon a level, or the most elegant sweep, amid abruptness and irregularities, will ever be discordant and disfiguring. That in undulating and simple surfaces, the parts ought to co-operate with each other in producing every variation and agreeable diversity of form; and in picturesque surfaces, the union of abruptness and broken ground should neither be forced, regular, tame, nor unmeaning. That a level surface, broken into holes, or covered with heaps, is totally different from a picturesque surface; and that even an irregular surface, uniformly abrupt or broken, is but another variation of the same deformity and defect. That in picturesque ground, the surface should either be rising, falling, or irregular; in the rising surface, the breaks and abrupt ascents should succeed each other, or be interpolated so as, standing below and looking upwards upon them, they may seem to favour the general tendency to rise; and standing above, and looking down over them, they may appear in union with the nature of the declivity. That a hollow without an outlet, or a circular mound without a uniform and continuous continuation of swell, are alike unnatural and disagreeable.

It is suggested, that wood may render undulating surfaces more characteristic, by being planted on the eminences; that it may give expression and effect to tame formal hills, by judicious disposition upon their sides, so as to vary both their surface and sky outline, and that it may even render an uninteresting common intricate and varied. That a few trees falling down a declivity or precipice, increase the appearance of steepness; and a wood covering the bafe, and creeping up to various heights on the side of a hill, adds greatly to its apparent height and grandeur. That a surface full of deformities, either hollows, pits, or unconnected excrescences, may, by a judicious distribution of wood, be rendered highly picturesque. That solitary hills, formally placed upon a level surface, the heights of small scale sufficing by adding earth to the angle formed by the junction of their base with the general surface, may, it is thought, by placing wood in the junction, be completely united with everything around. Accident has sometimes produced this effect, as where there is a conical hill which rises abruptly from the surface of a level or gently varied country; in which case the greater part of the base of the hill, and the lower parts of its sides, may often be also planted for the same purpose. But the effect of wood in changing the appearance of ground, though most striking upon a large scale, and in the hands of those skilful in handling for effect, it is thought, that even a few narrow-loads of earth on a knoll, or a continuation of swell on each side of a walk or fore-ground, will make some difference, even though clothed only with pasture: but if planted with trees, they produce shade and character immediately; and that they may conceal deformities in the distance, serve as a frame or fore-ground to distant beauties which might pass unperceived, or they may give importance to the scene itself from other points of view, or places from which they may be seen.

It is evident, therefore, that for connection of surface in ground where ornament, variety, and beauty, are to be produced, it is a matter of very great utility and importance in many different ways and intentions, and to which no inconsiderable attention is necessary in laying out all sorts of pleasure-grounds, but especially those of the more extensive kind.

**Surface, Planning and Modelling of,** that sort of planning and modelling which exhibits or displays the different kinds of improvements which are capable of being introduced in forming, improving, and beautifying all sorts and descriptions of country residences, and which includes or is connected with other objects and ornaments connected with them.

The models, in wood, of five different kinds of improvements in hot-houses, which form and constitute the principal ones, which Mr. Loudon, an ingenious improver of rural scenery, has introduced into such houses, are to be purchased and had in London as well as Edinburgh. These are said to have been found of great service to gentlemen, by enabling their workmen to construct such useful improvements with ease and certainty. Without some such assistance, it is well known this sort of business is often not only badly managed, but very tedious and troublesome.

It has been asserted by the writer of a late work on forming and improving country residences, that, before any thing is fixed upon relative either to the formation or improvement of a rural residence, or any of its parts, whether principal or complex, a plan or ideal scheme of the whole should be previously formed in the mind of the artist or improver, and embodied on paper, for the inspection or mature consideration of the proprietor and his friends. For this purpose, the situation should, it is said, be fully examined with respect to soil, visible beauty, and prospects, and also the relative advantages and disadvantages of climate and other matters. The best method of acquiring such knowledge is, it is thought, to visit the place at different seasons, before comple
SURFACE.

pleting the design. In this manner, observation may embrace, and reflection digest, the emotions excited in the mind of the artist or improver, by its diverse qualities, or in other ways.

It is suggested that the iconography, and bird's-eye views, of the present state of the whole should first of all be delineated, and geometrical sections made, where water or similar works may be hinted to be had. Upon these, especially the ground-plan, the designer may lightly sketch with red, or any striking colour, the proposed improvements, in some proper manner. After which he should make out a plan, bird's-eye views, sections, elevations, and other suitable designs, showing what may be the effect of the proposed improvements at a certain future period, suppose three or seven years, after they have been executed. This should be accompanied by perspective views of the most interesting parts or passages of the scenery, or of the buildings in their present state; and by other sketches, shewing the effect of improving them. The whole of which, except the larger ground-planes (which may generally be fixed on canvas and rollers), should be incorporated with a manuscript volume, giving some account of the present state of the place (which will always be interesting after the alterations are made), and mentioning the leading reasons for proposing the improvements, and the general directions for executing them. Either here, or more properly in a detached appendix, should, it is said, be given an estimate of the expense of the whole. In connection with these plans and other things, it has been found, it is said, of great advantage, in many irregular situations, to construct models both of the present state and proposed improvements; and not only of the buildings, but also of the ground-surface, the water, gardens, hot-houses, and villages, both in their present and improved state.

The fame writer has lately, it is said, invented a very ingenious method of modelling estates, which will be of very considerable advantage to landed proprietors, particularly those intending to improve, to decorate, or build upon their farms or grounds. In this kind of modelling, the variation of the surface is shown exactly as it is in reality; and all the trees, hedges, roads, rivers, buildings, and other matters, are accurately raised on the models, agreeable to a certain scale; and, afterwards, the whole is coloured from nature. There is annexed a manuscript volume of references, containing the names of the different farms and fields, the contents of each, and the nature of its soil and other matters, with every other requisite information. The inventor has also contrived such a model, which may not be used without previous preparation, and by which any gentleman may try, upon the model, the effect of any proposed alteration or improvement: and also a small wire net, each mesh of which is equal to an acre, by which the contents of any part may be instantly known by applying it, and numbering the meshes which cover the field or space to be measured. From the nature of the model, any changes which may afterwards be made in the ground can be inferred without injuring the piece; and hence no estate will ever, it is said, require to be remodeled. The remarkable objects upon an estate, such as the mansion house, &c., can also, to give a clearer view of them, be modeled separately, upon a larger scale than the general plan.

The unwieldiness and bulk of such a model would at the first sight appear to be an inconvenience; but by dividing it into separate parts, which parts are kept in a small chest or box, and may be taken out and fitted together in a few seconds, it occupies little more room than a plan of the ordinary kind,

The advantages which the inventor thinks will attend this mode of imitating estates are these: first, that a proprietor will see a correct imitation or miniature of his estate, in the clearest manner, and without the risk of being misled or deceived by a plan: secondly, that every proposed alteration or improvement, of whatever kind, will be clearly understood, and may be foisted out to workmen; so that they may, it is thought, execute it with superior ease and certainty. In planning and forming country seats, this will be of immense advantage; and, as a further assistance to it, the discoverer has also invented a kind of working-plan, which will enable workmen to execute exactly the arrangement of trees, shrubs, and flowers, about any place, in a manner agreeable to the principles which have been laid down and explained in the inventor's work on country residences. Those who understand the mode of arrangement there exhibited and explained, and can compare it with the common mode of mixing all sorts of trees indiscriminately, will, it is thought, be convinced that this improvement is of great utility; thirdly, that the effect of every alteration proposed may be clearly seen before it is executed; whether it be the effect that changing the lines of fences, roads, &c. will have, in altering the contents of the adjoining enclosures (and this can be infinitely found by using the wire-netting); or the effect of the addition of wood or buildings, whether useful or ornamental. It is almost needless to add, that the scheme of improvement can be altered and varied upon the model, until the best effect shall be produced, which effect may afterwards be exactly imitated upon the grounds. The making trials, on the model, of the effect of alterations, will, it is said, form a very instructive and rational amusement for proprietors at certain leisure times.

Two models of this kind, one shewing the present appearance and contents of an estate in general, and the other the effect of an intended new place of residence for the proprietor, have, it is said, been already formed; to the latter of which has been added an elegant manuscript volume, illustrated by drawings and sketches containing the inventor's ideas of the situation; his reasons for proposing the improvements, and practical directions for executing them; accompanied with working-plans, a large vertical profile, shewing the effect of the whole, and a general estimate of the expense of the execution, &c.

Several improvements in the method of constructing and forming such models have since the above, it is said, been made; so that ten thousand acres of surface may now be modeled on a sufficiently large scale, and the weight of the model of the ground, without any danger of being broken or tarnished: and, what certainly deserves the consideration of the landed interest, a plan of the whole may, it is said, be modeled in this way for little more than the expense of a common survey.

It is remarked, that the neglect of improvers, in not preconceiving a plan of the whole before proceeding to operate upon the parts, has often occasioned them much useless expense and trouble, of which they are commonly not aware until it be too late. So many instances of this occur in every part of the country, it is said, that it is allowing them they should not be more cautious in embarking in such extensive undertakings without a much greater certainty of success. Even some who have formed and arranged a plan in their minds previously to proceeding, have misconceived effects from deficiency in practical knowledge; and have often gone farther wrong than the others, from a false estimate of their own powers. The neglect of having a plan from an artist or proper improver, which will, it is said, at least always furnish some hints, is thought generally advices to the real interest of a proprietor; as confiding such matters or improvers may often save no little expense.
SURFACE.

Surface, Covering of, in Hot-beds, the means of covering over superficially the foil or mould of such beds. This has, for the most part, principally been confined to some sort of thin earthy material; but lately other sorts of substances have been had recourse to for the purpose, which are of a more dry and forcing nature, with great success in particular cafes of these beds, and in pinnaries, and other places.

A writer in the first volume of the "Memoirs of the Caledonian Horticultural Society," directed in this intention, the laying on the surface of such beds, fine drifted river or peat-sand, to the depth or thickness of three inches. This kind of covering, it is said, possessses many advantages. It will extirpate the flatter, or wood-louche, as the nature of the sand prevents the infect from concealing itself from the rays of the sun. In dung hot-beds, it keeps down the steam; and to fruit, it affords a bed as warm and as dry as tiles or flates. This covering also retains the moisture in the earth longer than any other, and is itself sooner dry. Besides, it gives the house a clean nest appearance; and though it cannot be expected to remove the infection where already introduced, it will be found a powerful preventive of that great evil, mildew.

Surface, Perforation of, the practice of boring into it, for the purpose of discharging any injurious water that it may contain within its internal parts, by means of the draining auger, and that of examining and searching into it by the borax or other implements, for the purpose of discovering and detecting any kind of substances that may be useful or valuable to the farmer or other person; such, for instance, as marles, chalks, and other earthy matters, coals, minerals, and various other bodies. See Bore, Spring-Draining, and Tapping of Springs.

Surface Land. See the next article.

Surface Soil, a term sometimes applied to the layer of earthy materials in which crops grow, and which is not unfrequently called the plant-feeding bed or stratum, in contradistinction to the layer or body of substances on which it rests.

The depths of the surface layers of cultivated lands have, however, in some measure, their limits, which may probably with propriety be fixed at from three or four to fifteen inches or more, according to circumstances; as though, in many instances, the component parts of these beds are of a pretty uniform state, to a greater depth than the greatest of these, an uniformity of colour and vegetative quality but seldom reaches to that depth. The influence of the surrounding atmosphere, the living and reduced dead fibres of vegetables, the operations and effects of animalculce and larger animals, which inhabit and infest such superficial beds of lands, and above all the powerful action and effects of substances of the manure kinds, tend to furnish the surface mouldy materials with qualities which the substrata have not the means of acquiring.

The medium depth of the cultivated layers of the surface soils of this country, may probably be set down with sufficient accuracy at about nine or ten inches, as though the larger part of them may not attain to that depth, the greater extent of them, it has been thought, might, under proper regulation and management, be brought to such a depth with great utility and advantage. See Soil.

Surface or Running Level, a term used to signify that sort of level which conducts water. It has been remarked, by the writer of a late work on landed property, that though it is a solecism in language, it is useful as a technical phrase. It is made use of in contradistinction to the dead level in the work of draining land, which, though that may be capable of conducting water through a pipe, is quite un

fit for carrying it along a trench. A living stream gives, it is said, a firmness and tightness to the bottom of a cut or channel, in which stagnant or slowly moving waters would sink. The fall of about one per cent. is sufficient, it is thought, in ordinary cafes of drains or runs of water. But where the bottom of the trench or channel is firm, one inch, foot, or yard, in two hundred, will suffice; and may be had recourse to in cases where a greater fall cannot, without disadvantage and inconvenience, be allowed in the run.

Surface-Drain, a name applied to that sort of tool of this kind which is employed for rendering the superficial parts of tillage lands clear of weeds, and in a fine powdery state, proper for the reception of the seed. These kinds of drags are most commonly used for preparing for wheat crops, and the working of small harrows; but they may be had recourse to for many other sorts of crops with equal utility and advantage. There are several different kinds of them sued for working on different sorts of soils or lands. They should always be well suited to the quality of the land on which they are intended to work.

They are sometimes formed with nine sharp spares in a sort of long triangular manner; which sort operates well on poor land in a high dry situation, making little furrows or drills at the distance of about two inches or two inches and a half apart, and two or three inches in depth, for the feed. It, however, requires some considerable strength of team or power in drawing it. At other times they are made in a kind of leaf manner, the parts of which fold together, in which form they are particularly useful on some occasions. See Swing-Drain.

In still other instances they are made large, wide, and heavy, without any divisions in them; a mode of construction liable to objections. These are occasionally too formed in the first manner as to their wood work, but have smaller tines hooked towards the points, and sometimes double rows of tines. In these modes they are more certain and powerful in removing and collecting all sorts of small root-weeds from land.

There is also a sort of very heavy coupled tool of this kind, in which both the wood and iron work are very strong, which has something of the harrow form, and the different parts of which are coupled or united together in somewhat a similar manner to that which is used for that tool in some cafes. These answer extremely well on lands of the more strong thistle kinds, when employed at proper feasons.

Tools of this sort are essentially necessary for, and of great utility to, the arable farmer.

Surface Dragging, a term applied to the practice of working over the surface of land of the arable kind, by means of tools of the drag kind. It is a necessary and very useful operation on most sorts of soils or lands at different times, but especially just before the sowing or putting in the seed, as the surface is thereby well broken down and rendered fine for it, from which a great many advantages are derived to the seed and growth of the crops. See the preceding article.

Surface-Drain, that sort of superficial drain or opening which is calculated to carry off the injurious wetness which remains on or in the superficial parts of lands or soils.

Depth and Width of the Drains.—The writer of the account of Elkington's mode of freeing land from water remarks, that in surface hollow drains, the depth must always vary according to the nature of the soil, the situation of the field, the expense the farmer is willing to incur, and a diversity of other circumstances. Many years ago, it is said, three fort
were the common depth in most foils; but for twenty years past, they have, it is thought, seldom exceeded thirty or thirty-two inches; and the number that are cut to only twenty-four or twenty-six is much more considerable. The main or receiving drains are always, it is noticed, made a little deeper than the others, having more water to convey, and farther to carry it in most instances. Whenever the spade reaches an impervious foil, through which water will not percolate, there is no occasion for making the trench deeper or lower in the foil. One general rule should never be departed from, which is, that the depth must be sufficient to prevent the impotence of the feet of cattle from affecting the position of the materials used in filling them.

It is said, that in forming these forts of drains in all the modern drainages in the eastern counties, the farmers have been very solicitous to cut them as narrow as possible, by which means a great saving is made in the materials used for filling them, such as bulks, poles, sprays, or fraws; but if bricks or stones are used, of course this rule cannot be adhered to. However, there is no occasion, it is thought, for the width being greater than one foot, if the foles are only coupled at bottom, or thrown in promiscuously, or more than fifteen inches, if laid in form of a conduit. Whatever the depth of material be, in making the furrows, the surface should never be less than one foot thick, or rather more, in all tillage fields. In pasturage land, gravel, if it be at hand, especially if the soil be very tenacious, is preferable to the mould thrown out, which may be spread on any adjoining hollow.

The depth and width of about thirteen inches in the former, and in the latter from eighteen to twelve, or more, are the proportions that ought, it is thought, to be adopted on all land that is wet from surface water, or from its stagnation in the rainy season.

Digging and forming the Drains.—The best modes of having these forts of work performed, both in cutting and filling, in order to perfectly secure the success of the drains, are perhaps to employ the labourers by the day, and to engage none but such as are fully acquainted with the business.

In the making of drains of the surface kinds, tools or implements of the simple spade kind were formerly, for the most part, had recourse to in all the eastern parts of the country. Three such spades were formerly used, levelling gradually up, so as to form a regular narrowing to the bottom; but by previous ploughing or making furrows, to all the spades, except the lowest one, have mostly been laid aside in many cases; and even where a greater depth than usual has been necessary, not more than two have commonly been employed. And the spade, which is pushed or drawn along the bottoms of the drains, in order to clear out the loose crumby or mouldy parts, and render them fit for receiving the materials that are to be used in filling them, is also various in the size and breadth, in proportion to the depth and width of the drains.

Different sorts of these Drains. Materials, and Molds of making and filling them.—These sorts of drains are sometimes open and sometimes covered, as particular circumstances may require. The former are chiefly used for intercepting and carrying off the water that descends from higher grounds, or such wetnesses as overspread the fields, in consequence of long continued falls of rain, differing more from each other in size than in the form which they may have. The latter, on the other hand, differ almost in every district, and not less in the size and form, than in the materials of which they are composed, both in this fort of draining and that of the spade kind.

These sorts of drains are formed with different materials; such as, in some cases, though rarely, with bricks, pipes, and free-stone, but frequently with land-stone, wood, loam, peat, fraw, and heath or ling; and they are occasionally simple open drains, pits, and furrows, or other such openings: both common bricks, and such as have a particular construction for the purpose, are used in these cases. Where such are moulded for the purpose are employed, when for small drains, they are often formed in the shape of an arch, and placed one by the side of the other in the bottom of the drain. But when the drains are meant to convey a considerable current of water, the bricks are sometimes made broad at the base, and to taper up on one side, as that which is placed next to the side of the drain, until it attains half the breadth of the base. This last-mentioned fort is occasionally placed in regular lines on each side of the bottom of the drain, and are covered over with broad flat pieces of stone fort of stone, and afterwards, as in every other case, the remainder of the drain or ditch is filled up with the earth which had been formerly dug out. See Spring-Drain, and Sursoil Brick-Drain.

Pipes may sometimes be employed for drains in this fort of draining; but they are not commonly used in it. In the county of Essex and some others, however, pipes of brick, about eighteen inches in length, with openings about four inches in width, are laid recoupe to, after being burnt, in forming drains for removing surface water; but they are mostly better calculated for the conveyance of the water of a small rill or spring, so as to supply a house, or other similar purpose. See Spring-Drain.

In filling up drains, where small stones collected from the adjoining lands are used, as is mostly the case in this kind of draining, as a means of preserving a passage to the water, there is no material variation in the practice of any particular district from that just given; but it appears that where bogs are formed in regard to the manner of placing these materials. They are usually thrown in, promiscuously, to the depth of about eighteen inches; and being covered with fraw, fern, or rushes, the remainder of the drain is filled up with earth. In some places, a method, which appears extremely well calculated for preventing the intermix between the stones from being choked up with earth, sand, or gravel, is adopted, that is, placing a layer of long brown rushes, &c. in the bottom of the drains before the stones are thrown in. But another method of constructing drains of this fort with stones collected from the land, is to select the largest and broadest of them, and to place them triangularwise in the bottom, leaving a small vacuity in the middle for the water to run through. When the stones best suited for the purpose are placed in the manner thus mentioned, small stones are laid over them to the usual depth, and over them again, fraw, earth, &c.

It has been stated, that there are two methods of forming surface hollow drains with stones, which are materially different from each other. The first for this purpose, where free-stone or stones from a quarry are employed, is by building two narrow walls, one on each side, in the bottom of the drain, which in such cases is made considerably wider than when land-stones only are used, and to connect these walls by a cover of stone on the top. The face of the open part of the drain, when thus finished, is about eight or ten inches in height, and fix or eight in breadth. When small land-stones can be procured, they are laid about the cover of the free-stone to the depth of 10 or 15 inches, and a layer of fraw, rush, &c. or of turf, with the green side downwards, being placed over the whole, the earth is then replaced.
The other kind of this sort of drain, which is constructed with free-stone, or those from quarries, seems extremely well adapted for the purpose of drainage, when the filterings from the subsoils, as well as the runnings, from any thing of the spring kind, require free passage. Two flat stones are placed edgewise, one edge of each coming into contact with the other at the bottom, and the others resting on the ends of the drain; on the top of which are laid horizontally other flat stones, by way of covers to them. A fort of conduit is thus formed for the water to pass in. This kind of drain is very useful in some cafes of this sort of draining, as it forms good passage for the water, and results preferrable; but it is most frequently made use of in the draining of land, where the water is caused by springs. See Spring-Drain.

It is said, that drains formed and filled with wood, are very common in Suffolk, Essex, Hampshire, and many other districts, and are constructed in the following manner. A surface-drain from 12 to 15 inches wide, is in the first place formed to the depth of 10 or 12 inches; and when the loose earth at the bottom is taken out with the common spade, the labourer, using one not exceeding three or four inches in width at top, and tapering nearly to a point at the bottom part, makes a narrow cut to the depth of six or eight inches more; and the loose soil at the bottom of the drain being taken out with a kind of scops, bent and formed for the purpose, the labour of forming the drain is completed. Then willow, thorn, or any kind of brusht, is used for the bounds of trees, &c. and planted at lengths of 12 or 15 inches, and laid to the depth of several inches, according to their strength, across the top of the small drain, and make to rest on the sides or shoulders which constituted the bottom of the larger drain before the narrow cut was made. By this means a clear passage, six or eight inches in depth, and from two to four inches wide, is left for the water. The brush-wood, being properly placed, and to a regular thickness, is covered with a layer of straw, to prevent the earth, when replaced, from falling into the gutter below. This, it is said, makes the drain a very superficial mode of draining; and when compared with drains made of stone, it no doubt is so; but it is stated as surprising, how durable, and in many instances how effectual, they are. The writer alluded to above was informed in the county of Essex, that inferences are there very common, where drains of this sort have been known to last upwards of 30 years. Much of their durability is underfoot to depend on using green new-cut wood, in place of that which had been allowed to remain so long exposed to the influence of the weather after being cut, that the natural sap is dried up. As this is a cheap, and when well executed, an effectual mode of draining, and durable beyond the period in which farmers in general acquire what may be called a permanent interest in the success of drains on any farm, it may be for the interest of those who pollute short leaves, and where stone is not to be had without an extravagant expense of carriage, to use wood, as being for that purpose next in durability to stone or brick.

Upon the subject of filling drains with wood, the following observations have been made by lord Petre: the drains filled with wood, and covered as usual with the fagots or rubes, are preferable to stones, or any other kind of materials; the reason is, as the wood decays, the water continues to pass. When filled with stones, and the drains stop up, which must be expected to take place in time, the earth becomes quite solid round the stones, and as they do not decay, the filtering of the water is for ever obstructed. Not so when bushes or wood are used; continual filtering and draining are then to be for ever perceived; and by repeating the operation a second time, cutting the drains transversely of the old ones, the benefit of the filterings through the rotten wood is secured, and the clogging or frowning up of old broken and damaged drains corrected and carried off. Moreover, as bushes form a much greater number of cavities than either stones or poles, they are less able to stop the earth; and the space left for the filterings is always kept open. A load of bushes, containing 120 fagots, will, it is thought, do about 360 rods; and a load of straw, containing 120 bottles, the same. The load of bushes is generally worth about 14s., and that of the straw 18s. per load. It is, therefore, calculated, that this expense may be about 1r. the acre, the ditches being a rod apart. And it is remarked, that Richard Preston, esq. of Blackmore, in 20 years experience, prefers black thorns to every other material for filling drains of this sort.

There is also another method, which is said, another method of filling drains with wood, which is by suspending the fagots or bushes upon crofs-billets, set on end in the bottom of the drain. This kind of drain has been successfully formed and practiced in Berwickshire, where it is said to have continued running for 30 years.

This is a kind of drain which is much recommended by the writer of the Agricultural Report of the County of Caernarthen, in Wales, who says, that the compleat method he has yet known, is to cut the strongest willows, or other aquatic brush-wood, into lengths of about 20 inches, and place them alternately in the drain, with one end on one side of the bottom, and the other leaning against the opposite side. Having placed the strongest wood in this manner, he fills the space left between them on the upper side with the small brush-wood; upon which a few rushes or straw being laid, as before mentioned, the work is done. Willow, alder, asp, or beech boughs, are exceedingly durable, if put into the drain green, or before the sap is dried; but if they are suffered to become dry, and then laid under ground, a rapid decay is the consequence. However, this form will form a secure vacancy below, and an arch capable of supporting any weight of earth necessary above.

Various methods have been devised of saving the expense of materials in the filling of drains of this sort. The sod or pipe-drains are, undoubtedly, it is said, the least expensive of any, and may be of considerable benefit on some soils; but their duration and safety in supporting heavy cattle or horses in the act of ploughing, cannot be very much depended on, unless when the opening is at a considerable depth from the surface, and when the upper mould becomes incrusted, or forms an arch, in some measure, above the open part.

The manner of forming them is by digging a trench of a certain width, to such a depth, and then by taking out the last spad with a narrow draining spade, a shoulder is left on each side, upon which a sod or turf, dug from the ground, is laid; the forward side downwards, and the mould thrown over it. It is ascertained, that such drains will continue hollow, and consequently discharge well for a great length of time. The manner of forming them, and the tools used in the work, are well described and represented in Hunter’s Georgical Essays, by a writer who has practiced the method largely.

An improved mode of cutting and forming drains of this
SURFACE.

set in about three inches from the left extremity of the farmer furrow; it penetrates, by means of its long coulter and increased depth, seven inches and a half below the bottom of the late made furrow, while the upper part of the plough, with its additionally attached brealt, calts the new raised earth. Several inches upon the solid unmoved ground, and a new furrow is now finally provided, which, when added to the former, of fully fifteen inches in depth, and the bottom of which is clean and clear, exactly fixes the inches wide, leaving on each side a kind of shoulder or ledge, of three inches breadth.

The whole is now ready for the land-ditch fpade, which has a sufficient length and breadth of mouth part for the ditcher to make a spit with it, of fifteen inches more in depth, and exactly in the middle of the last made furrow, by which a ledge or shoulder is left of an inch and a half on each side. This being properly cleared, a depth is ultimately gained of full thirty inches from the level of the surface of the field.

In putting in the straw or haulm, which is the next operation, it is done without any mixture or portion of wood whatever, as Mr. Taylor supposes that it generally does more harm than good, except only a very little at the sides of the croft ditches, and throughout the leading ones, which are always made several inches deeper.

The distance of the drains is varied, not only according to the several degrees of looseness and porosity of the soil, but also as there may be different degrees of declivity in the ground from ditch to ditch. In level lots of land generally a rod apart, and where there is a declivity above four yards a furder, as in the former cafes, the water mostly filtrates both ways, but in the latter only into one ditch.

There is still another manner or invention for cutting and forming the drains in the surface-draining of land, in the county of Essex, which is by means of a cutting-wheel constructed of cast-iron that has considerable weight, and is about four feet in diameter, the extreme circumference or cutting-edge of which has the thinness of half an inch, which increases in thickness towards the nave or centre, by which it will, at the depth of fifteen inches, score out or cut a drain half an inch in width at the bottom, and four inches wide at the top. The wheel is placed in a frame of wood, that it may be loaded to any weight at pleasure, and be thereby made to go to a greater or less depth in proportion as the resistence made by the ground may be more or less; parts being thus scored or cut out in the winter, the tracks or openings made by the wheel are either then filled up with straw-ropes, and lightly covered over, or left to crack and open wider and deeper during the ensuing summer by the heat. The slices are then filled with twirled straw or bushes, and covered lightly with some of the porous earth that may be most conveniently at hand. In this manner, upon graves or lay lands which are pretty free from stones, are surface or hollow drains made, it is said, at little or no expense, and which upon trial have been found to answer extremely well. This sort of wheel is flated to have cut the drains of twelve or more, and that it works or cuts best when the land is wet and soft. But no account has been given of either the expense of the wheel implement, or of the strength of draught which is required to draw it. Another more simple sort of wheel contrivance has also been made use of in Middlesex, by the writer of the account of the agriculture of that district, which has the property and advantage of making an indent in the surface of the soil sufficient for carrying off the water during the winter time, by prefling and forcing down the fward without destroying it. See Wheel-Draining.

Cesspools of forming and filling the Drains.—The expense of these kinds of drains will of course vary with the nature of the soil, depth, price of labour, &c. and these circumstances are different in different districts, and even in different parishes, that it accounts for the various reports of writers on the subject.

Duration of the Drains.—In regard to the duration of surface or hollow drains, it must necessarily depend on the nature of the materials with which they are filled, and some measure, on the quality of the soil, as certain species or kinds of land have the power of preferring wood or other perishable materials much longer than others. Stones left till accidental causes impede the flowing of the water, and may last for ever. Wood perishes in certain periods, but it is not plain that the drains should stop; if the earth arches over it, the water will necessarily continue to flow, which is found to be the case when wood, straw, and rubble are rotten and gone. Drains of this sort that have been filled with bushes and straw, both which were rotten, have been observed to run well forty years after making. As on this subject, Mr. Young, of Clare, observes, that he has never been able to ascertain the duration of the fluffy with any degree of exactness; neither has he ever drained a field in a second time; but a drain will sometimes be stopped by clay on the land of the water, some other accidental cause, in which case, as soon as it is discovered, by the wetness of the place, his practice is to make one or more fresh drains in different directions to the old ones; and he has many times observed old drains, when cut across, though there was not the least appearance of any vegetable substance remaining in them, but full of loose porous earth, it once run freely, or, according to his workmen's phrase, bleed freely. During the wet weather, about the middle of April, he examined a field of six acres, which he had drained in the month of November, a great number of years before, as above twenty; and had the satisfaction to find every drain in the field, except one, running.

Rules for marking out the Directions of the Drains.—In regard to the mode of marking out the drains, it is remarked, that for many years, probably for more than half a century, and possibly during a much longer period, farmers did not make a proper distinction in fields that had a declivity, between tracing their drains with the slope, or directing them obliquely across it. Large tracks have been drained, or have been meant to be drained, it is said, in the former way; and that many, even to this day, are guilty of the same error; but that the best farmers are now attentive to an important point, and studiously mark the direction of their drains obliquely. They are also careful to give them all the fall which is sufficient to carry off the water in a grade, but not a rapid current, by which means they are less apt to chock, or blow up, as it is sometimes called; whereby spots in the field have an artificial spring formed in them. Upon fields which are level, or nearly so, great number of which are found in the western counties of England, it has been usual and necessary, improperly done, if the wetness proceeds solely from rain, to mark the drains regularly at a rod, sixteen feet and a half, a rod and a half, or two rods a furder, across the land from ditch to ditch; or, if the drains, from any small inequality of surface, will flow only at one end, then to stop short, or discontinue their length on one side of the field, as soon as the ditch opens in laying it dry. Where the slopes of a field vary, and fall in different directions, the farmer should attend to such vari-
SURFACE.

tions, and directs his drains so as to cross obliquely the upper side of each declivity. It is a general rule not to conduct too many drains to the same mouth or outlet; for if much water flows in any drain, from having thrown many lateral branches into one main drain, the latter must not only be made larger and deeper, but will even then be liable to fail; and a failure in that case affects so much a large ground, by flowing the course of so many other drains. On this account it has been found better to make the drains detached, rather than to connect too many of them together, which occasions much water to be conducted to one mouth. Caves will, however, occur, in which, from the position of the ground, it may be found necessary to join several branches (wings) into one main drain. On this subject, Mr. Vancouver, in the Agricultural Report of the County of Eliza, has the following judicious remark. If the field proposed to be drained lies greatly upon the deficient, every care should be taken to make the drains bear sufficiently horizontally; in the first place, to prevent a too precipitant fall of the water, by which the bottoms of the drains would be worn uneven, and a temporary obstruction occasion them to blow up; and secondly, because the more perfectly horizontal the field is, so that it lie level, free, and afford a sufficient fall for the water, the less occasion will there be for the same number of drains as would be required upon a soil of equal closeness upon the side of a hill, the drains in the field that lie nearly level, drawing equally well on each side; whereas those on the bank of a hill, drawing only from the higher sides of the drains, consequently require them to be made much nearer or closer together.

The proper Season for performing the Work. — And in respect to the season for executing the business of cutting these kinds of drains, it is a point on which opinions, it is observed, vary considerably; some preferring winter, and others summer. When a great quantity of work is to be done, all seasons of the year, free from sharp frosts, must be made use of; and this is usually the case when a farmer enters on a lease to a farm which has not been drained, or which requires to be done a second time. Stubbles are usually done in the winter, and fallows in the summer season: but when a single field or two are only to be done, the farmer may choose the most convenient season for the business. Many excellent farmers would not do it at any other time than summer, from being then able to execute the cuts in a cleaner and neater manner, and fewer from that kneading and paltering which takes place in winter, and which they think tends to prevent the flowing of the water from those minute and imperceptible veins and interstices of the soil through which the water percolates. They have farther remarked, that opening the earth in a dry season gives a tendency to drain it, as the particles of the soil, after being separated and well dried, will not so easily unite again; whereas the kneading in winter tends to increase tenacity where it is moist to be avoided. Further, that carting on the fields in winter, to bring on stones or other materials, is more difficult and dangerous than in summer. In opposition, however, to these ideas, Mr. Young, of Clare, in Suffolk, it is remarked, is of a contrary opinion. He says, in summer: two inconveniences attend it; the increase of labour, in a clayey soil, when hard and dry, is very considerable, and the want of leisure, and when good labourers are scarce. Lord Petre on this observes, that the plough for opening the previous furrows, works better on a layer. He prefers a lay, if lowed down level, as he has a plough on a very simple construction, with which, and fix bories, he can plough from ten to twelve inches deep, and lay the furrows as regular as a man can with a spade; so that after the drain or ditch is digged and filled, the furrow can be put into its place again, and rolled down with a large roller quite level; and then he digs but one spit with the bottom land-ditching spade fourteen inches deep: the expense 2s. 8d. per twenty rods, the digger returning the furrows to its place. He also uses this plough on fallow, but it does not answer so well, as the moulds fall into the furrows. The expense of digging on fallow is 1s. 2d. the rod.

When the ground is in summer fallow it is certainly the best time for calling drains that are only for carrying off surface water, as the diminution betwixt the wet and dry parts of the field is then the most easily perceptible, and any prominent inequalities of surface may then be more easily levelled or reduced, by paring off the heights and adding to the hollows.

Various seditions, representing the manner in which these different sorts of surface-drains are made, as well as the several different kinds of bricks, tools, ploughs, and other contrivances which are employed in forming them, and which have been described under their proper heads, may be seen in the first volume of the "General Dictionary of Agriculture and Husbandry."

SURFACE Mole-Drain, a small sort of pipe-like drain, made by an implement for the purpose, a foot or more beneath the surface, by means of a thick iron spike, pin, or bolt, drawn along horizontally, at that depth. It is supposed, that for cold retentive grists-lands, which lie too flat and swampy to shoot off readily their surface waters, and which are free from stones, the mole-plough drains will perhaps be found of general benefit; but most especially, Mr. Marshall conceives, for moist sheep pastures. There is much merit in the thought of making them in this way; and, it is said, the construction is beautifully simple. The great strength and weight of draught which are required to work the tool appears, from what he has seen of it, to be the principal objection to its use in forming them. This has, however, been lately, in some measure, obviated by working the tool by means of a sort of windlass turned by women; and by the use of a lever of a one or two-horse power, ingeniously contrived for the purpose. See Mole-Plough and Surface-Drain.

SURFACE Open Drain, such a drain as is not closed on the upper part. It includes surface-drains of all kinds, from the inter-furrows of land under the plough, and the shallow trenches or cuts of meadow and grazing grounds, to the common sewers, or discharging channels of the higher lands, and the more insignificant ditches, or furrows, of low countries. This sort of drain is mostly proper for conveying rain-waters from the surfaces they fall upon, to their natural receptacles. But in taking off water from beneath the soil, they cannot be properly made use of in any other way than as main drains, to convey away the stream that may be collected. Mr. Marshall remarks, that operative drains, if cut to a sufficient depth across the area of a field, to draw out superfusious moisture properly from the soil, cannot be left open with any degree of propriety. When water issues, the subfrazmum is naturally looie, and liable to shoot into open trenches, which are likewise exposed to the tread of cattle; so that even in grists-lands they are ineligible, and still more impracticable, it is said, in lands under tillage. Even main drains, if carried across loose ground, require to be fenced on one side, or to be made wide and deep enough to prevent cattle from crossing them. It has been noticed by the writer of the corrected Report of the Agriculture of Berkshire, that the work of
SURFACE.

Making or cutting open drains and grips for taking away surface water, may be performed, in some cases, by the plough, though, in general, manual labour is necessary for the purpose. And that, in meadows and other low and wet situations, great attention should be paid to the surface open drains and ditches, which though the expense in his cleaning and scouring them out every year be not inconsiderable, there may be some recompense in the mud and soil which are thrown and got out of them. See SurFace-Drain.

Surface-Draining, that sort of drainage which is intended to remove the prejudicial wetness that is contained in or upon the superficial parts of the land or soils. It is evident, it is said, by the writer of the work on the improved principles and practices of draining land, that the Romans were not unacquainted with most of the modern methods of surface or hollow-draining, as appears from all their writers de re rustica, as Cato, Palladius, Columella, and Pliny, mention them particularly, and describe some circumstances which have lately been considered as modern improvements. Several circumstances are alleged, which have been thought sufficient to prove, that the Romans understood the business of common draining in great perfection, and that our best cultivated counties had little to boast of in this respect, in superiority to the ancients, until Mr. Elstington and others made the discovery of a method with which they were wholly unacquainted. The best French writer on agriculture, De Servès, who wrote in 1660 his Théâtre d’Agriculture, describes, it is said, surface or hollow drains particularly; they were filled with stones. In Dickson’s Husbandry of the Ancients, vol. i. p. 358, the passages alluded to above are put down and translated, as may be seen by the inquirer on this subject.

It is not easy to ascertain when this practice was first introduced into this country; some have thought, from a circumstance that occurred in Suffolk, that under-ground draining was practised three hundred years ago in this kingdom. We find also, it is said, that alder is of all other wood the best for filling drains. Probably no other, except that of aquatic plants, would endure nearly so long. Bulbs, as has been seen, are generally used, but sallow or willow is probably much better. The Board of Agriculture has, however, been informed by Richard Prefont, esq., that land drained according to the prefect practice of surface-draining, is not more than forty years flading great; for the upper stratum, where the moisture is chiefly lodged, being in some degree porous, the water is easily extricated from it by means of the drains. The under-stratum being also of a retentive quality, their depth does not require to be great. It is noticed, that when Mr. Young of Clare, who has had great experience in this mode of surface or hollow-draining land, observes that the improvement made by these drains, and this kind of drainage, is great on clay soils, he certainly means soils of this description or quality. That able farmer, that he knows from experience, that in “clayey soils it will answer perfectly; that it is the least expensive, and the most expeditious, as well as most durable improvement of any in the whole system of agricultural economy.”

In a soil also of a thin, black, moorish quality, relying upon a retentive till bottom, which in the winter falls when pulverized by frothing during wet times, afforded not any fort of resistance to the foot of the plough, on which instantly plumped down to the subsoil; and which, even when in pasture, and the surface firm’d by a few wind, was extremely subject to poach at the former taste; and in which, upon the second or third year of plantings,
the furrows between the ridges used to be completely grown up with rushes: this mode of draining has been introduced and employed, it is said, with the most complete success, by sir George Montgomery of Magbiehill, in his parks at Sunny-side, in Newland parish, in Scotland. It is flatted by the writer of the Agricultural Report of the County of Peebles, that in an hour or two after the heaviest rains, a horse may now gallop over this land, without almost leaving the impression of his feet; and that the rushes, which were beginning to take possession of the furrows, have literally all perished for want of moisture. Such a total change of the nature of any soil has indeed never been observed by the writer.

Equal advantages may probably arise from this sort of surface-draining, in many other cases and kinds of soil. The most common modes and cafes of surface-draining are those which are given below.

Drainage of Land, where the Soil is porous above and retentive below, &c.—It has been remarked by the writer of the Account of the Principles and Practices of draining Land, that in flat tracts of land, where the surface or upper soil is injured by a superfluity of stagnant water, not proceeding from springs, their drainage is an object of the first importance, and which, in moist cafes, be accomplished with very little expense. The upper soil being composed of a porous stratum of two, three, or four feet in thicknes, and having under this a strong retentive body of clay, the rain-water falling on the surface is rapidly drained. All it meets the clay; and there being obstructed from farther decr, the whole open part of the soil stands full of water, to retard the progress of vegetation, or at least greatly to injure it. This kind of soil is commonly denominated wet-bottomed land. To carry off this water requires only, it is said, one or a few drains, according to the situation of the field; and these no deeper than just to reach a few inches into the clay, betwixt which and the under part of the porous soil the greatest quantity of water will remain stagnant, when it does not appear to much on the surface. In this kind of drainage there is no need for the auger, there being no real spring or subterranean water to get rid of, but merely that which stagnates, and is retained in the superficial parts of the soil. If the field or ground to be drained should have a small descen from both sides, one drain cut through the porous to the clay soil, in the hollow part of the land, will effectually draw off all the water that the porous soil may contain; which will be greatly facilitated by properly forming the ridges to answer the declivity of the ground, and by deepening and clearing out the furrows with the spade. Where the situation of the ground or field corresponds with the above, the water will flow into the drain, as being made in the hollow part of it; through the porous strata, as well as through a number of small trenches cut up from it to both sides, which is the common practice in Effex, and some other counties adjoining: and, from its being so much practised there, is commonly called the Effex mode of hollow-draining. But it is, it is said, cutting up a whole field to no useful purpose. The drain, in such a cafe, may either be open, if it can serve as a division of the ground or field at the face of it; or closed, as circumstances may require. If the ground, or a field of this soil, has more than one hollow in it, in that case it is necessary to have more than one drain; but if it is almost level, or inclines only a little to one side, a ditch or drain at the lowest extremity, having the ridges and furrows properly formed, will answer the purpose effectually. In some cafes, however, it may be necessary to have a few side-cuts from the main drain, where the field is large or very flat, cut down also a little into the clay, as narrow as it is possible to dig them, and filled with stones in the usual manner. Such is the method of draining these sorts of soils with most advantage; but many fields suffer equally from wetness, that consist of a soil exactly opposite to the former in its nature, namely, a clay surface, having a porous sub-stratum. The drainage of such ground, where the wetness is little or more injurious nature, and where the impermeability of the soil that holds the water is of such a thickness as to require being perforated by the auger, has been already fully described in speaking of Spring-Draining (which fee); but here the depth of the drain being sufficient to reach the porous subsoil, without the help of boring, the description of such may with more propriety be introduced under this head. Fields or grounds of this kind commonly lie very flat, without any declivity, whereby the noxious water, stagnant on the clay-surface, might naturally discharge itself without the help of drains; for soils of the same nature, in a hanging situation, are seldom or never affected by the same cause. Such ground is more difficult to drain, and requires a greater number of cuts than any other soil whatever; as they must be laid out and conducted as to collect all the water from the surface, which can only discharge itself into the drains from above, being unable to flow into them through the clay: as in those soils of an opposite description, and where there is any irregularity in the grounds, the water will remain standing in the hollows within a few feet of the drains. The first thing in all stone cafes, is to make one main conductor in the lowest part, or at one end of the field, to receive and carry off the water collected by the smaller collateral cuts, which it may be requisite to make on each side of it. If it suits the situation or division of the field, this main drain had better be open than covered, and then the outlets of the other drains that fall into it can easily be inspected, and frequently cleared out, as occasion may require.

The proper formation of the ridges, to answer the declivity of the ground, should also be particularly attended to in such soils. The ridges should have rife enough in the middle to give the water a fall into the furrows, and these should have depth and fall enough to convey it into the drains. Thus would a great part of the rain-water, as it falls, be carried off, which would lessen the number of small cuts, otherwise necessary. The drains should all be dug as narrow as possible, and filled up in the usual manner with loose stones; only the bottom of the conducting drain, if it be not an open one, should be formed in the manner already described, with a small open conduit at bottom, the more easily to carry off the water. The small drains should also be coupled at bottom, or have two of the largest stones laid in the bottom, inclining on or against one another, so as to form a triangular opening of four or five inches below, in the way that has been described more fully in speaking of surface-drain. As the water is all received in at the top of these drains, it is necessary that they should be filled with small stones so near to the surface, as to leave only a space to be filled with loose gravel, sufficiently deep to prevent the plough or harrow from deranging them. Loose gravel, being so loose, as the wind and frost will turnout of the drain, as it more easily admits the water to be absorbed and pas through it into the stones, and the other can be spread on any adjacent hollow in the field. A thin layer of straw or rushes, or, if the field be in pasture, the upper turfs pared thinly off will answer this purpose better than straw or rushes, should be laid immediately above the stones, to prevent the smaller part of the gravel from filling up too closely the interfaces between them; but this is not so re-
SURFACE.

quite, when gravel is used in place of the mould. This mode of draining is calculated for very tenacious clay soil, whether porous below or not; but in many instances, the deepening of the furrows, with very few drains, might remedy the evil, where the retentive upper soil is only a foot or two deep, with a porous subsoil under it, through which the water would easily subside downwards, and again empty itself at some lower extremity of the field. The drains and furrows should, therefore, be deepened through the clay to the open soil, in order to facilitate the descent of the water; and thus much depends on the proper ploughing of such ground, by attention to which, many drains, otherwise necessary, might be dispensed with. The mode of draining these soils, which has been described, is that which has been recommended as the most effectual by Mr. Elkington, though it does not properly belong to his system of practice in the art.

The Essex mode of executing the drainage in ploughed spongy lands, where the surface soil is tenacious, as stated by Mr. Kent, is somewhat in these ways. Where the principal declination of the land is in the middle of the field or ground, it may often be drained by one main drain made there to a proper depth. In other cases, the ground, or a field, may be divided into the means of one of its directions in the room of a main drain. In still others, a field may be drained by a main drain cut in the middle, declining more at that part than the sides. And, lastly, a field may be drained by two outside main drains, the land being higher in the middle than on the sides.

Drainage of surface Water draining on Land of the moorish marsh kind, near the Sea, by artificial Means.—A great variety of drainages of this nature, of more or less extent, has lately been effected in several different parts of the kingdom, by drains. The mode of this sort; and some highly interesting improvements, accomplished by this mode of draining, in land of the above sort near the sea, have been executed, within these few years, in the county of Cornwall, and described in the Report of the State of the Agriculture of that district. It is stated, that great exertions have been there made in the mode of removing the wetness, recovering, and improving land, which for ages had not only been unprofitable, but dangerous, in consequence of confined and pent-up waters in it. At Trewarthnicken, the feat of Francis Gregor, Esq., a moor, of previously no value, it is said, may be drained of the means of one of its directions in the room of a main drain, which, will be converted into the finest meadow ground by a spirited attempt of this kind; a great part of which was then planted with potatoes, which promised well. This moor, it is noticed, was in a state of which none but an inhabitant of this county can form any idea. It had been formerly strewed for tin, which is searching for granules of it that lie in horizontal strata, from one hundred feet below the surface. The tin, intermixed with the gravel, is washed in a stream of water carried through the work, and then separated from all impurities, and becomes strewing. The old land of the stream-works was left in the above devasfted condition. By this strewing operation, the superficial soil had, it is said, been turned under and buried, and the subsoil and gravel heaped upon it in large irregular mounds. In this state, fedges, ruthes, furze, and fatted brash-wood, wholly occupied it; and after many attempts to reclaim it, the farmer had relinquished it to the sportman: besides, the river frequently overflowed its banks, and deluged the lower parts of it. The successful mode of draining and crop management was, after clearing away the surface-obstructing matters, draining, and preventing its being again overflowed, by bringing up levels from high-water mark through the bed of the river, by levelling, and the cultivation of proper crops as those of potatoes, fennel, &c. On the opposite side, a further improvement of the same kind was carried on: the river, which is at all times foul, but particularly so after heavy rain, was ponded back in such a manner, as that the upper surface of the river-water was permitted to flow over the land. The deposit made in this way confined, it is said, of the lighter particles; the heavier ones, particularly the gravel, linking lower in the ponded water. By this means, in no great length of time, a new surface soil is capable of being formed, and afterwards thickened at pleasure in the above manner. The bringing of this surface kind having been well performed.

The plan of drainage given below is that which has been practised with success by Mr. Moyle, of Marazion, in the same county, on a large tract of land overflowed by the sea. It is remarked, that in all those situations where lakes are formed near the sea, having access to them at springs, it is impossible to effect a drainage by the ordinary modes, from the want of levels; and, of course, such pieces of land, from being contantly covered with water, become unprofitable to the proprietors, and offensive to the public, by producing diseases. Several marshes, and some small lakes in the above country, fall under this description, and have been looked upon as irreclaimable, on account of the sea, at spring-tides, being several feet higher than the land; so that no levels, by the common modes of draining, can be procured to carry away the internal and surface waters. Purchasing an estate near the above town in 1799, where a piece of land of about thirty-fix acres was contantly covered with water, and overflowed at spring-tides, so as to leave about two feet of water over its surface, the above gentleman was induced to try an experiment of draining this land, by opening a sluice or drain about eight feet below the level of the sea, at high water, which, though numerous obstacles prevented themselves to the completion of the scheme, he perfected; and the land, already cultivated, is become of considerable value, from the production of oats and pasture for live-stock.

It is stated that, previous to the commencement of such an undertaking, it is necessary to form an accurate idea of the probable quantity of water which may be furnished by the under or internal and rain-water; for that a pipe of sufficient size may be provided to discharge both, and to render the surface completely dry, previous to any agricultural operations.

This marsh is situated in the parish of Ludgvan, about a mile from Marazion, and contains about thirty-fix acres: it exposes its fourth side, of fix hundred and thirty yards, towards the sea, from which it is separated by a large body of land, of one hundred and seventy-four yards, over which the road leading to Penzance parishes, and which serves as a natural embankment against the sea. On taking an accurate survey of the levels from the sea, at the point of half ebb, the surface of the ground in the marsh, being a distance of one hundred and seventy-four yards, it was found that fixed feet of levels could be gained, after allowing two feet for the run or flowing of the water.

As to the drainage, this was effected by means of a square wooden pipe of nine inches diameter, introduced from the point of half ebb through the sandy embankment, till it arrived at the marsh. This arduous and difficult undertaking was performed by throwing open the bank by a number of workmen, nearly at the level of half ebb, so as to give the pipe a very gentle elevation, of about fifteen inches to every hundred yards, as it approached the marsh. The two first pipes
SURFACE.

pipes were secured by large rocks or stones, to prevent them from swimming; and the others were successively joined, each pipe measuring about twelve feet in length, and the wood an inch and a half thick. The deepest part of this land was about twenty-four feet above the pipes, so that the difficulty of getting to a sufficient depth in this place became very great, as the land was apt to run on the workmen, and required the opening on the surface to be forty feet. As the work was approached, the depth of land became gradually less, so that there was introduced a reference about sixty feet under the surface of the land. The aperture of the first pipe in the sea had iron bars placed before it, to prevent the infestation of sea-weeds, &c. and also a valve, made of strong wood, hung with leather, and loaded with a plate of iron, to prevent it from swimming at the approach of the tides, which shuts it cloe as effectually to exclude the sea-water, which, at high spring, is about nine or ten feet above the pipe. There is also another valve in the last pipe, near the refferoir, to affit the total exclusion of the sea, in case of any accident happening to the other valve. The pipe from which projects a few feet into the refferoir, is considerably larger than the rest; and bars of oak of an inch square are placed upright, to exclude any extraneous body from getting into the drain; it was found necessary, too, to add a short piece to the sea-pipe, about a foot and a half long, to prevent the intrusion of pebbles between the valve and the pipe, which might obstruct its closely shutting: some little difficulty likewise arose from the confined air in the pipe, at the approach of the tide, but this was removed by introducing an extra small pipe, of about an inch and a half diameter, through the cover of the pipe nearest the refferoir, so as to carry away the air confined between the two valleys, at the approach of the sea, which prevented the discharge of the marsh water till the return of the tide, during which time the water accumulates in the refferoir and trenches to the height of three feet. These pipes were square, and made of bark an inch and half thick, and secured together by oak pins instead of nails, which would soon decay in saltwater; but the writer would recommend circular pipes of elm, which, from their shape, are not so liable to be injured by the tides.

In regard to the refferoir, it is eighteen feet square and eight feet deep, from which, on each side, a main drain or trench is carried to the extremity of the marsh on its south side, whilst other trenches, running north the whole length of the marsh, at the distance of one hundred and twenty yards, discharge their water into the main drain, so as to divide the whole into fields, which are subdivided into ridges of nine feet wide, across which, at the distance of every twenty-five yards, is a furrow, to collect and convey the surface water into the long trenches, so as to keep the whole completely dry. The main drains are from fix to four feet deep, five feet wide at top, and two feet and a half at the bottom. The substance of this marshy ground, to the depth of fix feet, is of a peaty kind, mixed with a muddy sediment; below this is a stratum of sand about five feet deep, which carries evident marks of its being the bed of the sea, of a very ancient date, and which has been gradually excluded by the accumulation of a muddy sediment, and the dropping of the leaves of aquatic plants, which united, it is said, form pent-mops. And as soon as the drainage, in this case, was effected, a strong embankment of turf or sod was made around the marsh, so as to prevent the river, surrounding its two sides, from overflowing the land, and through which river the sea flowed at spring-tides. The danger arising from the approach of the sea was also prevented by a flood-gate, placed in a narrow part of the river, which always shut by the coming in of the tide, and opened again on its return.

In further reclaiming the land, in this case, as soon as it was completely drained, and became firm, it was, it is said, frequently ploughed, harrowed, and burned, so as to pulverize it: large bodies of clay, sand, and manure, were carted on the same; but the saltness of the soil, from its being covered with the sea for ages, prevented any crops from springing for the first three years, after which it was repeatedly covered with fresh water, which, so as to destroy the soil, by disolving the saline particles, that crops grew in great perfection on the fourth year. Thus much useful land was well drained, and brought into profitable cultivation from the state of absolute waste, without any very great expense in any way. There can be little doubt but that this artificial plan of drainage might be had recourse to in many other similar situations with equal success and improvement. And in different moory and marshy tracts which are not so greatly overflowed by sea-water, something of the plan might often be adopted and practiced with great propriety and benefit, in removing the wetlands which is so injurious by flagrating and reftting in and upon them.

Drainage of Land, where the Soils are wholly of a clayey Nature, and much injured by Surface Water, or Wetness.——The drainage of clayey soils of this nature is probably the most difficult and troublesome of any in the whole practice of surface-draining, as from the nature of their stiff component materials, the wetness is drawn off to only a very small extent, or dilution, from any drains that may be formed in such lands, much cutting of the surface is, of course, unavoidably necessary for draining but small or trifling extents of ground. Something may, however, be done, and some advantages gained, by giving the drains a suitable form and direction, according to the different nature of the situations of the lands, and by running them sufficiently near to each other. However, in tillage lands, more often depends, in these cafes, as will be afterwards seen, upon a due form being given to the ridges, and the furrows being made to act well as drains, than upon any number of covered drains that may be formed in them, though attention should, in most instances, be paid to both practices. It is found, in very many soils of this nature, where the drains in this fort of drainage are carried in the same direction as that of the declivities of the fields, or somewhat straight up and down, then they will draw the water or moisture laterally, in some measure, to the distance of about two yards from their different sides, and consequently that they should be formed in a parallel manner to each other at about every four yards distance; but where the surface ridges and furrows are properly prepared at the same time, they may have a somewhat greater pace between them. They should never have more declivity given them than what is just necessary to cause a very gentle run or passage to the water. In the draining of clay soils wet from rain or surface water, but in which the upper surface part above the clay was from four to eight or ten inches in depth, and of a good quality, only lying in a mountainous part of the country, near to the sea, a great deal of rain fell upon it, which always kept the upper soil full of water, and produced a very coarse sort of grass, not worth more than three shillings the acre, when the land was in that state, and in which the under stratum of clay was of very great depth: Sir Henry Fletcher had recourse to a hollow coupled stone method, which has been described in speaking of surface-drains, with great success. He, however, first tried and pursued a mode which was the common one of the country, but which was found too expensive: the drains in it were made from twenty inches to two feet wide.
SURFACE.

wide and deep, square, and filled up promiscuously with quarried flones to within nine inches of the surface. The quantity of flones required in this way was so great, that the quarrying and dilant cartage came abundantly too high; so that the whole of the expense did not amount to less than three-pence halfpenny or four-pence the yard, and by the acre to ten pounds. In order to lessen so heavy an expense, he changed the method to that which has been alluded to, which is found to be cheap and effectual.

These, though not the exact sorts of clayey foils which are comprehended under the above head, the mode of draining employed in them may, probably, be found to answer well and cheaply, in many cases, of all the kinds. Besides, it is always a neat and simple, as well as a convenient method, in some situations, both in arable and grafts lands.

In draining the clofe, retentive, red, toagh, clay foxes in different places in the county of Essex, it is found necessary that the surface hollow drains should be made within ten or twelve feet of each other. They are commonly formed by the plough and the spade, as shewn under the head surface-drain, to the depth of twenty inches from the surface, and are left one inch in width at the part is in the higher portion of it filled with straw alone. Thofe leading to the outfalls are usually made about eight inches deeper than the lateral ones, and have elm-wood used with the straw in filling them. It is said that the whole, upon a fair trial, has been found to answer inimitably well.

The retentive compact clays lying upon a red rough clay, or tile-earth, in other places, have, however, been surface hollow-drained at a pole apart, at the expense of not less than a guinea the acre, but without the effect in any way equal to or above those formed by the means that are at present employed for relieving the land of its surface water, are, it is said, the use of the surface land-fall plough, and water-furring; but though these operations are performed in the best manner, the land is still left latured with water, and is much later in the seed-time and harvest than the neighbouring places. See Surface Land-Fall Plough.

In other cases, upon chalky and wet rough clays, as well as other sorts, the practice of surface hollow-draining has effected considerable improvements in the lands of the same districts.

In all foils of this clayey fort, when the lands are in the tillage state, whenever it is convenient, every opportunity should be taken of applying and incorporating different suitable earthy and other materials to and with them, in order that they may, as soon as possible, be in a proper drainable condition.

Drainage of Land where the Soil is stiff and retentive, by means of open Cuts, and the proper Formation of Ridge and Furrow.—It has already been hinted, that on some soils, where the surface is very retentive, no number of covered drains can operate effectually in drying the ground. It is ascertained, that in most of the central counties of England, and also in Flanders, the general mode of drying land is by ploughing it up into high and broad ridges, from twenty to thirty, and even forty feet wide, with the centre or crown three or four feet higher than the furrows. The successful practice of the Flemings shews clearly, it is thought, how effective this method is when well executed; for by attentively keeping the furrows perfectly free from water, the land is kept in so dry a state, that all sorts of crops flourish remarkably well. But in England the same observation would not be just, for want of the same attention to this mode of practice. In many instances, furrows are not properly directed, nor properly deepened, and the ridges are

too flat; by which the water flagellates in the hollow and, of course, renders that part of the field worse than lost. This bad management, it is thought, has brought the method itself into such discredit, that in many places they have been levelling their ridges at a considerable expense, in order to adopt some other method of draining, an operation which, on clayey foils, is certainly very imprudent; for when the ridges are well rounded, not too high, and the furrows kept open, and perfectly free from retaining water, it must be esteemed, for land of a very retentive surface, an excellent mode of draining, or keeping it dry. Water-furrowing is attended with very beneficial consequences, it is said, when performed in a proper manner, and at those seasons when the land requires it. It is likewise very simple in its nature; but the omission of it may be attended with the loss of a part of the crop, of whatever kind it may be; and the wetness in the land may often be removed by that means, without the aid of drains.

Much, it is remarked, has been written against high ridges, but not with due consideration of their propriety on such land; they have been applied on dry loams with advantage, and have been successful; and from latter parts of the country, no discrimination has been made: but their being improper in some cases, and ill-managed in others, certainly affords no just argument against them, when well adapted to the nature of the soil, and wetness of the climate.

The mode of ridging and cross-through, or, as it is usually called, furrowing land, as practised in the county of Gower, in Perthsire, is described in the following manner by George Paterfon, esq. of Castle Huntly, in that county. As clay is perfectly impervious to water, surface-draining is the only means by which that species of foot of improvement can be accomplished; and all over the county of Gower this operation is said to be extremely simple. There are certain large common drains, which pass through the district in different directions, sufficiently copious to receive the water drained from the fields by the ditches which furrow them, and of such a level as to carry it clear off, and empty their contents into the river Tay. There are also ditches which furrow every farm, or pass through them, in such a manner as to communicate with every field upon the farm. These ditches are made from two to four feet wide at top, and from one and a half to one foot at bottom, in a shape which prevents their sides from falling in; but even then they must be cleaned, and scour out every year at a considerable expense. If the fields be of an uniform level surface, the common furrows between the ridges, provided they be sufficiently deepened, will serve to lay the grounds dry; but seldom happens that any field is so completely free of inequalities, the laft operation, after it is sown and harrowed in, is to draw a furrow with the plough through every hollow in the field, which may lie in such a direction, that it can be guided through them, so as to make a free communication with any of the ditches which furrow the farm, or with any of the furrows between the ridges, which may serve as a conductor to carry the water off to the surrounding ditches. When this track is once opened with the plough, it is widened, cleared out, and so shaped with the spade, that it may run no risk of filling up. Its width is from six inches to two feet, according to its depth, which must depend upon the level of the field; but the breadth of a spade at bottom is a good general rule. It frequently happens that there are inequalities in several parts of the same field, which do not extend across it, or which do not pass through it in any direction that a plough can follow, but which may extend over two ridges, or one ridge, or even a part of a ridge: such re-
SURFACE.

quite an open communication to be made with any furrow which may serve as a conductor to carry off the water, which are always made with the spade. All these open communications are here called gaud, and to keep them perfectly clear, is a very essential part of every carle-farmer’s attention.

It may be observed, that on some need-paitures, the carrying off surface water may be effected in the simplest manner of forming drains that has been already noticed in speaking of Surface-Drains; which fee.

It may be stated, in conclusion, upon this very interesting point of management, that even the ancient Romans were sensible that wet land was fit neither for being ploughed, harrowed, nor planted, as Columella has observed: "Ne lutoos aegor tractatur—nam quae limosa verantur arva tota anno deinum pollre tractari, nec fung habilia fomenti, aut oxidationi utatione." Col. lib. ii. cap. iv.

Surface-Draining Level, that sort of implement of this kind which is used in draining land. There are several kinds of levels employed in this sort of work; as the common draining-level, the American draining-level, and the spirit draining-level: all of which may be found useful, in different cafes, in both forts of draining. See Level.

Surface-Draining Mill, that sort of mill which is constructed wholly for the purpose of raising or lifting water, so as to draw and drain it off from the surface or other parts of land. Where the quantity of water to be raised is considerable, and the depth at which it lies is not more than a few feet from the surface, as from five or six or eight, the common draining-mill of the marsh-land district may, it is said, be employed to force up the water into an open drain or cut, which is sunk to about half the depth for receiving it, with great convenience and utility. But in cafes where the depth of the water is still more considerable, and the covering materials of it of loof and mouldering a nature as not to admit of deep open cuts, and arched work being of too great an expense, pumps going by wind or water may answer the intention more cheaply and effectually.

Surface-draining mills of this kind are not unfrequently useful and necessary in level marhs and other tracts of land, where the water can neither be removed by the use of the deep-cut trenches nor the boring auger. Surface-Draining Plough, a sort of plough which is contrived for the purpose of cutting drains in land, in order to carry off the water from the superficial parts of wet foils. Various implements of this kind have been invented at different times for performing the necessary operations of draining; but perhaps none have yet been found sufficiently to answer the intention in all the varieties of soil on which they may be required. A plough of this sort, which was long since invented by Mr. Cuthbert Clarke, of Belford, in Northumberland, was found to answer exceedingly well in meadow ground, but could not be drawn in a stiff clay with the force or power of eight horses. It has of course long ago been wholly laid aside, but it might probably be so altered and improved, as to be made a good tool for the purpose in some cafes. It may be observed, that the mode of operation in this draining-plough is nearly the same as that with the common plough. But it would seem, that as the angle of the break part is greater than that by which the horses draw upwards, it must have too great a tendency to get into the earth; the consequence of which is, that when the soil is very stiff, it requires a great force to draw it, and cannot be held down properly by the handles. By the angle of the break part being therefore lefened to about thirty-three degrees, it is not improbable but that it would, in a great measure, remove this difficulty. In marly, boggy, and moosy foils, it is said to answer the intention extremely well, and to make a clean trench, working very well. From its requiring a great deal of strength of draught, it can, however, only be employed in particular cafes with convenience or success.

About twenty years ago, a bounty was also given by the Society of Arts to Mr. Makins, of Suffolk, for having invented a plough of this sort for cutting hollow drains. But though the tool, and notion of constructing it, were not without merit, the implement has long since been laid aside, both in the above county and in that of Essex. Afterwards another plough of this sort, for the same purpose, was invented by Mr. Arbutthnot, of Mitcham, in Surrey, which is described and represented in Young’s "Eastern Tour."

And more lately different trials, for forming drains of this sort, have been made with variously contrived tools of the mole-plough kind, which by forcing a pointed circular iron part or mole through the earth or ground, at a given depth, by means of a strong power of draught, a pipe-opening is formed in it, which is not to be filled with any fort of materials, but left open, so that the water may flow freely through the parts of the soil it has loosened, to a proper depth, and the roots of the grain or grass crops, and find its way by filtration into the furrows, as has been proved to be the case, it is said, by experience. Different improved implements of this sort have been contrived within these few years, which are said to answer the purpose of taking off the surface wetness of land in a very effectual manner. See Surface Mole-Drain.

It is thought imprudent by the writer of the work on the Principles and Practices of draining Land, where the wetness is caused by springs, to too readily suppose a limit to human invention; but it may be stated, that the probability of an effete or hollow draining-plough being invented, which will work so much cheaper than the spade, as to become an object of economy, is by no means flattering: none which have hitherto been tried seem, it is said, to fully and completely answer this intention; but there can be no sort of difficulty in making one to open and prepare the ground for the narrow drain-spade to make one slit at the bottom. The repeated ploughings or shovellings which are necessary with common tools are expensive, and might probably, it is supposed, be executed in a cheaper and more expeditious manner by a surface open-drain plough. How far that invented by Mr. Knowles, and rewarded by the Society of Arts, would at a sufficiently cheap rate answer this purpose, has not yet been fully and properly ascertained. But it is thought obvious, that from the force and number of horses or oxen which are requisite to work them, ploughs calculated for this use will never come into general employment.

The surface common draining-plough is likewise a plough of this kind, which is employed, in some of the midland counties, for the more general purposes of surface-draining, and which is a good and not very expensive tool. There is a draining plough of this sort, too, made use of in Leicestershire, with advantage in different cafes and sorts of land.

Surface-Draining Furrow-Plough, a plough of this clafs, which may be employed for making large open furrows, by which the water may be taken off from the surface of the land. It will be frequently found a necessary tool in those clayey soils where water magester on the surface of the ground, and which cannot be removed by the more general modes of surface or hollow-draining; a plough of this kind, employed for opening the furrows on tillage-lands in some district.
difficulties, is said to be a very useful implement. It is constructed with two mould-boards, which can be regulated and set off to different distances, so as to make wider or narrower water-furrows, as the nature and circumstances of the lands may be. It is also contrived so as to work to greater or lesser depths, as may be necessary. By these different means, water-furrows of very different sizes are capable of being formed by the same plough, which is a matter of much utility and advantage in different cases, and which saves a great deal of expense in many instances.

Surface-DRAINING Gutter-Plough, is a plough of the draining kind, made use of for forming gutter-drains in grass-lands. A plough of this nature has been lately recommended by the duke of Bridgewater, and which is said to have been found useful in forming gutter-drains on grass-lands, where the soils are of a retentive nature. The power of six horses is, however, required in drawing it in soils that have not been drained before; but in opening the old gutters, four horses are found sufficient for effecting the purpose. This great power of draught in all ploughs of this kind is a great objection against them, and greatly prevents their utility in different instances of this fort of drainage.

Surface Land-Fall Plough, a particular sort of plough made use of in some parts of Essex, it is said, with advantage, where the nature of the under-frates, in a great measure, forbids a regular and even course of hollow or surface-draining; and which acts or operates in bringing the land or field to a more uniform level, by filling up the small hollows with the earth which is removed from the unequal or higher parts of the grounds, by which means any open drains that may be necessary may be cut or formed upon a more evenly inclined plain, and the surface water be carried or taken away with a greater and more regular certainty: the earth or land, however, in these cases, it is suggested, from the want of proper hollow-surface-drains, is still liable to retain a considerable quantity of water, which not frequently perishes the seed which has been sown; and by the chill which it produces, even in the most favourable seasons, greatly retards and prevents the powers of vegetation. See Water-Furrowing.

The plough is constructed in a sort of box-like form, open in the front, but closed on the sides, and made so as to slant off levels, and reduce the inequalities of the land of the ridges, having handles behind for regulating it by, and hooks with chains and swingle-trees before for attaching the team to. It takes a breadth of about four feet at a time. A man, a horse, and a boy, will, it is said, in a dry time, do fifty rods a day with it. A representation of it may be seen in the second volume of the Essex Corrected Report on Agriculture.

Surface-DRAINING Mole-Plough, a sort of plough made use of for the draining of grass-lands, where it is a material object not to have the surface injured; yet to have the moisture removed at particular wet seasons, as in parks and pleasure-grounds, &c. It is a sort of draining-plough that has been said to answer well with six or eight horses. The first plough of this kind was probably invented by Mr. Adam Scott; but a great variety of implements of this sort have since been contrived, though none probably that perfectly answers the purpose in every intention. They have, however, been so far improved, as to be wrought with much less power or strength of team, and sometimes by means of human labour, without the treading of teams at all. The mole or breast parts of them have been so altered, as to slide through the soil with much greater facility than was the case at first, as has been seen in speaking of the improved tool of this fort under its proper head. See Mole-Plough.

It is a plough too which has been used on the arable peaty lands, in some parts of Lancashire, with great success.

Surface-DRAINING Pump, that sort of pump of this kind which is contrived for the purpose of raising and discharging the water which fluctuates in large quantities on lands in some situations, where there is none or very little drainage level. These pumps are mostly of a very simple nature, and contrived so as to lift the water over the banks by which it may be surrounded. The writer of the late work on "Landed Property" is of opinion, that by means of powerful pumps of this sort, many of the cold flat lands which lie at the feet of hills, in almost every vale district of the kingdom, might be drained and considerably improved in different ways. See Surface-DRAIN and Surface-Draining.

SURFEIT, an indigustion caused by excess in eating or drinking, that is, by over-charging the stomach; and usually attended with eruptions, and sometimes with a fever.

SURFEIT, among Animals, a particular sort of complaint which is incident to horses and other cattle belonging to farms, and which arises from various causes; but is commonly the effect of some affection not attended to, or ill cured, and frequently from the want of food and management. It also proceeds from excessive and immediate feeding, but especially upon unwholesome food; from cold and hard riding, &c. whereby the animals for take the meat, and are infected with hard swellings, which, if they happen to fall upon the joints, will, in process of time, occasion lameness, and many other disorders. Animals are said to be surfeited, when their coats become thin, and look ruddy and dirty, though proper means have not been wanting to keep them clean. The skin is full of scales and lumps, that lie thick and mealy among the hair, and are constantly supplied with a fresh succession of the same, for want of due inspiration. Some have hurdles of various sizes, like pessaries; others have dry fixed fitches of their limbs and bodies; still others a moisture attended with heat and inflammation; the humours being so sharp, and violently acting that the animals rub it incessantly, as to make themelves miserable, and some have no eruption at all, but an unwholesome look, and are dull, sluggish, and lazy. Some appear only lean and hide-bound, others have flying pains and lancets resembling a rheumaticin; so that, in the surfeits of animals, we have almost all the different appearances of scurvy and other chronic distempers.

In all surfeits of animals, care should be taken to have them well managed, both with respect to their food and other matters, frequent changes being highly necessary and useful.

SURFEIT-Water, is a water distilled from poppies, and other herbs, proper to cure indigestions.

SURFUNDKAR, in Geography, a town of Aşık Turkey, in Aladula; 25 miles S. of Marashe.

SURGAB, a town of Candahar, on the Kame; 41 miles S.E. of Cabul.

SURGERIES, a town of France, in the department of the Lower Charente, and principal place of a canton, in the district of Rochefort; 12 miles N.E. of Rochefort. The place contains 14,771, and the canton 11, 203 inhabitants, in a territory of 2614 square kilometres, in 18 communes.

SURGE. The sailors call a wave, or bellow of the sea, a surge.

After, when they are hearing at the capstan, if the cable happen to slip back a little, they say, the cable surge.

SURGE, in Ship-Building, the tapered part in front of the whelps, between the chocks of a capstan, upon which the
when judiciously hollowed, the messenger, &c. may surge itself without any other incumbrance.

To Surge, is to let a cable, or rope, round a capitan slide up it, by gently flacking the part held on.

SURGEONS, Company of. See Company. See also PHYSICIANS.

SURGERY, or Chirurgery, (derived from chirurgeon, from 264, the hand, and 4790, one.) has generally understood to be that branch of medicine which principally affects the cure of diseases by the application of the hand alone, the employment of instruments, or the use of topical remedies. (Encyclopédie Méthodique, Partie Chir. tom. i. art. Chirurgie.) But although this definition certainly conveys to one some idea of the nature of this most useful profession, it is not entirely accurate as applied to the present rate of practice. In ancient days, the surgeon was a mere assistant to the physician; the latter alone not only having the sole privilege of prescribing internal medicines, but even that of judging as to the performanc when surgical operations should be performed. The subordinate surgeon was only called in to execute with his knife, or his hand, duties which the more exalted physician did not choose to undertake; and, in fact, he visited the patient, did what was required to be done, and then took leave of the case altogether under the orders of his master. In modern times, however, the good fends of mankind has discovered, that surgery is deserving of an eminent rank among such arts as ought to be cultivated for the general benefit of society; that the man who is not himself accustomed to the performance of operations, cannot be the best judge of their safety and necessity; and that, in every point of view, the surgical practitioner merits as much favour and independence in the exercise of his profession, as he whose avocation is confined to hygiene. Hence the surgeon is now exclusively confided about many of the most important diseases to which the human body is liable. Being no longer under the yoke of the physician, he follows the dictates of his own judgment and knowledge; he prescribes whatever medicines the caxe may demand, internal as well as external; and under the encouragement of an enlightened age, he sees his profession daily becoming more scientific, more respected, and more extensively useful.

It is an observation made by the celebrated Bichat, that two things are essentially necessary to form a great surgeon, genius and experience. One traces for him the way, the other refines it; both reciprocally assist in forming him. Without experience, genius would be unprofitably fertile; without genius, experience would only be a barren advantage to him. (Œuvres Chr. de Defaut, par Bichat, tom. i. Décours Prél. Out of the large number of hospital surgeons who are to be met with in every country of Europe, and who enjoy ample opportunities of profiting by the lessons of experience, how few distinguish themselves, or even contribute a mite to the improvement of their profession. Opportunity, without talents and an aptness to take advantage of it, is not of more use than light to a blind man. On the other hand, splendid abilities, without experience, can never be enough to make a connoisseur surgeon, any more than a man with the greatest genius for painting can excel in his particular art without having examined and tasted the real objets which he wishes to delineate. In short, as a sensible writer has remarked, "les grands chirurgiens sont assi rares, que le génie, le favoir, et les talens." Mem. de l’Acad. de Chir. tom. i. pref. p. 41. edit. 18mo.

The description of the qualities which a surgeon ought to possess, as given by Celius, is excellent as far as it goes. A surgeon (says he) should be young, or, at any rate, not very old; his hand should be firm and steady, and never shake; he should be able to use his left hand with as much dexterity as his right; his sight should be acute and clear; his mind intrepid and pitted, so that when he is engaged in doing anything to a patient, he may not hurry nor outlasts he ought, but finish the operation just as if the safety of the patient made no impression on him. A. C. Celsi Med. Inst. ad lib. vii.

By the word "immiifferos," as Richerand has observed, (Noël Chr. tom. i. p. 42, edit. 2.) Celius did not mean that a surgeon ought to be quite intemperate to pity; but that during the performance of an operation, this passion should not influence him, as all emotion would then be more weakens. This undisturbed coolness, which is still more rare than skill, is the most valuable quality in the practice of surgery. Dexterity may be acquired by exercise; but firmness of mind is a gift of nature. Hailer, to whom nature was so bountiful in other respects, was denied this quality, as he candidly confesses. Although (says he) I have taught surgery seventeen years, and exhibited the most difficult operations upon the dead body, I have never ventured to apply a cutting instrument to a living subject, through a fear of giving too much pain." Bibl. Chr. 1775, tom. ii.

Surgery may boast of having an origin that well deserves to be called noble; for the earliest practice of it arose from the most generous sentiment which nature has implanted in the heart of man, vis. from that sympathetic benevolence which leads us to pity the misfortunes which we behold, and inspire us with an anxious desire to alleviate them. He who first saw his fellow-creature suffer, could not fail to participate in the pain, and endeavour to find out the means of affording relief. Opportunities of exercising this useful inclination were never wanting. In the first ages of the world, man in his deffinite status was under the necessity of earning, by force or frigatam, a subsistence which was always uncertain, and in the combats which this sort of life drew him into, he frequently met with wounds and other injuries. The consequence was, that he began at a very early period to pay attention to the mode of curing accidental hurts. Wars, by multiplying wounds, at the same time increased the necessity for assistance, and enhanced its value. Kings themselves then did not disdain to dres wounds, and several of the warriors sung by Homer, derived not less renown from their skill in surgery, than from their valour in war. Such were Chiron, Machan, and Podalirius. It is in the immortal poems of the Iliad and Odyssey, that we find the only certain traditions respecting the state of the art before the establishment of the republics of Greece, and even until the epoch of the Peloponnesian war. There it appears, that surgery was almost entirely confined to the treatment of wounds, and that the imaginary power of enchantment was joined with the use of topical applications.

In the cures recorded in the sacred writings of the Christian religion, the intervention of a supernatural power is always combined with what is within the scope of human capability. The same character evinces itself in the infancy of the art in every nation. The priests of India, the physicians of China and Japan, and the jugglers of the savage and half civilized tribes of the old and new continents, contumely affiliate with drugs and manual operations certain miraculous practices, upon which they especially rely for the cure of their patients. Such was also, no doubt, the character of the medicine of the Egyptians in the remote times, previously to the invention of the alphabet, and upon which so very little light is now thrown.

We next come to the epoch when, by the union and arrangement of scattered facts, the science truly arose. Hip-
Surgery.

pocrates, born in the island of Cos, four hundred and sixty
years before the common era, collected the observations of
his predecessors, added the results of his own experience,
and composed his first treatises. In the hands of this great
genius, medicine and surgery did not make equal progress.
The former reached the highest degree of glory. Hippo-
crates drew up the history of acute diseases in so masterly a
style, that twenty past centuries have hardly found occasion
to add anything to the performance. But surgery was far
from attaining the same degree of perfection. The religious
veneration for the aulums of the dead, and the impossibility of
disturbing the human body, formed an insurmountable
obstacle to the study of anatomy. An imperfect acquaint-
ance with the structure of animals, reputed to bear the
greatest resemblance to man, could only furnish venturous
conjectures, or false inferences. Their circumscribed no-
tions sufficed for the study of acute diseases. In these cases,
the attentive observation of strongly marked symptoms, and
the idea of the operation of a salutary principle, derived
from remarking the regular succession of such symptoms,
and their frequently beneficial termination, enlightened the
physician in the employment of curative means; while sur-
gery, deprived of the assistance of anatomy, was too long
kept back in an infant state. Whatever praefaces may have
been bestowed on those parts of the works of Hippocrates
particularly relating to surgery, and which amount to fix in
number (de officina medicis, de fracturis, de capitis vulneris,
de articulis vel luxatis, de ulcerebus, de fistulis), when
compared with his other acknowledged legitimate writings,
they appear only as the rough sketches of a picture by a
great master.

Excepting the fragments collected or cited by Galen, we
possess no work written by any of the successors of Hippo-
crates until the period of Celsus, which leaves a barren in-
terval of almost four centuries. In this space lived Eras-
tratus, as well as Herophilus, celebrated for the feats which
they established, and particularly for having been the first
who studied anatomy upon the human body.

Celsus lived at Rome in the reigns of Augustus, Tiberius,
and Caligula. He appears never to have practised the heal-
ing art, on which however he has written with much preci-
cion, elegance, and perspicuity. His work is the more
precious, inasmuch as it is the only one which gives us in-
formation with regard to the progress of surgery in the long
interval between Hippocrates and himself. The four last
books, and especially the seventh and eighth, are exclusively
allotted to surgical matter. The style of Celsus is so ele-
gant, that he has generally been regarded quite as the Cicero
e of medical writers, and long enjoyed high reputation in the
schools. His surgery was entirely that of the Greeks, not
withstanding he wrote at Rome; for, in this capital of the
world, phylaxis was then professed only by peripatetics who
had either come from Greece, or had received instruction in
the celebrated schools of this native soil of all the arts and
sciences.

Let us pass over the interval which separates Celsus and
Galen. This latter was born at Pergamus, in A sia Minor,
and came to Rome in the reign of the emperor Marcus Au-
relius. He practised surgery and physic there about the
year 165 of the Christian era. (Galeni Opera Omnia, 1521,
ed. Aldi, 5 vols. in fol.) These two sciences were at
that time still united; and though some writers of much
earlier date speak of the division of physis into dietetical,
chirurgical, and pharmaceutical, no such distinction was
followed in practice. As Galen had been a surgeon at Per-
gamus, he continued the same profession at Rome; but
being soon attracted by the predominating taste of the age
in which he lived, for a science which more easily yields to
the futes and dazzling speculations of philosophical foils,
he afterwards neglected surgery, which firmly rejected him.
His writings prove, however, that he did not abandon it en-
tirely. His commentaries on the treatise of Hippocrates,
"De Officina Medicis," and his essays on bandages, and the
manner of applying them, showed that he was well versed in
the minor details of the art. Besides, it is known that he
paid great attention to pharmacy; and in his work upon
antidotes, chapter 13, he tells us himself, that he had a drug-
shop in the Via Sacra, that fell a sacrifice to the flames,
which destroyed in the reign of Commodus the temple of
Peace and several other edifices.

After Galen come the compiler Oribasius, Elisis of
Amida, a physician who lived towards the close of the 5th
century, Alexander of Tralles, and Paulus Agnus, who
called from the place of his birth. This last collected into
one work, still justly esteemed, all the improvements which
had been made in surgery up to his own time. Paulus
concludes the series of Greek and Roman physicians, and
he may be looked upon as the last of the ancients, unless it is
wished to let the Arabians have a share in the honours of
antiquity. Paulus practised at Rome and Alexandria. Af-
fterwards the ruin of surgery followed that of all the sciences,
and from the capture of Alexandria by the Saracens under
Anrago, history of Egypt, in 641, until the end of the
ten century, nothing prevailed but the dark clouds of
ignorance and barbarism.

Matters of a great part of the Roman empire, the Arabi-
ans dug up the Greek manuscripts, which were buried
under the ruins of the libraries, translated them, appropriated
themselves to the doctrines which they contained, made them
poorer with additions, and transmitted to posterity only
enormous compilations. In a word, such are the treatises
of Rhazes, Hali Abbas, Avicenna, Averroes, and Almo-
ella, the most celebrated of the Arabic authors. Inven-
tors of a prodigious number of instruments and ma-
Chines, they appear to have calculated the efficacy of sur-
gery by the richness of its arsenal, and to have been more
anxious to inflame terror than confidence. As an instance
of the cruelty of their methods, we shall merely notice, that
in order to stop the bleeding after amputation of a limb,
they were in the habit of plunging the end of the stump into
boiling pitch.

The state of medicine was not more fortunate. In the
school of Salernum, founded about the middle of the
seventh century, some attempts to revive its fabour.
Medical science being fasted on the same beach,
where the doctrine of Aristotile, accommodated to religious
opinions, was the subject of endless controversies, the im-
bibed, as it were by contagion, the argumentative and
philosophical mania, and became enveloped in the dark hypo-
theses of scholastic absurdity. Richerand, Nonographie Chur-
scule, tom. i.

The universal ignorance (continues this author) is the
horror of blood; the dogma of a religion, which fixed it
as a torment to useless quarrels; an exclusive rehild to the sub-
eteties of the school, and speculative theories; are circum-
cstances which further explain the profound darkness which
followed such empty labours. About the middle of the
twelfth century (1163), the council of Tours prohibited the
ecclesiastics, who then shared with the Jews the practice
of medicine in Christian Europe, undertaking any bloody
operation. It is to this epoch that the true separation of
medicine from surgery must be referred. The latter was
abandoned to the laity, who in those ages of barbarism were
almost all entirely unlettered and delitute of education.
Surgery.

The priets, however, still retained that portion of the art which abdained from the effusion of blood. Roger, Rolandus, Bruno, Gulielmus de Salicetus, Lanfranc, Gordon, and Guy de Chauliac, confined themselves to commentaries on the Arabians, and mutilated surgery, by reducing it almost entirely to the use of ointments and plasters. Guy de Chauliac, however, the last of the Arabians, must be excepted from this censure. His work, written at Avignon, in 1363, on the artifices of Urban VI., whose physician he was, continued to be for a long while the only classical book in our schools. It may be observed, that as he imitated in every respect the other Arabian physicians, and like them thought that it did not become an ecclesiastic to devote from the superlevity of his profession, he has passed over in silence the disfaves of women.

Antonius Benvenius, a physician of Florence, was the first who perceived that the compilations of the ancients and Arabians ought to be relinquished for the observation of nature. (De Abditis Rerum Caesar, Florent. 1507, 4to.)

A new era was now begun. The moderns, faw, that, by treading servilely in the footsteps of their predeceffors, they should never succeed in equaling them. The work of Velatus gave birth to anatomy. Illuminated by this science, surgery, having been prepared by the works of some Italian physicians, put on a different appearance in the hands of Ambroise Paré, the first and most eminent of the French surgeons.

Obeying the dictates of his genius, Paré made authority yield to observation, or fought to reconcile them, when envy, bullly intent on persecuting him, represented his discoveries as a crime. Although he was the refoter, if not the inventor, of the art of tying the blood-veigs, he was compelled to make imperfect extracts from Galen, and alter the text, in order to rob himself, in favour of the ancients, of the glory which this disfigured improvement deferred.

Surgeon of king Henry II., Francis II., Charles IX., and Henry III. of France, he practiced his profession in various places, followed the French armies into Italy, and acquired much esteem, that his mere presence in a besieged town was enough to reanimise those employed for its defence. In the execrable night of St. Bartholomew, his reputation saved his life. As he was of the reformed religion, he would not have escaped the massacre, had not Charles IX. himself undertaken to protect him. The historians of those days (Mem. de Sully) have preferred the remembrance of this exception, so honourable to him who was the object of it; but which should not diminish the just horror which the memory of the most weak and cruel tyrant must ever inspire.

"Il n'en voulut jamais fauver aucun (fays Brantome) ficon maître Ambroise Paré, fon premier chirurgen, et le premier de la chretienitée; et l'envoya quitter et venir le foir dans fa chambr e et garderobe, lui commandant de n'en bouger; et disait qu'il n'était raisonnable qu'un qui pouvait servir à tout un petit monde; feut ainsi malçrée."

Ambroise Paré was not content, like his predecessors, with exercising his art with reputation; he did not follow the example of the Quatre-maîtres of Pitard, so jubily celebrated for having composed the first statutes of the College of Surgeons at Paris, in the reign of St. Lewis, whom he had attended in his excursions to the Holy Land; and of several other surgeons, the fruits of whose experience were lost to their successors. Paré transmitted the result of his own experience in a work that will remain immortal. See Œuvres d'Ambroise Paré, Confeiller et premier Chirurgen du Roi, diviées en 28 livres, in folio, edit. 4. Paris 1585.

His writings, fo remarkable for the variety and number of facts in them, are eminently disfigured from all theo of his time, insamuch as the ancients are not looked up to in them with superfluous blindness. Freed from the yoke of authority, he submitted every thing to the test of observation, and acknowledged experience alone as his guide. The French writers are with reason proud of their countryman Paré to this day: they allege, that he must ever hold amongst surges the place that Hippocrates occupies amongst physicians. Nay, they add, that perhaps there is no one either of the ancients or moderns, who are worthy of being compared with him. Richerand Nofographie Chirurg. tom. i.

After the death of this great man, surgery, which owed its advancement to him, continued stationary, and even took a retrograde course. This circumstance is altogether ascribable to the contemptible state into which those who professed the art fell, after being united to the barber by a moit disgraceful allocciation.

Pigrai, the successor of Ambroise Paré, was far from being an adequate substitute for him. A spiritless copier of his master, he abridged his Surgery in a Latin work, where the unaffected graces of the original, the sincerity, and the ineffable charm, inseparable from all productions of genius, entirely disappeared. He received, however, equal praise from his contemporaries; doubtful, because he filled a high station. But, as Richerand remarks, his name, which is to-day almost forgotten, proves sufficiently that dignities do not constitute glory.

Roulet and Guillemeau disfigured themselves in the art of midwifery; while Covilliard, Cabrol, and Habicote, enriched surgery with a great number of curious observations. See Obs. Chir. pleines de Remarques curieuses, Lyon, 1639, 8vo.; Alphabet Anatomique, Genève, 1622, 4to.; and Semaine Anatomique Quelton Chir. fur la Bronchotomy, Paris, 1620, 8vo.

In the next or 17th century, the fame impulse produced additional improvements. Then appeared in Italy Cesar Magatus, who simplified the treatment of wounds. (De Rara Vulnerum Medicationis, ib. iv. 1615, fol.) Fabricius ab Aquapendente, even left praiseworthy as a surgeon than as a physiologist (Opera Chir. Paris, 1613, fol.); and Marcus Aurelius Severinus, that reforer of active surgery (De Efficaci Medicinæ, ib. iii. Francfort, 1613, folio; De Recondita Abcefiium Natura, ib. viii. Neapoli, 1632, 4to.; and Trinembris Chirurgia, &c. Francfort, 1653, 4to.) Amongst the English surgeons flourished Wileman, who was the Paré of England (see Several Chirurgical Treatises, London, 1676, fol.); and William Harvey, whose discovery of the circulation of the blood had such an influence over the advancement of surgery, that he must be classed among the principal improvers of this science. (See Exercitatio Anatomica de Motu Cordis et Sanguinis in Animalibus, Francoforti, 1655, 4to.) In Germany, Fabriicus Hildanus (Obs. et Curationum Centuria, 2 vols. 4to. 1641.) This Fabricius was far superior to the other. Scultetus, so well known for his work, entitled, "Armamentarium Chirurgicum, Ulmæ, 1653, fol." Pürmann and Solingen, who had the fault of being too partial to the use of numerous complicated instruments. See Curie Obs. Chir. Lipphiæ, 1710, 4to. Mannala Obs. der Chirurgie, Amsterdam, 1684, 4to.

Holland, restored to liberty by the generous exertions of its inhabitants, did not remain a stranger to the improvement of surgery. This nation, so singular in many respects, presents us with one particularity, which claims the notice of a medical historian. Ruyfch, who was an eminent anatomist, and merits equal celebrity for his Obs. Anatomico-Chirurg-
Surgery.

Chirurgicum Centuriae, Amsterdam, 1691, in 4to. carried with him to the grave the secret of his admirable injections. (See also his Théaur. Anat. X. 4to. Adversari-orum Anatomicorum Medicos-Chirurgorum, Decad. 3. 4to. Amsterdam.) Rohouyer, he also made a secret of his lever, which, before the invention of the forceps, was the only resource in difficult labours. Raw, who successfully cut 1500 patients for the stone, took such pains to conceal his manner of operating, that Heister and Albinus, his two most distinguished pupils, have each given a different explanation of it. Such a disposition, which was extremely hurtful to the advancement of surgical knowledge, would materially have retarded the progress of surgery in Holland, had not Camper in the following century effaced this imputation by the great number of his discoveries, and his zealous desire to make them public.

In the midst of these improvements, of which Ambroise Paré may be considered as the promoter, surgery in France languished in a most humiliated state. The accoucheur Mauriceau (Tracté des Maladies des Femmes Grosses, Paris, 1668, 4to.), Dionis (Cours d’Opérations de Chirurgie, Paris, 1707, 8vo.), Saviard (Novveau Recueil d’Obst. Chir. Paris, 1702, 12mo.), and Belboeuf (Chirur-gien d’Hospital, Paris, 1669, 8vo.) were the only French surgeons of note, and most of them conversed with 10 or 15 distinguished men of other nations. Richerand observes, that the splendid days of Lewis XIV. were an iron age for discouraged surgery. This monarch did, indeed, escape from falling a victim to a surgical disease, a fistula in ano; but he was not cured till after a great number of blundering operations and useless experiments.

According to Richerand, the reign of Lewis XIV. presents us with much pomp and ostentation, the common attributes of the early state of societies. Poetry, eloquence, painting, and all the arts of pleasure and imagination, then shone with the most vivid light. On the contrary, the 18th century exhibits the character of maturity; calculators, naturalists, and philosophers, have taken the place of orators and poets; the useful arts and sciences have triumphed over the objects of pleasure; the empire of reason has succeeded that of imagination; and far more has been done, if not for the glory, at least for the happiness, of the human race. Let us hope, says Richerand, that the commencing century may not lead us back to infancy, through decrepitude. A more stern condition is imposed with it, that in all our actions, exposed to the views of others, we are more practised in opinion, and practice, condemned by experience, would be too certain a proof of it.

Chronology teaches only the history of dates. In the study of the sciences, the only method of impressing the memory with facts, consists in connecting the epochs of them with the learned men who have illustrated them. But the greatest surgeons of the 18th century have not altered the face of their profession, although they have powerfully contributed to its advancement. In surgery, as an author has remarked, some feathers always precede brilliant lights, and it approaches perfection in a very gradual way. In the 18th century, however, amongst the distinguished surgeons of France, there are two of extraordinary genius, round whom, as it were, all the others might be grouped and arranged, and whose names deserve to be affixed to the two most splendid epochs of French surgery. These are, first, L. Petit, whole glory has been shared by the Academy of Surgery; and, secondly, the celebrated Dufour.

It is not with surgery, as with physic, strictly so called; the epochs of the latter are distinguished by hypotheses; while those of surgery are marked by discoveries. The eminent men in this last branch of the profession have not, like the most renowned physicians, created facts, built systems, destroyed those of their predecessors, and contributed to a new edifice, which in its turn has been demolished by other hands. All of them have been satisfied with combating ancient errors, discovering new facts, and continuing their art, the sphere of which they enlarged by their discoveries, without making it bend under the yoke of systems, which it would have ill supported. To this steady and uniform course, says Richerand, which is a striking proof of the superiority of surgery, and of the certainty and invariable principles of its principles, all we oppose the numerous revolutions of physic? The Christian religion, which abounds in facts, has not more than physic. "Naturals, solidites, humornites, virtutis, comites, magnos, diversos, manerios, mendios, arescites, innumeris; le plus grand nombre des medecins honore Hippocrate d’un culte presque superstitieux: ceci marchent sous les bannières de Stahl; ceux-là s’appuient du grand nom de Bœhrave; tels autres inquovet, Sydenham, Hoffmann, Stoll, abolument comme les théologes combattent pour Luther, Zuingle, Calvin, ou Jasæ."

Nofogr. Chir. tom. i.

The elegy on J. L. Petit, delivered in the midst of the Royal Academy of Surgery, of which he was one of the first and most distinguished members, represents him as a blending of the study of anatomy with his amusements when a boy; and ardent seeking every opportunity to increase his knowledge by observation. He had had experience enough to publish, at an early period of his life, his "Traité sur les Maladies des Os," Paris, 1705, 12mo.; a work, which for a century was esteemed the best upon the subject. It may be noticed, that his success was most virulently opposed by the envious critics. It was not till after more than thirty years of academical labours and extensive practice, that he was unanimously elected as the chief of his colleagues. This acknowledged superiority was the more flattering, as J. L. Petit obtained it at a period when surgery was in a flourishing state in France, and where he held no place from which he could derive an influence foreign to his personal merit. While Marechal, La Peyronie, and La Martiniere, afforded him of the royal favour, Quefayry, Morand, and Louis, who corrected his writings, made him speak a language that does honour to the famous collection to which he contributed his observations (see Memoires et Prix de l’Académie Royale de Chirurgie, 10 vols. 4to.), and in which, if we except some theoretical explanations, nothing has lost its value by age. In short, it will ever be considered as one of the most valuable collections of surgical knowledge.

J. L. Petit was also the author of a "Traité des Maladies Chirurgicales, et des Operations qui leur conviennent: Ouvrage poïthume;" a production that will always hold high in the estimation of the judicious surgeon.

The history of this epoch, so glorious for the profession of surgery, is completely detailed in the "Memoires et Prix of the Royal Academy of Surgery," a work which is absolutely indispensable, and the various parts of which cannot be too often considered. In it are preferred the labours of Le Dran, Garengereot, De La Faye, Louis, Vedier, Fouquet, Bevin, Pibrac, Fabre, Le Cat, Borda, Sabatier, Pozos, Levret, and several other practitioners, who, though less famous, have contributed by their exertions and knowledge to form this useful body of surgical facts. The preceding surgeons also distinguished themselves by other productions. Le Dran published 1. Parallèle des différentes Manières de tirer la Pierre hors de la Vesic, 1 vol. 12mo.

2. Opération
Surgery.

2. Opérations de Chirurgie, 2 vols. 12mo.
4. Traité des Plaies d'Armés à feu, 1 vol. 12mo.
5. Confutations de Chirurgie, 1 vol. 12mo.

Garegeot wrote:
1. Traité des Instrumens de Chirurgie, 2 vols. 12mo.
2. Traité des Opérations de Chirurgie, 3 vols. 12mo.

Fabre was the author of:
Recherches sur l'Art de Guérir, 1 vol. 8vo.

Le Cat wrote:
Recueil des Pièces sur l'Opération de la Taille.

Sabatier published the:
Médecine Opératoire, 3 vols. 8vo.

Puzos composéd:
Traité des Aaccouchemens, Paris, 1759, 4to.

Levet wrote:
2. Art des Aaccouchemens, démontré par les Principes de Physique, Paris, 1761, 8vo.

The foregoing list of eminent French surgeons must be added the names of La Motte, Maître-Jean, Goulard, David, Ravaton, Mejean, Pouteau, David, and Frère Cofone.

La Motte published:
2. Traité complet de Chirurgie.
Maître-Jean was the author of:
Traité des Maladies de l'Oeil, 1 vol. 4to.

Goulard wrote:
Oeuvres de Chirurgie, Liege, 1763, 2 vols. 12mo.

Ravaton composéd:
Le Chirurgien d'Armée.

Pouteau:
1. Melanges de Chirurgie, 1 vol. 8vo.
2. Œuvres posthumes, 3 vol. 8vo.

David:
Observations sur la Nécrose, Paris, 1782, 8vo.

While surgery was thus advancing in France, other nations were not neglectful of it. At this period flourished in England, Cheffelden, Douglas, the two Monros, Sharp, Cowper, Alphonan, Percival Pott, Hawkins, Smellie, and the two Hunters.

Cheffelden's Treatise on the High Operation of the Stone, London, 1723, 8vo. and his Treatise on the Anatomy of the Human Body; Douglas's tract, entitled, "Lithotomy Douglaissiana;" Sharp's Treatise of the Operations, and his Critical Enquiry into the Present State of Surgery; Monro's Works, by his Son; Alphonan's Treatise on Amputation; Pott's Chirurgical Works; Smellie's Midwifery; and John Hunter on the Blood, Inflammation, &c.; his Treatise on the Venereal Disease; Animal Economy; and all the papers written by himself and his brother are productions, which reflect the highest credit on the state of Surgery in England.

At the period when the preceding distinguished men upheld the character of their profession in Great Britain, Molinelli, Bertrand, and Mofcati, were doing the same thing in Italy. Bertrand's Treatise on the Operations of Surgery is even at this day a work of the highest repute. In Holland flourished Albinus, Deventer, and Camper; and in Germany and the north of Europe, Heister, well known for his Institutiones Chirurgiae, Platter, Roederer (Elementa Artis Obstetriciae, Goett. 1752; Obi. de Partu Laborioso, Decad. ii. 1756; Stein; Bilguer; Acrel; Calliére (Principia Systemates Chirurgiae Hodiehens, 2 vols. 8vo.) Brambilla; Thedem (Progrès ultérieurs de la Chirurgie); and Richter, Traités des Heresies, 2 vols. 8vo.; Bibliotheca de Chirurgie; Anfanggr. der Wundarzneykunst, 7 vols.; and Obi. Chirurgicarum Fali.

On the continent, the Academy of Surgery at Paris was long considered quite as the polar light of this branch of science. The French revolution, which, by a fatal abuë, involved in the same prohibition useful as well as improper societies, did not spare even this beneficial establishment. Although the academy was deprived of the talents of M. Louis, who died a short time before its suppression, it yet lived at this period, several members worthy of continuing its labours and supporting its reputation. Sabatier, Default, Chopart, Lafu, Peyrilhe, Dubois, Percy, Baudeloque, Pelletan, Sue, &c. were still remaining.

Default wrote:
1. Journal de Chirurgie, 4 vols. 8vo.
2. Œuvres Chirurgicales, recueillies par Bichat, 3 vols. 8vo.

Chopart:
Traité des Maladies des Voles urinaires, 2 vols. 8vo.

Percy:
Pirotechnie Chirurgicale, &c.

Baudeloque:
Traité des Aaccouchemens, 2 vols. in 8vo.

The Academy of Surgery in France was succeeded by what is named the Ecole de Médecine. Default, who had been almost a stranger in the former, became quite the leading character in the latter. Several things recommended him strongly to the remembrance and admiration of posterity: the exactness and method which he introduced into the study of anatomy; the ingenious apparatus which he invented for the treatment of fractures (see Surgical Plates); a noble ardour in his profession, which he knew how to impart to all his pupils; his clinical lectures upon surgery, which were the first ever delivered; and the boldness and simplicity of his modes of operating. Indeed, such was his genius, that even when he practised only methods already understood, he did them with so much adroitness, that he rather appeared to be the inventor of them. From the Ecole de Médecine have issued Boyer, Dubois, l'Héritier, Manouvy, Lallement, Petit de Lyon, Bichat, &c.

The researches of Bichat, who quitted surgery, powerfully contributed to the advancement of physiological science. His mind, richly stored with the positive facts which he had learned in the study of surgery, conceived no less a project, than that of rebuilding the whole edifice of medicine. Some courses of lectures upon the materia medica, internal clinical medicine, and morbid anatomy, announced this vast design, which was frustrated by a premature death. Bichat died in the midst of his labours, and, in dying, his greatest regret was that of not having completed them. His example, says Richerand, proves most convincingly what Boerhaave always inculcated, how indefensible the study and even the practice of surgery are to him, who would wish to be a disinterested and usefulness physician. Nologr. Chir. tom. i. p. 25.

Perhaps nothing contributed so materially to the improvement of surgical knowledge, as the establishment of the Royal Academy of Surgery in France; a noble institution, which, for a long while, gave our neighbours an infinite advantage over us, in the cultivation of this most useful profession. Indeed, every one truly interested in the improve-
improvement of surgery, cannot fail to regret the discon-
tinuance of a society, in which emulation and talents were
so long united for the benefit of mankind. The various
difficulties, published by the illustrious members of the
Academy, will serve as a perpetual memorial of the spirit,
ability, and success, with which the objects of the institu-
tion were pursued; and centuries hence, practitioners shall
reap from the pages of its memoirs the most valuable kind
of surgical information. Unfortunately, this establishment,
which was overturned by the agitation of the French re-
volution, has had only a very inferior sublimation in the
École de Santé.

Were we to name any one thing, which, in our opinion,
would have the greatest influence in giving life to the study
and cultivation of surgery in this country, we should, with-
out hesitation, assign such importance to the establishment
of an institution in the metropolis, on the same ground, liberal,
and encouraged plan, as the late Royal Academy of Sur-
gery in France. At least, why should not the theatre of the
College of Surgeons be open to all its members once a
week, and a meeting be held, under the control of a worthy
president, for the purpose of reading and discussing original
surgical essays and observations? The present Medico-
Chirurgical Society of London, truly deserve the utmost
encouragement the profession can bestow; but in a sur-
gical point of view, it might be better, were surgery alone
the particular object of their consideration. No sooner did
the Academy of Surgery change into the École de Médecine,
than a manifést falling off occurred. It is right that phy-
cicians should understand surgery, and surgeons physic;
but it does not follow, that it is therefore advantageous to
have these two subjects continually blended together.
According to our ideas, a society, exclusively formed for the
discussion of surgery, will, ceteris paribus, prove much more
useful and successful, than another which embraces every subject
whatsoever connected with medical science.

Within the last twenty or thirty years, most important
improvements have certainly been made in almost every
branch of surgery; and it must gratify every Englishman
to find, that his own countrymen have acted a very leading
part in effecting an object, in which the interests of mankind
are so deeply concerned.

Before the time of Mr. John Hunter, our ideas of the
venereal disease were surrounded with absurdities; and it is
to this luminary, that we are in an eminent degree indebted
for the increased discrimination and reason, which now prev-
vail both in the doctrines and treatment of the complaint.

Strictures in the urethra, an equally common and dis-
tressing disease, were not well treated of before Mr. Hunter
published on the venereal disease; and the advantage of
armed bougies in the treatment of certain cases, has been
subsequently pointed out by sir Everard Home.

Ruptures, those common affections in every country,
have received in modern times highly interesting elucidations
from the labours of Pott, Camper, Richter, A. Cooper,
Hey, Gimbernat, Scarpia, Lawrence, &c.

The treatment of injuries of the head has been materially
improved by Quefnay, Le Dran, Pott, Hill, Aber-

nethy, &c.

The disease of the vertebra, which occasions paralysis
of the limbs, formerly always baffled the practitioner; but
the method proposed by Mr. Pott, is now frequently pro-
ductive of considerable relief, and sometimes of a perfect
cure.

The mode of treating lumbar abscesses has been rendered
much more successful than formerly, and for this change,
the world is indebted to Mr. Abernethy.

The almost infallible plan of curing hydroceles by an in-
jection, as described by Sir James Earle, may also be em-
owered amongst the recent improvements.

The increasing aversion to the employment of the gortex
in lithotomy, and the many distinguished advocates for the
ute of better instruments in this operation, may be hailed
as propitious omens of beneficial changes in this part of
practice.

In the treatment of united fractures, the simple un-
ingenuous practice proposed by Dr. Phyfie of Philadelphia,
merits particular notice; not only on account of the se-
veral successful trials which have been made of it in his
country and France (see Medico-Chir. Trans. vols. i.
and viii. and Boyer's Traité des Maladies Chir.,) but also
because it is perhaps the first improvement that has hitherto
been made in the practice of surgery by our transatlantic
brethren.

The indefatigable treatise of Dr. Jones on hæmorrhage,
has now produced quite a revolution in all the principles
by which the surgeon is guided in the employment of the lig-
ure for the formation of fluctuations, the removal of scrotal.
Instead of thick clumsy cords, small firm filks, or threads, we
now generally used; and so far is the practitioners from being
scared of tying arteries too tightly, left the ligature on
through them, that it is now a particular object with him to
apply the silk, or thread, with a certain degree of force, a
order that the inner coat of the vesse1 may be divided. If it
be not done, the effusion of coagulating lymph within the
artery, an important part of the process of obliteration,
cannot be expected as a matter of certainty, and secondary
hæmorrhage is more likely to occur. But in order to con-
vay an adequate idea of the beneficial changes which Dr.
Jones's observations are tending to produce in practice,
we have been careful in the article Hæmorrhage, to give a
tolerably full account of the results of all his interesting
experiments.

Besides using very small, firm, round threads, instead of
large, flat tapes, or cords, as was the custom a few years
ago, modern surgeons begin to use filks, that much better
may also arise from cutting off both portions of the ligur-
there to the knot, as to the removal of the breast, &c.
No one has infused so much as Mr. Lawrence
upon the propriety of examining further the merits of this
innovation. If no bad effects result from leaving so small
a filk by the knot, and noose on the artery, the
practice will form a considerable improvement. The
wound may then be brought together at every point; the quantity
of extraneous matter in the wound will be lessened to about
nothing; the danger of convulsive affection will be least
in proportion as a serious cause of pain and irritation is
diminished; and the chance of accomplishing perfect union
by the first intention, will be materially increased. Mr.
Lawrence has tried the plan in many instances, and his ex-
hperience has not detected any ill consequences whatever,
while it has proved, that many advantages are undoubtedly
the result of it. The method has been practised by many
of our military surgeons; and although they have proba-

bly not employed exactly such ligatures as this mode
absolutely requires, the greater part of them have met with
hardly any instances of future trouble from the bits of ligur-
ture enclosed in the wound. However, if large ligatures
be used, the practice is not fairly tried, or rather the practice
is not tried at all; because the great principle on which it
answers, is the very small atom of filk composing the extr-
aneous substance left in the wound, when such ligatures
as Mr. Lawrence particularly recommends are employed.

M. Delpech.
SURGERY.

M. Delpech, of Montpellier, and M. Roux, of Paris, have also sometimes adopted the new plan of removing the ends of the ligature close to the knot. See Parallèle de la Chir. Angloise avec la Chir. Françoise, p. 135.

Among other real improvements in modern practice, we must not forget the present more rational method of dressing the wound, after the majority of capital operations, with light cooling applications, instead of laying on the part a farrago of irritating pledgets and plasters, and a cumber-some mass of lint, tow, flannel, and other bandages, woollen caps, &c.,

The fewer the adhesive strips are the better, if they only hold the lips of the wound together. This is all they are intended to do. Whereas, if you apply more than are necessary for this purpose, they do harm, by heating the part, and covering the wound so entirely, as to prevent the diffusion of the discharge. Over the adhesive plasters, let the surgeon be content with placing a single pledge of spermaceti cerate, and some linen wet with cold water, which will often avert hurtful degrees of pain and inflammation, by keeping the parts cool.

Wars, which are unfavourable to most other sciences, are rather conducive to advances in surgery. The many new and interesting observations which M. Larrey has made in the course of his long and extensive military experience, are a proof of what we have been remarking. Ambroise Paré and General Windmill, the majority of whom are at the service of the army. To M. Larrey, we are indebted for many highly important observations relating to amputation in cases of gunshot wounds. In particular, he has added a larger and more convincing body of evidence, than was ever before collected, to prove, that in gunshot injuries, the operation of amputation should always be performed without the least delay, in every instance in which such operation is judged to be unavoidable, and the ultimate preservation of the limb either impossible, or beyond the scope of all rational probability. He has established the truth of this most important precept in military surgery by innumerable facts, drawn chiefly from his own ample experience, and partly from the practice of many able colleagues. The great operations of the shoulder-joint and hip-joint amputations, he has executed with success. The necessity for the former, however, he proves may sometimes be superceded, and the limb be saved, by making a suitable incision for the extraction of the splintered portions of the upper part of the humerus. This method, which was in many instances done with success in the peninsular war, was, we believe, originally proposed and practised by M. Boucher. (See Mem. de l'Acad. de chir. tom. ii. 410.) It was, however, more particularly described and even practised by Mr. C. White, of Manchester. (See his Caeae in Surgery.) Lately, it has been repeated with success by Mr. Morell, in the York hospital. See Medico-Chir. Trans. vol. viii.

Amputation at the hip-joint, performed only in the most dreadful cases, because it is itself the most dreadful operation in surgery, M. Larrey has performed five times, and twice with complete success. The method adopted by Mr. Browning, staff-surgeon, and Mr. Guthrie, deputy inspector of military hospitals, who in this way effected two recoveries. All these gentlemen, however, have had failures, and their successful attempts bear only a small proportion to the large number of deaths known to have followed amputation at the hip, in the many cases in which it has now been undertaken. We have no doubt, on the whole, that examples do occur, in which this severe operation is only means affording a chance of life; but we deem the chance so small, that it is to be hoped no surgeon will perform it, except under the authority of the united opinion of a board, or consultation of the best informed practitioners, whom circumstances will allow to assemble.

In the treatment of aneurismal diseases, English surgeons have much to be proud of. All the boldest operations are here the fruit of the spirit and skill with which this interesting part of surgery has been followed up in this country. The carotid artery, the external and internal iliac, and the subclavian, have all been successfully tied by British practitioners. We shall touch upon this subject, however, again in the sequel of this article. Scarpas' book on Aneurism, and Hodgson's Treatise on the Diseases of Arteries, merit the attention of every surgeon, as containing all that is at present known relative to this difficult and important branch of surgery.

The diseases of the eye, to which affections English surgeons seem to pay much less attention than was bestowed by foreign practitioners, now obtain due attention in this country. Although we have generally had some distinguished oculists, our surgeons at large have been wonderfully ignorant of this part of their profession, and uninformed in the subject, they have given up to professional oculists and quacks one of the most lucrative and agreeable branches of practice. However, the able writings of Daviau, Bevan, and Waire, begin to make the most of the specialty known among practitioners; and the observations of Scarpa, Richter, Wardrop, Saunders, &c. will soon have immense effect in diffusing in the profession, a due knowledge of the numerous diseases to which the organs of vision are liable.

As the practice of Mr. Saunders was unknown at the time when the article Cataract was -infected in this Cyclopaedia, we conceive that some account of it in this place may very well be introduced.

In the majority of cases of congenital cataract, after the lens has been converted into an opaque substance, it is gradually absorbed; and, in proportion as such absorption proceeds, the anterior and posterior layers of the capsule become approximated, and at length form one membrane, which is white, opaque, and very elastic. Among the exceptions to this order of events, is to be noticed a form of the congenital cataract, in which the centre of the lens is opaque, while the circumference is perfectly transparent. In such a case, the lens remains of its natural size, as long as its circumference preserves its transparency; but as soon as the capsule and lens are penetrated, even with the minutest instrument, the opacity spreads with rapidity. From this period, the bulk of the lens is diminished, with more or less celerity, according to the manner in which the wound has been made.

Congenital cataracts not only frequently attack children of the same parents; but, in this circumstance, are often precisely of a resembling constitution and nature. The lens may be either solid, soft, or fluid; but, more commonly, it is partially, or completely absorbed, and the cataract is capsular. Children, thus affected, partake of various degrees of organic changes. Some see external objects indistinctly; others can discern only bright colours, or vivid lights. If the blindingness is nearly complete, as the eyes are not attracted by any external objects, volition is not exercised over their muscles, their actions are not associated, and they roll about with rapidity, and tremble as they move.

In operating upon infants, Mr. Saunders used to overcome every difficulty by fixing the eye-ball with Feller's elevator; controuling the little patients by forceps, dilating the pupil with the belladonna; and employing a slender...
a slender needle, armed with a cutting edge from its shoulders to its point, and thin enough to penetrate with the utmost ease.

The extract of belladonna, diluted with water to the consistency of cream, was dropped into the eye; or, to avoid irritation, the extract itself was smeared over the eyelid and eyebrow. In about half an hour, and seldom later than an hour, the pupil is fully dilated, and the application must then be washed from the appendages of the eye. The child is now to be put on a table, parallel to a window, from which the eye, about to be operated upon, is farthest. Four assistants, and, when the child is stout, five, are required to confine it. The surgeon is to fit upon a high chair, behind the patient, with Pellier’s elevator in his left hand, and Mr. Saunders’s needle in his right, if it is the right eye on which the operation is to be done; or with the first instrument in his right hand, and the second in his left, if the operation is to be performed on the left eye.

Here it is necessary to state, that Mr. Saunders used to practise two operations; one is called anterior, in which the needle is introduced into the eye in front of the iris; the other posterior, the needle being introduced behind the latter membrane.

When the capsule contained an opaque lens, Mr. Saunders used gently to introduce the bow of Pellier’s elevator under the capsule, and then the needle, to a depth of the lower one. At the moment when he was about to pierce the cornea, he fixed the eye by making moderate pressure on it with the elevator. Such pressure was immediately discontinued, as soon as it was no longer needed. Mr. Saunders used to pierce the cornea, as near its junction with the sclerotics, as would allow the flat surface of the needle to pass in a direction parallel and close to the iris, without injuring this membrane. When the point of the needle had arrived at the centre of the dilated pupil, Mr. Saunders did not boldly plunge it through the capsule in the lens, nor perform any depressing motion. It was a material object with him, not to injure the vitreous humour, nor its capsule. Neither did he draw the capsule of the lens, with the point of the needle, towards the pupil; for it was an important part of his plan to avoid displacing the lens. On the contrary, he proceeded with a gentle lateral motion, working, with the point and shoulders of the needle, only on the surface and centre of the capsule, to an extent that did not exceed the natural size of the pupil. His purpose was to accomplish a permanent depression of this central portion of the capsule, and a simple puncture of it would not have answered the design. His next proceeding was to sink the needle gently into the body of the lens, and moderately open its texture.

Any inflammatory symptoms after the operation were opposed by the application of leeches, or even general bleeding. The extract of belladonna was also applied to the eyebrow, in order to keep the pupil dilated, and its edge out of danger of becoming adherent to the wounded capsule.

A simple operation sometimes sufficed, nature producing a disfollution and absorption of the opaque lens. On other occasions, one or more repetitions were necessary, an interval of at least a fortnight being always suffered to elapse between every two operations.

Fluid cataracts of the congenital kind are the least common, and when these cases are met with, the surgeon, after puncturing the capsule, and letting its contents mix with the aqueous humour, is to do no more for the present, but take the requisite steps for averting inflammation. The cæafe is thus changed into a capsular cataract.

When the capsule was opaque, the lens having been nearly, or quite absorbed, the practice of Mr. Saunders authorized a freer employment of the needle; though in the manner already detailed. When any portion of the lens remained, as a small nucleus in the centre of the capsule, his efforts were exclusively directed to the detachment of this portion, in order to effect a permanent aperture in the centre of the capsule. When this membrane alone prevented itself, his main plan was to form an opening in the middle of it.

When Mr. Saunders practised his posterior operation, for a capsule containing an opaque lens, he introduced the needle, in the common way, through the sclerotics. He then gently depressed its handle, so as to direct its point towards the capsule, through the thin edge of the lens; and, pushing the flat surface of the instrument between the capsule and the lens, he carried it as far as the centre of that membrane. Here he opened the capsule, taking care not to tear it extensively, lest he should dislocate the lens. He then cautiously opened the texture of the lens, and withdrew the needle. In repeating the operation, his aim was to complete the central opening in the capsule, and look to the texture of the lens. Small flecks were allowed to fall into the anterior chamber; but he endeavoured to avoid forming large fragments either.

When the posterior operation was done, and the eye was an opaque capsule, the lens having been nearly, or quite absorbed, the needle was introduced in a direction obliquely backward, in order to avoid the iris, which, in consequence of the absorption of the lens, was liable to be situated further backward. Any remnant of the lens was set detached; and then the same manœuvre were adopted, as in the anterior operation or capsular cæafes. The capsule was often so yielding, that a backward or depressing motion of the needle was sometimes necessary to rend its centre. It appears, that Mr. Saunders finally gave a preference to the anterior operation, which inflicted lighter injury on the eye, did not disturb the ciliary processes, or vitreous humour, and was less apt to excite inflammation.

The success of this gentleman’s practice may be conceived, when it is known, that of fifty patients, he relieved fifty-two to fight by his mode of operating. He operated both on infants and adults. It is observed, also, that his attempts were most successful in children between the age of eighteen months and four years.

In the modern practice of surgery, a variety of old prejudices are gradually vanishing. Peruvian bark, not many years ago, was regarded as a sovereign remedy and pledge for nearly all cases of gangrene; and in thefe and other infirmities was prescribed without any discrimination, and in doses beyond all moderation. But the false idea the this medicine has any specific effect in checking mortitude, no longer blinds the senses even of the ordinary practitioner. He neither believes this doctrine, nor the still more absurd opinion,
Surgery.

opinion, that strength can be mysteriously extracted from this vegetable substance, and communicated to the human constitution in proportion to the quantity which can be made to remain in the stomach. This subject, however, we have duly discussed in the article GANGRENE. The authority of a very distinguished professor may be added to what has there been urged upon this important topic. "I think," says Dr. John Thomson, "I have frequently seen it (bark) prove hurtful when administered in cases of mortification, by loading the stomach of the patient, creating a dislike to food, and sometimes by exciting an obstinate diarrhoea. I believe it to be, in mortification, a medicine completely inert and inefficacious." Lectures on Inflammation, P. 153.

The removal of this deeply-rooted prejudice concerning the virtues of bark in floribund mortification, will pave the way to better and more successful practice.

But upon the subject of mortification, the present day opens to us the investigation of a point which is of the first-rate consequence. Every surgeon is aware, that when a limb is feased with mortification, amputation is sometimes absolutely necessary to effect a cure. This is generally acknowledged; but the performance of the operation has, since the time of Mr. Port, only been fashioned when the mortification has manifestly ceased to spread, and a line of separation has formed between the dead and living parts.

All other inferences, in which the disorder was in a spreading state, were left to their fate. It is true, some of the old surgeons occasionally ventured to deviate from this precept; but as they did so without any discrimination, or knowledge of the particular examples which ought to form an exception to the general rule, their ill success cannot constitute a just argument against the plan of amputating earlier in a certain description of cases.

Now if modern experience can prove that many lives may be saved by a timely performance of amputation under circumstances in which it has until lately been generally condemned, we must allow that the established innovation will be one of the greatest improvements in the practice of the present time.

For reviving the consideration of this question, and venturing to deviate from the beaten path, the world is much indebted to that eminent military surgeon, M. Larrey. How different his doctrines and practice are from those usually taught by surgeons, the following extract from his writings will sufficiently prove.

"Writers on gangrene, or phæclus of the extremities," observes M. Larrey, "indiscriminately recommend the amputation of a phæclated limb never to be undertaken before the mortification is bounded or limited by a reddish circle, forming a true line of separation between the dead and living parts. This circumstance can only occur in a case of spontaneous gangrene from an internal cause; or if it happens, as is very unusual, in a case arising from a wound, its progress is different, and it would be exceedingly imprudent to wait for it. "The gangrene from external injuries almost always continues to spread; the infection becomes general; and the patient dies." (Larrey in Mem. de Chirurgie Militaire, tom. iii. p. 142.) On the other hand, this author affirms, that, in the dry or spontaneous gangrene, absorption takes place with more difficulty, and it is not uncommon to see the phæclated parts separate from the living ones by the powers of nature alone, without the general functions being impaired. He argues, that there is a manifest difference between what he terms the traumatic, and the spontaneous gangrene, or, in other words, between the humili gangrene from an external cause, and the dry gangrene, which ordinarily proceeds from an internal cause.

In cases of mortification arising from external injuries, M. Larrey maintains, that, "notwithstanding anything that writers and practitioners may allege to the contrary, we should not hesitate about promptly performing amputation, as soon as the necessity for the operation is distinctly established. There is no reason to apprehend that the stump will be feased with gangrene, as in the spontaneous mortification, that has not ceased to spread, because the traumatic gangrene, after having arisen from a local cause, is only propagated by absorption, and a successive affection of the texture of parts by continuity of the vessels. Amputation, performed in a proper situation, stops the progress and fatal consequences of the disorder.

"Supposing then the lower half of the leg should be affected with phæclus, in consequence of a gun-shot injury, attended with a violent contusion of the part, and a forcible concussion of the vessels, nerves, and ligaments, if the skin is elsewhere uninjured, the operation may be done in the place of election, without any fear of the stump becoming gangrenous, notwithstanding the cellular membrane of the upper part of the member may be already affected. But when the skin of the whole leg is struck with mortification, the operation must be done on the thigh, and no part should be lost. The same practice is applicable to the upper extremities. We must be careful not to mistake a limb affected with tæpor for one that is actually phæclated. In the first case, warmth, motion, and sensibility are still retained, although the skin may be blackish, and the parts may be swollen. Besides, if there were any doubt, it would be proper to try at first tonic repellent applications, and cordial medicines, &c." Larrey in Mem. de Chirurgie Militaire, tom. iii. p. 152, 153.

When amputation has been practised, this author recommends the exhibition of bark, good wine, tonics, &c. in order to promote the good effects of the operation. P. 154.

"The facts," says M. Larrey, "which I shall relate in the course of this dissertation, will prove, I think, in an incontrovertible manner, the truth of the principle which I lay down, that, "when gangrene is the result of a mechanical cause, and puts the patient's life in danger, amputation ought to be performed, without waiting until the disorder has acquired a tendency to spread."

"I have been a witness of the death of several individuals, from too rigorous an adherence to the contrary precept; and at length grievously impressed with this loss, I had long ago determined to depart from an axiom which was always considered by me as false. Besides, following the maxim of Celsus, I preferred employing an uncertain remedy, rather than abandon the patient, to an inevitable death. "Satius effem animae auxilium experi quam nullum."

"I made the first attempt at Toulon, in the year 1796, upon a soldier, who, in consequence of a violent contusion of the foot, was afflicted with a gangrenous ulcer, which soon threw the whole limb into a phæclaked state. While the mortification was yet spreading, I resolved to amputate the leg. The success of the operation surpassed my expectations; the stump healed; and, in less than forty-five days, the patient got quite well. This case served to encourage me.

"During the siege of Alexandria, in Egypt, in 1801, a second case, very analogous to the preceding, occurred in my practice; it happened in a dragoon of the 15th regiment, whose fore-arm and afterwards phæclated, in
consequence of a gun-shot wound in the articularization of the left arm. The mortification had extended nearly as high as the shoulder, and the patient's life was in great danger, when I determined to amputate the limb at the shoulder-joint. The disorder was manifestly spreading, and the patient's brain already affected, for he had symptoms of ataxia: the operation, however, arrested the progress of the spreading, and saved the patient's life, who, at the conclusion of the disease of Alzheim, was quite cured.

"After the taking of Ulm, M. Ivan, surgeon to his majesty the emperor, performed in my presence, and at my ambulance established at Elchingen, the amputation of the thigh of a soldiery belonging to the 76th regiment of the line, the leg having fphacelated, in consequence of a gun-shot injury. The gangrene was not limited, and evidently continued to extend itself; notwithstanding this, the effects of the infection were destroyed, and the patient was quite cured on our return to Aufterlitz.

"A fourth patient, an officer in the fame regiment, foot in the ankle, at the capture of the fame town, was conveyed to my ambulance, in order to be dressed: it was the third day after the accident; the foot was gangrenous, and the leg was swelled, and threatened likewise with infection. Febre symptoms had also come on. I hastened to amputate the leg a little above the place of mortification. The cellular membrane of the stump, of a yellow blackish colour, was already infected with the gangrenous principle, (as M. Larrey terms it.) The operation, however, stopped the progress of the mischief; suppuration took place in the stump; some fluid was collected; the wound as it had a cleaner appearance; and cicatrisation was completed on the 5th day. The patient could already walk with a wooden leg, when he caught the hospital fever, which was epidemic at Ulm, where he awaited his regiment, and, to my great regret, he was carried off by this disease, after having escaped the former danger.

"After the battles of Aufterlitz and Jena, (continues M. Larrey,) several of my colleagues, surgeons of the frst class, undertook, in consequence of my advice, and the example of the French, with which I had accosted them, the amputation of limbs equally fphacelated, although the mortification was not limited, rather than abandon the patients to a death which appeared inevitable. In general, these practitioners experienced the fame success as I did myself." Larrey, in Mem. de Chirurgie Militaire, tom. iii. p. 154.

In M. Larrey's memoir upon this subject, there are some additional facts and arguments in favour of what he endeavours to prove, viz. that in cases of mortification from external injuries, if the patient's life is in danger, amputation ought to be performed, although the mortification may yet be in a spreading state. We must be content, however, with having stated the particulars already explained; and the reader desirous of more, must refer to M. Larrey's own publication. Certainly, the facts which this gentleman has adduced are highly important: they tend to subvert a doctrine, and to prove the error of a practice, which have been urged in most forcible terms by all the distinguished surgeons of modern time. The sentiments of Mr. Sharp are rendered questionable; and the truth of the positive assertions of Mr. Pott is yet a matter to be examined. The latter, it is well known, tells us, that he has often seen the experiment made of amputating while a mortification was spreading, but never knew it answer. Are we to conclude, that all these cases which Pott alludes to, were mortifications from an internal cause? Or are we to suppose that the operations failed from having been delayed too long? Or must we imagine that the nature of the human constitutions has been changed between the era of Mr. Pott and that of M. Larrey? The last gentleman's facts are too well substantiated to admit of being disbelieved.

Mr. Lawrence, ever ready to give every laudable proposal the fairest trial, undertook amputation at the shoulder-joint in a spreading mortification of the arm, in consequence of external violence, and was quite successful. He had the pleasure of seeing his patient recover in the most favourable manner. See Medico-Chirurg. Trans. vol. vi. p. 184.

"The issue of the preceding case," says this gentleman, "clearly proves, that that humid kind of gangrene which occurs in a healthy subject from severe local injuries, which rapidly affects, or rather infects, a whole limb, and reaches the trunk in a few hours, must constitute one of the exceptions to the maxim of not amputating till the mortification has actually stopped. It may, indeed," says Mr. Lawrence, "be slated generally, that the operation, even if painful should be deemed hazardous, offers the only chance of life; and that without it, the patient's fate is certain. I would not be underfoot as meaning to recommend the practice in all instances of mortification from local injury. I can conceive that a gangrene may arise, in an unfounded constitution, from a comparatively slight accident, to that it may be regarded as the result of constitutional disposition, rather than of the local cause. Amputation, would be hopeless under such circumstances. I have in view the mortification following a very severe injury, in a subject otherwise healthy." Lawrence in Medico-Chirurg. Trans. 1809.

This gentleman has also mentioned another successful example of amputation, while a mortification from a wound was in a spreading condition.

The writer of this article was consulted, only a day or two ago, whether amputation was proper under the following circumstances. A matter glistening, a strong man, about forty years of age, slipped down a ladder with his feet forward. When he had descended some yards, the end of a spear-shaped iron railing came into violent contact with his arm, at the elbow, where it lacerated the skin, though not extensively, and wounded the brachial artery. Two hospital pupils, who happened to be in the street where the accident occurred, immediately secured the wound. The patient was conveyed home, and treated as the antiphlogistic regimen. In the course of thirty hours, however, the limb became gangrenous, being affected with considerable oedema, livid discoloration, and a large phlyctena on the fore-arm. The patient's countenance was beginning to put on a cadaverous appearance; his pulse was small and rapid, not less than 120, and irregular; and he was covered with profuse perspirations. He was also affected with a remarkable degree of fluoror, which made him seem to forget even his nearest friends and relations. As the mortification arose from great external violence, and the shoulder was not yet gangrenous, the author of this article concided in the propriety of attempting to save the man's life by amputation at the shoulder-joint, which was done without delay. He cannot at present state the result; but the patient bore the operation well, and what is particularly worthy of remark, the fluoror appeared to leave him the moment the limb was removed; for he immediately recognized his wife, and entered into rational conversation with his friends. In the evening after the operation his pulse was ten strokes less in a minute, and somewhat stronger; and he was in no particular pain. Indeed, there was every reason to expect that the case would end well. Since
Since the article Aneurism was written, many interesting observations have been published, and the boldness, skill, and success, with which operations are now performed in this country for the cure of that disease, are such as astonish and even stagger the belief of the French and other continental surgeons. We therefore propose to conclude this article with a few remarks, explaining some particulars which have not had a previous opportunity of laying before the reader.

Internal aneurisms have generally been considered beyond the reach of surgery. Debilitating remedies, abstinence, a salt diet, occasional bleedings, and the avoidance of all exertion, have been the means commonly recommended, rather with an expectation of retarding the disease, than of effecting a cure. The facts, however, which modern experience has added in favour of the efficacy of a treatment first proposed by the celebrated Valisalva, are certainly such as to justify a confident belief, that many internal aneurisms, even though large and much advanced, are capable of palliation, reduction, and cure. The cases recently published by M. Pelletan, surgeon to the Hotel Dieu, at Paris, furnish the most convincing evidence, that vaft aneurisms of the aorta, so large as to project through the abridged part of the ribs and sternum, may sometimes in a very moderate time be reduced and cured by Valisalva's method. This chiefly consists in bleeding the patient largely and repeatedly; in allowing only the most spare diet, nothing in fact but broth and acid drinks; in applying ice, or compresses wet with a cold lotion of vinegar and water, to the swelling; and, lastly, in enjoining a strict observance of silence and quietude. The quantity of blood that has been taken away in these cases is really astonishing; some of the patients, for the first few days of the treatment, have been bled several times a day. Besides aortic aneurisms, M. Pelletan effectuated the cure of a subclavian aneurism by pursuing Valisalva's treatment. See Clinique Chirurgicale, par J. P. Pelletan, tom. i. Mem. fur les Aneurismes internes, Paris, 1813.

But external aneurisms are the cases, in which the power and utility of surgery are strikingly displayed, and for which its aid is commonly demanded. With respect to these cases, we must notice, that they do sometimes undergo a spontaneous cure, in consequence of the artery affected becoming impervious, and no longer communicating with the cavity of the aneurismal sac. This beneficial change may be the effect of the preffure of the swelling itself on the vessel. It is sometimes produced by the skilful employment of compression. But there is another mode, in which a spontaneous cure of external aneurisms sometimes happens: When the tumour has become large and tense, it suddenly falls into an inflamed and gangrenous state, and the inflammation extending its effects to a sufficient depth, the artery, where it communicates with the aneurismal sac, is rendered impervious. At length the mortified parts, together with the mass of blood in the tumour, are cast off, and, if the patient's constitution holds out, a cure ensues. We have known an instance of an axillary aneurism getting well spontaneously without any inflammation or lancing. We have seen an inguinal aneurism, under Mr. Albert, get well by the tumour mortifying; and the inflammation extending to the artery. Whenever the lancing and inflammation are only superficial, and confined to the skin and sac, the patient bleeds to death on the detachment of the mortified part. But notwithstanding some patients are fortunate enough to have a spontaneous cure, this event is too rare to sanction much expectation of it, or to justify a surgeon in withholding his assistance.

Setting out of the question Valisalva's method, the ordinary principle on which aneurisms are cured, consists in preventing the entrance of fresh blood into the aneurismal sac; for when this is effectually accomplished, the blood already contained in the sac is gradually absorbed, and the tumour diminishes in proportion.

This object, as we have observed, may sometimes be fulfilled by a skilful application of pressure, provided the aneurism be small, and the whole of its contents can be made to recede: However, though it is generally proper to try preffure in the early stage of the disease, it cannot be said, that such practice is attended with much success. If the communication between the aneurismal sac and artery does not become obliterated in consequence of this means before the end of a fortnight, there is no great reason to expect that it will do so in a longer time. The inanities recorded of aneurisms being cured by a long perseverance in preffure, are probably cases which would naturally have got well without this means.

We shall not repeat a description of the mode of operating for the common popliteal aneurism. There is one remark, however, recently made by professor Scarpas, which we conceive to merit particular notice. He advises surgeons to make the incision in the upper third of the thigh, or a little higher than the situation which Mr. Hunter chose. His reasons for this are, to avoid the necessity of removing the sartorial muscles too much from its position, or of turning it back for the purpose of exposing the artery and tying it. The bell-shaped, even professed anatomists, are frequently embarrassed by having the sartorial muscles immediately in their way, after they cut through the skin. Also, as the artery is more superficial higher up, and lets likely to be in a morbid state, there is every consideration in favour of this part of Scarpas's practice.

Mr. Abernethy has rendered surgeons more confident in the success of operations for popliteal aneurism, by his bold, yet judicious attempts to cure aneurisms situated in the groin. Several times has he tied the external iliac artery, and effectually that the inoculations, even in this high situation, are quite sufficient for conveying a due quantity of blood into the limb below. By one of these attempts, he preferred the life of a peron, who, without the operation, would certainly have been hurried into the grave in a very short time by the rupture of the tumour. Similar operations have since been performed with the most successful consequences by Mr. Freer and Mr. Tomlinson, of Birmingham, Mr. Atley Cooper, Mr. Lawrence; and by several other surgeons in Ireland, France, and America.

The plan of doing it is simple, and consists in making an incision, about three inches in length, through the integuments of the abdomen, a little above Poupart's ligament, and half an inch on the outside of the abdominal ring, in order to avoid the epigastric artery. The aponeurosis of the external oblique muscle is then to be divided in the direction of the wound. The lower margin of the internal oblique and transverse muscles is also to be cut with a crooked bistoury. The finger may then be passed under the peritoneum, by the side of the psoas muscle, so as to touch the artery. A double ligature is to be carried under the vessel, and tied as in the operation for the popliteal aneurism, tightly enough to divide the inner coats of the artery.

The several operations, in which the external iliac artery has been tied, all tend to prove how sure the limb is of having an adequate supply of blood through the anastomosing vessels. The cases might almost warrant the conclusion, that the limb is in no more danger of mortifying on
Surgery.

This account, when the artery is tied above Poupart's ligament, than when tied low down in the thigh. No doubt, still greater success would follow such operations, if they were generally undertaken at an earlier period, before the tumours have become very large, and the health impaired by confinement. The fact, that the anatomomies are always fully adequate to carry on the circulation in the limb, being now well established, there is no excuse for delaying the operation, for the purpose of affording time for the dilatation of the anastomosing vessels. The first day after the operation afforded hopes of a cure; and the circulation in the fore-arm was returning; but a difficulty of breathing afterwards came on, the limb mortified, and the patient died on the fifth day. Doubtless this patient would have had a much better chance of preservation, had the operation been performed earlier, before a tendency to mortification began in the arm, and had the wound been closed with flichting-plaster, according to the most approved principles. At the same time, it must be confessed, that diffused false aneurisms are the most dangerous of all those which admit of observation, particularly when the arteries interposed are of large size. The injection of an enormous quantity of blood into the cellular texture, proves both an impediment to the free circulation in the limb, and a frequent cause of gangreneous symptoms, in addition to the obstructions to the passage of the blood through the main artery, occasioned by the ligature.

It appears that Mr. Keate has also tied the axillary artery by cutting below the clavicle. The ligature, however, which was passed with a needle, did not include the vessel by itself, as is most desirable. This operation proved entirely successful. See Med. Rev. and Mag. for 1801.

Mr. Pelletan, in 1786, had under his care a man, in the Hospice du Collège de Chirurgie at Paris, who was afflicted with an axillary aneurism, which had existed two years. The swelling occupied the whole axilla, advanced under the great pectoral muscle, and descended even below the nipple, while, behind, it pushed back the humerus, and appeared engaged under the front edge of the deltoid muscle. But, on the shoulder being raised, a considerable space was left without any aneurism. The true manner in which the artery could be felt under this bone, when the shoulder was elevated, and the case with which pressure on the vessel sufficed for stopping the pulsation of the swelling, seem to have induced Pelletan to think of operating. He was further encouraged by considering that the branches given off by the subclavian artery were numerous, as well as their communications with the branches arising from the axillary and brachial trunks.

Pelletan had made up his mind to divide the integuments below the clavicle the whole length of that bone, and, after passing a directeur under the clavicular portion of the pectoral muscle, to detach this part from the whole of its connection with the preceding bone. Thus he intended to have exposed the axillary artery, so as to have been able to apply a ligature to it. Unfortunately, some other surgeons, called into consultation, objected to the project of dividing the pectoral muscle; and Pelletan was foiled, after making in vain a deep and hazardous thrust with the needle, in the hope of being able to include the artery. The patient was afterwards feigned with inflammation and pain in his chest, and died on the twentieth day from the operation. Cliniques Chir. par J. P. Pelletan, tom. ii. p. 49.

In a periodical work, we find brief mention made of another case, in which the subclavian was tied on account of an axillary aneurism. The mode of operating is not stated; the object is said to have been easily accomplished; but the
Surgery.

In the whole, perhaps, the method adopted by Defaut is the safest, when the operation is to be attempted below the clavicle. There is another mode, however, which seems practicable.

An incision about three inches long, might be made through the integuments, a little below the clavicle, and immediately over the hollow between the deltoid and pectoral muscles. The axillary vein lies before the artery, and as a wound of it would probably be fatal, the utmost caution must be observed in the division. Care must also be taken not to mistake one of the cervical nerves for the artery. With an eye probe, a ligature is to be put under the vessel, as soon as it is distinctly ascertaind to be such, and the vein and any adjacent nerve should be carefully excluded. No man ought to undertake this operation, who is not a steady operator, and is not well acquainted with the anatomy of the parts. If the aneurismal tumour, however, should extend far inward, toward the sternum, this plan of operating would not be practicable.

Thus far of the mode of tying the axillary artery by cutting below the clavicle. When the aneurismal tumour extends far inward towards the sternum, the only place where the subclavian artery can be taken up, is just where it emerges from the chest, from behind the anterior scalene muscle, and the object can only be effected by cutting above the clavicle. On a dead subject, having no large aneurismal swelling, such an operation is much easier than on a living person, whose clavicle is pushed up by a vast tumour, so as to increase the distance between the artery and the wound in the skin. The most interesting example of this operation lately occurred in St. Bartholomew's hospital.

Mr. Ramden made a transverse incision, about two inches and a half in length, along and upon the upper edge of the clavicle. The cut was begun on the side towards the shoulder, and ended about half an inch from the outer edge of the sterno-clido-mastoideus muscle. This incision divided one small artery, which was immediately secured. The skin above the clavicle was then pinched up, and divided from within outwards and upwards, in the line of the external edge of the sterno-clido-mastoideus muscle, to the extent of two inches. The shoulder was now lowered, and the edge of the anterior scalene muscle exposed. The artery was then distinctly felt, presenting itself from between the scaleni, and it was detached with the finger-nail, in order that the ligature might be passed round it. Here some considerable difficulty arose, as Mr. Ramden was not provided with any kind of aneurismal needles that would allow their points to be brought up again, in the very short curvature which the narrowness of the space between the rib and the clavicle afforded. Though the ligature could be conveyed under the artery, it could not be got round the vessel. At length, a probe of duck's metal was got under the artery, and by this means a ligature was drawn under the vessel. The usual knot was then made. This patient lived five days after the operation, and, on division, nothing but the artery was included in the ligature. This case fully proved, first, that the arm may be duly nourished with blood, and suffer no diminution of its temperature, though the subclavian artery is tied immediately it comes out of the chest. Secondly, it proved, that an artery so near the heart as the subclavian, may be rendered impervious by the ligature, as, on division, this vessel, where the cord was applied, was nearly divided through, while the two ends were found coagulated and closed. See Obs. on Sclerocele, &c. by T. Ramden.

The judgment that we formed from the observation of this case, was, that in all probability a complete cure would have taken place, had the man chanced to submit to the operation before the tumour began to slough, and before the health was materially impaired; and had the operation itself been shortened and facilitated by the affixation of the needles represented in Mr. Ramden's publication.

These instruments undoubtedly resemble, in principle, Defaut's sanguine a retors, which consisted of a silver sheath, one end of which was straight, and the other curved in a semi-circular way. This sheath enclosed an elastic wire, one end of which projected a little beyond the bent end of the sheath, and had a transverse eye in it, for the reception of the ligature. The instrument being introduced under the artery, the sheath was kept fixed, while the elastic wire was pulled through it, till the transverse eye had ascended sufficiently to let the surgeon take hold of the ligature. This being disengaged from the instrument, the latter was withdrawn. The needle invented by Mr. Watts appears to us rather an improvement on Defaut's, inasmuch as it is made to let loose the eye and ligature together, as soon as they are conveyed far enough round the artery; a contrivance likely to save some little trouble.

Aneurismal needles, made on the foregoing principles, must certainly afford great assistance to any future operator who may attempt to tie the subclavian artery from above the clavicle, as they obviate the chief difficulty, namely, that of getting the ligature quite round the vessel.

It was this difficulty which baffled Mr. Asley Cooper in one attempt which was made some time since in Guy's hospital. London Med. Rev. vol. ii. p. 300.

Nothing is more possible than to mistake one of the cervical nerves for the subclavian artery, in consequence of the pulsation of this vessel being communicated to all the adjacent parts. We have been a mistake of this kind actually made by very skilful surgeons.

Pelleton practised on the dead subject the following method: the head was turned to the opposite side, and the shoulder lowered as much as possible. An incision was then made along the neck, at the back of the sterno-clido-mastoideus muscle, so as to bring into view the scaleni muscles. The anterior portion of these muscles being divided, a ligature was conveyed without difficulty under the subclavian artery, with the aid of an aneurismal needle, mounted on a handle, made by the French to have been invented by Deflambres. (Clinique Chir. tom. ii. p. 86.) With the exception of cutting the anterior scalenus, which seems unnecessary, Mr. Aberdeen has demonstrated in his lectures a similar operation thesfe many years past.

That the carotid artery might become obliterated, without any dangerous effect on the brain, and that an aneurism of the same vessel might undergo a spontaneous cure, was long since proved by the case related by Petit, who, on the patient's decease some time afterwards, found the right carotid obliterated from its bifurcation, as far as the subclavian of the same side. But, besides this kind of obliteration by a process of nature, modern experience has evinced, that the carotid artery may be suddenly tied with a ligature, and thus rendered impervious, without any pernicious consequences on the brain. In one instance, indeed, where Mr. Aberdeen was obliged to take up the carotid artery, the head seemed to be affected; but then the patient had lost an almost fatal quantity of blood; and had an immense lacerated wound of the neck, in consequence of being gored with a cow's
Surgery.

In the work referred to below, Mr. A. Cooper has recorded another case, where he tied the carotid artery; but the aneurism being too far advanced, and an abscess arising, the patient died from the prejudice produced on the throat. M. Burckhardt of Stockholm, is also stated to have operated for a carotid aneurism; but the result was not known. Mr. Cline has likewise taken up the carotid artery for an aneurism, which seems to have been attended with unpleasant circumstances: the patient died in about three days after the operation. London Med. Rev. vol. ii. p. 96.

Another successful instance, in which the carotid was tied for the cure of an aneurism, is related in a work, to which we always have the greatest pleasure in referring. See Hodgson’s Treatise on the Diseases of Arteries, p. 59.

In order to get at the carotid artery, Mr. Abernethy has recommended making an incision on that side of it just below the trachea, where no important parts can be injured, and the best method to pass a finger under the vessel. The par vagum must be carefully excluded from the ligature; for tying it would be a fatal blunder. See First Lines of the Practice of Surgery, by Samuel Cooper, edit. 3.

We might mention many other examples in which the carotid artery has been successfully tied; but the safety of the surgeon must say to us, that we are not able to authenticate that the operator took away a large tumour, including the whole of the parotid gland, from the side of the neck, without the smallest risk of hemorrhage. This mode of proceeding was adopted by Mr. Goodlad, surgeon at Bury, in Lancashire. See Medical Chir. Tran. vol. vii. p. 112.

We shall conclude with some interesting particulars, relative to another case of cure in surgery; we mean that of tying the internal iliac artery.

The gluteal artery is large; from its situation liable to wounds; from its size, subject to aneurism. Dr. Jeffry of Glasgow, was consulted in a case where the gluteal artery had been wounded. He urged the propriety of tying the vessel where it had been injured. This sensible advice was at first rejected, and when the friends at last consented, the operation was too late, as while preparation was making for it, the tumour burst, and the patient expired in a few moments. Mr. John Bell, however, had a case, in which he tied the gluteal artery, which had been wounded, and the patient was saved.

Mr. Stevens, surgeon in Santa Cruz, the gentleman who has proved the practicableness of putting a ligature round the internal iliac artery, informs us, that “one of the few surgeons in London had a patient with gluteal aneurism. The operation was undertaken, after preparation was made for it, the tumour burst, and the patient died.”

“I sincerely trust, that the following case may be a means of preventing such an occurrence in future.”

“Mallia, a negro-woman from the Bambara country in Africa, was imported as a slave into the West Indies in the year 1790. She was purchased for the estate Esteban Green; now the property of the heirs of P. Ferris, on the island of St. Christopher. She was first seen in the beginning of December, 1812. She had a tumour on the left hip, over the ischial notch. It was nearly as large as a child’s head, and pulling strongly. She could afford no cause for the disease. It had commenced about nine months before, with slight pain in the part, and had gradually increased to its present size. She...

perennial. Stam. shrubby, five or five feet high. Branches

erec, subdivided, round, rough, glaucous, downy. Leaves

short, flalks, clutered at the summits of the branches,

wedge-shaped, obtuse, thick, downy, or somewhat pil-

lous, pale green. Flowers small, yellow, gernally from

two to three, on a terminal, axillary flalk, which is shorter

than the leaves.

SURIGUR, in Geography, a town of Hindoostan, in

Bihar; 26 miles W.N.W. of Rotaigur.

SURINAM, a province of the Dutch Guiana, (which fee)
deriving its name from that of a river, on which the capital,

Paramaribo, is situated. It is bounded on the N. by

the Atlantic, on the E. by the river Marawina or Maroni,

on the S. by a country of Indians, and part of French

Guiana, and on the W. by the river Corentyn; about 150

miles from E. to W., and 60 from N. to S. The prin-
cipal rivers that belong to this settlement are the Surinam,

the Corentyn, the Elquino or Eloquino, which at its mouth

receives the Demerara, Berbice or Berbix, giving name to

a colony, the capital of which is Amsterdam, the Comme-

wijn, and the Maroni.

The banks of creeks or rivulets that recharge themselves in

these rivers are inhabited by Europeans, and cultivated with

fugar, cocoa, cotton, coffee, tobacco, and indigo plantations, which present a very
delightful prospect to the water-passengers. Captain Sted-

man says, that the province of Surinam has from six
eight hundred plantations of this kind, which produce an-
ually to the value of more than a million sterling. He

computes the number of slaves at 75,000, the annual supply

being 2500. The heats in this colony are tempered by

breeses from the sea, and are thus rendered more tolerable

than those of Guinea, situated like Guiana in the torrid

zone. The soil is, in general, very fertile; and all the ap-

pearances of fertility may be ascribed, not only to the rains

and warmth of this climate, but also to the low and marshy

situation of the country, which prevents the intense heats

from destroying vegetation, and to the extreme richness of

the soil, particularly in those parts that are cultivated by

European industry. Such situations, however, are by no

means favourable to health. The unevacuated parts are

furnished with immense forests, rocks, and mountains; some of

the latter enriched with a great variety of mineral substances;

and the whole country is intersected by very deep marshes

and swamps, and by extensive heaths or savannas. The stream

along the coast flows continually towards the N.W., and

...
the whole shore is rendered almost inaccessible, from its being
encircled with dunes, sandhills, banks, quicksands, bogs and
rocks, with prodigious bushes, and a large quantity of
brush-wood, which are so closely interwoven as to be impenetr-
able. That part of Terra firma which is called Guiana,
or the Wild Coast,” and in which lies the colony of
Surinam, is laid by some to have been first found out by the
jauntily celebrated Christopher Columbus, in the year 1498,
when he was sent home in chains; though others contend,
that it was not discovered till the year 1504, by Valco
Unes, a Spaniard. In 1579, it was visited by Sir Walter
Raleigh, under queen Elizabeth, who also sailed up the
river Oroonoko above 600 miles, in search of the supposed
El Dorado, and in hopes of discovering the gold mines
of which he had the most lively expectations, from samples
of maracaste, which the Spaniards call madre de oro.
In the year 1634, a Capt. Marshal, and about sixty English,
were discovered in Surinam, employed in planting tobacco,
according to the relation of David Piteale de Vries, a Dutch-
man, who converted them with the spot. In 1649,
Surinam was inhabited by the French, who were obliged to
leave it soon after, on account of the frequent invasions
which they justly suffered from the Caribbean Indians, for
having, like their neighbours the Spaniards, treated them
with the most barbarous cruelties. In the year 1650, this
colony being vacant, Francis lord Willoughby of Parham,
by king Charles II.'s permission, went there with some
vessels, equipped by himself, to take possession of it, in the name of
his royal master; a little after which he dispatched three
vessels more, one of them carrying twenty guns. All these
were well received by the Indians or inhabitants of the
country, with whom they entered into friendly treaties, and
a kind of negotiation. In the year 1662, the colony of
Surinam was granted by charter of Charles II. to Francis
lord Willoughby, and at that lord's desire, to be divided
with Laurence Hyde, second son of Edward, earl of Claren-
don, for them and their descendants for ever. In the
year 1665, Surinam was successfully cultivated, mostly by
planting tobacco. They had also raised above forty fine
fugitive plantations, and erected a strong fort with hewn stone
for their defence. It is proper, however, to remark, that
some improvements were effected by the Portu-
guese, though at what period is uncertain; while the French
strenuously dispute the point, and insist that they
were the work of Monseigneur Ponfray de Bretigny, when
France had possession of that country. However this may
be, the fort is situated about 16 or 18 miles from the
mouth of the river Surinam; and these industrious settlers
found themselves perfectly happy in a small town which
they had built under the walls. Their felicity was not of
long duration; for in the wars between Charles II. and
the United Provinces, the Dutch, having been driven, in 1661,
from the Brazil by the Portuguese, took the colony of
Surinam from the English, in 1667, under the command of
a captain Abraham Crivou, who was dispatched for that
purpose with three ships of war and 300 marines. The
English commander, William Biam, looted the settlement of
Surinam by surprise, when above 600 of the belt men in the
colony were at work on the sugar plantations. This neglect
appears from the trifling loss of the Dutch, who in forming
the citadel had but one man killed. They immediately
planted the prince of Orange's flag on the ramparts, and
gave now to this fort the name of Zeelandia, and that of
Middleburgh to the town of Paramaribo, after making
the inhabitants, among other contributions, pay 100,000
pounds weight of sugar, and sending a number of them to
the island of Tobago. This event took place in February,
caught of twelve or fourteen inches in length. Its fins also are yellowish, and have a slight blush of red, mixed with that colour. Its scales are large and broad, and thick, and are more firmly joined to the flesh. It has also three or four straight yellow lines, running parallel with one another down its sides. It is caught in the Mediterranean, and in the British seas, especially on the coast of Cornwall, and is everywhere esteemed a very delicate fish. Ray.

Mr. Pennant calls this species of mullet the striped mullet, but he expresses a doubt whether this is not a variety, as Gronovius apprehends, of the red mullet, or *mullus barbatus*. This last, he observes, was highly esteemed by the Romans, and bore a very high price. They presented it alive to their guests in a glass vessel, that they might observe the beautiful changes of its evanescent colours during its expiration. Plin. i. ix. c. 77. See Hor. Sat. lib. ii. sect. 2. 33. and Juvenal, sat. iv. See *Mullus*.

**Surname**, or **Sirename**, a name added to the proper or baptismal name, to denominate the person of such a family. They were the Roman surnames first introduced the use of hereditary names, and that on occasion of their league with the Sabines; for the confirmation of which it was agreed, that the Romans should prefix Sabine names, and the Sabines, Roman names, to their own.

These new names became family names, or surnames, and the old ones continued personal names. The former they called cognominis, and gentilitia nominis; and the latter *praenomina*. See *Name*.

When the former came to be used among the French and English, they were called surnames, or surnames, not because they are the names of the fire, or father; but, according to Camden, because they are superadded to the personal name; or, rather, with Du-Cange, because at first this family name was written over (*Sur*) the other name, thus:

de Bourbon
Louis.

In lieu of surnames, the Hebrews, to keep up the memory of their tribes, use the name of their father, with the addition of Ben, son; as Melchi Ben Addi, Addi Ben Copham, &c.; or the Greek Iacou ou Diodala; Icarus, the son of Diodalus; Diodalus, the son of Eupomus, &c.

* So also the ancient Saxons, Ceoer, Ceodweland, Ceolwald Cuthing; that is, Ceonred, son of Ceolwald, son of Cuth; and in the same fene, the Welsh use ap for bap, son; as ap Owen, Owen ap Harry, Harry ap Rhyi; and the Irish, Mac, as Donald Mac Neul, Neil Mac Gen, &c.; and the old Normans, Fitz, as John Fitz Robert, Robert Fitz Ralph, &c.

Scaliger adds, that the Arabs used their fathers' name or surname, without their personal name; as, Acew-Pace, Acew-Zoir, &c. q. d. son of Pace, son of Zoir, &c. As, if Pace had a son at his circumcision called Hal, he would be called Acew-Pace, concealing Hal; but his son, however he were named, would be called Acew-Hal, &c.

The Romans, in time, multiplied their surnames: besides the general name of the race, or family, called gentilium, they took a particular one, to distinguish the branch of the family, called also cognomen; and sometimes a third, on account of some personal distinction; as that of Africannus, by Scipio; of Torquatus, by Manlius.

These three different kinds of surnames had also their different names, *viz.* *nomen*, cognomen, and apynomina; but these last were not hereditary; being, in effect, a kind of fibriquets, or nick-names, if that word be indifferent with respect to good and evil. See the subject of the Roman names and surnames accurately treated of by Spahheim, De Praef. and Usu Numinum. Diff. 10.

In thee, too, they have been imitated by later times; thus, in our English History, we find that Edgar was called the Peaceable; Ethelred the Unready; Edmund, Ironside; Harold, Harfoot; William, the Bajhard; Henry I. Beauclerk; John, Lackland, &c.—But as these names were never borne by the sons, Camden, and others, think it strange, that Plantagenet should be accounted the surname of the royal family of England; till Henry VII.; or Tudor, or Tudour, that from Henry VII. to king James I.; or that of Stewart, or Stuart, from king James I. to king George I.; or that Yale should be esteemed the surname of the late family of French kings; or Bourbon of the present; or Oldenburg of the kings of Denmark; or Hayburg of the emperors.

Du Chêfife observes, that surnames were unknown in France before the year 957, when the lords began to assume the names of their demesnes.—Camden relates, that they were first taken up in England, a little before the Conquest, under king Edward the Confessor; but he adds, they were never fully established among the common people, till the time of Edward II.; till then they varied with the father's name: if the father, e. g. was called Richard, or Roger, the son was called Richardson, or Rogerion: but from that time they were settled, some say, by act of parliament.

The oldest surnames are tho' we find in Domesday Book, most of them taken from places, with the addition of *de*; as Godfredus de Manneville, Walerus de Vernon, Robert de Oly, &c. Others from their fathers, with filius, as Guilelmus filius Obberi; others from their offices, as Eudo Dapifer, Guilelmus Cameraurio, Gilebertus Cocus, &c. But the inferior people are noted, simply, by their Christian names; without any surname at all.

In Sweden, till the year 1514, nobody ever took surnames; and the common people have none to this day, nor have even the native Irlins, Poles, and Bohemians, &c.—It is very late that the Welsh have any; and tho' they have are generally only formed by leaving out the *a* in *ap*, and annexing the *p* to their father's name; as in lieu of Evan ap Rice, they now say Evan Price, for ap Howell, Powell, &c. Du Tillet maintains, that all surnames were originally given by way of sobriquets, or nick-names; and adds, that they are all significant and intelligible to those who understand the ancient dialects of the several countries. The greatest part of our surnames, and those of the greatest account, Camden shews, are local, and borrowed from the places in Normandy, &c. where the respective persons who came over with the Conqueror, and first bore them, had their poffessions, or their births: such as Mortimer, Warren, Albigny, Piercy, Deroure, Tankerwil, Neill, Tracy, Montfort, &c. He adds that there is not a village in Normandy but gives name to some family in England.—Others were taken from places in England, as Afton, Sutton, Wotton, &c.

The Saxon common people generally took their father's or their mother's Christian name, with the addition of *en*; though many were surnamed from their trade, as Smith, Carpenter, Taylor, Weaver, Fuller, &c.; others from their offices, as Porter, Shepherd, Carter, Cook, Butler, &c.; others from their complexion, as Fairfas, i. e. fair hair; Blunt or Blond, i. e. flaxen or yellow; others from birds, as Wren, Finch, &c.; others from beasts, as Lamb, Hare, Hart, &c.; others from the winds; others from sains, &c.

**SURO**, in *Ichthyology*, a name given by some to a fish of 4F 2 the
the culcus kind, much resembling the mackarel in taffe and in shape, and more usually known by the name of the tarchuwan.

Suroorpourn, in Geography, a town of Hindoostan, in Oude; 40 miles S.E. of Fyzabad.

Surow, a town of Hindoostan, in Oirma; 20 miles S.E. of Balfoore.

Surowna, a town of Bengal; 23 miles S. of Ghidore.

Surey, or Sorox, an island in the North sea, on the coast of Norway; 44 miles long, and 8 broad. N. lat. 70° 34'; E. long. 22° 14'.

Surplice, the habit of the officiating clergy in the church of England. By Can. 58, every minister laying the public prayers, or administering the sacrament or other rites of the church, shall wear a decent and comely surplice with sleeves, to be provided at the charge of the parish. But by 1 Eliz. c. 2. and 13 & 14 Car. II., the garb prescribed by act of parliament, in the second year of king Edward VI., is enjoined; and this requires that in the saying or singing of matins and even-song, baptizing and burying, the minister in parish churches and chapels shall use a surplice. And in all cathedral churches and colleges, the archdeacon, dean, prebendaries, and fellows, being graduates, may use in the choir, besides their surplices, such hoods as may be proper to their several degrees. But in all other places, every minister shall be at liberty to use any surplice or not. And hence in marrying, churching of women, and other offices, not specified in this rubric, and even in the administration of the holy communion, it seems that the surplice is not necessary. Indeed, for the holy communion, the rubric appoints a white ALB plain, which differs from the surplice in being close-deeved, with a veemment or cope.

Surplusage, in Common Law, signifies a superfluity or addition of more than is needful; which sometimes is the cause of a writ abateth. But in pleading it is frequently set aside; the rest remaining good.

Surplusage is sometimes also applied to matters of accounts, and denotes a greater disbursements than the charge of the accountant amounteth to.

Surplusage of Intestate's Effects. See Intestate's Surplusage.

Surprise, To, in War, is to fall on an enemy unexpectedly, in marching through narrow and difficult passes, as in the passage of rivers, woods, inclosures, &c. There are various ways of surprising an enemy or place. See STRATEGEM.

Surebutter, in Law, is second rebutter; or the replication of the plaintiff to the defendant's rebutter.

Surrectorium, the name of a surgical instrument, mentioned by Ambrose Paré, and intended to keep the arm in an erect situation when required.

Surrejoinder, is a second defence of the plaintiff's declaration; by way of answer to the defendant's rejoinder.

Surrender, in Common Law, a deed or instrument, testifying that the particular tenant of lands and tenements for life, or years, doth sufficiently consent and agree, that he who has the next or immediate remainder or reversion of them, shall have the present estate of the same in possession; and that he hereby yields and gives up the same to him, so that the estate for life or years may be conveyed by mutual agreement of the parties. Of surrenders, there are three kinds; a surrender properly taken at common law, a surrender of copyhold or customary estates, and a surrender improperly taken, as of a deed, a patent, &c. The first is the usual surrender, and it is usually divided into that in deed, and that in law. Surrender in deed, is that which is really made by express words in writing, where the words of the lessor to the lessee prove a sufficient act to surrender his estate back again. But a surrender in law, is that wrought by operation of the law, and which is not actual. A man may have a lease of a farm for life, or years; and during the term he accepts a new lease; this act is, in law, a surrender of the former.

Surrender of a Bankrupt. See Petition of Bankruptcy.

Surrender of Copyholds, is the yielding up the estate by the tenant into the hands of the lord, for such purpose are expressed in the surrender; as to the use and behoof of A. and his heirs, to the use of his own will, and the like. This method of conveyance is so essential to the nature of a copyhold estate, that it cannot possibly be transferred by any other assurance. No feeoffment, fine, or recovery, (in the king's courts) hath any operation upon it. If I would exchange a copyhold with another, I cannot do it by a ordinary deed of exchange at the common law, but we must surrender to each other's use, and the lord will admit us accordingly. If I would devise a copyhold, I must surrender it to the use of my last will and testament; and in my will I must declare my intentions, and name a devisee, who will then be entitled to admission. Blackstone's Com. vol. i.

Surrender of Letters Patent and Oath. A surrender may be made of letters patent to the king, so that he may grant the estate to whom he pleases, &c.; and a second patent for years to the same person, for the same thing, is a surrender in law of the first patent. (10 Rep. 66.) If an officer for life accepts another grant of the same office, it is in law a surrender of the first grant; but if such an officer takes another grant of the same office to himself or another, it may be otherwise.

Surrender, in War, is to lay down one's arms, and yield yourself prisoner.

To surrender a place, see CAPITULATION.

Surreptitious. See Surreptitious.

Surrey, in Geography, one of the inland counties of England, is situated in the southern part of the kingdom, and is bounded by Sussex on the south, by Kent on the east, by Berkshire and Hampshire on the west, and by the north separated from Middlesex and a small part of Buckinghamshire by the river Thames. Surrey ranks below most of the other counties of England in extent; in greatest width from north to south about 15 miles, and its utmost length from east to west about 38. The best modern authorities compute its contents at 811 square miles, or 519,000 acres.

Historical Events.—The earliest inhabitants of this county were the Segontiacei, originally a people of Belgic, who settled at first in the western part of Hampshire, whence they were obliged to retire, on the arrival of another people of the same nation. After some time, however, each of them as had remained in Hampshire rejoined the main body, and thus they became confined within the tract which forms the present counties of Surrey and Sussex. According to the Roman division of England, the former county formed a part of the province of Britannia Prima. At the Saxon heptarchy, it constituted, with Sussex, a distinct state, under the title of Suth-Seaenna-ric; and on the division of England into five kingdoms, the present county of Surrey was called Suthrese, since modulated to Surrey. On the Danish invasion, and the Norman conquest, the landed property of this county, like most others, was divided and
SURREY.

given to the followers of the vicious monarchs. In later times, the history of Surrey is trivial. During the civil wars, it adhered closely to the parliament, and petitioned for the removal of the "evil counsellors" who were around the king. Surrey, as early as the time of the Saxons, conferred the title of earl; as Huda, the first who bore that distinction, was slain in battle with the Danes in 853.

General Aspect, Soil, and Climate.—The soil of this county is greatly varied, the different species lying intermixed in small patches. These, however, may be reduced to the general heads of clay, loam, and chalk. The most extensive and uniform tract of soil is that which occupies the whole southern border of the county, and forms what is denominated the Weald of Surrey; a district about thirty miles in length, and from three to five in breadth. This consists of a pale, cold, retentive clay, upon a subsoil of the same nature; its surface is flat, covered with wood, and its elevation is said to be less than any other vale district in the whole island. Proceeding northwards, the soil is chiefly loam, stretching across the whole county. Near Godalming, it runs to a great depth, and rests on a base of sandstone, veined with iron-ore. Contiguous to this commences the most remarkable district of the chalky downs, which lie nearly in the middle of the county; entering from Kent, into Surrey, by Croydon and Limpsfield, where their width is about seven miles: they, however, gradually decrease towards the west, till their termination near the border of Hampshire, where there is merely a narrow ridge, but little broader than the turnpike-road. Along the elevated summits of the downs, particularly about Walton and Hedley, and between the Mole and the Wey, is a large extent of heath, which, for a considerable depth, separates the chalk of the northern from that of the southern compartment of the downs. From the eastern extremity of the downs, running northward, is a variety of soils, consisting chiefly of brown clay and sandy loam, with patches of gravel, which continue almost to Dulwich, from which place to the extremity of the county, near Rotherhithe, is a brown unmixed clay. The climate of Surrey, as of other counties, where the soil is so varied, must likewise considerably vary. It is generally supposed that less rain falls in most parts of Surrey, than either in the metropolis, or in the vale of the Thames. From this circumstance the climate may, upon the whole, be regarded dry; but the southern border is damp, through the nature of the soil, and the flats of the surface. From these causes, the low parts near the Thames may be also considered as damp; but the atmosphere of the chalk hills, which crow the county from east to west, is dry, keen, and bracing. On the wide and exposed heaths, near Bagshot, Alderholt, and Hindhead, a similar climate also prevails.

Mineralogy.—Iron-ore is found in considerable quantities in the south-west part of the county, about Haselmer, Dunsfold, and Cranley; and in the south-east quarter, about Lingfield and Horne; but in consequence of the high price of fuel, the iron works of Surrey have been totally neglected. Fuller's-earth is discovered both to the north and the south of the downs, but the former is of inferior quality to the latter. This mineral has been dug for a great length of time in Surrey, as the oldest pit now wrought is said to have lasted for 50 or 60 years. Extensive quarries of stone, of a peculiar quality, are worked near Godstone, and its vicinity. When first taken from the quarry, it is incapable of bearing a damp atmosphere; but after being kept covered for a few months, it becomes sufficiently firm to reful the heat of a common fire, and is hence called fire-flone. In consequence of this property, it is much in demand for fire-places in the metropolis, and its neighbourhood. These flones are procured in various sizes, from 10 inches thick to 72 superficial feet. Chalk, brick-earth, sand, and coal, are likewise found in this county. The sand is in great request for hour-glasses; and the brick-earth produces those articles denominated fire-bricks, from their property of retarding heat. Camden and Evelyn notice jet-pits in Surrey, but no traces of them can be now discovered.

Rivers.—The principal rivers of this county are the Wey, the Mole, and the Wandle; whilst the Thames also washes its northern border. The former streams, after watering the county in different directions, finally discharge themselves into the Thames. A considerable branch of the Medway rives in the parishes of Godstone and Horne, and, passing through the parishes of Lingfield, quits Surrey, and enters Kent. The river Loddon skirts Surrey on its west side: its waters are used for the supply of the Basingstoke canal. In the western and south-eastern parts of the county are several ponds, some of which are preferred as fishponds, to keep fish to supply the London market. The mineral waters of Surrey were at one period in very high repute, but are now wholly neglected. This county is in general well furnished with springs; but for wells it is sometimes found necessary to perforate to the depth of 300 feet.

Tenure, Estates, &c.—The tenures are principally freehold, and the estates in Surrey are by no means extensive. The yeomanry are not so numerous as in the neighbouring county of Kent; though in the western division of the Weald, there are several gentlemen who farm their own estates, at from 200l. to 400l. per annum.

Leases, Size of Farms, Rents, &c.—The size of farms in Surrey may be considered rather small, the most extensive of which does not exceed 1600 acres: there are a few others from 600 to 1200, but the most common size is from 200 to 300; there are some, however, below that standard, and the average of the county is computed at 170. Most of the farms are leased for twenty-one years, though some for twenty-five, or thirty. A few are let for three lives; but there are many extensive farms held without a lease, from year to year. The rents, excepting in that part of the county which lies within the influence of the London market, may be deemed low. In the clays of the Weald many farms are let for ten, and there are few that amount to twenty shillings per acre. The rich sandy loams produce from twenty-five to thirty shillings per acre. But towards the vicinity of London, the rents rise in a considerable degree: at the distance of seven or eight miles, they run from two to three pounds; and within that distance, the ground lets for six, eight, and even ten pounds per acre.

Agriculture.—Surrey may be considered as inferior to many other districts of Great Britain, as it respects agricultural improvement. The drill method is chiefly practiced in the west of Surrey, near Bagshot, Elmer, &c. The produce of wheat is from two to five, and sometimes six quarters in an acre; and that of barley, from five to seven and a half. The latter is used only for malting, for which purpose it is considered equal to any in the kingdom. The climate and soil of Surrey seem to be less favourable to oats, than to wheat or barley. As the first is often grown on foul land, the produce is sometimes very low, not exceeding three quarters per acre; but when sown on clean lay, or after turnips, it frequently yields from six to eight quarters. Garden peas and beans are cultivated near the
the metropolis, and on the sandy loams about Mortlake, near the Thames; while the field varieties of both are extensively grown in most other parts of the county, and on the chalk-hills. Turnips are here raised in large crops: they are always sown, as strong objections prevail against drilling. When sown to be drawn off the field, from ten to twelve guineas are commonly given by cow-feeders; but when packed for market, they may be reckoned worth 40/- per acre.

The crops which are only partially cultivated in Surrey, are those of cabbages, potatoes, lucern, and grass, of which latter it has a much smaller proportion than most other counties in England. Carrots, clover, tainfoul, and hops, are extensively cultivated; and a greater quantity of land is employed in raising physical herbs, than in any other shire in Britain. Those which are chiefly reared, are peppermint, lavender, camomile, anised, liquorice, and poppy. Upwards of 350 acres of land in Surrey, are thus given to medicinal purposes. The whole quantity of garden ground employed for the London market in this county, amounts to about 3500 acres. Surrey is not celebrated for any particular kind of cattle; the Hereford, or short-horned breed of cows, is preferred; of which there are kept about 600, for the supply of London with milk. Rearing of calves for the market of the metropolis was once a common employment in this county, but this system is now diused. The cattle chiefly bred in Surrey are sheep, oxen, and hogs; many geese are also kept on the commons, and in the Weald. Within the last five or six years, large tracts of the heath- lands have been enclosed and cultivated; and it must gratify the philanthropist to see thousands of acres of ground, heretofore not only profitless, but almost a nuisance, rendered profitable to the proprietor, and useful to man.

**Forests, Woods, and Plantations.**—Under the Norman race of kings, a large portion of this county was reserved as part of the demesne of the crown, and preferred for the purpose of the chase. Under Henry II. the limits of Windlor forest were gradually extended, by the enclofure of his manors in Surrey, till he had converted the greater part of the county to a forest. On the accession of his son Richard, great part of this undertaking was entirely destroyed; and in succeeding times has been so much reduced, that very little forest remains. The district of Surrey most remarkable for its timber is the Weald; and the most common kinds in the county are oak, beech, walnut, ash, elm, box, yew, fir, birch, and maple; in addition to which, lime and chestnut are found about gentlemen’s seats.

**Waste Lands.**—Before the recent enclosures, it was computed that nearly one-sixth of Surrey was in this unprofitable state: but within the last 15 or 20 years, about 12,000 acres have been enclosed. A vast quantity, however, still remains entirely useless; and of heaths, which might be planted with every prospect of successe, there are no less than 48,180 acres. The whole amount of waste lands in the county of Surrey is computed at 73,540 acres.

**Roads and Canals.**—The turnpike-roads here are not in general remarkable for their excellence, and their faults are ascribed to various causes. The cross-roads on the hills, and in some other parts of the county, may be considered good; but on the clay of the Weald, on the sands, and in the low tract near the Thames, they are very indifferent. The Surrey iron railway from Wandsworth to Croydon was first projected in 1802, and is the first instance of the formation of roads of this nature for general use. The breadth of the road which is occupied by the going and returning railways and a foot-path, is twenty-four feet, and the rife is one inch to every ten feet. A large basin, capable of holding more than thirty barges, has been made at Wandsworth, for the purpose of forming a communication between the Thames and the rail road. It has been supposed, that the first locks used in England, were those erected on the river Wey, in Surrey. This county contains three canals; entitled the Bagshot, which runs from that place to the Thames; the Surrey, which communicates with the Thames at Rotherhithe; and the Croydon, which commences there, enters the Surrey canal at Deptford. The expence of constructing this latter work was estimated at 64,100l.

**Civil and Ecclesiastical Divisions.**—Surrey is divided into thirteen hundreds; which together contain one county-town, fourteen boroughts and market-towns, and 140 parishes: all of them in the diocese of Winchester, with the exception of nine parishes, which are peculiarities of the see of Canterbury. According to the population report of 1811, the number of houses in the whole county was 55,684, and that of the inhabitants 325,851. Surrey is represented in parliament by fourteen members: two for the county, and two for each of the boroughs of Southwark, Guildford, Reigate, Haslemere, Bleckingly, and Gatton.

**Antiquities.**—The situation of this county being contiguous to the capital of the Roman settlements in Britain, it is by no means surprizing that numerous remains of Roman antiquities are to be found within its limits. St. George’s Fields, Southwark, where coins and pavements have been found at different periods, was the centre of several Roman ways. One of these was the Ermine-street, which ran nearly parallel with, and but a short distance easterly of, the present turnpike-road. It proceeded from Mickleham Down to Dorking, and passing along a ridge of hill to Farnham, left Surrey, and entered Hampshire. The Stane-street or Stone-street of Cæsar branched out from the Ermine-street at Dorking, and passing throught Oakley, continued onwards into Sussex. Remains of Roman encampments are to be seen on Holmbury-hill, the parifh of Oakley, about two miles to the west of the Stane-street; and on Bottle-hill, in the parifh of Wadingham, near another military way, which also bore the designation of Stane-street, and passed through the easterly part of the county. But the most extensive work of this nature is that of St. George’s hill, near Walton on the Thames. Here Cæsar seems to have encamped previous to his confing the Thames at Coway Stakes, so named from the entrance of the Britons to obstruct his passage over the river. At Walton on the Hill, also, great quantities of Roman bricks and other relics have been discovered within an enclofure of earth-work; and on Blackheath are the remains of a Roman temple, surrounded with embankments. Various other military antiquities exist in Surrey on Latchhill, War-Coppehill, and on a common in the parifh of Effingham. — Historv and Antiquities of the Countv of Surrey, by the late Rev. Owen Manning, and continued to the present time by William Bray, Esq.; 3 volumes, 1804—1814. General View of the Agriculture of the County of Surrey, by William Stevenson, 8vo. 1809. Beauties of England, vol. xiv. by F. Shoberl, 1813.

**SURREY.**—See SURREY.
SUE

190. to the bishop of the diocese, for the due execution of his office. See Marriage.

SURROGATION. See Surrogation.

SURROOL, in Geography, a town of Bengal; 35 miles S.S.E. of Nagore. N. lat. 23° 40'. E. long. 87° 46'.

SURROPOUR, a cecar of Bengal, bounded on the N. by Rpongour; on the E. by Rpongour and Goragot; on the S. by Goragot and Dinagore; and on the W. by Dinagepur; about 15 miles long, and 12 broad. The chief town appears to be Samaung.

SURROWNAH, a town of Hindoostan, in Allahabad; 12 miles S.E. of Jionpur.

SURROWRY, a town of Hindoostan, in Dowlatabad; 22 miles S. of Reapour.

SURRY, a county of America, in the Salisbury district of North Carolina; bounded E. by Stokes, and W. by Wilkes; containing 10,366 inhabitants, of whom 14,695 are slaves. The Moravian settlements of Wachovia are in this county. Near the river Yadkin is a forge, which manufactures bar-iron. The Ararat (see Mount Ararat) or Pilot mountain, about 16 miles N.W. of Salem, is a high mountain, discernible at 60 or 70 miles distance, rises from a broad base in an easy ascent, like a pyramid, near a mile high, where it is not more than an acre broad; and then a vast rock presents itself suddenly to view, appearing like a large castle with its battlements, and erecting its perpendicular altitude upwards of 300 feet, and terminating in a level plain. The summit commands a delightful prospect of the Apalachian mountains on the N., and on the S. extended level country; while the streams of the Yadkin and Dan, on the right and left hand, are discovered at several distant places, winding their way, through the fertile low grounds, towards the ocean.

SURRY, a county of Virginia, bounded N. by James river, which separates it from Charles-city county; E. by the Isle of Wight, and W. by Prince George's county. It contains 6867 inhabitants, of whom 3440 are slaves.

SURRY, a county of the island of Jamaica, containing seven parishes, two towns, and eight villages. The towns are Kingston and Port-Royal, which are repectively.

SURRY, a town of Hancock county, in the district of Maine, on the W. bank of Union river at its mouth; containing 360 inhabitants.—Alfo, a township of New Hampshire, Cheshire county, containing 564 inhabitants; lying E. of Walpole, and incorporated in 1769.

SURYA, a town of Hindoostan, in Oude; 33 miles S.W. of Lucknow.

SURSAH, a town of Hindoostan, in Oude; 30 miles N.N.W. of Kairabad.

SURSEE, a town of Switzerland, in the canton of Lucerne, on the lake of Sempach; 13 miles N.W. of Lucerne. N. lat. 47° 4'. E. long. 9° 55'.

SUREFF, a town of Africa, in the kingdom of Tunis, usually called "Sarufa;" 8 miles W. of El Medea.

SURESH, a town of Persia, in the province of Khorasan; 30 miles W. of Sebxvar.

SUREOII, a town of Russia, in the government of Archangel; 140 miles E.S.E. of Archangel.

SURET, or SUREST, in Arithmetic, the fifth power of a number, or the fourth multiplication of any number, considered as a root.

The number 2, for instance, considered as a root, and multiplied by itself, produces $4$, which is the square, or second power of 2; and 4 multiplied by 2, produces 8, the third power, or cube, or solid number of 2; 8, again, multiplied by 2, produces 16, the fourth power, or quadrato-quadratum, or 16 multiplied once more by 2, produces 32, the fifth power or surfealt, or surfealtid number of 2.

SURESOLID Problem, is that which cannot be resolved, but by curves of a higher kind than the conic sections.

Thus, $a. gr.$ to describe a regular endecagon, or figure of eleven sides in a circle, it is required to describe an icosane, triangle on a right line given, whose angles at the base shall be quintuplicate to that at the vertex; which may easily be done by the intersecion of a quadratix, or any other curve of the second kind, as they are by some called, but not by any lower curve.

SURSOOTY, in Geography, a fort of Hindoostan, on the borders of Cachemire, which commands the paffes on a river of the same name; 114 miles N.W. of Delhi. N. lat. 29° 15'. E. long. 75° 35'.—Allo, a river of Guzerat, which runs into the Indian sea, 40 miles S.W. of Junagur.

—Allo, a river of Hindoostan, which rives in the northern parts of the country of Delhi, and joins the Caggur, 103 miles N.W. of Delhi. This is one of the seven faceted rivers of the Hindoos.

SURSUDEE, a town of Hindoostan, in Bahar; 34 miles E.S.E. of Bahar.

SURSUR, a town of Hindoostan, in Bahar; 8 miles E.N.E. of Chuprah.

SUSWUTTY, a river of Hindoostan, which runs into the Puddar; 26 miles W. of Pattun.

SURTAINVILLE, a town of France, in the department of the Channel; 15 miles W. of Valognes.

SURUBDY, a town of Hindoostan, in Bahar; 21 miles N.N.E. of Durbangh.

SURUBDYPOUR, a town of Hindoostan, in Bahar; 20 miles W. of Durbangh. N. lat. 25° 1'. E. long. 85° 44'.

SURVEY, in Law, is the ascertaining not only of the boundaries and royalties of a manor, or estate in lands; but also of the tenure of the respective tenants, and the rent and value of the same. In this last sense it is taken for a court, because in the falling of an estate, confiding of manors, to a new lord, where there are tenants by lease and copyholders, a court of survey is generally held; and sometimes upon other occasions, to apprise the lord of his right and interest, &c.

SURVEYS of the Board of Agriculture, those reports which have been made of the state of the agriculture of different counties under the direction of that board, in which the facts and particular practices of the different districts are recorded and brought to notice. A great part of the whole of the kingdom, has now been surveyed in this way, and much useful information brought to the attention of the farmer. The model or plan on which the reprinted reports are formed and conducted is somewhat as below, one uniform model being adopted for the whole: and which, after fully considering the subject, was pitched upon, as that which would include in it all the particulars which it was necessary to notice in an agricultural survey.

The plan of these improved reports is comprised in seventeen different heads or chapters, each of which include all the particulars which relate to that particular head, in different sections.

The material heads are those of the geographical state and circumstances of the county or district; the state of property in it; the buildings; the mode of occupation; the arable implements; the modes of enclosing fence-gates, crops, and land, tillage and crops; the grazing, grass-lands, and management; the woods and plantations; the live-stock; the improvements; the warehouses; the obstacles to improvement; the rural economy; the political economy, as connected with or affecting agriculture; the obstacles to improvement, including
SUR

cluding general observations on agricultural legislation and police; miscellaneous observations; and the conclusion, including the means of improvement, and the measures calculated for that purpose.

Under these different heads, all the various facts, practices, and processes, relating to, or connected with the business of husbandry, are comprehended and mostly explained in a full, distinct, and pretty clear manner.

Survey, in Sea Language, denotes an examination made by several naval officers, into the state of the provision or stores belonging to a ship, or fleet of men of war.

SURVEYING, in a general sense, denotes the art of measuring the angular and linear distances of objects, whereby to delineate their several positions on paper, and to ascertain the superficial area or space between them. This is of two kinds, land surveying and marine surveying; the former having generally in view the measure or contents of certain tracts of land, and the latter the position of remarkable objects, as beacons, towers, shoals, coasts, &c. Those extensive operations which have for their object the determination of the latitude and longitude of places, and the length of terrestrial arcs in different latitudes, are also placed under the general term surveying, though they are frequently distinguished by the designation trigonometrical surveys, or geodetic operations, and the science itself by geodesy.

Of Land Surveying.—This consists of three distinct cases: 1. The measuring of the several lines and angles. 2. Protracting or laying the fame down on paper, so as to form a correct map or representation of the estate or country. 3. The computation of the superficial content, as found by the preceding operation.

Various instruments are made use of for the purpose of taking the dimensions, the principal and most indispensible of which is the chain, commonly called Gunter's chain, which is 22 yards long, and is divided into 100 links, each link being .39 yard, or 7.92 inches: 10 of these square chains, or 100,000 square links, is one acre; that is 625 square links is 1 perch.

35,000 square links are 40 perches, or 1 rood.
100,000 square links are 160 perches, or 4 roods = 1 acre.

This is used for taking the linear dimensions, when the area of the land is required; but when only the positions of objects are to be laid down, a chain of 50 or 100 feet is more commonly employed instead of it.

Befide the chain, the surveyor must provide himself with ten small iron pins or arrows, about a foot long, for marking the several chain-lengths; these being successively put down by the person leading the chain, and taken up by him who follows, and whose business it is to direct the survey. He should also be furnished with several long object-flares, with small flags, for setting up at the several angles, &c. and a rod, divided into links, for measuring the offsets and bearings in the hedges or boundaries of the fields. These are sufficient for measuring an estate of considerable extent, but it frequently happens a deal of labour to be furnished with proper instruments for measuring of angles; the most usual and the best adapted for this purpose, are the circumferentor, theodolite, and semicircle, for a description of which see the former articles. The surveyor's crofs, or crofs staff, is likewise very convenient for ruling perpendiculars. See Cross-Staff.

The methods of measuring or surveying single fields with the Chain, Cross, Plain Table, &c. will be found explained under those articles: we shall therefore in the present instance merely offer a few observations with regard to the nature of larger operations, in which a manor, a lordship, or a county, is to be surveyed and transferred to paper, but without treating it according to the precise and strict rules employed in what is termed trigonometrical surveying, this having been already explained under the article Delineas.

Referring to Plate VII. we shall note, C, D, E, F, G, H, &c. represent any remarkable objects in a county, as towers, fleeples, mills, &c. the respective positions of which are to be determined.

First, an elevated situation is to be chosen, as a tower, a fleeple, &c. from which the greater number of those objects can be seen; after which, it will be necessary to rejoin to all the places where we can obtain a general knowledge of them, in order to make a rough sketch, which will afterwards serve to indicate the measures to be taken in the course of the operations.

The names of the objects should also be written upon this sketch, and notes be made of all the most remarkable particulars, by which they may be afterwards distinguished from each other, as by this means many mistakes, which might otherwise arise in this respect, will be avoided. In short, for the sake of greater certainty, it is proper to define the distances nearly at which we judge them to be, that they may not be confounded with other objects which may have little or no resemblance to them, or be situated in the same directions.

This being done, a base A B, chosen on a convenient spot, and as much as possible in a central position with respect to the several objects, is to be carefully measured. The instrument with which it is proposed to take angles (a theodolite for example) is then to be taken to the extremity A, of that base, and so disposed, that its centre will exactly correspond with the point A, and the fixed index be directed along the line A B, to a signal placed at the point B: the base should also be taken to render the instrument perfectly horizontal, according to the indications of the spirit-level which are attached to it. The fixed index still remaining in the direction A B, the moveable one is to be pointed successively to all the objects that are conveniently situated, and that can be seen from the point A, as C, D, E, F, G, H, in order to measure the angles B A E, B A D, B A C, B A H, B A G, and B A F, which the visual rays directed from the point A upon each of these objects, makes with the base A B; and after each observation, the measure of the angle should be written in a register, which ought to be headed with the name of the place where it is taken; and the objects to which the moveable index is directed should also be entered in the same register.

The observations to be made at the extremity A being completed, the theodolite is to be placed at the other end of the base B, in the same manner as at A, and the angles A B C, A B D, A B E, A B F, A B G, A B H, made by the visual rays directed from this station to the objects C, D, E, &c. to be measured; the distances of their objects from the points A and B are then to be found by calculation from the triangles which they form on the base A B, in each of which there are obviously given one side and the two adjacent angles.

With regard to the objects K and L, (which we have proposed could not be observed from the extremities A and B) it will be necessary to remove to the points C and D, which have already been determined, and from which those two objects can be conveniently seen. Then, considering C D as the base, the angles L C D, K C D, L D C, K D C, which the visual rays drawn from the extremities C and D to the objects L, K, make with it, are to be measured, and the triangles C L D and C K D are then to be computed; but as the angles only are known, it will first be requisite to compute the side C D, which is readily done by means of the triangle A C D, in which we know the angle C A D, its
SURVEYING.

difference between the two angles \( \angle C A B, \angle D A B \), and the
fides \( \angle A C \) and \( \angle A D \), which are given by the preceding
calculation.

Let I be another objeçt, which has not been taken either
from the extremities of the base \( A B \), or from those of
CD. Here it is obvious that the side \( \angle C L \) of the triangle
\( \triangle C L D \), the length of which has been previously determined,
may be taken for a base; and after having observed the two
angles \( \angle C L I, \angle I L C \), the other parts of the triangle may be
readily found, from having one side and the two adjacent
angles given.

It is by such proceedings as the above, that those points
in a map which appear doubtful are verified and new ones
introduced.

The secondary triangles are also formed in the same man-
ner, for if we suppose that the point \( m \), within the prin-
cipal triangle \( \triangle C L D \), is to be taken, it is evident, that by ob-
serving from \( C \) and \( D \), the angles \( \angle C D \) and \( \angle D C \), we
shall have the triangle \( \triangle C m D \), in which the side \( C D \)
is known and the two oberved angles.

This example has been limited to a small number of ob-
jects, in order to simplify both the explanation and figure,
as without this contraction of the design, they would both have
been necessarily embarrassed and confused. What has been
said, however, will doubtless be sufficient to show the man-
ner in which a survey may be extended at pleasure by means
of a series of triangles commencing at a measured base, and
conveniently carried on according to the position of the ob-
jects to be taken and the localities of the situation. We
shall therefore only add, that in extensive surveys which
require great accuracy, the most certain way is to measure from
one base to another by different series of triangles leading to
the same two objects, and then to take the mean of the
results.

It will be important to make a few practical observations
in this place, which may not otherwise occur to the prati-
cioner, till dear-bought experience has pointed them out by
repeated inaccuracies and failures.

1. In the first place, then, it may be observed, that in
theoretical computations, if two angles of a triangle be
given, the third becomes known; but the surveyor must
never be satisfied with getting his third angle in this manner,
if there be any possibility of obtaining it from observation.

2. When it is absolutely necessary to measure a very acute
angle, it will require uncommon care; and, after all, the
result must still be considered as doubtful. It is likewise
essential in the calculation of distances, any
angle which is very acute or very obtuse.

3. At the same time that the angles, formed by the objects
which have not yet been surveyed, are measured, we should
avail ourselves of all suitable stations, in order to connect
with new triangles points already determined, particularly
if they be considered as doubtful; and by resolving these
triangles, it will be seen whether the calculations align the
fame situations to those points as they were previously made
to occupy.

For example, suppose the point I had been determined
by means of the triangle \( \triangle C L I \), and that, on account of
the situation of this point being considered as doubtful, we
wish to verify it from the station \( D \), where we are placed
in the course of the observations; if the two points I and
\( \angle D \) be conceived to be joined by the line \( \angle I D \), and the angle
\( \angle C I D \) to be measured, we shall have the triangle \( \triangle C I D \), in
which, besides this angle, there will be known the side \( CD \),
as previously determined, and the angle \( \angle C I D \), equal to the
two angles \( \angle L C D \) and \( \angle I C L \), which have also been ob-
erved. The triangle \( \triangle C I D \) may, therefore, be resolved;

Vol. XXXIV.
frequently used for this purpose, which give the reduced length of the Duping line from observation; but where great accuracy is required, the above is by far the most to be depended upon.

**PROB. II.**

Suppose it were determined to require the triangle \( A B C \) (Fig. 8.), the side \( A B \) and the angle \( A B C \) only being given; and that a wood, or some other obstacle, situated in the direction \( AC \), does not allow of any other angle being observed: suppose also, that on account of a pond, or morass, or the like, the length of \( BC \) cannot be accurately measured.

In this case, measure on the side \( BC \), or on that side produced, the greatest length possible, \( CD \), so that the object \( A \) may be seen from the point \( D \); then if the angle \( ABD \) be observed at \( B \), and the angle \( ADB \) at \( D \), one side and two angles will be known in the triangle \( ADB \); and, therefore, \( BD \) may be computed; and, consequently, if \( CD \) be added to it, or subtracted from it, according as this length was measured on the side \( BC \), or on its prolongation, the side \( BC \) will be obtained; but by hypothesis, the angle \( ABC \) is also known; and the triangle \( ABC \) may, therefore, be resolved by the common principles of trigonometry.

Again, let us suppose the length \( CD \) cannot be measured, either upon the side \( BC \), or on its prolongation, or that \( BC \) cannot be sufficiently extended in that direction, to allow the point \( A \) to be seen.

In this case, a right line \( CE \) is to be measured in any direction, either to the right or left of the point \( C \); then if there be observed at \( B \) the angles \( CBA \), \( EBA \), and at \( E \) the angles \( AEB \), \( AEC \), etc., the angles, and the side \( AB \), which is known, will furnish sufficient data for computing the lines \( BE \), \( BC \), and then revolving the triangle \( ABC \) in the manner above stated: thus the line \( BC \) will be connected with the preceding triangles, and may be used as a base in the series of operations.

**PROB. III.**

Let \( AB \) (Fig. 9.) be any known distance, at the extremity of which the necessary observations cannot be made for determining the right line \( CD \), from which it is required to form a series of triangles, connected with those by which \( AB \) was found. Suppose also, that it is impossible to measure \( CD \), either wholly or in part, or even any other line, of which \( C \) or \( D \) is one of its extremities: in short, that nothing farther can be done than to observe the angles \( AEC \), \( BCD \), at the point \( C \); and the angles \( CDA \), \( ADB \), at the point \( D \).

Here, as the line \( CD \) cannot be measured, any length \( CD \) must be assumed for it; and whatever length may be, it will not change the values of the angles taken at the points \( C \) and \( D \). These angles remaining the same, the sides of the triangles, which result from the assumed length \( CD \), will be proportional to the homologous sides of those which the true length of that line would give, since the former triangles are similar to the latter.

This being premised, if the angles \( AEC \), \( BCD \), be observed at the point \( C \), and the angles \( CDA \), \( ADB \), at the point \( D \), two angles and the side \( CD \), the assumed length of \( CD \), will be known in the triangle \( AC \), which is similar to the triangle \( ACD \); therefore, the sides \( CE \) and \( AD \) may be computed; and as two angles and the side \( CD \) are also known in the triangle \( BCD \), the sides \( CB \) and \( DB \) may likewise be computed. And, lastly, in the triangle \( ADB \), the two sides \( DA \) and \( DB \), and the contained angle \( aDB \), are known, from which \( AB \) will be found; and we shall then have the true distances by means of the following proportions, viz.

\[
\begin{align*}
\frac{cD}{aC} & = \frac{aD}{A D} \\
\frac{bC}{bD} & = \frac{bD}{B D}
\end{align*}
\]

the lines whose dimensions were required.

**PROB. IV.**

To find the position of a place from which three points, previously determined, can be seen, but such that from these points the place cannot be perceived.

Let \( A, B, C \) (Fig. 10.) be the three points, the positions of which are given, so that all of the parts of the triangle \( A B C \) are known; and let \( D \) be the point to be determined. It is required to find the distances \( BD, AD, \) and \( CD \), by observing the angles \( m \) and \( n \).

Let \( x, y \), and \( z \), represent the angles \( BAD, \angle DBC, \) and \( BCD \), respectively; then in the triangles \( ABD, ABD, \) which have the side \( BD \) common, we have

\[
BD = \frac{AB \cdot \sin x}{\sin m} = \frac{BC \cdot \sin z}{\sin (m + n)}
\]

But \( x = 180^\circ - n = y = 180^\circ - n - (180^\circ - B - z) = x + B - n \); therefore, also,

\[
\sin x = \sin x \cdot \cos (B - n) + \cos x \cdot \sin (B - n)
\]

\[
= AB \cdot \sin (m + n) \times \sin x
\]

\[
= BC \cdot \sin m
\]

By dividing this last equation by the \( \sin x \), we obtain

\[
cot x = \frac{AB \cdot \sin (m + n)}{BC \cdot \sin m \cdot \sin (B - n)} - \cot (B - n)
\]

or, for the sake of greater convenience in the calculation,

\[
cot x = \cot (B - n) \left\{ \begin{array}{c}
\frac{\sin C \cdot \sin (m + n)}{\sin BAC \cdot \sin m \cdot \cos (B - n)} - 1
\end{array} \right\}
\]

from which equation the part \( x \), of the angle \( BAC \), and consequently the other part \( CAD \), will be known; and the resolution of the triangles \( ABD, ACD \), will give the distances required.

This solution possesses the advantage, that the equations from which it is obtained holds good in all cases, as appear from the following observations.

1. If we had \( B - n \), the cot. \( B - n \) would be negative, which is the only change in the equation.

2. If the point \( D \) be within the triangle \( ABC \), we shall have \( m + n \) greater than \( 180^\circ \); in which case, the \( \sin (m + n) \) will likewise be negative. Besides, although all of the angles \( A, B, C \), may be obtuse, yet the segment of one of the acute angles is to be sought, in order to avoid any embarrassment and uncertainty respecting the species of the angle \( x \); and we have always our choice of this respect.

3. If \( B \) were equal to \( zero \), which happens when the three points \( A, B, C \), are in a right line; the point \( B \) must then be supposed at \( y \), and the angle \( x \) changes into \( B + D ) \), and we should have

\[
cot x = \cot n \left\{ \frac{AB \cdot \sin (m + n)}{BC \cdot \sin m \cdot \cos n} \right\} - 1
\]

\[
cot x = \frac{AC \cdot \cot n - A \cdot B \cdot \cot m}{BC}
\]
4. When $B = a$, the problem is indeterminate, as in this case, cot. $(B - a)$ is infinite, and the point $D$ may have an infinite number of positions, each of which will satisfy the conditions of the question, as is evident from the following construction, which will in fact supercede in many cases the necessity of any computation; as for instance, when the absolute lengths of the lines $AB, BD$, and $CD$, are not required, but merely the position of the point $D$ on the map.

Construction.—If a circle be supposed to pass through the points $A, B, D$, we shall have $\frac{1}{2}AB = \text{fin. } m$. And as this line is proportional to the radius of the circle, it will be easy to find the radius, by dividing $\frac{1}{2}AB$ by fin. $m$, as taken from the tables.

In this manner, $\frac{AC}{\text{fin. } m}$ will be the radius of the circle, which would pass through the points $A, C, D$.

Therefore, if these two circles be described with their respective radii, such as found by the calculation, they will intersect each other in the point $D$, from which the position of that point will be determined.

**PROB. V.**

From the top of an eminence, the height of which is given, to determine the horizontal distance between two objects situated below.

Let $R$ (fig. 11.) be the elevated point, the height of which above the common horizontal plane of the objects $A, P$, is equal to $RE$; the distance $AP$ may be determined from $R$, in the following manner.

Take the angle $ARP$, and the angles of depression, or the complements of $PARE$ and $ARE$. Then, in order to reduce the angle $ARP$ to $APE$, we find in the triangles $APR, APE$, the common side $AP$, and

$$AP = AR^2 + PR^2 - 2AR \times PR \cdot \text{cot. } ARP$$

$$= AE^2 + PE^2 - 2AE \times PE \cdot \text{cot. } APE;$$

from which last equation, we obtain

$$\text{cot. } AEP = \frac{AR \times PR \cdot \text{cot. } ARP - RE}{AE \times PE}$$

and this gives

$$\text{cot. } AEP = \frac{\text{cot. } ARP - \text{fin. } RAE \cdot \text{fin. } RPE}{\text{cot. } RAE \cdot \text{cot. } RPE}$$

or, to simplify the computation,

$$\text{cot. } AEP = \tan \cdot \text{RAE} \cdot \frac{\text{cot. } ARP}{\text{tan. } PRE \cdot \left(\frac{\text{fin. } RAE \cdot \text{fin. } RPE}{\text{fin. } RAE \cdot \text{fin. } RPE - 1}\right)}$$

From the former of these, which is the easiest to enunciate, Cagnoni deduces the following rule for reducing an angle, having its vertex out of the plane of reduction: vis.

"The cofine of the reduced angle is equal to the cofine of the observed angle, minus the rectangle of the sides of the angles of elevation; the remainder being divided by the rectangle of the cofines of the same angles."

The angle $ARP$ being thus reduced to $APE$, the two others, with the side $RE$, will serve to calculate $AE$ and $PE$; and, consequently, the requisite data will thus be obtained for finding the distance $AP$.

**Note.**—Instead of the preceding formulas of reduction, that given by Delambre may be employed, which is more convenient for the purposes of computation: vis.

$$\text{fin. } \frac{1}{2}AEP = \sqrt{\left(\frac{\text{fin. } (ARP + \text{RAE} - \text{PRE})}{\text{fin. } (ARP + \text{PRE} - \text{RAE}) \times \text{cot. } RAE \times \text{cot. } RPE}\right)}$$

It may be observed, with regard to the practical utility of this problem, that, as it is easy to measure an altitude with great accuracy by the barometer, we may determine from a projecting part of a steep mountain, the positions of the towns and other objects situated in the valleys which it overlooks, without the necessity of measuring a base.

For further information on this subject, the reader is referred to the "Trigonometrical Survey of England and Wales," by Col. Mudge; "Base du Systeme Metrique Decimal," by Delambre; "Exposition des Operations faites en Lapponie," by Swanberg; and the treatises on "Topography and Geodézia," by Puissant; and to the "Mémoire Topographique," lately translated into English by M. Marlotte.

**SURVEYING Crofts.** See Cross.

**SURVEYING Quadrant.** See Quadrant.

**SURVEYING Scale.** The same with reducing scale.

**SURVEYING Wheel.** See Perambulator.

**SURVEYOR.** One that hath the oversight and care of considerable works, lands, or the like. See Supervisor.

**SURVEYOR of his Majesty's Woods and Parks.** An officer of the king's privy chamber, who is in the office of surveyor of the king's woods;

**SURVEYOR of the Crown lands, &c.**

**SURVEYOR of the Highways.** See Highway.

**SURVEYOR, Marine.** See Marine Surveyor.

**SURVEYOR of the Mells, &c.** An officer of the mint, whose business is to keep the bullion cast out; and that it be not altered after the delivery of it to the melter.

**SURVEYORS of the Navy, &c.** Two officers who are issuing to the naval board, being invested with the charge of building and repairing his majesty's ships at the several dock-yards of the kingdom, for which purpose they are trained to the theory and practice of ship-building. It is also their office to know the state of the navy; to audit the accounts of all boatmen and carpenters serving therein; and to enquire into the condition of all the naval stores, at home and abroad, in order to supply whatsoever may be deficient.

**SURVEYOR of the Ordnance, &c.** An officer, whose charge is to survey all the king's ordnance, store, and provisions of war in the custody of the storekeeper of the Tower of London; to allow all bills of debts, to keep checks on labourers' and artificers' works, &c.

There are also many other officers called surveyors, in the different departments in the state and revenue; as the surveyor of the pictures in the royal household; surveyor of the private roads, and surveyor of gardens and waters, belonging to the Board of Works, &c.; surveyor-general of the duchy of Cornwall; general surveyors, and surveyors of counties, belonging to the tax-office; surveyors of land and woods, belonging to the duchy court of Lancaster; surveyor-general, surveyor, surveyors-general, resident in London, and also of the riding officers; land-surveyors; surveyors of paper, keys, baggage, land-carriage officers, buildings, coal-warehouses, king's warehouse, East India warehouse and navigation, belonging to the customs; general surveyors; general surveyors of distillery; surveyors of glass and coaches, in the excise office; surveyors of the salt-office; resident surveyors of the general post-office, and bye-letter office; surveyors of the stamp duties; surveyors of the hawkers' and pedlars' office; surveyor of the royal hospital at Greenwich; surveyor of the victualling-office, &c.

**SURVEYOR is also used for a gauger.** And also for a person who measures and makes maps of lands. See Surveying and Gauging.
and superintends private and public buildings. See Building, and Party-Walls.

SURVIVOR, in Law, signifies the longer liver of two joint-tenants; or any two persons joined in the right of any thing.

Thus, when two or more persons are seised of a joint-estate of inheritance, for their own lives, or per stirres, or are jointly possessed of any chattel intereath, the entire tenancy upon the decease of any of them remains to the survivor, and at length to the last survivor; and he shall be entitled to the whole estate, whatever it be, whether an inheritance or a common freehold only, or even a less estate. This right of survivorship is called by our ancient authors the jus accrescenti
di, because the right upon the death of one joint-tenant, accumulates and increases to the survivor; or as they themselves express it, pars illa communis extricit superficibus, de personis in possessum usque ad ultimum super-

ditem. And this jus accrescenti ought to be mutual; which judge Blackstone apprehends to be the reason why neither the king, nor any corporation, can be a joint-tenant with a private person; for here is no mutuality; the private person has not even the remotest chance of being seised of the entirety, by benefit of survivorship; for the king and corporation can never die. For the encouragement of husbandry and trade, it is held, that a flock on a farm, though occupied jointly, and also a flock used in a joint undertaking, by way of partnership in the same, shall always be considered as common and not as joint property; and there shall be no survivorship therein. Blackst. Comm. b. ii.

SURVIVORSHIP. Payments which are not to be made till some future period, are termed reverstions, to distinguish them from payments which are to be made immediately.

Reverstions are either certain or contingent. Of the former sort are all sums or annuities payable certainly at the expiration of any terms, or the extinction of any lives. (See Rescusions.) Of the latter sort are those which depend on any contingency; as, particularly, the survivorship of any lives beyond other lives. These form the most intricate and difficult part of the doctrine of reverstions and life-annuities; and the books in which this subject is treated most at large, and at the same time with the most precision, are Mr. Simpson's Select Excerpts; Dr. Price on Reverstional Payments; and Mr. Morgan on Annuities and Assurance on Lives and Survivorships.

The whole likeness of the third volume of Mr. Dodfon's Mathematical Repository relates to this subject; but Mr. Dodfon's investigations being founded on M. De Moivre's hypothesis, of an equal decrement of life through all its ages, the rules are very incorrect, when the lives are either under 15, or exceed 60 years of age. For this reason, Dr. Price, and also Mr. Mares, curator baron of the exchequer, (in two volumes, entitled the "Principles of the Doctrine of Life-Annuities," have discarded the "Principle of the Doctrine of lives ground upon it; and the former, in particular, in order to set aside all occasion for using them, has sublittuated in their room a great variety of new tables of the probabilities and values of lives, at every age, and in every situation, calculated not upon any hypothesis, but in such conformity to the best observations. These tables, added to other new tables of the same kind in Mr. Baron Mares's work just mentioned, form a complete set of tables, by which all questions relating to annuities on lives and survivorships, may be answered with as much correctness as the nature of the subject allows. See Life-Annuitas.

It should be observed, that in all computations of contingent reversions involving together the lives of males and females, the shorter duration of the former is a circumstance which ought not to be disregarded. The following tables therefore, derived by Dr. Price from the probabilities of lives in Sweden among males and females separately, are inserted here, not only as being well fitted for calculating the values of reverstions of the above-mentioned description, but also as they serve to prove the truth of an important fact, not previously ascertained, in the doctrine of life-annuities.

**Table I.**

Shewing the probabilities of the duration of human life among males and females, deducted from observations of the proportions of the living to the numbers that have died at all ages for twenty-one years, from 1775 to 1796, in the kingdom of Sweden.

Interest 4 per cent.

Differences of age 0, 6, 12, and 18 years.
The preceding tables furnish the means of determining the exact difference between the values of annuities, as they are made to depend on the furvivorship of any male or female lives; which hitherto has been a desideratum of considerable consequence in the doctrine of life-annuities. What has made this of consequence is chiefly the multitude of societies, established in this and foreign countries, for providing annuities for widows. The general rule for calculating from these tables the value of such annuities is the following.

**Rule.**—Find in Table III. the value of a female life at the age of the wife. From this value subtract the value in Table IV. of the joint continuance of two lives, at the ages of the husband and wife. The remainder will be the value in a single payment, payment of an annuity for the life of the husband, should he be left a widow. And this last value, divided by the value of the joint lives increased by unity, will be the value of the same annuity in annual payments during the joint lives, and to commence immediately.

**Example.**—Let the age of the wife be 24, and of the husband 30. The value in Table III. (reckoning interest at 4 per cent.) of a female life aged 24, is 17.257. The value in Table IV. of two joint lives aged 24 and 30, is 31.457, which, subtracted from 17.257, leaves 3.797, the value, in a single payment, of an annuity of $1. for the life of the wife after the husband; that is, for the life of the widow. The annuity, therefore, being supposed 20l., its value, in a single payment, is 20 multiplied by 3.797, that is 75.94. And this last value divided by 14.455. (that is, by the value of the joint lives increased by unity,) gives 5.25, the value in annual payments beginning immediately, and to be continued during the joint lives. If an annuity of 20l. to a wife aged 24, for her life, after her husband aged 30.

In order to give as full directions as possible in this important case, we shall here insert the following table, taken from the Treatise on Reversionary Payments, vol. i. p. 431. 7th edit.
**TABLE VI.**

Shewing the value of an annuity for the use of a wife after the death of her husband, deduced from the Sweden observations, on the separate probabilities of the duration of life among the males and females.

**Annuity 10l. Interest 4 per cent.**

</table>

and then multiply it again by the probability that the two given lives shall both continue the given term. This last product will be the answer in a single present payment. And this answer, divided by the value of the joint lives increased by unity, will be the answer in annual payments, to commence immediately, and to be continued during the joint lives.

**Example.**—The value is required of an annuity of 1l. for the life of a wife aged 20, after her husband aged 25; provided the husband lives four years. Interest at 4 per cent.

**Answer.**—The given lives increased by four years become 24 and 30. The value of an annuity for the life of a wife aged 24, after her husband aged 30, has been found to be 3.797, which discounted for four years, (that is, multiplied by .8548, the value of 1l. due at the end of four years, by Tab. II. under Annuities,) becomes 3.245. The probability that a female life, aged 20, shall continue four years, is (by Tab. I.) 3.245. The probability that a male life, aged 30, shall continue four years, is 3.245. The probability, therefore, that the two lives shall both continue four years, is 3.245, multiplied by 3.245, which, multiplied by 3.245, gives 1.357, the answer in a single payment. And 3.245, divided by 15.144, (the value increased by unity of two joint lives aged 20 and 25, by Tab. IV.) gives 190, the value in annual payments, to commence immediately, and to be continued during the joint lives of the husband and the wife. The annuity, therefore, being supposing 20l. (to be enjoyed for life by a wife aged 20, after her husband aged 25, provided he lives four years,) the value is, in a single present payment, 69.341; and, in annual payments, 5.994.

**Problems in the Doctrine of reversionary Sums and Annuities payable on Survivorships.**

**PROBLEM I.**

To find the value of an annuity payable for what shall happen to remain of a given life, after it has survived another given life.

**Solution.**—From the value of the life of the expeéntant subtract the value of the joint lives. The remainder will be the number of years' purchase which ought to be given for the annuity.

**Example.**—Let the expeéntant be a male aged 24, who is to enjoy 10l. per annum for his life, after a female aged 30. The value of his life, reckoning interest at 4 per cent., is (by Tab. III.) 16.742. The value of the joint lives is (by Tab. IV.) 13.458; which, subtracted from 16.742, leaves 3.287, the number of years' purchase to be given for the annuity; which being 30l., its value is 65.742, in a single payment. And 65.742, divided by 14.855, (that is, by the value of the joint lives increased by unity,) gives 4.47l., the value, in annual payments, to commence immediately, and to be continued during the joint lives.

**N.B.**—It has been before shown, that had the expeéntant been a female aged 24, and the survivor a male aged 30, the former value would have been 75.041, and the latter 5.251. Such is the difference in this case depending on the survivorship being that of a female rather than a male. In many other cases, the difference is much greater.

**PROBLEM II.**

To find the present value of an estate of a given yearly value, to be entered upon on the survivorship of a given life beyond another.

Vol. XXXIV.
SURVIVORSHIP.

Solution.—Find the value of an annuity on two equal joint lives, whose common age is equal to the age of the oldest of the two proposed lives, which value subtract from the perpetuity, and take half the remainder. Then say, as the expectation of the youngest of the two lives is to that of the oldest, so is the said half remainder to a fourth proportional, which will be the number of years' purchase required, when the life of the expectant is the oldest of the two. But if the expectant is the youngest, then add the value so found to that of the joint lives, and let the sum be subtracted from the perpetuity, and the answer will be obtained.

The value thus found, divided by the value of the joint lives, increased by unity, will give the value in annual payments, beginning immediately, and to be continued during the joint lives.

N.B. In this and all the following solutions, no distinction is made between the lives of males and females.

Example.—Suppose the ages of the two lives to be 30 and 34, the former of which is the expectant. Let the yearly value (or net rent) of the estate be 20l., and the rate of interest 4 per cent. The value of two equal joint lives, aged 30, is (by Tab. IV.) 12,965; the perpetuity is 25; the difference is 13,035; the half of which is 6,017; the expectation of the youngest life is (by Tab. II.) 35,29; and of the oldest life, 31,21. Therefore, as 35,29 is to 31,21, so is 6,017 to 5,324 years' purchase, which, multiplied by 20 (the rent of the estate), gives 106,48, the required value in a single payment of a reversionary estate to come to a person aged 30, provided he survives a person aged 24. And 106,48, divided by 14,455, (the value of the joint lives increased by unity,) quotes 7,36, the value required in annual payments during the joint lives.

Had the youngest life been the expectant, the value just found in years' purchase (that is, 5,324) must have been added to 13,455, the value (by Tab. IV.) of the joint lives, which would have made 18,779; and this sum subtracted from 25 (the perpetuity,) would have given 6,221, the value in years' purchase of the estate, supposing it to come to the younger of the two lives aged 24 and 30, provided it survives the oldest.

PROB. III.

To find the value in present money of a legacy, or any gross sum, payable to a person of a given age, on his surviving another person, whose age is also given.

Find by the last problem the value in years' purchase of an estate, whose net rent is the same with the interest of the given sum; and this value divided by 1/t, increased by its interest for a year, and the quotient multiplied by the interest of the given sum, will be its value in a single payment. And this single payment, divided by the value increased by unity of the joint lives, will be the value in annual payments, to commence immediately.

Example.—Suppose, as in the last example, the ages of the two lives to be 30 and 24, the former of which is expectant. Let the legacy be 500l., the interest of which at 4 per cent. is 20l. The value of an estate of 20l. per annum, to come to a person aged 30, if he survives a person aged 24, is, by the solution of the last problem, 5,324 years' purchase, which divided by 1,04, (that is, 1/t, increased by its interest at 4 per cent. for a year,) and multiplied by 20l., gives 102,2, the required value in a single payment of 500l. payable to a person aged 30, on his surviving a person aged 24. The value in annual payments, during the joint lives, is 7,011. The reason of the difference between the value of an estate, and a sum equivalent to it, may be seen in Dr. Price's Treatise on Reversionary Payments, vol. i. chap. 1. quod. 10.

This rule, first given by Mr. Simpson, in his Seu Exercitii, is partly founded on M. De Moivre's hypothesis, and, in the middle stages of life, gives the values sufficiently correct; but if either of the two lives be very old or very young, it is by no means to be depended upon. In these cases, the following rule, deduced from the real probabilities of life, and given by Mr. Morgan in the 78th volume of the Philosophical Transactions, should always be adopted. Let F denote the value of an annuity on a life one year younger, and P on a life one year older than B; A, A', A F, and A B, the values of an annuity on the joint lives of A and F, A and P, and A and B. Let a denote the number of persons living in the table at the age of F; b, the number at the age of B; c, the number at the age of P; and let r be 1/t, increased by its interest for one year, then will the exact value of the sum S, payable on the contingency of B the elder life surviving A the younger, be equal to

\[ \frac{S \times F - A F - c \times P - A P}{r} + r - 1 \times B = \frac{A F}{b} \]

The value of S, on the contingency of A the younger surviving B the elder, is obtained, as in Mr. Simpson's rule, by subtracting the value found above from the whole value of the reversion, after the extinction of the joint lives.

It may not be improper to observe, that M. De Moivre has given a very erroneous solution of this problem; and the reader, if he has any doubt, may be convinced of its inaccuracy, by referring to Dr. Price's Treatise on Reversionary Payments, vol. i. chap. 3. 7th edit.

PROB. IV.

To find the annuity payable during life to a person of a given age, if he survives another person whose age is given, and which is equivalent in present value to a given fixed legacy payable on the same contingency.

Solution.—Find the difference between the value of a single life of the expectant, and the value of the joint lives. Find also, by the last problem, the value of a single payment of the given sum or legacy. The latter, divided by the former, will give the required life-annuity.

Example.—Let the ages be 30 and 24, the former of which is expectant. Let the sum be 500l., and the rate of interest 4 per cent. The value of the life of the expectant (in the columns for lives in general, in Tab. III.) is 16,005; the value of the joint lives is (by Tab. IV.) 13,455; the difference is 2,551. The value, by the last problem, of 500l. payable, if a life aged 30, survives life aged 24, is 102,2; which, divided by 2,551, gives 40,06, the life-annuity, equivalent to the sum, reckoning interest at 4 per cent.

The single and annual premiums, in the following table, have been computed by Mr. Simpson's rule in the last problem, and the equivalent annuity by the rule in the fourth problem.
Survivorship.

Table VII.

Shewing the value of 100l. depending on the contingency of one life surviving another, according to the Northampton Table of Observations, (see Tab. III. under Life-Annuities,) reckoning interest at 3 per cent.

|---------|------------|--------|---------|--------|---------|---------|------------|--------|---------|--------|---------|---------|------------|--------|---------|--------|---------|---------|------------|--------|---------|--------|---------|---------|------------|--------|---------|--------|---------|---------|------------|--------|---------|--------|---------|

4H2 The
**SURVIVORSHIP.**

The preceding table is one of the tables of the Equitable Society for Annuities on Lives and Survivorships, which has been adopted, with little or no variation, by all the other societies lately established for the assurance of lives. It was computed in the year 1782, when Mr. Simpson's was the only rule in existence. In the middle stages of life it is sufficiently accurate, but it fails when the life in expectation is very old; and in this case recourse is always had, in the Equitable Assurance Office, to Mr. Morgan's correct rule in the Philosophical Transactions. See **ASSURANCE.**

**Explanations.**—The annual premium in this table is supposed to be payable during the joint continuance of the lives of the **pensioner** and **expeitant;** and the first payment is supposed to be made at the time of purchasing the assurance.

The **equivalent annuity** signifies that annuity to which either the single premium, specified in the table, or the **annual** premium, will entitle an **expeitant** during his survivorship, should such an annuity be preferred to a gross sum payable on survivorship. Thus the payment of either £25,588/ (34l. 11s. 11d.) in hand, or of £2,566l. (2l. 11s. 5d.) annually, during the joint lives of a woman aged 25, and a husband aged 35, the first payment to be made immediately, will, according to this table, entitle the husband, should the wife survive the husband, either to 100l. payable to her when she becomes a widow, or to an annuity payable during her life, after becoming a widow, of 6l. 4s. 6d. (6s. 4d.) If she is 35, (or of the same age with her husband,) a single payment of £31,472d., or an annual payment of 2l. 13s. 4d., will, by the table, entitle her to 100l. payable on her survivorship, or to an annuity for her life of 7l. 4s. 6d., after survivorship.

Any payments greater or less will entitle to gross sums or annuities proportionally greater or less.

**PROB. V.**

To find the value of an estate to be entered upon at the decease of B, provided he survives A.

**Answer.**—Find the value of an annuity on the **longest** of two equal lives (see **LIFE-ANNUITIES**), whose common age is that of the older of the two lives A and B, which value subtract from the perpetuity, and take half the remainder.

Then it will be, as the expectation of the duration of the younger of the lives A and B is to that of the older, fo is the half remainder to the number of years' purchase required, when B is the oldest of the two. But if B be the youngest, then to the number of years' purchase thus found, add the value of an annuity on the longest of the lives A and B, and subtract the sum from the perpetuity for the answer in this case.

The value of the reversion in annual payments, till the claim is determined, is found by dividing the single present payment by the value of the two joint lives; and the same value in annual payments, till the claim becomes due, is found by dividing the single payment by the value of the life of B.

**Example.**—Let the age of A be 50, and that of B 60 years. Let the given estate be 400l. per annum and interest at 5 per cent. The value of the longest of two lives, whose common age is 60, is, according to col. 3, Tab. III. and by the rule under **LIFE-ANNUITIES**, 11,474d., which, taken from 25, the perpetuity, leaves 15,526 for the remainder: therefore it will be, as 31,21, the expectation of A by Tab. II., is to 12,63, the expectation of B, fo is 6,762, the half remainder, to 2,733, the number of years' purchase required, which being multiplied by 40, gives 109,32 for the value in one present payment.

But if A had been 60, and B 50, the value required would have been 5,435, multiplied into 40, or 217,411 be-
came the value of the longest of the two lives A and B (by col. 5, Tab. III. and the rule under **LIFE-ANNUITIES**), is 16,828 years' purchase.

This rule of Mr. Simpson is founded on the same principles with his rule in Prob. III.; and is, therefore, equally incorrect in the earlier and later periods of life. The following rule, deduced by Mr. Morgan from the real probabilities of life, and published in the 78th vol. of the Philosophical Transactions, is correct in all cases.

Retaining the same symbols as in the solution of the third problem, the exact value of an estate of 1l. per annum, depending on the contingency above-mentioned, will be

\[ S = \frac{F}{r} - \frac{F}{r} \cdot \frac{A}{B} - \frac{A}{B} \]

when B is the oldest of the two lives. If B is the youngest, the rule is found as directed above, by substituting this from the value of the reversion after the longest of the two lives A and B.

The value of a given sum S may be obtained by multiplying the above expression into

\[ \frac{S}{r} \]

These problems include all the cases of survivorship between two lives for **their whole duration.** The two following problems, given by Dr. Price in his **Treatise on Reversionary Payments,** relate to cases of survivorship between two lives, when the survivorship is restricted to a term of years less than the whole duration of the lives.

**PROB. VI.**

"A, expectant, will lose a given sum, should he survive, within a given time. What ought he to pay for the assurance of it?" In other words: "What ought he to pay for a given sum to be received at the death of A, should it happen to survive him within any given time?"

**Answer.**—Divide the sum of the decrements of life in the Table of Observations, from the age of A, for the given time, by the given sum; and, by the quotient, divide the number of the living in the table at the age of A; and, again, by this second quotient, divide the given sum, referring the third quotient.

[N. B. When the age of A is under 60, and the term is large as to exceed the difference between it and 70, it will be best, when the London table is used, to divide the given sum, not by the second quotient here mentioned, but by the complement of the life of A.]

Find the value of an annuity on the life of B, for the given time. To this value add the quotient, that will arise from dividing the value of an annuity certain, for the given time, by twice the complement of the life of B; and the sum multiplied by the referred quotient, will be the required rate in a single present payment.

**Example.**—Let the Table of Observations be Mr. Simpson's for London. (See Tab. I. under **EXPECTANCE.** Let the rate of interest be 5 per cent.; A, seven years of age; B, 50; the given time 14 years, the given sum 100l. The sum of the decrement for 14 years from the age of 7, is 73, which, divided by 14, gives 5.1. The number of the living at 7 is 430, which, divided by 5.2, and 10th divided by the quotient, gives 137. The quotient to be referred.]

The value of an annuity for 14 years on the life of B, is by Prob. III. under **LIFE-ANNUITIES**, 9.5. The value of an annuity certain for 14 years, is by Tab. III. under **ANNUITIES,** 11,956, which, divided by 9.44 (twice the complement),
SURVIVORSHIP.

Complement of the life of B), gives \( 13 \), which, added to \( 9.5 \), gives \( 22.5 \); and this again multiplied by \( 1.11 \), the referred quotient, gives \( 24.64 \), the present value in one payment of \( 100 \) dr. payable at the death of A, aged \( 7 \), to B, aged \( 30 \), should A die and leave B the survivor within \( 14 \) years.

N. B. The expectation of B is \( 35.6 \) by Tab. II. under Expectation; and it should be remembered, that twice the expectation is always the complement of a life. The present value for \( 14 \) years of two joint lives, one \( 7 \), and the other \( 30 \) a year or more, may be found in the method explained under Life Annuities, to be nearly \( 9 \) years' purchase; and \( 11.646 \), divided by this value, with unity added, or by \( 10 \), gives \( 1.164 \), the foregoing value in annual payments during the joint lives for \( 14 \) years, the first payment to be made immediately, and the left payment at the end of \( 14 \) years, should the joint lives not fail.

Sebulum.—It deserves particularly to be remembered, that in this method likewise may be calculated, what sums ought to be paid on any survivorship, within a given time, of one life beyond another, in consideration of any given sum now advanced. The following example of this is a case which has offered itself in practice.

"A person, aged \( 50 \), has in expectation an estate which is to come to him, provided he survives a minor, aged \( 7 \), before he is out of his minority; that is, provided he should be himself living at the time of the minor’s death, should that happen before he is \( 21 \). In these circumstances, he wants to borrow \( 1000 \) on his expectation. What reservoir out of the estate depending on such a survivorship, is a proper equivalent for this sum now advanced, interest being reckoned at \( 3 \) per cent. and the probabilities of life being supposed the same with those in Mr. Simpson’s Table of London Observations?"

Answer.—It appears from what has been just determined, that for \( 11.646 \) now advanced, the proper equivalent in such circumstances, is \( 100 \) to be paid in case the survivorship should take place; or as much of the estate as \( 100 \) will buy at \( 3 \) per cent., supposing the first rent to be received immediately, that is, \( 2.912 \) per annum. By the rule of proportions, therefore, for \( 100 \), the proper equivalent will be \( 8591 \) in money, or \( 250 \) per annum cut of the estate.

Pro B. VII.

"100 will be left to B’s heirs, should he happen to die after A, within a given time. What is the price of the assurance of it?—That is, what is the present value of \( 100 \) payable at the death of B, provided his death should happen after A’s death, within a given time?"

Answer.—Divide the sum of the decrements of life in the Table of Observations, from the age of B, for the given time, by the given time; and by the quotient divide the number of the living at the age of B; and again, by this second quotient, divide the given sum, referring the third quotient.

Find the value of an annuity on the life A for a number of years, less by one year than the given time, which subtract from the value of an annuity certain for the same number of years. Multiply the remainder by the referred quotient, and divide the product by the amount of \( 11 \) for one year, and let it be a second referred quotient.

Again: Multiply into one another the first referred quotient, and the value of an annuity certain for the given time; and divide the product by twice the complement of A’s life. This left quotient, added to the second referred quotient, will be the answer in a present single payment.

Example.—Let the age of B be \( 40 \) of A, \( 30 \); the sum \( 100 \); rate of interest \( 4 \) per cent; the given time \( 20 \) years; the Table of Observations, Mr. Simpson’s. See Expectation.

The sum of the decrements of life, in this table, from the age of \( 40 \), for \( 20 \) years, is \( 127 \), which, divided by \( 20 \) (the given time), gives \( 6.38 \). The number of the living at \( 40 \) is \( 239 \), which, divided by \( 6.38 \), gives \( 36.8 \); and \( 100 \) (the given sum) divided by \( 36.8 \), gives \( 2.79 \), the first referred quotient to be referred.

The value of an annuity for \( 19 \) years, on a life at \( 30 \) years of age, is \( 10.3 \); which, subtracted from \( 11.646 \), the value of an annuity certain for \( 19 \) years, by Tab. III. under Annuities, and the remainder multiplied by \( 2.79 \), gives \( 7.89 \). This product, divided by \( 1.04 \) (the amount of \( 1l. \) in one year), gives \( 7.60 \); the second referred quotient.

\( 2.79 \) multiplied by \( 13.59 \) (the value of an annuity certain for \( 20 \) years), gives \( 37.916 \); and this product, divided by \( 94.4 \) (twice the complement of A’s life), gives \( 401 \), which, added to \( 7.60 \), gives \( 8l. \) the answer; or the value of \( 100 \) payable at the death of B, on the contingency of his surviving A, aged \( 50 \), and B’s dying in \( 20 \) years.

It is plain that this is likewise the sum that ought to be lent to B now, on the expectation of \( 100 \) at his death, provided it should happen after A’s death in \( 20 \) years.

This rule gives the just solution in all cases, except when B, the expectant, is the youngest of the two lives, and at the same time the term of years greater than the complement of A’s life. In this particular case the following rule must be used.

Find, by the preceding rule, the value of the assurance of the given sum for a term of years, equal to the complement of A’s life, and let this value be referred. Multiply by one another the given sum; the value of \( 1l. \) to be received at the end of a number of years equal to the complement of A’s life; and the value of an annuity certain for as many years as the given term exceeds this complement; and the product, divided by the complement of B’s life, and the quotient added to the value referred, will be the true value sought.

Example.—Let the age of B be \( 30 \) of A, \( 40 \); the term \( 47 \) years; and every thing else as in the last example.

The complement of A’s life is \( 49.2 \). The value of \( 100 \) to be received at the death of B, if he survives A within \( 39 \) years, may be found by the preceding rule to be \( 15.15 \); the value to be referred. The value of \( 1l. \) to be received at the end of \( 39 \) years is, by Tab. II. under Annuities, \( 2166 \). The value of an annuity certain for \( 8 \) years (the excess of the given term above the complement of the life of B) is \( 6.733 \).

And these two values multiplied by one another, and by \( 100 \), give \( 145.83 \); which divided by \( 47.3 \) (the complement of the life of B), and \( 16.15 \), added to the quotient, make \( 10.34 \) the value sought.

Remark.—As after finding the present value of an estate, or annuity, it is necessary to divide that value by the amount of \( 1l. \) in one year, in order to find the present value of a sum equivalent to the annuity; 10, after finding the value of a sum, it is necessary to multiply that value by the said amount, in order to find from it the value of an equivalent annuity.

In the first example, therefore, the value of an estate of \( 1l. \) per annum, would be \( 8.32 \); in the second example, \( 20l. \) and this is, as it ought to be, the value for the whole duration of the lives.

The cases in which three lives are involved in the survivorship are so numerous and complicated, that it would far exceed the limits of this article to enter into a minute investigation of them. The four following problems, however,
SURVIVORSHIP.

being almost self-evident, require no explanation: the remaining ones are all taken from Mr. Morgan’s Treatise on the Doctrine of Annuities and Assurances, with the exception of Prob. XII., which has been taken from his paper in the Philosophical Transactions for the year 1789, to which the reader is referred for its demonstration.

PROB. VIII.

To find the value of an annuity of 1l. during the life of A, after the extinction of the lives of B and C.

Solution.—From the value of an annuity on the longest of the three lives, deduct the value of an annuity on the longest of the two lives of B and C; the remainder will be the number of years’ purchase required: so that if A, B, C represent the values of annuities on the single lives of A, B, and C; A B, A C, and B C, the values of annuities on the two joint lives of A and B; A and C, B and C, and A B C, the value of an annuity on the three joint lives, the value required by Prob. IV., and the rule under Life-Annuitates, will be A + B + C - A B - A C - B C + A B C - B C + C B = A + A B C - A B - A C - B C.

Example.—Let the ages of A, B, and C, respectively, be 24, 46, and 48, the rate of interest 4 per cent., and the probabilities of life as among males and females collectively in the kingdom of Sweden. By Tab. III. A is equal to 10.862; by Tab. IV. Life-Annuitates, A B C may be found = 9.372; and by Tab. IV. and V. A C and A B are equal to 12.801 and 10.862: hence the required value will be 2.706 1/4, or 2l. 12s. 6d. nearly.

PROB. IX.

To find the value of an annuity of 1l. during the life of A, after the extinction of the joint lives of B and C.

Solution.—Deduct the value of an annuity on the three joint lives, from the value of an annuity on the single life of A, and the remainder will be the answer.

Example.—Supposing the ages, the rate of interest, and the probabilities of life, to be as in the preceding problem, the value in this case will be 16.997 - 9.372 = 7.625, or 7l. 12s. 6d.

PROB. X.

To find the value of an annuity of 1l. during the longest of the two lives of A and B, after the decease of C.

Solution.—From the value of an annuity on the longest of the three lives (found by Prob. IV. Life-Annuitates), deduct the value of an annuity on the single life of C, the remainder will give the value required; or retaining the same symbols as in Prob. VIII., it will be A + B + A B C - A B - A C - B C.

Example.—The ages of A, B, and C, the rate of interest, and the probabilities of life, being as in the two preceding problems, the value will be 16.997 + 14.939 + 9.372 = 34.208; and by multiplying each of these by 100, the value is 3420.8. Also, if the lives are all equal, the value will be 7.625.

PROB. XI.

To find the value of an annuity during the joint continuance of the two lives of A and B, after the decease of C.

Solution.—Find (by Prob. IV. under Life-Annuitates) the value of an annuity on the three joint lives; deduct this from the value of the two joint lives of A and B; and the remainder will be the answer.

Example.—Let the ages be 30, 42, and 60, the rate of interest 4 per cent., and the probabilities of life as among males and females collectively in the kingdom of Sweden.

By Prob. IV. under Life-Annuitates, and Tab. IV. in this article, the value of the three joint lives may be found = 6.998; and by the same table, the value of the two joint lives of A and B is 11.543; the value required, therefore, will be 4.545, or 4l. 11s. nearly. Had the ages been 14, 36, and 48, the value would have been 12.801 - 9.372 = 3.429, or 3l. 8s. 6d. nearly.

PROB. XII.

To determine from any Table of Observations the value of a given sum, payable on the contingency of C’s surviving B, provided the life of A shall be then extinct.

Solution.—Let k represent the number of persons living in the table at the age of K, a person one year younger than C; β the same number at the age of P, a person one year younger than B; ε and δ the number of persons living at the respective ages of C and B; m the number of persons living at the age of F, a person one year younger than B; and d the same number at the age of T, a person one year younger than C. Let F K, A F K, B K, A B K, &c. be the value of an annuity on the joint lives of F and K; A, F, and K; B and K; A, B, and K, &c. Let r be 1l. increased by its interest for a year, and S the given sum; then will the value required, when either B or C are the oldest of the three lives, be

\[
\begin{align*}
\beta \cdot F K - A F K & \cdot B K - A B K + S \cdot b \\
FC - AFC & \cdot S \cdot \frac{r - 1}{3r} \cdot BC - ABC - S \cdot m \\
FC & - APC + S \cdot \frac{d}{6r} \cdot BT - ABT - S \cdot \frac{m \cdot PT - APT}{b}
\end{align*}
\]

If A be the oldest of the three lives, let α represent the number of persons living in the table at the age of A, j the same number at the age of B; L the number at the age of N; and let the former quantities denote, as in the former case, the values of the joint lives H and K; of H, I, and K; of A, B, and K, &c. Further, let R denote the value of the given sum, payable if C should survive B, found by

Prob. II., then will the value required be

\[
R = \frac{A H K - H B K + A K - A B K}{a} + \frac{H C - H B C}{6a} + \frac{N C - NBC}{6a} + \frac{S \cdot r - 1}{6r} \cdot X
\]

If the lives are all equal, the value will be

\[
S \cdot \frac{r - 1}{6r} \cdot X
\]

V - 3 C C - 2 C C C, where V denotes the perpetuity.

Mr. Simpson, in his Select Exercises, has given the following solution of this problem, founded partly on M. De Moivre’s hypothesis, and which is a sufficiently near approximation in those cases where neither of the lives is very young or very old.

Case 1.—If the life C be the oldest of the three; From the value of an annuity on the life of C, take the value of the two joint lives B and C; multiply the remainder by the given
given sum, and the product divided by twice the expectation of \( A \), will give the value sought.

\textit{Cæsa 3.---If the life of \( B \) be the eldest of the three.} From the value of an annuity for as many years as \( C \)'s life as are expressed by the double of \( B \)'s expectation, subtract the value of the two joint lives \( B \) and \( C \); multiply the remainder by the given sum, and divide the product by twice the expectation of \( A \), as in the preceding case.

\textit{Cæsa 3.---If the life of \( A \) be the eldest of the three.} Find the value of the life \( C \), if older than \( B \); otherwise find the value thereof for as many years as are expressed by the double of \( B \)'s expectation. And from the value thus found, let the value of the joint lives \( A \) and \( C \) be substracted; multiply the remainder by the given sum, and the product, divided by twice the expectation of \( B \), will give the answer in this case.

\textit{Example.---Let the age of \( C \) be 25, that of \( B \) 49, and that of \( A \) 30. Let the given sum be 1000l., the rate of interest 4 per cent., and the probabilities of life as they are among males and females in the kingdom of Sweden. This example, it is plain, belongs to \textit{caèsa 2.} The expectation of \( B \) by Table II. being 19.09, the double of it will be 38.18. The value of an annuity on the life of \( C \) for 38.18 years by Table III., and the third problem under the article \textit{Life-Annuities}, is 15.032, from which deducting 10.613, the value of the joint lives of \( B \) and \( C \) by Table V., we have 4.42, which being multiplied into 1000, and the product divided by 63.42, or twice the expectation of \( A \) by Table II., the quotient 86.196l., or 86l. 5l. 10d., will be the value required.

\textbf{PROB. XIII.}

To find the value of a given sum payable on the death of \( A \), if his life should be the \textit{first} that fails of the three lives of \( A \), \( B \), and \( C \).

\textit{Solution.---Find by Prob. XII. the value of the given sum payable, if \( C \) (the elder of \( B \) and \( C \)) should be living at the decease of \( A \), in case \( B \) is then dead. Find next by Prob. III. the value of the given sum payable, if \( C \) is living at the decease of \( A \), whether \( B \) is then living or not. Subtract the former value from the latter, and the remainder will be the value required.}

\textbf{PROB. XIV.}

To find the value of a given sum payable, if \( A \) should be the \textit{second} that fails of the three lives \( A \), \( B \), and \( C \).

\textit{Solution.---Find by Prob. III. the value of the given sum on the contingency of \( C \)'s surviving \( A \), and also on the contingency of \( B \)'s surviving \( A \). Find by Prob. XIII. the value of the given sum on the contingency of \( A \)'s life being the \textit{first} that fails. From the sum of the two former substract twice the latter value, and the remainder will be the value required.}

\textbf{PROB. XV.}

To find the value of a given sum payable on the death of \( A \), if his life should be the \textit{last} that fails of the three lives of \( A \), \( B \), and \( C \).

\textit{Solution.---Find by Prob. XII. the value of the given sum payable, if \( C \) should live till the decease of \( A \), in case \( B \) should then be dead \( C \) being supposed the elder of \( B \) and \( C \). Find next by Prob. V. the value of the given sum payable, if \( A \) should die \textit{after} \( B \). Subtract the former value from the latter, and the remainder will be the value required.}

\textbf{PROB. XVI.}

To find the value of a given sum payable on the extinction of the lives of \( A \) and \( B \), should they be the \textit{first} that fail of the three lives of \( A \), \( B \), and \( C \).
SURYA, in Hindu Mythology, is the common name of the Sun, or rather a personification of that luminary. In all idolatrous nations, among all people indeed unenlightened by revelation, the Sun was an object of early and ardent adoration. (See Idolatry.) With the Hindoos, the Sun appears to have been almost universally invoked, and by the lower classes no doubt superstitiously; but by Brahmanas and the initiated, it is adored typically of that divine and incomparably greater light, which illumines all, delights all, from which all proceed, to which all must return, and which alone can irradiate (not our visibl organs merely, but our souls and) our intellects." Thence, as we are told by Sir W. Jones, may be considered as the words of the most sacred text in the Indian scripture. See Om.

We must not be surprised, as remarked by the same author, at finding, on a close examination, that the characters of all the Pagan deities, male and female, melted into each other, and at last into one or two: for it seems a well-founded opinion, that the whole crowd of gods, of good deities in ancient Rome and modern Benares, mean only the powers of nature, and principally those of the Sun, expressed in a variety of ways, and by a multitude of fanciful names. A plausible opinion has been entertained by learned men, that the principal source of idolatry among the ancients, was their enthusiastic admiration of the Sun; and that when the primitive religion of mankind was lost amid the distractions of establishing regal governments, or neglected amid the amusements of vice, they ascribed to the great visible luminary, or to the wonderful fluid of which it is the general reservoir, those powers of pervading all space, and animating all nature, which their wiser ancestors had attributed to One Eternal Mind, by whom the substance of fire had been created as an inanimate and secondary cause of natural phenomena. The mythology of the East confirms this opinion; and it is possible that the triple divinity of the Hindoos was no more than a perfonification of the Sun, whom they call Triyutu, or three-bodied, in his triple capacity of producing forms by his genial heat, preserving them by his light, or destroying them by the concentrated force of his igneous matter. (See Pavanaka.) This, with the wild conceit of a female power (of which see under Sakti), united with the godhead, and ruling nature by his authority, will account for nearly the whole system of Egyptian, Indian, and Grecian polytheism, distinguished from the sublime theology of the philosophers, whose understandings were too strong to admit the popular belief, but whose influence was too weak to reform it.

So grand a symbol of the Deity as the Sun "looking from his fole dominion like the God of this world," will of course have attracted the earliest adoration, and almost necessarily have been the primary and principal object of idolatry and superstitition. The investigators of ancient mythology accordingly trace to this source, wherein they are re-absorbed and lost, almost every other mythological personage, who, like his own light, diverge and radiate from his glorious orb; or, in the words, and in the popular feile, of the sacred text above quoted, "whence all proceeded, and to which all must return. But the Brahmanas and the initiated deities are as implied by the interpolated gloss on the sacred text, the application of this attribute of "all-producing, all-absorbing" to the Sun. The noble truth, so well expressed in the concluding stanza of an ode addressed to Surya by the elegant writer already named, is fully recognized by intelligent Hindoos.

"Yes! though the Sanfrict fong
Be fraught with fancy's wreathes, and
And emblems rich, beyond low thoughts refer'd,
Yet heav'nly truth it breathes
With atf hection aright.
That, loftier than thy sphere, the Eternal Mind,
Unmov'd, unrival'd, undefin'd,
Reigns with providence benign.

—Since thou, great orb, with all-enlightening ray,
Rulest the golden day,
How far more glorious He, who said serene,
Be—and thou wait—Himself uniform'd, unchang'd,
Unseen!"

Praising by the popular belief of the divinity of Surya, or the Sun, we find the Hindoos ascribing to him the properties or attributes of the three persons or powers that constitute mythology and form their trimurti, or Trinity, as it hath been usual to call it, or that, physically contemplated, are the secondary causes of natural phenomena. (See Siva and Trumurti.) It is noticed above, that one of the names of the Sun is Triyutu, or in shorthand Trisus, meaning three-bodied, as embracing the creative power of Brahman, in his capacity of producing forms by his genial heat; the progressive power of Vishnu, in the property of light; and the destructive energy of Siva, in the concentrated force of his igneous matter. And where these are in fact the attributes of the One God, the Eternal Mind, of Hindoo theologians, He is called Brahman. The Sun, or Surya, is therefore desired to be Brahman, Vishnu, and Siva. At night and in the Wd., he is Vishnu; he is Brahman in the East and in the morning; from noon to evening he is Siva. We know of no reason for this arrangement.

Surya is usually represented in pictures four-handed, seated in a golden car drawn by seven green horses, a simile encircling his head, and sometimes blazing round the whole. Sometimes his car is drawn by one horse with seven heads. (See Ochzubava and Shazza.) A legible character, with a red face, named Aruna, guides the charriot with most of variegated hue. But we are deduced, by the poetical allusion that so pleasingly distinguishes the Hindoo Phoebus and Apollo, to refer to again to the hymn addressed to this "lord of the lotus."

"Whole substance Indra with his heav'nly bands,
Nor fogs nor underfands;
Nor ev'n the Vedas three to man explain.
His mystic orb triform, though Brahman turn'd in train."

"First o'er blue hills appear,
With many an agate hoof,
And patterns fring'd with pearl, seven coursers run;
Nor boast'st thou arched woof.
That girds thee with spheres,
Such hear'st a span threads of colour'd light sere,
As ting in the reins which Aruna guides.
Glowing with immortal grace,
Young Arum, loveliest of Vinataian race;
Though younger be, whom Madhava bestrides,
When high on eagle-plumes he rides.
But Oh! what pencil of a living for
Could paint that gorgeous car,
In which, as in an ark, supremely bright,
The lord of boundless light,
As resting calm o'er the bay, the rocks fail,
And with ten thousand beams his awful beauty reigns."

Oh
SURYA.

On the above lines we have to observe, that Surya’s seven horses, as well as Aruna’s variegated reins, are supposed to have reference to the tints of his preceding raś; but we have yet to learn if the Hindoos have attained a knowledge of optics warranting a supposition of their being acquainted with the prismatic divisibility of a ray of light. The regents of the sun and of fire, intimately connected as their primary properties are, we may expect to find agreeing in their emblems or attributes. Thus, Surya’s “mythic orb triform,” and Agni’s “triplicate of legs,” are deducible from the three descriptions of sacred fires venerated by the Hindoos, and proceeding from, and re-absorbed in, the sun, as the three great powers of nature proceed from, and return to, the Eternal Mind. Of these sacred fires, see under our article PAVAKA. We may thus discern an additional reason for a people of idolatrous propensities identifying the sun with Brahm, or that being who said Ṛṣi and the sun ēsas. Surya’s seven horses, and Agni’s seven legs, are again referable to the idea of the common properties of light and heat. On this point also, see PAVAKA.

The theory of the learned author of the Analysis of Ancient Mythology, would in great measure have derived a considerable accession of strength in his mind, had he been professed of the speculations of the Hindoos on the universality of the sun. Sir W. Jones, not altogether agreeing with Newton, that ancient mythology is nothing but historical truth in a poetical dress; nor with Bacon, that it confuted in moral and metaphysical allegories; nor with Bryant, that all the heathen deities are only different attributes and representations of the sun, or of deceased progenitors; reasonably conceived that the whole system of religious fables rove, like the Nile, from several distinct sources; and inclined to the opinion, that one great spring of idolatry, in the four quarters of the globe, was the veneration paid by men to the sun; and another, the immediate respect shown to the memory of deceased ancestors, especially the founders of kingdoms, legislators, and warriors, of whom the sun and moon were wildly supposed to be the parents. Of the great respect shown by the Hindoos to the memory of departed ancestors, see our article ŚRĀMA; and of the idea of solar and lunar races of mortals, see RAMA and SURYAVANSA.

Although the sun is found, in the Hindoo system, to include the three great powers, Surya externally more resembles Viṣṇu than either of the others. His forehead is marked with the sectorial hieroglyphic of the Viśāvatvas, that is, with perpendicular lines; the Śaivas, or Śeṣāṅkṣis of Śiva, marking their and their gods’ foreheads with horizontal lines. Surya is also frequently seen with Viṣṇu’s monomēt attributes, the shank or shell, and loto’s. Viṣṇu is farther considered as more immediately the sun, than either Brahma or Śiva; and his most glorious incarnation in the person of Kṛṣṇa is of direct solar reference. Among the names of Surya will be found both Viṣṇu and Kṛṣṇa; and it may be here remarked, on the authority of general Vallancey, that Kṛṣṇa is the sun in Ṣanskrit as well as in Saṅskrit; and Arun is the precursor of the sun (that is, the dawn, Aurora) both in Ṣanskrit and Hindoo mythology. See TRIVENI.

The extract from Sir William Jones’s hymn given above, adverts to the equipage of Madhava “borne on eagle-plumes,” being, like Aruna, “of Vinarian race.” This alludes to the man-eagle of Madhava or Viṣṇu, the Indian Jove, which vehicle, or mascot, is named Supreme, brother of Aruna, and son of Vinata. See SUPREMA, VINATA, and YAMA.

The names of the sun are numerous among the Hindoos. It is said they amount to nearly fifty, which limits will not allow us to introduce. It may lead to extended speculation, to consider that the primary name of the sun means the Attractor. See Sir William Jones’s admirable essay “On the Philosophy of the Aṣṭāṅgas,” in the 4th volume of the Aṣṭāṅga Researches, and in his Works, edited by Lord Teignmouth.

As well as many other of the Hindoo deities, Surya has wives alluded to him. These sexual tales are allegorical of the powers or attributes of the principal. These hiepabetes are termed Sāśi; which see. The comfort of Surya that we often left read of is Prabha, which means brightness or effulgence.

Under the article SOMA, it is shewn that the Hindoos, like some other diffus people, generally consider the moon as a male deity; and as conjunctions of the sun and moon are a common language with all astrologers and mythologists, we find sexual fables invented for bringing them together, and into separations, or oppositions. The sun and moon are, therefore, both male and female with the Hindoos, and are duly married, separated, &c. The Greeks had similar tales. Bacchus is sometimes spoken of as the sun, and the offspring of the moon, sometimes as brother to Luna. See Potter’s Arch. Graec. c. xix.

Among the Anglo-Saxons, as we are told in Turner’s History, the moon was a male and the sun a female deity; and the same peculiarity of gender, the author says, obtained in the ancient northern language. It is curious, he farther remarks, that in a passage of an Arabian author (in Not. ad Carmen Tograti, p. 13.), we meet with a female sun and masculine moon. The diūthich is,

"Nec nomen femininum Soli dedecus, Nec masculinum Lunae gloriam."

There is also a solar race in Hindoo fable, like the Heliades of Greece, and the similar families of the Peruvians. Suryavansa, or offspring of Surya, is the Sanctific designation of these illustrious descendants. (See SURYAVANSA.) The river Yamuna, called Jumna by European geographers, is riled in Hindoo poetries, “the blue-eyed daughter of the sun.” See YAMUNA.

So early as the appearance of the first volume of that noble deposit of Oriental lore, the Aṣṭāṅga Researches, Sir William Jones, in his very curious dissertation on the gods of Greece, Italy, and India, had discovered many striking and unsuspected coincidences. On the subject of the offspring of Surya, and his avatars or descents on earth, we will here extract a passage from that dissertation. “Surya is believed to have descended frequently from his car in a human shape, and to have left a race on earth, who are usually renowned in the Indian stories with the Heliades of Greece. It is very singular that his two sons, called Āfwina, or Āfwini-Kumara in the dual, should be considered as twin brothers, and painted like Cato and Pollux; but they have each the character of Eklepius among the gods, and are believed to have been born of a nymph, who, in the form of a mare, was impregnated with fun-beams. I suspect the whole fable of Kalypso and his progeny to be astronomical; and cannot but imagine that the Greek name Calipopsis has a relation to it.” This idea has been fully confirmed by Mr. Wilford’s ingenious essays in the subfollow ing volumes of the Aṣṭāṅga Re researched. (See KALYPSO, in which article, line 7, for att, read att.) In the 11th volume, art. ii., it is shewn, that the name of Eklepius is also Sanctific; in which tongue, Afwikulapu, a name intimately connected with the Difciur of Hindoo fable, means chief of the tribe of Avi; it means also mare-destroyed. The name, country, and history of Eklepius having
having so much puzzled the Greeks and other fabulists, gives a great probability of the whole story having originated with the Hindoos, in whose books a great deal respecting it may be found.

The worship of Surya, from what has been said, may be supposed very extensive in the Hindoos. Tho' of the sect who exclusively worship him are called Saura. But besides those who may be said to worship the sun exclusively, a great many other sects make joint adoration and offerings to him with other deities.

Reference being made from the article O'M to this, we will here take occasion to correct two or three errors of the prefix, that have crept into that article; in vol. 5. l. 37 from the bottom, for researches, read researques; l. 27 from the bottom, for monyssylabic, read monoyssylabic; l. 4 from the bottom, for of one their, read of one their; in col. 6. l. 24 from the top, for composed of a, read composed a.

Representations of Surya are very common throughout India, in pictures, sculptures, and casts; both separately and associated with other deities. Several engravings of him, in both fictions, are given in, the Hindoo Pantheon, from the three several originals. He is seen seated in his car, surrounded by a blaze of glory, drawn by seven foaming steeds, or by one seven-headed, drawn by the imperious horse, Aruna. And he is described as followed by thousands of worshiping him and modulating his praises. The following is a translation of the first verse of a hymn addressed, with obligations, to the regents of the nine planetary spheres, extracted from Colebrooke's essay "On the Religious Ceremonies of the Hindoos," in the 7th volume of the Asiatic Researches. "The divine sun approaches with his golden car, returning alternately with the shades of night, routing mortal and immortal beings, and surveying worlds. May this oblation to Surya be efficacious!" In some zodiacal representations, Surya is mounted on a lion, and placed in the centre, indicating an early knowledge of the true solar system. (See ZODIAC.) His car is sometimes followed by a black ill-favoured figure, a personification, probably, of the darkness that the god of day is dispelling.

Enthusiastic devotees are encouraged to penances in honour of different deities, by stances in their sacred romances of boons having been heretofore obtained through the favour of the deities so propitiated. Gazing on the sun, a mode of moving Surya's favour, must be exceedingly hurtful and distressing. So important are the penances, that the modes and objects of performance have been reduced to a system. The penance is generally termed Tapas; which see. For farther particulars, see the Hindoo Pantheon.

SURYA-SAVITRI is a name of the sun, or rather two of his names joined, masculine and feminine; the Hindoo Phoebus being of both sexes. Of this, and other points connected with the important regent of the sun, see Surya and Savitri.

SURYAVANSA, in Hindoo Romance, is the name of a solar race of mortals: offspring of the sun is the best translation of the compound word; Surya being the sun; of its regent, corresponding with the Phoebus of European heathens. In the older histories extant in India, it is usual to designate the heroes as being of the solar or lunar race.

SURZUR, in Geography, a town of France, in the department of the Morbihan; 6 miles S.E. of Vannes.

SUS, or Susis, a river of Africa, which rises at Ras-el-Wed, about 30 miles from the city of Terodan, in the empire of Morocco, at the foot of mount Atlas, and discharges itself into the ocean, about six miles S. of the town of Santa Cruz. At its mouth is a bar of sand, which at low water separates it from the ocean. It gives name to a province, which it bounds on the south.

SUS, a town of Peris, in the province of Chufian; 45 miles N.W. of Susa.

SUS, Susa, or Susis, the most extensive, and, if we except grain, the richest province in the empire of Morocco; it is the most southerly province of the empire, and is bounded on the N. by a part of the Atlas, on the E. by Darah, or Dra, on the S. by Nune, or Vdie de Nune, and on the W. by the Atlantic. It contains many warlike tribes, both Arab and Shelluks. The climate is remarkably fine; hot in the months of June, July, and August, and about the beginning of September, the thyme, or hot wind from Sahara, blows during three, four, fourteen, or twenty-one days. Their violent winds are succeeded by the rainy season. The soil is in general fertile; and it produces figs, cotton, indigo, gum, and various kinds of medicinal herbs. The thick lizzare's fo abundant, that it is called (afk Suf) the root of Sus. The olive plantations are very extensive, and those of the almond are abundant. It is said that Sufis produce more almonds and oil of olives, than all the other provinces collectively. Of corn, the inhabitants of this province cultivate only enough for their own annual consumption, and they pay little attention to the vines. Dates are found here in perfection. Wax is very abundant; and so are aloes, gum euphorbium, gum sandarsch, wild thyme, worm-wood, orris-root, orchis, weed, and coloquintia. Antimony, folsuite, iron, copper, lead, silver, and gold, are found here. It is also richly furnished with a variety of quadrapeds, birds, and fish. Its chief towns are Terodan, Aqaudeer, or Santa Cruz, Aka, Teko, and Meffa. Sus was formerly a province of great trade, on account of its connection with the southern districts; but when the Santa Cruz was destroyed, it was deprived of many of its resources and conveniences for trade. Its inhabitants, who are very numerous, are generally reckoned more brave and industrious than others of Morocco; and many of them, especially in the mountainous districts, are governed by their own sheiks, and acknowledge no obedience to the emperors.

SUS, the Hog, in Zoology, a genus of the class and order Mammalia, Bello, of which the generic character is as follows: The four upper fore-teeth are convergent; the lower fix are prominent; the two upper tusks are shorter; the two lower flanging out; the front prominent, truncate, and moveable; and the feet are mottly cloven. The individuals of this genus dig in the earth with the front, which is furnished at the end with a strong, round cartilage; they feed indifferently upon almost every thing, even the most filly; they wallow in the mire, and are in general extremely prolific. There are fix species.

*SCROFA; Hog. Back brilly on the fore-part; the tail is hairy. There are two varieties: 1. Tail hairy; or short, roundish; being the wild hog. 2. Tail hairy; or long, acute; being the common hog; which is beloved by those that have their hogs undivided; and into whose whole backs are nakedly, belly reaching almost to the ground. This is the Chinese hog, as it is denominated.

The common hog is found, either in a wild or domestic state, in almost all the temperate parts of Europe and Asia; but it is not met with in the moat northern parts of these continents. It is found in many parts of Africa. Dr. Shaw remarks, that it is not indigenous to the British Isles; but Mr. Pennant affirms that the wild boar was formerly a name of this country, as appears from the laws of Holc dda, who permitted his grand huntman to chase that animal from the middle
middle of November to the beginning of December. William the Conqueror was satisfied with the loss of eyes those that were convinced of killing the hog, or the ree-buck; and it is assayed by Fitz-Stephen, that the vast forest which in his time grew on the north side of London, was the retreat of hogs, wild boars, and bulls.

The wild boar inhabits woods, living on various kinds of vegetables, such as roots, maize, acorns, &c. It also occasionally devours animal food: it is in general considerably smaller than the domestic hog, and is of a dark brindled-grey colour, sometimes blackish; but when only a year or two old, it is of a pale red or dull yellowish-brown coat; and when quite young, it is marked with alternate duney and pale stripes, disposed longitudinally on each side the body. Between the bristles, next the skin, is a finer or softer hair, of a woolly or curling nature. The snout is somewhat longer in proportion than that of the domestic animal; but the principal difference is in the superior length and size of the tusks, which are often several inches long, and capable of inflicting the most severe and fatal wounds. The hunting of the wild boar forms one of the principal amusements of the great in some parts of Germany, Poland, &c. and is a chase of some difficulty and danger, not on account of the swiftness, but the ferocity of the animal. Wild boars, according to Buffon, which have not puffed the third year, are called by the hunters beasts of company, because previous to that age they do not separate, but follow their common parent. They never wander alone till they have acquired sufficient strength to repel the attacks of the wolf. These animals, when they have young, form themselves into flocks, and it is upon this alone that their safety depends. When attacked, the largest and strongest front the enemy, and by preying all around, force them into the centre. Of the same hog, white is the most general colour; but other colours are often intermixed in various proportions. In some respects, the hog seems to form an intermediate link between the whole and the cloven-footed animals; in others, he seems to occupy the same rank between the cloven-footed and digitated. Delineate of horns; furnished with teeth in both jaws; with only one stomach; incapable of rumination; and producing at one birth a numerous progeny: the union of these faculties confers on the hog a remarkable peculiarity and advantage. He does not, like other animals, shed his fore-teeth, and put forth a second set, but retains his first set for life.

Hogs seem to enjoy none of the powers of sensation in eminent perfection. They are said to be deaf and dim-sighted; and the wild boar distinguishes the scent of the hunter and his dogs, long before they can approach him. But so imperfect is their feeling, that they suffer mice to burrow in the fat of their backs without discovering any uneasiness, or appearing even to notice it. In their tale they flew a flingral degree of caprice. In the choice of herbs they are more delicate than any other herbivorous animal, yet devour the most nauseous and putrid carrion with more voracity than any beast of prey. At times they do not scruple to eat their own young; they will even mangle infants out of desperate voracity.

The hog is remarkable for the smallness of his eyes: hence a person whose eyes are very diminutive, and deep sunk in his head, is said to be pig-eyed. The form of the hog is indelicate, and his carriage is equally mean as his manners. His unwieldy shape renders him less incapable of swiftness and frigidity, than he is of gracefulness of motion. His appearance is always drowsy and stupid. He delights to bathe in the sun, and to wallow in the mire. An approaching form seems to affect his feelings in a very sigular manner. On such occasion, he runs about in a frantic state, and utters loud shrieks of horror.

The hogs are often very troublesome in cultivated grounds, ploughing them up with their snouts, and thus entirely frustrating the labours of the agriculturalist. Worms, the wild carrot, and other roots, are the objects of their search. The wild boar having a longer and stronger snout than the domestic, digs deeper, and continues his furrow nearly in a straight line. The inhabitants of America find the hog very beneficial in clearing their lands of rattlesnakes and other serpents, upon which it constantly prey, without apparently suffering any injury.

The sow brings forth in the beginning of the fifth month after conception, and she has often two litters in a year. She generally produces a numerous progeny at a birth; but her first litter is less numerous than those that follow. Hogs, when suffered to see the natural term of life, live from 15 to 50 years. Their size and strength continue to improve till they are five or six years old. They are infested with lice, and are subject to many disorders, such as the scurry, icab, and farcula.

Contemptible as the hog may appear, he is, in a very considerable degree, beneficial to mankind. His flesh is pleasant, substantial, and nutritious. It affords magnificent materials for the table of the epicure; among these is a brawn, which seems peculiar to England. Pork takes salt better than the flesh of any animal, and is, in consequence, preserved longer, and always makes an important article in naval stores. The lard of the hog is used in various medical preparations, and is compounded by the perfumer into pomatum. The bristles are made into brushes, and are, moreover, of great use to the shoemaker. The skin is worked into coverings for pocket-books, and other articles.

The Chinese hog is distinguished from the common, by having the upper part of its body almost bare, its belly hanging nearly to the ground; its legs are very short, and its tail still more disproportionately short. The flesh of this variety is whiter and more delicate. The colour is commonly a dark grey. It abounds in China, and is diffused through New Guinea, and many islands in the South Sea. The New Hebrides, the Marquises, the Friendly and the Society islands, pollute this animal, and cultivate it with great care, as it is almost the only domestic animal of which they can boast.

PORCUS; the Guinea Hog. Back brightly on the hind parts; tail reaching to the ground. A variety has erecct ears, a little pointed; the tail reaching nearly to the ground. It inhabits Guinea; and the variety is found chiefly at Siam. It is less than the hog; the tail is naked; ears long and pointed; the body is red; hair longer on the head and buttocks.

TAJABU; Peccary, or Mexican Hog. Back with a glandular orifice; it has no tail. The tails of this species are scarcely conspicuous, when the mouth is shut; the ears are short, erect, pointed; the eyes are funk in the head; the neck is short and thick; the bristles are nearly as large as those of the hedge-hog, long on the neck and back; in colour it is hoary, black, annulate with white; from the shoulders to the breast is a collar of white. In fine and figure this animal bears an imperfect resemblance to the hog of China. From the gland on the back constantly difficult a thin fetid liquor, which is the most remarkable peculiarity of this species. The first Europeans who became acquainted with this animal imagined the gland referred to was the navel.

The habits of the Mexican hog are not very different from those of Asia and Europe. It is found in great abundance...
dance in all the warm climates of South America. Their instincts, and arms of offence and defence, are the same as those of our own hog, but their teeth never yet set upon anything more gregarious. They are usually found associating together in parties. Though only an individual be singled out, the whole body of the animal is against an enemy. They groan with a stronger and harsher voice than the hogs of Asia and Europe. Forests are their favourite haunts; they do not frequent like our own hogs or the wild boar, to marshes and mires. Fruits, seeds, and roots, are their chief food; but they will devour with great eagerness serpents, toads, and lizards; and they display great dexterity in tearing off the skins of their reptiles; but they do not swallow and become fat, like the common hog. They produce a number of young at each litter, and the mother treats them with the tenderness and solicitude of a kind parent. Though existing in a wild state, they are susceptible of domestication, but nothing can overcome their natural fickleness. Beasts of prey, no less than man, are hostile to this species. The American leopard, or jaguar, one of their most formidable enemies, offers themselves to them, and commits upon the herd the most cruel slaughter. If killed in the night season, provided the ground on the back be taken off, and the liquor which it secretes carefully washed away at the instant of death, the flesh of the Mexican hog is reckoned agreeable food.

AFRICANUS; Cape Hog. Two fore-teeth in the upper jaw. This hog is of a superior size, and peculiar to Africa. It is found in abundance between the Cape de Verde and the Cape of Good Hope. The head is long; the snout slender; tusks large, and hard as ivory; and that in the upper jaw thick, and truncated obliquely; the ears are narrow, erect, and pointed; the tail is slender, and terminating in a tuft reaching down to the highest point of the leg; both jaws furnished with twelve grinding teeth; the body is covered all over with long fine bristles. This species has sometimes been confused with the ethiopicus (next to be described); but the form of the head, the structure of the mouth, and the manner in which the body is covered, establish a sufficient specific difference.

ETHIOPECUS; Ethiopian Hog. This species has no fore-teeth; under the eyes is a soft wrinkled pouch. It inhabits Madagascar, and the bot parts of Africa. They are, in fact, diffused from Sierra Leone to Congo. The manners and economy of this species are but very imperfectly known. They live chiefly under ground, where the texture of their flesh enables them to make their way as readily as the mole.

The Ethiopian hog is nearly five feet long, and between 24 and 30 inches in height; the body is thick and broad; the snout is somewhat prominent; the mouth is narrow, as well as destitute of fore-teeth, but it is furnished with hard gums to supply their functions; the tusks in the lower jaw are small, in the upper very large; the eyes are small, and situated high in the fore-head, the horizontal lobe or wattle under them intercepting from the sight of the animal all objects placed immediately below. The skin is of a dulky hue; the bristles thinly dispersed in separate parcels over the body, between the ears and on the shoulders longer than on any other part.

BABYRUSUS. Two crooked tusks piercing through the upper part of the face. It inhabits the islands of the Indian ocean; is gregarious; feeds on herbs and leaves; of quick scent; swims and dives well; grunts: it is the fize of a stag, and the flesh is good. See BABYRUSUS.

SUS AFFRITIS. See WILD BOAR.

SUS PICTUS, in Leichthyology, a name given by Ovid, and some other of the ancient writers, to the fish called Ἁρτος και κέρας, and by the later writers caprifius. See GOAT FISH.

SUSA, in Geography, a town of Africa, in the kingdom of Tunisia, near the E. coast, near which are considerable remains of ancient buildings. The chief trade of the place is for oil and linen, and it may be reckoned one of the most considerable and wealthy towns of the Tunises. Here are several vaults, granite pillars, and other parts of its having been formerly a place of some repose; probably one of those towns which submitted to Caesar in his march to Rufspinus; 24 miles E. of Cairoan. N. lat. 35° 46'. E. long. 10° 3'.

SURA, a town of Persia, in Khorassan; 150 miles S.E. of Nezibfahr. N. lat. 36° 16'. E. long. 59° 49'.

SURA, called in Scripture Shubban, in Ancient Geography, a town of Persia, and the metropolis of the province of Sultana. It was built on the banks of the Eoleus (called by the prophet Daniel, Ulai) by Memnon, as one of the sons of Tithonus, who was slain by the Thetians in the Trojan war. Strabo and Faustinius compare the walls of Sura with those of Babylon. It was called Susa, from the number of lilies which grew in its vicinity, as Stephanus says, and in the Persian language bore that name. It is also called "Memnonia" by Herodotus and others, from Memnon, its founder. The city was sheltered by a high ridge of mountains from the northern winds, which rendered it very agreeable during winter, and the refuge of the kings of Persia; but in summer the heat was so parching, that the inhabitants were forced to cover their houses, as Strabo writes, with earth two cubits deep. In ancient times, Susa was a wealthy, extensive, and magnificent city, as its ruins indicate. Alexander found it a 50,000 talents of gold, besides jewels of an inestimable value, and an immense quantity of gold and silver vases. Here Ahafuerus kept his great feast, which lasted 11 days. Some have supposed that the present Shekerar is from its ruins. See SHUS and SHUSTER.

SURA, See ZUSAN.

SUSANYAMA, in Hindoo Mythology, a name of the ruler of the infernal regions, corresponding with the Pluto of Western heathens. Its commonest name is Tam; which see.

SUSCE, in Geography. See SCHUTZENHOFEN.

SUSCEPTOR, among the Romans, a citizen chosen by the decurions to collect the debts belonging to the public.

SUSCEPTOR is also a term used by ecclesiastical writers for sponor.

SUSCEPTOR AURARIS, in Middle Age Writers. See ARA.

SUSEAPOUR, in Geography, a town of Hindostan, in Bahar; 35 miles S.E. of Durbungah.

SUSELL, a town of the duchy of Holtstein; 8 miles E.S.E. of Eutyn.

SUSERAT, a town of Cordtian; 15 miles N. of Van.

SUSHENA, the name of an ape, who bore a part of some importance in the war of Lanksa, carried as by Rama to recover his spouse Sita from the power of her ravisher Ravanas.

SUSHUMNA, in Hindoo Mythology, a name of Soma or the moon. Sushumna is the perfumery of a ray of light proceeding from the sun; which illuminating the moon, is falsed to have produced him.

SUSIA, in Ancient Geography, a town of Asia, in Aria, a province of Persia.

SUSIANA.
SUSIANA, a province of Persia, which derived its name from Susa, its capital. It was bounded on the N. by Affrizia, on the W. by Chaldea and the Tigris, on the E. by Elamais, and on the S. by the Persian gulf. Susiana was extended by Ptolemy to the coast, so as to include the province called Elamais, which, as Ptolemy observes, lay within the bounds of this province, and was severed from it by the river Elamais.

SUSICANA, a town of India, on this side of the Ganges, and one of those which were situated on the banks of the Indus, according to Ptolemy.

SUSOONDEE, in Geography, a town of Hindooistan, in Oude; 4 miles N.E. of Gazipour.

SUSOUNDAR, a town of Hindooistan, in Bahar; 35 miles W.S.W. of Arrah. N. lat. 25° 22'. E. long. 84° 15'.

SUSPENSE, Suspensio, in Common Law, denotes a temporary stop or cessation of a man's right for a time. As, when the rent, or other profits of land, by reason of the unity of possession of the rent, and the land out of which it issues, is not in esse for a certain time, but tum dormit, or remains asleep; but so as it may be revived or awaken. By which Suspension differs from extinction, where the right dies for ever.

SUSPENSION, Suspensio, the act of preventing the effect or course of any thing for a certain time.

In rhetoric, suspension is a keeping the hearer attentive and doubtful, in expectation of what the speaker will conclude with.

The principal point urged in the philosophy of the Sceptics and Pyrrhonians, is a suspension of mind.

Suspension, in Law, denotes a centurie inflicted, by way of punishment, on an ecclesiastic, for some considerable fault.

It is of two kinds, vis. ab officio, and a beneficio. The first is that by which a minister is, for a time, forbidden to execute the office of a minister. The second is when a minister is, for a time, deprived of the profits of his benefice.

Where the fault is more notorious, the two kinds of suspension are sometimes joined; and the person both suspended ab officio and a beneficio.

The penalty for a clergyman officiating after suspension, if he shall perfide therein after a reprieve from the bishop, is (by the ancient canon law), that he shall be excommunicated in all manner of ways, and every person who communicates with him shall be excommunicated also.

There is another sort of suspension, which extended also to the laity; suspension ab inregra ecclesiae, or from hearing of divine service, and receiving the holy sacrament, which may be, therefore, called a temporary excommunication.

It is an undoubted rule in admiralty and ecclesiastical courts, that a person suspended for a trumped up offence, of which he is afterwards acquitted in a proper court, is entitled to all the intermediate profits. Thus, in case of capture of prize at sea, the officer in arrest being actually on board, and afterwards duly acquitted, or relitig to his station, shall have the prize-money. So in civil causes in admiralty, if a matter turns his mate, without just cause, before the mast, and he uses for wages as mate for the whole time, he may recover, though he did not perform the duty. So if a clergyman be suspended ab officio et beneficio, and, upon an appeal, be declared innocent, he will recover the profits of the living.

Suspension, in the Law of Scotland, is that form of law by which the effect of a sentence condemnatory, that has not yet received execution, is stayed or postponed till the cause be again considered. The first step towards suspension is a bill preferred to the lord ordinary on the bill. This bill, when the desire of it is granted, is a warrant for influing letters of suspension, which pafs the signet; but if the preferer of the bill shall not, within fourteen days after passing it, expedite the letters, execution may, by act of feudal 1677, proceed on the sentence. In practice, however, it is usual for the charger to put up a protestation in the minute-book for production of the suspension, which may be expedited at any time before this is done; and if the suspender shall allow the protestation to be extracted, the bill falls. Suspensions of decrees in foro cannot pass, but by the whole lords in time of lection, and by three in vacation time, but other decrees may be suspended by any one of the judges. By the late act of feudal (1875), in order to remedy the abuse of presenting a multiplicity of bills of suspension of the decrees of inferior judges, in small causes which have passed in absence, it is declared, that all bills of suspension of decrees by inferior judges, in absence of the defenders in causes under 12l. sterling value, shall be refuted and remitted to the inferior judge, if competent; the suspender, however, being heard in the inferior court, reimbursing the charges of the expenses incurred by him previous to the remit.

As suspension has the effect of staying the execution of the creditor’s legal diligence, it cannot, in the general case, pass without caution given by the suspender to pay the debt, in the event it shall be found due. When the suspender cannot, from his low or suspected circumstances, procure unquestionable security, the lords admit jurisdiction caution, i.e. such as the suspender swears is the best he can offer; but the reasons of suspension are, in that case, to be considered with particular accuracy as passing the bill. Decrees in favour of the clergy, of university, hospitals, or parish-schoolmasters, for their stipends, rents, or salaries, cannot be suspended but upon production of discharges, or on notification of the sums charged for. A charger, who thinks, himself secure without a cautioner, and wants dispatch, may, where a suspension of his diligence is fought, apply to the court to get the reasons of suspension fully discoursed on the bill.

Though he, in whose favour the decree suspended is pronounced, he always calls the charger, yet a decree may be suspended before a charge be given on it. Nor is suspension competent even where there is no decree, for putting a stop to any illegall act whatsoever; thus, a building, or the exercice of a power which one assumes unwarrantably, is a proper subject of suspension. Letters of suspension are considered merely as a prohibited diligence; so that the suspender, if he would turn provoker, must bring an action of reduction. If, upon discoursing the letters of suspension, the reasons shall be sustained, a decree is pronounced, suspending the letters of diligence on which the charge was given simpliciter; which is called a decree of suspension; and takes off the effect of the decree suspended. If the reasons of suspension be repelled, the court find the letters of diligence orderly proceed, i.e. regularly carried on; and they ordain them to be put to farther execution.

Suspension, in Mechanics. Points of suspension in a balance, are those points in the axis or beam in which the weights are applied, or from which they are suspended.

Suspension, in Music. Every forced of a chord to a given base, which is continued to another base, is a suspension. If, for instance, after the common chord of the key-note C has been played to the first note of a passage, if the base moves to G, the fifth of the key, and the chord of C; or any part of it, is continued to G a few instants before
before the chord of $G$ is struck, it is a suspenison. There are certain suspensions which are figured, and belong to the fundamental harmony. When they are discomposed, they are always chords by supposition; which fee. Other suspensions are notes of taste; but of whatever kind they may be, they should always be subjected to the three following rules.

1. A suspenison or binding note should always occupy the accented part of a bar.

2. A suspenison note should always be resolved diatonically, either in ascending or descending; that is to say, each part suspended should not rise or fall more than one degree, to arrive at the natural found which the ear expects, and which belongs to the base to which the note is suspended.

3. All suspensions expressed by figures ought to be resolved by descending, except the sharp 7th of the key, which the French term la note fênsible, and which is resolved by ascending.

With these precautions, there is no suspension that may not be practised with success; as the ear, prepared by the base for the motion of the parts, predicts what is coming. But the use of these suspensions, and distributing them with effect in the melody and the harmony, depends on good taste.

**Suspension of Arms, in War.** is a short truce which the contending parties agree on, for the burial of their dead, the waiting for succours, or the orders of their masters, &c.

**Suspensorium Ligamentum Hepatis, in Anatomy.** See Ligamentum.

**Suspensorius Oculi, a muscle surrounding the optic nerve in animals.** See Mammalia.

**Suspensory, in Surgery, a bandage to keep up the scrotum.**

**Suspental, a spring of water, passing under-ground towards a conduit or cistern.**—Allo, a breathing-hole, or vent indicated.

**Susquehana, in Geography, a large river of Chesaapeake bay, in the Atlantic ocean, rises in the state of New York by a great number of branches that spread from east to west in the extreme points, over a tract of country of about 160 miles. The most norther point from which any of these streams run south is within 8° of 43° of N. latitude. These numerous streams are collected by two large branches, viz. the Troga, and the east branch, or proper Susquehanna, which takes its name at the outlet of Otgo lake, at the village of Cooperstown. From this place it runs south to Delaware county, then turns south-west, and forms the boundary of Otgo and Delaware counties; runs across the south-east angle of Chemango, the east end of Broome county, into Pennsylvania, whence it turns west, north-west, and west, across Broome, and the south-east angle of Tioga county, again into Pennsylvania, about three miles before it meets the great western branch at Tioga Point. Its whole course, which is very devous, and abounding with small turns, may be near 145 miles within the state of New York. Its navigation is favourable for export trade, and immense quantities of timber, in all the various forms of boards, scantlings, shingles, &c. &c. deflected by this river to Baltimore, on an arm of the Chesaapeake. This large river has many rapids; and after running across the state of Pennsylvania, it enters Chesaapeake bay in the north-east corner of the state of Maryland, 69 miles in a right line about N.E. from the city of Washington.

**Sus, a town of Switzerland, in the Lower Engadine; 9 miles N.N.E. of Zuèz.**

**Susac, a town of France, in the department of the Upper Vienne; 15 miles S.E. of Limoges.**

**Sussex, the north-westernmost county of New Jersey, in the United States of America.** This county is mountainous and healthy; it has several iron-mines and works for the manufacture of bar and pig-iron. Its crops of wheat are excellent, and it abounds with herds of cattle. The produce is floated down the Delaware on boats and rafts. In this county are five Presbyterian churches, two for Anabaptists, one for German Lutherans, and one for Quakers. It contains fifteen ships; the chief of which are Newport, Greenwich, Harlequin, Knowlton, and Oxford. The population is 25,549, including 478 blacks. It is bounded N.E. by the state of New York; N.W. by Delaware river, which separates it from Northampton county, in Pennsylvania; and S.E. and S. by Morris and Hudson counties. The court-house in this county is 13 miles S.W. of Hamburg.—Allo, a county of Virginia, bounded N.E. by Surrey, and S.W. by Dinwiddie. It contains 14,632 inhabitants, of whom 6,344 are slaves. Allo, a maritime county of Delaware, bounded W. and S. by the state of Maryland, N.E. by Delaware bay, E. by the Atlantic ocean, and N. by Kent county. It contains 73,674 inhabitants, of whom 4,777 are slaves. The land is generally low, sandy, and poor. The chief town is Georgetown.

**Suffolk, one of the southern counties of England, is bounded on the west by Hampshire, on the north by Surrey, on the east and north-east by Kent, and on the south by the British Channel. The superficial area of the district has been computed at 933,560 acres; its length 76 miles, and its medium breadth nearly 20; making it a square in proportion to its breadth, and not varying at any point it reaches the boundary of Kent, where it is constricted to an obtuse point.

**Historical Events.**—Suffolk, and the adjoining counties of Hants and Surrey, were by the Romans denominated Belse, from the circumstance of their being inhabited by a people so called. These were afterwards joined by the Regni, who settled in the same district antecedent to the invasion of England by Julius Caesar. After that event, during the Roman dominion of Britain, there were four large flatboats or towns in Suffolk, which included the minor tribes of the Bibraci and the Rheni. Under the Britons, Suffolk formed a part of the Suth-Saxena-rice, as already mentioned in Surrey; and by a similar modulation, has been reduced to its present form. Like the other counties of England, Suffolk was, at the Norman invasion, divided into lordships, and assigned to some of the followers of king William. At that period the title of earl of Suffolk was given to one of these, and the title continued till 1801, when it became extinct: it was then constituted a dukedom, and given to Augustus Frederic, sixth son of his majesty.

**General Aspects, Soil, and Climate.**—The aspect of Suffolk is varied in a pleasing manner, by the inequalities of the downs, with the intervening vallies, through which the many little streams of the county pursue their respective courses to the sea. The wooded scenery which it presents, and the pasture-land with which it is contrasted, gives to the county in general a rural and a rich diversity of appearance.

The soil may be classed under the usual divisions of clay, sand, loam, and gravel. The first is the general soil of the South Down hills; the second, of the wooded district, termed the Weald; the third principally occupies the north part of the county; the fourth is found on the north side of the hills; and the last lies between the rich loam of the coast and the chalk.

The climate upon the downs, fronting the south-west, is bleak, being exposed to violent winds, which are imper-
nated with saline particles, occasioned by the spray driving against the beach. In the western part of the maritime district, the climate is warm, and highly favourable to the purposes of vegetation; and in that division called the Weald, the circulation of air is impeded, and the climate is cold and damp.

Mineralogy.—The Sussex minerals consist principally of lime-fence, which is found in the eastern parts of the Weald, of every species; marble, which is equal to that of its beauty and quality; iron-fence and ore, fuller's-earth, red ochre, chalk, and marl. The Sullfris or Pettalls marble was formerly much used in ecclesiastical architecture, and in monumental sculpture. It is now in much requite for ornamental chimneys-pieces. The stratum lies from ten to twenty feet beneath the surface, and is about nine or ten inches in thickness.

Rivers.—The waters of this county are insignificant streams, when compared with those of other English provinces. One of the principal is the Arun, which Harrison, in his "Description of Britain," entitles "a goodly water." It rises from two different heads in the northern part of Sussex, and falls into the sea at Little Hampton. This stream is noted for its mullets, trout, and eels. The other rivers of the county are the Adur, the Ouse, and the Rother, all of which run into the British Channel.

Leaves, Size of Farms, etc.—Leaves, in Sussex, are in general granted for seven, fourteen, and twenty-one years; but sometimes there are none allowed, and the tenant is entirely dependant on the honour or caprice of the landlord. Farms differ in extent according to their situation; those on the dry soils being more superior to the damp ones. The latter seldom exceed 200l. per annum, and even rarely that, but are usually about half that sum. The former average 350l., and in the vicinity of Lewes extend beyond it.

Rent varies with the quality of the land, and is from 7s. to 26s. per acre.

Agriculture.—The proportion between pasture and arable land varies in different parts of this county. In the Weald, one-third is pasture, one-third arable, and one-third wood and wattle. On the south side of the downs, the arable exceeds the pasture in the proportion of thirty to one. The rotation of crops in Sussex entirely depends upon the district in which they are grown. Some instances have occurred on very rich land, where wheat has been repeated four or five years in succession, and the product amounted to four or five quarters per acre. The crops commonly raised in Sussex are wheat, oats, clover, turnip, peas, barley, and tares. This county is particularly celebrated for its breed of sheep, fed on the South Downs: they require but a very slight quantity of food for their subsistence, and the quality of their fleeces is peculiarly sweet and tender.

See Sheep.

Forrest, Woods, and Plantations.—Sussex, like the adjoining county of Surrey, was at one period nearly covered with an extensive forest; and the quantity of wood-land which at present it contains cannot be less than 170,000 or 280,000 acres. The timber is principally oak; and its quality may be ascertained by the circumstance of its being preferred to any other species of oak, for the purposes of the navy. The Weald is principally covered with timber. St. Leonard's forest consists of about 10,000 acres of land, and Ashdown forest of at least 18,000 more.

Wolfe Lands.—The tracts of land which come under this denomination are very considerable. They chiefly occupy the northern side of the county, and are estimated at about 1,100,000 acres; yet they are everywhere intersected with turnpike-roads, and are not more than 45 miles distant from London.

Roads and Canals.—The turnpike-roads of this county are in general good, being composed of whin-fence and Kentish rag; and where these have not been used, the roads are found to be inferior, as in some of the eastern parts, where they are narrow and sandy.

There are no canals in Sussex, but the river Arun has been made navigable from the sea to its junction with the New Cut, a distance upwards of 17 miles; and from thence a company of merchants have extended it to Newbridge. A similar process has also been taken with the Rother, a branch of the former river, which constitutes part of a grand plan for connecting London with Sussex, by means of the junction of the Arun with the Wey at Guildford. A plan has also been proposed for cutting another canal from Newbridge on the Rother to Horsham, and thence to the iron railway at Merstham, near Reigate in Surrey.

Civil and Ecclesiastical Divisions.—Sussex is divided into six rapes, which are subdivided into 63 hundreds, and contains one capital city, 16 boroughs and market-towns, and 342 parishes. According to the parliamentary returns of 1811, the population of the county was estimated at 1,790,083, and the number of houses at 50,698. Sussex is represented in parliament by twenty-eight members; two for the county, two for the city of Chichester, two for each of its boroughs, and two for each of the four Cinque Ports that are situated within the county. Sussex is in the diocese of Chichester, and province of Canterbury.

Manufactures.—The principal manufacturer carried on in this county was the making of iron into bars; but this has decayed, on account of the great establishments in Scotland and Wales, where, by the use of pit-coal, the article is supplied at a much cheaper rate.

Antiquities.—The county of Sussex contains many Roman and some British antiquities. The Ermine-street, one of the eight British roads, led from this coast to the south-east part of Scotland. Here also was the Stan-street of the Romans, which passed from east to west of the county, with a vicinat, or branching road, towards Porchell. There are also many remains of Roman encampments in this district: these are situated in the vicinity of the downs, and overlook the Weald. Mr. Dallaway, in his "History of Western Sussex," recounts eleven of these relics of early encampment. Over the downs, and other parts of Sussex, are scattered various tumuli, or barrows, which, when opened, have been found to contain either bones, urns, or entire skeletons.

In 1717, a tessellated pavement, bath, and other antiquities, were discovered near Eastbourne. Similar remains have been found at Chichester, and at Bignor, very near the Roman road from that city; and coins of the lower empire have been dug up in several other places.—Beauties of England and Wales, vol. xiv. Sussex, by F. Shoberl, 5vo. History of Western Sussex, by the Rev. James Dallaway, M.A. Agricultural Survey of Sussex, by the Rev. A. Young.

Sussex Marble, a name given by many to a peculiar species of marble found in the county, the name of which it bears, and formerly much used in the pillars of churches, and other buildings, but now less regarded. The ground of this marble is grey, with a faint cast of green, and it is very thick-set in all parts with shells; these are chiefly of the turbinated kind, and they are generally filled with a white spar, which adds very greatly to the beauty of the stone.

Sussex Noodles, in Agriculture, a sort of tool of the terti-
SUS

flying kind, which is much employed in that district or county, and thought an implement of great power and utility in working the surface of ploughed land, and extirpating and clearing away the weedy matters that may be present upon it. It is strongly formed, in somewhat a long triangular shape, the neck part, or that to which the team or moving power is attached, being considerably drawn or lengthened out, and supplied with a wheel, by which the working of it is, in a great measure, regulated in regard to the depth it may have. It has fix or eight sharp triangular cutting flanks or hoes, as the size of it may be, fixed on strong shanks of some length, which are inserted and fastened into the strong side-pieces, and the three cross-bars or framing-pieces, by means of strong nuts, screwed firmly down upon the upper ends of the thanks. And there are two shafts or handles fixed behind for regulating the implement by.

When kept well sharpened in the hoe parts, it acts in a very ready and powerful manner, breaking down and reducing the surface parts with great effect and expedition. A representation of it may be seen in the Corrected Agricultural Report of the County, published a few years ago.

SUSITONGS, in Geography, a branch of the Sioux Indians, in North America. See Sioux.

SUSSMILCH, John Peter, in Biography, a German Lutheran divine, was born about the beginning of the last century, and applied with diligence not only to the study of history, but to that of mathematics, so that he became an expert calculator in political arithmetic. In the year 1759, he evinced his talents in this kind of science by a memoir, that was published in the Transactions of the Academy on Sciences at Berlin, on the population of the cities of London and Paris, to the latter of which he alluded, in 1750, 500,000 inhabitants. But he is principally known by a superior work, entitled "Die Gottliche, &c.," i.e. the order observed by God in the changes of the human race, demonstrated by the births, deaths, and propagation of man; a fourth edition of which, improved and corrected by J.C. Bauman, was published at Berlin in the year 1775, in 3 vols. 8vo. In this work the author first treats of the multiplication of men in general, and shews that the number of births is always almost always greater than that of the deaths: he then enumerates the obstacles to the increase of mankind; examines how many persons live on the earth, and how many it could contain; treats on the different causes of fecundity; the propagation of the two sexes, and the proportion of one to the other; of the proportion of those who die at different ages; of diseases and their proportion; of the use made of bills of mortality to determine the number of the living; and of the best method of keeping registers of the whole, illustrated with copious lists of births, deaths, and marriages, in the states of the king of Prussia, the cities of London, Vienna and Breslau, Paris and Berlin, in different years. This work has been of great service to writers on population, and is often quoted by Mr. Malthus on this subject. The Abbé Denina says, that the religious zeal of Susmilch sometimes led him to indulge a spirit of persecution; and that in the Confinitory, of which he was a counsellor, he often appeared forward and ambitious. He died in 1767, at the age of 61 years. Gen. Biog.

SUSTENAL, in Geography, a town of Prussia, in the province of Ermeland; 15 miles S.W. of Heilberg.

SUSTERT. See Stutter.

SUSTEREN, a town of France, in the department of the Roer; 5 miles S.S.W. of Ruremond.

SUSTERS, a small island in the North Sea, on the coast of Norway; 13 miles S.E. of Tonberg.

SUSTENENTE, a town of Italy, in the department of the Misson; 11 miles S.E. of Mantua.

SUSU, a town of Asia, in the province of Natolia; 16 miles S.W. of Iffartisch.

SUSUGHERLIK, a town of Asia, in Natolia; 44 miles S.W. of Burfa.

SUSUN, a town of Arabia, in the province of Hedeja; 20 miles N.W. of Karac.

SUSZA, a town of Russia; 42 miles S. of Polotsk.

SUTAGOTCHY, a town of Bengal; 8 miles N. of Hoopyly.

SUTALARY, a town of Hindoostan, in Bengal; 65 miles S. of Dacca. N. lat. 23° 40'. E. long. 95° 15'.

SUTARBOY, a town of Bengal; 8 miles S.E. of Rogonatpour.

SUTCHAVA. See Suczava.

SUTCHUTZ. See Schitterhofen.

SUTE, SUTIB, or Suits. See Suit.

SUTEMA, or Sutamon, in Geography, a town of Africa, in the kingdom of Krimen.

SUTER POINT, a cape of England, on the coast of Durham. N. lat. 55° 2'.

SUTERRA, a town of Sicily, in the valley of Mazzar; 16 miles N.E. of Girgenti.

SUTHAUSEN, a town of Welfphalia, in the bishopric of Osnabruck; 2 miles S.S.W. of Osnabruck.

SUTH-DURE, in Ancient Customs, denotes the south door of a church, mentioned in old authors as the usual place where canonical purgation was performed. This is, with a few exceptions, almost always proved by sufficient evidence, the party accused came to the south door of the church; and then, in the presence of the people, made oaths that he was innocent.

This was called judicium Dei. And it is for this reason that large porches were anciently built at the south doors of churches.

SUTHERLAND CREEK, in Geography, a creek of Upper Canada, which runs into lake St. Francis, between Pointe au Bodet, and Pointe Moutilie, in the township of Lancaster.

SUTHERLAND POINT, the S. point of entrance into Botany Bay, so called from — Sutherland, one of Capt. Cook's seamen, who was buried there in the year 1770.

SUTHERLANDIA, in Botany, so named by Mr. Brown, in Ait. Hort. Kew. v. 4. 327, (in memory of Mr. James Sutherland, who published in 1683 an extra catalogue of the phytic-garden at Edinburgh,) is found solely on the Colutus fruticos, Linne. Sp. Pl. 1045. Cor. Mag. t. 181, with the following.

E. Ch. Calyx with five teeth. Standard without calli-
ties at the base, folded back at the sides, shorter than the long keel. Stigma terminal. Style bearded longitudinally at the back; transverse in front at the summit. Legum inflated, membranous.

We always differ with reluctance from our able and judicious friend, and might perhaps admit his present genus, did not Swainson (see that article) appear, in our opinion, to invalidate it. See Colula, n. 4. and n. 6.

SUTHERLANDSHIRE, in Geography, one of the most northerly counties of Scotland, extends the whole breadth of the island; and is bounded on the N.E. by Caithness; on the E. and S.E. by the German ocean, and the Frith of Dornoch; on the S. and S.W. by Ralston; on the W. by the Atlantic ocean; and on the N. by the
great North fes. This county is one of the largest in Scotland, and contains about 2310 square miles, or 1,478,400 English acres; yet, in consequence of its vast mountainous districts, its value is inconceivable. The whole extent of Sutherlandshire is about 80 miles in length, and 40 in breadth, and its population, in 1811, amounted to 25,629 inhabitants, and 4882 houses.

General Aspects of the Country. The surface of Sutherlandshire is mountainous and rocky, and presents a series of vast hills towering above each other: some of these appear clothed with heath, and as they descend, become gradually covered with verdure. Amidst this rude magnificence of nature are many valleys, each of which contains a stream, and not unfrequently a lake of considerable extent; the scenery round which, during the summer, is extremely interesting. Upon the coast are many arable fields; but the surface, though in a less degree, partakes of the rugged appearance of the interior of the country. The chains of mountains diverge like rays from the centre of this county towards the east, west, and the northern seas; forming between the mountains long and narrow glens, or straths, which constitute separate districts, sometimes 40 miles in length. The inhabitants at each extremity of these glens, have a much more ready communication with each other, than with those who only dwell at the distance of eight or ten miles in the next valley.

Mineralogy. Sutherlandshire has in many parts large quantities of free-flone, lime-flone, and slate. The lime-flone, in some places, assumes the form of marble, particularly near the coast. In the mountains, on the well-coafted, traces of ancient iron-mines are yet visible; and as the county was at one period an extensive forest, charcoal was readily procured. Some years since, a large piece of forged iron was discovered in these mountains, of a circular form, and from seventeen to twenty pounds in weight. Rock-crystals and pebbles are found in many parts; and beautiful garnets on the coast in the parish of Tongue. There are also several veins of coal, but the quality is too small for working, and the quality is far from being good. Native gold, is often found, especially near the base of the mountains; and lead-ore, veined with silver, is also found. The river Clay is the mother of these minerals, and in a few years, a mine will be established, to work the lead and silver ores. In the parish of Reelig, there is a mine of lead, which is worked, and the products conveyed by boats to different parts of the country. The rocks along the coast are hallowed into caves, or formed into arches or pillars, some of which run so regular as to appear to be the work of art. One of these, the "Great Cave of Fradigill," extends more than half a mile under ground. It is about fifty feet high, and twenty feet wide at the entrance, and grows narrow by degrees; its sides are beautifully variegated with colours that blend and melt into each other. Numbers of seals resort to this cave.

Climate. The climate of Sutherlandshire varies, according to the different districts into which it is clasped. These are the eastern, upon the German ocean; the western, upon the Atlantic ocean; and the central, or middle districts. The air in the eastern district is sometimes keen and penetrating, but is on the whole healthful and salubrious; and the western coast, from the activity of its hills, attracts the clouds; by this means, heavy rains and mists settle upon it, so as to produce a damp and wet climate.

Soil. The soil of the long valleys between the mountains is a sharp loam, capable of every improvement, if it were cleared of the great lumps of fliche which are found in it. With the exception of those farms converted into town or village, the arable land is in the proportion of one to four acres. The flat of the roads is very bad, from the little attention that is paid to them. The western coast of Sutherland is wild, rocky, and mountainous; and a confiderable part of it is an assemblage of rugged mountains, piled on each other. There are many goats in this part of the county; and in consequence of the great elevation of the hills on which they feed, the clouds from the Atlantic are strongly attracted as to occasion a very wet climate. In the southern district, which runs to the easterly of Sutherlandshire, considerable quantities of grain are raised, and black cattle are reared for sale. Some linen-narms is also spun for the manufacturers of Aberdeen, and other places. The other divisions of Sutherlandshire differ but little in their agricultural productions; peas are in general much cultivated, and a species of barley denominated bear.

Antiquities. Over the whole of the country are to be found vestiges of those ancient buildings denominated Pits; and in various parts are also to be seen remains of fortifications of different sorts. Some of them are old towers and others confit of large stones, which appear to have been intended as places of concealment for confiderable bodies of men and cattle. On the east coast, on the south side of Loch Broom, there is a hill called Craig Bar, fortified with a ditch of circumvallation. It is a steep and rocky precipice, every way inaccessible, but by a narrow neck of land between it and an adjacent hill; it contains in its whole area about eight acres. In many quarters cairns are found, which are considered as monuments erected to the glory of the heroes who fell in battle; and many spots are pointed out, in which the rival clans are supposed to have contended with each other. In the parish of Afflin, in the isle of Oldney, is a considerable cairn, in which is a stone hollowed, having a cover alof fliche. The hollowed fliche once contained a rounded one of varied colours, for which a great veneration was entertained; it was supposed to have been an object of Scandinavian idolatry. In the parish of Durness, are the remains of the tower called Dun Dornadilla. That portion of the wall which is now standing, is 18 feet at the highest part. The area appears to have been surrounded with two concentric walls; and a large triangular fliche covers the door-way as a lintel. The opposite side has been destroyed. At Milnes, in the parish of Tongue, are the remains of an ancient building; but so ruinous, and so covered with earth, that its original form cannot be traced; it is called the Yellow Heap, and is supposed to have been erected by Dornadilla, king of Scots; two skeletons were found buried near it, one of which measured seven feet in length. Two other antiquities remain to be noticed: the one consists of several heaps of fitches; and ruins of circular buildings, erected on a rising ground near the sea; and the other is Dunrabin castle, the seat of the ancient earls of Sutherland, founded by Robert, the second earl, in the year 1100.—Beauties of Scotland, by R. Forsyth. Statistical Account of Scotland.

SUTHALLI, a town of Abacish, on the Black sea; 20 miles S.W. of Mamak. N. lat. 43° 20', E. long. 48° 4 K. SUTLER.
SUT

SUTLER, in Military Language, denotes one who follows the army, and furnishes provisions for the troops. The sutlers pitch their tents and build their huts in the rear of each regiment, and about head-quarters.

SUTO, in Geography, a town of Benguela, near Cape Ledo.

SUTORS, two capes or promontories of Scotland, at the entrance of the bay of Cromarty, confiderably above the level of the sea; the one on the north, the other on the south side of the mouth, which is about 14 mile broad.

SUTRAPARAH, a town of Hindoostan, in Guzerat: 18 miles N.N.W. of Puttan Sumnaut.

SUTRI, a town of Italy, in the Patrimonio, the see of a bishop, united to Nepi; 22 miles N.W. of Rome. N. lat. 42° 15'; E. long. 12° 15'.

SUTTEE, or SATI, a word in the Sanscrit, or sacred language of the Hindoos, meaning pure, and hence extensively applied to their female deities, and to acts of purification, especially to that pre-eminent species, the self-immolation of the widow on the funeral pile of her deceased husband. This horrid sacrifice is commonly written Suttee by the English; but Sati (under which word the following account was accidentally omitted) is the correct mode of spelling it, according to the orthodoxographical system of the late sir W. Jones.

From some recent publications and speeches, we may be led to infer that the sacrifice in question is one of frequent occurrence in India; but this is not the case: it is indeed very rarely seen, as any of our readers may be convinced by enquiring of their friends or acquaintance returned from that country, if they ever witnessed it. Nine in ten, and perhaps a much greater proportion, even of those who have passed many years there, will reply in the negative. In the whole of India, under the British government, this suicide is of course never permitted; and under native governments, it is said to be practised less frequently than formerly. As it is the greatest victory that pietiecraft has achieved over the natural feelings and instincts of mankind, we may expect to find it oftenest at the chief feast of Brahmanical superition. And Poona being the only capital of a Brahman government, we have good reason to believe that it occurs more frequently at that city than in any other throughout India.

The Hindoos have a mystical reverence for the confluence of rivers. See Indus.

On the interesting subject of this article, we are induced to make an extract of some length from the Hindoo Pantheon.

"Human victims," says the author, "were formerly immolated at the flurine of offended or avenging deities, as I have had occasion to notice in another place; but the practice is now, perhaps, entirely discontinued. In the countries under our government, it is of course, in that instance, as well as in every other of an atrocious nature, whether voluntary or otherwise. But a few years have elapsed since a widow in Bombay wanted to become Sati, that is to burn herself; which being of course prevented, she applied to the governor, and on refusal, crossed the harbour to the Mahratta shore, and there received her crown of martyrdom.

"Prodigality, or carelessness of life, has on another occasion been remarked as a conspicuous trait in the Hindoo character; hence has arisen such an army of martyrs, as no other religion, perhaps, can outnumber; as well as meritorious suffering for religion's sake. Suicide is in some cafes legal, and even commendable: that for instance of the Sati, or self-immolated widow, the only one that came under my notice, and to which sacrifice I have attended several victims. This triumph of pietiecraft, the greatest perhaps it has in boast, occurs at Poona, in ordinary and quiet periods, usually about twelve times, on an average of as many years. I was lately a whole year at Poona, and I knew of its occurrence only six times; but it was a tumultuous and revolutionery period, and people were of course put out of their usual and ordinary routine of thought and deed. As this terrible ceremony is generally performed at Poona, at the junction of the Muta and Mula rivers, a quart of a mile from the skirts of the city, at which junction, these called Sangam, the English residency is situated; and any habituation was as near as possible to the river, on the bank opposite to the spot of sacrifice, and not more distant than two hundred yards, I most likely knew of all that occurred; and, with the exception of one that took place at midnight, attended them all.

"As this affecting scene has been so often described, I shall not here enter into any detail of particulars; it may be observed, however, that on no two occasions were the ceremonies, which sometimes are very numerous and striking, exactly alike. They seemed prolonged or abridged, in a degree corresponding to the fortitude or timidity of the victim.

"The first that I attended was a young and interesting woman, about twenty-five years of age. From the time of her first coming on horsecarriage to the river-side, attended by mufic, her friends, Brahmanas, and spectators, to the period of her lighting the pile, two hours elapsed; so evinced great fortitude. On another occasion, an eldery, sickly, frightened woman was hurried into the pile in a quarter of an hour.

"Of the first of these I took particular note. Soon after I arrived at the pile, the rescuing, the law, and beckoned me to approach her. All persons immediately made way, and I was led by a Brahman close up to her, when I made an obeisance, which she returned, looking full in my face, and proceeded to present me with something that she held in her hand. A Brahman flapped her, and desired me to hold my hand out, that what she was about to give me might be dropped into it; to avoid pollution, I suppoze, by touching any thing while in contact with an impure person. She accordingly held her hand over mine, and dropped a pomgranate, which I received in silence, and reverently received. I was sorry that it was not some ornament, or something of an imperishable nature, that I might have preferred it. My wife, who was in the house on the other side of the river, observing the ceremonies through a glafs, was also dill pointed, and was of course curious to know what was the article presented in fo interrelling a manner at such a solemn time.

"After the Sati was seated in the hut of straw built out the pile, with the corpse of her husband beside her, and just before the fire was applied, a venerable Brahman took me by the hand, and led me close to the straw, through which he made an opening, and desired me to observe her, which I did attentively. She had a lighted wick in each hand, and seemed composed. I kept sight of her through the whole of her agony; as, until forced to retire from the intensity of the heat, which I did not, however, until a good deal scorched, I was within five feet of the pile.

"When the victim is a person of consequence, the sikhs are, it is said, collected and thrown into the Ganges. I do not imagine that such attention is paid to persons of inferior condition, but I may be mistaken. Of my interesting victim I was deferous to obtain some of the ashes, to preserve in lockets, &c. but was not able to get any. A military
SUTTEE.

guard is generally placed over the spot of sacrifice, and my application was refused by an attendant Brahman; who, after some solicitation, told me, that he could not imagine of what utility the ashes of the Sati could be to me, unless for the purposes of forcery. A firm belief in the power of witchcraft and necromancy exists very extensively among all ranks and religions in India; and some inferences of its effects, both of a ridiculous and terrible nature, have come within my knowledge." Hind. Pan. p. 355.

On this subject, the following passage occurs in another place. "In the neighbourhood of temples, it is not unusual to see a flat stone emblazoned or engraved with two feet: several are about the temples at the Sangam near Poona; and I was told by a Brahman that they are in remembrance, and in honour of widows who have become Sati there, being their last earthly or human impression carved on the stone which served to rep by up to the pile of their husbands. At this affecting sacrifice I have observed a flat stone placed for this purpose, and that the family of the victim, and the attendant Brahman, received their bierlings and thatms while the flood on it. Having quitted this stone, she is no longer human; she commences a participation of the beatitude to the fruition of which she is hastening. It chills me to reflect, that I have for several minutes been close to a beautiful young creature in this awful situation, even to the moment of the flames reaching her, when her soul could scarcely be thought more in this than in another world. What my feelings may have been, when witnessing this tremendous scene, I cannot say or recollect. But I know that I could not then, however much it would have relieved me, shed a tear; although, when reflecting on it, it cannot always be withheld." Ib. p. 435.

The Hindoos, in common with several other ancient people, a veneration for divine impreions of feet. These are called Srijapa; which fee.

Although most of the fanguinary atrocities and fooletries practised by enthuasietic individuals among the Hindoos, are not only discomteeeed but condemned by the Brahmas, this of the Sati is certainly sanctioned by their preference; but they deny its being promoted by their prayers. The Sacred books only are said by them to be directing the people to immediately await the human soul on its purification by the proceSs of Sati. This benefit is also extended to the husband and family of the purified widow. The latter are exalted in the estimation of their neighbours, and probably often find their worldly circumstances amended by it.

This sacrifice, viewed in its variety of bearings on human action and fortitude, is one of the most extraordinary offered to our contemplation, exceed ed or equalled only by that of infanticide, found to be so prevalent in the same quarter of the world. (See Infanticides.) Referring to this under our consideration, we are induced to extend this article by the insertion of some particulars of the most authentic kind, taken from Mr. Colebrooke's paper in the fourth volume of the Asiatic Researches, entitled "The Duties of a faithful Hindoo Widow."

After noticing the great want of judgment in several late compilations in the slection of their authorities, and the consequent perpetuation of error; and the ncecessity of, therefore, reverting on every topic to original authorities for the purpose of correcting the errors or of verifying the facts already published, he proceeds to the selection from the Vedas, or Puranas, or commentaries, fundry texts and expositions, connected with the immolation of the Hindoo widow.

"Having first bathed, the widow, dressed in two clean garments, and holding some kusa grass, 6ps water from the palm of her hand. Bearing in her hand kusa and tala, she looks towards the east or north while the Brahman utter the mystic word O'm. (See O'm.) Bowing to Narayana, he next declares: on this month, &c. (describing the time) I (naming herself and family), that I may meet Arundhati and reside in Sverga; that the years of my stay may be numerous as the hairs on the human body; that I may enjoy with my husband the felicity of heaven, and sanctify my national and maternal progeny. May my husband's family; that lauded by the Upasanas, I may be happy through the reigns of fourteen Indras; that expiration be made for my husband's offences, whether he have killed a Brahman, broken the ties of gratitude, or murdered his friend, that I ascend my husband's funeral pile:—I call on you, ye guardians of the eight regions of the world, fun and moon! Air, fire, ether, earth and water! My own soul! Yama! Day, night, and twilight! And thou, conscience, bear witness: I follow my husband's corpse on the funeral pile."

This declaration is called Sankalpa. Of the mythological perons, &c. mentioned in it, some account will be found under our articles Sverga, Upana, and Yama. Sanctifying her own and her husband's ancestors is done usually by the ceremony called Sradha; see that article. Arundhati was the wife of the sage Valisuta.

The ritual quoted above is of the first authority. It shews that there are different forms and ceremonies observed on this occasion. The widow is made to sit by the husband's corpse; and the following text points out the method. "When the corpse is about to be consumed in the Sathotaja, the faithful wife, who fixed without, rushes on the fire." The Sathotaja is said to mean the cabin of straw or leaves, that is usually erected over and round the pile, in which the living and the dead are placed; but it would seem rather to describe the pit used in another description of Sati. On this occasion, a pit about ten feet long, six feet deep, and nearly as wide, is filled with flames, before which a cloth is loofily fupended. The body is placed in the pit, and the victim throws herself headlong against the cloth and into the pit. This is by no means in common a process as ascending the pile, and the gradual consummation of the dead and living.

In the latter mode, having repeated the Sankalpa, she walks thrice round the pile: and the Brahman utters the following texts, called Mantra, from the Rigveda, and a Purana. See Mantra, Veda, and Purana.

"O'm! Let these women, not to be widowed, good wives, adorned with collyrium, confine themselves to the fire. Immortal, not childless, nor husbandless, excellent; let them pass into the fire, whose original element is water."

"O'm! Let these wives, pure, beautiful, commit themselves to the fire with their husband's corpse."

It is said in the Sankalpa above quoted, that "though her husband had killed a Brahman, the Sati expiates his crime:" but some commentators are at the pains to shew that this expiation must refer to a crime committed in a former existence, for funeral rites are refused to the murderer of a Brahman; and although, in some other texts of sacred books, expiations for this heinous sin are mentioned, the commentators do modify them, as to deprive them of any authority on account of their Brahmanical sanctity of character. Although it is doibtful held to be the duty of a widow to devote herself, she has the alternative, on the death of her husband, to live as Brahmachari, or commit herself to the flames." The austerity of Brahmacari conveys in chastity, and in divers acts of piety and mortification: such as using no ornaments
ornaments in her drees, or costly implements at meals; eating only once a day, and then only of simple food; not sleeping on a bed, &c. The acts of piety comprise an increase in the usual duties of alms, ablation, and pilgrimage, and frequent use of the name of God in prayer.

After undertaking the duties of a Sati, that is, perfor- 

minating in her determination, for the first declaration is not 

binding, should the widow recede, she incurs the penalties of 

defilement. ‘If the woman,’” says the text, “regretting 

life, recede from the pile, she is defiled; but may be purified 

by observing the fast called Prapapata.” This is a severe 

penance: it extends to twelve days; a sparse meal once in 

each day on the first three; one in each night of the next 

three; on the succeeding three nothing may be eaten but 

what is given unsoiled; the last three are a rigid fast.

We have before observed, that in some cases suicide is 

allowed. Generally, it is certainly discouraged and for- 

bidden. The Hindu legislators have doubtless seen them- 

selves disposed to encourage the sacrifice of Sati; it is de- 

clared not to be suicide. The obsequies called Srdha, are 

forbidden for common suicides; but the Rigveda expressly 

declares, that “the loyal wife who burns herself, shall not be 

deemed a suicide. When a mourning of three days hath 

been completed, the Srdha is to be performed.” (See 

SRDHA and SUICIDE.) It may be noticed here, that the 

period of mourning is different in different tribes: its mortu- 

rafe is honourable, the longest mourning being for the lowest 

tribe.

In certain circumstances the widow is disqualified for this 

act of a Sati. “She,” says the legislator Vrihaspati, “who 

has an infant child, or is pregnant, or whose pregnancy is 

doubtful, or who is unclean, may not, O princes, ascend 

the funeral pile. So said Nareda to the mother of Sagaras.” 

(See NAREDA, SAGARAS, and VRISHAPATI.) The mother 

of an infant shall not relinquish the care of her child to 

ascend the pile; but she may, if the care of her child can 

be otherwise secured. Uncleanliness alludes to periodical 
causals, or to certain purifications after childbirth. It has 

been erroneously asserted, that a widow, pregnant at the 
time of her husband's death, may burn herself after de-

livery. This is pointedly contradicted by Hindu authorities, 
as well as by the general maxim, “what was unlawful 
or prevented in its seacon, may not afterwards be re-

fumed.”

In the event of a Brahman dying in a distant country, his 

widow is forbidden to burn herself; but with other tribes 

this proof of fidelity is not precluded by the remote decease 
of the husband. If he die within a day’s journey, and the 

widow desire to die on his pile, the corpse is to be kept till 

her arrival. Many other contingencies are noticed and pro-

duced for by the commentator; but it were superfluous to 

pursue them through all their frivolous distinctions, and 

fabulous illusions on latent difficulties.

All the ceremonies essential to this awful rite are included 
in Mr. Colebrooke’s very curious paper; and we have in 
this article given many of them. But many practices have been 
introduced, unbacked by any ritual. A widow who de-

clares her intention of burning herself is expected and re-

quired to prove her fortitude; and it is confidently said, that 

one who should recede after the commencement of the cere-

mony, would be compelled by her relations to complete the 
sacrifice. This may explain circumstances described by 

some who have witnessed the melancholy scene.

Other ceremonies noticed in such descriptions are directed 
in several rituals. The following is a translation from a work 
of authority, comprising several particulars of those cere-

monies: “Adorned with all her jewels, decked with minutum 

and other cumbuary ornaments, with the box of minum is 
hers hand, having made puja or adoration to the gods, the 

reflecting, that this life is sought; my lord and master 
to me was all;” she walks round the burning pile: the 

be Southwests on the Brahman, comforts her relations, and 
throws her friends the attentions of civility—while calling 

the fun and elements to witness, she distributes minum as 

pleasure; and having repeated the falkala, proceeds into 

the flames: there embracing the corpse, she abandons her-

self to the fire, calling Sattyal Sattyal Sattyal”

This differs in the material point from the common 

usage at Poona, where it is reasonably believed that the 
spectacle is witnessed oftener than at any other city or 

place in India. At that capital the corpse, after purifi-

cation in the river, is placed on the pile, over and round 

which a cabin or hut of straw is erected. This the widow 

enters; and after divers ceremonies, as before noticed, a 
furnished with lighted wicks. The sides of the combustible 

but are within her reach, and she is supposed to 

apply the fire. It is also applied externally; and the hy-

flanders throw on butter, wood, straw, reusious gums, &c. 

according to the circumstances of the parties. For its 

they are taught that they acquire great merit, exceeding, 
in their hyperbolical style, ten millions fold the merit of 

an AFWAMEDA, which is the sacrifice of a boar, or 

sum any other great ceremony. On one occasion, and 

other insinuations known notes that might be only 

more horrible. The merit of participation is extended to 

those who join the procession from the house of the 
deleaded; for every step they are ridiculously punished, as 

by grave authors, indulgences as for an AFWAMEDA. The 

promises afford additional grounds for the inference, that 

martyrs of this horrid superstitious have never been nume-

It is certain, and we are confirmed in our assurance by Mr. 

Colebrooke’s authority, that the sacrifice is now rare: at 

this point he reasonably appeals to the fact of few of the 

numerous British residents having witnessed or known of 

its occurrence. Had they ever been frequent, supersti-

tion would hardly have promised its indulgences to spe-

cators.

SUTTIKO, or SEITIKO, in Geography, a town of 

Africa, in the kingdom of Wooly.

SUTTLE WEIGHT, in Commercial, the weight so called 

when trett is allowed. See TRET.

SUTTON, in Geography, a township of America, is 
the State of New Hampshire, and county of Hillborough, 
first called Perrytown, incorporated in 1748, and con-

taining 1328 inhabitants. Alfo, a township in Worces-
ter county, Massachusetts, 46 miles W.S.W. of Boston, 
incorporated in 1718, and containing 2660 inhabitants. 
The cavern called "Purgatory" is a natural curiously 

situated in the south-eastern part of the town. In this 
township there are several mills and manufactories of paper, 
pot-ash, nails, &c.

Sutton’s Quadrant. See QUADRANT.

SUTTON-COLDFIELD, in Geography, a town 
situated in the division of Birmingham, hundred of Ham-

ingford, and county of Warwick, England; it lies near 

the north-west border of the county, adjoining Stafford-
shire, and is placed upon a bleak and barren soil. In the 
time of Henry I., the lordship of Sutton was pref- 

ered to Roger, earl of Warwick, wif a yearly rent refer- 
ted to the crown: in the reign of Edward I., a succeeding 

earl obtained the grant of a fair and market. In the 
time of Henry VII. these were forfaken, and the town 

nearly deferte; when John Vefey, bishop of Exeter, who 
in Henry VIII.'s time had acquired allience, proceed for
for Sutton a charter of incorporation, erected a moot-ball and market-place, founded and endowed a free-school, and by other benefactions greatly improved the town and church of his birth-place. Sutton-Coldfield contains many respectable houses; and its church, consisting of a nave, chancel, and two side-aisles, was built by bishop Veysey, in the latter part of the reign of Henry VIII. The nave, however, was taken down and rebuilt in its present form about the middle of last century. Sutton-Coldfield has a separate jurisdiction, and its municipal government consists of a warden, twenty-four aldermen, a town-clerk, sheriff, and other officers: the warden for the time being is also the coroner. The grammar-school, founded by bishop Veysey, is conducted by trustees; but the gift of the mastership is in the corporation. The present school-house was built in 1728.

Sutton is endowed with a weekly market on Monday, and two annual fairs. Its population, in 1811, amounted to 2059 inhabitants, with 639 houses. The Coldfield, from which this place derives its name, lies to the west of the town; it is a bleak and cheerless tract, supposed to contain 14,000 acres, part of which is in the county of Stafford. Sutton park lies to the north-west of the town, and consists of 3500 acres, which were once granted by bishop Veysey, as a common palfreyage for the poor of the town.—Beauties of England and Wales, vol. xlv. Warwickshire, by J. N. Brewer. Antiquities of Warwickshire, by Sir William Dugdale, folio.

SUTURE, in Anatomy, the peculiar connection by which the bones of the head are joined together. See Cranium.

SUTURE, in Surgery, is a term employed to express the method of bringing the edges of a wound together by means of a needle and ligature. Formerly, the common plan of dressing wounds with sticking-plaster received the appellation of the dry future, while the real futures were distinguished by the epithet of bloody. Of the numerous kinds of futures practiced by old surgeons, there are now only four ever employed. These are the interrupted, the quilted, and the coiled future, with another one, named epigastrium. For an account of the twisted future, see HARLE LIP; and for that of the future named gastrophore, see the article Gastrorrhaphion.

With regard to the interrupted future, it is that which is by far the most frequently made use of. The curvature of the needle employed should form the segment of a regular circle. When the needle is foreshaped as to be curved towards its point, and straight towards its eye, it is obvious that it is not advantageously constructed for passing through parts with facility. It should be double-edged to the extent of one-third of its length from the point, and its breadth part should be somewhat broader than the ligature, in order that the latter may traverse the wound with the utmost ease.

In the case of a recent wound, when the bleeding has been suppressed, and all extraneous substances have been removed, the surgeon is to place the limb or part in such a posture, as shall enable him to bring the edges of the injury easily into contact with each other. If adhesive plaster be deemed insufficient of itself to maintain the part in this state, and a future be considered proper, the needle, armed with a ligature, is then to be introduced into the right lip of the wound, at a small distance from its edge, and is to be directed across the bottom of the wound, so as to come through the left lip, from within outward. The needle is now to be cut off, and the ligature tied in a bow. As many futures of this kind are to be made as the length of the wound may require; but they should always be at least an inch from each other. Strips of adhesive plaster, dressings, and a bandage, are at the same time usually applied.

The quilted future is so called from a quilt being formerly used in making it. This method of uniting wounds has been occasionally practiced when the muscles have been deeply wounded, and it was preferred, on the supposition that it produces a more perfect union; but it is the practice of a future than is done by the interrupted future. The same kind of needle is used as for this last future; but it must be armed with a double ligature. When the double ligatures have been introduced through the lips of the wound, at as many places as the length of the wound may require, their ends are to be separated, and then tied in a bow, over a piece of bougie, or quill, or any similar thing, placed along each lip of the wound.

Dinon first reprobated the adoption of this future, and it is justly rejected by almost all the moderns, so that it is unnecessary to consider any of its modifications.

In the present schools of surgery, the use of futures is not recommended as it was in former times. It is now known, that by the combined operation of position, adhesive plaster, and a bandage, almost all wounds are capable of being united as expeditiously and well as they could be, were futures to be employed. Therefore, were it only to avoid superfluous pain, we ought to reprobate the practice in general. Did futures only create a little additional pain, and no other evil, till their employment would be justifiable, if they really possessed the power of rendering union by the first intention a matter of greater certainty in only a limited proportion of cases to which they are applied. In the cure of the hare-lip, and a few wounds of the face, and, perhaps, in the treatment of large wounds penetrating the abdomen, we must admit their utility. In wounds of the lips, the incessant and unavoidable motion of these parts, and in those of the abdomen, the distension arising from the visera, and the danger of their being protruded, are reasons which explain the advantage of futures in these particular instances. But, in general, the promotion of union by the first intention cannot be set forth as a valid argument in favour of futures being commonly used. Inflammation, above a very moderate pitch, always destroys every prospect of this nature, and occasions the secretion of pus, instead of the exudation of coagulating lymph. Sutures have fallen into disrepute, principally because they tend to increase inflammation. The new wounds which they make; their irritation as extraneous bodies; the forcible manner in which they drag the living parts together; and their incapacity, in general, to accomplish any useful purpose which position, adhesive plaster, and bandages cannot effect, are strong motives for repudiating their being commonly used. In fact it often happens, when futures are practiced, that considerable inflammation of the wound is the consequence, and its swollen edges evince marks of suppuration, unless soon relieved from the irritation of the ligatures. In this case, if the surgeon be fagacious enough to cut the ligatures and remove them in time, suppuration may still be frequently avoided. Extensive erythematous redness, surrounding wounds, will often be found to originate from the irritation of futures.

Mr. Cramer’s remarks on this subject are highly worthy of universal consideration. After relating many convincing facts, he concludes with asking, what practice the partizans of futures would adopt, were they necessitated, as they frequently are, to cut the ligatures and remove them? Or, were they to find, as is often the case, that the ligatures had made their way through the lips of the wound, so as to leave them gaping? They would then never think of introducing
new futures; but would have recourse to a bandage in order to unite the wound. Sur l’Abus des Sutures, in Mem. de l’Acad. de Chirurgie, tom. iii. 420.

They who assert, that the good effect of futures is, in many cases, supported upon the solid bases of experience, ought at least to make it appear probable, that the same effect could not be produced by the combined operation of a proper posture, adhesive plaster, and the pressure of bandages.

Whoever wishes to investigate this subject further, should peruse the observations of M. Louis on the first principle of the art of uniting wounds. (Mem. de l’Acad. de Chirurgie, tom. xii. p. 118, edit. 12mo.) This eminent French surgeon, so distinguished in his profession, proved, that even the hare-lip could be united very well without the assistance of a future. Cooper’s First Lines of the Practice of Surgery, edit. 2.

SUVARTI, in Geography, a river of Darien, which runs into the Spanish Main, N. lat. 8° 37’. W. long. 77° 50’.

SUUNPOUR, a town of Bengal; 25 miles E.S.E. of Dacca. N. lat. 23° 53’. E. long. 85° 26’.

SUULPOUR, a town of Bengal; 38 miles N.N.E. of Ramgur.

SUWAIDA, a town of Arabia, in the province of Hedjaz; 50 miles N. of Medina.

SUWAIRON ZOK, ALEXANDER, Comte, in Biography, a distinguished Russian commander, descended from a Swedish family, was born in 1730, and designed by his father for the profession of the law; but he preferred a military life. He began his career as a private soldier, and rose through the subordinate ranks to that of brevet commodore of lieutenant, with which he quelled the military guards in 1754, and in the course of his advancement he obtained the command of Memel, with the rank of lieutenant-colonel. Having served his first campaign in 1759 against the king of Prussia, and having distinguished himself on various occasions, he came to Peterburg in 1763, with a recommendation from count Patin to the empress Catharine, who presented him with a colonel’s commission. In 1768 he gained considerable advantages against the Polish confederates, and was recompensed, in 1770, with the rank of major-general. In this year also he was honoured by the empress with the order of St. Alexander, and after the partition of Poland, received at Peterburg with every mark of distinction. In the Turkish war of 1773 he had many opportunities, of which he availed himself, for gaining reputation; and on the conclusion of the peace with the Turks, he was employed to check the rebellion of Pugachew in the interior of Russia; and in 1783 he compelled the Tartars to take an oath of allegiance to the empress, who then sent him the cros of Wolodimir, and nominated him general in chief. Upon the renewal of the war with Turkey in 1787, he distinguished himself in the defence of Kinburn, and at the siege of Széco-coburg, when he was surrounded by the Turks, after the victory in which he participated with him at Fockzan, and brought on the great battle against 100,000 of the Turkish troops near the river Rymnika, in September 1791, which terminated in a complete victory to the combined armies, and obtained for Suwari the title of “Rymnikski,” splendidly presents both from his own sovereignty and the empress. To him he was committed, by Potemkin, the enterprize against the strong fortresses of Haimil; when he promised to the victors, upon ordering of an assault, the plunder of the place, and directed (as it is said) that no quarter should be given. This was one of the most fan-guinary actions upon record. When the Russians, after being twice repulsed with great loss, scaled the ramparts and

burst into the fortresses, a horrible massacre ensued, 33,000 Turks were killed or desperately wounded, and about 10,000 were made prisoners after the carnage. Some persons have preferred against the general the charge of cruelty on this occasion; but whether or not he could restrain a body of victorious soldiers, exasperated by the resistance of the besieged, he acted a very disinterested part respectimg the booty, not referring for himself so much as a single lira. After the peace of 1791, which surrendered Oczakof to the Russians, Suwari received an accumulation of red honours, and was appointed commander of all the troops stationed in that part of the Russian empire, fixing his headquarters at Cheritou, where he remained nearly two years. He was employed afterwards in the disgraceful business of extirpating the liberty of Poland, and gained several victories over the patriots. In 1794 he laid siege to Propo, fortified suburb of Warsaw, and carried it by assault, with a carnage little inferior to that of Haimil. On this occasion new honours and rewards were bestowed upon him by his own sovereign, and the two other sharers of Poland, and he remained two years at Warsaw for the dissipating purpose of securing the servitude of that ill-fated country.

When the emperor Paul joined the confederacy against France in 1799, Suwari was appointed to command in the troops that co-operated with the imperialists in Italy. In the campaign during which he commanded the combined army of Russians and Austrians, the French lost all the principal towns in the north of Italy, and sutfained a defeat in the bloody battle of Novi. After that event Suwari crossed the Alps, and marching into Switzerland, drove the French from mount St. Gothard. On the defeat of another body of Russians, under general Korzakof, by Miles, Suwari, who was opposed by Moreau, was obliged to retreat towards the lake of Constance. The sitz he endured on this occasion is brought on an island; and he was ordered to return to Peterburg. The resentment which he manifested in complying with these orders offended his capricious master; and they were followed with a more positive command to the same purpose, by which he was feebly mortified. At length, however, he reached Peterburg, where he found himself fligkhted. He soon afterwards fell into a state of childildness, and died on the 18th of May, 1800, at the age of 70. Paul manifested his resentment, by refusing to his remains the ordinary military honours, and even deprived his only son of his rank of major-general. The emperor Alexander, however, repaired this injustice, by erecting his statue in the imperial gardens.

Suwari was hardy in his constitution and in his mode of living; accustoming himself, through all the gradations of his military advancement, to sleep on the ground upon hay, with a flight covering, and contenting himself with the common soldier’s fare. In winter and summer he rose at 4 o’clock; he frequently bathed the bath; and by his temperance and activity preserved the fire of youth to an advanced age. According to his mode he was pious and devout, punctually performing the offices of religion, and on Sundays and festivals reading lectures on religious subjects to his attendants. He never gave the signal of battle without making the sign of a cross, and kissing a little image of St. Nicholas, which he always carried with him. We may hence infer that his religion approached very nearly to superstition. In his purpofes he was inflexiblestrictly true to his word, and of incorruptible probity. In his speech and writing his style was laconic, interspersed with tedious expressions, and even in his dispatches and orders, with dogged veris. He was well acquainted with modern
languages, but declined political or diplomatic correspondance,
 allegation, that a pen did not suit the hand of a soldier.
His coarse manner, disregard of luxury, and contempt of
danger, rendered him the darling of his soldiers, while his
principal officers were his secret enemies, on account of the
strict duty he exacted, and the privations to which he sub-
jected them. It was one of his military maxims, that a
general should be always in the front of his army. "In
courage and activity, and rapidity," says one of his biogra-
phers, "he had no superior; but the critics in the art of
war have censured him for want of depth in his combina-
tions and skill in his manoeuvres, as well as for violating hu-
Biog.

SUYA, in Geography, a town of South America, in the
province of Quito; 12 miles S.E. of Guayaquil.

SUYAHILA, a town of Africa; 65 miles S.S.E. of
Sugarnefla.

SUZA, a city of France, in the department of the Po,
formerly capital of a marquisate, and province of Fiemont,
situated on the river Dora Riparia, in a valley to which it
affords name, at the foot of the Alps, anciently called
"Secuflum," or "Segraflum," or "Seguflina." It was the
capital of the kingdom of Cottius, and the place of his
usual residence. The possession of it has been often con-
tinned, and it has suffered much in passing from the pos-
session of different successor conquerors and proprietors.
The Goths, Lombards, and Saracens, have successively
plundered this place; but it suffered most from the capture
of Flanders by the Normans, who, in passing from Germany into
Italy, destroyed it to its foundation, and reduced it to ashes.
It anciently gave the title of marquis to the descendants of
Charlemagne, and was transferred to the dukes of Savoy
by a marriage with Adelaide, the only daughter of the last
marquis. It is now small and poor, with single walls, and
defended by a citadel with a strong garrison. It contains
three parish churches, and several religious houses. In its
vicinity is a triumphal arch, erected to the honour of
Augustus. Suza has of late experienced the vicissitudes
occasioned by the French revolution in the province of
Fiemont; 23 miles N.N.W. of Turin. N. lat. 45° 30' E. long. 7° 10'.
The marquisate of this name is about 30 miles long, and 10 broad, watered by the Dora and the
Cinflera. The principal towns are the Suza, Giavenna,
Avigliano, and Novale.

SUAZBAD, a town of Bengal; 15 miles N.E. of
Rognantpur.

SUZAO, a town of Portugal, in the province of Beira;
31 miles N.E. of Braganca Nova.

SUZARA, a town of Italy, in the department of the
Mincio; 14 miles S. of Mantua.

SUZAVIN, a town of Peru, in the province of Irak;
90 miles E. of Hamadan.

SUZAY, a town of France, in the province of
Eure; 14 miles E.N.E. of Grand Andelys.

SUZDAL, a town of Ruffia, in the government of
Vladimir, on the Nerl, the fee of a bishop. Peter I.,
after divorcing his wife, Eudoxia Fedorowenna, confined her
in the convent of St. Basil in this town; 24 miles N.E.
of Vladimir. N. lat. 56° 10'. E. long. 40° 44'.

SUSE, a town of France, in the department of the
Savoie, and chief place of a canton, in the district of Le
Mans; 9 miles S.W. of Le Mans. The place contains
1414, and the canton 8907 inhabitants, on a territory
of 170 kilometres, in 13 communes.

SUSE, a river of Switzerland, which runs into the
lake of Bienna, about a mile below the town of Bienna.

Suzza la Rouffe, a town of France, in the department of
the Drôme; 18 miles S. of Montelimart.

SWAB, a fort of mop formed of a large bunch of old
rope-yarn, and used to clean the decks and cabins of a ship.
Hence

SWABBER, the title of an inferior officer on board of a
man of war, whose office is to take care the ship be kept
neat and clean.

In order to this, he is to see her washed well once or
twice a week at least; especially about the gun-wales and
chains.

He ought also to burn pitch, or some such thing, now-
and-then between decks, to prevent infection, and to ac-
quaint the captain with fitch of the men as are nalty and
offensive.

SWABENITZ, in Geography, a town of Moravia, in
the circle of Olmutz; 17 miles S. of Olmutz.

SWABIA, or SUABIA, a circle of Germany, bounded
on the N. by the Palatinate of the Rhine and Franconia,
the E. by Bavaria, on the S. by Switzerland, the lakes of
Constance, and the Tyrol, and on the W. by France,
from which it is separated by the Rhine; about 120
miles from east to west, and 80 from north to south.
The ancient county of Swabia was rather more extensive.
The name is suppos'd to be derived from the Suevi, who first
inhabited the country between the Wefer and the Oder,
but afterwards crossed the Elbe to the Main and Danube,
and in the time of Julius Cæsar to the Neckar and the
Rhine. In the fifth century, this country was conquered
by the king of the Franks, who erected it into a dukedom,
which Charles the Great abolished, but Conrad I. reformed.
The title became hereditary about the year 1094; the
dukes of Swabia being at the same time dukes of Franconia,
but with very limited prerogatives of these dukes, many
of them became kings of Germany; the dukes became ex-
alted about the middle of the 13th century. In the middle
ages, Swabia was divided into a great number of gens, in
Latin pagi, the names of some of which are still in use.
The states of Swabia, at the diet, were divided into five
benefices, viz. 1. The ecclesiastics, or bishops and abbots
2. Temporal princes and abbots 3. Counts and barons
4. Free imperial towns. The princes summoned to the diet of the circle were, the bishop of
Constance and the duke of Wurtemberg, but the latter was
the sole director. The diets of the circle were commonly
held at Ulm, and in time of peace twice a year. Each of
the five benches had its director, but without any peculiar
prerogative above the rest of his order. The directors of
the five benches let their seals to all the reccefs, or acts of
the circle, and other dispatches. The bishop of Constance
was the perpetual director of the bench of ecclesiastical princes, as
the duke of Wurtemberg was of that of the temporal princes.
The directors of the benches of prelates and counts were
chosen only for life. Ulm, indeed, was perpetual director
of the bench of the Imperial towns; but Augsburg always
voted first. The chancery and record office belonging to
the circle were kept at Stuttgart, the residence of the
director of Wurtemberg. In the year 1581, the military
force of the empire, by a decree of the diet, was settled in
time of peace at 40,000 men, and the quota of the circle
of Swabia alone came to 1321 horps, and 2707 foot; and
in the year 1707, at the division of the 300,000 florins,
which was the sum granted for that purpose, its proportion
was rated at 31,271 florins, 58 kruots, 5 deoers. The
number of troops in this circle, constantly kept on foot,
confined of four regiments of infantry, each composed of
twelve companies, one regiment of dragoons, and one of
cuirassiers.
cui-raisers, each confiding of eight squadrons. The com-
mander of the circle was styled general field-marshall. With
repeal to religion, this circle was reckoned among the
mixed ones. Under the emperor Frederic III, the circle
of Swabia was, for the sake of the peace of Germany,
divided into four quarters. The head of the first was
the duke of Wurtemberg, of the second the margrave of
Baden, of the third the bishop of Constance and the abbot
of Kempton, and of the fourth the bishop of Augsburg.

Swabia, Austrarian, was composed of the ancient hereditary
estates of the house of Habsburg, and the remains which
had fallen to Austria, since it has been elected to the
empire. Maximilian I. was the first prince of this house
who took the name of the prince of Swabia. It paid an-
nually more than 400,000 livres to the military chief of
Austria. These estates were composed of Burgau, Nellen-
burg, the prefecturate of Swabia, Hohenberg, the Ortenau,
Brigau, and some towns and convents.

SWAD, in Agriculture and Gardening, a provincial word
signifying a pod, as of peas, beans, &c.

SWADHA, in Hindoo Mythology, is said to be a goddes-
son whose whole adventures are very poetically narrated in one
of the Puranas, or sacred romances, entitled "Brahma-Vai-
wartika." (See Purana.) She was originally a nymph of
Galaka, the paradise of Krifna. Her celestial charms excite
the ardor of the bard, Radha, who represents the Greek
Juno in her caprices, her jealousy, and sometimes in her
fury; while at others she is all tenderness and attraction.
Hurling by the goddess from the empyrean, Swadha was
confided by being given in marriage to the Dii Manes.
She is hence the goddes of funeral obsequies; conveying
to the manes the offerings of men, and rewarding the
latter for their piety to their ancestors.

The word Swadha is further used as a sort of grace or
benediction, after eating the food offered in the ceremony
of the Braga in honor of deceased ancestors. (See
Swadha.) It seems to mean enough; and to be applied
to the food of the manes, and of those who eat of the
offerings made to them. (See Lakshmi.) The word Swadha is,
however, of profound and mythical import, being some-
times used as equivalent to Maya, or illusion.

SWAFFHAM, in Geography, a large respectable market-
town in the hundred of South Greenhoe, and county of
Norfolk, England, is situated 28 miles W. from Norwich,
and 93 N.E. from London. The town is extensive; the
houses being distributed over a considerable space of
ground. Near the centre is a large open area, in which is
a pool of water. The chief public structure is the parish
church, a spacious handsome edifice, the greater part of
which appears to have been built about the time of
Henry VI. or Henry VII. It consists of a nave and two
aisles, with two transepts on the south side, one to the north,
and a lofty well-proportioned tower, surmounted by
embraced embrasures and pinnled pinnacles. The nave is
very lofty, and has twenty-six clerestory windows. Some
of the pews are curiously carved; and in the library is pre-
ferrable literature. Here are some handsome genealogies,
among which is an altar-tomb, with an effigy of Dr. John
Botwright, a native and rector of this parish, and chaplain
to king Henry VI. In ancient days, the earls of Richmond
had a priory in this town; and at the present time here is
a house of correction, or bridewell, which was erected in
the 41st of queen Elizabeth, for the hundreds of South Greenhoe,
Weyland, Grimhioe, Shropham, Giltercas, Freebridge, and
Clackeioe. Swaffham being an ancient demeine of the
crown, its inhabitants enjoy many exclusive privileges.
The population was returned to parliament in the year 1811,

as 2,350, occupying 400 houses. A weekly market on
Saturdays is well supplied with provisions; at which time
is held a great mart for butter, recently removed from Down-
ham. Here are also three annual fairs. In the year 1795,
a cross was erected on the market-hill by the late earl of
Orford. An assembly-room has been lately built on the
west side of the hill.

About five miles from Swaffham is Narborough, a small
village, but peculiarly interesting to the antiquary. John
Brane, in a manuscript history, quoted by Spelman in his
"Iceni," says, "this was a British city in the time of
Uter Pendragon, about the year 500." The name is Saxe,
and the works in the vicinity point out its antiquity. It is
supposed a small Roman station was once established here.
From this place to Ealalm-leen, a large foss and rampart
extend, by which the hundred of Clackeioe was bounded.
At the head of this foss was a lofty fortified mound, called
the burgh. In making a garden near its base, in the year
1600, several human bones and pieces of armour were

discovered.

In the contiguous parish of Narford, is Narford Hall,
the seat of Brigg Fountaine, esq., erected by Sir Andrew
Fountaine, knight of the Bath, who rendered himself so
useful in the place conspicuous, by cultivating the friendship of Pope
and other literary characters. The house was not only
a rendezvous of literary genius, but a repository for works
of art and learning. At present it displays a choice collection
of pictures, ancient painted earthenware, and a valuable
library. Among the old china are several pieces painted
by Raffaello, particularly two very large ciphers of the
form and execution, measuring three feet by eighteen inches
each.—Bromfield's History of Norfolk, vol. vi. Beauties
of England and Wales, Norfolk, vol. xi. by J. Britton,
F.S.A.

SWAGLERS, an Indian town of West Florida, near
the Apalachicola. N. lat. 31° 41'. W. long. 84°.

SWADA, in Hindoo Mythology, is the fakir or enemy,
or in more popular language, the confessor, of Parava, the
god of fire.

SWAIN. See BOATSWAIN and COCKSWAIN.

SWAIN, in Geography, a river of Prussian Lithuania,
which runs into the Ilmen; 4 miles W. of Malchins.

SWAINMOTE. See SWAINMOTE.

SWAINSON, in Botany, more correctly SWAINESON,
was so named by Mr. Salisbury, after the late Mr. Isaac
Swainson, who having derived considerable profit from the
sale of a medicine called Velno's Vegetable Syrup, believed
part of his income in the maintenance of a botanical garden
at Twickenham, to which his acquaintances, it seems, were
liberally admitted. Still it does not appear that he was
entitled to the distinquishing appellation of "a second
Clifford," nor that he was a cultivator of botanical science.
We have always gladly concurred with Mr. Salisbury in
his prudent reserve in beftowing such honorary generic
names, as well as in his attention to classical propriety in
constructing others; and we will always do so, while, with
pride, we confess the approval of a competent judge in
weeping away all that are incorrect or unmeaning.

If the present genus were to remain, Venetan's name of
Loxidium, previously printed, might be adopted, as it is
more expressive of the ambiguity of its character. We
incline, however, to the opinion of Dr. Sims, who hold
that this genus, as well as SUTHERLANDIA, (see that article)
are too nearly allied to Colutea. The reader may consult
Salib. Parad. t. 28. Curt. Mag. t. 1725; t. 792; and
Brown in Act. Hort. Kew. v. 4. 326. In the latter we
find the following.
in the jaws of the wolf-fish, or in the palates of some of the lefs known kinds.

**Swallow-Wort, Hirundinaria, or Asclepias, in Botany.** See Asclepias.

The common swallow-wort of the shops, with a white flower, called vincetoxicum and birundinaria, is denominated tame poison, because it has been deemed a powerful counter-poison. The flowers appear in June, and the seeds ripen in September. It grows naturally in the south of Spain, and Italy; and is important as an instance of such a distinction between Colutea and Sutherlandia. See those articles.

**SWALE.** East and West, in Geography, the two branches of the Medway; the East Swale branches off to the right, and runs S. of the island of Sheppey, and joins the Thames below Sheernes: the West Swale, or main stream, proceeds due N., and joins the Thames at Sheernes.

**Swale,** a river of England, in the county of York, which runs into the Oule, near Boroughbridge.

**Swale,** in *Rural Economy,* a term signifying shade.

SWALLOW, or SWALLOWS, a term applied to the operation and practice of dressing a hog for bacon, by singeing or burning the bristly hairs off by means of flar, or from other similar substances. It is a method often used in the southern districts of the kingdom.

**SWALLOW,** in Ornithology. (See HIRUNDO.) For an account of the migration of swallows, see MIGRATION.

**Swallow, Sea,** is also a name given to the *Sterna hirundo* of Linnaeus; which see. See also TERN.

**Swallow, Water, Hirundo aquatica,* a name very improperly given by Beller, and some others, to the northern columbus, commonly known by the name of the lume. See COLOMBUS TRIOLE.

**Swallow Bay,** in Geography, a bay on the north coast of Egmont island, between Hanway's Point and Swallow Point.

**Swallow Harbour,** a harbour in the frigates of Magellan, on the coast of Terra del Fuego. This harbour is well sheltered from the winds, and excellent in every respect. There are two channels into it, both narrow, but not dangerous, as the rocks are easily discovered by the weeds that grow near them. The mountains round it have a horrid appearance. S. lat. 53° 29'. W. long. 74° 35'.

**Swallow Island,* one of those called Queen Charlotte's islands, in the South Pacific ocean; about fix leagues in length. S. lat. 10° 58'. E. long. 165° 28'.

**Swallow Point,** a cape on the N. coast of the island of Egmont, in the South Pacific ocean. S. lat. 10° 42'. E. long. 165° 28'.

**Swallow-Fish,** Hirundo prisca, or, as it is called in Cornwall, the sub-prisca, a sea-fish of the trigla kind, remarkable for the size of its gill-fins; called the justiphere gurnard. See TRILOGA HIRUND.

**Swallow-Fly,** in *Natural History,* the name of the chelidonius, a fly very remarkable for its swift and long flight.

**Swallow-Stone,** Chelidonius lapidis, the name of a stone which Pliny, and many other authors, affirm to be found in the stomachs of young swallows. It is always described to be small, roundish, convex on the outside, and concave on the other, and of a brownish, yellowish, or blackish colour; this, and the figures given of it, plainly shew that it is either a small species of the lygodium, or bufonite, or else a detached piece of one of the compound ichthyopera, or; as they are vulgarly called, *fugughra.*

De Boot tells us, that he cut up several young swallows, but never found any such stones in them; and indeed it is no wonder, since they are not to be looked for there, but

Vol. XXXIV.
as a beacon to vessels making for the road of Surat, and to point out the anchoring place. This tower is about 30 feet high, and was erected as a monument over the grave of an English captain, named Vaux, who was buried there many years ago. Near this place lies the celebrated English traveller, Thomas Coryate, who finished his earthly perambulations here in the year 1617; 15 miles W. of Surat. N. lat. 21° 10'. E. long. 72° 32'.

SWALM, a town of France, in the department of the Roer; 4 miles N. of Ruremond.—Allo, a river of France, which runs into the Meuse, 5 miles below Ruremond.

SWAMMA, a town of Algiers; 13 miles S. of Tagadampt.

SWAMMERDAM, John, in Biography, a distinguished anatomist and naturalist, was born at Amsterdam in 1627, and designed by his father, who was an apothecary in that city, for the church; but his own inclinations were directed to physic, which became the object of his study, together with several branches of natural history, particularly entomology. At an early age he made many excursions for the purpose of enlarging his collection of winged insects. At Leyden, where he studied physic, he was distinguished by his skill and affability in anatomical experiments and the art of making preparations. At Paris he was intimate with Nicholas Stenonius in 1654, whilst he visited that city and France for a short time to view the famous museum.

On his return to Leyden he took the degree of M.D. in 1657, publishing on the occasion a thesis on respiration. At this time he began to practise his invention of injecting the vesels with cereaceous matter, which seemed to keep them diffused when cold; a method from which anatomy has derived very important advantages. He applied very closely to dissection with Van Horne: and in the dissection of insects he was singularly dexterous by the aid of instruments of his own invention. The grand duke of Tuscany, who visited Holland in 1668, and who was introduced to Swammerdam by Thevenot, made him a liberal offer for his share of the collection, on condition of his removal to Florence; but he rejected the offer, on account of his abhorrence of the refinements of a court-life, and impatience of any control in his religion. Entomology was his favourite and principal pursuit; and in 1669 he published, in Dutch, "A General History of Insects," Utrecht, 4to.; afterwards reprinted, and translated into French and Latin, the latter with splendid figures. In 1672 he published, as a medical anatomist, a work entitled "Miraculum Naturae, seu Uteri Muscles Fabr. Systema in J. V. Horne Prodrom. Illustratum," Leid. 4to., many times reprinted. By intense application he became hypochondriac, and wholly unfit for society. In this state he was so impressed by the reverses of Antoinette Bourignon, as to be plunged into the depth of melancholy, and to be induced to abandon all his scientific pursuits. At her desire he presented to the world, in 1675, his last publication, which was an account, in Dutch, of the insect called Ephemera. He followed this fanciful female to her retreat in Holstein; and on his return to Amsterdam, his constitution was worn out by his mortifications, and he died in 1680. In the capacity of the paroxysms that seized him not long before his death, he burned all his remaining papers; but in a state of indigence he had disposed of the greater part to Thevenot for a trifling sum. On the lapse of about a half a century, these came into the possession of Boerhaave, who caused them to be published in Dutch and Latin by Gauibus, under the title of "Biblia Natura, sive Historia Insectorum in certa clausis redacta," &c. &c.: a vol., large folio, 1737, with plates; translated also into German, English, and French. The history of bees in this work is highly esteemed, as peculiarly valuable. Life by Boerhaave. Haller.

SWAMP, in Agriculture. See BOG and SWAMPT Land.

SWAMP-ORE, or indurated Bog-Iron-Ore, in Mineralogy, is ore of iron which occurs in swamps or moraines; it is a variety of bog-iron-ore, partially indurated by drying. The colour is a dark yellowish-brown, or grey; it appears coarsely, and contains cavities, but is sometimes compact. The fracture is earthy; the darker varieties have a small degree of lustre, but it is more common dull: it is very soft and friable. The specific gravity is 2.944.

This, with the other varieties of bog-ore, are sometimes used as ores of iron; but the phosphoric acid contained in them injures the tenacity of the iron; they are therefore generally melted with ores which yield the most duculites, to improve the quality. The phosphoric acid in bog-ore is probably derived from the animal matter in swamps.

The formation of bog-ore and its varieties takes place, according to Werner, in the following manner: "The water which flows into marshy places is impregnated with vegetable acid, formed from decaying vegetables, which enables it to dissolve the iron in the rocks over which it flows, or over which it stands. This water, having reached the lower parts of the country, becomes stagnant, and by degrees evaporates; the dissolved iron being accumulated in the additions of silt, becomes detached and forms the plates which are at first yellowish, earthy, and of little consistence; this is called morasche-ore; but as the ore becomes harder, the colour changes to brown; thus swamp-ore is formed. When the swamp is completely dried up, this ore becomes much harder, and at length passes into meadow-ore. Morasche-ore occurs in which all the different degrees of induration may be observed." Jameison's Mineralogy, 2d edit. vol. ii.

SWAMPY BAY, in Geography, a bay on the coast of North Carolina. N. lat. 35° 42'. W. long. 76° 7'.

SWAMPY LAKE, in Agriculture, such as is of a boggy marshy nature. Under this title are sometimes included, according to Mr. Marshall, "inland swamps, wet meadows and flat pufhure lands," which lie at the way of floods; yet are liable to be chilled by surface waters, and poached in, in wet seasons; by reason of the natural water-courses below them being "a state of neglect; or for the want of artificial courses being opened, to relieve them from surface waters, as they collect. And he adds, that lands of this description are now more particularly seen, in forests or other unappropriated and unregularized areas of lands that has taken place, they are less conspicuous. It is evident, that all lands of the swampy kind, whatever their situation may be, must require to be first drained before any other improvement can be effected. When this has been well accomplished by proper feeding and managing, they may, in most instances, be brought into a good state of sand, which is in general the best application of them, as they are seldom fit for the purposes of tillage. See Boa Draining of Land, and Spring-Draining.

In the appendix to the account of Elkington's mode of draining land, I have fully considered all the several different methods of improving these forts of ground may be seen, after they have been drained, laid down, and the various objects and intentions of them well pointed out and explained.

Lands of this nature are not unprofitably raised from a very trifling, or scarcely any value at all, to a very considerable one, simply by planting them with withy for the use of basket-makers and others. There are different sorts cultivated in this intention on such lands, as the red and
the yellow kinds for basket and sieve-makers, and the brown for being made into hurdles. The former are cut over frequently, mostly annually; but the latter only once in about five years.

In these cafes, the ground may be trenched up into beds about six feet in breadth, in the autumnal season, allowing two feet or more between each bed; then in the early spring they may be planted with the forts of withy which are most wanted for the above purposes, in three or four rows, at about a foot from plant to plant, or more, according to the wants.

The hurdles are very useful for hurdlng off tursips, natural and artificial grafts, and various other crops, which are to be fed by sheep or other sorts of stock.

SWAMRY, in Geography, a town of Hindoostan, in Mylore; 16 miles N.N.E. of Chitteldoog.

SWAMSCOT, the Indian name for Exeter, called the Great River, by way of distinction from another much lfs, also denominated Exeter river, an American river that rises in Cheever, in New Hampshire, and after running through Sandown, Poplin, and Brentwood, and a considerable part of Exeter, affording many good mill-fasts, precipitates itself over a fall 20 or 30 rods in length, and meets the tide from Piscataqua harbour in the centre of the township of Exeter. The smaller river rises in Brentwood, and joins the great river about one-third of a mile above Exeter. Here it affords plenty of alewives, and some oysters.

SWAN, in Abyronomy. See Cygnus.

Swan, Cygnus, in Ornithology, a species of the anas or duck kind, in the Linnean system, of which there are two varieties, the wild and tame swan. See Duck.

The wild swan, or anas oralus of Linneaus, called also elia and hooper, is less than the tame sort; the lower part of the bill is black; the base of it, and the space between that and the eyes, is covered with a naked yellow skin; the eye-lids are bare and yellow; the whole plumage in old birds is of a pure white; the down is very soft and thick, and the legs black.

The cry of this bird is very loud, whence its name hooper.

The wild swan frequents our coasts in hard winters in large flocks; but Mr. Pennant apprehends that it does not breed in Great Britain. Swans come in October in great numbers to Lingey, one of the Western isles, and continue there till March, when they retire more northward to breed. At Mainland, one of the Orkneys, swans are the countryman's almanac; as on their quitting the island, they presage good weather, and on their arrival, they announce bad.

See Cygnus under Duck.

The same swan, or anas cygnus manuactus of Linneaus, is the largest of the British birds. It is distinguished externally from the wild swan, first, by its size, being much larger; secondly, by the bill, which is red, and the tip and sides black, and the skin between the eyes and bill is of the same colour. Over the base of the upper mandible projects a black callous knob; the whole plumage in old birds is white; in young, ash-coloured till the second year; the legs dusky, and in some varieties red. The swan lays seven or eight eggs, and is nearly two months in hatching. It feeds on water-plants, insects, and shell-fish. No bird perhaps makes so elegant a figure out of the water, or has the command of such beautiful attitudes in that element, as the swan; thus described by Milton, Paradise Lost, book vii.

The swan with arched neck
Between her white wings mantling, proudly rows
Her face with easy grace.
SWAN-SHELL. See CIGNE.
SWAN’S-Egg Pear-tree, in Gardening, that fort of this
tree, which produces this fine eating pear. See PEAR-
Tree, and PYRAMID MAZE.
SWAN ISLAND, in Geography, an island of the United
States, in the district of Maine, and county of Hancock,
about seven miles long, situated on the Kennebec river,
which it divides into two navigable canals; 3 miles from
the shores of Merry-meeting bay. It contains 51 inhabi-
tants.

SWAN LAKE, a lake of Canada; 171 miles N.W. of
Quebec. N. lat. 49° 34'. W. long. 73° 15'.

SWAN POINT, a cape of the coast of Maryland, in the
Chesapeake. N. lat. 38° 11'. W. long. 76° 22'.

SWAN RIVER, a river of America, which runs into the
Mississippi, N. lat. 4° 34'. W. long. 93° 15'.

SWAN TRAIL, a town of America, in the district of
Maine, and county of Hancock; containing 251 inhabi-
tants.

SWANAGE BAY, a bay of the English Channel,
on the coast of Dorsetshire, S. of Studland bay.

SWANEVELT, or SWANEFELD, HERMAN, in Biogra-
phy, was born at Woerden in 1620, and, as it is said, was a dis-
ciple of Gerard Douw, whose style, however, he did not long follow; but as his disposition inclined him to landscape he traveled there in 1640, had the good fortune to become acquainted with the prince of landscape painters,
Claude de Lorraine; the beauty of whose excellent works
had long been his great object of emulation and delight. As
the pupil of that great artist, he became acquainted with his
principles of composition and colour; and having a fincer
attachment to his art, he studied with incessant care, devot-
ing whatever time he could to the contemplation of the
effects of nature among the interesting scenery which sur-
rounds the capital of Italy. So much did he incline him-
self among her antiquities, her ruins, and variety of mountain,
wood, and water, that he acquired the surname of the
Hermit; but his meditations were not destitute of himself
alone. The fruit of these combined studies was a high
rank among the professors of the branch of art he had
chosen; and though the scenery he adopted is less grand
and extensive than that of Claude, and his colouring less
beautiful and chaste, yet there is enough of talent to afford
great pleasure; and his figures are defined and executed
more correctly than those of his master.

He was among the few artists who receive the due meed
of praise and profit during their lives; his works were
eagerly coveted, and he received very high prices for them.
Since his time, a greater honour has been rendered to many,
at the expense of amateurs and connoisseurs, who have not
unfrequently purchased as the works of Claude de Lorraine,
pictures which were completed on the easel of Swanvelt.

Swanevelt was not only an agreeable and excellent painter,
but he also handled the etching-needle and the graver with
great taste and skill; and has left us many plates of land-
scapes and animals, which rival the best with considerable
effect.

SWANG, in Agriculture, a grassy or other piece of
meadow, lying low, or in a bottom covered, or liable to
be covered, with water.

SWANIMOTE, or SWAINMOTTE, a court touching
matters of the forest, kept, by the charter of the forest,
thrice in every year, before the verderers, as judges.
This court is as incident to a forest, as a court of pie-
poudre to a fair.
Its jurisdiction is to inquire into the oppressions and
grievances committed by the officers of the forest, and to
receive and try pretentions certified from the court of
attachments against offences in vert and venison.

SWANLINEBAR, in Geography, a fair-town of the
county of Cavan, Ireland, much referred to in the summer,
on account of its medicinal sulphureous springs. It is
situated in the midst of the mountains in the N.W. of the
county, and is 13 miles N. by W. from Killefadra, and
74 N.W. from Dublin.

SWANNO, the east head-water of French Broad
river, in Tennessee.—Also, the name of a settlement within
about 60 miles of the Cherokee nation.

SWANSBOROUGH, the chief town of Onslow county
and Wilmington district of North Carolina.

SWANSEA, or SWANSEY, a sea-port and market-town of
considerable importance, in the hundred of the same name,
Gloucseshire, South Wales; is situated 45 miles W. from
Cardiff, and 205 miles W. from London. The Welsh
name of this place, Abertawe, is derived from its situa-
tion on a point of land near the junction of the river Tawe
with the sea. The etymology of its English appellation is
said to be eald-ascertained: it is supposed that it was originally
written Swinelea, or Swanley, as intimated by Camden,
from the porpoises which abound in the Britifl Channel.
The town lies on the western side of the Tawe, which is
here navigable for ships of large burden; and has extensive
canals, with every facility for loading and unloading the cargoes.
It extends in length about a mile and a half; the greatest width does not exceed half a mile.
The streets are numerous, and contain some well-built	house, occupied by opulent individuals, among whom are
many professional men of eminence, merchants, and substan-
tial tradesmen. In the return to parliament in the year
1811, Swansea (including the hamlet of St. Thomas) was
certified to contain 1702 houses, and 8195 inhabitants.
The population in the summer season, from the great influx
of strangers who resort hither for the purpose of sea-bathing,
must, however, be much more considerable. This circum-
stance has occasioned the erection of a great number of
lodging-houses, in general very handsomely, and many of them
adapted for the reception of families of the first distinc-
tion. The principal manufactories at Swansea are the potteries,
for which there are two establishments on a large scale.
Large quantities of the ware are annually shipped for the
English markets. A soap manufactury has been recently
established by the river-side, which promises to reward the
speculation of the proprietors. The commerce of Swansea
is very considerable; the numerous population of the town
itself, with the important addition of the persons employed
in the collieries, iron and copper works, and other manu-
facturing establishments in the vicinity, cause a large demand
for manufactured shop-goods and articles of consumption,
which are imported from Bristol and other English towns,
while the mineral treasures supplied by the hills in the in-
terior, create an export trade of great extent. The chief
article furnished for exportation is coal, particularly of
those kinds called stone-coal and culm, brought down by
the canal which conveys them to the river-side. Some idea may be formed of the shipping-trade of Swansea,
and of its rapid increase of late years, by the following
comparative statement, taken from the custom-
house books. The number of vessels entered out in

The corporation have been laudably exerting themselves...
SWA

many years in improving the harbour. In 1791, an act was obtained for raising the necessary funds, and great sums have been expended in clearing and deepening the bed of the river, and removing some obstructions at its entrance from the sea. Two large and handsome piers have also been run out, one from the eastern, the other from the western side, to confine the channel, and afford shelter for large ships, which might be loaded here without proceeding to the quays. But the intent not having been fully answered, a short crofs pier was formed in 1814, to supply the deficit.

Swansea is divided into three parts; the town, the facing, and the parish, each of which has its own officers for parochial and local purposes. The town is corporate, and shares the privilege of Cardiff, as a contributory borough, in the return of a member to parliament. The corporation consists of a portreeve, twelve aldermen, two common attorneys or chamberlains, a recorder or town-clerk, and two serjeants at mace. By its charter it is empowered to hold two weekly markets, on Wednesdays and Saturdays. The former is little more than nominal; but the latter is one of the best attended of any in the principality. Here are four annual fairs. The Michaelmas quarter-days for the county are held here; as are also the courts-leet and courts-baron of the duke of Beaufort for the lordship of Gower. The town-hall is a spacious modern edifice, built on a part of the castle inclosure in the centre of the town. A commodious theatre has been lately erected by Toutine shares of 10l. each, the survivor of the holders to become the sole proprietor. Some public rooms have been since built on a similar plan. A free school was endowed, in 1684, by Dr. Hugh Gore, then bishop of Waterford; and many low-chapels have been recently established for the education of the poor. The whole of Swansea is comprised in one parish, the church of which, a modern structure, consists of three aisles, separated by two rows of pillars, with a large square tower. The old church fell down in 1753; some fragments of the walls still remain. Near the upper end of the town is a small church, called St. John’s; but the parish to which it belongs is a mile distant. Here are also several places of worship, for various denominations of dissenters. The Presbyterian meeting is one of the oldest in South Wales. On an elevated spot in the middle of the town, are the remains of the castle; the principal portion which remains entire, is a lofty-circular tower, on the eastern side of which is a large part of the original building, surmounted by a parapet. According to Caradoc of Llancarvan, this castle was built, in 1099, by Henry Beaumont, earl of Warwick, to secure his new conquest of the district of Gower, (in which district Swansea is situated.) After the subjugation of Gower, Henry Beaumont brought over a colony of English settlers from Somersetshire, to whom he gave a large portion of the lands. Their descendants yet remain here, separated by their manners and language from the native population, with whom they scarcely ever intermarry. Swansea castle is the property of the duke of Beaufort, who holds the lordship of Gower. The ancient mansion of the lords of Gower stood near the castle, but was taken down about thirty years ago, and a street formed on its site. Swansea was the birthplace of the celebrated Richard Nafi, master of the ceremonies at Bath. He was born in October 1673, and died in February 1761. The poet Gower, contemporary with Chaucer, is considered by the Welsh antiquaries as a native of Swansea.

About five miles from Swansea is Oystermouth castle, a bold and majestic ruin; the grand gateway and some other parts of the building are in good preservation. This edifice is supposed to have been another of the earl of Warwick’s fortresses, as are also Penmarth castle and Penrice castle, of which some remains are at a short distance from Oystermouth.

On Cefn Bryn, a mountain which rises to the northward of Penrice, is an immense cromlech, called Arthur’s stone, noticed by Llwyd in his communications to Gibbon’s edition of Camden’s Britannia. The supporting stones are in number, and about four feet high; and the covering stone is supposed to weigh about twenty tons.

Stoutcastle, at the foot of this mountain, is the elegant seat of John Lucas, esq., who has displayed great taste in the disposition of his pleasure-grounds and gardens. In the latter he has excavated a cave of prodigious depth, calculated to be sufficiently capacious to contain two thousand men.

At Llangennith, in this vicinity, was once a priory, founded by Roger, earl of Warwick in the reign of Stephen. Henry VI. granted it to All Souls’ college, Oxford, in 1441.—Beauties of England and Wales, vol. xviii. South Wales, by the Rev. T. Rees, F.S.A.

Swansher, a town of America, in Bristol county, Massachusetts, incorporated in 1667, and containing 1839 inhabitants; 51 miles S. of Boston.

Swanshal, a town of Sweden, in Weft Gothland; 25 miles W.S.W. of Linkoping.

Swanton, a post-town of America, in Franklin county, and state of Vermont, on the E. bank of Lake Champlain, and S. side of Michicou river, which is navigable for the largest boats seven miles to the falls in this town. The town contains 1679 inhabitants.

Swantown, a small town of the state of Maryland, in Kent county; 3 miles E.E. of Georgetown.

Swanzey, a township in Cheshire county, New Hampshire, adjoining Chetserfield on the E., 97 miles W. of Portsmouth; incorporated in 1753, and containing 1400 inhabitants.

Swape, in Rural Economy, a provincial term signifying a long pole, turning upon a fulcrum, for raising water out of a shallow well, for churning with, or other similar purposes.

Sward, or Sward Land, in Agriculture, the green or gravel surface of the ground. In order to have a fine sward, much attention is necessary to feeding down the grass, as well as keeping it free from all sorts of rubbish of the weed kind. See Laying down to Grass, and Grass-Land.

It is that sort of land which is in the state of grass, or which has a sward upon it.

Sward-Cutter, an implement invented by Mr. Sandlands, and described in the sixth volume of the Bath Papers, for the purpose originally of preparing old grass-land for the plough, by cutting it across the ridges, in the beginning of or during winter, when the land is soft, in order to answer all the intentions propounded by Mr. Tull with the four-coultur plough, for bringing grass-land that has been long refitted into tility. This the sward-cutter has been found to do, the inventor says, much more effectually and expeditiously; as Mr. Tull’s plough, with four coulters, cuts the sward in the same direction with the plough, and is liable from every stone, or other obstruction any of the coulters may meet with, to be thrown out of its work altogether, or the instrument be broken, to which the sward-cutter, consisting of four, six, or more cutting-wheels, is never liable, from their being entirely independent of one another, cutting the ground across the ridges before ploughing, and rendering that operation easier to two horses than it would
be to three, without its being cut. The furrow, being cut acros, falls finely from the plough in squares of any faze required, not under six inches, in place of long slips of tough sward, felldom and imperfectly broken by the four-coulted plough. It is suppos'd, that any person who sees Mr. Tull's description of his four-coulted plough, and what he propos'd by it, will soon see the great advantage the fward-cutter has over it, in producing the desired effect of bringing old reed gras-ground into tilth; an object universally allowed to be of no small importance to agriculture.

Besides, it is an implement which is suppos'd very fit for preparing ground for burnishing, as it will save much hand-labour. It may also be properly used in croft-cutting clover, of one or two years' standing, to prepare the ground for wheat, if the land be stiff and moist enough. It may also be applied to cutting and croft-cutting pasture-ground, intended to have manure of any kind put upon it to meliorate the soil. In that, it will far exceed the scythe-cutter, as that instrument is liable, as well as the four-coulted plough, to be thrown out of its work when meeting with a stone or other interruption. This the fward-cutter is proof against; which is looked on as its greatest excellence. And in preparing for barley, the fward-cutter, it is said, excels a roller of any kind, in reducing the large hard clods in clay-land, occasioned by a sudden drought, after its being ploughed too wet; and it is likewise very proper for reducing such clay-land, when under a summer fallow. In this operation the fward-cutter is greatly to be preferred to the cutting-roller, both from its wheels being all dependent on one another, so that when one is thrown out by a stone, three or four more share the same fate: besides, the cutting-roller has but seven wheels in six feet, and the fward-cutter has fix in four feet three inches, at nine inches distant; and, if necessary, may have them so near as six inches. It is added, that after old gras-ground is cut acros with the fward-cutter, and ploughed, it has a very uncommon and work-like appearance, from each square turned over by the plough being raised up an inch or two at the side last moved by the fward-cutter, so that the ground, when plough'd, is all prettily waved, and resembles a piece of water when blown on by a gentle breeze. By this means, a very great deal of the land's surface is exposed to the frost, and other influences of the air, which cannot fail to have a good effect on it. And it is found that two horse are sufficient for the draught of a double-horfe fward-cutter, and one horse for a single-horfe one: one man manages the machine, and drives the horfes. The workman begins his operation by first measuring off twenty or thirty paces from the machine, fels or more, as he inclines, and thence fixes a pole. He then cuts the field acros, as near at right angles with the ridges as he can. When the cutting-wheels are past the last furrow about a yard, and the machine is upon the outmost ridge of the field on which it must turn, he must ftop the horfes, then take hold of the levers, and by pulling it to him, raise the cutting-wheels out of the ground, which are kept fo, by the loop of the rope being put over a pin for the purpose, in the lever, till the machine is turned and brought to its proper place, which is done by measuring off the same distance formerly done on the opposite side of the field. When the cutting-wheels are exactly over the outmost furrow, then, on the horfes being ftopped, fip off the pin, and the lever returns to its former place, which allows the weights to force the cutting-wheels into the ground again. He then goes on till the interval betwixt the first and second froke of the machine is all cut. In this manner the field is to be finished, after which you may begin to plough when you please. It is remark'd, that there must be a pole at each side of the field. But it is of no confequence whether the land to be fward-cut is in crooked ridges, or at right; in flat ridges, or in very high-raised ridges, such as are frequently met with in Scotland. Be the surface ever so uneven, it does not signify, as the cutting-wheels, being all independent of one another, are forced by their weights into the furrows cut by the machine.

Farther, one fward-cutter, it is said, will cut as much as one day on six ploughs will plough. It is added, that the land may lie several months in winter after being fward-cut, when there is no vegetation to make the cuts grow together again before it is plough'd; but the sooner it is plough'd after cutting, the better, that it may have the benefit of all the winter's frost, which makes it harrow better and easier at feed-time. When the ground is harrowed, the harrows ought to go with the waves that appear after ploughing, not against them, as by that means they are apt to tear up the furrows. The cut into squares. This not only be allowed to respecting the first two times or three, as they are called, or the harrowing. And it is observed, that any common wright and smith may make the implement. It is very strong, very simple, and easily managed, and moved from place to place; and if put under corn, will last many years. A representation of it may be seen in the work noticed above. Other implements of this kind have been invented, and recommended by different other persons; and one is said to have been lately invented and confuted in Lancashire, which has no tooth tappet.

**Sward-Dresser**, the name of an implement contrived for the purpose of drefling and improving the sward of land in the state of graces. An useful tool of this fort has been described by Mr. Amos, in his Minutes on Agriculture and Planting, where he has advised the use of it for levelling and drefling graces-land, whether it is to be mown or depurated with animals; and that the best time of performing the operation with it, is from the middle of February to the middle of April. And that, in general, drefling the land in this way may be sufficient; but if the sward be very mossy or weedy, the field is first mown with a mow and cross, then drefled with a large cross-cutter, cleaned and rolled; the implement being occasionally cleared from rubbish.

And it is suggested, that if the sward be thin, it may be thickened very much, by laying eight or ten tons of rota dung on, and fowing seven pounds of white clover, four pounds of wild or cow-clover, four pounds of trefoil, four pounds of rib-graces, and one peck of the best ye-graces feeds, per acre, previously to its being drefled in this way; bultharrowed, cleaned, and rolled. He thinks, that by drefling land in this way by this tool, moss is torn up, set and mole-hills levelled and destroyed, the roots of the grass cut, and horfe-hoed, which causes them to throw out fresh lateral shoots or flemes, the sward thickened, and the grass made so clean as to put on the finest appearance, when kept clofe fed down. And that by such management, and grazing as much fcock as will keep the graces in a young proficient state, and hobbing or mowing all the tufts and weeds three times in the course of the summer, the grazier will be enabled to receive every benefit from his land, and likewise prevent the flemes of several graces from running to foal, and being thereby injured, as well as the land.

**This fort of tool is contrived in somewhat the same manner as other implements of the same nature, having two strong pieces of wood which form the outer side-frames, 12 feet long, and twelve by three inches square, shaped as in the ordinary tools of this fort: there is a coultter-bar, 6 feet 8 inches long, and four by three and a half inches square, and...**
The people who manage bees, are informed of the time when they are going to send out new swarms by several signs. One is, when the hive is so peopled, that many of the bees cannot find room within; but stand in clusters on the outside of the hive; another is the appearance of a large number of drones, or male bees, especially if the weather be clear, calm, and warm; for in a cloudy, wet, and floridly seafon, the first swarms seldom or never rise, though the cathers, or second swarms, often rise in indifferent weather: these, however, are not certain signs, nor do they point out the very day of the swarming; but there is one which declares it very punctually, which is the obseving, that though the hive be very full, and the day very fine, yet very few bees go out in search of honey; in this case it is a certainty that they are assembling themselves in the hive, and preparing to be gone in a very little time. If a person go near the hives, that are ready to send out swarms, in the evening, or even in the night, he will hear a fort of humming noise in them, which is not to be heard at inch times on any other occasion: in short, the whole is in agitation on the occasion, and the tumult never ceases till the new colony goes out.

The signal of the going out of a swarm from a hive is sometimes only a humming noise made by one single bee, but that a very particularly acute and clear sound: this seems to be the voice of the new queen, or female bee, calling together the swarm that is to follow her out, and animating them with a fort of martial music for the great adventure they are going to engage in.

It is rare to hear these previous notices given for a first swarm; but the time of second swarms may generally be fixed within a day or two; by means of these distinct and musical notes, which are always heard two or three days before they rise. Eight or nine days after the first swarm is gone, one of the young princesses, addressing herself to the queen-mother, petitioning for leave to withdraw and erect a new empire, with a select body of the populace. For a day or night the regent gives no answer, but the young princess perfils in her suit, and at last succumbs. The second night the queen, with a very suldible voice, issues her royal grant, and proclames it through the whole kingdom; and the following day, the weather being tolerable, you may expect the swarm. When it is ready to come forth, the notes are louder, quicker, and more constant; when the greater part of the swarm is out, the music is then at an end.

All the different modulations of sounds made by the bees, are the effect of the different vibrations of their wings in the air. It has been supposed by Swammerdam, that the air issuing from the stigma of the body was very instrumetal to the making of this sound; but this is proved to be an erroneous conjecture, by the easy experiment of cutting off a bee's wings, which always renders the creature perfectly mute, though this could not be the case, if the voice proceeded from other parts. It is evident, therefore, that all the sounds of the bee are made by the stiking of its wings against the air; and it seems very easy to imagine, that when the motion of wings can make a sound, the more quick or slow motion of them can modulate it in a different manner, and the moving them in several different directions may add greatly to the variety.

The hours of going out of swarms are generally between eleven in the morning and one or two in the afternoon; the air is at this time very hot, and the sun often shines brightly on the surface of the hive: the effect of this, in causing them to go out, is easily conceived. The few who are nearest the mouth of the hive, and are ready to follow their queen, soon find that this is a pleasant season for their expedition, and the numbers of others, which remained irreligion the inner...
SWA

parts of the hive, now find the natural heat of the place increased to a great degree by the action of the external warmth, that it is very natural for them to resolve at once to depart with those which are going off, in order to find a place where they may be more at ease, or less crowded and heated in their habitation. People who have the care of bees should attend to their swarming, or going out on these occasions; and if they are not at leisure to watch them in the hours before mentioned, should defend the hives, during that part of the day, from the heat of the sun, that they may not go off and be lost.

Immediately before the going out of a swarm, there is heard a peculiar humming in the hive, much greater than what is heard at any other time, and immediately after this, the openings of the hive are crowded with bees, in a violent hurry to get out; those which first come out immediately take flight, and if the female, or queen, be among these, vast numbers immediately follow, and the air is seen as full of them as it is of flakes of snow in a winter storm; and, in fine, it is not a minute before all the bees that are to make the new swarm, are out of the hive: when the body is thus joined, they rise and fall in the air, and seem very curious in circling the hives of bees, and there to fix themselves. It does not appear that the female bee chooses the place for them, but they all seem to be affiant in it; and as soon as they have fixed upon a proper branch of a tree, or the like, they all fly towards it, and begin to form a cluster in one part of it. The female does not place herself at the head of this cluster, but sits on the branch near it, to see how it approves the management: as soon as the cluster is of a proper size she adds herself to it, and from that instant it thickens in a surprizing manner, all trying first to fix themselves to the leaf, so that in a quarter of an hour they are all collected together in a vast mass, hanging to one another by the legs. In this condition they remain absolutely quiet, though exposed to the open air, and there are no more of them seen flying loose about, than there are about the hives in a summer's day.

When the time of a swarm's going out of the hive is expected, the people who have the care of them, should always be prepared with a hive to receive them; and when the swarm settles upon some branch of a bush, or low tree, the hiving of them is an easier matter than could be imagined. See Hiving.

Bees are commonly placed in gardens, that the bees may have some flowers at least in their own neighbourhood, and not be compelled to go far in search of food; and the swarms from these hives always succeed best, when there are some bushes, as of filders, barberries, or the like, in the garden, as well as high trees; for when the bees take a high flight, they often take a very long one before they settle, and sometimes go so far, that the eye cannot trace them to the place of their settling; in which case, all attempts to search for them are uselessly vain, and they are lost entirely. The low bushes in view usually determine them to low flights, and if they are seen to be ascending too high, the culom is to throw handfuls of dust and sand upon them; this usually brings them down, as they probably mistake the particles for drops of rain.

When the weather, for some days after swarming, is unpropitious for the bees going out, they should be fed with care until it gets fine, otherwise there will be great risk of the young swarm dying, or being destroyed.

Another very ancient custom, and which is continued to this day, is the placing upon instruments of brass, and the like, to make a great noise while they are gathered in the air: it is pretended, that this compels to fix themselves the sooner. The origin of this custom has been an observation, that thunder always sends those bees which are abroad, from the flowers back to the hive, and it is supposed that this artificial noise may have the same effect; but, in all probability, the bees are better acquainted with thunder than to be thus deceived: there is indeed much more probability of their mistaking the particles of dust falling upon their backs for drops of rain, than taking to unlike a sound for thunder; for it is found by experience, that the making all the noise that can be conceived this way, never was able to drive one bee from a flower where it was busy, or to lead one to a fraggler home. Reaumur Hist. Inf. vol. x. p. 390. Tho- ley's Enquiry, &c. c. 6.

SWARM. After See AFTER-SWARM.

SWAROCHESHA, in Hindu Fabulous History, is name of one of the holy men named Menus. (See Maxe.)
The name of this person is seldom met with.

SWARTA, in Geography. See SCHWARTA.

SWARTA, a town of Sweden, in Sudermanland; 4 miles N.E. of Nykoping.

SWARTEBERG, a town of West Gothland; 16 miles N.W. of Uddevalla.

SWARTH, in Rural Economy. See SWATH.

SWARTH-HORN, in Geography, a mountain of Switzerland, in the country of the Cufions, being part of the Scaletta Alps, which communicate with the Julian Alps, the Satt, and the chain that separates the Valteline from Upper Engadina and Pregalia.

SWARTOW, a river of Holstein, which joins the Tawe; 3 miles N. of Lubeck.

SWARTSLUYS, a forter of Holland, in the department of Overyssel, situated on the river Vecht, in a marshy country, defended by five bastions; 28 miles W. of Corisandor.

SWARTZIA, in Botany, a name given by Schreber to the Tournata of Aublet, in honour of Olof Swartz, M.D., the present Berigian professor of botany at Stockholm, a faithful pupil of Linneus, and one of the best botanists of this or any age. His various Cryptographic works, to his credit than his West Indian flora, entitle this amiable and liberal writer to universal respect. Ritter of Schreber, let the article, proves the fame genus. Another Swartzia was indeed founded by Hedwig, in his Crypt. v. 2. 72; but this latter, a genus of Molluscs, is unquestionably not dihid on Thalamostomum, as was supposed, but in its proper place.—Schreb. Gen. 518. Wild. Sp. v. 2. 1219. Mart. Mill. Dict. v. 4. (Tournatae; Aubl. Gen. 594. Juss. 440. Lamarck Dict. v. 7. 716. Illutr. t. 46.) Ritter; Schreb. 564. Swartz Ind. Occ. 955. Pallas; Aubl. Guian. 934. Swartz Prod. 81. Juss. 557. Lamark Dict. v. 5. 576. Illutr. t. 461.—Cladis and arbors, Polyandra Mongomyn. Nat. Ord. Putamince, Linn. Coparides, Juss.

Gen. Ch. Cal. Perianth inferior, of one leaf, coriaceous, permanent, in four deep, ovate, rounded, concave, reflexed, nearly equal segments, coloured on their inside. Cor. Petal one, lateral, erect, roundish or oblong, fringed, with a short claw. Stam. Filaments numerous, longer than the corolla, inserted into the receptacle, awl-shaped, some of them, which are opposite to the petal, shorter and imperfect; others roundish, incumbent. Pili. German small, oblong, compressed, declivous, or incurved; style short; stigma oblique. Peric. Pod oblong, tumid, compressed, of one cell and two valves. Seeds few, oblong, tunicated.

Exf. Ch. Calyx in four deep segments. Petal foliaceous, lateral. Pod of one cell, with two valves, and a few tunicated seeds.

Obf. As the Swartzia and Ritter of Schreber are in-
satisfied by Vahl and Willdenow to be one and the same genus, we have endeavoured to make our description of the fruit answer to both, presuming there may be some inaccuracy in one or other of Aublet's descriptions, and not having more than the enlarging germs of Rittera only.

1. S. simplicifolia. Simple-leaved Swartzia. Willd. n. 1. (Rittera simplicifolia; Vahl Symb. n. 2. 60. Swartz Ind. Occ. 936.)—Leaves simple, elliptical, with a blunt point. Petal roundish, longer than the calyx. Stamens very numerous. —Native in thick woods; flowering in June. A shrub, ten feet high, with alternate, round, smooth, leafy branches, minutely dotted with whitish elevated points. Leaves flaked, alternate, somewhat coriaceous, broadly elliptical, about three inches long, or more, entire, with a short, blunt, rarely emarginate, point; bright-green and smooth on both sides, with one rib, and numerous, transverse, parallel, interbranching veins. Footstalks half an inch long, smooth, channelled, with two small, acute, deciduous, terminal teeth. Stipulas opposite, falcate, deciduous, Flower-stalks naked or terminal, racemose, shorter than the leaves, bearing from two to eight or ten large, yellow, fragrant flowers; whose upper stamens are thickest and longest, with oblong curved anthers; the lower, next to the petal, shorter and capillary, with ovate twin anthers. Seeds scarcely more than two, black, with a white scar, attached to the lower future of the pod; we nevertheless can hardly term it a legume.

2. S. grandiiflora. Large-flowered Swartzia. Willd. n. 2. (Rittera grandiiflora; Vahl Eclog. n. 2. 37. Plant. Amer. 90. t. 91.)—Leaves simple, oblong-ovate, pointed. Teeth of the footstalks oblongate. Stalks about three-flowered. Petal very large, kidney-shaped.—Native of the island of Trinidad. Very much like the last, but apparently different. The leaves are narrower, thinner, and more pointed. Teeth of the footstalks not deciduous. Petal larger. Better characters may hereafter be discovered by those who have an ambition of comparing good specimens of both plants. Vahl.

3. S. dendracandra. Dendracandrous Swartzia. Willd. n. 3. (Rittera dendracandra; Vahl Symb. n. 2. 60. t. 34.)—Leaves simple, ovate, nearly sessile. Petal oblong, about the length of the calyx. Stamens less than twenty. —Native of South America. Von Robr.—The branches are round; downy towards the extremity. Leaves alternate; on very short, minutely toothed, flanks, ovate, two or three inches long, membranaceous, very smooth, with a blunt emarginate point, one rib, and many transverse veins. Stipulas falcate, rather longer than the footstalks. Clusters axillary, shorter than the leaves, lax, slender, of four or five flowers, with a pair of falcate bracteas under each partial flake. Petal obvate-oblong, rather longer than the calyx, but shorter than the stamens, which are from fourteen to nineteen in number, yellow and thread-shaped. Vahl.

4. S. triphylla. Larger Three-leaved Swartzia. Willd. n. 4. (Polifra triphylla; Swartz Prod. 82. Ind. Occ. 937, note. P. arborescens; Aubl. Guian. 354. t. 355. Rittera; Schreb. Gen. 364.)—Leaves ternate, elliptic-oblong. Stamens about twenty-five, longer than the petal. —Found by Aublet, in the forests of Guiana, bearing flowers and fruit in May. The French call it Nota a flekis, or Arrow-wood, because the wood serves the natives to make points to their arrows, being very hard and close, of a yellow colour. The tree is of a middling size, with a trunk seven or eight feet high, and as many inches in diameter, crowned with spreading, round, smooth, wavy branches. Leaves ternate, dark-green, smooth and shining; paler beneath; the middle leaflet most elliptical, acute at each end, three or four inches in length; the lateral ones more ovate, and much smaller. Common footstalk flattened above as if winged; convex beneath; short in the part below the lateral leaflets, each portion tipped with a pair of very conspicuous, acute, deciduous teeth. Stipulae orbital-shaped, somewhat hairy. Clusters axillary, slender, of but few flowers, with pairs of falcate bracteas like the former. Petal round, emarginate, yellow, twice as long as the calyx. Stamens twenty-five or twenty-six (Aublet), fix or free of which, next the petal, are shorter and imperfect. Pod smooth, coriaceous, containing from one to four angular seeds, of an acrid and even caustic quality, all "attached by a fringed umbilical cord to a marginal receptacle." 

5. S. myrtifolia. Myrtle-leaved Swartzia. Leaves terminal or pinnate, lanceolate-oblong; with a bordered flake. Stamens very numerous, polyadaphous, as long as the calyx, scarcely so long as the petal. —Gathered in the Caraccas, by J. Mzrtor, M.D. who favoured us with a specimen on his return from that country in 1791. This resembles the last in general appearance, but the flowers, which are only one-third as large, and often pinnate of five or seven petals, as well as terminal, on the same branch. The footstalks are similarly toothed at the top of each joint; but the stipulas are mostly lanceolate, leafy, and considerably larger. Petal orbital, white or yellowish. Stamens extremely numerous, capillary, variously combined at the base, in which they accord with our seventh species.

6. S. pinnata. Pinnate Round-flaked Swartzia. Willd. n. 5. (Rittera pinnata; Vahl Eclog. n. 2. 38.)—Leaves pinnate, their common flake deciduous. —Native of the island of Trinidad. We know nothing of this species but from Willdenow, whose specific character is decisive.

7. S. alata. Pine Leaf-flaked Swartzia. Willd. n. 6. (Swartzia; Schreb. Gen. 518. Touantes guaniensis; Aubl. Guian. 550. t. 218.)—Leaves pinnate, elliptical; with a bordered flake. Stamens numerous, polyadaphous, much longer than the calyx.—Found by Aublet in the forests of Guiana, bearing flowers and fruit in November. —A tree, whose trunk attains the height of twenty-five feet, or more, and is above a foot in diameter. The bark is smooth, ash-coloured; the wood whitish, not very compact. The wide-spread branchlets are round, smooth and leafy. Leaves alternate, as large as those of our common Walnut, but firmer, of five leaflets, whose length is from three to eight inches; their upper side polished; under opaque, finely reticulated with veins. Each joint of the winged common flake is obliquely toothed at the summit. The flowers, of which we have seen no specimens, are described by Aublet as very small, growing many together in simple lateral clusters; about fix inches long, with a little scale, or bracteas at the base of each partial flake. Calyx in four deep acute segments, of a dirty white. Corolla none. Stamens very numerous, twice the length of the calyx. Capule ovate, yellow, of two concave valves, containing one vertical, oval, black seed, filling the cavity of the seed-coat, and enveloped at its base with a white, membranous, notched tunic. Such is Aublet's account, confirmed, in the main, by Schreber, who appears to have examined a dried specimen himself, and who found no petal, unless what he took for an occasional fifth segment of the calyx might be a bud. What has that appearance in Aublet's plate, is perhaps the genua. The fruit differs much, in shape at least, from the other species; but probably Vahl, who had more ample materials than have come in our way, has settled all these difficulties, and we have not his work at hand.

SWASH, Lower, Upper, Nine-feet, and Twelve-feet, in
Vol. XXXIV.
Both these Menus are said to have had ten sons by wives named Satarupa, who appears sometimes as the confessor of fakti both of Brahma and Siva; corresponding, in the case, with Saraswati and Parvati. See SAKTI.

The following extract from Wilford's learned Essay on the Chronology of the Hindous (Afas. Ref. vol. v.), will introduce us more particularly to the subject of this stick, and to some other important personages mentioned herein. "Swayambhava, or the form of the self-existing, was the first Menu, and the father of mankind; his confessor was Satarupa. In the second Veda, the Supreme Being is introduced thus speaking: 'From me Brahma was born; he is above all; he is Pitama, or the father of all men; he is Aja, and Swayambhava, or self-existing.' From him proceeded Swayambhava, who is the first Menu: they call his Adima (or the first, or Progenitous): he is the first of men; and Parama-Parutha, or the first male. His brother, Parakrta, is called also Satarupa: the is Adima, or the first; she is Visva-jenni, or mother of the world; she is Iva, or like I, the female form of nature; or if she is form of, or descended from I; she is Parva: both are like Mahadeva and his fakti, (the female energy of nature,) whose names are also Iva and Iva."

Another legend from the sacred books of the Hindous, explaining, after their manner, the origin of Satarupa, and of Brahma's four faces or heads, may be here introduced. "According to the Matiya Purana (see Purana) Brahma, in the north-west part of India, about the Assam, assumed a mortal shape; and one half of his body sprang out of it without his suffering any diminution whatever: he framed out of it Satarupa. She was so beautiful that he fell in love with her; but having sprung from his body, he considered her as his daughter, and was ashamed. During this conflict between shame and love, he remained motionless with his eyes fixed upon her. Satarupa perceiving his emotion, and to avoid his looks, stepped aside. Brahma was able to move, but still desirous to see her, caused a fire to spring up in the direction to which the moved. She filled her place four times, and as many faces, corresponding with the four quarters of the world, grew out of it. Having recovered his heart, he despatched his body to sprang from him, and became Swayambhavata."

(Willard, in Afas. Ref. vol. vi.) A legend, something similar, of Brahma's producing and falling in love with his own work, is given in the article MUNI. In these several allegories, to which the Hindous, common with the poetical chroniclers of Egypt and Greece, were so prone; and in which, if taken literally, we see little more than absurdity and incoherence.--In many of these allegories are doubtless buried historical and physical facts. We shall not endeavour to develop whatever may be hinted in the tales above quoted. We may, however, just hint, that in the consideration of Brahma being a perfonament of matter, or the earth, a clue may be found to some of the fables relating to his offspring, emanations, absorptions, &c., &c. See SARASWATI.

SWAYING, in Sea Language. See JERKS.

SWAYING of the Back, among horses and other animals, is a kind of lumbago, known by a pain and weakness in the loins. It may be caused by a fall, the carrying of a heavy burden, or some other violent accident; or a relaxation of the muscles of the back. Bleeding, blistering, and sweating, are useful in these cases, for the moat part; and the diet must be opening, and all imaginable care taken to keep down a fever. If a horse, he ought to be girt pretty firm over the loins, but not so as to hinder the motions of his flanks. SWEAING.
SWEALING. See Swallowing.

SWEARING. Porrane. See Porpaness.

SWEARING the Peace. See Peace.

SWEAT, a saline moisture issuing out of the pores of the skin of animals, through too much heat, exercise, or weakness; or through the action of certain medicines, called sudorifics. See Inrumentum and Perspiration.

SWEATH. See Swath.

SWEATHY. See Sweaty.

SWEAT, a disease of the natives of North America, when first settled among them, had a great many houses to sweat in, being their general remedy for diseases of whatever kind; but at present they are little used among them.

The cave, or sweating-house, was usually eight feet in diameter, and four feet high, the roof being supported by sticks, or boards. They usually dug these caves in the side of a hill, and near as could be to some river, or pond. The entrance into the cave was small, and when any person was sweating in it, the door was covered with a blanket or skin. Near the cave they used to make a large fire, and but in this a quantity of stones, perhaps five hundred weight: these they rolled into the cave, and piled up in a heap in the middle. When this is done, the Indians go in naked, as many as please, and sit around the heap of stones; and as soon as they begin to grow faint, which is usually in a quarter of an hour, they come out, and plunge themselves all over in the water, remaining in it a minute or two; and repeating this a second time, they dry themselves, and go about their business.

This has been for many ages used among them with success, in cases of colds, fevers, scalds, and pains fixed in their limbs; and the English have often used the same means, and found relief by it. It is practised equally at all times of the year, and the Indians do it not only in sickness, but by way of refreshment after long journeys, and other fatigues, and to strengthen themselves for any expeditions. Philos. Trans. 1384. p. 151. See Bath and Sudatorium.

SWEATING-Turf. See Turf-Sweating.

SWEATING-Iron, in the Mancro, is a piece of a fishy bone of about a foot long, and of the breadth of about three or four fingers wide, and is used only as cut up with one side. When a horse is very hot, and the grooms have a mind to leffen the sweat, or make it glide off, they take this knife or iron in their two hands, and gently run the cutting edge along the horse's skin, commonly with the grain, or as the hair lies, and but seldom against it; with intent to scrape off the sweat, and dry the horse.

SWEATING-ROom. See an account of the remains of a Roman sweating-room in the Philosophical Transactions, 1384. See Hypocaustum.

SWEATING-ROom for Chetfes, in Rural Economy, that fort of room or place which is appropriated to or for the purpose of sweating them in. It should be constructed, as to be readily capable of being kept up to the most suitable temperature for this use; and be conveniently situated for the chef's-room, and other places destined for carrying on the practice of cheese-making. It has been well observed by the writer of the Corrected Account of the Agriculture of Cheshire, that every dairy should be provided with a regular sweating-room; as when cheese is made, there is certainly a specific time when its contained air and juices incline to fermentation; and that the natural tendency should, at that particular time, be suffered. But that in the present mode, the whole is left to chance; and that at the very period, probably when a cheese is beginning to ferment, the weather becomes suddenly cool, or changed in other respects; which, if the process be then checked, the enclosed air becomes putrid, especially if the cheese has been ill made, and the next fermentation is really putrefactive.

SWEATING-Sickness, in Medicine, a febrile epidemic disease of extraordinary malignity, which prevailed in England at different periods, towards the end of the 15th and beginning of the 16th centuries, and which spread very extensively in the neighbouring countries on the continent. It has been described by various writers under the names of ergotism, ephemerain, ephemeris furtidoria, hydropsitus, and hydoproseps. It appears from their accounts to have spared no age or condition, but to have attacked more especially persons in high health, of middle age, and of better rank and condition. The invasion of the disease was exceedingly sudden, and was marked by the affection of some particular part, producing the sensation of intense heat, extending through the limbs, and afterwards diffusing itself over the whole body. This was immediately followed by profuse sweating, which generally continued more or less through the whole course of the disease, and was attended with intractable thirst. Extreme reflexions, delirium, nausea, cardialgia, and an irresistible propensity to sleep, characterized its progress; together with great prostration of strength, producing frequent fainting, and irregularity in the action of the heart, which sometimes palpitated violently, while at other times the pulse was weak and fluttering. In this way the patient was carried oft frequently in one, two, three, or four hours from the eruption of the sweat. Those more especially who bore their sufferings with impatience, and who sought relief from the face of a brest, by which they were tormented, by exposing their bodies to the air, or even by putting their arms out of bed, were often suddenly struck with death. The sweat, when promped, is represented as being unprofitably clammy, as well as abundant, and as having a very strong and peculiar fetid odour. The violence of the attack generally fubsides in fifteen hours, yet the patient was not out of danger till the expiration of four-and-twenty hours.

The history of the rise and progress of this singular and formidable disease constitutes one of the most curious articles in the annals of medicine. Its origin is involved in a good deal of obscurity; and among various explanations, reasoning, concerning the mode in which it was propagated, is to be met with even among the most authentic authors who describe its ravages. It seems, however, to be generally admitted, that it first appeared in the army of the earl of Richmond, afterwards king Henry VII., upon his landing at Milford Haven, in 1485; and that it soon spread to London, where it raged from the beginning of August to the end of October. Whether the troops, which were foreign soldiers, levied by the earl of Richmond, brought the disease with them from the continent, or whether the contagion was generated in the crowded transports, on board of which they were embarked, it is impossible, amidst the deficiency of evidence, to determine. It may readily be supposed, however, that a highly malignant contagious disease might have been generated under the circumstances, especially as this body of troops is described by a contemporary historian (Philip de Comines) as most wretched he had ever beheld; collected, it is probable, from jails and hospitals, and buried in filth. The general opinion at the time, however, certainly appears to be, that it arose from some peculiar state of the atmosphere, and was propagated by contagion; but no writer has distinctly pointed out the connection of this, or of other epidemic, with a specific condition of the air, nor testified any peculiarity in the circumstances attending its appearance, or subfequent return.
The sweating-sickness broke out in England four different times after this, but at unequal intervals. The summer season was always the period of its commencement, and it continued rife from three to five months. It appeared during the summer of 1506; and again in 1517, from July to the middle of December; and it raged with peculiar violence, proving fatal in the course of three hours; extending its havoc to many of the nobility, and carrying off, in many towns, half the inhabitants. Its next recurrence was in 1526; at which time, though it was somewhat less fatal, many of the courtiers of Henry VIII. fell victims to it, and that monarch himself was in danger. Bellay, bishop of Bayonne, then ambassador in England, who was affected with it, reports, that of 40,000 persons attacked with it in London, only 2000 died. The last time that it visited England was in 1551, when its fatality was so great, that in Westminster 120 died of it in a day, and, among others, the two sons of Charles Brandon, both dukes of Suffolk. In Shrewsbury, particularly, according to the testimony of Dr. Caius, who resided in that city, 900 died within a few days. The disorder had also, in the mean time, been decimating many parts of the continent. In 1549 it first shewed itself in Holland, and thence spread to the Netherlands, and to Germany, destroying a great number of lives. It is stated to have interrupted a conference at Marburg between Luther and Zwinglius, about the eucharist. From the description which Wierus has given us of this epidemic, as it appeared in Germany, it seems to have commenced with a violent cold shag and shivering, which continued half an hour or more, accompanied with great pains in the region of the diaphragm and groin, and the other symptoms already mentioned as characterizing the disease, when observed in England. Swelling and redness of the hands at the beginning of the attack, and vomiting of black blood or bile, are also noticed by this author in particular. Erazmus, an eye-witness of its devastations, describes it in very forcible terms, "vium eft ex amne Phlegetoneo emphium hoc malum."

For a long time physicians were at a loss how to treat this new and singular malady. The fatal effects of exposure to cold, however, suggested the propriety of accumulating heat round the patient, with a view of stimulating the sweat, which appeared to manifestly be a critical discharge. The moment a person was seized with the symptoms of the disease, he was to lie down immediately in bed, without taking off his clothes, and to be completely covered, all but the face, with bed-clothes; in which situation he was to remain perfectly still, not flitting a limb, if possible, nor putting a hand out of bed. He was enjoined abstinenence from food during the whole twenty-four hours, and even from drink the first five hours: then a little ale or beer, or wine and water, was to be given in small portions, and sucked through a spout, the patient still lying in the same posture. At the expiration of about fourteen hours, the bed-clothes were gradually to be removed, and the sweating reformed; and after it was quite over, proper food was to be given to recruit the exhausted strength. This was the process, when the sweat flowed spontaneously: when this was not the case, attempts were made to excite it, such as by dry and warm friction, wine, aromatics, vinegar whey, China root, and other sudorific medicines. By this method of practice, actively purified, and properly adapted to the circumstances, we are told that the disease, though so fatal when neglected or mismanaged, was got over with a tolerable certainty of success; so that, according to the observations of lord Bacon, who has given us a short account of it in his "History of Henry VII.," it might be looked upon "rather as a surfeit of nature, than obstinate to remedy." Great stress is laid by some physicians on the danger of indulging the propensity to sleep, which accompanies the paroxysm. "If they were suffered to sleep," says Cogan, "commonly they fwooned, and so departed, or else immediately upon their waking." (Haven of Health, p. 262.) It appeared, however, from the testimony of the continental physicians especially, that much harm, and frequently fatal consequences, arose from the extremes to which the hot regimen was carried.

Dr. Willan, in his publication on cutaneous diseases, has thrown out a suggestion concerning the origin of this affection, which he supposes might have been owing to some diffease or depravation in wheat, or to some noxious vegetable growing with it in particular situations. This seems to have been suggested by some analogy to be tried between the fatal epidemic, called feu facré, feu St. Antoine, mal des arènes, &c. which is supposed to have originated from eating rye damaged by a parasitic plant, constituting the disorder in corn termed by the French rye. This opinion appears, however, to be untenable, and has been ably combated in a paper in the Edinburgh Medical Journal, vol. iv. p. 64.

The books from which original information may be collected on the subject of this article are the following: "A Boke or Confess against the Difease commonly called the Sweat, or Sweating-Sicknes, made by John Caius, Docthe in Physic," 1552, 12mo.; which was afterwards revised, enlarged, and put into a more scientific form, by the author, and published in Latin, in 1556, under the title of "De Ephemera Britannica:" a short account by lord Beaumont in his "History of Henry VII.," Joh. Wierus, "De Sueco Anglico," C. V. Dubrégol, "De Peste," Erasimus, in "Epistolae ad Carolum Utenheimi," Febres, "Schol. Observationes," vi. 8.; Severntus, iv. 15.; Thomas Cogan's "Haven of Health!" "Lord Bacon's Relation of the Sweating-Sicknes examined, &c. by Henry Stubbe, Physician at Warwick," 4to. Lond. 1671; J. Fortis, "Ephemera Anglica Pefilenes."
SWEDEN.

the Norwegian Alps to the limits of Russia about 600. The contents in square miles have been computed to be 208,913; and the inhabitants, supposing some years ago to have been 2,077,345, must have been 14 to the square mile, including Swedish Pomerania, estimated at 1440 square miles, and 103,545 inhabitants. The population of Sweden is very disproportioned to the extent of its territory; a circumstance which is attributed partly to the mountainous nature of the country, and partly to the severe climate of the northern districts. Accordingly Swedish Lapland is supposed to contain no more than 7000 inhabitants. Although geographers are very much disagreed in their statements of both the extent and population of this kingdom, its population at present is thought to exceed 3,000,000. According to the information communicated to Mr. Coxe by M. Wargentini, the rate of population, in the annexed years, was as follows: viz.

By this statement it appears, that the country has been gradually recovering from that exhausted state, to which it was reduced by the wars of Charles XII.; and that within the interval of 30 years, the number of inhabitants has increased 551,961, or a fifth part of its population in 1781; and as it has been upon the increase, it is supposed that it must now exceed 3,000,000. The nobility are supposed to include 2500 families, and the classes of peasants to comprehend 2,000,000.

The manners and customs of the Swedes, in the higher ranks, resemble those of the French; and the peasants exhibit such a degree of vivacity and address, as to have acquired the appellation of the French of the north. The complexion is less fair than that of the inhabitants of northern latitudes, and in some provinces it has a cast of brown. The men are commonly robust and well-formed, and the women slender and elegant. Their attachment to luxury is, in some measure, compensated by their love of hospitality. As trade and manufactures have made no great progress in this country, the peasants in general make their own furniture and garments. The natives of the western province of Dalecarlia retain many customs, and are distinguished for their probity and courage; but for any remarkable peculiarities of manners we must have recourse to Swedish Lapland. The language of Sweden is a dialect of the Gothic, being nearly akin to the Danish, Norwegian, and Icelandic. However, in the south of Sweden, some German and French words have been adopted; whilst the Dalecarlian on the north-west is esteemed a peculiar dialect, because it retains more of the ancient words and idioms. The Swedish language is sufficiently honorific, if the pronunciation were more emphatic. Mr. Coxe, during his progress through that kingdom, was struck by a surprising resemblance between the English and Swedish languages, not only in single words, but in whole phrases. To him the Swedes appeared as if they had been talking broad Scotch; and he thinks it probable, that the Scottish mode of speaking is the same as was formerly used in England, and that, while we have gradually softened our original pronunciation, the Scots have retained theirs. It is observed that the resemblance between the Scotch and Swedish is greater than between the Swedish and English, both in words and pronunciation; and that several obsolete Swedish words are very common in Scotland.

With respect to the similarity between the Swedish and English tongues, we may remark that they are both dialects of the Teutonic or German; and if in pronunciation they resemble each other more than their original stock, it is owing to this circumstance, that we are descended from the Swedes and Danes, whose languages are only different dialects; and the old Saxons, which gave rise to the English, was probably first introduced into our island by settlers, or invaders, from these northern kingdoms.

With respect to antiquity of literature, Sweden cannot vie with Denmark, Norway, or Iceland; but in modern times the Swedes have distinguished themselves in many departments of literature and science. It is needless to mention St. Bright, who flourished in the 14th century, and whose prophecies were published in Latin, or John and Olaus Tegnus, who retired to Rome, when the bishops were expelled from the kingdom by Gustavus Vasa; because Swedish literature can hardly be said to have dawned till the middle of the 17th century, when queen Christina invited Grotius, Descartes, and other learned men, to fow the seeds of literature, which gradually prospered under the reign of Charles XI. The names of Linnaeus, Wallerius, Cronstadt, Bergman, &c. in natural history, are well known. Sweden may also boast of other persons, who have distinguished themselves as historians, orators, and poets; and of academies which have encouraged the diffusion of literature and the sciences. Sweden has three universities, viz. those of Upsal, Lund, and Albo, and twelve seminaries for the education of youth, called "Gymnasia," of which six were founded by Christina. In every large town there is also a school, maintained at the expense of the crown, in which boys generally continue to the age of eleven, when they are sent to the Gymnasia, and from thence, at sixteen, to one of the universities. In the Gymnasia, and many of the greater schools, the Greek, Latin, and Hebrew languages are taught. The bishops inspect the seminaries and schools of their respective dioceses, in which they are bound to reside. The chief cities of Sweden are Stockholm the capital, Upsal, Gothenborg, and Carlserna; which see respectively. The improvement of the country by inland navigation has of late become an object of laudable attention. (See CANAL and TROLLETTA.)

Although the manufactures of Sweden are not numerous, yet they are not wholly neglected. They are chiefly those of iron and steel, of copper and brass, together with those of cloth, hats, watches, and fail-cloth, and the construction of ships. Many perfumes are employed in the manufactures of wool, flax, and cotton. But the chief article of export is iron. The commerce of Sweden is chiefly concerned in the exportation of its native productions, iron, timber, pitch, tar, hemp, and copper. Herrings also furnish an article of exportation; and the Swedish merchants import from their own island of St. Bartholomew, and from China, commodities which they afterwards transfer to other nations. The chief article of import is corn of various kinds, together with hemp, tobacco, sugar, coffee, drugs, flax, wines, &c. From a table of commerce published by Mr. Coxe, it appears that the balance in favour of Sweden in 1781, was 350,437L.

As the kingdom of Sweden is situated between the 10th and 50th degrees of E. long., and the 5th and 70th degrees of N. lat., the winters are long, cold, and dreary; and the summers are short, and alio hot, on account of the reflection of the mountains and the length of the days. The transition from fertility to luxuriant vegetation is in this, as it is in similar climates, sudden and rapid. The dreariness and darknes of winter are relieved by the duration of twilight and moonlight, by the reflection of the snow, and by the aura
SWEDEN.

aurora borealis. No country can be diversified in a more picturesque manner, with extensive lakes, large transparent rivers, winding streams, bold castriata, gloomy forests, verdant vales, suspended and cultivated fields, than Sweden. Although the soil is not very propitious, it is cultivated with skill and industry; and in the south of Sweden, such has been the progress of draining, and other agricultural improvements, that a sufficient quantity of wheat may be raised for the supply of the kingdom. Its rivers are numerous, and the largest of them are in the native language denominated äker or äf. The most considerable, such as the Göta, flow from lakes, and have a short course; others assume the form of creeks, and outlets of lakes. The Motlidae: and the first river of considerable course is the Dahl, consisting of two streams, the eastern and western, which rise in the Norwegian Alps, and after a course of about 260 British miles, enter the gulf of Bothnia, about 10 miles E. of Gjesle, presenting not far from its mouth a celebrated castriata, little inferior to that of the Rhine at Schaffhausen; the breadth of the river being near a quarter of a mile, and the perpendicular height of the fall between 30 and 40 feet. Further northwards, and especially in Swedish Lapland, there are many considerable rivers, that rise in the North Alps, and after a course of about 300 miles, discharge themselves into the gulf of Bothnia. The Torne, springing from a lake of the same name, and receiving the Kengis, and other considerable rivers, joins the northern extremity of the Bothnia gulf, after a course of about 300 British miles. Few countries can rival Sweden in number and extent of its lakes: such are the Wenner, the Wetor, the Meier, &c. which see respectively. The most considerable lake in Finland is that of Pejond or Pejans, about 80 miles long, and 15 broad, from which flows the river Kymmen. The lake of Salmo to the E. is a mere expanse, estimated at about 150 British miles in length, by 25 at its greatest breadth; which flows into the Ladoga, by the seifly current of Woxen, a vast castriata about a mile from its mouth.

The chief mountains of Sweden are found in that elevated chain which divides this country and Swedish Lapland from Norway. The highest mountain of this chain is supposed to be Swuchu, of acompact flaty freeone, but having towards the west mafoes of a different nature; and where it inclines to the lake of Finsmad, there are apartments that rise even by the fose taphorns in width, and other a depth, not exceeding in length from two to three hundred ells. Bergman also mentions the high mountain of Moeforen, near the same lake, as being formed of a puddingstone, conflagint of balls of free-stone, with a few of hornblende and lime-stone, united by a fandy cement. The calcareous mountain of Rattvijk is extinguished by him to be 6000 feet high above the sea; and he observes, as a sanguinarity, that upon this mountain, and that of Roddougb, are found vast blocks of reddish felspar, mingled with quartz and brown mica. On the mountains of Samund, there are also numerous fragments of transparent felspar, mingled with quartz and mica. In the centre and south of Sweden, the red granite becomes very common; but in Weftor-Gothia, the mountains are often of trap. The foreka of this kingdom are numerous; and Dalecarlia especially, abounds with those of beech, poplar, mountain asf, pine, and fir; and the lakes of Sweden are generally filled with wood to the margin of the water. But our limits will not allow us to give a detail of the various trees and plants that are to be found in this country. The horses, good and after circuit of mony small, but spirited, and are preferred, by lyving with out litter, from many diseases. The cattle and sheep pre-
SWEDEN.

by continual encroachments, carried to such an exorbitant height, as justly to excite the fears and indignation of the three other orders. Charles XI. artfully availing himself of this dissatisfaction, obtained from the states a formal grant of absolute sovereignty, which quietly devolved upon his son Charles XII. Upon his decease, Charles Frederic, duke of Holstein, son of his eldest sister Hedwig, ought, by the law of succession, to have ascended the throne; but the Swedes conferred the crown on Ulrica Eleonor, the youngest sister of Charles XII. Ulrica purchased her election by raising the limitations of prerogative imposed by the states; and her husband, Frederic I., in whose favour she resigned the crown, secured their concurrence by similar stipulations.

The new form of government established at this juncture, consisted of fifty-one articles, all tending to abridge the power of the crown, and rendered the Swedish sovereign the most limited monarch in Europe. The supreme legislative authority, and the power of declaring war and making peace, reposed in the states of the realm, which regularly assembled every fourth year, and could only be dissolved by their own consent. During the recess of the diet, the executive power was vested in the king and senate; but as the king was bound to abide by the opinion of the majority, and possessed only two votes, and the casting voice in case of equal suffrages, he was subordinate to the senate, and could be considered in no other light than the senate. The king enjoyed the mere name of royalty; he was only the officiable instrument in the hands of one of the two great parties which divided and governed the kingdom, as either obtained the superior influence in the diet. The great defects in this new form of government originated from frictions between the sovereign and subjects, on one side to increase, on the other to depref, the royal prerogative; until Gustavus effected the revolution of 1712. In consequence of this revolution, the whole executive power is virtually vested in the king; for though it is said to be entrusted to him conjointly with the senate, yet as he appoints and removes all the members of that council, and in the administration of affairs only sifts their advice, without being bound to follow it, he is absolute master of the senate. The king has the command of the army and navy, but is not charged with the despatch of the state affairs by all commissions; he likewise nominated to all civil offices. He has the sole power of convening and dissolving the states, and is not obliged to assemble them at any fatted period; he has rendered many of the taxes perpetual, enjoys a fixed revenue, and has the disposal of the public money.

Such are the prerogatives which are annexed to his crown; but however enormous they may appear, especially when compared with the slender degree of authority possessed by the throne before that period; yet, says Mr. Coxe, they by no means amount to despotic. The two great features, which essentially distinguish an arbitrary from a limited monarch, are the right of enacting and repealing laws, and the imposition of taxes without consent of the subject; neither of which are exercised by the king of Sweden. The legislative authority resides jointly in him and in the states; and the 40th article specifies "that the king shall have no power to make new laws, without the knowledge and assent of the states; nor abrogate an old one received formerly." Concerning the imposition of taxes, it is stipulated, that the king shall not levy money without the consent of the states, except in the case of actual invasion; but at the conclusion of the war he shall be obliged to summon them, and the new taxes shall be abolished. In addition to these two important restrictions, he cannot declare war, nor alter the coin, without their concurrence, and if called upon by them when convened, is obliged to account for the expenditure of the public money.

Though the king is subject to these material limitations; yet, as his ordinary revenue is perpetual, and the meeting of the states depends solely upon his pleasure, he may, if he please, govern without control, so long as he requires no additional subsidies. But as he cannot enact laws, declare war, or levy taxes, without consent of the diet; emergencies must occur, which may render it necessary to convene that assembly; when grievances may be redressed, and breaches in the constitution repaired.

Whatever be our opinion concerning the nature of the government subsisting after the year 1772, it is unquestionable that by the Act of Union, &c. in 1780, the constitution became an absolute monarchy; the sovereign having arrogated not only the rights of peace and war, and the administration of justice, but the imposition of taxes, without the consent of the diet, which cannot deliberate upon any subject till it be proposed by the sovereign. The diet consists of nobles and landed gentlemen, clergy, burgesses, or representatives of towns, and members of the council. Each of the four states has a speaker: the archbishop of Upsal being always the speaker of the clergy, while the king nominates the others. The diet of 1780 consisted of 49 counts, 136 barons, 188 knights, 396 gentlemen, 51 ecclesiastics, 94 burgesses, and 165 deputies of the order of peers. The revenue of Sweden is computed at about 14 million fylsterling; which is equalled by the expences of government. The revenues are chiefly drawn from the rents of the royal demesnes, part of the great tithes, a poll-tax, duties on exports and imports, on mines and forges, on distilled spirits, on hatchments, pensions, and places, tax on chimney, and monopoly of salt. The national debt amounts to little less than 10,000,000 fylsterling. The Swedish army consists of national troops, and of foreign infantry; the latter being computed at about 12,000. The total amount of the army may be about 48,000: and the soldiers are brave and hardy, and actuated by the former fame of the Swedish arms.

In order to raise the Swedish army, the kingdom is divided into districts, which are respectively bound to furnish and maintain a certain number of troops. Each holder of a certain quantity of crown land, called a hemman, provides a soldier, affords for his maintenance a small portion of ground, a cottage, and a barn, and allows him 100 copper dollars, or 1 l. 7s. 8d. per annum, a suit of coarse clothes, and two pair of shoes. During the absence of the soldier, either with the army in time of war, or during the annual reviews, or when he is employed in the service of government, the landholder cultivates his ground for the subsistence of his family, and, when he is present, may call upon him to work at the rate of the common wages bestowed on labourers. On the death of the soldier, his widow and children cede the ground and house to his successor, whom the landholder is bound to provide within the space of three months, on pain of being fined.

With respect to the cavalry, a certain number of hemmans are joined to furnish a man and horse fully equipped, and maintain them both.

Each province being divided into a number of hemmanns sufficient to support a regiment; the smaller provinces furnish the regiments of infantry, and the larger those of cavalry. The estate appropriated to the colonel is situated towards the centre of the province, and of the grounds assigned to his regiment; that of the captain in the middle of those belonging to his company; and in a similar gradation to the corporal.
SWEDEN.

In every year, either before or after harvest, when the peasants are least employed, the companies of each regiment are separately assembled for a fortnight or three weeks. The landholder is obliged to transport the man and his baggage to the place of rendezvous, and maintain him during his stay at the review. Befide these annual encampments, once in three years a general review of each regiment takes place. The men are also constantly exercised on Sundays, after divine service, in small parties, and in larger corps for some time before the encampment, but particularly in spring. If, in time of war, these troops march out of the country, the crown receives the usual contributions from the landholder, and provides the soldiers with clothes, provisions, and pay.

The Swedish fleet, which in 1792, consisted of 30 ships of the line, suffered so much by the naval operations of that year, that it cannot now reckon half that number. In the Baltic, which abounds with low coasts and isles, galleys of a flat construction are found more serviceable than ships of war, and of course great attention is paid to the equipment of such by Sweden as well as by Russia. Prior to the late revolution in France, Sweden had remained a faithful ally of that kingdom, which excited against her many enemies in Germany. Of late this alliance seems to have been sacrificed to a more useful connexion with Denmark and Prussia, which alone can guard the north of Europe from the progress of the Russian preponderance. The disorder of the finances unites with many other causes of discontent, both among the aristocracy and peasantry, to render the power of Sweden little apparent in the political balance of Europe.

In Sweden there are four superior courts of justice, called hof-rett: at Stockholm for Sweden Proper, at Jonköping for the kingdom of Gotland, at Abo for South Finland, and at Vaasa for North Finland. No sentence of death passed by the inferior courts can be executed, unless ratified by these tribunals.

The usual modes of execution in Sweden are beheading and hanging. Every criminal capitally convicted is indulged with the privilege of petitioning the king; he either complains of unjust condemnation, and demands a revial of the sentence; or, if he confesses his guilt, may implore pardon, or a mitigation of punishment. So mild are the penal laws, that several offences, which in other countries are considered as capital, are chastised by whipping, condemnation to bread and water, imprisonment, and hard labour; more than 72 strokes of the rod are never inflicted; nor is a criminal sentenced to bread and water for more than 28 days.

Many flagrant abuses in the courts of justice have been reformed and corrected by the king. In all cases of high treason, previous notice must be sent to the crown before any court can commence an inquiry, and an ordinance has put a stop to many frivolous and vexatious accusations. Before the ascension of Gustavus III., it was common for persons indicted, but not convicted, of crimes, to suffer an imprisonment of several years without being tried; but, by the abolition of many tedious forms, every criminal is arrested within a short period after commitment, the good effects of which alteration require no comment. He mainly increased the salaries of the judges, and conferred their share of the fines inflicted by their decision to other uses; by this judicious regulation he greatly lessened the corruption and injustice which prevailed in those tribunals; for the scanty incomes of the judges exposed them to bribery; while a share in the fines rendered them interested in conviction the criminal. The king also promoted the rights of humanity, by supressing, in 1773, the cruel and absurd practice of torture, which was employed for the purpose of obtaining a confession of guilt.

One excellent regulation in the courts of Sweden deserves to be mentioned, and adopted in all countries; a criminal is tried without expense to the plaintiff or defendant. The prosecution denounces a person suspected of guilt to the king's officer of justice, who carries on the proceed at public charge.

In Sweden there are four orders of knighthood: I. The order of the Seraphim (see Seraphim), or the blue ribbon, which is appropriated to perfons of the first rank; it admits only 24 members, exclusive of the royal family and foreign princes. II. The order of the Sword, or the yellow ribbon, for the officers of the navy and army. There are three classes of this order: 1. Commanders of the Great Cross, who wear the ribbon over the shoulder, and a star on the cost. 2. Commanders, who wear the ribbon in the same manner, but without the star. Each of these classes contains 24 members. 3. Knights, who wear the small cross pendant from the button-hole. The number of the star is indefinite, but generally amounts to above 1000. III. Pol Star, or the black ribbon. Of this order there are two classes: 1. Commanders, who wear the great cross pendant round the neck; there are 24 of this class, exclusive of four to be added for the bishops. 2. Knights, who wear the small cross pendant from the button-hole, are, exclusive of foreigners, 48; and are to be added for the bishops. The order, before the institution of the following order of Val, was conferred on men of letters. IV. The order of Val, or the green ribbon, established at the coronation of Gustavus III., is divided into three classes: 1. Commanders of the Great Cross, who wear the ribbon over the shoulder, and the star on the cost. 2. Commanders, who wear the ribbon over the shoulder, without the star. 3. Knights, who wear the ribbon over the neck. This order is conferred on persons who have distinguished themselves in agriculture, commerce, the arts, and sciences.

The gold coins of Sweden are double, single, and half ducats. The single ducats are to pass for 1 rigsdaler 45 skilling specie, or 11 daler 24 ore silver, or 31 daler 8 ore copper. The copper coins are single and double flatts, at 1 and 2 ore silver, or 3 and 6 ore copper, and rundbycken of 1 ore copper, and also half rundbycken of 96 double flatts, 192 single flatts, or 576 rundbycken, are to pass for 1 specie rigsdaler; but in large payments, no person is obliged to take more copper coin than the value of half a rigsdaler. As the Swedish ducata weighs 33 English grains, and contains 524 grains of fine gold, it is worth 0s. 2d. Sterling in English gold coin; but in Sweden this ducat passes for 94 skilling, which are worth only 0s. 1d. in English silver coin. The following is the report of an average alloy made on a quantity of Swedish dollars at the London mint, by order of the bank of England: "weight of 1000 dollars 1871½ oz.; average weight of each, 18 dwt. 17 gr.; average fineness 14½-dwt. more than English fineness." Hence the value is 4s. 6d. in English silver coin; but the dollar falls more, in proportion as the market price of silver in England exceeds the mint price. See Money and Rigsdollar.

The smallest denomination of weight in Sweden is the sk, which is the same as the as of Amsterdam, where 10000 skills are equal to 7417 grains, English Troy weight. The mark for weighing gold and silver, called "Silver-march," is 4384 skills = 3352 grains, English Troy weight; hence so much mark = 271 ounces Troy. In apothecaries' weights the pound is 7416 skills = 5400 grains Troy: hence 1 sk.
**SWEDEN.**

There are four other weights used in Sweden for different purposes: their proportions to each other, and to English weights, appear in the following table.

<table>

The pound visuable-wigt is divided into 32 lods, or 128 quintains: the mark of all the other weights is divided into 16 lods, or 64 quintains: 20 lbs. visuable-wigt make 1 lispund, and 20 lispunda 1 skippund: 32 lbs. vis. wigt make a ron: 120 lbs. a centner: and 16'7½a. a wangi.

Corn, and other dry commodities, are measured by the tunna. The tunna is divided into 2 spanna, 4 half-spanna, 8 fjerdinger, 32 kappar, 56 kannor, 112 flop, 448 quarters, and 1792 ort. With the allowance for good measure of 4 kappar for every tunna of wheat, rye, barley, oats, and peas, and 6 kappar for every tunna of malt, and of 2 kappar for salt or lime, a tunna of corn contains 65 kannor, of malt 66¼ kannor, and of salt or lime 59½ kannor.

The common tunna of 32 kappar measures 8940 English cubic inches, and therefore contains 4 Wincheffer bushels, and 5 quarts.

The liquid measures are as follow: the oxhufvud = 1½ spanna = 3 emer = 6 akare = 90 kannor = 180 flop = 730 quarter = 2880 jumfrur: 2 oxhufvud = 1 pipe, and 2 pipes = a fuder. The tunna of liquids or soft substances, and also of flour, meat, and fish, must contain 48 kannor, and a tunna of pitch or tar may contain 1 flop, or half kannor, less.

The oxhufvud measures 14.281 English cubic inches, and therefore contains 62.5 English wine gallons. The kannor, both for dry and liquid measures, contains 1594 English cubic inches; hence 100 kannor = 69¾ English wine gallons.

The Swedish foot = 1.316 French lines, or 11½ English inches, and 40 Swedish feet = 39 English feet. A Swedish ell = 2 Swedish feet; a fathom = 3 ells; and a rod = 8 ells, or 16 feet. A Swedish mile is 6000 Swedish fathom = 11,700 English yards; so that 11 Swedish miles are as 1 English mile. It is a degree of the meridian, fixed in 1820, in N. lat. 66° 20' 10" by M. Swanberg, is = 59706.15 English miles. A Swedish square foot contains 13.64 English square inches; a Swedish square rod = 27 English square yards; and a Swedish square mile = 44 English square miles. A Swedish tunneland or acre = 56,000 Swedish square feet, or 5900 English square yards, i.e. 1 acre and 35 perches, English statute measure; and hence 32 Swedish tunneland = 39 English acres.

A half of pitch, pottash, Luneburg salt, or beer, is 12 tunna of tar, or train-oil, 13 tunna of Spanisch and French salt, 18 tunna of fish, 12 tunna, or 12,000 herrings; 1 hemp, flax, cordage, tallow, or hops, 6 kippunds, or 120 lipfunds, answering nearly to a ton avoirdupois. A wall is 20 kafts, or 80 pieces. Stockholm and the other cities of Sweden exchange with London at 4 right-daler 15 skilling, more or less, for 1l. sterling, at 75 or 90 days.

Theulance is reckoned at one month after flight; six days of grace are allowed for the payment of bills, in cases of necessity, but a person who wishes to preserve his credit, must not claim any days of grace, but pay his bills on the day when they are made payable. The paper currency of Sweden, which is very extensive, is of two sorts, viz. banco and riksgold. The former is issued by the national bank, and the latter by the riksgold bank, which is under the direction of government. Banco is 50 per cent. better than riksgold: that is, two dollars of the former are worth three dollars of the latter. Banco is a legal tender, and has been declared by royal authority the national currency. Bank notes are issued in great variety, and as low as 3ths of a dollar. Riksgold is current in all payments.

Of the history of Sweden we can give only a brief and imperfect sketch within our prescribed limits. The first population of Scandinavia seems to have consisted of Finns, who probably about 7 or 8 centuries before the Christian era were supplanted by the Goths. (See SCANDINAVIA and GOTHS.) The southern parts of Scandinavia were inhabited by the Situnes in the time of Tacitus; and Ptolemy mentions five or six tribes, among which are the Gute of Gothland, as inhabiting the portion of Scandinavia known in his time. Jormander, in the fifth century, described Scania or Scandinavia, and mentions various nations by which it was occupied. The fabulous or traditional history of Sweden commences about the year of Christ 520. Before the eighth century it contained many provincial sovereigns, of whom the king of Upulf was chief. As cultivation spread, and deferts were converted into fields, new kingdoms arose; and of these Swoore esumeers nineteen. The king of Upulf subjected these inferior rulers, and Ingialld, who perished in the invasion of Ivar Vidfadam, destroyed by treachery 12 of the petty kings, and the king of Upulf received tribute from the, called on that account tributary kings. But these subordinate rulers sometimes anadied so much wealth and power, as to be more powerful than the superior lord.

Sweden had not a very extensive population till after the beginning of the eighth century. In the preceding age it was so full of woods and deferts, that it required many days journey to pass over them. The father of Ingialld exerted himself to convert many heaths and forests into arable land. He made roads through territories previously unexplored, and by his skill and industry, great extents of country were adorned, for the first time, by the cottages, corn, and people of a flourishing cultivation. This continued, however, was still insufficiently peopled, that Olaf, the son of Ingialld, flying from Ivar in the eighth century, found the country from the W. of the kingdom of Upulf to the Senner or Wener lake, an uninhabited forest. He cleared, by the axe and fire, the regions about the river, which runs into the lake; and the province and kingdom of Vermaland rose under his auspices. It was not till the ninth century that Jamtia and Hellingia, the two northern provinces of Sweden, received a permanent colony. Sweden was for a long time a favourite prey to the pirates of Denmark and the Baltic. In the eighth century (about A.D. 760) the Upulf kingdom was conquered by Ivar Vidfadam, the little potentate of Scania, whose father was one of the chiefs de-
stroved by Ingialld. Upal afterwards continued to gain increasing power and preponderance. From the year 760 there is an obscure period till the reign of Birn i A.D. 321, commemorated, with his immediate successors, by Adam of Bremen. Jægerbrong, one of the bold native historian, divides the ancient kings into the Yngling race, the most ancient according to traditional records, and terminating at the conquest by Ivar Vidfadne, who was succeeded by his grandson Hareld Hilddat, and his great grandson Sigurd Ring, and the race of Sigurd derived from another branch. In the reign of Olaf III. A.D. 1000, Sweden was partially converted to Christianty, but Paganism was not finally abandoned till the reign of Ingii the Pious, A.D. 1066, whole father, Stenkl, is regarded as the founder of a new dynasty, though he sprung from the house of the Sigurd. At this time the crown, which was before hereditary, became elective. The Swedes, discontented with their king, Albert of Mecklenburg, elected, A.D. 1888, as their sovereign, Margaret, heiress of Denmark and Norway. Thus ended the Fölkung race, whose accession had taken place about the middle of the 13th century; and by the celebrated treaty of Calmar, A.D. 1370, the three kingdoms of the north were supposed to be for ever united. But after the death of Margaret, in 1412, the Swedes began to struggle for their liberty, and in 1449, Karl or Charles VIII. was elected king of Sweden. However, having affaile the property of the church, he was forced to leave the kingdom in 1457, but was afterward restored. The struggles between Denmark and Sweden continued until the cruel and tyrannic reign of Christian II., king of Denmark, Norway, and Sweden; called the Nero of the North. His conduct incensed the whole nation against him; and after a contest which forms one of the most interesting portions of modern history, Gustavus Vasa delivered his country from the Danish yoke, and under him Sweden recovered its independence. The revolt may be considered as having commenced when Gustavus appeared at Mola, in Dalälard, A.D. 1520, and complete three years afterwards, when he entered Stockholm in triumph. Diff cered with the power of the clergy, which had repeatedly subjugated the kingdom to Denmark, this great prince, A.D. 1527, introduced the reformed religion, and died in his 70th year, September 1560, after a glorious reign of 37 years. Austria, Spain, and the other Catholic kingdoms, having conspired to extirpate the Protestant religion in Germany, Gustavus Adolphus, whose reign lasted from A.D. 1611 to 1632, and who exhibited a model for heroes and kings, was invited to assist the reformed, and carried his victorious arms to the Rhine and the Danube. Christina, the daughter of Gustavus, was very young at the time of her father’s death, but when she succeeded to the throne, she shewed herself worthy of it as long as the wife Oxen- tiern was Her miniter and confidential counsellor; but did regarding the counsel of that respectable veteran, the affection of her subjects abated; and fatigued with the cares of government, and having formed a kind of classical attachment to Italy, she abandoned the Swedish throne, her country, and her religion, and retired in 1654. Charles Gustavus, or Charles XIII., was requested to succeed her, and the states confirmed this choice. The northern powers took up arms against this kingdom, and the career of Charles was terminated by death soon after the repulse of Charles from the siege of Copenhagen. The peace of Oliva, concluded in 1660, soon after his death, restored tranquillity to the North. Charles XI. was mediator at the peace of Rywick in 1657, and died in that year. At this time the arts and sciences flourished, and the power of the kingdom was carried to its height. Charles XII. next assumed the reins of government, and by his frantic conduct, and notwithstanding all his conquests, sunk Sweden into a state of political humiliation, and it was afterwards regarded as little better than a province of Russia. His death, in 1718, was succeeded by a variety of diftaters, and by revolutions of territory in Russia, until at length, at the peace of Abo, in 1743, Sweden ceded part of Finland; and Adolphus Frederic, of the family of Holstein-Gottorp, and descended by the female line from the family of Vasa, was declared successor to the throne. The revolution under Gustavus III. in 1772, though perhaps upon the whole beneficial to Sweden, prepared the way for a despotic government. In 1792 this prince was affianced at a ball by a nobleman, of the name of Ankerforn, a captain of the guards, who con- fessed that he was the performer who had endeavoured to deliver the country from a master and a tyrant. Gustavus IV. was deposed in 1809, and succeeded by his uncle Charles XIII. duke of Sudermania. Subsequent events are of little general importance. Coxe’s Travels. Pinkerton’s Geog.

SWEDENBORCH, EMANUEL, in Biography, the son of a Swedish bishop, was born at Stockholm in the year 1689, and educated under the tuition of his father. Such were his talents and progrcis in literature, that, at the age of 20 years, he published a miscellaneous collection of Latin poems, entitled “Ludus Helecionis sive Carinna Mitel- Lines.” At this time he set out on his journey to England, France, Holland, and Germany. Two years after his return, in 1716, Charles XII., by whom he was highly esteemed, appointed him a fellow to the college of mines; and having directed his attention to physical and mathematical subjects, he published a work, entitled “Dedalus Hyperboreus,” containing an account of experiments made by himself and others in mechanics and natural philosophy; and also a proposal for determining, in a new manner, the longitude of places by the moon. He also printed a treatise on algebra; and he is said to have been the first person who, in the year 1716, published the method of integral and differential calculus. At the siege of Frederickshald in 1718, his scientific acquirements qualified him for rendering service to the besiegers; but having lost his patron on this occasion, he was taken under the protection of Ulrica Eleonora, the sister and succressor of Charles; and in 1719 was ennobled by her. Although he was thus distinguished by royal favour, his zeal in the promotion of science was not at all abated. From some experiments, of which he published an account, he concluded, agreeably to a well-established fact, that the earth is flatter at the poles than at the equator. Affiduous in his attention to the duties of his office, as asfessor to the mines, he visited foreign countries, in order to acquaint himself with their mines; and on his return in 1722, he devoted his time partly to his official services, and partly to his private studies, in which he died in 1753. He had completed his great work, which was published in the following year, under the title of “Opera Philosophica et Mineralia,” in 3 vols. fol. His name has now been most deservedly enrolled among those of the members of the academies of Upsal, Stockholm, and Peterburg; and several distinctions have also been bestowed upon him, as a mark of distinction of his country, by foreign academies and the government. About this time, however, his views were directed to subjects which he conceived to be of much higher importance than those of literature and science. “Whatever of worldly honour and advantage,” says he, “may be in these things, I hold them as matters of low estimation, compared with the honour of that holy office to which I have been called by the Lord himself, who was graciously pleased to manifest himself to
me, his unworthy servant, in a personal appearance, in the year 1743; to open to me a sight of the spiritual world, and to enable me to converse with spirits and angels; and this privilege has continued with me to this day. From that time I began to print and publish various unknown arcana, which have been either seen by me or revealed to me, concerning heaven and hell, the fate of men after death, the true worship of God, the spiritual sense of the scriptures, and many other important truths tending to falsify the false Jesusism and the doctrine in the Lord Jesus; and he published we may enumerate the following, &c.: "De Cultu et Amore Dei," Lund. 1745, 4to. "De Telluribus in Mundo nostro Solari," 1758; "De Equo albo in Apocalypsi," 1758; "De Nova Hierofolyma"; "De Carlo et Inferno"; "Sapientia Angelica de Divina Provenientia," Amsterdam, 1764; "Vera Christianna Religio," Amst. 1730. Concerning the spiritual world he supposed that he had discovered, that it existed not in space. To this purpose he alleges, in his "Universal Theology," that he could there find Americans and Indians every near him, and that he was visited by horses of different nations, and could converse with the inhabitants of other planets, not only in our system, but in other worlds. In this way, as he says, "I have conversed with apostles, departed popes, emperors, and kings, with the late reformers of the church, Luther, Calvin, and Melanchthon, and with others from different countries." After death a man in his opinion, is so little changed, that he does not know but he is still living in the present world; he eats and drinks, and enjoys conjugal delight as in this world; and so great is the resemblance between the two worlds, that in the spiritual world there are palaces and houses, and also books and writings, employments and merchandise, gold, silver, and precious stones. But all these objects are in an infinitely more perfect state than they are in this world. His zeal in propagating these whimsical, not to call them sensual, doctrines was so ardent, that he travelled into distant countries, and circulated his works at an immense expense. At home, it is said, that he was free and social in his disposition; but in foreign countries he was a recluse, and almost inaccessible. He declined worldly wealth and employment; and he lived in the world with the labour of the instruction and benefit of mankind. He had no trait of preciosity or melancholy in his conduct or temper, nor of enthusiasm in his conversations or writings. Thus he is described by his partial friends; and others, less attached to him, represent him as an inoffensive visionary, subdued by the delusions of a disordered imagination. He died in London, in the month of March, 1772; and his remains, after lying in state, were deposited in a vault at the Swedish church, in Well close square. Gen. Biog. SWEDENBORGIANS, the followers of Swedenborg, who form a considerable sect; and whole number of its adherents has increased after the death of its founder, and full subordinates in England, Germany, Sweden, &c. and also in America, under the name of "The New Jerusalem Church;" so called in allusion to the New Jerusalem mentioned in the book of the Revelation of St. John. The following summary will comprehend the discriminating genet of this sect. Whilst the Swedenborgians maintain the unity of God, they conceive that this one God is no other than Jesus Christ, and that he always existed in a human form; and that, in order to redeem the world, he assumed a proper human or material body, but not a human soul; and that this redemption consists in bringing the helle or evil spirits into subjection, and the heavens into order, so as to prepare the way for the introduction and establishment of a new spiritual church; and that, without such redemption, no man could be saved, nor could the angels preserve their state of integrity: that this redemption was accomplished by means of conflicts with evil spirits; and that the last of them, by which Christ glorified his humanity, performed the union of his divine with his human nature, was the passion of the cross. Although the Swedenborgians maintain that there is but one God, and one divine person, they ascribe to this person a real trinity, containing the divinity, the humanity, and the operation of the trinity not being eternally, but commencing at the incarnation. This trinity, composed of Father, Son, and Holy Spirit, resembles the human trinity in every individual man, of soul, body, and operation; and they hold, that as the latter trinity constitutes one man, so the former trinity constitutes one Jehovah God, who is the creator, redeemer, and regenerator. This doctrine, and some other tenets of the Swedenborgians, have been the occasion of a controversy between Dr. Priebsch and some members of the New Jerusalem church, particularly Mr. R. Hindmarsh, a printer. Swedenborg's doctrine is to be interpreted in three distinct senses, denominated celestial, spiritual, and natural; which senses are united by "correspondences," and that it is divine truth, accommodated respectively to the angels of the three heavens, and also to men upon earth. This science of correspondences, left since the time of Job, and revived by Swedenborg, is used by him as a key to the spiritual or internal sense of scripture; every page of which, as he says, is written by correspondences, that is, by such things in the natural world as correspond to it, in the spiritual world. He says, that men are attended by angels, who rejoice in their affections; that temptation consists in a struggle between good and bad angels within men; and that, by these means, God afflicts men in these temptations, since of themselves they could do nothing. He maintains, indeed, that there is an universal influx from God into the souls of men, inscribing them more especially with the belief of the divine unity; and this influx from God, of divine light on the spiritual world, is compared by him to the influx of light from the natural world. Swedenborg denies the doctrine of vicarious sacrifice, predetermination, unconditional election, justification by faith alone, the resurrection of the material body, &c.; and on the other hand, he maintains, that man is possessed of free-will in spiritual things that salvation is not attainable without repentance, and a life of charity and faith, according to the commandments; that man, immediately on his decease, rises again in a spiritual body, which was inclosed in his material body, and which he denominates substantial; and that in this spiritual body he lives as a man eternally, either in heaven or hell, according to the conduct of his past life. Baron Swedenborg and his followers farther maintain, that the passages of scripture, which have been generally supposed to signify the destruction of the world by fire, &c. commonly called the last judgment, should be interpreted agreeably to the above-mentioned science of correspondences, which teaches, that by the end of the world, or consummation of the age, is meant, not the destruction of the world, but the destruction or termination of the present Christian church, both among Roman Catholics and Protetants of every description; and that the last judgment actually took place in the spiritual world, in the year 1775; from which era they date the second advent of the Lord, and the commencement of a new Christian church, which, they say, denotes the new heaven and new earth in the Revelation, and the new Jerusalem descending thence.
SWE

SWEDEN. In their worship, the Swedenborgians use a liturgy, resembling that of the established church of England, as nearly as the difference of doctrines will allow. They introduce into their public services much vocal music, accompanied by the organ; and the dress of their ministers is similar to that of the established church. They have several places of worship in London, Birmingham, Hull, Manchester, and other places in the country. Gen. Biog. Motheim's Eccl. Hist. by Coote, vol. vi. Priezley's Letters to the New Jerusalem Church.

SWEDES, in Agriculture, a term often applied by farmers to signify the Swedish turnip. See Ruta Baga.

SWEDESBOROUGH, in Geography, a small port-town of America, in the state of New Jersey, and county of Gloucester, on Raccoon creek, three miles from its mouth, in Delaware river; 17 miles N. by E. from Salem, and 20 southly of Philadelphia.

SWEDISH TURNIP, in Agriculture, the name of a hard turnip, of which there are two kinds, the yellow and the white, the first of which is by far the best for all purposes in farming. See Ruta Baga.

SWEDISH TURNIP CUTTER, a very neat and simple contrivance, invented for expeditiously cutting or flacing this hard turnip. It is prepared and to be had of most implement-makers.

SWEDLER, in Geography, a town of Hungary; 7 miles S. of Kapffdorf.

SWEDONG, a town of the Birman empire, on the left bank of the Ava; 10 miles N.E. of Pagonmew.

Sweep, among Refiners, the almond-furnace. See Almond and Furnace.

Sweep, among Goldsmiths, Moneyers, &c. See Washing.

Sweep, in the Sea Language. The seamen call the mold of a ship, when the begins to compass in at the rung-heads, the sweep of her, or the sweep of the futlock.

Sweep of the Tillar, in Ship-Building, a semicircular plank of oak, three inches thick and eleven broad, fixed up under the beams near the fore-end of the tillar, which it supports. On the fore-side of the sweep is a groove for the tillar-robe, in which groove-rollers are fitted to enline the rope. On the aft-side is a ledge or rabbit, defended with an iron plate, on which the gooseneck of the tillar traverses.

Sweer-Bar of a Waggon, is that which is fixed on the hind part of the fore-guide, and paifes under the hindpole, which slides upon it.

Sweer, Hay, in Agriculture, that fort of tool or contrivance which is employed for readily getting hay together. It is of great importance to every hay-farmer, who is in the practice of making his stacks of this fort in the field, to be in possession of a machine of this kind, as it not only saves the labour and trouble of loading carts, but is capable of being managed without any difficulty by few persons, and as much hay being often capable of being got together, and to the stack by it in a few hours, as two or three, as is usually done in half the day, in the ordinary cart-code.

Sweeping, at Sea, signifies dragging along the ground, the bight, or loose part of a small rope, in a harbour or road, in order to hook or recover some anchor, wrack, or other materials sunk at the bottom. It is performed by fastening the two ends of this rope to the sides of two boats which are abreast of each other, at some distance. To the middle of the rope are suspended two cannon shot, or something which weighs heavy, in order to sink it to the ground; so that, as the boats advance, by rowing a-head, the rope draws along the bottom, to hook any anchor, &c. for which they are searching.

SWEEPING APPARATUS, in Practical Astronomy, an apparatus contrived and used by Dr. Hertieh, for turning his telescopes to any part of the heavens, for the purpose of making observations, which he calls sweeping the heavens; for an account of which, see Telescope.

SWEEPING OF CHIMNEYS, in Domestic Economy. See Chimney.

SWEEPINGS OF STREETS AND HOUSES, in Agriculture, used as manure, are to be regarded as a composed material, and to be moily capable of being applied to the land, without undergoing any kind of preparatory process for that purpose. This is a manure that may be employed in different ways, and which is often capable of being done, by hand, over the ground, or a town was a top-dressing.

Sweeps, in Ship-Building, the various parts of the bodies shaped by segments of circles; such are the lower sweeps, lower-breadth-sweep, upper-breadth-sweep, and back-sweep, or top-timber-hollow.

Sweeps are large oars, used sometimes by ships, &c. See Sweepstakes.

Sweepstakes, in Geography, a town in the tract of Magellans. S. lat. 52° 42'. W. long. 71° 24'.

SWEET. By a sweet is understood any vegetable, whether obtained by means of a fungus, raifin, or other foreign or domestic fruit, which is added to wines, with a drop to improve them. It is plain, from the making of such must, or flum, by means of fine sugar, with a small addition of tartar, that the art of sweet-making might receive a high degree of improvement, by the using pure sugar, as one general wholesome sweet, instead of those infinite mixtures of honey, raifins, raisins, treacle, flum, cyder, &c. with which the sweet-makers supply the wine-coopers to lighten on, or amend their wines: for pure sugar being added to our poor wine, will ferment with it, and bring it to a proper degree of round or arrow, as the sweet is to be amended by tartar. So tartar should be added to the sugar; but if it be too sweet or luscious, that the addition of tartar is necessary. Shaw's Lectures, p. 106.

See Artificial Stomach.

By 43 Geo. III. c. 69, every maker of sweet woods, other than mead, for sale, shall take out a licence at 2s., and renew it annually, on pain of 30l.; and by 10 & 11 W. c. 21, every person who shall sell or use any materials used in the making of wines, and in whose custody or quantity exceeding two gallons of any kind is found, shall be deemed a maker of sweet woods for sale. By 43 Geo. III. c. 69, a duty on sweets or made wines is imposed, and by 43 Geo. III. c. 81, a farther duty. By the same act, every retailer of sweet woods or British-made wines shall take out a licence at 2l. 4s., which shall be renewed annually; and retaining without licence incurs a forfeiture of 50l. Persons dealing in sweet woods or sweet wines in their own houses or places adjoining are required to take out a licence for selling ale and beer from the same house, 28 Geo. III. c. 37. 32 Geo. III. c. 59; subject to the same penalties as selling without licence, referred to 3 Geo. III. c. 45. The house or place where British-made wines or sweets are sold shall be entered. Any person shall be deemed a retailer, who sells twenty-five gallons, or a less quantity. By 26 Geo. III. c. 74, retailers are required to put up in some conspicuous place in the front of his house, the words 'Dealer in British wine.' Persons making sweets or wines shall give notice of their names and places of abode, and of the rooms and places used for making or keeping them, to the excise-officers, on pain of 20l. (10 Geo. II. c. 17.) Concealing sweets from the eye of the gauger, incurs a forfeiture of 40l. for every barrel (7 & 8 W. c. 50.) Removing sweets, that have paid the duty,
duty, without a permit, incurs a forfeiture of 10s. a gallon, and also the liquor and caffs. (6 Geo. c. 21.) See Wines, Domestic.

Sweet Almonds. See Almonds.

Sweet Apple. See Annona.

Sweet Briar, the English name of a shrubby plant of the briar kind, not unfrequently cultivated in gardens and pleasure-grounds, for the sake of its fragrant and delightful smell. (See Rosa.) The sweet briar is also employed for the purpose of forming hedges in particular situations. See Quickset Hedge.

Sweet Corn, a term used by the Indians to express a fort of corn they are very fond of, and generally keep in their houses.

While the ear of the maize, or Indian corn, is yet green, but full, they gather it, and ffirk boil, and afterwards dry it, and lay it up for use in bags or baskets. When they eat it, they boil it again, either whole or grobly beaten in a mortar; they then mix it with fish, or with venison, or beaver flesh, and account it a very fine dish. The green ears, or fresh sweet corn, they also sometimes eat, as soon as it is gathered, roasting it before the fire, and then picking out the grains. This is a new supply of food for them many times, when their winter, or last harvest-store is exhausted. Their soldiers also commonly go out to war against their enemies about this time of the year, and find this supply in their enemies' fields. See Maize.

Sweet Flag. See Acorus.

Sweet Meadow-Grafs, a name sometimes applied to a gräf of the meadow kind by writers on husbandry. See Holcus.

Sweet-Scented Soft Grafs, a fort of grafs which is met with in moist meadows and, which, from the results of the trials lately made under the direction of the duke of Bedford, appears to contain considerable nutritive properties. They are given in Sir Humphrey Davy's work on Agricultural Chemistry.

The proportional value which the grafs, at the time of flowering, bears to that, at the time the feed is ripe, is as 17 to 21.

The grafs of the latter-math crop, and of the crop at the time of flowering, taking the whole quantity, and their relative proportions of nutritive matter, are in value nearly as 6 to 10. The value of the grafs at the time the feed is ripe, exceeds that of the latter-math, in the proportion of 21 to 17.

It is noticed, that though this is one of the earliest of the flowering grafs, it is tender, and the produce in the spring is inconsiderable. If, however, the quantity of nutritive matter which it affords be compared with that of any of those species which flower nearly at the same time, it will be found greatly superior. It sends forth a small number of flower-flakks, which are of a slender structure compared to the size of the leaves. This will account, in a great measure, for the equal quantities of nutritive matter afforded by the grafs at the time of flowering, and the latter-math. See Holcus Odoratus.

Sweet-Scented Vernal Grafs, an early field-grafs, which is cultivated to advantage on some forts of soil. It has been recommended in a paper in the third volume of the "Transac- tions of the Highland Society of Scotland," that this grafs flowers early, grows in every variety of soil, is closely eaten down by cattle in pastures, but feeds chiefly advan-
tageous in meadows for hay, which it sweetens to a high degree. No plant, it is thought, answers better in manured soils conferring of peat-earth. In soft soils, it arrives at a very considerable size, and is certainly grateful to all do-

meatly grazing animals. The feeds are all bearded, have a peculiar appearance, and are easily collected. It is perennial, and makes no great appearance in newly-own'd meadows, but enters generally into the hay of most of our natural meadows, and is eaten sweetly in the sap. For although it does not much abound in leaves, that is not, it is sup-
posed, a good reason for calling the plant into disrepute. The flaky, when taken in the juice, either for pasture or for hay, is undoubtedly grateful to sheep and cattle, being then in the succulent state.

In the Cheshire Corrected Report on Agriculture, it is thought, that though cattle are extremely fond of this grafs, and it makes excellent hay, it may be doubtful whether it is profitable as a meadow-grafs. It is by no means produc-
tive, and as it flowers and ripens its seeds much earlier than any of the other grafs, it is ill adapted to mix with them. It is common in that district on sandy loams.

Its properties and qualities have, however, been set in a full and clear point of view, by the results of experimental trials which have lately been made, under the care of the duke of Bedford, at Woburn Abbey, by Mr. Sinclair, his grace's gardener, but our limits will not allow a detail.

It appears upon the whole, that the proportional value which the grafs, at the time of flowering, bears to that at the time the feed is ripe, is as 4 to 13. And that the proportional value which the grafs of the latter-math bears to that at the time the feed is ripe, nearly as 9 to 18.

It is thought, that the smallness of the produce of this grafs renders it improper for the purpose of hay; but that its early growth, and the superior quantity of nutritive matter which the latter-math affords, compared with the quantity afforded by the grafs at the time of flowering, causes it to rank high as a pasture-grafs, on such foils as are well fitted for its growth; such as peat-bogs, and lands that are deep and moist. See Stock, Live, Choice of Food in. See also Grass, and Grass-Land.

Sweet Gum. See Liquidambarr.

Sweet John. See Dianthus.

Sweet Maudlin. See Achillera.

Sweet Pea, the English name of an ornamental pea, not unfrequently cultivated in the garden and other places for that purpose. See Lathyrus.

Sweet Root. See Liquorice.

Sweet Ryf. See Acorus.

Sweet Sorb. See Annona.

Sweet Sultan. See Centaurea.

Sweet Weed. See Capraria and Scoparia

Sweet William, the English name of several species of pink. See Dianthus.

Sweet William of Barbados. See Scarlet Convol-
uulus.

Sweet Willow. See Myrica.

Sweet Milk Cheese, in Rural Economy, a term used to signify that which is made from the whole milk, without abstractive the cream. It is seldom made for sale in this way, but sometimes, for private family use, it is prepared from the whole of the milk. (See Cheeses.) The theory of preferring all the richness possible to cheese of this kind, seems, it is laid by the writer of the Account of the Agricul-
ture of the County of Pekock, to depend upon the follow-
lowing principles and circumstances, which experience seems to have fully and abundantly ascertained: 1. That the cream is evaporable in a degree of heat not very intense; as is evident from the equal poorness, both of the cheese and of the whey, when the milk is too much heated before putting the rennet or yearning to it. 2. That the adhesion of the cream to the curd part of the milk is but slight as is evi-
S W E

Swell, in Sea Language, generally denotes a heavy and continual agitation of the waves, according to a particular direction; as there is a great swell setting into the bay. It is, however, more particularly applied to the fluctuating motion of the seas, which remains after the expiration of storms, and also to that which breaks on the shores of rocks and shallows, called surf; which see. Falconer.

Swell, in Surgery. See Tumour.

Swellimg or Leg-Eat, or Ill, a disease among sheep, which afflicts them in the legs as well as some other parts. It is said in a paper in the third volume of the "Transactions of the Highland Society," that in the most part, begins at the knees, which swell and enlarge to a considerable degree, causing so much lameness, as to prevent the sheep so affected from following the rest of the flock. But sometimes it begins at the head part of the leg, or even in the hinder part. In some instances, it is indeed frequently, having small blisters scattered over the leg affected, of a red colour, and filled with a black-coloured watery fluid. When the skin bursts, it leaves below it a loose flabby subsidence of the same colour, or rather darker, which extends even to the bone. It commonly first begins in one of the hind-legs, but as it advances to the four, unless death takes place before this happens. It occasionally spreads from the hind-legs to the belly, and in every case the kidneys are affected, being loose and flabby, having some resemblance to the swelling of the legs, and being sometimes of a livid colour. In some cases the disease proves very quickly fatal, while at other times it will continue in a mild state for weeks. It spreads very rapidly after appearing in a flock, and if not speedily attended to, will injure them materially. It is, in general, very dangerous, cutting off the greater proportion of those which are affected with it. Indeed, many shepherds kill the diseased sheep whenever they are seen to be affected with it, in order to prevent its spreading. In this disease, too, the eyes of the sheep is languid, its tongue dry, it cannot eat, and in general is soon cut off by the complaint.

It commonly appears about the latter end of summer, but at times in the beginning of the autumn; arising at first, it is supposed, from such sheep as have unhealthy conditions, being too much exposed to wetness during rainy weather. Scratches in the legs, it is said, will produce it in such sheep as have bad constitutions. If the sheep get their legs dirtied in the time of clipping, or smearing, a houle where there is much dung, they will be liable to be readily affected with the disease. Boggy ground has also a tendency to produce it, from the similarity of circumstance.

The sheep most subjects to this disease are, the sheep on the diseased estate, the Scotch and English breeds; but that, when it has appeared in a flock, the black-faced, heath, or Scottish sheep, are equally liable and subject to it. It has almost never appeared to the north of the Tweed, although it has of late been pretty common on its southern banks, in the shires of Selkirk, Roxburgh, and part of that of Peebles. It is conjectured that the

S W E

gent from the richnefs of the laft drainings of the whey, which, in sweet or whole milk cheefe, are very rich cream, if the curd be too hard wrought by the hand, or if it be too hard prefled at firft, immediately upon its being committed to the cheefe-pres. 3. That the whey, if not soon separated, speedily contracts the acid state, and then the perfect fermentation in the cheefe; making the cheefe fwell, tainting its smell and taste, and rendering it unfit for keeping.

Hence the propriety and utility, it is thought, are fhewn and indicated, firft, of putting the rennet or yeaming to the milk as cool as may be; secondly, of the moderate working of the curd by the hand in extrac ting the whey; together with a due and well-regulated preffure, moderate at firft, and gradually increafing, when it is put into the cheefe-well or vat, and submitted to the action of the cheefe-pres; or the praftice which is in ufe in fome places, of taking the curd repeatedly from under the cheefe-pres, and fifting it into small pieces, which areexpo led, at each fuch operation, upon a fieve, for the purpose of draining and drying by the air; that, thus, the aq ueous particles of the whey drippings off or exhaling, the cream becoming dry, may continue adhering to the curd, while undergoing the laft more strong confolidating preffure.

The length of time of the preffure is moftly about twenty-four hours, as fuiting the usual praftice in this forte of businesses, without increafing the expence of apparatus.

The cheefe, in these cafes, is sometimes failed in the curd; at others, only by rubbing fat in upon the skin or outside of the cheefe after it is made; and occasionally, by putting it in fat pickle, but which is thought to extract fome of its richnefs.

The praftice on which the praftice is founded of making the richest cheefe of this forte, is, it is faid, etablis hed in experience; and is, that a fmall quantity of the whey taken off, made boiling hot, and poured upon the remainder, caufes the curd infinitely to confolidate and expel the whey, the cream part meantime remaining united with the curd; the mass of curd is then fifted from the whey, and plunged into the coldest spring-water, which congeals the cream, from its state of liquefaction by the heat; and it is then put into the cheefe-well or vat and submitted to the preffure.

This praftice of making fuch rich cheefe is highly deferving of the notice and attention of thofe gentlemen and families who have it made for their own particular ufe.

SWEET Sublime of Mercury. See Mercury.

SWEET Herb Lake, in Geography, a lake of North America. N. lat. 54° 40'. W. long. 99°.

SWEET Edinburgh's Keys, a cluster of islets and rocks in the Spanish Main. N. lat. 14° 55'. E. long. 82° 55'.

SWEET Spring, a poft-town of America, in Virginia; 38 miles S.W. of Philadelphia. The mineral springs of this place draw four or five hundred people together for health and amufement, during the months of July, August, and September.

SWEET Water Creek, a river of Kentucky, which rises among the eastern branches of Bear creek and Tombigby; runs N., and discharges itself into the Tennessee three miles above Long Island. It derives its name from the springs of excellent water with which it is supplied.

SWEG, a town of Sweden, in Jerekalen; 32 miles S.E. of Langhaldan.

SWEIN, a town of Africa, in the kingdom of Dar Fur; which is a place of general retort for merchants trading to Egypt; 45 miles N. of Cobe.

SWELL of an Organ. See Organ.
may, in part, be owing to the long or white-faced sheep being there principally kept as the flock.

It is suggested in regard to the cure, that, as this is a very dangerous disease, the sheep affected with it should be brought home as soon as possible, to prevent it from infecting the flock, and its legs be well washed with soap in water; afterwards bathed with lime-water, or a solution of alum in water, and then anointed with what in the shops is known by the name of *citrine* ointment, which is made with mercury dissolved in aqua fortis, and mixed with hog’s-lard. If this be not at hand when the legs break out and run, a little quick-lime may be dusted on the foughs, and the leg dressed with a clot, spread with fresh butter, and a little tar. These dreslings should be changed every second day: care should also be taken that the sheep have good and dry pastures during the time of the cure; and water, in which moss or peat-earth has been soaked or steeped, may sometimes be preferred, in cases where it can be had, on account of its astringent or antiseptic quality, to common water, for their drink, as well as for washing the legs with.

After clipping or smearing in grounds subject to this disease, driving the flock through a pool or river, so as to wash their legs well, is, it is thought, a very proper practice; and that clipping the hair short upon them prevents any dirt from lodging on them. This disease has sometimes the name of *black-leg* given to it. There is a disease somewhat similar to this affecting the tails of sheep.

By properly applying means of this nature, this disease may mostly be, in some measure, either guarded against, or got the better of, without any very great trouble or difficulty.

**Swelling or Rolling Away**, a disease of the itching inflammatory kind on the backs of sheep. It is said that these animals are the most liable to die away, or of this disorder, in those farms which it suddenly grows or becomes worse, after showery weather, in the early spring, as from towards the beginning of the month of May until they are thorough.

The appearances of it are, that they lie down, roll on their backs, to relieve the irritation and itching there; when, if the ground happens to be level or hollow, or if they should be week, heavy with lamb, fat, or full-fed, they are not uncommonly unable to get up, and of course soon sinken, swell, and die. It is noticed also, that the fleece of the sheep which die away, or of this swelling disease, resembles much in the taffe, colour, and fimeal, that of sheep which are carried off by the fribing-ill, blood, or sickness.

In this situation of the disease, where the sheep are found down, they should be lifted up gently, care being taken constantly, towards the evening of every day, to see that none of them are thus down upon their backs. It is not improbable that small doses of calomel might be used daily, for two or three days, with much advantage, as about half a drachm for each dose; and that, at the same time, a weak cooling solution of white vitriol might be poured on the itching part of the back, so as to abate the itching there, and thereby relieve the animal from much diffus and uneafines.

**Swelling in Chees** in, *Rural Economy*, the heaving or enlarging of it in the dairy or other place. The cause of this injury and mischief to it, has been very differently considered by different dairy farmers, and for which various causes have been assigned.

Allowing for the operation of some other causes, it may be suspected that the rankfees of the herbage is the most common and prevailing one. Under some sorts of dairy management, particular farms in some districts have been noticed for producing heaved or swelled cheeves, whereas, by other kinds of management, this has scarcely ever been the case. This is often supposed to depend on some substance being secretly employed as an antidote, which has either the power of lowering the milk, or of counteracting its disposition or tendency to ferment and beast. Such a secret substance is pretended to be poffessed by many in some cheese-dairy counties, though it is not attended with success in preventing this effect in all cases.

A farmer of this farm has, however, been stated to have come to a farm on which the cheeves had always been spoiled by heaving or swelling, and which, as the land was extremely good, was supposed to depend upon that as the cause of the injury; yet little mischief of this nature is said to have been experienced by him since he came upon it, and which is ascribed to the practice of constantly using in mixture with the rennet, previously to its being put to the milk, about a table-spoonful of a solution of blue vitriol, in proportion to that which is necessary for the milk of about twenty cows. In other cases, the same practice has, however, failed of success.

In Chefs they consider this mischief as constantly arising from the too great generation of air in the cheeves, as the swetting in it is unquestionably a fermentation; and that where this proceeds has been regular and complete, the over-proportion of air is expelled, and the cheese subject afterwards to heave or swell. But that when this fermentation or swetting has been incomplete, as may happen from all the causes that check it in other cases, the cheese will be liable to swell or hove at any time, by any sudden change in the state of the atmosphere, as the approach of thunder, the variations of the weather from fair and dry to rain, and others of a similar kind; such changes producing alterations in the state of the air in the cheefe, those are made to swell or hove the moft, which abound moft with impure air; which are mostly thofe made from rich, narrow, artificial, granful patures.

It is, of course, thought advisable to produce this sweating in the cheefe as soon as possible after the making of it has been finished, as that is the most likely means of preventing this mischief. Little or nothing has, however, yet been done to properly regulate the heat or temperature of cheeves-rooms in this or other views. See Sweating-Rooms for Cheefe.

There can be no doubt that the more completely the whey is got out of, and removed from the curd, the less air will be left, and the less danger there will be of its being generated. This should, therefore, always be done as completely as possible.

It has been suggested too, that cheeves may perhaps be les subject to heave or swell, if made wholly of cold or of warm milk, that is, of one equal temperature; as the blending of warm and cold liquids together may disperse the generation of air in the cheeves. The most usual method of counteracting and restraining this evil in the above districts, is that of forcing it down by the use of light weights. Blistering in cheeves is also an effect which proceeds from the same cause, but which only affects the superficial parts.

The common means of removing blisters of this nature is by the use of a sharp instrument to open them, and by pouring hot water or whey into the openings, then pressing the ind well down, covering it with salt, and placing some flaty substance, with a small weight on it the parts.
Careful management is, of course, all that can be really depended on in this business.

SWELLY, in Geography. See Swilly.

SWERGA, in Hindu Romance, is the heaven of Indra, the regent of the firmament. (See Indra.) The Hindu gods have a paradise celestial and terrestrial. Sitanta is the name of the earthly abode of the Hindu Jove, placed on the wonderful Meru. (See Meru and Sitanta.) The Hindu heaven has many mansions. Swurga seems to be the fifth, whence demigods may be banished for misdemeanors, and condemned to be again on earth.

SWEERT, FRANCIS, in Biography, was born at Antwerp in 1567, and being a man of letters, employed himself in the composition of a number of learned works. Of these, the principal are "Rerum Belgicarum Annales Chronicos et Historicos Antiquos et recentiores" 2 tom. fol.; "Athene Belgice," fol.; "Deorum et Deorum capita ex antiquis Numismatis," 4to. in LinnEus's Greek Antiquities; "Monumenta Sepulchralia Ducatus Brabantiae." He died in 1629. Moretti.

Geo. Ch. Cal. Perianth inferior, in five deep, lanceolate, flat, permanent segments. Cor. of one petal, wheel-shaped; limb flat, in five deep lanceolate segments, larger than the calyx, connected to the base of the flower. Nectaries ten, composed of two small depressions, at the bottom of each segment of the corolla, on the inner side, each surrounded with minute upright bristles. Stem. Filaments five, awl-shaped, moderately spreading, shorter than the corolla; anthers oblong, incumbent. Pist. Germin superior, ovate-oblong; style very short, deeply divided; stigma two, simple. Peric. Capsule ovate, slightly compressed, acute at each end, of one cell and two valves. Seeds numerous, small, nearly orbicular, with a membranous border, "all inferted into the margins of each valve." Gartn.

Eff. Ch. Corolla wheel-shaped, with two stamens and orbicular stigmas, at the base of each segment. Capsule superior, of one cell and two valves. Seeds numerous, bordered, inferted into the margins of the valves.

Obf. Some species, as Linnaeus remarks, have four-cleft flowers; others have the nectaries projecting behind, in the form of little horns.

Germs often abortive. The leaves are staked, ovate, or ovate-lanceolate, mostly radical, entire, of a fine shining green. It is to be regretted, that this handsome plant can scarcely be cultivated in a garden; or rather, growing always in inundated ground, can hardly be transported from its native alps. Its qualities agree with Gentiana; see that article.

2. S. difformis. Various-flowered Swertia. Linn. Sp. Pl. ed. 1. 126. ed. 2. 318. Willd. n. 2. (Swertia; Gron. Virg. ed. 2. 30. Chironia paniculata; Michau Boreali-Amer. v. 1. 145. Sabattia paniculata; Pursh 138.) Stem erect, quadrangular. Leaves linear-lanceolate. Panicle oppositely branched, somewhat level-topped, with very long stalks. Flowers with five segments; the terminal one with six?—Found in the bogs and cedar swamps of New Jersey and Carolina, flowering in July and August. Flowers white. "Clayton, Pursh." Not having seen a dried specimen of this plant, we retain it here merely a conformity to Linnaeus, who, after having described the species from a specimen of Clayton's, subseqently lost its appearance, and placed in his herbarium, under the short name, a herbarium of the following, which we have Mr. Pursh's authority for being totally different. As to our idea of his genus SABATTIA, we refer the reader to that article, not having, as yet, had the means of coming to any conclusion on the subject.

3. S. Fraera. Fraerian Swertia. (S. difformis; Herb. Linn. but not Sp. Pl. Fraera carolinensis; Wal. Carol. 88. F. Walteri; Michaux Boreali-Amer. v. 1. 97. Pursh 101.) —Stem erect, opposite or whorled. Flowers in aggregate clusters, four-cleft.—Found in the swamps of Lower Carolina, and on the borders of lakes in Pennsylvania and New York, flowering in July. "Nerious branchial. Stem from three to five feet high. Flowers greenish-yellow, sometimes mixed with purple. The whole plant has a very flat appearance. Pursh. We received from the late Mr. Fraer, in 1788, a very incomplete specimen of this, much like what Linnaeus poissled, and mistook for his own Swertia difformis, and which led us into an error respecting that plant. See the foregoing species, and our article Fraerra.

4. S. rovata. Wheel-shaped Swertia. Linn. Sp. Pl. 326. Pall. Roff. v. 1. part 2. 98. t. 89. (S. n.; Gmel. Sib. v. 4. 112. t. 53. f. 1.) Gentiana rovida; Willd. Sp. Pl. v. 1. 157.)—Stem erect, panicled, leafed. Leaves lanceolate, sessile. Flowers five-cleft, flat.—Native of swamps in Siberia, flowering in August and September. The root is small and annual. Stem about a foot high. Flowers very various in breadth. Flowers copious, show an inch wide, of a fine blue. It appears to us as evidently that this is a genuine Swertia, as that Gunner's S. rovata, figured in Fl. Dan. t. 343, is a real Gentiana. See below, as above.

SWE

—Native of the loftiest mountains of Carinthia. Annual. Stem very short, leafy; in stunted plants quite simple and single-flowered. The flowers are bright blue, nearly as large as the leaf, each on a simple stalk, about two inches in length, which is almost the height of the whole plant.

7. S. corniculata. Spreading-horned Swertia. Linn. Sp. Pl. 328. Willd. n. 4. Pall. Roff. v. 1. part 2. p. 99. t. 90. f. 1. (S. n. 80; Gmel. Sib. v. 4. t. 53. f. 3.)—Flowers four-cleft, bell-shaped, with four ascending spurs. Leaves lanceolate, sessile. Branches elongated.—Native of birch thickets, and open groves, in Siberia. Gmelin. The root is annual. Stem erect, round, slightly angular, leafy, about a foot high, either simple, or branched from the bottom. Leaves ovate-lanceolate, three-ribbed, an inch and a half long. Flowers axillary and terminal, numerous, on longish stalks, yellowish-green, not much expanded, each segment of the corolla furnished, at the base behind, with a spreading ascending spur to the nectary, nearly as long as the corolla itself.

8. S. deflexa. Drooping-horned Swertia. (S. corniculata; Pursh n. 1.)—"Flowers four-cleft, bell-shaped, with four deflexed spurs. Leaves ovate. Branches short."—In swamps of Canada, and round the lakes of the western part of the United States, flowering in July. —Root biennial. Flowers greenish-yellow. Pursh. This author has hinted the propriety of distinguishing the American S. corniculata of Linnæus, first found by Kalm, from the Siberian, and we adopt the characters he has pointed out, not having ourselves seen the former species.

9. S. recurva. Curve-horned Swertia. — Flowers four-cleft, bell-shaped, with four recurved spurs. Leaves linear-lanceolate; the lower ones tapering down into long-winged footstalks. — Gathered in Mexico by Escallon, and sent to Linnæus by Mutis. The stem, in our only specimen, is a foot high, slightly angular, leafy, smooth, quite simple, except a few short leafy branches at the bottom. Lower leaves lanceolate, three-ribbed, above an inch long, on winged stalks of nearly equal length; upper almost leafless, shorter, and nearly linear. Flowers few, apparently yellowish or whitish, in a short, simple, terminal cluster. Spurs shorter than the corolla, more or less hooked, or curved upwards.

10. S. dichotoma. Forked Swertia. Linn. Sp. Pl. 329. Willd. n. 5. Pall. Roff. v. 1. p. 2. 100. t. 91. (S. n. 79; Gmel. Sib. v. 4. t. 113. f. 3.)—Flowers four-cleft, without spurs, drooping. Leaves elliptical. Stem much branched.—In thickets, and gruffy muddy places, in Siberia, flowering in May and June. Annual, from three to six inches high, many leafy, leafy, and profusely covered with small, white, four-cleft flowers. Nectaries as described in the generic character.

11. S. tetrapetala. Cruciferm Swertia. Pall. Roff. v. 1. p. 2. 99. t. 90. f. 2. Willd. n. 6.—Flowers four-cleft, flat, without spurs, erect. Leaves lanceolate. Stem simple.—Gathered by Steller in Kamtschaktska, at the mouth of the river Appallas. Pall. Annual, six inches high. Leaves elliptic-lanceolate, nearly or quite sessile. Flowers about half an inch in diameter, all four-cleft, blue; not, as the name implies, of four distinct petals. We cannot help observing that the numerous errors of the editor of the Flora Siberica, in quoting his own plates of this genus, are implicitly copied by Pall as well as Willdenow; an inference, among many others, of the negligent manner in which synonyms are too often compiled.

13. S. pufilla. Dwarf Swertia. Pursh n. 3.—"Corolla flat, twice the length of the calyx. Stem quite simple and single-flowered. Leaves obovate."—In the more elevated regions of the White hills of New Hampshire, flowering in June; as well as of Labrador. Annual. The whole plant scarcely above an inch high, with one or two pair of small leaves, and a considerable-sized blue flower. Segments of the corolla obovate, pointed; those of the calyx obtuse. Pursh.

SWETADEV, a name of the Hindoo goddess Parwati; which fee.

SWETARA, in Geography, a river of Pennsylvania, which falls into the Susquehanna from the N.E., about 7 miles S.E. of Harritsburg.

SWETOE, a small island in the Capian sea, separated from the W. coast by a narrow channel, called the "Straits of Aperhon," through which vessels often fail. In this island is found black and dark grey naphtha, which is carried from the springs into pits or reservoirs by means of troughs, whence it is conveyed into boats; 25 miles E. of Buchu.

SWIDDEN, in Rural Economy, a provincial word signifying to finge or burn off, as heath, or the coats of swine.

SWIECICA, in Geography, a town of Lithuania; 50 miles N.E. of Pink.

SWIERZNO, a town of Lithuania, in the palatinate of Novogrodok; 36 miles E. of Novogrodok.

SWIETEN, Gerard van, Baron, in Biography, first physician to their imperial majesties at Vienna, was born at Leyden, on the 7th of May, 1700. He was a deceiver of an ancient and reputable family of the Low Countries, but left his parents at an early age, in consequence of which his early education was said to have been somewhat neglected.

Having passed through the usual grammatical studies, he was sent at the age of sixteen to the university of Louvain, where he was soon distinguished by his industry and superior attainments in the philosophical classes. Determining, however, upon following the profession of medicine, he returned to Leyden, where he became a most zealous and favourite pupil of the illustrious Boerhaave. After seven years of study under this great master, he took the degree of doctor in 1725, at which period, the indefatigable industry with which he had profited, not only from the learning and knowledge of his tutor, but from the most unremitting personal research, had already raised him to a high rank among men of science, and he was immediately appointed to a medical professorship, which he occupied for many years with great distinction. To his lectures, as well as to those of his celeb
brated colleague, the medical students of Germany, France, and England, reformed in crowds; a circumstance calculated to excite the enmity of the invidious, who were illiberal enough to cover their opposition under the mask of religion, and to demand the enforcement of the law, which prohibited those not professing the religion of the state from holding any public appointment. Van Swieten was of the Roman Catholic religion, and was consequently obliged to resign his chair, which unless acquired, he devoted to the composition of his excellent Commentaries on the Aphorisms of Boerhaave; the first volume of which had already appeared, and the second was nearly concluded, when the high reputation which he had acquired throughout Europe, obtained for him an invitation from the empress Maria Theresa to settle at the court of Vienna. He accepted this invitation, and removed to Vienna in the summer of 1745, after having stipulated that he should be allowed to follow his usual course of life. He would not even change his mode of dress, but appeared at court with his own lank hair, and without ruffles, till the empress presented him with a pair worked by her own hands.

His indefatigable zeal, his rigid love of order, his knowledge of the ancient and modern languages, his general erudition, and his intimate acquaintance with all the branches of medicine, and the collateral sciences, together with his inflexible love of justice and decorum, rendered Dr. Van Swieten the person in all respects qualified for taking the lead in the medical school of Vienna; and that city and medical science in Germany were ultimately beneficial to his exertions. One of his first attentions was directed to reform the medical studies of that university, for which purpose he undertook the labours of a professorial chair, which he held till 1753; and he displayed great firmness and zeal in eradicating the abuses which had long prevailed in this department, and contributed not only to supply the country with able physicians, but laid the foundation of the flourishing school of medicine, for which that capital has since been celebrated. Having obtained the full confidence of his royal mistress, he was enabled to procure all possible advantages for the prosecution of medical science in that university. He obtained the rebuilding of the college, with the addition of a chemical laboratory, of schools of surgery and anatomy, and of a clinical establishment in one of the first hospitals, and the augmentation of the botanical garden. His extensive erudition obtained for him the full farther honour of being deemed the most proper person to be entrusted with the interests of learning in general in the Austrian dominions, and he was appointed imperial librarian, vice-president of the imperial commission superintending the studies of the Austrian territories, and president of the censorship of books, as well as perpetual director of the faculty of medicine throughout Austria. He had the merit of introducing a liberal improvement in the conduct of the imperial library, that of permitting visitors to make notes and extracts from the books, which a barbarous regulation had before prohibited. In discharging the duties of the censorship, the rigour of his temper and principles induced him to proceed without mercy the writings of the French philosophers, some of whom repaid his hostility by vilifying epithets. The same inflexibility of character also led him to maintain a long opposition to the salutary practice of inoculation. In addition to the many honours and emoluments conferred upon him by the imperial family, who also created him a baron of the empire, he was voluntarily enrolled in the list of their members by almost all the distinguished literary societies of Europe, in testimony of their respect for his reputation and character. He continued, even in advanced age, sided by good health, to fulfil his various duties with unremitting fidelity; but the vigour of his constitution began to fail about the year 1770, and after three years of declining energy, he was attacked with a mortification in one of his toes in June 1772, which terminated fatally, after he had prepared for death by an exemplary performance of all the acts of devotion enjoined by his religion. He died at Schönbrunn, but the remains were not interred in the church of the Augustines at Vienna, and erected a statue to his memory in one of the halls of the university. She had placed his portrait there, with a complimentary inscription, during his life.

The great work, upon which the reputation of baron Van Swieten will be handed down, is his copious and learned commentaries upon the aphorisms of his respected master; it is entitled "Commentaria in Hermanni Boerhavii Aphorismos de Cognoicendis et Curtandis Morbis," and extended to five volumes quarto. It is a vast magazine of medical practice and pathological research, the result of the author's extensive reading and of his personal experience; and though much alteration has taken place both in the theory and practice of medicine, since the commencement of its work, yet the immense mass of well-lecited and well-arranged fact which it contains, and the judicious summary of the knowledge of the best ancient writers as well as of his own time which it presents, will always maintain its value. It has been translated into most of the European languages, and a very good English translation, in eight small octavo volumes, with a copious general index, was printed at Edinburgh in 1775. In addition to this repository of medical erudition, the author published another useful work, entitled "Description abrégée des Maladies qui regent communément dans les Armées, avec la Méthode de les traiter," 8vo. printed at Vienna, 1759. See Ely, Dict. Hist. de la Med. Gen. Biog.

was introduced at Kew early in the last century. - A tree of very handsome appearance, lofty and branching, with a trunk frequently from four to six feet in diameter. Leaves pinnate, reclining, alternate, shining, numerous on the younger branches; leaflets mostly in four pairs, without an odd one, opposite, stalked, entire, pointed. Petals corolla, with about eight flowers in each, small, whitish, occasionally of a reddish or fawn colour. Fruit large, woody, russet-coloured.

The excellence of this, the old Jamaica Mahogany wood, is sufficiently known.

2. S. flabellata. Febrifuge Mahogany-tree. Wild. n. 2. Roxb. Coromandel. v. 1. t. 18. t. 17. - Leaves pinnate, of about four pairs of elliptical, rounded leaflets; unequal at the base. Panicule terminal, divaricated. - Native of mountains in the East Indies. - A very large tree, with a lofty straight trunk, covered with a grey, scabrous bark. Branches numerous, the lower ones spreading, the upper ascending. Leaves alternate, abruptly pinnate, about a foot long; leaflets opposite, stalked, oblong, entire. Panicles large, terminal, diffuse, bearing numerous, small, whitish, white inodorous flowers. Fruit large, greenish. The wood is of a dull red colour, remarkably hard and heavy. The bark is internally reddish, and has a bitter, astringent flavour. The Telingas call this tree Syconia.

Method of Culture. - This plant may be increased by frowing the seeds obtained from abroad in small pots, filled with light sandy mould, in the spring, planting them in a hotbed, and watering them occasionally: when the plants are a few inches high, they should be carefully removed into other pots separately, replanting them in the hot-bed, giving them shade till re-rooted: they should afterwards have the management of other flovo plants. They afford variety and curiosity in flower collections with other plants.

SWIETLA, in Geography, a town of Bohemia, in the circle of Czaklaw. N. lat. 49° 35'. E. long. 15° 3'.

SWIFT, Johnson, in Biography, the celebrated dean of St. Patrick's, was descended from the younger branch of an ancient family in Yorkshire, of so small note and considerableness. His grandfather, Thomas Swift, was a clergyman, possessed of a good estate near Ros, in Herefordshire, but by his sufferings in the cause of Charles I. his fortune was ruined. He had ten sons, one of whom, named Jonathan, married Abigail Erick, a lady of good family in Leicestershire, with little or no fortune. He died young, about two years after his marriage, seven months before the birth of his only son, the subject of our article, and left his widow in very distressed circumstances. Being kindly invited by her husband's eldest brother, Godwin, she removed to his house in Dublin, where her son Jonathan was born on the 30th of November, 1667. When he was but a year old, he was carried away by his nurse, without the knowledge of his mother or kindred, to Whitby, whither he went to visit a friend, from whom he expected a legacy; and here he continued for almost three years, his nurse taking care of him, and teaching him to spell, so that he could read any chapter in the Bible before he was five years old. At the age of six he was sent to the school of Kilkenny, founded and endowed by the Ormond family; and at the age of fourteen he was admitted into the university of Dublin, where the expense of his education was defrayed by his uncle Godwin Swift, the eldest of his father's brothers, who had settled in Ireland. His uncle, who impaired his fortune by expensive projects, could afford him but a small pittance; and the strictness of his circumstances restrained the efforts of his genius, and discouraged his application to those branches of literature which his attention was directed. For mathematics, and the barbarous logic of that age, he had no taste; and as he had employed his hours of study in history and poetry, which were more suitable to his inclination, his proficiency had been so inconsiderable, that in his first examination for the degree of bachelor of arts, he was rejected on account of his disqualification for it. This disappointment, so far from inducing him to devote his time to college studies, served only to increase his dislike of them, and to occasion some reflections of contempt which occur in his writings; and therefore it was not in a manner very honourable to himself that he obtained this degree, which was conferred upon him "speciali gratia," or by favour rather than merit. In other pursuits adapted to his taste he was diligent, and employed eight hours a day in study. It was at this time, or at the age of nineteen, that he planned and partly executed his "Tale of a Tub," in which he displayed an uncommon second of miscellaneous reading. Soon after this his uncle Godwin died; and the incompetent support he then continued to enjoy was derived from the bounty of another uncle (William), whose circumstances would not allow any very liberal contribution. In possession of a scanty income derived from this source, he formed some expectations of additional assistance from a cousin, named Willoughby Swift, the eldest son of his uncle Godwin, who was then a considerable merchant at Lisbon. This cousin, hearing of his destitute condition, sent him a supply; the bearer of which was an honest tar, who declared receiving any reward for his trouble; alleging, "that he would do more than that for good master Willoughby." From this time he never knew what it was to want any thing in his purse.

Swift was now in his twenty-first year, altogether without prospect of advancement either in the church or in any secular department, without any great reputation as a scholar, from the disgraceful manner in which he obtained his degree, and with a spleenetic, morose temper, occasioned, or at least aggravated, by his dependent, penurious, and distressing circumstances, and disqualifying him for making personal friends. Nevertheless, it is to these circumstances, says one of his biographers, that the world owes a "Swift," and the want of money, want of learning, want of friends. His poverty and his pride were the subordinates guards of his virtue at college; and hence it happened that during his residence there, no flaw was to be found in his moral character, however low his talents and attainments might be rated. In 1688, being then in his twenty-fifth year, Swift left Ireland, and determined to visit his mother, who had found an asylum, in her state of penury and distresses, among some of her relations in Leicestershire. His mode of travelling was that of a pedestrian, with an occasional receipt, if the weather proved unfavourable, in a carrier's wagon.
SWIFT.

His mother, altogether dependent, could afford him no permanent protection and affiance. But she was related to the lady of Sir William Temple, who then lived in retirement at Moor Park in Surry; and his father had been the intimate friend of Godwin Swift. To him, therefore, Swift was advised to apply; and by him he was kindly received, continuing with him, as an inmate, at Moor Park and Shenhe for two years. This circumstance greatly contributed to the prosperous events of his future life. In the company and conversation of Sir William Temple, he made considerable improvement, and was actually employed by him in the revision and correction of his works; and by him he was introduced to King William, and had repeated opportunities of intercourse with him. The king offered him a captain’s commission in the horse; but he had no disposition for engaging in the military profession. The church was his choice, and hopes were entertained of his majesty’s favour to him in this way, but they were never gratified. He fought relief at this time from a disorder of the stomach, which occasioned such fits of giddiness that occasionally afflicted him, till they destroyed his reason, by a visit to Ireland, but deriving no benefit from this excursion, he returned to Sir William Temple’s, and renewed his studies. In the year 1692, he made a journey to Oxford, with a view of taking his master’s degree, hoping thus to obtrude his disgrace at Dublin. Here he was treated with great civility, and obtained the honour of which he was desirous on the 5th of July in the same year. After paying a visit to his mother, he returned to Moor Park, where he remained for two years; but finding no disposition in Sir William Temple to promote his settlement in the world, he left him in 1694, not without some tokens of displeasure. During his residence at Moor Park, he received frequent remittances from his uncle William, and his cousin William Swift. In the above-mentioned year, he went over to Ireland, and took orders in September, being then about twenty-seven years old. Soon after lord Capel, then lord-deputy of Ireland, to whom he had been recommended, gave him the prebend of Kilroot, in the diocese of Connor, worth about 100l. a year. During his retirement in this part of Ireland, he received various intimations that Sir William Temple of the rest of the benefit had faltered from him, his departure, and that he was sinking under infirmities, he much wished his return. A kind letter from Sir William himself confirmed these previous intimations, and he immediately determined upon returning to England. Having resigned his Irish prebend, he, very much to the honour of his benevolence, procured the presentation for an old incumbent nearly 60 years of age, who was no less grateful than Swift was generous. With about 80l. in his pocket, the whole flock which he then possessed, he embarked for England, and arrived at Moor Park in the year 1697. In this situation he remained about four years, in the greatest harmony, with tokens of mutual confidence and esteem, till the death of Sir William in 1699, who bequeathed to him a pecuniary legacy and his MSS. During this period of his life, Swift diligently prosecuted his studies, and regularly discharged his clerical functions in the family. He also became preceptor to a young lady, niece to Sir William Temple, who resided at the house; and at the same time Miss Johnson, afterward well known by the name of Stella, parlor of the benefit had faltered from him. Miss Johnson was daughter to Sir William’s Stewart, and being at that time about fourteen years of age, beautiful in her person, and possessed of fine talents, Swift took great delight in cultivating and forming her mind. At this time he also wrote his famous digresses, found in the “Tale of a Tub,” and the “Battle of the Books,” in honor of his great and learned friend. From the MSS. of Sir William Temple, Swift selected two volumes of letters, which he published, with a dedication to King William; to whom he also addressed a memorial, reminding him of the promise given by his majesty to the deceased, that the first vacant prebend of Canterbury or of Westminster should be conferred on himself; but no farther notice of him was ever taken by the king. Failing in his expectations from this quarter, he accepted an invitation from the earl of Berkeley, appointed one of the lords-justices in Ireland, to accompany him in the quality of chaplain and private secretary. Upon their arrival at Dublin, the earl was persuaded to take a secretary; and as his lordship intended to present his chaplain to the deanery of Derry, just become vacant, Swift was again disengaged by an application which secured that preferment to another person; so that he was put off with the livings of Laracor and Rathbeggin, in the diocese of Meath, which conjunctly were not of half or one-third the value of the deanery. The effect of these disapprobations was the increase of that irritability and misanthropy, which so strongly marked in Swift’s writings, and in his general conduct. Swift continued in the family of Berkeley during that nobleman’s stay in Ireland; and it was at this time that his true humorous vein in poetry began to display itself in several little pieces, written for the private amusement of the earl’s family. After lord Berkeley’s removal from Ireland, Swift went to reside at Laracor, where he continued for some time in the strict and constant discharge of his duty, occasionally diversifying into strains of humour. Soon after his settlement at Laracor, Swift is called “Stella” to Ireland; and the same, accompanied by another lady of the name of Dingley, who was related to the family of the Temples. These ladies occasionally resided in the parsonage-house when Swift was absent; but they were never known to lodge in the same house, nor to be each other without a witness. This mysterious connexion lapsed till her death, and he usually celebrated her birthday by verses, exhibiting almost the only strokes of tenderness that have ever fallen from his pen. Ambition now took full possession of his mind; and under the influence of this passion, he abandoned the duties of his parish, and the charming conversation of the amiable Stella, in hope of finding some favourable opportunity of distinguishing himself and pushing his fortune in the world. In 1701, being in his thirty-fourth year, he published his first political tract, without his name, entitled, “A Discourse of the Conquests and Difficulties in Athens and Rome,” the main scope of which seems to have been to bring discredit upon the impeachments then carrying on by the house of commons against some of the whig-leaders, to which party Swift was then attached. Upon the accession of queen Anne, when Swift found upon the throne in his next visit to London, his friends were in power, and he had gratified them by the fore-mentioned publication. He declined, however, all overtures made to him by the heads of the whig-gift party, and after some time determined to have no concern in their affairs. For several years he kept himself neutral, and abstained from meddling in politics. Finding that he could be of use in his political capacity, he turned his thoughts to other matters; resided on his living for the greatest part of the year, performing his episcopal duties, and therewithout ever employing his pen, except in writing sermons. In 1709, however, he published his “Meditation on a Broomstick,” in which he was much cenured on account of the ridicule contained in it of the fable and manner of so great and pious a man as Mr. Boyle, though it has been said that it was not
his intention to ridicule Mr. Boyle, but merely to furnish occasion for much innocent mirth on lady Berkeley's enthusiastic and simplicity of heart, and to exonerate himself from the task of reading to her writings, which were not at all suited to his taste. In the same year he also published the "Critical Essay on the Faculties of the Mind." In 1704 it was published, anonymously, the "Tale of a Tub," known to be his composition, though never avowed by him, a work which learned judges have pronounced to be rather indecorous than irreligious. The "Battle of the Books," printed with the former, is a burlesque composition of ancient and modern authors, to the disadvantage of the latter. The prominent object of ridicule is Dryden; but this poet was of too high a class to be permanently injured by Swift's wit. In 1708 he appeared as a professed author, by the publication of four different works. The first of these, entitled "The Sentiments of a Church-of-England Man with respect to Religion and Government," appeared on a change in the ministry; and this, together with the "Letter concerning the Sacramental Teft," afforded full proof of his adherence to the principles of the Tories. In his "Argument against the Abolition of Christianty," he exhibits a spirit of the age, with which the author is almost unsullied. His other piece was a ridicule of astrology, under the title of "Predictions for the Year 1708," by Isaac Bickerstaff, Esq., the popularity of which induced Steele to borrow the name for his Tatler. In the following year he wrote a serious work, entitled "A Project for the Advancement of the Christian Religion," dedicated to lady Berkeley, for whom he seems to have entertained an affectionate respect, and written (as Dr. Johnson says) with sprightliness and eloquence. Upon his return to Ireland he cultivated an intimacy with Addison, then secretary to the earl of Wharton, lord lieutenant; but, as for himself, he had no prospect of advancement, till the Tories came into power, in 1710. In a commission on the Irish prelacy for soliciting the queen to remit to the clergy of Ireland the first-fruits and twentieths, payable to the crown, he became acquainted with Harley, afterwards earl of Oxford, and secretary St. John, afterwards lord Bolingbroke; and having gained their confidence, he became one of the fifteen members of administration and their supporters, who called themselves "brothers," and dined weekly at one another's houses. He wrote a number of papers in the "Examiner," concerning the late administration, but, as Dr. Johnson thinks, though he exerted his powers both of argument and wit, he did not in the latter equal the papers in which Addison opposed him. He published at this time "A Letter to the Océbon Club," a set of Tory country gentlemen, who wished to stimulate Harley to more vigorous measures, and his address had the effect which he proposed of preventing cabals against his party.

Deeply immersed as he was in politics, he still adhered to the cause of literature, and in 1711 published "A Proposal for correcting, improving, and ascertaining the English Tongue," in a letter to the earl of Oxford. The institution of an academy for settling the language was a part of his project. Towards the close of the year 1711, he published the most celebrated of his political tracts, entitled "The Conduct of the Allies." This work, which was designed to disprove the nation to peace, was much applauded, and furnished the Tory members with all their arguments in parliament. The same strain of argument was pursed in his "Reflections on the Barrier Treaty," published in the following year. He also printed "Remarks on the Bishop of Sarum's Introduction to his Third Volume of the History of the Reformation," written by Burnet to excite in the nation an alarm of popery. In these remarks, Swift indulged the rancour of his personal aversion to that prelate. It has been observed of Swift, that no man of letters was more assiduous and maintained so much confuseness, as he did, in his association with men of power. The services he rendered them induced them to gratify his pride in this respect. When Harley once sent him by his secretary 50l., he returned it with a letter of protestation and complaint; but he afterwards accepted a draft of 1000l. upon the treasury, which he was prevented from receiving by the death of queen Anne. When Harley dired Swift to introduce Parnell to him, he declined doing it upon the principle, that a man of genius was superior to a man of high station; and he obliged the treasurer to walk with his staff of office from room to room, searching for Parnell, to requite the honour of his acquaintance.

Swift had been long aiming at a bishopric in England; and when a vacancy occurred, he was recommended to the queen by his ministerial friends; but archbishop Sharp, having infused into her mind fulspsicions of his faith, and other prejudices being raised against him, he was overlooked. The highest preferment which he enjoyed was that of chaplain of the deanery of St. Patrick's in Dublin, which he obtained in the year 1713, and which he retained for life.

In a pamphlet, published in the next year, anonymously, "The Public Spirit of the Whigs," in answer to Steele's "Cruïs," he reflected so severely and contemptuously on the Scots nation, that the peers of that nation went up in a body to the queen, and demanded reparation. A proclamation was issued, offering 300l. for the discovery of the author, and orders were given for the prosecution of the printer; but by some management, the storm was averted. The antipathy that prevailed between Oxford and Bolingbroke in the course of this year, cauèd him to be sent for, in order to reconcile the contending parties; but failing in his endeavours for this purpose, he withdrew from town, and wrote "Free Thoughts on the present State of Affairs," which it was not thought advisable to print; though they have since appeared among his works. The death of the queen terminated all contests among the Tory ministers, by annihilating their power; and Swift was constrained to take up his residence in a country which he always disliked.

On his return to Dublin, his haughty imperious temper was severely tried by the triumph of the Whigs, and the indig-nity with which he was treated. He, therefore, withdrew to the functions of his clerical office, and by the exercise of integrity and firmness, made many reforms in the chapter of St. Patrick's, and obtained an authority never before possessed by any one in his station. He opened his house twice a week to good company, and extended his acquaintance among the most cultivated and respectable of both sexes.

Mrs. Johnson, who had lodgings near the deanery, regulated his table on public days, though she sat at it merely as a guest. In 1716 he was privately married by Dr. Atthe, bishop of Clogher, to this lady, long known as his Stella; but before the event took place, he had formed another amorous connection, which was attended with circumstances more favourable than any other occurrence of his life. About the year 1712 he became acquainted, in London, with Miss Esther Vanhomrigh, an accomplished young lady of fortune, with a literary taste, which Swift took pleasure in cultivating by his influence, who he always became enamoured of his person, and actually made proposals of marriage to him. The flame on his part seems to have been mutual, and dictated his "Cadenus and Vanessa," the longest and most finished of his poems. Although he was engaged to Stella, he
he had not resolution to terminate the intercourse. When absent, he corresponded with her, and the followed him to Ireland. After his marriage with Stella, he still visited Vanella, and encouraged her hopes. Having questioned Stella whether or not she was really married, an answer was sent to her in the affirmative; and Stella sent her note to Swift, and went into the country, without seeing him. He went immediately to the house of Vanella, threw a paper on her table with a very indignant aspect, and then left her without uttering a word. Thus their connection terminated. The shock was fatal to the lady, who died in 1724, leaving in charge to her executors to publish all the letters that had passed between Swift and herself, together with the poem of "Cadenus and Vanessa." The poem was published, but the letters were suppressed.

In 1730, the dean of St. Patrick's claimed an interest in the regard of his countrymen, by publishing a pamphlet, entitled "A Proposal for the universal Use of Irish Manufactures." In 1734 he resumed his political character, by exerting all his powers for defeating a scheme for supplying the currency of that country by copper money, a pernicious plan of Wood of Wolverhampton having obtained a patent for the purpose. With this view he wrote a series of letters under the name of "M. B. Draper," which caused the coin to be universally refuted, to the great displeasure of the Irish government, which offered a large reward for the discovery of the author. The only person with whom Swift had entrusted the secret was his butler, who had transcribed the papers. This man, being absent from home one night, was surprised of having betrayed his master. On his return he was ordered to fling off his livery, and to quit the house: "I know (said he) that I am in your power, but for that reason I will not bear either your insolence or neglect." The butler, who had been drinking all night, confessed his fault, and intreated forgiveness; but the dean was inexorable. He was dismissed with disgrace, nor received again till the term of the offered reward expired. The dean rewarded his fidelity by making him verger of St. Patrick's; but he served his master still as butler. Thus government was baffled, the Draper triumphed, and the dean became the idol of the Irish nation.

In 1736 he published his "Gulliver's Travels," which was the product of spleen, as the author himself affirms; for in a letter to his friend Pope, he declares, in reference to this work, "the chief end I propose, in all my labours, is to vex the world rather than divert it."—"I have combated all nations, professions, and communities, and all my love is toward individuals."—Upon this grand foundation of misanthropy, though not in Timon's manner, the whole building of my travels is erected, and I will never have peace of mind till all honest men are of my opinion." These declarations are fully authenticated by the Travels themselves, which are, upon the whole, an outrageous satire on mankind, though the jujfns of many of its stokes cannot be denied. Some of the pictures are also highly disgusting, and others violate the probability of fiction; yet it is a work that will always be read.

In the same year, Swift, being in England, published three volumes of Miscellanea. In conjunction with Pope, to whom he relinquished the whole profits; for he seems never to have regarded his literary exertions as objects of pecuniary emolument.

On the death of George I. in 1727, Swift paid his duty to the new king and queen; he also paid his court to the favourite, Mrs. Howard; but eventually he gained nothing, and always afterwards spoke of queen Caroline with malignity. His Stell had been long languishing in a state of decline, her complaint being probably mental, on account of her extraordinary situation, combined with her bodily malady. Denied the honour and reputation of being his wife, her life was rendered intolerable to any female of spirit and delicacy. When in the ruined state of her health he offered to acknowledge her, she replied, "It is too late!" Another narrative is much less honourable to the character of Swift; this is, that within a few days of her dissolution, she adjured the dean, by their mutual friends, not to deny her the satisfaction of dying his acknowledged wife, though she had not lived as such; and that he turned upon his heels, left the room in silence, and never saw her afterwards. She died in January, 1728, bequeathing her fortune, in her own name, to charitable uses. Notwithstanding the doubts that have been thrown upon the validity of the marriage, the proof of it seems to be incontrovertible. They were probably suggested by some determined pamphlets, who wished to vindicate his conduct with respect both to this lady and Mrs. Vannanourgh; but each of these causes fixes an indelible blot on his memory, nor can any talents he polished or popularity he acquired, ever efface it.

The death of Stella very much afflicted Swift, though afterwards continued to vent his rancorous feelings in various effusions, both in prose and verse, on public topics. As an Irish patriot, anxious to meliorate the condition of the poor, he distinguished himself; and with this view he devoted a third of his income to charity. The most finished and interesting of his poems, written about this time, was the "Veres on his own Death," formed on a misanthropic maxim of Dacier. Having indulged his hatred of the Pretender in a bitter poem, in which he introduced the name of a counsellor, Bettefworth, who was obnoxious to him as an active leader in the Whig party, in Dublin, he was threatened with corporal retaliation; but his popularity was such, that the inhabitants of St. Patrick's district resolved to embody in his defence. In other instances he made little discrimination in the failures which he circulated; and such was the malignity of his temper, that it manifested itself in a kind of declared hostility against all mankind, a few of his own favourites excepted. At this time his most familiar associates were selected from the inferior classes, and especially from among people, who were always ready to administer obsequious flattery. In 1747 his constitution sustained a shock from a fever of phlegmes, to which, as well as deafness, he was habitually subject; so that after this period he undertook no work that required much thought or labour. It is hardly necessary to mention such pieces as his "Polite Conversation," and "Directions for Servants," which may be reckoned among his later publications. Whilst his bodily infirmities increased, his mind also decayed, and a gradual decline of reason, which he had long dreaded, settled into abysmic idiocy. His irascibility also increased, and at length he was a torment to himself and to all about him. During the violent pain which accompanied a tumour in one eye, it was with difficulty that he was prevented from tearing it out. A total failure of speech for some months preceded his death, which happened in October, 1744, in his 78th year. He bequeathed the greatest part of his property to a hospital for lunatics and idiots, the intention of which he had announced in the verse on his own death,

"To flee by one satiric touch, 
No nation wanted it to much."

He was buried in St. Patrick's cathedral, under a monument, for which he wrote a Latin epitaph; one clause of which displays very forcibly the state of his own feelings:

"Of
“Ubi fava indignatio ulterior cor lacerae nequit.” His predominant temper and distinguishing character are strongly marked in his life and writings. We shall select some sketches of both from the portraits furnished by his biographers. “A stern inflexible temper, and pride in a supreme degree, were the balsam of his character,” on which were built frugality, sincerity, integrity, and freedom from all mean jealousies; but alloyed with arrogance, implacability, cant and affectation of giving pain, and total want of candour. Numerous are the anecdotes of his rudeness and petulance in society, some of which were of a kind that meanest alone could tolerate. Of his obdurate and unfeeling nature, many more examples might be adduced, if those already given were not more than sufficient.

“As a writer, Swift was original, and probably will always remain unparaleled. In wit, he stands first in the walk of grave irony, maintained with such an air of serious simplicity, that it would deceive any reader not aware of his drift. He also boasts in ludicrous kind of being, with which his poems are abundantly interspersed, but which too often deviate into offensive grossness. Indeed it is remarkable, that so fatuously nice, should take a pleasure in descriptions full of physical impurity, and which cannot be contemplated without absolute disgust. His style in verse is the most perfect example of easy familiarity that the language affords; and his readiness in rhyme is astonishing, the most uncommon resolutions of sounds coming as it were spontaneously, in words the best adapted to the occasion. That he was capable of high polish and elegance, some of his pieces sufficiently prove; but the humorous, familiar, and farcical, was his habitual taste. His style in prose has been held up as a model of clearness, purity, and simplicity; it is, however, void of all the characters of genius, and has only the common merit of expressing the author’s meaning with perfect precision. Were Swift to revive, he would probably attain little distinction as a didactic or argumentative writer; but in wit and humour he certainly would not find a rival. He has secured a lasting place among the chiefs of English literature; and his name is still honoured in Ireland as a patriot, with a fervour that excites and almost panegyrizes his defects.”

SWIFT, in Geography, a river of England, which rises in the county of Leicestershire, and runs into the Avon, near Rugby, in Warwickshire.

SWIFT’s Creek, a river of Virginia, which runs into the Appamatax, N. lat. 37° 20’. W. long. 77° 57’.

SWIFT, in Ornithology. See SWALLOW.

SWIFT, in Zoology. See SWALLOW.

SWITTER, a rope used to confine the bars of the captnets in their sockets, while the men are heaving it about; for which purpose it is passed through holes in the extremities of the bars, so as to strain them firmly together like the spokes of a wheel, which is accordingly called a swifting.

SWITTERS are also a strong rope sometimes used to encircle a boat longitudinally, as well as to strengthen and defend her sides, so as to enable her the better to resist the imprefion of other boats which may run against her occasionally. It is usually fixed about a foot under the boat’s upper edge or gunnel.

SWITTERS are likewise two thongs fixed on the starboard and larboard side of the lower mats, above all the other thongs, as an additional security to the mats.

SWITTERING OF THROBS, denotes stretching of them by tackles, to prevent any future extension.

SWITTERING DESCENT, Line of the. See CYCLOID and DESCENT.

SWIFTING OF A SHIP. See SWITTER.

SWIG, or SWigo, in Mathemata, a name given by farmers, probably by corruption from youging a pulley with ropes that are not parallel. When the directions of the ropes of pulleys are oblique, the forces applied to them require to be modified accordingly. Thus, if two threads be attached to a weight, and pulled over two pulleys fixed at a distance from each other, so that two equal weights may be attached to their extremities, the depression of the first weight below either pulley will be to its distance from the pulley, in the same proportion as half of the weight to either of the other weights; and if, instead of having a weight attached to it, one end of a thread be fixed to a firm obstacle, the effect will be precisely the same. See PULLY.

SWIGAN, in Geography, a town of Bohemia, in the circle of Bohemia; 13 miles N.N.E. of Jung-Buntzel.

SWIGGING, a particular way of caressing rams.

The operation is performed by throwing the creature on its back, in which posture he is held; then a string is drawn about his teatsicles as tight as possible, and fixing it there, the part is anointed with fresh butter. The beast is then left to feed, and in two or three days the teatsicles grow so rotten, as to fall off with the string, or may be pulled away with a small force. Boyle’s Works, 4th. vol. i. p. 87.

SWIGGING-Off, in Rigging, denotes pulling upon the middle of a tight rope that is made fast at both ends.

SWIHAAU, in Geography, a town of Bohemia, in the circle of Pilzen; 18 miles S.S.W. of Pilzen.

SWILL, in Rural Economy, a term applied to the wash used for swine; it is also applied to a vessel to wash in, standing on three feet, a fort of shallow tub.

SWILL-THAB, a term applied to a fort of hog-tub.

SWILLY, Lousha, in Geography, a large bay of the county of Donegal, Ireland, as a patriot, with a fervour that excites and almost panegyrizes his effects.”

SWILLY, in Geography, a small island or rock in the South ocean, about 15 miles S. from the South Cape of New Holland, surrounded with rocks and shoals. B. lat. 43° 55’ E. long. 149° 40’.

SWIMMING, the act, or art, of sustaining the body in water, and of advancing in it by the motion of the arms, legs, &c. See MUSCLE.

Man alone learns to swim; all other perfect animals seem to take it naturally; though several of the imperfect swim not at all.

Among the ancient Greeks and Romans, swimming must be essential a part of the discipline of their youth, that to reprove a man perfectly rude and uneducated, they used to say proverbially, that he had neither learned to read nor to swim.

In fishes, it is the tail that is the grand instrument of swimming, not the fins, as has been generally imagined: for this reason, fishes are more strong and muscular in that part than in all the rest of their body; according as we find it in all other animals; the motive parts of which are still the
SWI

the strongest, as the thighs of men for walking, the pectoral muscles of birds for flight, &c.

The manner in which fishes row themselves forwards by the tail, is well explained by Borelli, De Motu Animal. part I. cap. 23. The fins of fishes serve only to keep the body well poised and balanced, and to prevent vacillation. See Air-Bladder, and Swimming of Fish.

Of swimming, a curious piece in French, called "L'Art de Nager," the art of swimming, demonstrated by figures. Before him, Everard Digby, an Englishman, and Nicholas Winman, a Dutchman, had also laid down the rules of this art: Thevenot has done little more than copy from them. Had he but read, with half that application, Borelli's treatise "De Motu Animalium," he would fearlessly have maintained, as he has done, that men would swim naturally, like other animals, if they were not prevented by fear, which magnifies their danger. We have abundant experience against this: throw any brute, newly born, into a river, and it swims; throw an infant in before it is yet capable of fear, and it swims not, but is drowned. The reason is, that the human machine differs very notably in its structure and configuration from that of brutes; and particularly, which is very extraordinary, in the situation of its centre of gravity. In man, the head is exceedingly heavy, with regard to the rest of the body; by reason the head is furnished with a very great quantity of brain, and has, besides, a deal of flesh and bones, and no cavities only filled with air; so that the head, emerging under water by its own gravity, the nose and ears are soon filled: thus the heavy carrying down the light, the man is soon drowned and lost. But in brutes it is otherwise: for the head, here, having but little brain, and there being abundance of sinues therein; its weight, with regard to the rest of the body, is much less considerable; so that they are easily able to keep their nose above water; and thus respiring freely, are out of danger of being drowned, on the principles of hydrostics.

In effect, the art of swimming, which is no otherwise to be acquired but by exercise, consists principally in keeping the head above water, so that the nose and mouth being at liberty, respiration may be carried on: for as to the feet and hands, it is enough to stir them, and to use them as oars to conduct the vessel.

Swimming of Fish. The swimming of fish, in general, is greatly assisted by their air-bladder. Those kinds which have not this bladder, either have regular lungs, and contain air in them, as is the case in the cetaceous fishes; or they have remarkably thin and flat bodies, as the rays and thornbacks, and the pleuronectes; or remarkably long and flexuous ones, as the petromyzon; and by these means are capable of easy flexuous motions, which, with the help of the fins, thrust them, any way at pleasure; though their bodies are not so nicely poised, as to the weight of the water, as those of such fish as have the assistance of these air-vessels.

It has been supposed by some, that the motion of fish in the water depends principally upon the pectoral fins, but this is easily proved false by experiment: for if the pectoral fins of a fish be cut off, and it be again put into the water, it will be found to move forward or sidewise, upward and down, as well as it did when it had them on. If a fish be carefully observed, while swimming in a basin of clear water, it will be found not to keep these pectoral fins constantly expanded, but only to open them at such time as it would float or change its course, this seeming to be their principal, if not their only use. The pectoral and ventral fins, in the common

fins of the cathetoplateous or compressed form, serve in the same manner in keeping the fish still, and serve scarcely any other motion than that towards the bottom; so that this motion of the fish, which has been generally attributed to their fins, is almost wholly owing to the muscles, and to the equipoise of their air-bladder. The use of the pectoral and ventral fins is to keep the fish steady and upright in the water, is evident from the consequences of their loss:—if they are cut off, and the fish put again into the water, it cannot continue in its erect natural posture, but staggers about, and rolls from side to side. The fins of the back and anus are of great use to the keeping of the creature in its usual position, as is easily seen by cutting them off, and observing the motions of the fish afterwards.

Though a great deal depends on the motion of the muscles of the several parts of the body in the swimming of the fish, yet the tail, and those muscles which move the lower part of the body to which it is affixed, are the great instruments by which their swift motions in the water are performed. The moving of the tail, and that part of the body to which it adheres, backward and forward, or sideways any one way, throws the whole body of the fish strongly the contrary way; and even in swimming forward, the motion and direction are both greatly aided by the vibrations of this part, as may be experienced in the motion of a boat, which, when impelled forward, may be firmly guided by means of an oar held out at its side, as it is moved in the water as occasion directs. The dorsal muscle, and those of the lower part of the body between the fins and tail, are the principal that are used in the motion of the part, and these are therefore the most useful to the fish in swimming. The muscles of the body seem to have the principal use in contracting the belly and the air-bladder. They have been supposed of use to move the belly-fins; but there are too many of them for such a purpose, and the fins have each its peculiar muscle, fully sufficient to the business. The use of the tail in swimming is easily seen, by cutting it off, and committing the fish to the water without it, in which case it is a most helpless creature. See Air-Bladder, and Fish.

Swimming of Giddiness in the Head, a disease sometimes afflicting men and animals, and which is not frequently a troublesome and dangerous disorder in these parts of the world. Where the brain is affected with a fort of irritation or inflammatory state in some of its parts, the complaint is often the title of "foolishness" or "frenzy" given to it; but when there is nothing of this kind, but merely a sort of reeling and unsteadiness in the gait and manner of the animals, it is mostly of the nature of staggerers.

The cure or removal of the complaint is commonly to be managed in the manner of one or other of these disorders, according as the nature or the appearance may be, both regard to medicine and diet or food, which is proper and necessary. See Staggerers.

Swimming of Salt-Water, in Agriculture, the practice of floating it in a tub or other vessel full of water, nearly full of salt-water, in order to prepare it for use, by having the light imperfections removed. The methods of effecting this are performed somewhat differently in different districts. In Essex and some others, common water, in which a certain quantity of lime has been mixed, or salt-water, is poured into a tub which is capable of containing twenty or thirty gallons; into this water the wheat is put, until the whole is full within about three or four inches of the brim; the whole is then well stirred together with a flote stick, &c. which is better, a light shovel. All the light and imperfect
of defective grains naturally rise and swim upon the surface of the water; these are repeatedly taken off by a skimmer, until few or none remain behind. The whole residue of the wheat, with the water, is then put together into a basket-fraiser, which is placed over another tub of similar size and capacity; the water passes freely through into the tub underneath, and the wheat left behind in the basket is emptied out upon the floor of the place where the operation is performed, whether it be brick, clay, or any other. When a sufficient quantity for the next day’s sawing is thus prepared, the heap is spread out and levelled to about three or four inches in depth or thickens, on to such a thickens as may be thought the most proper and convenient, and then some well-flaked lime is evenly sifted over it; after which it is stirred over and over again, until the line and wetted wheat be as uniformly mixed as possible, and the grain sufficiently dried to be capable of being sown on the following morning. In some places, different saline or other substances are diffused in or mixed with the water used in swimming the wheat, but this is not a very common practice.

The useful practice of swimming wheat is now, however, a good deal left off in many districts, and other modes substituted in its stead, such as sprinkling and liming it only on the floor, the use of medicated and other feeds, &c. as have been shewn under the proper heads. See STEARING OF SAWD-GRAIN AND SEEDS.

By the practice of swimming wheat for feed, there would seem to be much advantage gained; as, from all the light defective grains being taken away, there is no danger of laying that which is improper for affording a strong healthy vegetation and growth; and besides, such good and perfect washing may have the effect of removing any sort of minute contagion that may be present, as well as all sorts of light feeds of the weed kind that may be among the wheat.

SWINCANY, in Geography, a town of Lithuania; 39 miles N.N.E. of Wilna.

SWINDON, a respectable market-town in the hundred of Kingbridge, Wilts., England, is situated 36 miles N. from Salisbury, and 87 miles W. from London. From the silence of our early historians respecting this town, it is presumed to have been of anciently of little importance, and no way connected with any remarkable civil or military event.

The name, however, is at least coeval with the Conquest, “Swinonde” being the appellation by which it is distinguished in Domedal-book. According to the parliamentary returns of the year 1811, the parish contained 260 houses, and 1341 inhabitants. There is no particular trade carried on here; but as a number of persons of independent fortune reside in the town, their constant intercourse gives a degree of life to the place, while, at the same time, their mansions contribute materially to ornament it. The pursuits of husbandry, and the working of some extensive quarries in the vicinity, afford employment for the most of the people. The stones raised from these quarries are usually of great magnitude; and, in respect to the quality of beauty and durability, scarcely yield, when cut, to the most celebrated Portland stone. A market is held every Monday for corn and other commodities; and on every alternate Monday for cattle. Fairs are also held annually. The petty fairs for the Swindon division of the hundred are held here. The parish church stands at the south-east end of the town, is neatly fitted up in the interior, and contains several monuments; one of which, on the east side of the north aisle, commemorates Mrs. Millecent Neate, who died July 9, 1764, in the 73rd year of her age. Adjoining the churchyard, on the south-west, is a mill, worked by water cons-
ducted by pipes from a well called Church-Well Pond. At the extremity of the horizontal pipes another is fixed, vertically, in height about ten feet, through which the water is raised to a trough, whence it falls upon the mill-wheel, and turns it with perfect regularity. A respectable free-school, situated in Newport-street, was established in 1764, for the instruction of twenty boys and five girls in reading, writing, and arithmetic, and is supported by voluntary contributions.

Swindon-House, a seat of the family of Goddard, stands at a short distance from the north side of the church-yard. It is a neat, modern edifice, with a fine lawn, and extensive pleasure-grounds attached to it.

In a field at Brome, a small hamlet to the northward of Swindon, is an upright stone, called Long-stone, ten feet in height; and, in the meadow below, is a range of smaller stones, placed in a straight line. These are conjectured to be remains of a Druidical work. Beauteis of England and Wales, vol. xix. Wiltshire, by J. Britton, F.S.A.

SWINE, in Agriculture, a well-known animal of the quadruped kind, which is of much importance to the farmer in many situations; and which, under proper modes of management in respect to breeding, rearing, feeding, and fattening, often affords a good profit. See Sul.

It is well known that the hog is a native of all the temperate climates of the old world, but was not found in America, until introduced by the first discoverers, the Spaniards, whose white breed has had a wonderful increase both on the American continent and on the islands. But it has been affected by naturalists, that swine are not indigenous to these islands; probably, however, without any sufficient authority. They are, however, no longer found wild either here or in France. But the European wild boar, the original stock of our domestic breed, is still to be found in the forests of Germany, and other countries on the continent, being generally preferred as a beast of chase. According to the writer of a late Treatise on Live-Stock, he has a dark brindled, grey colour, sometimes nearly black, or of a dunkey yellow, with longitudinal stripes, like those of the domestic kind, called corders dappled. He is smaller than the tame hog, with upright, wide ears, long powerful snout, large head and shoulders, high crest, deep short body, and thin hinder-quarters, and endowed with considerable activity. The African hog is red or sandy in colour, with a small head, long, slender pricked ears, soft and short hair, and a long tail, touching the ground. But the writer is not informed whether this be the same variety as that which is used in this country as a croft, under the name of the African. He farther states, too, that the Ethiopian hog has wattles under the eyes, is large, and in a wild state. And that the Cape Verde hog, another African variety, is also large, with more length than the former. It is added, likewise, that the South American hog, with the white, have been long well known in this country, as a croft for fines of bone and quickness of proof. But whether the Portuguese, of nearly similar form with the last, be only a variety of that species, he is not informed, or whence we derive the large, thick-hided tomy. In Batavia, he affords, they have long used the tomy, or croft. And he has heard that our sandy or rufous pigs are of Italian origin, and that the neighbourhood of Turin is celebrated for its excellent breed. The Bofian and Servian pigs, with which the markets of Vienna are supplied, if we may credit travellers, have the character, he contends, of being at once the hardest and the handiest in the world, and such as will stand travelling with the least fatigue.
However, in regard to the native pigs of Ireland, France, and Germany, at least such of them as he has seen, they are of the large, flat-hided, heavy-eared breed, with longer legs, and of still worfe form, but refembling our old breeds of York and Shropshire. And it is further stated, that the hogs of Curdlan, in Asia, are of the largest size and weight. Also, that Articole and other ancient writers mention a peculiar variety, the thin skin of Inarva, which di not divide the hoof. Mafcal says, this whole-footed breed existed in his days in the neighbourhood of Windsor, and that they were a large and superior species; and, on enquiry, the first of the above writers finds some remains of this variety have been found in Berkshire of late years, but that they have now ceased to be a distinct variety, and a few individuals only of them are occasionally met with.

The variety of hog with undivided hoofs occurs, it is said, in the canton of Neorot, not far from Safetn, in the island of Sardinia.

Indeed it may be noticed, that there is evidently much diversity in these animals, in different situations and circumstances, which require to be particularly attended to by the farmer, as it is a point of much advantage in this, as well as all other sorts of live-stock, to have a good breed, for it will confantly pay better than those of the more inferior kinds. But, like most other descroptions of farm animals, they should probably, in some measure, be adapted to the nature of the keep, and the circumstances of the management under which the farm is conducted. They should poiffet, as much as possibly, the points and properties mentioned below; which the farmer should never neglect or be indiffertent to in selecting them for his different ufe. The chief marks made ufe of in distinguishing the breeds of this animal, are those of the form or shape of the ear, and the quality of the hair. The pendulous hanging down, or lop-ear, and the coarse harfthair, are commonly ascribed to indicate large measures of size, and thickness of skin; while creft or prick-ears shew the size to be more small, but the animals more quick in feeding. And it has been observed by some of the older writers, that the smooth soft-haired pigs are most suitable for warm climates.

But the hog or swine, to be well formed, should not be too long, but full in the head and cheek; thick and rather short in the neck; fine in the bone; thick, plump, full and compact in the carcass; full in the quarters; fine and thin in the hide; and of a full size, according to the sort, whatever it may be; having a disposition to fatten well and expeditiously at an early age. Varro, and also Columella, however, describe what was considered in their time as the marks of a good hog, to be a small head, short legs, long bodies, large thighs and neck, and the bristles, particularly on the neck, thickfet, creft, and strong.

And it is observed by the author of the General Treatise on Cattle, that depth of carcass, lateral extension, breadth of the loin add breast, proportional length, moderate shortness of the legs, and subsidence of the gammons and fore-arms, are great essentils. These are qualities, he thinks, to produce a favourable balance in the account of keep, and a mass of weight which will pull the scale down. In proportion too as the animal is capacious in the loin and breast, it will be generally the vigour of his constitution; his legs will be thence properly extended, and be will have a bold and firm footing on the ground, to which, however, it is farther necessary, that his claws be upright, even, and found. He adds, however, that a good hog may have a coarse, long, ugly head and ear; and these may be safely claffed among the non-essentils; yet a short, handsome, sprightly head, with light, pointed, pendulous ears, of moderate fixe, are pleasing to the view, and may sometimes have a favourable effect in the market. For head and ears, the Ox- ford, or rather smaller Berkshire pigs, are good models; and for true shape, the improved Shropshire, Hereford and Gloucester. If colour deferve any consideration, he would prefer the light and candid and yellow-spotted, at least such skins appear far the most delicate when dead. In repels the skin of Inarva, gives a preference to the thick over the thin skin. And he remarks, that our belt bred pig are often thick-skinned, but such skin is tender, gleamous, shining, easy to matricate, even in the shape of rough crackling, and very nutritious; whereas to eat the cracking of thin-skinned pork, cafe-hardened by the action of fire, requires teeth equal to the division of block-tin. The health of swine is to be estimated by their cheerfulness, by the glosa upon their costs, and their skin being while unfree from eruption. It is an extremely unfavourable indica tion when the head is hung down, the fount approaching the earth like a fifth leg, and when the flanks heave and are hollow. If pigs bark (short) on being alarmed, it is an excellent sign of found health and good keep.

It may be observed, that the breeds or varieties of these animals are so extremely numerous, that almost every county or district of the kingdom is possessed of a particular kind. But they may be distinguished into the large and small sort, of the former of which, the following are the most notable breeds:—the Berkshire, the Hampshire, the Shropshire, the Gloucester, the Hereford, the Rutland, the Woodburns, the Wilthire, the Yorkshire, the Northampton, the Lincolnshire, the Norfolk, the Suffolk, the Essex, &c. And the principal difference in the breeding and rearing of these animals at present, are Berkshire, Hampshire, Shropshire, Gloucester, Hereford, Wilthire, Northampton, Lincolnshire, Yorkshire, Norfolk, Suffolk, Essex, and Suffolk of Surrey.

The Berkshire Breed. —This is a breed which is distinguished by being in general of a tawny, white, or red colour, spotted with black; large ear hanging over the eyes; thick, close, and well made in the body; legs short; small in the bone, having a disposition to fatten quickly; when well fed, the flesh is fine. The above county has been long famous for its breed of swine. But according to the author of the Treatise on Live-flock, the old breed is now so totally worn out, that he believes for many years past, no possibility has existed of obtaining a living model. They were described to him as being long and rather crooked-nouted; having large heavy ears; body long and thick, but not very deep; legs short, with much bone. They formed made great weights. But the new breed is, he maintains, lighter in the head and ear, shorter in the carcass, with somewhat less bone, and higher in the leg, in colour generally dark-spotted. He supposes that the Berkshire breeders have made a very judicious use of the pig breed by not repeating it to the degree of taking away all flage and power of growing fleshy, in their flock; and he believes they now mean to discontinue any further mixture. The breed, as it now stands, is about in the third class of pig, most excellent in all respects, but particularly as crofs for heavy flow-feeding forts. The small pork variety of Berk, and those of Oxfordshire, with small carcasses, short and handfome heads, appear to him to have descended from the Axford breed. On the whole it is a useful breed, that has extended itself from the district of Berkshire, its name, over most parts of the island; it is the fort mostly fattened at the distiller; it feeds upon great weight, and is good for either pork or bacon. The
SWINE.

sort is supposed by many as the most hardy, both in respect to their nature, and the food on which they are fed. The Berkshire is, however, a sort of hog that requires constant good keep, declining fast under other circumstances.

The Hampshire Breed. — This is a kind of large hogs which is longer in the body and neck, but not of so compact a form as the Berkshire; they are mostly of a white colour, or spotted, and are well disposed to fatten, coming up to a great weight, when properly managed in respect to food. But the writer of the late work on Live-flock says, they are generally dark-spotted, some black, of a longer and flatter make than those of Berks, ears more pointed, head long and sharp, resembling the Essex. However, he speaks of them as they are found in the range of Basingstoke and Andover. They are generally, he says, bought up with the Berks flock, the dealers themselves being inattentive to any distinction between the two varieties. The goodness of the Hampshire hog is proverbial, and he has never observed in any breed greater or quicker proof.

The Shropshire breed is another large fort of hogs, which are found valuable where the keep is in sufficient abundance for their support. They are not so well formed as those of the Berkshire kind, or equal to them in their disposition to fatten, or to be supported on such cheap food. The standard colour of this breed, according to the above writer, is white or brindled; and that anterior to the late improvement, they might be looked upon as nearly as possible the original large breed of England. They are a breed of the largest size, flat-boned, deep and flat-furred, hair in rather wavy-haired, the ear large, head long, sharp and coarse, leg too long, loin, although very subtiliant, yet not sufficiently wide, considering the extent of the whole frame. With all these defects, they were, he says, ever excellent stock, and have been improved within the last fifteen years by the Berkshire crofs, which has reduced the length both of their legs and carcase, and rendered their heads lighter; in consequence the new variety, shewing the Berkshire spots and form, feeds quicker than the old fort of these animals. Shropshire has long been employed in breeding stores for the supply of the London feeders, and of the Exelex farmers, who thus turn their closers to the most profitable account.

The Gloucestershire Breed. — This is likewise a large breed, but inferior to either of the above, being tall and long in shape, and by no means so well formed. The colour is in general white. It has two wattles hanging from the throat. Mr. Marshall supposes this to be the prevailing breed of the island. It is said to be thinner in the skin than the Berkshire breed, and to require better forts of food. According to the above writer on Live-flock, this breed is a size under the Hereford fort, and a shorter and more truffled pig; there is also, he thinks, a handfome roundness of the bone and frame, which distinguishes this breed. Formerly it was used to feed many fandy pigs among them, and some with very heavy, thick ears, but they are not now so heavy-eared. They are, he says, good flock for any purpose.

The Herefordshire Breed. — This is also a large useful breed, but perhaps without possessing any advantage over those that have been described above. The same writer on Live-flock thinks it a variety of the Shropshire, or an intermixture, which cannot now be traced. He says they are shorter, have legs bone, and lighter heads; ears smaller, thinner, and more pointed; coats somewhat less harsh than those of Shropshire; and are quicker feeders; colour originally light. There may be found in this breed many individuals of the true fruit; they are generally good sound stock, full of growth, and assuredly among the most profitable bacon-hogs we have. They have been of late crossed with the Berkshire breed, of which the best of them did not, he thinks, lend any great need.

The Rutland Breed. — This is a large kind of swine, with the author of the Survey of Middlesex says is the largest in the island, met with at the village of that name, on the borders of Suffolk and Surrey. They feed to an extraordinary size, and weigh, at two years old, nearly double or triple the usual weight of other forts of hogs of that age. As large breeds pay the farmer the best in many cases, such a breed deserves to be attended to in the system of hog management.

The Large Spotted Wooburn Breed. — This is a breed introduced by the late duke of Bedford, being large in size and of various colours. It is hearty, well-formed, prolific fort, rising quickly to a large weight.

The Wiltsire breed is a long-bodied low hog, hollow about the shoulder, and high on the rump; middling, large pointed ears; round bone; light in colour. It is stated by the above writer on Live-flock, that of late years this breed has been crossed with the pug and the Berkshire forts, and that the new variety appeared to him smaller than the old breed, and darker in colour, spotted, with round carcase, handfome pug face, and some with prick-ears; and that this crofs is by no means a new thing. The boars originally made use of, were of the wild breed from Barbadoes, in colour red, or red spotted with black, which were sent from that island, more than fifty years since, by a gentleman to his relation at Axford, near Marlborough, and thence the variety produced were long called the Axford breed. Without doubt, he says, the Axford smaller variety, and part of the new Berkshire, originated in the same source.

The Yorkshire Breed. — This, in the old kind, was, it is said by the writer above cited, probably the worst large variety we had; extremely long-legged and weak-joined, their constitution not of the foundled fort; and bad fay-pigs in the winter feast; they were yet quicker feeders than some of the superior breeds. They have been improving, he thinks, some years from the Berkshire crofs, but are full inferior to the north-western flock, fetching a less price at market. Probably short-legged Gloucestershire boars might succede with this breed, or the entire adoption of Hereford flock might be attended with still more profit.

Besides these, there are some other breeds in different counties of a middle size.

The Northamptonshire Breed. — This breed was formerly, according to the above writer, a handfome, light-eared, white, deep-furred pig, with middling bone, and quick of proof; the breeders have since, he says, tried the new Leicester, and, if he is rightly informed, without success. They have again, it seems, returned to their old breed; adopted fome improving crofs, and at present breed mixed-sized well-shaped pigs, both for their own and the Buckinghamshire dairy farmers.

The Leicestershire breed is, in the original flock, large, deep and flat-furred, light-spotted, with rather handfome head and ear. The above writer on Live-flock is not informed whether the Bakewell variety has much merit in its own county.

Some improvements have been made in the Devonshire fort of hogs, it is said by the writer of the Agricultural Report of that district, by a crofs with the Leicestershire boar, which has much spread, and given a roundness to its frame.
SWINE.

with a proportionable depth of body; its legs have also been shortened; a finer bone produced, with a disposition to look much better, when growing as a store, and to feed quicker and more kindly in the fly. By a farther crofs with the Chinese breed, these crofses have considerably reduced its size; but the advantages accruing therefrom, are the constitution and habits of a profitable animal, weighing, when 18 months old, and fattened to its frame, from 16 to 20 score per hog.

The Lincolnshire breed is a breed that was formerly, according to the above author, light-coloured and white, like those of Northamptonshire, many of them having curled and woolly coats. They are flint, he fay, middle-sized, quick-proving pigs.

The Norfolk breed is a small, short, up-eared, porking fort, various in colour, white, blue, bifi, friated; generally an inferior kind, which the same writer on Live-stock thinks it would be to the interest of that great corn county to improve; they are, however, of a thin-skinned, quick-proving kind. But in the vicinity of Lynn, and generally on the Lincoln side of the county, there is a larger-spedted variety of very good form and quality, which should be encouraged.

The Suffolk Breed.—This is a small, delicate, white fort of pig, which, the same writer says, has for many years had great reputation, and at this time, there is not only a strong prejudice in their favour in their own county, but they have many advocates outside of it. They are shorter, and more pig-formed than the Norfolk; and by their diff face and pendent belly, it may be supposed that the variety proceeded originally from the white Chinese. Some of the Suffolks are very handsome, and very regularly shaped; their defects are, he thinks, that they are great consumers in proportion to their small bulk, and that they produce little flesh. He supposes that the small Hampshire boar would be a profitable crofs for the sows of this breed.

The Essex breed is a fort which are up-eared, with long sharp heads; roach-backed; carcasses flat, long, and generally high upon the leg; bone not large; colour white, or black and white, bare of hair, quick feeders, but great consumers, and of an unquiet disposition. A mixture of the toonky with this old breed produced an improved and shorter variety, called the half-black, a very useful kind of pig.

This breed, called the Essex half-black, in the best forts of them, is thought in that district to be inferior to none in the kingdom. They feed remarkably quick, grow fast, are thin in the skin, and light in the bone and offal, and they are also an excellent quality of meat. The sows are good breeders. There are, in the said, a great many pigs bred and fattened in the above neighbourhood, and sent to market for jointed pork, weighing from fix to eight or ten stone, which weight they come to at five or six months old, without putting up: they have some bones given them as they run.

In other counties, also, there are many other varieties, which is unnecessary to mention here.

In respect to the varieties of these animals, Mr. Donaldson remarks, that the Berkshire and Hampshiring hogs are the largest; but that it is most probably from the Berkshire stock, that the greatest number of varieties of the country have sprung. And that they are of a very large size, the four quarters frequently weighing, when fat, not less than from 600 to 800 weight; the medium weight of the hams and bacon do not, however, exceed from 300 to 400 weight. The above writer speaks of a breed in the northern parts of Scotland, whose appearance, being very different from that of any other fort in the island, denotes them, it is thought, to have been the original breed of the country. They are small, ill-formed, bristly, wild-looking animals, and are very probably the remains of that breed, which we may suppose to have ranged through the forests and woody parts of the kingdom for ages in a state of nature.

It may be further noticed, too, that in the smaller breed of these animals, there is likewise much diversity or difference in regard to the size, as well as other qualities. But that the principal forts of them are these: the Chinese, the English white, the swing-tailed, &c.

The Chinese breed is a breed which is distinguished by the neck being thick; the body very close, compact, and well-formed; the legs very short, and the size small; the flesh delicate; the colour various, as black, white, brown, and tawny. This breed is particularly disposed to fatten in an expeditious manner, and has, in consequence, spread over a great part of the kingdom. It is most adapted for being used as pork; but is much too small for being used for bacon. It is miscible when not well rung.

The small white English breed is another breed of the small kind of hogs, that is met with in many districts; it is of a white colour, and well made in the body; short in the leg; the head and neck well formed, and the ears slouching a little downwards. It is well disposed to fatten, and perfectly hardy. It prevails much in the northern districts.

The swing-tailed breed is an useful fort of the smaller kind of hogs, that is hardy in its nature, and of considerable weight in proportion to its size.

It is, however, common for some farmers to prefer minid breeds, as being more beneficial than either of the large or small perfect breeds. Where this is the case, the Berkshire, with a crofs of the Chinese, has been found a very profitable fort, as being capable of feeding to a considerable weight with a moderate proportion of food, and is a short time.

It has been well remarked by the author of the Good Treatise on Cattle, that nothing can be more groundless than the common assertion, that there is no such thing as a breed in pigs, the only meaning of which is, he thinks, that the alligators have not taken the pains to seek it. The number of regular breeding counties is very considerable, and the peculiar characteristics of form, in each variety, are distinctly marked as in any other class of animals. That there are numberless intermixtures, that radical changes are introduced in the course of time, even those districts most prejudiced in favour of their own peculiar variety, and that in many counties, where a few only are bred for home use, they have no settled breed, is a common thing with every other species of cattle-stock and animals. There can, however, be no doubt, but that the difference of breed in this fort of live-stock, is as obvious as in that of most other kinds; and that in order to have good pigs, it is necessary to be attentive to the breed, or in the other forts of domestic animals. And it may be noticed, that in the breeding and crossing the different forts with the view of improvement, much care is requisite to adapt them to the nature of the different objects aimed at, on the principles that have been laid down in considering the nature of breeding animals for the purpose of the farm, in order to have them to the greatest advantage.
SWINE.

... other proper kind should be selected for the purpose. And in providing hogs or swine for the purpose of breeding, they should constantly be well fed, and taken care of, as by being flouted in their food and neglected, their growth and healthy condition are considerably affected.

By some it has been observed, that in cafes where there is a certain vent for the flock produced, the breeder will be well repaid for growing and purchasing food in this view. And that breeding, in proportion to the greater trouble and risk, is more profitable than purchasing the fowls. Further, that if it be intended to breed for sale, in a frote flate, it is of the more conquence to procure a regular and well-shaped breed; as such will always meet a preference in the fair or market, especially if they are to be driven to the southern directions. The nature and size of the breed should depend upon the abundance or scarcity of food. In the former case, the large breeds are said by Mr. Knight to be the most profitable, from the circumstance of the difference in the proportions between the living and the dead profitable weight, being the least in the largest breeds.

It has likewise been suggested, that the best flock may be expected from the boar at his full growth, but not more than from three to five years old. And that no fows should be kept open for breeding, unless they have large capacious bellies. Being well fed from the teat, the fow was more prolific in nine months; and the he of the kind in which the strong tendency to fat increases the risk of bringing forth, probably the suffering her to breed as early and as quickly as possible may contribute to amend the defect. It is also hinted, that if a fow of this description would admit the boar the third, or within a few days after pigging, impelling her to the severe task of constant breeding and fucking, would double her sufficiently lean and roomy for the production of a good litter. It is probable, however, that the quality and size of the pigs would suffer. But some suppose it better to defer the fow's taking the boar till ten or twelve months old, as she becomes more strong, and affords better litters of pigs; and that the boar should always be a year old or more before he be put to the fow, as by this delay he attains a better growth, and is more vigorous.

It may be remarked in respect to the period of being with young, that in the fow it is about four months; and the usual produce is from about eight to ten or twelve pigs in the large, but more in the smaller breeds, which in general bring forth a greater number.

General Management and Stock-feeding.—In the ordinary management of swine, fows, after they have had two or three litters, may be killed; but no breeder should part with one, whilst she continues to bring large litters, and to rear them with safety, although custom often induces the farmer to kill such fows, and to sublimate others of not perhaps half the value in their places. In cafes where swine are made an object to the farmer, great care should be taken to have a good boar constantly along with the fows, in order that a proper succession of young pigs may be produced. And by this means the fows are likewise made to take the boar more expeditiously.

Farther, it has been observed by a late writer, that as there is great difficulty and expense attending the rearing of young pigs in cold seafons, the farmer should contrive as much as possible to have his litters early in the spring and autumn seafons, as about the end of March or beginning of April, and the latter end of July, August, or beginning of the following month; as at these periods much lefs lotts will be fulfilled in the death of the pigs, and lefs expence be incurred in food. The litters which are pigged in June, or the early part of the following month, should always be reared, as being highly profitable and advantageous. But it is seldom advisable to keep the late autumn litters, as the cold in the winter is almost sure to destroy many of them, and much lost thereby. With a late litter, it may, however, sometimes be beneficial to suffer them to fuckle and feed with the fow, the keeping being of the most forcing kind, during three or four months, from which management the most delicate pork might be provided at a farce lean.

In all cafes, however, great care should be taken that the fows, as they advance in their pregnancy, be lodged separately, lest their bellies be hurt by others lying upon them; and it is of still more consequence, that no other fow be within reach of them at the time of bringing forth, since in that case the pigs would most probably be devoured as they fall. The fows should also be attended in pigging with much care in order to preserve the pigs; and it may be necessary sometimes during three or four days afterwards. Such fows as have the unnatural propensity of devouring their young, should be well secured at the time, and be dispoled of as soon as possible, as they never do any good in keeping as breeders. It is found that dry, warm, and comfortable lodging is of almost as much importance as that of food; in this system of management, the fows and pigs not being turned abroad by any means in bad weather. The pigs may be weaned in about eight weeks, after which the fows may be shut up, feeding them well, and on the return of their milk, they will most finely express very plainly their desire of taking the boar. The fows require to be fed in an extraordinary manner while they are nursing, particularly if they have a number of pigs to support.

And in the pig system it is allo of much consequence, both in respect to economy in the labour of their attendance, and the raising a large proportion of manure, as well as the advantage of the hogs, to have regular and convenient piggeries upon an extensive scale, containing separate apartments for every description, with offices for boiling, steaming the food, and rowsage, and ciphers to contain wish for the animals. See Hog-By.

Allo in the management of these animals, it is of great utility and advantage to keep the different forts separate and distinct from each other, as the fows in pig, those with pigs, and the others according to their ages; as it is only in this way that they can be kept to the most profit and advantage, as most early.

It may be observed in regard to the food of this sort of farm-stock, that as the breeding of pigs is a businef that affords the farmer a considerable profit and advantage in various views, it is of essential importance that he be provided with suitable kinds of food in abundance for the support of the numerous fows that it will be neccessary for him to keep, and the great number of pigs that must be raised. Upon this being properly and effectually done, his success and advantage will in a great measure depend. The crops capable of being cultivated with the most benefit in this innation, are beans, peas, barley, buck-wheat, potatoes, carrots, parnips, Swedish turnips, cabbages, lettuces, clover, lucern, chicory, &c. The proportions in which these crops should be grown for this purpose must vary according to circumstances; as the kind of hogs, their extent, and the manner of dispoing of them; but whatever number may be kept, an equal proportion of root crops, and those of the grafs kind, will be requisite, with about half as much of the farrnaceous or grain kind, as those of the root fort; and a quantity of the luxuriant vegetable kind, fully in proportion to the number of hogs that are to be fed on such.
SWINE.

such sorts of food. And that in the supplying of the hogs with food, a distinction is to be made according to the different kinds, in order that the fust may be made of the food. The fows considerably advanced in pig, and thofe with pigs, should be fed in a better manner than the store pigs. The former should be supplied with good wash twice or oftener in the day, and have a sufficient allowance of cabbages, potatoes, carrots, or other similar vegetables, so as to keep them in good condition; which is shown by the glossy of their coats. The fows with pigs should be kept with the litters in separate fives, and be still better fed than those in pig. Where dairying is practiced, the wash of that kind which has been prepared for the purpose, while the dairying was at the height, in brick cellars, constructed for receiving it from the dairy, must be given them, with food of the root kind, such as carrots, parsnips, potatoes, and cabbages, in as large proportions as they will consume them, in order that the pigs may be properly supported and kept in condition. But where the business of dairying is not carried on so as to provide wash of that sort, meal of some kind or other must. Mr. Young thinks, be had recourse to for the making of wash, by mixing it with water, which, in the summer season, will be sufficient for their support; and in winter it must be blended with the different sorts of roots prepared by boiling, or, where the young pigs, with oats and pea-soup. With this soup and dairy-wash, where proper attention is bestowed, young pigs may, he conceives, be weaned and reared in the winter season even with profit and success. The pea-soup is an admirable article when given in this intention; it is prepared by boiling six pecks of peas in about ninety gallons of water, till they are well broken down and diffused in the fluid; it is then put into a tub or cistern for use. When dry food is given in combination with this, or of itself, he advises oats, as being much better than any other sort of grain for young pigs, barley not answering nearly so well in this application. Oats coarsely ground have been found very useful for young hogs, both in the form of wash with water, and when made of a somewhat thicker consistence. But in cafes where the fows and pigs can be supported with dairy-wash and roots, as above, there will be a considerable saving made, by avoiding the use of the expensive articles of barley-meal, pea-beef, or bran and pollard. The farmers should however, as cautiously as possible, avoid having recourse to such substances in their circumstainces, as being unprofitable. Indeed Mr. Donaldson remarks, that in the usual mode, the pigs reared by the farmer are fed, for some weeks after they are weaned, on whey or butter-milk, or on bran or barley-meal mixed with water. They are afterwards maintained on other food, as potatoes, carrots, the refuse of the garden, kitchen, scullery, &c. together with such additions as they can pick up in the farm-yard. Sometimes they are sent into the fields at the close of harvest, where they make a comfortable living for several weeks on the gleanings of the crop; at other times, when the farm is situated in the neighbourhood of woods or forests, they are sent thither to pick up the beech-malt and acorns in the fall of the year. And that when they are arrived at a proper age for fattening, they are either put into stalls fitted up for the purpose, or fold to distillers, flarch-makers, dairy-men, or cottagers. And he adds, that swine are sold to the butcher at different ages, and under different names; as pigs, when a few weeks old; as porkers, at the age of five or five months; and as full grown hogs, from eighteen months to two years old. The young pigs are commonly roasted whole; the porkers are used as fresh or pickled pork; and the full-grown hogs are for the most part converted into ham and bacon. The demand for porkers, which for London in particular is very great, and which continues almost throughout the year, is chiefly supplied from the dairy-farms within reach of that metropolis. From the time they are weaned, they are kept constantly on whey, or skimmed or butter-milk, with frequently an addition of peas or beans, or barley-meal. Such good keeping not only makes them increase rapidly in size, but renders them fit for the butcher at an early age, which is a point of some importance. It is also a matter of importance in the management of fows and pigs, to keep them constantly well littered down with clean straw, or some other familiar article, as by this means they are kept perfectly clean and healthy, and at the same time a large quantity of manure will be raised. And it is obvious, that when the practice of cultivating crops of various kinds purposely for the food and support of swine prevails, the fows and store pigs will of course be supported during the winter season, as from the beginning of November to the middle or latter end of May, by the various roots, as above, that have been flored in this intention, in combination with the preferred dairy-wash, and other articles. Besides, it is advised by Mr. Young, that at the latter of the above periods, the whole of the hogs in the yard should be looked over as forted; such as have attained half or more of their growth being drawn and turned upon the clover field, or choy crops, where they should be kept till towards the latter end of September, the fences being kept in perfectly good order, and proper ponds and other places provided for the hogs to drink at. Under this management they are said, he fays, to grow rapidly, the food in general agreeing well with them, and they are then taken up in excellent condition for being fattened. In this system, the material difference from the former mode, he says, in feeding the sufficiently grown hogs from the fows that have pigs, and the weaned pigs and only leaving the latter to be fed with the dairy or other wash, with suitable green food, such as letuces, cabbages, tares, &c. by which a much larger flock of breeding hogs may be kept. The tares and cabbages may be used for the fows that have spring litters, and the letuces for those that have autumn litters. It is observed, that these plants are of great use for fows and pigs, promoting the increas of milk in a great degree; affording great assistance where the dairies are small; and in all cases tending to prevent the consumption of grain, which is of great importance in this age of economy. From the sweet juicy quality of the lettuce the hogs are not only extremely fond of it, but it becomes highly nutritious. In this way, the swine may be well supported and carried forward till the flubbles are cleared, when they may be turned upon them, and thus the whole year be provided for, in these different ways, with the greatest economy and profit.

The Swedish turnip and the seed of the sunflower may also be used in this way, it is said, with great benefit.

Further, it has however been stated by some, that though this system of management be advantageous, that of foiling the hogs in the yards with green food is, notwithstanding the increased expense of it, and the unavoidable waste of a certain portion of the food, highly preferable, on account of the vast store of manure that may fall upon them. It cannot, however, be attempted with propriety, unless the farmer be provided with abundance of some fort or other of materials for the purpose of litter, and substances of the paste or earthy kinds, for the purpose of covering the floors of the hog-yards, in order to absorb and prevent the waste of any portion of the liquid matters that may fall upon them. In this method, clover, chicory, tares, and lucers, are the kinds of food that are most commonly employed; but there are
SWINE.

others that may be brought to their affinitie when necess
fary, especially on the stronger forts of land, such as beans
eaten green, which afford a large quantity of food in pro
portion to the land they occupy, the whole items being con
sumed; and cabbages may likewise be had recourse to for
the summer, as well as winter food of these animals. Mr.
Young advises, that the yards of the hog-flies should have
gates sufficiently large for bringing in carts loaded with the
different articles of both food, floors, and litter, as well as
for removing the manure that is made in them. In this sys
tem of prudence, instead of a few, there only being kept, as
was usual in combination with the dairy system, great
numbers may be maintained, and a great many young pigs
be raised. But in order to derive the greatest advantage
from it, the above writer thinks it should as much as possible
be so contrived that the fows only pig twice in the year, as
has been mentioned above; as by this means there will
never be a long and expensive feast for rearing pigs before
they are put to the staple food of clover or pota
toes, &c. But this circumstance is much removed by the
provision of crops raised expressly for swine.

Also the use of hay-tea in the flour-feeding of hogs has
been attempted by Mr. Saunders of Stroud, Gloucestersi
shire, with much success. He was led to the use of this
liquid, from considering its effects in weaning of calves. In
his experiments, as stated in the Agricultural Magazine, the
forts of hay made use of were clover, fainfoin, and lucerna;
and he thickened the tea or wash, indifferently, with
either grains, or bran, or pollard, or any kind of meal, or
boiled cabbages, or boiled potatoes (carrots, though ex
cellent, he had none); sometimes adding two or more of
these articles, as his flock of either most enabled him. And
he had the great satisfaction to find, that he made a single
fack of boiled potatoes, when mixed with wash, and with
out any other ingredient, go as far as four or five facks
(though boiled), when he gave them to the pigs alone; and
the expence of the wash, thickened with potatoes, is con
siderably lower than potatoes alone. With the view of
shewing the practicability of prosecuting the plan individ
ually upon a larger scale, he gradually increased his flock
to upwards of four hundred; and in the course of his ex
periments he used nearly fifteen hundred hogheads of the
wash, confomming, when his fock was at its highest, about
five hogheads daily. And incredible as it may appear, he
maintained them, collectively, at the very low rate of one
penny a-head per day; and in excellent foor order, and
many of them fit for the butcher. It deferves particular
attention, he says, that in a week or fortnight after he
commenced his experiments, the pigs, which he had before
been feeding with potatoes alone, improved in their coats,
which, from looking coarse, assumed a gloss, and became
fine and short; a proof sureiy, it is thought, of the great
nutrition of the food, and of its perfectly agreeing with the
pigs. Nor is it, says he, less remarkable, that this voracious
animal, though fed with this food but twice a day (which
he prefers to oftener), would lie down contented for the re
mainder, provided he was well ringed, and had a warm
and dry place to shelter himself under. And this he attributes
to the following causes, beside the nutritive properties of the
wah. He found it beneficial to feed the boiled potatoes in
large cahes (in which he conceives they would be kept above
a twelve month), and when they had remained in them some
time, freed from the water that they were boiled in
(which is considered noxious), they not only went further,
but they generated a spirit; and the wash being also, as he
apprehends, of considerable strength; they dispofed the an
imal to betake himself to rest, from their loporific and in

toxicating qualities; a circumstance evidently conduci
his quicker growth. Nor can an objection be raised, it is
supposed, to this food, when applied to the flesh of the ani
mal. So far from poissfing any pernicious quality, it com
municates, perhaps, a richer and more delicate flavour to
the pork and bacon than they receive when fed after the
common mode; and the butchers and others not only e
agerly purchased his pigs, but commonly remarked that they
rapidly improved when put up to fatten. And hence, says
he, arises another most important consideration. He is con
siderent, he could make one fack of meal, of whatever de
scription, go as far as two facks in the common mode of
fattening. For, by gradually thickening the wash with
meal, it forms, he thinks, the best introduction to the higher
and last stages of fattening, both for pork and bacon: in
deed that method should be followed throughout the pro
cess, using the wash instead of water. The increased quan
tity of a cheap and highly nutritious food, thus admi
tered, will satisfy the voracious habits of this animal, and
yield, he says, the greatest profit; and this alone would
causet an immense annual saving of cere, which would tend
to ensure plenty and cheapness; the grand desiderata in all
experiments. For the price of a commodity, is a
great degree, depends on the relative quantity produced,
and the regular consumption; to lessen the consumption,
therefore, diminishes the demand, and has the same effect
as increasing the supply, which must necessarily cheapen
the article.

He oberserves further, that clover, or fainfoin hay, at
$2.15. 32. per ton, is $2.80. 60. per hundred, and one half
penny per pound; and that twenty pounds of either, well
boiled, will make, with the addition of the incorporating
ingredients, sufficient wah or food to maintain throughout
the day fifty flore pigs, from three months old to an in
definite age upward.

It is remarked that carrots, either raw or boiled, are ex
cellent; and thafe, with oatmeal and grains, would make a
cheap and good addition. And that the hay, when put into
the furnace to boil, should be inclosed in a net, or a bask
et with a lid to it, or in a tin-kettle and cover, filled with large
beads, and the potatoes (or carrots, &c.) should be fleamed
over the hay-tea, whilst gently boiling or simmering. This
may easily be done, by letting to the furnace a vefel, hav
ing a number of holes of the size of a common auger bored
through the bottom of it, so as to allow the steam to pafs
through the potatoes with which the vefel is filled; and
having a little moill clay, or a wet flanne: or cloth put cir
cularly round the bottom, where it rests on the mouth of
the furnace, fo as to secure the vream from escaping: By
this mode of fleaming the potatoes, a considerabie faving
will be made in the article of coal. The potatoes should
not be slightly fleamed or boiled, and not reduced to a pulp,
and whifht hot, should be trod or rammed in cafs for future
ufe. The hay, after boiling, may be dried, and perhaps
offered to flore cattie; or else thrown to the pigs as litter,
or, to add to the dung-heap. The wah should be carefully
given to the pigs in a lukewarm state, and if meal or pollard
be added, it should be thrown into the tub or cooler imme
diately after boiling the wah, and well mixed together;
but fleaming the meal or pollard, and even the grains, might
be done over the fire. The water, where there is a suf
ficient fall, may be led into the furnace, without any trouble
whatever, by means of a leaden pipe; or may be conveyed
into the furnace by a spout from the pump; and the tea
may be drawn off through a cock into a cooler, which
should be placed by the fide of the furnace. To convey
the wah to the pigs, he used an open barrel or hoghead,
suspended
SWINE.

suspended upon a pair of shafts, with wheels to it, and drawn by a single horse.

But it is added, that in these estimates of the expense of maintaining the pigs, it should be observed, that he has taken no credit for the article of manure; and thus his pigs will make the farmer a present of their dung, as well as pay him a good price for their keep. Fifty strong sows, with a sufficient quantity of lean hogs (which is frequently ploughed into the land), or carpenters' shavings and sawdust, or virgin earth, or sand, especially sea-sand (where obtainable), laid down in the yard, will make, he says, in the course of the year, from two to three hundred waggon-loads of excellent manure: the sea-sand will add false particles to the manure, and check evaporation. And he thinks it necessary to remark, as a most favourable circumstance, that the hay-sea binds the dung of swine, and renders it hard and black, like sheep's dung; and if it does not produce this effect, it must affinely be either bad in quality, or not properly boiled, or not rendered sufficiently strong; all which particulars should be most carefully attended to; and the state of the dung is an admirable guide to go by. The hay should always be of an excellent quality; and that which heated best, and contains most of the succulent juices, should have the preference. Bad hay is certain destruction to the pigs. Clover stands first, next sainfoin, and lastly meadow hay. Indeed, most of his experiments were made, he says, (though not by choice,) with meadow hay.

However, on the former of the above plans of keeping swine, the taint for lean hogs should, Mr. Young observes, annually take place in October, the litter of April being then dispofed of as sows, and those of August kept till the fall period in the following year, in order to be sold as baconers, when none are fattened on the farm.

And in regard to the expense of keeping all sorts of store-swine, it must obviously vary considerably, according to the convenience of procuring their food, and the excellence of the management that is pursued. In failing years, it has been estimated upon the average at from eighteen to twenty shillings per head a week; and while in pig, from one shilling to eighteen-pence; weaned pigs, at first, from one shilling and sixpence to two shillings and sixpence per head; and afterwards, till they are become fully grown, at from one to two shillings each in the week. Calculations of this sort are, however, liable to much error, or differ greatly under different circumstances.

Fattening.—It may be noticed, in respect to the practice of fattening of hogs, that it is a business usually performed at two different times of the year, as in October, and February or March; the former is, however, the most principal period. In this system, various substances have been recommended; but those most commonly employed are certain substances fit for fatteners, material, with skimmed milk, and dairy or other kinds of whey. For the smaller sorts of fattening hogs, coarsely ground oats mixed with these wheys are excellent. Barley-meal and pollard are likewise frequently made use of for the purpose, with much success. The meals of peas and beans, when given in sufficient proportions for the purpose of fattening, are apt to heat them too much, and produce a difficulty of breathing; the first and second, or the large or full-grown hogs, pea-meal, or peas unground, are probably the best material that can be made use of. A portion of bean-meal, or whole beans, may likewise be given occasionally with advantage, as both these articles contain a much larger proportion of nutritious matter in the same bulk, according to Darwin, than any other sort of grain, and are more laiting in their effects on the system, from their undergoing the process of digestion more slowly, per-
founded, since, upon inquiry, it has been found that the hogs fattened at the distilleries fetch the same price, both at the bacon merchants and Victualling-office, as any other.

Into some parts of the county of Essex a practice has recently found its way, which was first tried, it is believed, by Mr. Pattison, of Maldon, of fattening larger hogs in separate stalls, so constructed that the animal can, at his pleasure, conveniently rise up and lay down, but cannot turn round. It is said that they will thrive in this manner faster than in any other way: they are certainly fed by these means more cleanly, as they cannot get at dirt or filth of any kind; the stalls they are in are paved upon an inclined plane from the head to the tail of the animal, and they are cleaned out every day by means of a hoe and broom. Barley-meal mixed with water is the food; and the above farmer has found the improvement so great, that he will engage that a pig forward in 8f, weighing 70 lbs., shall in twenty-eight days increase in weight to 140 lbs.; the gain of 70 lbs. live weight may be called 45 lbs. dead, which, at 8d. per pound, is 30s., or 72.6d. a week. This is very considerable, and affords sufficient reason for considering that the method is a real improvement. The quietness of these stalls causes them to fatten more quickly, as they have only to eat and sleep. See Pan-Cafe.

These are the principal modes of fattening these useful animals.

It may be observed in regard to the quantity or weight of pork produced by a given quantity of peas, beans, meal, or other materials employed in the fattening of hogs, that it has not been well ascertained, and it is probable that a great deal will depend upon the fixe, breed, and disposition to fatten; but, judging from the value of the animals before and after they have been fattened, it is supposed by Mr. Knight, in a paper in the second volume of Communications to the Board of Agriculture, that a Winchester bulk of the first of the above articles may add about nine or ten pounds to the weight of a good hog of twenty score, or perhaps something more upon a larger, and considerably less upon one of a small size. A hog, he says, when put up to fatten in good condition, and (they should never be put up in the contrary state,) when fat when weigh twenty score, will consume in the proportion of fix or even bushels of peas or other similar materials.

It is said, that the produce of the native Devonshire hog, crossed with the Hampshire or Leicester, will, if fed in the following manner, double its weight in about twelve weeks. Begin with about two-thirds of boiled or steamed potatoes, and one-third of peas and barley ground in equal quantities into meal, well mixed together. The meal must be feaunched and enriched with the meal, as the appetite of the animal may require; and when fat, he will be found to have consumed from fourteen to sixteen bushels of ground peas and barley. This breed, again crossed with the Chinese, will fatten in two-thirds of the time, when it will be found to have nearly, if not quite, doubled its weight also.

It is noticed, that the proportion of fat to lean, or, in other words, of pork to bacon, in the above breeds, may be thus stated. The Devonshire country hog, when well fed, will produce, for one pound of pork, one pound and a quarter of bacon. This, crossed with the Leicester or Hampshire breed, will produce, for three quarters of a pound of pork, one pound of bacon. This cross, again varied with the Chinese, will, in two-thirds of the time, produce, for two-thirds of a pound of pork, one pound of bacon. The breed, therefore, seems to have much influence in this business.

And in respect to the method of giving the different ma-
Vol. XXXIV.

terials that are employed in the fatteniny of swine, there are different opinions entertained; some contending that they should be used as much as possible in a solid form, wafis, as drink, being occasionally given; while others prefer the contrary method, as the most beneficial: as, in the latter mode, there will be less time taken up by the hogs in feeding, and of course more left for them to sleep and rest in, as well as more economy in the food and labour of giving it. It is probably the most advisable. Mr. Young supposes the most profitable method of converting corn of any kind into food for hogs, is to grind it into meal, and mix this with water in cisterns, in the proportion of five bushels of meal to one hundred gallons of water, stirring it well several times a day for three weeks in cold weather, or for a fortnight in warmer weas, by which it will have fermented well, and become acid; till which time it is not ready to give. This mixture must always be stirred immediately before feeding, and two or three cisterns should be kept for fermenting in succession, that no necessity may occur of giving it not duly prepared. The difference in profit between feeding in this manner, and giving the grain whole, or only ground, is so great, that whoever tries it once, will, not he, thinks, be apt to change it for the common methods. He further states, that pea-foup is an excellent food for hogs, and may, though he has not sufficiently compared them, equal the above, especially if given in winter, milk-warm. It is, however, well observed, that wherever food is prepared by heat, the expenses of fuel and labour are a great drawback on the profits of the farmer. It should, therefore, be well considered, before it is undertaken. But in whatever way the food may be given, great care must be taken that the hogs have a full allowance at sufficiently short intervals, to keep them constantly in a state of rest; as it is on this principle that they become fat in an expeditious manner. It is indeed frequently observed, in fattening hogs, that they pay better for their keep in the latter part of their fattening than in the former, which probably arises, in some measure, from their not being fed in a sufficiently full manner, or with sufficient frequency in the beginning, so as to keep them in a state of perfect quietude in the flies.

And with regard to the length of time that is necessary in fattening these animals, it varies much according to the state in which they are put up, their fixe, and the difference in their dispositions to fatten; but it is in general from five or six weeks to two or three months, while this process is going on. It is likewise of great importance to keep the hogs clean, dry, and warm, by having them frequently well watered down, the advantage of warm flies, with warm food in cold weather, has been found to be very great in promoting the object of the feeder.

Further, in all cafes, it is the best practice to have the pigs castrated while young, as the male pigs may be gelled at about three weeks old without danger, and the female ones be cut or spayed when a month old; though, in the latter cafe, the operation is frequently performed at a much later period. The fows, when not wanted for the purpose of breeding, may also be spayed. This business is mostly done by persons who are in a flourishing practice of it, and requires experience and care. See Spaying.

It may be stated, that there is a constant necessity to keep all sorts of swine constantly well ringed, in order that they may rest quietly in the flies, and of course thrive in a more perfect manner. This has also been effected by cutting away the cartilage of the nose, in which there is no danger.

On the whole, in the management of hogs, much loss seems to have arisen from the supposition that they can only be kept with profit, in so far as they may consume the ma-
towards that would otherwise be wasted on the farm. There cannot, however, be any doubt, that swine will pay for their keep, as well as any other sort of live-flock whatever, where a judicious system of cultivating crops purposely for them is pursued. This has indeed been fully flown by the various statements that have been made on the subject by different writers.

The author of the Treatise on Cattle has well observed, that it is not improbable that the reputation of Westphalia, for the excellence of its cured pork, is derived from an high antiquity; that the superior delicacy and luxurious flavour of young milk-fed pork is acknowledged, although such a commodity is not to be obtained in every part of the country. And he adds, that pork, of all other flesh meat, is best adapted to curing and preservation with salt, and has the further merit of never cloying the appetite; for it appears that men will subsist longer upon that diet, without desire of change, than upon any other flesh. In various parts of the country the labourers, and even the farmers themselves, very rarely taste, or desire to taste, any other.

It is doubtless, from its solidity, the most economical and the most nutritious food. But it must not be forgotten, that the best is taken out of the trough, and there to be attributed to the superior food which they require; and that pork or bacon will always be sold and good, in exact proportion to the solidity and goodness of the articles on which the animals have been fed. For although graze, hay, roots, or oil-cake, will fatten a sheep or an ox perhaps to the maximum point of goodness, nothing hitherto discovered will do the same with a swine, but milk, corn, or pulse. When fattened with all other sorts of materials, the flesh is loofe, flabby, and of very inferior flavour and quality.

It may be noticed, that in different districts there are different modes of curing the flesh of swine, according to the intention for which it is wanted. In the county of Kent, when cured as bacon, it is the practice to singe off the hairs, by making a straw-fire round the hog, an operation which is termed "sawing." The skin, in this process, should be kept perfectly free from dirt of all sorts. When the fitches are cut out, they should be rubbed effectually with a mixture of common salt and saltpetre, and afterwards laid in a trough, where they are to continue three weeks or a month, according to their size, keeping them frequently turned; and then laid out upon a clothe or board, and covered by a flack fire, which will take up an equal portion of time with the farmer; after which they are to be hanged up, or thrown upon a rack, there to remain till wanted. But in curing bacon on the continent, it is most the custom to have closets contrived in the chimneys, for the purpose of drying and smoking them by means of wood-fires, which is said to be more proper for the purpose. And a more usual mode of curing this sort of meat is of salting it down for pickled pork, which is far more profitable than bacon.

In this method, after the hog is cleaned of the hair, and the head taken off, together with the legs and hands, and the necks, loins, and all the lean bones cut out, which will amount to nearly two-thirds of the whole hog, the remaining part, which is the fat or prime pork, is to be cut into pieces of the size proportioned to the circumference of the faits-tub, and every piece rubbed upon each side and on every part with common salt, having some beaten saltpetre sprinkled on each. The bottom of the tub should also be covered with salt, and when the pork is sufficiently powdered, the pieces laid in, with the wind upwards, and every one pressed down with all the strength that can be used, and Wedged in so close as to leave no apparent chasms. Over this layer is to be spread a covering of salt, with a very slight sprinkling of saltpetre, as too much makes it hard. In about a month or six weeks, the brine will begin to rise, and in a short time afterwards, cover the whole surface of the tub; but if, from a defect in the salt, it should fail to dissolve into brine within that period, it will be necessary to make a quantity of brine, and pour over the pork; for unless the whole be covered with brine, it will not keep well. In adding the brine, care should be taken not to disturb the pieces of pork, as that often does much mischief to the meat.

But in the county of Westmoreland, where the curing of hams has been long practised with much success, this method is for them to be at first rubbed very hard, generally with bay-falts; by some they are covered clove up; by others they are left on a stone-bench, to allow the brine to run off. At the end of five days they are again rubbed as hard as they were at first, with salt of the same form, mixed with rather more than an ounce of saltpetre to a liter. Having lain about a week, either on a stone-bench, or a hogheads amongst the brine, they are hung up by some in the chimney amidst the smoke, whether of peats or coal; by others, in places where smoke never reaches them. If not, a fold is thrown over the hoghead, to keep off the weather becomes warm. They are then packed in hogheads with straw, or oatmeal feeds, and sent to the place of sale. It has been found by experiment, as stated in the survey of that district, that hams lose 20 per cent. of their weight in the curing, which fully demonstrates the want of and economy of confining them without this form of preparation.

Bacon is said to be best cured in Yorksithire, and the best cut up in Wiltshire; but it is well managed in many districts.

Further, swine are subject to many disorders, not of which will be found under their proper heads. Where the parts behind the ears, as is often the case in some forts of them, crack and become sore in hot weather, they should be thickened with a little fatunine ointment; and where the udders of the cows take on hard glandular swellings, as sometimes the case, the use of camphorated fatunine waters or ointments may be employed with benefit, care being taken to have the parts clean wiped before the pigs are admitted to suck. And in such cases, half a dram of calomel may be given every second or third night, for two or three times, by which a favourable change may be induced.

Upon the whole, the hog, from the excellence of its flesh, its prolific nature, and its quick fattening properties, may be considered as one of the most profitable and advantageous of our domestic animals; and which might probably be reared and fattened in many situations, in which it is yet but little regarded by the farmer.

SWINE'S CRATER. See CRATER.

SWINE-CAFE, the name of a fort of wooden building for containing and fattening swine, in some places. See SWINE, CAFE, and SWINE.

SWINE-COUNT, a term provincially applied to a hogsty in many places, as in most of the northern districts of the kingdom. It signifies a fort of hovel of this kind. See HOG, Sty, and PIGEONS.

SWINE-CREW, is also a provincial term used for a hogsty. SWINE-HERD, a term applied to a keeper of swine.

SWINE-OUT, Piles, or Piles, in Agriculture, a particular kind of out, which the are cultivated for the use of pigs in some places, as in some parts of Cornwall. It is the same as or ares a nipt at botanists. By the writer of the correct account of the agriculture of the above district, the cultur
of it is said to be confined to the western parts of the county; and that it is generally the farewell crop, in the bad husbandry of that tract, to such pieces of ground as have been completely exhausted of vegetable food by preceding crops of potatoes, wheat, and common oats. The plant is flated to grow something like the common oat, but that the stem or straw is much finer, being almost as good as hay for fodder; the grain is small, being only about the size of the shelled common oat, but that it weighs as heavy as wheat by the bushel; that the grain is excellent for the feeding of pigs and poultry.

In the former of which applications, one gallon of it, mixed with twenty of potatoes, forms a rich very fattening mela. It should be ground, and be well mixed and incorporated with the potatoes. It was, however, noticed, that in some of the little howels and cottages in the tract for this grain, in the above county, they stirred the whole or un-ground grain over the top of the potatoes, in preparing them; the flour from which it swell much, when it is mixed with the potatoes, and the swine devour it with avidity.

In using it for poultry, they mostly consume it in its natural state, without being in any way reduced.

In many of the other districts, it is probably scarcely known at all that there is such a grain anywhere in cultivation. It has been chiefly grown in black, moorly, mossy soils; and the tillage, culture, and harvesting of it is much the same as for oats.

How far it can be grown in this intention, and for fodder, with advantage, remains yet probably to be proved by further and more correct trials.

Swine-Pipes, in Ornithology, a name used in many parts of England for the red-wing.

Swine-Pow. See Varicella, and Chicken-Pow.

Swine-Stone, or Stink-Stone, in Mineralogy, a name given to those kinds of lime-flour which emit a fetid odour when rubbed, resembling that of naphtha combined with sulphuretted hydrogen. Several kinds of lime-flour possess this property; the most important is the black, or the common black marble, sometimes called Lucullite, from Lucullus, the Roman consul, by whom it was much admired. The colour is a greyish-black; it is hard, and receives a high polish, but is sometimes spotted with shells, and other organic remains, nearly white, as well as that, as well as more distinctly visible, when the marble has been exposed to a warm temperature, as is the cafe in chimney-pieces. When this kind of marble is dissolved in sulphuric acid, a smell of sulphuretted hydrogen is emitted. It contains a portion of oxyd of carbon, to which it probably owes its colour, and also a minute portion of sulphur, and some alkali.

Black marble forms one of the upper bed of mountain lime-flour in Derbyshire, and one of the middle beds of mountain lime-flour in the mountains of Craven, in Yorkshire, adjoining Westmoreland. The latter is extremely black, and takes a most beautiful polish. It was first discovered in that district by Mr. Francis Webster, turass of Kendal, by whom it is extensively used for chimney-pieces, and other articles. The dark-brown lime-flour in the vicinity of Bristol is another variety of (wine-flour, forming an upper stratum in the mountain lime-flour.

Some beds of the magnesian lime-flour near Sunderland are swine-flour; these occur above the coal formation. In other characters, swine-flour resembles common lime-flour and marble. See Marble and Lime-stone.

Swine-Thistle, in Agriculture, the same as the cow-thistle. See Thistle.

Swineford, in Geography, a small poât-town of the county of Mayo, Ireland; 103 miles N.W. by W. from Dublin, and about 14 N.E. from Cashel.

Swinehead, or Swinburne, an small market-town in the wapentake of Kirton, Holland division of the county of Lincoln, England, is situated 7 miles W. from Bothen, and 113 miles N. from London. A degree of importance has attached to this town, from its having been the first retting-place of King John, after he left the whole of his baggage, and narrowly escaped with his life, when crossing the marshes, in his military progress from Lynn to Shrewsbury, the castle of which latter place was then in his possession. He left Swinehead on horseback, but being taken ill with a dysentery, was moved on a litter to Shrewsbury, and thence to his castle at Newark, where he died on the following day. Matthew Paris and other historians ascribe the king's death to a fever, brought on by vexation, and heightened by improvidently eating peaches and drinking new cyder. But an author, who lived about a century after the event, asserts that the king died in consumptions of poisons, administered by a monk of a religious houle which then existed at Swinehead. This afflication is combated, and the circumstance fully discussed, in a letter from Mr. Pegge to the Society of Antiquaries, published in Archaeologia, vol. iv. This religious houle was an abbey of Cistercian monks, founded in the year 1154, by Robert Greelie. The site was granted, 5 Edward VI., to Edward lord Clinton. Of the abbey buildings no vestiges now remain; but a manse was erected out of the ruins by one of the family of Lockton. In the parish church, a spacious edifice, with a lofty chancel, is a monument of Sir John Lockton, who died in 1610. Swinehead was rated, in the population return of the year 1811, to contain 273 houses, occupied by 1561 persons. A weekly market is held on Thursdays, and two fairs annually.

In the adjacent parish of Surfleet is Creley-Hall, the property of Mr. Heron, a descendant of Sir John Heron, privy councillor to Henry VII., whose mother was here once fumpoumously entertained by Sir John. The state-bed on which the lay is described by Stukeley to be made of curiously embossed oak: it is preserved in a farmer's houle in the neighbourhood. Creley-Hall was rebuilt in 1695, by Sir Henry Heron, knight of the Bath. At Surfleet is one of the greatest heronries in the kingdom, though it has been considerably reduced, and that, as well as the trees of the wood of the birds do to the land.—Beauty of England and Wales, vol. ix. Lincolnshire, by J. Britton, F.S.A.

Swinemunde. See Swinemund.

Swinesund, a town of Norway, in the province of Aggerhuus; 5 miles S.W. of Frederichshall.

Swing, To, in Sea Language, is to turn round the anchors, or moorings, at the change of the wind or tide. It is usually expressed of a ship, either when she is moored by the head, or riding at single anchor.

Swine-Bridge, or Swineford Bridge, a kind of moveable bridge on canals, much used for occupation bridges.

Swing or Leaf-Drug, in Agriculture, a name applied to that sort of tool of this kind, which is formed in somethings of a leaf-manner, by which it is enabled to give way in the middle part, and to be folded up into half the size; by which means it not only works better on rounded ridges, but takes up much less room when out of use.

There is a patent tool of this sort which is constructed in a good deal in the same manner, but in which the tines or teeth are often placed much too upright, in the sense, which, in the opinion of many farmers, has an inconceivable fault; as they are said to work better, and more easily, where they are set in a somewhat leaning-forward direc-
tion, thereby cutting the land over in a more effectual manner.

This sort of tool, when made use of on five-bout lands or ridges, or three and other number of bouts of small dimensions, should constantly be formed so as to suit pretty exactly to the fixes of them, and in such a manner, as that they may clear both the outside furrows at once, in which the team or moving power may go.

This sort of tool is often found of very great utility on the stronger kinds of land, which have laid some length of time in the ploughed state, before they are intended to be prepared for the seed, and which have not had deep folded upon them. Some of the lighter sorts of these tools also, in some fields, answer well to be run over the ground after the feed has been sown.

SWING-GEN: See GATE.

SWING-PLough. See PLough.

SWING-Tail Hog, a name applied to a particular breed of these animals. See SWINE.

SWING, or Waggon, is the bar softened across the fore guide, to which the traces of the horeses are fastened.

SWING-Wheel, in a royal pendulum, that wheel which drives the pendulum. In a watch, or balance-clock, it is called the crown-wheel.

SWINGING, in Geography, a river of Germany, which runs by Stade, and discharges itself into the Elbe, a little below.

SWINGING was prescribed by ancient physicians, as good exercisf in some cafes. See AGITATION.

SWING, or ISIN, in Geography, a town of Istria; 6 miles N.W. of Mitterburg.

SWINGLE, in the Wire-work: in England, the wooden spoke which is fixed to the barrel that draws the wire, and which, by its being forced back by the cog of the wheel, is the occasion of the force with which the barrel is pulled.

SWINOLE, in Rural Economy, a term signifying a crank; also an implement used for beating rough flax, which is sometimes called a towpin.

SWINOLE-HAND, another term applied to the same implement; also to the hand which uses it.

SWINOLE-Tree, a term signifying a plaster-bar whippis, or whistle-tree. See WHIPPLE-Tree.

SWINOLE-Trees, Indented, in Agriculture, that sort of contrivance to which the wood of an indented or toothed iron rack, of about a foot or a foot and a half in length, firmly fixed on, in, or about the middle of the strong wooden or bar part of it, in which, by the removal of the loop of the draught chain into the different indents of the rack, the draught is capable of being nicely equalized and adjusted according to the particular circumstances of the team or working-power. The bar is formed from a strong piece of tough ash-wood, made the thickest and broadest in the middle, and so as to gradually taper a little, in both these respects, to each of the ends, on which loops are mostly fastened for receiving the hooks of the traces. The indented part is made of a strip of thin iron about an inch in breadth, doubled up together at every tooth, and nailed fast upon the fore-part of nearly the middle of the swingle-tree, on which the draught loop moves in each direction.

This sort of swingle-tree is much used in the Furness part of the north of Lancashire, as a very convenient contrivance for equalizing the draught of horses, in ploughing with the teams double. Thus, when two animals walking in the furrow are yoked to that end of the swingle-tree which is towards it, and only one upon the land-side draws by the other end; if the moveable middle loop, which is connected with the plough by a chain, be placed in the indented part of the swingle-tree, at one-third of the length of it from the end towards the furrow; the land-horse, taking two-thirds of the implement or bar, will perform one-third of the labour, with as much ease and convenience as his companions.

In practice, however, as the performance of the fore-ends horse is commonly less than either of those behind, probably in consequence of being at a greater distance from the post or centre of draught; so the land-horse usually draws works with less length than two-thirds of the swingle on his side of the loop, which has been found to be necessary by actual experience.

And when the draught consists of two or four hors, the sliding loop is placed in the first notch from the side, which is equidistant from the ends of the implement, by, or contrivance of this kind.

This sort of swingle-tree is consequently of much importance in all cafes where the teams are employed double, but more especially where the number of animals is not equal. They should be had by all farmers who have teams working double.

SWINGING. See BRAKE.

SWINHOLM, in Geography, one of the small Shetland islands.

SWINHULT, a town of Sweden, in Est Gothland; 40 miles S. of Linkoping.

SWINNA, one of the smaller Orkney islands, being about 20 inhabitants, near the S.W. coast of South Ronaldshay.

SWINOE, one of the Faroe islands, in the North sea.

SWINOGROD, a town of Russian Poland, in the palatinate of Braclaw; 70 miles E. of Braclaw.

SWINOY, a small island in the Caspian sea, about 11 miles from the W. coast. N. lat. 59° 52'.

SWINTON, JOHN, in Biography, a learned antiquary, was born at Baxton, Cheshire, in 1703, and entered as a scholar at Wadham college, Oxford, in 1719, and admitted to priest's orders in 1727. In the following year he was elected fellow of his college, and soon after accepted the office of chaplain to the English factory at Leghorn. While abroad, he visited Venice, Vienna, and Feiburg, and became a member of the academy "Dei Apulfus" at Florence, and of the "Estrafcan Academy" of Cortona; and in 1730 he was elected fellow of the Royal Society. On his return he settled at Oxford, and was appointed chaplain to the county gaol, and keeper of the archives to the university. He married, but had no family, and died in 1777, at the age of 74. He was a recluse scholar, and subject, like others of that description, to absence of mind. His erudition was profound and recondite. His dissertations on antiquities, coins, and inscriptions, Estrafcan, Phoenician, and Persian, were numerous, and most of them may be found in the Philosophical Transactions. He was also a writer in the Universal History, and composed in that work the account of the Carthagins and other ancient African nations, the Turks, Tartars, Moguls, Indians, and Chinsefs, and dissertations on the peopling of America, and on the independency of the Arabs. Gen. Biog.

SWIRSEN, in Geography, a town of Farther Finland; 7 miles E.S.E. of Polnow.

SWIT, in Natural History, a name given by the people of the Philippine islands to a very small bird of the humming-bird kind, frequent in that part of the world. It is beautifully coloured, and lives on the honey of flowers.
SWITAWKA, in Geography, a town of Moravia, in the circle of Olmutz; 38 miles W. of Olmutz.
SWITHA, one of the smaller Orkney islands. N. lat. 58° 41'. W. long. 2° 58'.
SWITOCZ, a town of Lithuania; 65 miles S.E. of Mink.
SWITZERLAND, SWITZERLAND, Helvetic Republic, or Helvetica, a country of Europe, comprehending under this denomination, not only the 13 cantons of the League, but other states or districts allied to the Swiss, or subject to them; extending in length from E. to W. about 190 or 200 miles, and in breadth from N. to S. about 130 or 140 miles. It contains about 14,960 or 15,000 square miles, and about 1,800,000 inhabitants. It is bounded on the N. by Alsace and Swabia, on the E. by Tyrol and Trent, on the S. by the Venetian territories, the Milanese, Savoy, and the lake of Geneva, and on the W. by Burgundy and Franche Comté. Its boundaries are rather arbitrary than natural; though on the W., mount Jura separates it from France, and on the S. the Pennine Alps form a kind of partial barrier from Italy.

History.—This country lies between 55° 50' and 60° 50' of E. long., and between 43° 50' and 47° 43' of N. lat. The provinces to which the appellation of Switzerland is now applied, were in ancient times variously denominating. The Romans regarded them as a part of Gaul; and they were principally poissified by the Helvetii on the W. and the Rhetti on the E., the chief city of the Helvetians being Aventicum, now Avenche. The origin of the Helvetii is uncertain. Some have supposed that they were of Celtic extraction; others, with greater probability, deduce their origin from a Gothic race, and regard them as an ancient colony of Germans. (See HELVETIA.) The Rhetti are said to have been a Tufcan colony; but this hypothesis is liable to objections. (See RHETIA.) Before the commencement of the Christian era, the territories of the Helvetii were divided into four provinces, whose capitals were Zurich, Zug, Orbe, and Avanches or Avenches. These cantons formed one state, in which Caesar found 12 towns and 400 villages. When Helvetia was reduced to the form of a Roman province, it lost its name; a part of it being united to Sequania, and the remainder to Rhettia superior. After the fall of the Roman empire, this country may be considered, in a general view, as poissified by the Alemanni on the E., who made an irruption in the beginning of the fourth century, and are suppos'd by some authors to have extirpated the ancient Helvetians. They also held Swabia and Alsace. This country on the W. may be regarded as a part of Burgundia; the inhabitants being styled "Burgundi trans Juraenses," because, with regard to France, they were situated on the other side of the mountains of Jura. When the western part of Switzerland, as far as the river Reus, was subjugated by the Franks, they annexed that portion to Burgundy. The Grisons on the E. were subject to Theodoric, and other kings of Italy. The conversion of the country to Christianity, by the Irish monks Columbanus, Gallus, and others, took place in the beginning of the seventh century. Alemannia was invaded by the Huns in the year 909, and subsequent contests with these barbarians lasted till about the middle of that century. The abbey of St. Gall was ravaged by the Huns; but they were afterwards defeated by Conrad, king of Burgundy, about the year 918. About the year 939, the provinces which now constitute Switzerland began to be regarded as a part of the empire of Germany. Divided among several lords, secular and spiritual, the inheritance of the former at length, in the course of about two centuries, chiefly centered in the house of Hapsburg, afterwards the celebrated family of Austria; and on its emancipation in the beginning of the fourteenth century, first appeared the modern denomination of Switzerland, either derived from the canton of Schweiz, distinguished in that revolution, or from the general name of Schweitzer, given by the Austrians to the Alpine people. For the sake of precision, modern writers restrict the orthography of Schweiz and Schweizer to the canton; while the general appellation for the people is the Swiss, and for the country, Switzerland or Swissland. While the greater part of the country was rent in pieces by faction and civil discord, the three cantons of Uri, Switzer, and Unterwalden, environed by ridges of mountains, lakes, and rivers, remained in profound tranquility. When, indeed, the greater part of Helvetia was subject to the German empire, the inhabitants of these cantons had long enjoyed very considerable privileges; particularly the right of being governed by their own magistrates; and though the clergy and many of the nobles had seizes and subjectias in these respective territories, the bulk of the people formed several communities almost independent. During the twelfth century, various disputes between the three cantons and the emperors united them more firmly, and they were accustomd every ten years, to renew formally their alliance. Such was their situation at the death of Frederic II. in 1250. From this period, or soon afterwards, commenced the interregnum in the empire; during that time of anarchy and confusion, the nobles and bishops endeavouring to extend their power and to encroach upon the privileges of the people, Uri, Schweiz, and Unterwalden, threw themselves under the protection of Rhodolph of Hapsburg, who, in 1273, being chosen emperor, terminated the interregnum. Rhodolph received a small revenue from these cantons, and appointed a governor, who had cognizance in all criminal causes, and expressly confirmed the rights and privileges of the people. Soon after his ascension to the imperial throne, Rhodolph listened to the ambitious schemes of his son Albert, who was desirous of forming Helvetia into a duchy. For this purpose the emperor purchased the domains of several abbeys and other considerable seizes in Switzerland, as well as in the canton of Schweiz as in the neighbouring territories. The three cantons, alarmed at this increase of power, obtained a confirmation of their privileges, which, upon the death of Rhodolph, was renewed by his successor Adolphus of Nassau. But when Albert was elected emperor, he refused to ratify their rights, and this refusal led to consequences, detailed under the article SCHWEITZ, which terminated in the famous revolution of January 13, 1538, and laid the foundation of the Helvetic confederacy. This confederacy became afterwards very formidable by the accession of the other ten cantons, and by the additional strength of its numerous allies; and hence it has remarkably happened, that Switzerland is the only country which, on the one side, has confined the limits of the German empire, and on the other has, until a very late period, set bounds to the French monarchy. The accession of Zurich, Berne, Lucern, Zug, and Glarus, gave strength and solidity to the union; and a century and a half elapsed before a new member was admitted. At length, in 1501, Fribourgh and Soleure, being, after much difficulty, received into the league, the eight ancient cantons, on that occasion, entered into a covenant, called the "Convention of Stans," by which the articles of union and mutual protection were finally settled. No change was effected by the subsequent reception of the three remaining cantons, Basle, Schaffhausen, and Appenzel; as they subscribed to the same terms which Fribourgh and Soleure had accepted.

The code of public law between the combined republics of
of Switzerland, is founded upon the treaty of Sempach in 1353; upon the conclusion of Stans; and upon the treaty of peace concluded in 1712 at Aarau, between the Protestant and Catholic cantons. From these several treaties it appears, that the Helvetian union is a perpetual defensive alliance between the 13 independent contracting powers, to protect each other by their united forces against all foreign enemies. Another essential object of the league is to preserve general peace and good order: for which purpose it is covenanted, that all public disquisitions shall be finally settled between the contending parties in an amicable manner, and with this view particular judges and arbiters are appointed, with full power to decide of all the cantons from being current within their own territories; may impose taxes and duties; and, in short, perform every other act of absolute sovereigntiy. The public affairs of the Helvetian body and their allies, are discussed and determined in the several diets: and these are, 1. General diets, or general assemblies of the 13 cantons and of their allies; and 2. Particular diets, as diets of the eight ancient cantons; of the Protestant cantons, with the deputies of the Protetants of Glarum and Appenzel, of the towns of St. Gallen, Bienne, and Mulhausen, called the "evangelical conferences;" 4th of the Roman Catholic cantons, with the deputes of the bishops of Glarum and Appenzel, of the abbots of St. Gallen, and of the republic of the Vallaiss, called the "golden alliance;" and of the diets of particular cantons, which, beside being members of the general confederacy, have distinct and separate treaties with each other. The ordinary meetings of the general diet are held once a year, and continue sitting one month; the extraordinary assemblies are summoned upon particular occasions. The canton of Zurich appoints the time and place of meeting, and the deputy of Zurich presides; unless the diet of the territory of any other canton shall, at their request, cause the deputy of that canton to preside. Each canton sends as many deputies as it thinks proper. The last diet of "Free Switzerland" assembled at Aarau in January, 1798, and all the deputies, that of Basle excepted, which withdrew from the confederacy, took an oath to defend the Helvetic constitution to the last extremity; but this solemn appeal to heaven in defence of their liberties produced, as the sequel proved, no substantial effect. Their confederacy was dissolved by the French invasion A.D. 1798.

The whole republic is composed of 13 cantons, 13 incorporated territories, and 21 dependent lordships. The cantons are Zurich, Berne, Lucern, Uri, Schwyz, Unterwalden, Zug, Glarus, Basal or Basle, Friburg, Solothurn, Soleure, Schaffhausen, and Appenzel, which see respectively. The number of inhabitants in the 13 cantons is said not to exceed 975,000.

The canton may be divided into "affiliated" and "confederated" states; of the latter are the abbot and town of St. Gallen, Bienne, and Mulhausen; and of the latter are the Grisons, the republic of the Vallaiss, Geneva, Neuchatel, and the bishop of Basle. The following landvogtei, bailiwicks, districts, and towns, belong, as joint property, to certain cantons. As subjects of the cantons, we may enumerate Thunraug, Rheinhal, containing Rheinneck, the capital, the market towns of Alfelden and Berne, and several villages; Sargans; Gafier or Gold, a mountainous territory, bounded on the W. by Gluma, on the N. by Utznach and Topgenburg, on the E. and S. by Topgenburg and Sargans, lying in N. lat. 46° 10', watered by the Linth, and now belonging to the cantons of Schwyz and Gluma, the inhabitants of which principally subsist by spinning, and the principal town of which is Sargans (which see); Utznach; Rapplreichweil; Baden; the territory of the Free Amts, called the county of Rohr, or Rori; and Waggenthal, bounded on the S. by Baden and on the S. by Stuttgart, on the W. by Lucerne and Berne, lying in 47° 20' N. lat., 40 miles long and 5 broad, containing 20,000 inhabitants, the upper division of which belongs to the 8 cantons, and the lower to Berne, Zurich, and Glars. The Italian territories are those which lie beyond mount St. Gothard, in Italy, bounded by the canton of Uri, the Grisons, and the district of Milan; the three first belong to Schweiz, Uri, and Unterwalden; the other four to the cantons in general, Appenzel excepted. These are Bellinzona, or Bellinz, 5 leagues long and 2 broad, in N. lat. 46° 10', containing 5,000 inhabitants; Pontebre, or Polle, 4 leagues long and 2 broad, watered by the Tsen and the Blegno; Val di Blegno, or Val Bressa, a fertile valley, environed by lofty mountains, and watered by the Blegno, all which contain 5,000 inhabitants; Lugano, 5 leagues long and 2 broad, containing 5,000 inhabitants; Maymatt, or Val Maggia, about 28 miles long, bounded by high mountains, watered by the river Maggia, or Maym, yielding fine wines and noble manufactures; Aranzona, or Aranzo, a fertile and extensive country, containing 30,000 inhabitants; the small district between the lakes of Como and Lugano, very fertile, and containing 15,000 inhabitants. The allies of Switzerland are Gerfaw, or Gerfau; the Benedictine abbey of St. Gall, and its territories lying in Brifan, Swiss, and Austria, and containing 91,800 inhabitants; the county of Topgenburg; the city of St. Gall, and the territory, containing 8300 inhabitants, who carry on flourishing linen manufactures, and a considerable trade; the ancient towns of Biel or Bienne, having about 5500 inhabitants; the three units of the territory of Biel or Bienne and the counties of the country, composed of three bodies, called Buns or leagues, viz. the Grey or Upper League, the League of God's House, and the league of the 10 juridictions, all of which were united A.D. 1471, and now form one republic, consisting of 135 parishes, and 98,000 inhabitants. The vassals of the Grisons occupy a valley upwards of 30 miles from W. to E., watered by the Adda, at the foot of the Alp Alp, containing three counties, and 87,000 inhabitants. This valley comprehends the county of Chur, (which see,) the western part of the valley, 20 miles long, and 5 broad; and the barony of Heldenstein, in N. lat. 46° 50', confining a semicircular plain, about five miles long, and scarcely one broad, with a population not exceeding 400 persons. For an account of the Vallaiss, Neuchatel, Valais, Geneva, and the Glacier, see the respective articles.

Constitution and Government.—Under the former head we have already given some account of the government of Switzerland. The cantons of Berne, Zurich, Lucern, and Friburg were aristocratical; those of Uri, Schwyz, Unterwalden, Zug, Glarus and Appenzel, were democratic. The aristocracies were composed of a great council and senate; the latter, in some cantons, enjoying exclusive power.
SWITZERLAND.

Authority, and in others acting under the control of the great or supreme council, that assembled at stated times, and superintended the administration of public affairs. In the democracies the supreme power was wielded in the people at large, who, in several cantons, assembled annually for the purposes of legislation, and in others to choose their magistrates and councils of regency. Notwithstanding this great variety in their forms of government, an almost uninterrupted tranquility reigned in those small independent republics. The constitution of the 13 cantons was abolished by the French in 1798, and by the constitution of the 29th of May, 1801, Switzerland was divided into 17 departments. In February, 1803, a new government was presented to the 19 cantons into which Switzerland was divided. According to the constitution now established, the legislative power in every canton was vested in a grand council, and the executive power entrusted to a little council or senate. The number of members in each council, their times of assembling, their jurisdictions, and other circumstances, are specified. Thirteen of the cantons send 13 deputies, and five of the most populous cantons send 12 deputies, to form a general assembly, called a diet, to meet successively at Friburg, Berne, Soleure, Bale, Zurich, and Lucern. Contributions levied in proportion to the population of each canton. What may be the future constitution of Switzerland, since the expulsion of Bonaparte from France, and the restoration of the Bourbon government, time must develop. If the Swiss should emancipate their country, their chief object should be protection against the power of France, to which no measure will be more conducive than a strict alliance with Austria.

Revenue and Military Force.—Before the late revolution, the military force was reckoned at 20,000; the Swiss regiments in foreign service were computed at 25. By the constitution of 1803, the national force of 15,203 men was apportioned in various proportions to the 19 cantons. The revenue was formerly computed at somewhat more than a million sterling, arising from moderate taxation, tolls, national domains, and foreign subsidies. The cantons of Berne and Zurich were considered as opulent, while in others the resources hardly equaled the expenditure.

Population and Manners.—The population of this interesting country has been generally computed at 2,000,000, or at least 1,000,000; it is usually reckoned at 1,200,000. The number of families is about 300,000. The population probably exceeded 1½ million. The inhabitants are divided into two classes; the first composed of citizens and gentlemen, who reside either in the towns or in the country, the latter of whom enjoy the privileges of citizenship in the capital of their respective cantons; the second class consists of the inhabitants of the villages and country, some of whom live by the culture of their fields and vineyards, and by the profits arising from their cattle, and the others by manufactures and trade. From the Swiss cantons every appearance of pomp and luxury is excluded, and the strictest economy is practised. Equality is preferred by a custom that is prevalent; which is, that, of dividing estates among all the children, male and female, with this exception, that a father may bequeath one-third of his property to any one of his sons, as he pleases, so that the one is raised too much above the level of the rest of the community. A spirit of independence and freedom, tempered by decency and good order, pervades all ranks of these people. Jealous of their privileges, and tenacious of their liberty, they are enamoured of their country, the mild government and sublime scenery of which are often discovered to them its indefitible attractions. They are honest, sober, industrious, brave, and remarkable for their fidelity. Religious in principle, they are addicted neither to superstition nor fanatical enthusiasm. Their customs and diversions are of the warlike kind. Plays, gaming, dancing, &c. are discouraged. The higher orders, in their dress and general mode of life, imitate the Germans and the French; but the drest and manners of the inferior classes are plain and simple, not subject to the laws of fashion. Their houses, except in some less fashionable valleys, are chiefly furnished with furniture, and ready to be furnished with the least expense. They indulge in up delicacy of fare, their ordinary food being the fruit of their labour and the product of the soil. The original simplicity of the pastoral life is everywhere preferred; none seem to be discontented; none are miserably poor, and scarcely any beggars are to be seen. Under a mild government all live at ease, excepting in some populous cantons, where liberty is abridged, and justice partially administered.

Language and Literature.—The language of Switzerland is a dialect of the German, but the French is much diffused, and often employed by the better class of people in the southern parts, bordering on Italy, the common tongue is the Italian. Among the Grisons the Romansch prevails. In Vailais there is a particular dialect. The French is the language of the Pays de Vaud; and the language called the Vaudois is confined to the valleys of Piedmont. Since the reformation of letters and the reformation of religion, Switzerland has given birth to many persons distinguished by their literary attainments and performances. Among these are the names of Boller, denominated the father of German literature; John and Jacob Bernouilli, eminent mathematicians; Bonnet, a natural historian; Bullinger, a theologian; Buxtorf, celebrated for his rabbinical learning; Euler, a famous mathematician; Fussi, a classical scholar; J. Gofner, an antiquary and philosopher; Conrad Gofner, a philosopher and mathematician; Pliny, a mathematician and architect; J. Mallet, a distinguished scholar; H. Mallet, an antiquary; Necker, a statesman and financier; Otherwalt, a theologian; Paracelsus, an alchymist; Rouxseau, a well-known writer; Saffi, a physician and writer; Saffi, a writer and philosopher; Fussi, a natural historian; the Turcati, theologians; Wettstein, a learned critic and divine; Zimmermann, a physician; and Zuingle, a zealous reformer, &c. &c. Education has been an object of attention in Switzerland, so that even the peasants are well informed. Besides the universities of Geneva and Baze, the Calvinists more especially have public schools and academies at Zurich, Berne and Lausanne, and they have also literary societies in different parts of the country.

Religion.—The reformation was introduced into Switzerland by Zuingle, who differed in some speculative points from Luther and Calvin. The Roman Catholic system is established in the cantons of Lucerne, Uri, Schweitz, Unterwalden, Zug, Friburg, Solothurn, part of Glarus, and the interior part of Appenzell. The Calvinistic or reformed cantons are, Zurich, Berne, Bazz, Schaffhausen, great part of Glarus, and the exterior communities of Appenzell. The lordship of Haldenstein, and the town of Neufhadt, are Lutheran. Every town and state has its own particular constitution for the management of its churches, but the academies, schools, and other ecclesiastical affairs, but all live in mutual amity, without invading the rights and privileges of one another.
SWITZERLAND.

Manufactures and Commerce.—The staple commodities of Switzerland are flax and cotton, which are manufactured in various ways; and a considerable quantity of leather is tanned. The country produces excellent butter and cheese in great abundance. Although Switzerland has many navigable rivers and lakes, commerce has been too much neglected. Among the articles of export are horseth, cattle, butter, cheese, raw hides, silk stuffs, linens, watches, distilled liquors, &c. The imports are corn, flax, hemp, flax, cotton, wine, salt, and a variety of manufactured goods.

Climate, Soil, and Products.—The climate is deferently celebrated as fabulous and delightful. The best of the southern parts, though sufficient to mature the grape, is attempered by the cold gales from the Alps and glaciers. When the sun defends beyond mount Jura, in a summer's evening, the alpine summits long reflect the ruddy splendour, and the lakes for near an hour assume the appearance of burnished gold. The winter, however, is in some parts extremely severe, and the fummer heat in the deep valleys is sometimes oppressive. The face of the country is generally mountainous, and though Thurgau, and part of the cantons of Basle, Berne, Zürich, Schaffhausen, and Fribourg, are the most level districts, yet these present eminences which may be called mountains, as they are from 2000 to 3000 feet above the level of the sea. No country exhibits a diversified an appearance as Switzerland; the vast chain of Alps, with ®ne precipices, extensive regions of perpetual snow, and glaciers that re semble seas of ice, are contrasted by the vineyard, and cultivated field, the richly wooded brow, and the verdant and tranquil vale, with its happy cottages and crystal streams. Although in such a country sculpture cannot be expected to flourish, yet the industry of the inhabitants affords a supply of goods sufficient for domestic consumption. Barley is cultivated even to the edge of the glaciers; oats in regions a little warmer; rye in those that are much sheltered; and spelt in the warmest parts. But the produce being uncertain, granaries are provided for furnishing a supply in case of any deficiency. The country, however, being best adapted for pasturage, the Swiss chiefly depend upon their cattle, and much land is laid out for winter forage, which would otherwise be productive of corn. As calculated in considerable quantity, and tobacco has been lately introduced. The Solow, or those of the Pays de Vaud, the cantons of Berne and Schaffhausen, the Valais, and the Valtellin, which latter also produces afrom. The country affords abundance of fruits, apples, pears, plums, cherries, and siberes; with mulberries, peaches, figs, pomegranates, lemons, and other products of a warmer climate, in those districts which border upon Italy. But pasturage forms the chief province of the Swiss farmer; and the frequent irrigation of the meadows is practised in order to increase the produce of hay. In the beginning of summer the cattle are conducted to the accessible parts of the Alps by cow-herds, who are called "Sennen" in the language of the country, and who either account to the proprietor for the produce, or agree for a certain sum. These herds also support many swine, with the butter-milk and other refuse.

The rivers of Switzerland are numerous; and among the most sublime scenes of the country may be classed the fountains of the Rhine and the Rhone, two of the most important streams in Europe. If we estimate their length of course through the Swiss dominions, the Rhine is the most considerable; and this is followed by the Aar, the Reuss, the Limmatt, the Rhone, and the Thur, which serve respectively. The lakes are also numerous and interesting: the most considerable are those of Constance on the N.E. and Geneva on the S.W. Only a part of the lake Maggiori, or that of Locarno, is subject to Switzerland; but the lake of Lugano forms an extensive body of water in that region. The lakes of Neufchatel and Zurich are each about 15 miles long, and about four broad. That of Lucern is about 12 in length, and its greatest breadth not exceeding three. Near to these are the lakes of Thun and Brienz; of Joux and Roula, on the French confines; the lakes of Morat and Bienne, of Sempach, Zug, Wallenstadt, and others of inferior note.

The mountains of Switzerland are the most celebrated in Europe, and are supposed inferior in height to none, except those of South America, which derive their advantage from standing on an elevated plain. In a general point of view, the Alps extend, in a kind of circular form, from the gulf of Genoa, through Switzerland, which contains their centre and highest parts, and close in the Carnic Alps, on the north of the Adriatic sea. (See Alps.) Of forests there does not seem to be any remembrance in Switzerland; and wood is so scarce, as well as turf, that the dung of cows and sheep is often used for culinary fires. Switzerland has a southern climate, and its elevated situation, may be considered, with regard to its botany, as an epitome of all Europe.

The horseth of Switzerland are esteemed for vigour, and spirit, and its cattle often attain great size. Among the animals peculiar to the Alps are the ibex, bouquet, goat of the rocks, the chamois, and the marmot. Among Alpine birds we may enumerate the vulture, called also the golden or bearded vulture, the red-legged crow, and turke caeruleus. The lakes of Switzerland have few peculiar fish; but to the mineralogy of Switzerland, we may observe the softhearted, or down particles of gold, as the Rhine, the Emmat, the Aar, the Reuss, the Adda, and the Goldbach. It has also mines of silver, and also copper and lead; the chief mines are those of iron, in the district of Sargans. The canton of Berne has valuable quarries of rock-salt; and it is said that coal and sulphur are not unknown. But the great stores of minerals are in Feldman, and the southern sides of the Alps. Rock-crysalt is thought to be the chief export of Switzerland, pieces having been found that weigh from seven to eight hundred-weight. The most remarkable parts of the Alps are the satin marble, and good slates are not uncommon. The country is said to consist of granite and porphyry. Among the Alps are also found serpentines, felsates, albitos, and amethysts, with jaspers, agates, and various petrifactions. Near Chiasso is a quarry of grey lapis olari, which has been brought into pots of various dimensions, and which will stand the fiercest fire. Among the mineralogical curiosities may be named the adularia, or glasy felspar, on the mountains of Adula; and the tremolite, thus called from the valley of Tremola near St. Gothard. The most remarkable mineral waters are those of Leuk. In the country of Sargans are the singular warm baths of Fabara, or Pfersch; to the south-east are the sulphureous baths of Almert. Coxe. Playfair. Pinkerton.

In the year 1798, when the several cantons of Switzerland were united under the appellation of the Helvetic Republic or Confederacy, an uniform mode of keeping accounts was adopted, viz. in franken or francs of 10 batzen; each franc being divided into 10 rappen. The franc was equal to 14 francs of the new money of France. The money coined from 1798 to 1803 bore the flamen of the "Helvetic Republic," and consisted of gold pieces of 32 and 16 francs, silver pieces of 40 and 90 batzen, or 4 and 3 francs, and base silver pieces of 10 and 5 batzen. In 1805 Switzerland became
became again a federative republic; each canton was allowed the right of coinage; but the standard of the pieces was to be uniform, and the coins of each canton were to be current throughout the whole country. These consist of silver pieces of 1, 2, and 4 francs; and base silver pieces of 5, 1, and ½ batzen and 1 rappen.

The coinage of all the cantons has been abolished by a law of the following: the franc is to contain 127½ Swiss grains (or 104½ English grains) of fine silver, and the price of the mark of fine silver is to be 36½ francs.

The pieces of 1 franc are to be at the rate of 32½ to the mark; and the pieces of 2 and 4 francs in proportion: the silver is to be 10 deniers 19½ grains fine, with an allowance of 1 grain for remedy in the fineness. The remedy of weight in the francs is 16 grains per mark; in the 2 frank pieces, 12 grains; and in the 4 frank pieces, 8 grains per mark. The ½ batzen pieces are to be at the rate of 74 to the mark, 8 deniers fine, the remedy 4th of a piece per mark, and 1½ grain in the half batzen, 120 half batzen, 36 rappen, to weigh a mark; the batzen are to contain 1 part of silver in 6½ the half batzen, 3 parts in 32; and the rappen, 1 part in 24. No law has been made for gold coins, except that each of the cantons may with to have them, must regulate the coinage in such a manner, that the franc may contain 8½ Swiss grains of fine gold.

The franc, according to the above law of the diet, is worth 14½d. sterl., or 17 sterl. = 16 francs 4 batzen 7 rappen, in new Swiss money. Kelly's Cambi.

SCHWITZ. See Schwytz.

SWIVELS. A kind of rings made to turn round in a staple, or other ring. These are used when a ship lies at her moorings in harbour, to which the cables or bridle goes are bent, that the ships may swing round to the tide; also in tendrers for cattle, that they may turn round without warping the tender.

SWIVEL-Cannon. A small piece of artillery, belonging to a ship of war, which carries a shot of half a pound, and is fixed in a socket on the top of the ship's side, aero, or bow, and also in her tops. The trunnions of this piece are contained in a socket of iron crotch, whose lower end terminates in a cylindrical pivot reeling in the socket, so as to support the weight of the cannon. The socket is bored in a strong piece of oak, reinforced with iron hoops, in order to enable it to sustain the recoil. By means of this frame, which is called the swivel, and an iron handle on its cap-cabell, the gun may be directed by the hand to any object. It is, therefore, very necessary in the tops, particularly when loaded with musket balls, to fire down on the upper decks of the adversary in action.

SWIVEL-Hook. A hook that turns in the end of an iron block bar, &c. for the ready taking the turns out of a tackle.

SWIVEL-Headed Churn-Staff. In Rural Economy, that kind of staff of this sort which turns upon a swivel. See STAFF-Churn.

SVOJANOW, in Geography, a town of Bohemia, in the circle of Chuden; 9 miles S.E. of Politzka.

SWOONING. See Swoon.

SWORD, an offensive weapon, worn at the side, serving either to prick, or cut, or both. Its parts are the blade, guard, hand or grasp, and pommel; to which may be added, the bow, scabbard, hook, and sheath. The matters of defence divide the sword into the upper, middle, and lower part; or the front, middle, and foible or small and weak part.

Anciently, there was a kind of two-handed swords called spades, which were to be managed with both hands; and which in those days they accustomed themselves to brandish so nimblly, as to cover the whole body with them.

The favages of Mexico, when first visited by the Spaniards, had a kind of wooden swords, which would do as much execution as ours. In Spain, swords are only allowed of such a length, determined by authority. The ancient names gave names to their swords; Augo, was that of Charlemagne; Durandal that of Orlando, &c.

Before the discovery of metals, swords were fashioned probably, like those of the Mexican favages already mentioned, of some heavy wood, hardened by fire; next to their brazen, or rather copper swords were introduced, of which fort many have been found in Ireland. (See Archaeologia, vol. iii. p. 555.) And after the art of tempering steel was understood and practised, they were made of this metal. In early ages, swords were of such value as to be kept in temples and sanctuaries, and to be specially bequeathed in the wills of princes and great warriors; and in the days of chivalry they were distinguished by proper names, descriptive of their supposed qualities, or alluding to their destructive powers; a method of distinction borrowed from the Persians and Arabsians, and practised by Mahomet. Swords were also of various forms, and used with one or with both hands, for thrusting or cutting, or for both purposes. The swords used by the Roman legiary troops were very short and strong, the blade rarely exceeding nineteen inches in length, two-edged, and made for either stabbing or cutting. The swords of the Britons, called spathe, were large, long, and heavy; as were also those of the Saxons. The Norman swords were also long and heavy.

The sword was carried in a belt of buff or other leather, girded round the body, or thrown over the right shoulder; these shoulder-belts were called baddirck. Among modern swords we read of a bracemart or short sword, the fucado or long sword, the elpadon or two-handed sword, the Swiss or balsket-hilted sword, a Spanish sword or toledo, a tuck inclosed in a walking-stick, a poniard, dagger, which seems to have been a constant companion of the sword, at least since the days of Edward L., fabre, and fychtar, to which may be added the fable, a broad sword with only one edge.

SWORD, Broade, sometimes called the back-sword, has only one edge, and is balte-handled.

Sword-Bearer, an officer in the city of London, who attends the lord mayor at his going abroad, and to carry the sword before him, as the emblem of justice.

It is observed by an ancient writer of armoury, that the bearer must carry it upright, the hilts being hidden under his bulk, and the blade directly up the middle of his breast, and between the sword-bearer’s brows. The sword was likewise carried before the principal officers of boroughs, and other corporate towns, to represent the state and princely office of the king, as the chief governor. See Sword-Bearer. See Port-Glave.

Sword-Belt. See Belt.

Sword-Blade, Mill for. See Mill.

Sword, Plies of. See Plies and Janus Gladii.

Sword, St. James of the. See James.

Sword-Fish, Xiphias, in Ichthyology, the name of a genus of fish of the order of Apodes.

The characters of this genus, according to Linnaeus, are, that the membrane of the gills has eight bones, and the point or extremity of the nose, snout, or upper jaw of the fish, is shaped like a sword, and the body taper and without scales. There is only one species, viz. the Xiphias
SYA

According to the Artedian system of ichthyology, the characters of this genus of fish are these: the branchial membrane on each side contains about eight bones; the snout is extended into a very long and depressed point, imitating the figure of a sword, and of a bony substance; the body is oblong and roundish; the back-fin is small, and is very low in the middle; there are no belly-fins at all. The air-bladder in this fish is remarkably long, and the anus very near the tail.

The sword-fish is so remarkable for the shape of its snout, which is extended in form of a sword, that it has been called by all nations by a name expressive of that character. Its common name, *spatius*, is from the Greek, *spatios*, a sword, and it is called *gladius* in Latin, and in English the sword-fish.

It grows to a very considerable size, so as sometimes to weigh an hundred pounds. It is of a long and rounded body, large near the head, and tapering by degrees toward the tail; its skin is considerably rough, its back black, and its belly of a silverly white; its mouth is of a moderate size, and has no teeth; its four points, cut into the figure of a sword in the upper jaw, the under is much shorter, and terminates in a very sharp point; it has one only fin on the back, running almost the whole length of it; its tail is very remarkably forked; it has only one pair of fins at the gills, having none on the belly. It is common in the Mediterranean, and some other seas, and is esteemed by many a very delicate fish for the table. The manner of fishing for it is the same at this time that the old writers have described it to be in theirs, by the harping-iron. Willughby.

The ancient manner of taking this fish is particularly described by Strabo (lib. i. p. 16), and agrees exactly with that practised by the现代人. A man ascends one of the cliffs that overhangs the sea; as soon as he spies the fish, he gives notice of the course it takes. Another that is stationed in a boat, climbs up the masts, and on seeing the sword-fish, directs the rowers towards it: as soon as he thinks they are got within reach, he descends, and taking a spear in his hand, strikes it into the fish, which, after wavering itself with its agitation, is seized and drawn into the boat. It is much esteemed by the Sicilians, who buy it eagerly for about 6 L. per pound, at its first coming into season. The seafarers fetch from May till August. This fish is said to be very voracious, and a very great enemy to the tunny, which, according to Belon, are as much terrified by it as sheep are at the sight of a wolf. Ovid. Halieut. 97. Pennant.

**Sword-Grass**, or *Sweet Ryes*, in Botany. See ACORUS.

**Sword-Hand**, in the *Manege*. See HAND.

**Sword-Shape Leaves**, in Botany, *Folius ensiformia*. See LEAF and ENSETE.

**SWORDS**, in Geography, a poft-town of the county of Dublin, Ireland, not far from the sea, and on the great northern road. There is in this place one of the most perfect of the ancient round towers, which is 73 feet high, and 50 or 60 feet distant from the church. Here are also some other ruins. Previous to the union, Swords was one of the boroughs called potwallaping. It is seven miles N. from Dublin.

SYA, a town of Sweden, in Wett Gothland; 13 miles S.W. of Linkoping.

SYALCOLE, a town of Bengal; 30 miles N. of Pulcule.

**SYAMA**, a name of the Hindoo goddess Parvati. The name means black, similar to kali, another of her many names. (See KALI and PARVATI.) Syama is also the name of a dog attendant on Yama, the Hindoo king of hell.

**SYANG**, in Geography, a small island in the Pacific ocean. N. lat. 0° 25'. E. long. 130° 50'.

**SYANPOUR**, a town of Hindooftan, in Oude; 113 miles S. of Canoge.

**SYASKUTAN**, one of the Kurile or Kurilofk islands, about 50 versts from another island, called At-Amazut, between which the current is very rapid. This island, which is 5000 feet long, and 5000 feet broad, has a large port. Upon it are two high rocky mountains; one of which stands in the northern half, on the north-east shore, extends ridgewise, and has formerly burnt; the other, being a huge rock, is on the promontory near the north-west side, and from the peninsula to the sea-shore, on both sides, consists of nothing but rock and crumbling stone.

**SYBARIS**, in Ancient Geography, a town of Libya, on the mouth of a small river of the same name, in the Gulf of Tarentum, at the point of division between Bruttium and Lucania. The Greek and Latin historians concur in giving that ancient and famous city a Greek foundation. It bore successively the appellations of Sybaris, Thurium, and Copia; all which terms, according to their etymologies, denote abundance. According to Strabo, Sybaris was founded, or at least re-established, by the Achaeans. According to Justin, it was founded by Philoctetus. Whatever might be its origin, it became so considerable, that if we give credit to ancient authors, it gave law to four nations and twenty-five cities, and could muster 30,000 fighting men. The walls of the capital included a space of five miles and a half, and its suburbs, extended near seven miles along the Crathis. The natural richness of the adjacent soil encouraged agriculture, and furnished abundance of articles for commerce; and the convenience of its situation between two considerable rivers, the Sybaris and the Crathis, favoured a great exportation. From these sources wealth flowed copiously into the state, and with it brought such luxury and degeneracy of manners, as have excited astonishment and indignation of all ancient writers; so much that the term "Sybarite" became proverbial to denote a man devoted to pleasure. So enfeebling were the effects of this luxury, that 70,000 inhabitants, says, in- fact, to destroy all their grandeur and prosperity; 147 years B.C. the Crotoniates, amounting to 100,000, under their famous commander, the athlete Milo, encountered them at Siagre, and totally defeated them. Breaking down the dams that kept out the Crathis, they let the furious stream into the town, which soon overturned and swept away every edifice of use or ornament. The inhabitants were massacred without mercy; and the few that escaped the slaughter, and attempted to reform their state, were cut to pieces by a colony of Athenians, who afterwards founded the new city of Thurium, on or near the same spot, which, in process of time, became subject to the Lucanians. Diodorus, differing from Strabo, says, that 50 years after its destruction, it was repeopled by the Tar- tarians, who were afterwards expelled by the Crotoniates; and that it was at that time that the Athenians came hither with ten vessels. After the destruction of Sybaris, Thurium became a considerable state, under the discipline of Car- ronies, who died a martyr to the spirit of his own laws. Having fixed the pains of death upon any citizen that should enter the senate-house armed, and being reminded that his hurry he had brought a sword with him into the senate-room, he immediately plunged it into his own breast, and seals his decree with his own blood. Thurium flourished for a long time under the dominion of Rome; till falling into decay,
decay, it was judged expedient to send a colony thither, under the confulate of T. Sempronius Longus and Scipio Africanus, in the year of Rome 559. After this event, it assumed the name of Copia. The coins of Sybaris are amongst the most ancient known; being of the fort called "incus," i.e. convex on one side, and concave on the other. They bear a bull, which some have thought to be an emblem of the subdued river, long their friend and purveyor, but in the end an instrument of their destruction. The great works undertaken to drive back its waters are probably, it is said, expressed by the head of the animal being turned back on its shoulder. The spot on which this city stood, noted to a proverb in ancient history for the luxury and effeminacy of its inhabitants, is now merely indicated by a few degraded fragments of aqueducts and tombs.

Sybaris, a fountain of the Peloponnesus, in Achaia Propria, near the town of Bura, according to Strabo—Allo, a town of Asia, in the Colchide, which was the residence of the king of the country.

SYBER, or SYBORG, in Geography, a town of Germany, in the county of Mark; at which place stood anciently the strong citadel of the Saxons, called "Sigeburg," or "Syburg," at the confluence of the Ruhr and Lenne, which was wholly destroyed in the year 1287; 3 miles S.W. of Schwiert.

SYBILHEAD, a cape on the west coast of Ireland, in the county of Kerry; 8 miles W.N.W. of Dingle. N. lat. 53° 10'. W. long. 10° 18'.

SYBOTA, in Ancient Geography, a port of Epirus, upon the coast of Almene, between the mouth of the river Meanias and the city of Torona, according to Ptolemy—Allo, the name of an island on the coast of Epirus.

SYCABIS, in Ornithology, a name by which some authors have called the atricapilla, or black-cap, a small bird well known in England.

SYCAMINOS, a word used by some for the mulberry fruit, and by some for the tree.

SYCAMINOS, in Ancient Geography. See CAJPHA.

SYCAMINOS is also a town which Phileteutus places on the confines of Egypt and Ethiopia. Ptolemy calls it "Hieria Sicaminos!" and places it on the E. bank of the Nile, and S. of the lesser cataract.

SYCAMORE, a species of ficus, or fig-tree. See FICUS.

The sycamore grows to a large size; the wood is soft, white, and valued by the turners: this tree thrives better than most other trees near the sea, and is frequently cultivated to screen plantations of other kinds from the spray. It is a tree of the timber kind, which throws out a wide spreading head. Its leaves are vine-shaped, and on their first appearance are of a pleasant green; but their beauty is soon defaced by the perforations of insects, which leaven its value for ornamental purposes. And it is a fort of a tree which is easily increased, as in the autumn, when the keys are ripe, they may be gathered, and in a few days after from, about an inch and a half deep, in beds of common mould. In the spring the plants will appear, and make a shoot about a foot and a half by the autumn following, if the ground of the nursery be tolerably good, and they are kept clean from weeds. In the spring after they come up, they should be planted in the nursery in rows two feet and a half asunder, and their distance in the rows must be one foot and a half. Here they may remain till they are big enough to plant out finally, with no further trouble than taking off unsightly side-branches, and such as have a tendency to make the tree forked, except digging between the rows, which must always be done every winter.

The sycamore is likewise a tree that grows very well on moat of fords of soils, and of course may be usefully cultivated in many cafes by the farmer. It is observed by Mr. Young, in the 7th volume of his "Annals of Agriculture," to be the only tree which grows erect, and refits the wind and spray of the sea; but the beech has lately been found to answer well in such situations.

Sycamore-Tree, a name improperly given by us to the Acer majus. See MAPLE.

Sycamore-Moth, in Natural History, the name of a peculiarly large and beautiful moth, or night-butterfly, so called from its caterpillar feeding on the leaves of the sycamore. This caterpillar is remarkably large, very often growing to three inches and a half long, and three quarters of an inch in diameter.

These caterpillars being put into a box, each spun itself a strong and firm case, which it fastened to the side of the box, and in it waited the time of its last transformation: in each of these shells there was left a small aperture, by means of which the creature was to get out when in its butterfly state, and the head of this animal was placed exactly against this aperture. In this state it lay all the autumn, winter, and spring, and in the beginning of summer comes out in the shape of a very elegant moth. The wings, when expanded, measure more than five inches, and each has an eye, like that on the peacock's tail, near the extremity. The horns are of the feathered kind, and are very large and elegant; and the body and origins of the wings are covered with very long hairs. Med. Acad. Par. 1692.

SYCE, in Ancient Geography, an island situated on the coast of Ionia, according to Pliny.

SYCHEUM, a maritime town of Arabia Felix.

SYCION, a word used by some authors to express a decoction of dried figs.

SYCITES, the fig-stone, a name given by some authorities to such natural nodules of flint or pebbles, as happen to approach to a fig in shape.

SYCTES, or SYCTES, a term used by the ancients to express a wind verged with figs.

SYCOMA, or SYCOSIS, from σκομαί, a fig, an excrecence like a fig.

SYCOMANTIA, σκομαντια, in Antiquity, a species of divination performed with fig-leaves; for which see Potter, Archaeol. Græc. lib. ii. cap. 18. tom. i. p. 353.

SYCOPHANT, σκοπαθειν, formed from σκοπειν, a fig, and θαυμα, I discover, a Greek term originally used at Athens, for persons who made it their business to inform against those who filled figs, to the owners, or against them who, contrary to the law, which prohibited the exportation of figs, praefaced the thing, and deceived the officers, the inspectors of the ports, &c.

At length the term became used, in the general, for all informers, tale-bearers, parasites, flatterers, &c. especially those in the courts of princes: and at last, for liar, impostor, &c.

SYCOPHANTIC PLANTS. See Parasites.

SYCOSIS, in Medicine, σκομαντια, from σκομαί, a fig, an eruption of inflamed and hardish tubercles, affecting principally the beard or the face, and forming a granulated prominent ulceration, which somewhat resembles the soft infide pulp of a fig.

This cutaneous malady was mentioned by Celsus as occurring at Rome. "Et etiam ulcus, quod ad faciem similitudinem σκοματικας ad Graecas nominatur, quia caro in eo excrecit." (Celsus, De Med. lib. vi. cap. 3.) The later Greek
Greek writers are not all agreed in their use of the term; but Paul of Aegina properly describes it as an eruption on the face of "round, red, somewhat hard, painful, and ulcerating tubercles." (Lib. iii. cap. 22.) And Aëtius mentions the disease as "one of the affections of the chin, which," he justly observes, "differs from Acne in the nature of the humour which it discharges, and in its greater tendency to ulceration." (Tetrabib. ii. Serm. 4. cap. 14.) Dr. Willan intended to include it in the eighth order of his classification of cutaneous diseases, in which place it is described by Dr. Bateman in his "Practical Synopsis" of that arrangement, as assuming two forms, one when it occurs on the chin, ycosis mentis, and another, when it occupies the hairy scalp, S. capillitii. See that work, p. 297.

In the first species, the tubercles begin to arise on the under lip, or on the prominent part of the chin, in an irregular but somewhat circular cluster; and these are followed by succedaneous clusters, spreading along the course of the jaw up to the ears, and even under the jaw towards the neck, as far as the beard grows. The tubercles are red and smooth, and elevated, some of them nearly attaining the flesh. Their progress is a steady one, often occupying the space of three or four weeks; but gradually a thick matter oozes out, matting together the hairs of the beard, and rendering shaving impracticable. This rugged and scabby condition of the eruption, intermixed with the matted and encrustcd beard, not only occasions a considerable degree of deformity, but becomes very troublesome, from the violent itching which accompanies it. Its duration is various; but it is commonly slow and tedious, and will sometimes discharge again after being healed.

This form of ycosis necessarily affects principally men; but women are not altogether exempt from it, though they suffer but little from it, when it occurs in them.

The second species, ycosis capillitii, appears chiefly about the margin of the hairy scalp, and the tubercles are arranged in clusters of an irregularly circular form. They are softer and more pointed than those of the chin; and they all pass into suppuration in the course of eight or ten days, becoming confluent, and producing an elevated, unequal ulcerated surface, which often appears granulated, so as to exhibit some resemblance to the internal pulp of a fig. The ulceration, as Celsus states, is generally humud; for there is a considerable discharge of a thick ichorous fluid, which emits an unpleasant rancid smell. "Ex duro exiguum quiddam et glutinosum exit: ex humido plus, et mali odorire."--Celsus, De Med. lib. vi. cap. 5.

The ycosis, under its former species, may be mistaken for the violent kinds of acne, which is situated chiefly upon the face; it if it is not observed that the disease is limited to the part occupied by the beard; that the tubercles are softer and more numerous than in acne, and arranged in clusters; and that they tend to produce ulceration. When it is seated on the scalp, as in the second species, the ycosis may be confounded with the porrigo, or putrefactions and ulcers, called favè. But an attentive observer will mark the tuberculated, hard, and elevated base of the suppuring tumours in the disease in question, which does not occur in the soft scabbing putrefactions of porrigo. The latter, too, is a contagious disease; the former not.

The cure of the ycosis is sometimes slow, but not in general difficult. When the tubercles are numerous, inflamed, and confluent, and especially when the suppuration is either beginning or considerably advanced, the most speedy benefit is derived from the application of poultices at night, of bread and milk, linseed powder, or other simple ingredients. In the less severe forms, warm ablations or fomentations may be substituted. When the inflammatory symptoms are reduced, and in cases where they are from the first moderate, the healing process is much promoted, and the discharge moderated and restrained by the application of the ointment of nitrate of mercury, diluted with three or four parts of simple cerate, or by the ointment of the white precipitate, united with an equal portion of zinc or fumigerum nitrate. At the same time it is useful to prescribe antimonials, with alternative dozes of mercury, followed by cinchonas, or mercurialis, and the fixed alkanes, especially where there appears to be any affection of the digestive organs, which not unfrequently accompanies this eruption. See Bateman's Practical Synopsis of Cutaneous Diseases, p. 291, 3d edit.

SYCOTA, a word used by some of the ancients to express a sort of food prepared of figs.

SYCOTON, a name given by the ancients to the liver of a pig fed with figs. This was esteemed a very elegant dish among the old Greeks.

SYCTA, in Ancient Geography, a town of Aisa, is the interior of the territory of the Tereus. Procopius.

SYCURRUM, a town of Syria, in Magnesia, situated at the foot of mount Osia. Livy.

SYCUSSA, an island situated in the vicinity of liss. Pliny.

SYDABAD, in Geography, a town of Hindostan, in the fubah of Agra; 14 miles N. of Agra.---Allo, a town of Hindostan; 50 miles W. of Benares.

SYDAPOUR, a town of Bengal; 28 miles S.E. of Boglipour.---Allo, a town of Hindostan, 44 miles N. of Nellore.

SYDBY, a town of Sweden, in East Bothnia; 10 miles S. of Christianstad.

SYDENHAM, Thomas, in Biography, a physician of extraordinary genius, was born at Winford-Eagle, in Devonshire, about the year 1624. He was the son of a gentleman of independent fortune, and was sent to Oxford in 1640, where he was admitted a commener of Magdalen Hall. But on the occupation of that city as a garrison for Charles L in the civil war, Sydenham, whole connections were with the parliamentary party, his eldest brother being a colonel in their service, quitted it, and went to London. Here, as he informs us himself, an accidental illness of his brother brought him into an acquaintance with Dr. Thomas Coke, an eminent physician who had been called in, and who, finding him altogether undecided as to the choice of his profession, and perceiving him to be a young man of great acuteness, persuaded him to commence the study of medicine, on his return to Oxford. Sydenham adopted this suggestion, and returned to Magdalen Hall, for the purpose of carrying it into execution, as soon as that city was delivered up to the parliament; and in April, 1666, he took the degree of bachelor of physic. About this time, through the interest of a near relation with the parliamentary party, he obtained a fellowship of All Souls College, in the place of a member ejected for his political opinions. After pursuing his studies a few years, he quitted Oxford without any farther degree, and subsequently obtained that of doctor of physic at Cambridge, and settled in the practice of his profession in Westminster.

The extensive practice which he is said to have enjoyed from 1660 to 1670, is perhaps only to be accounted for by the greater success which his superiority of skill in the discrimination and treatment of diseases would necessarily command, and which, from the novelty of his plans, would become more readily a matter of notoriety; for, from this period, namely, after the restoration, his opinions and prac-
SYDENHAM.

tical connections must have been on the wrong side. He appears to have met with opposition, too, on the part of the college; since he never was admitted to the rank of a fellow, and was only made a licentiate at a late period of his life. It is certain, indeed, that he experienced no small share of the enmity and calumny which is usually excited by innovation; yet he appears, from his dedications to Drs. Mapleton, Brady, Faman, Cole, &c. to have possessed some intimate and valuable friends in the profession; and he seems to have conducted himself towards all without any of that arrogance which too often accompanies originality of talent.

An anecdote has been related, on the authority of Sir Richard Blackmore, in proof of Sydenham's contempt for all medical writings. He is said to have replied to an inquiry respecting the best books to be read to qualify a man for practice, "read Don Quixote." Sir Hans Sloane, however, who affirms that he never knew a man of brighter natural parts, believed this to be a joke. It is certain, indeed, that Sydenham paid little attention to the prevalent medical doctrines which were taught in the principal schools of Europe, and were adopted by most of the practitioners of his time. His sagacity led him to a more philosophical mode of acquiring pathological knowledge. He tells us that, on commencing practice, he was immediately convinced, that the only means of acquiring a correct knowledge of his art, was by a diligent and laborious study of the phenomena of disease, by giving up his whole mind to the investigation of the changes and progress of symptoms, from which the true and natural indications of cure would be readily deduced; an opinion which every subsequent year served only to confirm. (See his "Epistola Dedicatoria" to Dr. Mapleton.) He adds, that his friend Mr. Locke (the celebrated writer on the human understanding) approved of this method, and there is a complimentary cantos of Latin verses by that able author, prefixed to his treatise on fevers.

It was to febrile diseases that he first applied this inductive method, and he admits that it was after several years of anxious attention and perplexity that he satisfied himself respecting the proper and successful mode of treating these maladies. In 1666 he published the result of his observations on these fevers, in a work entitled "Methodus curandi Febres, propriis Observationibus superfructi." After he had published, with remarks suggested by subsequent experience, under the new title of "Observations Medica circa Morborum Acutorum Historiam et Curationem," 1670, 1675. In this work, however, as in some of his other writings, we find hypothetical language pretty largely intermixed with found practical observation. He commences with a definition of febrile after the Hippocratic doctrine, viz. that it is "a violent effort of nature, for the benefit of the constitution, to expel a morbid cause." Thus, the plague he deemed a struggle to drive out the contagious matter by means of buboes, perspiration, or various eruptions; and the gout a providential exertion to depurate the blood by expelling its impurities; and according to the degree of violence with which this is effected, and the rapidity with which the critical depuration takes place, the disease, he affirmed, was acute or chronic. Nevertheless, in his practice he seems to have been little influenced by hypotheses; but to have regulated his views by an attentive consideration of the symptoms, and of the juventatis and sedentia; and in this respect he was the author of much practical improvement. In the treatment of the small-pox especially, then a most frequent and fatal epidemic, he was led to adopt a most salutary method of cure, by repressing the eruptive fever, by means of cool air and antiphlogistic remedies, by which the subfebrile eruption and consequent danger were greatly diminished; although this was in opposition not only to the prevailing practice, which confided in forcing the eruption by heat and stimulating medicines, but to the hypothetical doctrine, which he had himself admitted. Subsequent experience has not only fully confirmed the propriety and success of his practice, but has shown the necessity of extending it to other eruptive and febrile diseases. The sagacity and found observation of Sydenham were also particularly manifested in the correct histories of some diseases which he has left. His descriptions of the small-pox, mealect, and gout, have been deemed models of medical history; and his detail of the singular variety of deceptive appearances, which hysteric affluences in females, is a display of extraordinary acuteness. He was extremely attentive also to the varieties which occurred in diseases, especially of the febrile clafs, in different feasons, and which required a corresponding modification of the treatment; and he has pointed out what he terms the epidemic constitution of particular years, by which all the prevailing diseases were in some degree modified.

The other works in which Sydenham promulgated his mode of practice, were "Epistola Relpouforis due; prima, De Morbis Epidemicis ab Anno 1675 ad 1680, ad R. Brady; secunda, De Luís Veneræ Medica et Cura- tione, ad H. Faman," 1680; "Differtatio de Febribus ad G. Cole, De Observationibus superis circa Curationem Variolarum confluentium, necnon de Affectione Hyste- rica," 1682; "Differtatio de Febre putrida Variolis consuetibus supereveniente; et de Mortu Sanguineo, a Calculo Renibus impaèto," 1682; "Tractatus de Podagra et Hy- dropsia," 1683; "Schedula Monitoria de Novæ Febris ingreffe," 1685. On the subject of stone in the kidney and gout, this author had but too much opportunity of acquiring ample information, having been subject to both these maladies for more than thirty years, which impaired his constitution, and ultimately terminated his life. He died in December, 1689, at the age of sixty-five. After his death, a manual of practice, which he had composed for the use of his son, was published by a friend, to whom he had consigned the MS., under the title of "Processus Integri in Morbis fere omnibus Curandis," 1693; which contains a very brief notice of the symptoms of many diseases, both acute and chronic, with some familiar formule.

Sydenham ever maintained the character of a generous and public-spirited man; and has been universally acknowledged the first physician of his age. The numerous editions of his works, indeed, both singly and collectively, in almost all the countries of Europe, the deference paid to his authority, and the commendations bestowed upon him by almost all practical writers since his time, amply prove the solidity of his title to the high reputation attached to his name. The College of Physicians, which admitted him late in life even to the privileges of a licentiate, have subsequently placed his bust in their hall, near that of Harvey. Haller gave his name to the age of medical history, in which experiment and observation began to be substituted for hypothetical doctrines; and Boerhaave, who never mentioned him but with a sort of veneration, thus expressed his praise in a public discourse. "Unum eximum habeo, Thomam Sydenham, Anglie lumen, Artis Phæbum; cujus ego nomen fine honorificæ pretiatione memorare ere- becerem; quenque quoties contemptur, occurrat animo vera Hippocratifæ viri species, de cujus erga Rempublicam Medicine meritia nuncum ita magnificè dicam, quin ejus iod fit suprætura dignitatis." See Eloy. Dict. Hist. de la Mé- dicine.

Gen. Ch. Cal. Periarch inferior, of three, linear-lanceolate, acute, spreading, permanent leaves. Cor. Petals three, roundish, concave, spreading, the length of the calyx. Stam. Filaments three, capillary; anthers oblong. Fg. Germin superior, roundish; style thread-shaped; stigma trifid. Peric. Capsule globular, crowned with the style, of one cell and three valves. Seeds five, globular, flattened, two affixed to each valve, one above the other.

SYNE, or ASSUN, in Geography, a city of Egypt, situated on the east side of the Nile. This town is celebrated for the first attempt to ascertain the measure of the circumference of the earth, by Eratosthenes, a native of Cyrene, who, about the year 276 before Christ, was invited from Athens to Alexandria by Ptolemy Euergetes. Near it, as a small island on the Nile, anciently called Elephanta (Elephantine), is a temple of Cnopus still standing, very little injured; here was likewise a Nilo-meter, but this is not to be discovered. In this town, which was situated under the tropic, according to the report of Strabo, a well was sunk which marked the summer solstice, and the dry season is not known when the style of the sun-dial cast no shade at noon: at that instant the vertical sun darted his rays to the bottom of the well, and his image was reflected on the water. Syene is at present a miserable place, with a small fort, commanded by an aga of the Janizaries: the remains of the ancient town are on an eminence to the south. Columns and pillars of granite, scattered here and there, denote its former glory. There is an ancient building, perhaps the observatory of the ancient Egyptians; 375 miles S. of Cairo. See ASHQUAN.

Juvenal was exiled at Syene, under a pretext of commanding a cohort there.

Pliny says that the name of Syene was also given to a peninsula 1000 paces in circuit, upon the confines of Ethiopia, on the Arabian coast, in which was a Roman garrison. SEE NITE, in Mineralogy. See SINITE.

SYER, in Geography, a river of France, which rises about two leagues to the N. of Thionville, and runs into the Moselle near Waffersbich.

SYESSA, in Ancient Geography, a town of Italy, in Tyrrhenia.

SYFER, in Coinage, a copper coin of Ecbatana. As a money of account, 6 syfer = a silver. See Coin and Money.

SYGAROS, an island situated on the coast of Arabia Felix. Pliny.

SYIA, a small town of the island of Crete, which served as a port to the town of Elyrus.
SYKE, in Rural Economy, a roll or small brook, in a low boggy situation.

SYKES, ARTHUR ASHLEY, D.D., in Biography, a learned and liberal divine of the church of England, was born in London about the year 1684. Educated at St. Paul's school, he was admitted of Bennis College, Cambridge, in 1701. When under-graduate, he composed a copy of Hebrew verses on the death of King William. He took the degree of M.A. in 1708, and engaged as one of the assistans in St. Paul's school. Quitting this situation, he devoted himself to study, and particularly to that of the scriptures; and in 1712-13, he was collated by archbishop Tenison to the vicarship of Godmornham in Kent. In answer to a sermon of Dr. Thomas Brett, he published an examination of that part of it which related to the incapacity of persons not episcopally ordained to administer Christian baptism. Although he took occasion to speak respectfully of Difenters, this circumstance did not prevent his obtaining from the duchess-dowager of Bedford a presentation to the rectory of Dry-Drayton, in Cambridgeshire, on which he resigned his vicarage. In 1715 he published a tract, intitled "The Inocuity of Error averted and vindicated," which served as an argumentative defence of a position advanced by him, "that no hereby is so destructive to religion as a wicked lie; no schism so damnable as a couple of sin, nor the ground of his reasoning was, "that no errors, if involuntary, are or can be punishable." In subsequent editions he animadverted on the objections that had been urged against the doctrine which he advanced. In several of the controversies which took place in the reign of Queen Anne, and on the introduction of the house of Hanover, with regard to the doctrines of passive obedience and non-resistance, the power and danger of the church, and its connection with the state, he took a part, always appearing the decided advocate of Whig principles in the state, and of those called Hoadletian in the church; always allowing himself the ally and defender of such men as Hoadley and Clarke. In a tract, intitled "The external Peace of the Church only attainable by a Zeal for Scripture in its just Latitude, and by mutual Charity; not by a Pretence of Opinion," he argued, "that a latitude of opinion is intended and allowed by the legislature to librifiers, as they are members of the church of England;" which position was proved to be untenable in the "Confessional." In 1718, Mr. Sykes was instituted to the rectory of Rayleigh, in Essex, and resigned his living in Cambridgeshire; and in the same year he was nominated by Dr. Clarke, as rector of St. James's, to be afternoon preacher at King's-court chapel, Golden-square, Sir Isaac Newton confirming the appointment. In 1721 he was nominated by Dr. Clarke to the office of morning preacher at this chapel. In the mean while he published an answer to Mr. Rogers's "Discourse of the visible and invisible Church of Christ;" and a letter addressed to the earl of Nottingham, who, in answer to Whiston's letter to him on the eternity of the Sou and the Holy Ghost, for which his lordship was thanked by the university of Oxford, had advanced some intolerable maxims. In 1721 he published a pamphlet, intitled "The Cafe of Subscription to the XXXIX Articles considered, occasioned by Dr. Waterland's Censure of Arian Subscription," in which he again defended latitudinarian subscription. This controversy produced replies and rejoinders. In 1725, on the recommendation of Dr. Clarke, he was appointed assistant preacher at St. James's. To Collins's "Discourse on the Grounds and Reasons of the Christian Religion," published in 1744, Sykes published a reply in 1753, intitled "An Essay on the Truth of the Christian Religion, wherein its real Foundation upon the Old Testament is shown." This has been pronounced by good judges one of the best books on that subject. Upon receiving his degree of D.D. at Cambridge in 1726, he is said to have "flood like the stately oak to receive and return back the fiery darts of the orthodox." On the death of Dr. Clarke in 1729, an eulogy of that eminent man was published by Dr. Sykes. He afterwards engaged in a controversy with Dr. Waterland, and in another with Whilton, Chapman, and Douglass, on Phlegon's Eclipse. In 1736 he wrote in favour of the Difenters a tract, intitled "The Reasonableness of applying for the Repeal or Explanation of the Corporation and Test Acts unprofitably condemned;" which was regarded as an able defence of Christianity. His other works were a "Brief Discourse on Miracles," "The Rational Communicant, &c.;" "Examination of Mr. Warburton's Account of the ancient Legislators; of thedouble Doctrine of the old Philosophers; of the Truth of the Jews; and of Sir Isaac Newton's Chronology," 1744; "An Essay on the Nature, Design, and Origin of Sacrifices;" "Two Questions previous to Dr. Middleton's Free Inquiry, impartially considered;" and "A Paraphrase and Notes upon the Epistle to the Hebrews." His publications, which amounted to a very large number, many of them being, indeed, pamphlets, evince his industry. Dr. Sykes suffered much from the gout and stone, but his death was occasioned by a paralytic stroke, which seized him in November 1756, and carried him off a few days after, in his seventy-third year. He had been married, but had no children. In his manners," says his biographer, "he was mild and obligeing, cheerful in temper, and unfournd by the many controversies in which he engaged. He was punctual in the discharge of his public and domestic duties, and passed through life with general respect." Memoirs of the Life and Writings of Dr. Sykes, by J. Dibdin, D.D.

SYL, in Geography, a river of Walachia, which runs into the Danube; 16 miles S. of Krajova.—Alfo, a town of Walachia; 28 miles S.S.W. of Brancovani.

SYLEUS, in Ancient Geography, a town of Asia Minor, in Pamphylia.

SYLAX, a name anciently given to the Tigris.

SYLBURGIUS, FREDERIC, in Biography, a learned philologist, was born near Marburg, in Hesse, in 1546. He passed his early years in the instruction of youth, and in 1565 became a corrector and reader of the editions of ancient authors, printed by Wechel and Comenio. The editions which he superintended are held in high estimation, and his reputation as a Greek scholar was acknowledged by the first writers of his time. He was the author of a Greek grammar much commended by Vossius; and he had a considerable share in Stephensi's Greek Thesaurus. He also composed Greek poems, and some other works, which manifested learning and judgment. He died at Heidelberg in 1596, wrought out by his literary labours. Moreri.

SYLEUM, in Ancient Geography, a town of Asia Minor, situated
SYLLA.

Situated towards the confines of Phrygia, Caria, Lycia, and Pisidia. It was subject to the tyrants of Cibyra and in its vicinity.

SYLLA, Lucius Cornelius, in Biography, a Roman commander, and head of a party, was descended from a branch of the Cornelius family. Funk into indigence and obscurity. He passed a licentious youth, and having acquired the qualities of a gay libertine, he ingratiated himself so much with a celebrated countess of that period, that she bequeathed her whole property. He also was a favourite of his mother-in-law to such a degree, that at her death she made him heir to a large estate. Having thus indulged himself in licentious pleasure and gained wealth, he became the votary of ambition; and succeeded in obtaining the office of questor to the celebrated Marius, at his first consulship, B.C. 107. When Marius went to his African campaign, Sylla was left in Italy to raise recruits, and did not join the army till it was going into winter-quarters. He now began to pursue a course very different from his youth; spending all his time in the fields, undertaking the most laborious duties, and imitating his great commander, whose friendship he thus acquired. Many opportunities soon offered themselves for the exercise and display of his military talents. Being deputed as an ambassador to the court of the king of Mauritania, in an important negotiation, he moved boldly and without molestation through Jugurtha's army, from which circumstance he gained the appellation of Felix. He succeeded in his embassy, and induced Bocchus to become a traitor, and to deliver Jugurtha into his hands. The credit which Sylla thus acquired excited the jealousy of Marius, which was further aggraved by his cauing a signet to be engraved, on which he was exhibited in the act of receiving the illustrious captive. Marius, however, disguised or unfriended his jealousy so far as to avail himself of his services; for when he was appointed to the command against the Cilician Gauls and Cimbrians, B.C. 104, Sylla acted as his lieutenant-general. In this office he was singularly successful; and conceiving himself entitled to civic honours, he went to Rome, and declared himself a candidate for the praetorship. Failing in this acquisition, he accomplished his design in the following year by bribery. When the time of his magistracy expired, he was sent, B.C. 96, into Cappadocia, to settle Ariobarzanes on the throne, and having soon effectuated this business, he received a friendly embassy from Arbaces, king of Parthia; and on occasion of an interview, he manifested his lofty and aspiring disposition, by placing three chairs and seating himself in the middle, whilst those on each side were affixed to Ariobarzanes and the Parthian ambassador. In the Social war, B.C. 91, Sylla had a command in Samnia, and distinguishing himself above all other commanders, he was elected to the consulate B.C. 88, and now commenced the rivalry and Moffit between him and Marius. He was now 50 years old; and he strengthened his interest by marrying Cecilia Metella, daughter of Metellus, the high pontiff. The object of competition between these two aspiring Romans was the command in the Mithridatic war. Sylla having gained the field, succeeded in this attainment of his object; but the measures that were adopted by the partisans of both competitors were violent and fangnariat. The successful competitor having taken possession of the city, and being at the head of six legions, procured articles of impeachment against Marius and his partisans; a decree of proscription, and a price to be set on their heads.

Sylla remained at Rome some time after the expiration of his consulship; but through the influence of Cinna, one of the Marian faction, who had been elected consul, he was cited to give an account of his past conduct. In order to avoid this danger, he embarked his troops, and set sail for the East. Having landed in Thrasybule, he immediately received the submission of the Grecian cities, which had been forced to declare for Mithridates. In order to furnish himself with money for his enterprise against Athens, which refused to surrender, he seized the treasuries of several temples, and violated the sanctity of the Demeter Apollo. After a long siege, Athens was formed with great slaughter of the inhabitants. Having in several battles defeated the forces of Mithridates, he prepared a fleet to pass over into Asia. But being desirous of hastening to Rome, he manifested an inclination to negotiate a peace with Mithridates, with whom he held a conference in person; and they agreed to articles for this purpose. The king professed to reign all his conquests, to confine himself to his paternal territory of Pontus, to pay a large sum of money to the Romans, and to deliver to Sylla the sons of his family; and thus terminated the first Mithridatic war. Sylla possessed unconstrained power in Asia, which he exercised in conferring freedom on several states, which had taken part with the Romans in the late war; and in laying heavy fines upon those which had been hostile. He was thus enabled to carry with him vast treasures to Rome; and he also took with him, as part of the spoils, several valuable libraries, particularly that of Ariobarzanes, which belonged to Apelleion, the Teian, a very wealthy peron, who had expended large sums in forming a collection of rare books. Marius, Sylla's competitor, was now dead, and the chief authority at Rome was vested in Cinna, who had been repeatedly appointed to the consulship, with Carbo, a man equally violent and fangnariat, for his colleague. At Dyraxchium, the deputies of the senate had an interview with Sylla, who was entreated by them not to suffer his resentments to plunge the country in a civil war; but the answer they received led them to conclude that it was determined on ample revenge.

Cinna was killed in a mutiny of his troops; and in the following year, B.C. 83, Cornelius Scipio and Juba Norbanus went to Rome, and on their orders, and the chief authority at Rome was vested in Cinna, who had been repeatedly appointed to the consulship, with Carbo, a man equally violent and fangnariat, for his colleague. At Dyraxchium, the deputies of the senate had an interview with Sylla, who was entreated by them not to suffer his resentments to plunge the country in a civil war; but the answer they received led them to conclude that it was determined on ample revenge. Sylla was killed in a mutiny of his troops; and in the following year, B.C. 83, Cornelius Scipio and Juba Norbanus went to Rome, and on their orders, and the chief authority at Rome was vested in Cinna, who had been repeatedly appointed to the consulship, with Carbo, a man equally violent and fangnariat, for his colleague. At Dyraxchium, the deputies of the senate had an interview with Sylla, who was entreated by them not to suffer his resentments to plunge the country in a civil war; but the answer they received led them to conclude that it was determined on ample revenge.
ruls were successful in various parts of Italy, and Carbo was obliged to withdraw to Africa. Sylla's progres, however, was checked by a new enemy: this was Pontinus Teleinus, a noble Saturnine, who, with an army of 40,000 men, joined the Marian party, which had been always favorable to the rights of the Italian states, and advanced to the relief of Praeneste; but being surrounded by the armies of Sylla and Pompey, he determined to fall upon Rome and hasten towards Rome. Sylla marched speedily to its relief, and rashly attacking Teleinus, exposed himself to danger, and was obliged to fly to his camp. Marcus Claudius, however, falling unexpectedly upon the victors, put them to flight, and Teleinus fell in the action.

Sylla having no longer any enemy to fear, indulged, without restraint, the spirit of revenge by which he was actuated. Having treacherously induced the Saturnines to surrender, he carried about 6000 of them to Rome, caused them to be shut up in the circus, and whilst he was haranguing them, the fold was opened, and the circus was, in indifferently massacred them. The senators, who were assembled in the neighbouring temple of Bellona, heard their cries and groans, not knowing the occasion of them nor the fate that awaited themselves. Sylla, without apparent emotion, continued his discourse, and informed them, that the noise proceedd mostly from some offenders whom he had ordered to be chastised. Praeneste soon after surrendered, and Marius, the consul, escaped the victor's cruelty by a voluntary death. The inhabitants of a military age were ordered to be put to death, and the place was committed to pillage. Sylla, according to Plutarch, was the calm spectator of the promiscuous slaughter of 12,000 men. He now returned to Rome, avowing the sanguine purpose, that he would not spare one who had borne arms against him, but that they should perish to a man. Immediately after, a table of proscription was fixed up, containing the names of 40 senators and 1600 knights, and death was denounced to all who afforded shelter to the proscribed, however nearly related to them, while large rewards were offered to their affianzins. Rome was by these measures made to flow with blood, till at length Sylla was reproached for his cruelties by his best friends. After the murder of about 6000 persons of different ranks, he told the people that he had now proscribed as many as he could think of; but if he recolected any more, they should be added to the number. These proscriptions extended from Rome to all the Italian towns which favoured the opposite party, being accompanied with insults, and in some instances confiscations of the effects of the inhabitants. Sylla's tyranny produced such terror, that no one could venture to rest it, or even to complain, if we except Catone, when a boy. See his article.

After the death of the consul Marius and Carbo, an interrex was created, who, at the suggestion of Sylla, proposed the appointment of a dictator, and that dictator was Sylla himself. After his introduction to the office, he caused to be enacted a number of laws, some of which, if must be acknowledged, were wise and salutary, and continued to be part of the Roman law long after his death. For supplying the places of massacred citizens, with men devoted to himself, he enfranchised 10,000 slaves, and gave them the rights of Roman citizens. He rewarded his legionaries with lands, and decreed himself a triumph on account of his foreign conquests, which was celebrated for two days with extraordinary magnificence. In the following year, B.C. 80, Sylla was both consul and dictator; and in order to acquire popularity, he feasted the whole Roman people. Declining the consulae for the next year, he formed the singular purpose of resigning his dictatorial authority, and returning to the condition of a private citizen. This must be regarded as a resolution, which in its situation, and in reference to his past conduct, was very extraordinary. For the execution of his purpose, he assembled the people, and concluded his address to them, by saying that he was ready to give an account of his whole administration, and to answer in his private capacity any accusation that might be brought against him. He then dismissed his lieutenants, descended from the rostra, and before the astonished multitude walked for some time in the forum, conversing familiarly with his friends. After his retirement from power to private life, he disgraced himself by the most dissolute company and manners. Having lost his wife Metella, he again married Valeria, sister to the orator Hortenius; but she could not refrain him from indulging in low and scandalous amours. His intemperance occasioned a loathsome disease, from which no art could relieve him. He died in the year B.C. 78, at the age of 60, and his funeral was singularly magnificent. The meaning of the epitaph which he composed for himself was this, that "he had returned with interest all the good he had received from his friends, and all the evil from his enemies." Sylla might well claim the epithet of "Fortune." Fortune was the goddes to whom he attributed all his successes, and with the superstition common among the heathens, he would not offend her by affuming to himself the merit of his actions. The belief that he was her favourite, which he derived from the predictions of astrologers, inspired him with courage in his enterprises, and induced him probably to that act of his life, which was upon the whole the most remarkable, the renunciation of his power. Plutarch Vit. Sylla. Un. Hist. Gen. Biog.

SYLLABA, Lat. a name given by some of the ancients, and among others by Nichomachus, to the consonance of the fourth, which they commonly call diastroron; and which proves, by its etymology, that the Greeks regarded the tetrachord in the same light as we regard the octave, including within its compass all the radical sounds of a syllable.

The modern Italian fissing-masters call solmisation by the hexachords, syllabicising; and ascending and descending the scale by the vowels, vocalising.

SYLLABIC, in the Greek Grammar. There are two kinds of augment es; the first called syllabic, which is when the word is increased by a syllable; the other temporal, which is when a short syllable becomes long.

SYLLABLE, SYLLABA, in Grammar, a part of a word, of an articulate sound, consisting of one or more letters, which are pronounced together; or which in itself conveys either no idea, or part only of what is denoted by the word. The word is derived from the Greek σύλλαβη, which literally denotes comprehension or affimiation.

Or, a syllable is a complete sound, uttered in one breath, consisting either of a vowel alone, or of a vowel and one or more consonants, not exceeding seven.

Scaliger defines a syllable to be an element under one tone or accent, that is, which can be pronounced at once.

Prícin, more intelligibly, calls it a comprehension of several letters falling under one accent, and produced at one motion of the breath. But some grammarians reject this definition, as excluding all syllables of one letter.

Another defines syllable, a literal or articulate voice, of an individual sound.

The learned bishop Lowth defines syllable, a sound, either simple or compound, pronounced by a single impulse of the voice, and constituting a word or part of a word.

In every word, therefore, there are as many syllables as
there are vocal sounds; and as many vocal sounds, as there
are simple or compound vowels, each of which requires a
distinct motion of the pharyngeal muscles. Thus, a, a, a,
make three syllables, formed by 30 many motions, distin-
guished by small flops betwixt each expiration.

In the Hebrew, all the syllables begin with consonants, al-
lowing aleph to be one; nor has any syllable more than a
single vowel.

From the number of syllables in words, they become de-
nominated monosyllables, bisyllables, trisyllables, and polysyllables,
g. d. words of one syllable, two syllables, three syllables,
and many syllables.

As it is the number of syllables that constitutes the mea-
sure of English verse, it were to be wished we had fixed and
settled rules to determine the precise number of syllables in
each word; for we have words very dubious in that respect;
and there are even some which have more syllables in verse
than in profe. Many of the words ending in inus, occasion
great embarrassment to such as pique themselves on exact-
ness: as odious, precious, &c.

With respect to the division of syllables, we may observe,
that any letter, or combination of letters, which will begin
a word, may likewise begin a syllable in the middle of a
word, and no other; for each syllable being as much a per-
fected sound as a more syllable word, can properly commence
with such letters only as will suit the beginning of a word.
Accordingly, there is no letter in the English language, that
may not begin a word, except e mute, which therefore in
the middle of words always goes with the former syllable.
Moreover, every syllable ends in the middle of a word, when
a sound is complete, and the next letter or letters will begin
a new syllable, of which the first at least is a consonant,
unless where two vowels meet, which do not unite in a
diphthong. However, there are some few exceptions to
this general rule.

A syllable in the beginning or middle of a word ends in
a vowel, unless it be followed by s, or by two or more
consonants, which are for the most part to be separated;
and at least one of them always belongs to the preceding
syllable, when the vowel of that syllable is pronounced
short. Particles in composition, though followed by a
vowel, generally remain undivided in spelling. A mute
generally unites with a liquid following; and a liquid, or a
mute, generally separates from a mute following: e, and e,
are never separated from a preceding mute, e. g. ma-nis, is

But the best and easiest rule for dividing the syllables
in spelling, is to divide them as they are naturally divided in a
right pronunciation; without regard to the derivation
of words, or the possible combination of consonants at
the beginning of a syllable. See this subject pursued in
Ward's Essay upon the English Language, p. 44, &c. See also
Lowth's Introduction to English Grammar, p. 23; and

With regard to the accenting of syllables, to what has
been delivered under Accent we may here add, that all
words of one syllable have either an acute or circumflex
accent, agreeably to their quantity. In words of more than
one syllable, the Latin and Greek language differ very much
from each other, as to the use of accents. Many words
of two or more syllables, are accented on the last syllable
in Greek, but none in Latin, except a few compounds of
fio, as maleis, &c. In words of more than two syllables,
if the penultima is long, the Latin accent is placed there,
otherwise on the antepenultima. But in Greek words it is
sometimes placed on the antepenultima when the penultima
is long, and at other times on the last syllable; but when
this is long, it is never carried farther back than the pen-
tulima. No word in the Latin or Greek language is ac-
cented farther from the end than the antepenultima.

English words are not only accented upon each of the
two last syllables, but several upon the fourth, and some
few upon the fifth from the end. In pronouncing long
words, a variation of the tone is necessary upon some other
syllable, besides that where the accent is placed, though
not equally high, both for the sake of casting the voice, and
modulating the sound. Many English nouns and verbs
written alike, are distinguished from each other, by pro-
nouncing the former with an acute accent on the penultima,
and the latter on the last syllable: as subject and object,
image and image, &c. In the inflections of verbs, the accent
always remains on the root, as love, loved, loves, &c. In
derivatives, the accent is always on the theme, except sub-
finitives from the French, ending in eer and ier, where it is
carried to the termination, as volunter, &c. Most com-
ound words have their accent on the former part, and
which is a preposition, and then often on the latter. But
the exceptions from either are more easily known from ob-
ervation than reduced to any certain rules. If the accent
be on the vowel, a vowel or syllable is long, as fall; a
syllable is short, when the accent is on the consonant, which
occupies the word, it will be quickly joined to the preceding
letter, as ans, hungär. Unaccented syllables are generally
short, as admir, but this rule has many exceptions, as in-
pire, firendly. When the accent is on a consonant, the
syllable is often more or less short, as it ends with a single
consonant, or with more than one, as fiddly, persif. When
the accent is on a semi-vowel, the time of the syllable
will be protracted, by dwelling upon the semi-vowel, as ar,
can't but when the accent falls on a mute, the syllable
cannot be lengthened in the same manner, as abed. With
a mixture of long and short syllables are the most
melodious. Ward, ubi supra, p. 32, &c. Murray's Gram-
mar, vol. i.

SYLLABES, Quantity of. See Quantity.
SYLLABUB, a kind of compound drink, made of
in the summer season; ordinarily made of white wine
fugger, into which is sifted new milk with a syrinx, or
wooden cow.

Sometimes it is made of canary, in lieu of white wine:
in which case the fugger is spared, and a little lemon and
muscat added in lieu of it, e. g. musca-
To prepare it the best way, the wine and other
agents, excepting the milk, are to be mixed over snow, and
the milk or cream added in the morning. The proportion
is, a pint of wine to three of milk. For
SYLLABUB, Whips, to half a pint of white wine or
Rhineh, is put a pint of cream, with the whites of three
eggs. This they feast on with fugger, and beat with broken
rods, or work with a syrinx. The froth is taken off
it rises, and put into a pot; where, after standing for two
or three hours, it is fit to eat. Rout.

SYLLECTUM, in Ancient Geography, a maritime town
of Africa Propria, a league from Carthage, according to
Procopius.

SYLLEPSIS, in Grammar, conception, a figure by which
we conceive the sense of words otherwise than the words
import; and thus make our construction, not according to
the words, but the intention of the author. See Sub-
stitution.

The syllepsis, says an ingenious author, is a figure
of construction, which agrees rather with our ideas than
with the words; and expresses rather the sense of our mind
than the sense of the terms themselves.
Syllogism is also used for the agreement of a verb, or adjective, not with that word next it, but with the most worthy in the sentence: as rex et regina beats.

Some authors call the syllogism, synthesis; others, substantiation. It is a figure of considerable use for the well understanding of authors. Scoppius divides it into two kinds, simple and relative. The former is when the words of a discourse either disagree in gender, or number, or both; and the latter is, when the relative is referred to an antecedent which is not expressed; but which we conceive by the sense of the whole period.

**SYLLOGISM.** In *logic*, an argument, or form of reasoning, consisting of three propositions: having this property, that the conclusion necessarily follows from the two premises; so that if the first and second propositions be granted, the conclusion must be granted in like manner; and the whole allowed for a demonstration.

If the premises be only probable, or contingent, the syllogism is said to be dialectical; if they be certain, apodictical; if false, under an appearance of truth, sophistical or perologiastic.

As often as the mind observes any two notions to agree to a third, which is done in two propositions; it immediately concludes, that they agree to each other: or if it find, that one of them agrees, and the other disagrees, which is likewise done in two propositions; it immediately pronounces that they disagree to each other. And such is a syllogism; which, it hence appears, is nothing but a mental discourse, or reasoning, by which, from any two propositions granted, a third is necessarily deduced.

Hence, as the Greeks call it *syllogism*, the Latins call it *collectio*, or *rationes*, as being a kind of composition, which, either by adding, or subtracting, gathers either the sum or the remainder: for, as we add two and three, we may thence collect five: so, if to this proposition, "man is an animal," you add this, "every animal thinks," you thence deduce this, "therefore man thinks."

Of the three propositions of which a syllogism consists: the first is, by way of eminence, called the *proposition*, as being proposed for the basis of the whole argument; the second is called the *assumption*, as being assumed to assist in inferring the third: though they both are called *suggestions*, because assumed for the sake of the third; and both premises, as being premised to it; and for the same reasons both are called *antecedent*, only the first the major, and the latter the minor.

The third is called the *conclusion*, as being the close of the whole argumentation; and sometimes *conclusio*, as including the two notions, before separately compared; and *consequent*, because it follows from the antecedent; and lastly, *illatio*, because inferred from the premises by means of the illative particle *ergo*, therefore, &c.

As the conclusion is the principal part of a syllogism, it hence arises, that though both the proposition and assumption consist each of its subject and attribute, yet the subject and attribute of a syllogism are properly understood of those of the conclusion.

Again, in the instance above mentioned, *animal* being used both as subject and attribute, it is held a kind of intermediate between the two, and frequently called *medium*; in respect to which, both the subject and attribute, *man* and *thinks*, are called *extreme* or *term*; only the subject the *greater extreme*, and the attribute the *less*.

In the constitution of a syllogism, we may consider the matter and the form of it. The matter is three propositions made up of three ideas, or terms, variously joined. The three terms are named the *major*, *minor*, and *middle*.

The predicate of the conclusion is called the *major term*, because it is generally of larger extent than the minor term, or the subject. The major or minor terms are called the *extremes*. The middle term or medium is the third idea invented and disposed in two propositions, in such a manner, as to shew the connection between the major and minor term in the conclusion; whereas the middle term is sometimes called the *argument*. The proposition, which contains the predicate of the conclusion, connected with the middle term, is usually called the *major proposition*, whereas the minor proposition connects the middle term with the subject of the conclusion, and is sometimes called the *assumption*. The major proposition is generally placed first, the minor second, and the conclusion in the last place, when the syllogism is regularly composed and represented.

The form of a syllogism is the framing and disposing of the premises according to art, or just principles of reasoning, and the regular inference of the conclusion from them.

Syllogisms are distributed, with regard to the question to be proved, into *universal affirmative*, *universal negative*, *particular affirmative*, and *particular negative*: and with respect to their nature and composition, into *single* and *compound*. Single syllogisms are made up of three propositions, and may be divided into *simple*, *complex*, and *compound*.

Simple or *categorical* syllogisms are made up of three plain, single, or categorical propositions, in which the middle term is evidently and regularly joined with one part of the question in the major proposition, and with the other in the minor, whence follows a plain single conclusion. For complex syllogisms, see *Complex*.

*Conjunctive* syllogisms are those, in which one of the premises, viz. the major, has distinct parts, joined by a conjunction, or some such particle of speech; the chief of which are *conditional*, *disjunctive*, which have the major proposition *disjunctive*; *relative*, requiring the major proposition to be *relative*; and *conditional*, or *categorical*, which require that two or more ideas be connected either in the complex subject, or predicate of the major, that if one of them be affirmed or denied in the minor, common sense will shew what will be the consequence.

*Compound* syllogisms are made up of two or more single ones, and may be resolved into them: the chief kinds are *epichoresis*, *dilemma*, *prosyllogism*, and syllogism. Watts's *Logic*, art. iii. c. 3.

A syllogism, wherein one of the premises is suppressed, but so as to be understood, is called an *enthymeme*, e. g. "every animal thinks, therefore man thinks!" in which the proposition, "man is an animal," is understood.

The demonstrations of mathematicians, it is observed, are only syllogisms of enthymemes: so that every thing in mathematics is concluded or proved by syllogism; only omitting such premises as occur of their own accord, or as are referred to by the citations. (See *Syllogism*.) There are two general methods of reducing a syllogism to a test of their truth or falsehood. The first is, that the premises must contain the conclusion, or one of them must contain the conclusion, and the other must shew that the conclusion is contained in it; and the second is, as the terms in every syllogism are usually repeated twice, they must be taken precisely in the same sense in both places. Watts, ubi supra.

As to the advantage which syllogism affords to reason, Mr. Locke observes, that of four things, which reason is employed about; viz. the finding out of proofs, the regular disposition of them so as their connection may appear, the
the perceiving of their connection, and the making of a
right conclusion; syllogism only assists in one, viz., shewing
the connection of the proofs in any instance. Nor is it of
any great use even here; since the mind can perceive such
connection, where it really is, as easily, nay perhaps better,
without it. We fee men reason very strongly who do not
know how to make a syllogism.

Indeed syllogism, the fame author adds, may serve to
discover a fallacy in a rhetorical flourish, or by tripping
an absurdity of the cover of wit and good language, shew it
in its natural deformity. But it only shews the weaknesses or
fallacies of such a discourse by the artificial form it is put
into, to those who have thoroughly studied mood and figure,
and have so examined the many ways three propositions may
be put together in, as to know which of them does cer-
tainly conclude right and which not, and upon what grounds
they do so.

The mind is not taught to reason by these rules: it has a
native faculty of perceiving the coherence or incoherence of
its ideas, and can range them right without such perplexing
repetitions. Add, to shew the weaknesses of an argu-
ment, one need not more, than to sketch it of the super-
ficial ideas, which blended and confounded with those on
which the inference depends, seem to shew a connection
where there is none; or at least hinder the discovery of the
want of it: and then to lay the naked ideas, on which the
force of the argumentation depends, in their due order.
In this position, the mind taking a view of them, sees what
connection they have, and so is able to judge of their inference,
without any need of syllogism at all.

Nor must it be omitted, that syllogisms are as liable to
fallacies, as the plainer ways of argumentation; for which
one might need no more, than to imagine an old man
common observation, which has so many ways esteemed these artificial methods of reasoning more
adapted to catch and entangle the mind, than to instruct and
inform the understanding. And if it be certain that fal-
cacy can be couch'd in a syllogism, as nobody will deny but
it may, it must be something else, and not a syllogism, that
must discover it.

The fame author proceeds to shew, that this way of rea-
soning discovers no new proofs, nor makes any discoveries;
but is wholly converfent in the marshalling and ranging of
those we already have; a man must know, before he be able
to prove syllogistically; so that the syllogism comes after
knowledge, when we have but little need of it. To the
same purpose it is observed by Dr. Campbell, in his "Phila-
osophy of Rhetoric," that the method of proving by syl-
logism appears, even on a superficial view, both unnatural
and prolix. The rules laid down for distinguishing the
conclusive from the inconclusive forms of argument, the
tru syllogism from the various kinds of sophism, are at once
cumbersome to the memory, and unnecessary in practice.
No person, one may venture to pronounce, will ever be
made a reasoner, who stands in need of them. In a word,
the whole bears the manifest indications of an artificial and
ostentatious parade of learning, calculated for giving the
appearance of great profundity, to what is, in fact, very
shallow. See Reason and Logic.

SYLLOGISM, Figure and Mood of a. See Figure and
Mood.

SYLLOGISMS, Reduction of. See Reduction.
SYLLOGISTIC FORM. See Form.

Syll, the principal of the Hebrew accents, used to
close a period, and called king and prep. It is marked
under a letter thus ( ).

SYLT, in Geography, an island of Denmark, in the
North sea, about 12 miles from the W. coast of the duchy
of Sleswiek, of an irregular form, about 40 miles in cir-
cumference, and no where more than two miles from the
sea. N. lat. 54° 35'. E. long. 8° 30'.

SYLVA, among the Romans, a ludicrous kind of hunt-
ing exhibited in the circus; so called, because the circus
was really planted with trees, which had been dug up with
the roots by the soldiers and brought thither, and tied to
large beams, after which earth being thrown upon their
roots, the circus actually resembled a wood; there was
then filled with all sorts of herbivorous animals, the peo-
ple were let loose upon them, and carried all clear off.

SYLVA, or Sylvus, in Poetry, a poetical piece composed,
as it were, at a flint; or in a kind of rapture or transport,
and without much thought or meditation. Such are de
Sylva of Statius, which, he affirms us, were all composed
after this manner.

Quintilian extends the use of the word sylva to any wir-
ing done in hafhe, and on the spot.

The word is Latin, and literally signifies forst; whose
its chief use in our language is metaphorically to express
certain collections of poetical pieces of various kinds, on
various subjects; as a forest is an assemblage of trees of
different sorts.

SYLVANS, in Mythology. See FAUNS, SATYRS, el
SILVI.

SYLVES, in Geography. See SILVEs.

SYLVIUS, Francis, De le Boe, in Biography, a dis-
tinguished physician, and founder of a sect in medicine,
as born at Hanau in 1614, and was defended of a good f
amily. After the usual grammatical education, he was sent
to the university of Bafié, where he commenced the way
of physic, and received the degree of doctor in that folly
in 1677. In order to inform the learned of different in-
scriptions, he visited several of the principal universities
in France and Germany, and became extremely skilful in
anatomical pursuits and in the pharmaceutical branch of
chemistry. Being thus qualified to enter upon the profes-
sion of his profession, he settled first at his native place; but
looking to higher advantages, he removed to Amsterdam,
and obtained a distinguished reputation among the physi-
cians of that capital, which he continued to enjoy several
years until he was called to Leyden, in 1658, to assume the
place of professor of the practice of medicine in that uni-
nityr. This situation was well calculated for the exercise
of his genius and eloquence, and he soon attracted a nu-
sous audience from all parts of Europe. He was one of
the earliest advocates for Harvey's doctrine of the circula-
tion of the blood, and was the principal cause of its re-
ception into that medical school. In other respects, how-
ever, he was instrumental in retarding the progress of med-
ical science, by the invention of an hypothesis respecting
the cause of diseases, which contributed much to excite the
attention of the medical world, and to extend his own name.
He ascribed all the most important operations of the vital
forces to certain chemical operations, to fermentations, and
conjunctions, which he believed gave origin to an excess of sol.
alkali, to the neutralization of which all the efforts of
the medical art were of course to be directed. Whence he
administered volatile alkalii, absorbent earths, and cords
largely, paying little regard to the different stages of dis-
order, or the character of prevailing epidemics. The ex-
tent to which this doctrine was received and defended in
most parts of Europe, founded as it was upon a generous
hypothese, and therefore productive in many cases of much
mischief, is surprising, and the interruption which it op-
tioned to the improvement of medicine was considerable.
It was in fact one of the greatest benefits which Sylvius
conferred.
SYL

conferred upon the art, to have detached physicians from this and other hypothetic systems, and led them to the only true path of inquiry, that of observation and experience. The works of Sylvius were principally controversial threads, in which the doctrines which he propounded were flated and defended; and they were frequently reprinted during the prevalence of the system; but they have long been confounded to the neglect, which a mass of fanciful speculation is sure to experience when the light of the day is thrown upon it, and an ultimate incursion. Sylvius died at Leyden in 1672, at the age of 56. See Eloy Diet. Hist. Gen. Biog. See also Medicine, History of.

SYLV\VUS, JAMES, Du Bois, a learned physician, was one of the fifteen children of a camlet manufacturer at Amiens, where he was born in 1478. His elder brother being professor at the college of Tournay in Paris, and a great promoter of learning at that dark period, James had the opportunity of acquiring under him a more perfect knowledge of the Latin and Greek languages than was usual at the time. When he had determined upon adopting the profession of physic, he applied himself most assiduously to the perusal of the writings of the ancients, especially of Hippocrates and Galen, of the latter of whom he was all his life a zealous disciple and defender. But he was not less affluence in the pursuit of other branches of medical study, and especially in experimental researches in anatomy, pharmacy, and botany, and he made several journeys for the purpose of examining medicinal plants in the countries where they were produced. Upon his return to Paris, he delivered a course of lectures, in which he expounded the whole circle of medical practice from the works of Hippocrates and Galen, and in the course of two years obtained a reputation, which attracted to his school a crowd of pupils from various parts of Europe. This, however, did not fail to excite the jealousy of the Parian physicians, particularly as he had not yet taken a medical degree, and he was under the necessity of going to Montpellier in 1520, for the purpose of graduation. But his extreme avarice, which accompanied him through life, would not permit him to undergo the necessary expenses at that university, and he returned without a degree. After some time, however, he succeeded in compromising his differences with the Parian faculty, and was admitted a bachelor of physic in 1531. Four years afterwards he became a lecturer at the college of Triquet, while Fernel taught in that of Cornouaille; and he was attended by a numerous train of students; while the latter attracted but few. His anatomical dissections, and his lectures on botany and pharmacy, which were omitted by Fernel, were probably the principal cause of this preference. He was appointed professor of medicine at the royal college in 1550, which he continued to hold till his death, which took place in 1556, in the seventy-seventh year of his age.

This physician was never married, and is said to have shown an aversion to the other sex. His manners were rude, and his temper full; and his parimony so extraordinary, that he is reported to have used no fire in the winter, but to have kicked a foot-ball, and carried a log of wood up and down stairs, to keep himself warm. He was such a friend to parsimony, indeed, that he published a tract for the benefit of poor scholars, entitled, "De Vitiis ratione facili et salubri Pauperum Scholasticiarum." In fact, his passion for money obfuscated the lustre of his many great qualities. His works were popular during the reign of the old school, but are now obsolete. As an anatomical writer he merits the greatest praise; for though he had few opportunities of human dissection, he made various discoveries and improvements, which are contained in his "Insegni Anatomica," and in his "Obeserva in variis Corporibus fecundis." Several of his writings related to the subject of pharmacy, in which he was well skilled for the age; and he published a valuable edition of Mefius, with a translation and comments. He wrote with great violence against Vesalius, who had been his pupil, and became his rival in anatomy; but especially on account of his presumptuous in correcting Galen, whose very errors he was led to defend by his bigoted attachment to the ancient. Sylvius was also author of a French grammar; he had studied mathematics very successfully; and had cultivated mechanics so far as to have gained considerable notoriety with the public by some machines of his invention. Gen. Biog. Hutchinson, Biog. Medica.

SYL\\RU\\S, in Ichthyology. See Silurus.

SYMA, or SY\\ME, in Ancient Geography, an island north of Rhodes, at the entrance of a small gulf of the Doride. The ancients represent it as having been inhabited by Chthonius, the son of Neptune and Syme, and as having been peopled by the Carrians after the war of Troy; and when abandoned by them, as having been occupied by a colony of Lacedaemonians and Argives. See Syme.

SYMB\\CA\\CA\, a town of Alba, in Media, according to Strabo.

SYMBACCHI, συμβαχχιον, in Antiquity, a designation given to the two men, who purified the city of Athens at the festival Thargelia.

SYMB\\ARD, or SYM\\ARD, in Geography, a town of France, in the department of the Saone and Loire; 4 miles N. of Louhans.

SYMBOL, Symbolum, formed from νυ\\μας, a mark, sign, or badge, of νυ\\μαςα, to compare, a sign or representation of any moral thing, by the images or properties of natural things.

Thus we lay, the lion is the symbol of courage; the pelican of paternal love, &c. Symbols were in very great repute among the ancient Hebrews, and especially among the Egyptians; and served to cover a great part of their moral mysteries; being used not only to represent moral things by natural, but even natural by natural.

Symbols are of various kinds, as types, enigmata, parables, fables, allegories, emblems, hieroglyphics, &c.; each of which see under its respective article, Type, Enigma, Parable, Fable, &c.

The Chinesse letters are most of them absolute symbols, or significative. The symbols in algebra, &c. are arbitrary. Medallists also apply the term symbol to certain marks or attributes peculiar to certain persons or deities. The thunderbolt, for instance, accompanying the heads of certain emperors, is a sign or symbol of the sovereign authority, and of a power equal to that of the gods: the trident is the symbol of Neptune; the peacock of Juno; a figure seated on an urn, of a river, &c. See Medal.

Symbol, among Christian, is particularly used for the creed, or the articles of religion, which every Christian is to know and believe. See Apostles' Creed.

In the emperor's library is a Greek MS. of the symbol of the apostles, divided into twelve articles, with the names of the respective apostles, who are said to have composed each article. The first is attributed to St. Peter, and the rest successively to Andrew, James major, John, Thomas, James minor, Philip, Bartholomew, Matthew, Simon, Thaddæus, and Matthias.

But the testimony of that MS. does not much confirm the opinion, that each apostle composed an article of the symbol;
SYM

symbol; yet the opinion is, at least, as old as St. Leo, who seems to have believed it.

Authors are in doubt why the name symbol should be given to this compendium of the articles of the Christian faith: some say, it is thus called in allusion to a military custom; that as soldiers were known by signs and tokens, this was to be the mark or characteristic of a Christian. To the purport of Rufinus says, that the Greek word συμβολος may be rendered in Latin by indicium. Others derive it from an assembly or conference of the apostles, where each expressing his sense of the faith, and what each had chiefly preached, the creed was framed, and called by the Greek word συμβολη, which signifies collection or conference.

Lord King derives the signification of the word with greater probability from the sacra, or religious services of the heathens, where those who were initiated into mysteries had certain signs or marks, called symbols, delivered to them, by which they might know each other, and claim admission to the secret worship and rites of that god, whose symbols they had received. He produces many instances of the common use of symbols, both mute and vocal; and in allusion to these he apprehends the creed is thus called, because it was studiously concealed from the Pagan world, and not revealed to the catechumens themselves, till they were initiated by baptism into the visible church; when it was delivered to them, as that secret mark or sign, by which they should be known from all others, and mutually know each other. Hist. of Apostles' Creed, p. 11, &c.

SYMBOLS of Pythagoras. See Pythagoreans.

SYMBOLICAL Characters, Column, Fountain, Fountains. See the subjoined.

SYMBOLICAL Philosophy. See Hieroglyphic.

SYMBOLICAL Physics. See Physics.

Clemens Alexandrinus, Eusebius, &c. observe, that the Egyptians had two ways of representing their sibylline mysteries: one by the virtues of animals, herbs, &c.; the other by geometrical figures. Thus, the sun and moon were represented, in the first manner, by the beetle and ibis; and in the latter, by their own figures. Again, the four elements they represented, after the first manner, by four animals which have qualities corresponding thereto; and after the second manner by +.

SYMBOLISM, a word used by some of the chemical writers to express a confused part of.

SYMOLOGICE, is used by some for that part of the science of medicine, which treats of the symptoms of diseases.

SYMBOLUM, in Ancient Geography, a place of Thrace, between the town of Neapolis and that of Philippos; so called by the Greeks, according to Dion Cassius, because the mountain denominated Symbolus here joined another mountain, which extended into the middle of the country.

SYMBRA, a town of Asia Minor, in the interior of Lycaia, according to Ptolemy.

SYME, See Syma.

SYME, in Geography, an island in the Grecian Archipelago, situated near Cape Volpe, on the coast of Carmania, at the entrance of a gulf which bears its name. Although this island is scarcely two leagues in length, by one in breadth, it has two good harbours fit for the reception of large ships, without reckoning several little bays or coves, in which small craft may find shelter. The north harbour, barred by shoals, is the most spacious as well as the most commodious. The most northern of the shoals which protect its entrance is named San Paolo, because it is opposite to a place of that name, on the coast, at the very head of the gulf. On the other side of Symia the gulf is formed by Cape Crio. Symi was formerly cultivated, and fertile in grain; but at present there are discoverable hardly any vestiges of its ancient culture. Its inhabitants are almost wholly occupied in the fisheries of sponges, which cover the rocks at the bottom of the sea that surround their island. They are reckoned the boldest and most experienced men in the world, diving into the sea to the depth of 120 feet, and there detaching the sponges from the rocks to which they adhere; and having done this, they rise to the surface of the water, in order to take breath for a few moments, and then dive again. The Symiots are also excellent good navigators: with very small boats they cross the intervals of sea which separate them from the coasts, and from the other islands; and, with the produce of their sponges, they carry thither the fruits of their activity, which afford a small traffic, adequate to the wants and ambition of a nation of divers. They are a robust race of men, of a handsome stature. The life of these islanders is simple; and tyranny has spared, or, more properly speaking, defined a tribe, which, in lieu of opulence, presents only a few habits and laborious occupations, the most certain pledge of independence. N. lat. 36° 28'. E. long. 27° 34'.

SYMITHA, in Ancient Geography, a town of Africa, in the interior of Mauritanias Caetariensis. Ptolemy.

SYMMACHUS, Q. Aurelius Avianus, in Biography, a Roman senator of the fourth century, became prefect of Rome, pontiff and augur, and pontiff of Africa. He vigorously refuted the changes that were made in the national religion by the triumphs of Christianity, and headed a deputation from the senate to the emperor Valentinus II., begging the re-establishment of priests and veils, and of the altar of Victory. This application was refused by St. Ambrose, bishop of Milan, who composed an answer to the petition of Symmachus, as did also the poet Prudentius. Symmachus lost his cause, and for some reason was banished by that emperor, or by Theodosius, the latter of whom recalled him, and raised him to the consulate A.D. 391. The petition above-mentioned is preserved in the tenth book of Symmachus's Epistles, still extant. His oratory was of that kind which charactarized the decline of Roman literature. "The luxuriancy of Symmachus," says Gibbon, "confined barren leaves, without fruits, and even without flowers. Few facts, and few sentiments, can be extracted from his verbose correspondance." Of these epistles the best edition, as far as the text is concerned, is that of Scholius, 4to. Augment. 1668. Moreri. Gibbon.

SYMMACHUS, Pope, a Sardinian, and deacon of the Roman church, whose elevation to the pontifical chair terminated a schism which took place in the church at the decease of pope Anastasius II., in the year 498. His opponents attempted to depose him, and laid before Theodoric, king of the Goths, a charge against him of various crimes, requesting that a delegate of his appointment would take cognizance of the cause upon the spot. The emperor summoned the pope; and the tumults at Rome, which had subsided on his election, were universal. Theodoric visited the city, and pacified its disturbances. He summoned a council, which assembled at Rome in July 500, and Symmachus, being summoned to appear, proceeded from the college of pope Anastasius II., attended by a great body of the populace. These were encountered by the opposite party, and in the conflict Symmachus was wounded, and with difficulty made his escape to St. Peter's. At the final meeting of this council, a decree passed, in which Symmachus was acquitted of the crimes laid to his charge, and all persons were enjoined to submit to his pontifical authority, on pain of excommunication. It was on this occasion that the petition
position was first advanced, that no assembly of bishops is authorized to judge the pope, who is accountable for his actions to God alone. In 503, Symmachus held a council at Rome, in which the law of Odoacer, declaring that the election of a pope could not be made without the concurrence of the sovereign, was annulled; and another council, held in 503, confirmed the acts of the council which had abdicated Symmachus; and another was convened in 509, which passed a decree, anathematizing all who should fease or appropriate the goods or estates of the church, though they held them by grants from the crown. Towards the close of his pontificate he made various regulations for reforming discipline in the churches of the West, and he expended large sums out of the papal revenues on religious edifices, and for the support of the Catholics, who were persecuted in Africa. He died in 514, and received the honour of canonization. Eleven of his epistles, and several of his decrees, are extant. Moreri. Bower.

SYMMETRY, συμμετρία, formed from σύμμετρος, with, and μέτρον, measure, the relation of parity, both in respect of height, length, and breadth of the parts necessary to compose a beautiful whole. Comments on how Symmetry, according to Vitruvius, consists in the union and conformity of the several members of a work to their whole, and of the beauty of each of the separate parts to that of the entire work; regard being had to some certain measure: so that the body is framed with symmetry, by the due relation which the arm, elbow, hand, fingers, &c. have to each other, and to their whole.

Symmetry arises from that proportion which the Greeks call analogy, which is the relation of conformity of all the parts of a building, and of their whole, to some certain measure, upon which depends the nature of symmetry.

SYMMETRY, Uniform, in Architecture, is that where the fame ornamentation reigns throughout the whole.

SYMMETRY, Reflection, is that where only the opposite sides are equal to each other.

Under the article Veterinary Anatomy, it was proposed to discuss at large the subject of the symmetry of horses; but we now find that our limits will merely allow of our referring to that article, and also to that of Horse. See also Bacteriology.

SYMPARATAXIS, a word used by Hippocrates to express the confidé between nature and disease, and the agents or medicines given in it.

SYMPASMA, a word used by many authors to signify a cataplasm.

SYMPATHETIC, συμπαθητικός, something that has a sympathy; or that acts, or is acted on by sympathy.

SYMPATHETIC, in Anatomy, an epithet applied to two nerves, from the idea that their communications are the cause of sympathies. One of these is the sympathetic maximus, or great intercostal nerve; the other is the facial, called sympathetic minor by Winslow. See Nerve.

SYMPATHETIC is particularly applied to all diseases which have two causes; the one remote, the other near. In which sense, the word is opposed to idiopathic.

Thus, an epilepsy is said to be sympathetic, when produced by a remote cause; i.e. when the disorder in the brain, embarrassed with blood, is preceded and produced by some other disease.

There is sympathetic palpitation of the heart, and an idiopathic one. There is but one idiopathic cause of the palpitation; but there are several sympathetic ones.

Among chemists and alchemists, the term sympathetic is principally applied to a kind of powder and of ink.

SYMPATHETIC Ink. See Ink.
nefs, &c. &c. These are called sympathies, or content of parts. An organ, to which no direct application is made, suffers in consequence of what is done to another. See, for a further account of this subject, Nervous System, under the head of Nerves of the animal life.

We have some practical remarks on the sympathy of the parts of the body, in the Medical Essays of Edinburgh, vol. v. part 2. art. 45.

For the force and effect of sympathy, in the production of monsters, see Monster.

SYMPHESIS, a word used by the old Greek writers to signify connection or digestion.

Gen. Ch. Cat. none, unless the corolla be so denominated. Cor. regular, or four oblong, equal, deciduous petals, cohering at the base. Nectaries none. Stam. Filaments four, inserted into the middle of each petal, linear, cohering at their upper part; anthers terminal, oblong, dilated. Pilt. Germ. four, similar to the rudiments of two seeds; style simple; stigma rather abrupt. Peric. Nut cylindrical, with a solitary kernel.

A genus of humble shrubs, or herbs, either smooth, or bearing a few flatter glandular hairs. Leaves in three deep, divided segments; the lower ones opposite. Sepals simple, terminal, and partly from the bottoms of the uppermost leaves. Flowers yellow, alternate, sessile, with foliaceous, hooded, permanent bracteas. Mr. Brown considers his Symphionema as not particularly allied to any other, except perhaps to his Agathachys, which has separate filaments, and an unilateral stigma. Two species only are known.

2. S. montanum. Symphonema. Br. n. 2.—Segments of the leaves flat, linear, fine-ribbed. Bracteas and flower-flalk downy, with very short glandular hairs.—Gathered by the same botanist, on moist rocks, in the same neighbourhood.

Gen. Ch. Cat. Perianth inferior, of five roundish, spreading, imbricated leaves, permanent. Cor. Petals five, roundish, rather coriaceous, concave, much larger than the calyx, folding obliquely over each other, and converging, so as to form a slightly depressed globe. Stam. Filaments united into a circle, even, cylindrical tube, the length of the petals, slightly inflated at the bottom, sheathing the fyle; anthers five, ovate, acute, sessile on the margin of the tube, spreading. Pilt. Germ. superior, ovate; fyle cylindrical, rather longer than the corolla; stigmas five, oblong, acute, spreading, alternate with the anthers. Peric. berry globose, of five cells. Seeds solitary, nearly globular, smooth, flat, rather oval, the inner side.

Eff. Ch. Calyx of five leaves. Corolla globose, of five petals, folding obliquely over each other. Style one. Berry superior, of five cells. Seeds solitary.

1. S. globulifera. Linn. Suppl. 502. (Moronoboa esculenta; Aubl. Guian. 788 t. 353. f. a–x ?)—Native of Surinam, from whence Dalberg first specimens, preferred a spiritus, to Linneus. This is a fragrant and lovely tree; its smaller branches rather quadrangular, smooth, leafy, lightly scented. Leaves crowded about the ends of the branches, flat, opposite, crossing each other, elliptic-lanceolate, pointed, entire, very smooth, three or four inches long, with one rib, and many fine transverse parallel veins. Foliage channelled, half an inch long. Flowers four or five, red, forming a sort of terminal, simple umbel, whose flals are angular, smooth, above an inch long. The berry has a coriaceous coat, enclosing a very yellow slimy pulp, in which are lodged the partil-coloured seeds. The latter are said to be a favourite food of parrots.

Such is the plant of Dalberg, preferred in the Linnean herbarium. Neither him, nor the original species of Aublet agrees with it as to inflorescence. But his four representations of the fruitification, fig. a to j, undoubtedly agree with the Linnaean specimem, and are of the same sort; while his fig. k to z, represented larger, though described smaller, are certainly very different, particularly the fruit. Aublet appears to have conceived two different sorts of fruits, as well as the trees he describes yield a resin, which serves the natives of Guiana as a strong and useful cement.

SYMPHONIACA, a name given by some authors to the common bayberry or herbane.

SYMPHONIACO STILIO. See STILIO.

SYMPHONIALE, in the Italian Muysc, is sometimes prefixed to a canon, or fugue, to shew that it is at mid-mass. In. i. the that the second part is to follow, or imitate the first is the same intervals, founds, notes, &c., the third to observe the same with regard to the second, and so on.

SYMPHONY, the name of a musical instrument often mentioned in the Fabliaux and old French poetry. It is sometimes called Chiphonie, sometimes Cicëne, but more frequently Sympoïne. Some of the quotations given by Du-Cange describe it as a wind-instrument, and others as a species of drum, pierced with holes like a siffle.

"Je fai jugler de vielle; Je fai de mufe et de fafielle, Et de harpe et de chiphonie. De la gigue, de l'harmonie."

Here are seven instruments mentioned in the compass of four lines.

"All the minfrel art I know, On the vielle I well can play; I the pipe and lynx blow, Harp and jeg my hand obeys, Paltry, symphony, and note."

Zarlino speaks of a Tuscan instrument, which he says was very ancient, and which was called Singonie. According to his description, it was a kind of cithar, upon which the strings were tuned, 4th, 5th, and 8th. The three strings were perpetually foundning in the bafe, while an air was played on the most acute string.

Zarlino adds, that some authors, among whom was Otto-marus Licinius, imagine that this instrument was the tre
SYM

ancient lyre, and probably that of which Horace speaks in the "Ars Poetica."

"Ut gratas inter menas symphonia dics or."%

It should seem from Zarlino's account of this instrument, that he was persuaded the ancients had harmony, or music in parts, and such instruments as he has described.

It is not easy to conceive how this instrument was tuned: for if the 4th and 5th were diatonic close to each other, when struck together, they would produce the harsh discord of the tone major. Perhaps Zarlino means to say that the fourth strings were tuned in the following manner: the first, or highest string C, the second G, the fourth below, the third C, the fifth below G, and octave to the first C, and the fourth C, double octave below the first. But to play an air upon the first string, implies a neck to the lyre, of which we are acquainted with no instance.

The instrument called symphony is mentioned in Daniel, ch. iii. 5, 7. If it was in the shape of a longish chest, or a trigon, strung at the top and played with little ivory rods, as some imagine, we think it more resembles the modern dulcimer than any instrument in present use.

SYMPHONY, Σωμφορία, formed from σωμφος, proper denotes a coinage, or concert of several sounds agreeable to the ear; whether they be vocal or instrumental, or both; called also harmony; which see.

Some authors refrain symphony to the sole mode of instruments: in this sense, say they, the recitatives in such an opera were intolerable, but the symphonies excellent.

The symphony of the ancients went no farther than to two or more voices or instruments set to unison; for they had no such thing as music in parts; as is very well proved by M. Perrault: at least, if ever they knew such a thing, it must be allowed to have been early lost.

It is to Guido Arsenties, about the year 1022, that most writers agree in ascribing the invention of composition; it was he, they say, who first joined in one harmony several distinct melodies; and brought it even to the length of four parts, vis. bass, tenor, counter-tenor, and treble. But there is nothing, says the ingenious Dr. Burney, more difficult than to fix such an invention as this upon any individual; an art utterly incapable of being brought to any degree of perfection, but by a slow and gradual improvement; and the successive efforts of ingenious men during several centuries, must have been trivial and inconceivable in its infancy; and the first attempt at its use necessarily circumcribed and clumsy. This excellent writer has impartially examined and rectified the evidence for and against the antiquity of harmony or counterpoint; and, after an elaborate detail, expressed his own opinion against it; and he has also given a lift and analysis of the writings of Guido, in order to ascertain how much modern music has been indebted to this celebrated monk of Arezzo. Hift. Music, vol. i. p. 112, &c. vol. ii. p. 72, &c.

The word symphony is now applied to instrumental music, both that of pieces designed only for instruments, as sonatas and concertos, and that in which the instruments are accompanied with the voice, as in operas, &c. A piece is said to be in grand symphony, when, beside the base and treble, it has also two other instrumental parts, vis. tenor and fifth of the violin.

Before the above was written, symphony had been highly cultivated in Germany, particularly at the Hanover school, by Stamitz, Holtzbruner, Canabich, Toetschi, and Filtz; by Vanhal, Ditters, and Kozeluch, at Vienna; and since that period, the symphonies of the immortal Haydn have exceeded in number and excellence all that modern times can boast; and seem to include every perfection that can render instrumental music interesting and sublime: invention, science, knowledge of instruments, majesty, fire, grace, and pathos by turns, with new modulation, and new harmonies, without cruelty or affectation. All these excellencies the admirable Mozart had nearly attained; and perhaps he is only inferior to Haydn in the number of his symphonies, from the circumstances of his vital count. Beethoven (pronounced Beethoven), a disciple of Mozart, is now (1804) so rapidly advancing into fame, that there would be little risk in predicting, that, if he lives, he will be the great man among musicians of the present century, as Haydn and Mozart were of the latter end of the last. He is said to be a young man; but writes with the freedom and boldness of long experience, and a fertility of invention that promises inexhaustible resources.

SYMPHORICARPOS, in Botany, is a genus founded by Dillenius, in his Hortus Elthemenis, 371. t. 278, and named by him from Σωμφορίας, to clumber, or accumulate, and κάστρον, frut, alluding to its copiously clustered berries. Jullien has retained this genus, Gen. 211, with some others, which, like it, have been reduced by Linnaeus to Lonicera. (See that article). Dillenius perceived the resemblance of its foliage to that tribe of Honeysuckles called Chaemerae; but seems to have had no idea of any affinity to them in its fructification, which he compares to Cynarita. We may remark that the Chaemerae connect Symphoricarpos with the genuine Honeysuckles, (Castrifusus and Parthenocerus,) however unlike, at first fight, the two extremes may be. They, like their relation Diervilla, are all easily kept separate by artificial characters; but the question is, whether they all together constitute a natural genus, or a section of a natural order, into which section Jullien has well introduced Linnea and Triofeleum, though he has now wisely removed Oenula from hence to his Vitaceae.

SYMPHYSIS, in Anatomy, a general term for those concretions of bones, in which they are immediately joined together, without forming a moveable joint. See Joints.

Gen. Ch. Cal. Perianth inferior, permanent, ere, five, five-edged, cloven into five, acute segments. Cor. of one petal, bell-shaped. Tube very short. Limb tubular, ventricose, a little thicker than the tube; mouth five-toothed, obtuse, reflexed; throat fuscous by five lanceolate rays, shorter than the limb, converging into a cone. Stam. Filaments five, awl-shaped, alternating with the rays of the throat; anthers acute, ere, concealed. Fil. Germens superior, four; syle thread-shaped, the length of the corolla; stigma simple. Peric. none, except the enlarged, widened calyx. Seeds four, gibbous, pointed, converging at the tips.

SYMPHONY

Engl. Bot. t. 817. Curt. Lond. fasc. 4. t. 18. Woodv. Suppl. t. 215. Pl. Dan. t. 664. — Leaves ovate-lanceolate, decurrent. — Found on the banks of rivers and ditches, flowering in May and June. — Stem perennial, flaxey, mucilaginous; black externally. Stem two or three feet high, erect, leafe, winged, hispid with deflexed hairs. Leaves rough, decurrent; the radial ones stalked, broader. Clusters in pairs, hispid, dichotomous at the base. Flowers yellowish-white. — There is a variety of this species with red or purple flowers.

"Comfrey root abounds in a pure, tafteleaf mucilage, like that of the Marsh-Mallow; and being (as Woodville observes) more easily obtained, it ought not to be omitted in lists of medicinal plants. Such medicines are useful in irritations of the throat, inflamations, and, above all, the bladder." — 2. S. tuberosum. Tuberous-rooted Comfrey. Linn. Sp. Pl. 195. Engl. Bot. t. 1523. Jacq. Auct. t. 225. — Leaves ovate, slightly decurrent; the upper ones opposite. — A native of Germany and of Scotland, in moist, shady places, though by no means a common plant. It flowers in July. — Stem perennial, tuberosous; white externally. Stem a foot high, scarcely winged, rough, with deflexed hairs. Leaves ovate, on winged stalks, which are a little decurrent. Clusters in pairs, terminal. Flowers few, yellowish or greenish-white, cylindrical.

3. S. orientale. Evers. Comfrey. Linn. Sp. Pl. 195. (S. confantinopolitanum boraginis folio et facie, flore albo; Buxb. Cent. 5. 46. t. 68.) — Leaves ovate, slightly stalked. — Native of Turkey, on borders of rivulets; flowering from May to July. — Stem perennial. Stems about two feet high. Leaves ovate, rather broad, armed with rough, prickly hairs. Flowers clustered as in the foregoing species, of a blue colour.

4. S. asperum. Prickly Comfrey. Ait. Hort. Kew. n. 4. Sims in Curt. Mag. t. 929. — Stems prickly. Leaves oval, acute, stalked, the floral ones opposite. Clusters in pairs. — Native of Caucasus, flowering through the summer. — "This species (says Dr. Sims) is by far the largest of the genus, growing to the height of five feet, and is really an ornamental, hardy perennial, which will thrive in any soil or situation." — Stem upright, rather wavy, covered with curved prickles. Leaves large, dark green. Flowers in drooping clusters, of a rich blue; the buds of a deep crimson.

SYMPHYNUM, in Gardening, contains plants of the hardy, herbaceous, perennial kind of which the species cultivate are; the common comfrey (S. officinale); the tuberous-rooted comfrey (S. tuberosum); and the Oriental comfrey (S. orientale). In the first sort there are varieties with white flowers, purple flowers, with blue flowers, and with red flowers.

Method of Culture. — These plants may be increased by seeds or parting the roots, but the latter is more practicable. The seeds should be sown in the spring, in a border of common earth; in the autumn the plants will be proper to set out where they are to remain, or to remove into other pots. The roots should be parted in the autumn, and planted out either in beds about a foot from plant to plant, or where they are to remain; almost every part will grow, and the plants are hardy, and succeed in any soil or situation; they only require to be kept clean afterwards. They produce variety in mixture in the borders and other parts of ornamental grounds.

SYMPLEXIUM, in Natural History, the name of a genus of foills, of the class of the seleritaceae, but not of the subclass of regular figure of most of the genera of those bodies, but composed of various irregular connections of differently shaped, and usuflally imperfect bodies. The different bodies that form this kind are seldom quite perfect, having usually fallen together before they were wholly hardened; but generally, whether they form a larger or smaller mass, they together affect the external figure of a flat column, though variously notched at the sides, and truncated at the ends. Hill.

Gen. Ch. Cul. Perianth superior, bell-shaped, in deep, roundish-ovate, concave, permanent segments, as if of one petal, bell-shaped, longer than the calyx, composed of from five to ten ovate, entire, reflexed segments, or petals, united by their claws into a tube the length of the calyx, and all falling off together. Stem. Filaments numerous, linear, flat, erect, attached to the tube of the corolla in several imbricated rows, and combined equally at their base into one set; anthers roundish, two-celled, erect. Pist. German inferior, truncate; style thick, the length of the filaments; stigma capitate, distinctly five-lobed. Pericarp elliptic-oblong, dry, one cell, crowned with the calyx. Seed. Nut of the same form, striated, of from three to five cells, with an oblong cylindrical kernel in each.

Eff. Ch. Calyx superior, in five deep segments. Petals five to ten, united at the base. Stamens in several rows, inserted into the corolla. Drupa dry. Nut of from three to five cells.

1. S. martincinaco. Martincio Symposcos. Linn. Sp. Pl. 747. Willd. n. 5. Jacq. Amer. 185. t. 175. f. 6. Swartz Obs. 293. t. 7. f. 1. — Stalks somewhat racemose. Leaves crenate, very smooth on both sides. — Found in the woods of the island of Martinico, flowering November. A branching tree, twenty feet high. Leaves scattered, stalked, ovate, acute, two or three inches long, shining, somewhat coriaceous. Flowers stalked, stiltie, solitary or slightly racemose, white, smelling like hawthorn, and about the same size.

2. S. Cipinoma. Guiana Symposcos. Willd. n. 2. (Cipinoma guianensis; Aubl. Guiana, 567. t. 276. Ceva Diff. 271. t. 217.) — Stalks many-flowered, the length of the footstalks. Leaves nearly entire; villous at the back. — Native of woods and waste ground in Guiana, bearing flowers and fruit in September. A middle-sized tree; trunk seven feet high, and seven inches in diameter, with grey bark. Leaves stalked, about three inches long, elliptical, pointed; smooth above; clothed when young, as well as the branches, with flesh-coloured hairs. Flowers little axillary tufts; their corolla white, edged with yellow.

SYM

flowered. Leaves ferrated, nearly naked."—Gathered by
Dombey in the woods of Peru. L’Heritier considered this
as intermediate between the two former, and supposed they
might all possibly be varieties of one species.

Occ. 1837. Wild. t. 14.—Petalas eight, slightly connexed.
Stalks single-ferrated. Leaves finely ferrated, smooth on
both sides. — Native of lofty mountains, in the south
part of Jamaica, flowering in July and August. A tree
20 to 30 feet high, with smooth brittle branches. Leaves
bright green, broader than in the first species. Flowers
about the size of a lemon-blossom, white, fragrant, with a
very short tube, and always eight divisions. Fruit the size of a
filbert. Swarts.

Wild. n. 5. Alt. n. 1. (Hopea tinctoria; Linn. Mant.
195. Pursh 451. Arbor laurifolia, floribus ex foliorum
alis; Catechu. Carol. v. 1. 544, with a plate.) — Flowers
nearly sessile, axillary, crowded. Leaves slightly ferrated,
rather glaucous. In the low woods of Virginia and Caro-
olina, flowering in April and May, when its scent is very
agreeable. Dr. Garden sent it to Linneus, and called it
Hopea, after Dr. Hope, professor at Edinburgh. (See our
Hopea.) We believe it was also sent alive to Dr. Fothergill
by the same person. This is a shrub or small tree. The
trees are oblong-lanceolate, occasionally downy beneath,
have a sweet taste, and dye a fine yellow. Flowers yellow,
small, very fragrant.

Wild. n. 6. (Allontia theciformis; Linn. Suppl.
264.)—Petals about ten, slightly connexed. Flowers axi-
illary, sessile, about three together. Leaves elliptical, ob-
tuse, slightly ferrated, smooth. — Gathered by Mutis in
New Granada. A smooth rigid shrub, with coriaceous,
veiny, shining leaves, hardly an inch and half long, on
short thick stalks. Flowers white, nearly the size of a
hawthorn. The younger Linneus thought the leaves tasted
like tea, and might serve as a substitute for that plant, but
they would be even more out of our reach. It is singular
that the genera dedicated to two Edinburgh professors,
should thus coalesce under another previously established.

SYMPOSIAC, συμποσιακός, formed from συμποσίω, feast; a conference or conversion of philosophers at a
banquet.

STANDARD, which has nine books, which he calls Symposiacs; or
symposiac questions, q. d. disputations at table.

SYMPOSIARCH, συμποσιαρχός, in Antiquity, the direc-
tor, or manager of an entertainment. This office was some-
times performed by the peron at whose charge the enter-
tainment was provided; sometimes by another, named by
him; and at other times, especially in entertainments pro-
vided at the common expense, he was elected by lot, or
by the suffrages of the guests. He was otherwise called
Bacchus, rex, and moderator, &c. he determined the laws
of good fellowship, and observed whether every man drank
his proportion, whence he was called opisthaleus, occator, the
eye.

SYMPTOM, in medicine, denotes any change in the
body, or its functions, perceptible either to an observer, or
to the patient himself, which indicates disease. On some
occasions, the diseased condition may itself come under the
consciousness of our senses, as when an external part has re-
ceived a mechanical injury. But in the great majority of
cases, the essential natural state, or that which constitutes
the disease, is concealed from our immediate view, and its
existence can be inferred only from the observation of some
of the remote effects which it has produced, either on the
appearance and external qualities of some parts of the body,
or on the condition of some of its functions; among which
must be comprehended the disordered sensations which the pa-
tient may experience. They are the observable effects, that
are properly the symptoms of a disease; they are the signs
or indications of the existence of a certain morbid condition,
of which they are the usual concomitants; and their affirma-
blage constitutes a fort of language, which it is the business
of the physician to understand and interpret.

It is in this interpretation of the phenomena, that the
chief application of science consists, as is indeed the case
in all the departments of human knowledge; but in medi-
cine, our reasonings in regard to the series of changes
which have preceded the observed effects, are liable to a
peculiar source of fallacy, from the disordered nature of
the phenomena on which they must be founded. The
more important internal changes are removed from our
view, and all that we are admitted to view, in the course
of a disease, is a certain number of symptoms, which are
generally not the immediate result of the primary, or, as it
has been termed, the proximate cause. A long and laborio-
ous induction is, therefore, required to enable us to trace
the intervening steps which connect the appearances together,and
assign to each its proper rank. The infensibility of
many organs, even of those connected in the with the
symptoms which prevail between contiguous and dif-
tant parts; the subtle organisation and obscure nature of the
functions of others, introduce much ambiguity in a variety
of cafes. But in the determination of diseases, we gen-
erally derive much more assistance from the presence of par-
ticular symptoms, which are observed more uniformly to
accompany a certain morbid condition, than we do from
that of others, which are not so constantly met with in con-
junction with, or which may exist totally independent of,
such a state. The former are the characteristic symptoms
of the disease; or, as they have been termed, the patho-
nomonic or diagnostic symptoms; being those on which
reliance is to be placed in establishing the diagnosis:
the latter are more accidental, and contribute less directly
to the same object; or may, in other cases, be altogether dis-fis-
regarded, as of no value in the solution of the problem.
Many symptoms of this latter class, on the other hand,
which are but remotely connected with the primary morbid
affection, are the source of much suffering to the patient,
and their removal or palliation is an important object in the
treatment. It is, however, a common error of superficial
reasoners, to suffer their attention to be so wholly engrossed
by the consideration of some predominant symptom, as to
overlook the remote source of the disease, and to limit their
efforts to the relief of the one, without providing for the
cure of the other. This may happen even when the symp-
tom in question is essential to the disease, as is strongly ex-
emplified in enteritis, where the removal of pain and con-
stitution of the bowels, which are the most prominent symp-
toms of that disease, is sometimes injudiciously considered
as the leading indication, to the neglect of remedies cal-
culated to remove the inflammation, from which these
symptoms have in fact originated; and which, if suffered to
continue, would reproduce them in an aggravated degree,
even had we succeeded in obtaining a temporary alleviation.
See ENTRITAS.

A general classification of the symptoms of diseases, and
a review of the principal kinds, has been already given
under the article DIÁBÁSIS.

SYMPTOMATIC is a term applied to diseases, which
are the consequences of some prior disorder in some other
part of the body. It is opposed to idiosyncratic, which see.
SYMPTOMATICAL Classification of Diseases. See Nosology.

SYNÆRESIS, συναρέσις, contraction, in Grammar, a figure, by which two syllables are united in one. As compare Government. See CONTRACTION.

SYNAGOGUE, συναγωγή, literally importing family, congress; a particular assembly of Jews, met to perform the office of their religion. Allo the place in which they meet.

The Jews used the term in the primary sense, when they speak of the great synagogue; meaning the court of the seventy elders, which they pretend to have been intituted originally by Moses, and the members of which they afterwards increased to one hundred and twenty. See SANHEDRIN.

Some authors take the use of synagogues to be of no old standing among the Jews; and maintain, that it was not till after their return from the Babylonish captivity, that the opinion first prevailed, that the worship of God was not to be restrained to the temple at Jerusalem, that it could not be held any where else. The consequence of which new opinion was, that the Jews began to build for themselves synagogues in all their cities.

Others hold that there were synagogues even in the time of David, and that they were as ancient as the ceremonial law (see Levit. xxii. 3. 4. Deut. xxxi. 11, 12. P. ixxiv. 4. 8.) but be this as it will, no assemblies of the Jews appear to have been called synagogues till a little before the coming of Jesus Christ, who is said to have preached in the middle of the synagogue. That they had been in use before this time, is evident from the declaration of St. James (Acts xv. 21.) "Moses of old time hath in every city them that preach him, being read in the synagogues every sabbath-day."

The synagogues were used, not only for divine service, but for holding courts of justice, especially upon ecclesiastical affairs. To this use of synagogues, some have supposed that St. James refers, ch. ii. 2—4.

The Jews erected synagogues not only in towns and cities, but also in the country, especially near rivers, for the convenience of obtaining water for washing and purifying.

They were not allowed to build any synagogue in a town, unless there were in it ten persons of piety; i.e. as the Talmudists have interpreted this phrase, ten persons of learning and approved integrity, free from all worldly occupations, and disengaged from all civil affairs, who were maintained and hired by the public, that they might always resort first to the synagogue, so that whoever came in might find ten persons there; which number was necessary, as the Jews thought, to make a congregation. When a synagogue was built, it was consecrated by prayer, without much ceremony or formality; and it was regarded as a sacred place, which was carefully guarded from profanation. There might be several synagogues in the same city; and as the Jews say, they had 480 in Jerusalem. The most famous synagogue the Jews had, was the great synagogue of Alexandria, of which the rabbins say, that he who hath not seen it, hath not seen the glory of Israel.

The chief things belonging to a synagogue were the ark or chest, in which was deposited the book of the law, i.e. the pentateuch; the pulpit, with a desk in the middle of the synagogue, in which stood up the person who was to read or expound the law; the seats or pews in which the people sat for hearing the reading and exposition of the law; of which seats some were more honourable than the others, those of the elders being called in the gospels the "chief seats," (Matt. xxiii. 6.) the women sitting by themselves in a kind of balcony or gallery; the lamps that were fixed in the walls, or hung to the ceilings, and the rooms or apartments in which the utensils belonging to the synagogue were kept.

For the regulation of the synagogue service, there was a council or assembly of wise and grave persons, well versed in the law, over whom was appointed a president, who was called the "ruler of the synagogue," a name which was sometimes given to all the members of this assembly, (Mark. v. 35. &c. Luke, xiii. 41.) The business of these persons was to order every thing belonging to the synagogue, and also to teach the people. The government which they exercised in the synagogue consisted of several particulars: they punished the disobedient and refractory cenfures, excommunication, fines, and scourging; they took care of the alms, called by the sacred writers, as well as the rabbins, "righteousness," (Matt. ix. 18. Mark. v. 36. Acts, xvii. 8. iv. 5.) and the chief ruler, or one of the rulers, gave leave to have the law read and expounded, and appointed the person who should do it. In the ancient synagogue, as it was first established by Ezra, the priests and Levites delivered their discourses for the purpose of facilitating the understanding of the text of the sacred writings. And in our Saviour's time, the duty of preaching and of permitting others to do it, belonged to the ruler of the synagogue. (Acts, xiii. 15.) Some persons have expressed their surprise, that our Saviour and his disciples should obtain the permission of the president, or ruler, to preach in the synagogues; but it should be considered, that they were Jews, and strict observers of the law; that they were well versed in it and even in the rabbins and doctors, (Acts, xiii. 1. Matt. xxvii. 55. Acts, xiii. 14. 1 Cor. iv. 30.) and moreover, that if they had not been doctors, they might have claimed this privilege, as persons of gravity, learning, and unblamable conduct.

In every synagogue there were several ministers, to whom different employments were assigned; one, called the "advocator, or angel of the synagogue," (theiach siebhor) the rood before the ark in which the seriptures were kept, and repeated the prayer "Cadich," before and after reading the law; another, called "minister of the synagogue" who, from the pulpit, gave notice to the Levites when they were to found the trumpet; this minister sometimes read the law; and another minister, called "guardian or keeper" (chafan,) whose business it was to take the book of the law out of the chest, to give it to the reader, and to lay it up again; to call out to him that was to read the lesson out of the law or the prophets, to stand near him, and to correct him if he read amiss; to blow the trumpet, and thus give notice of the sabbath, of the beginning of the new year, to publish an excommunication, &c.; to inform the people when they should say "Amen," after the prayer repeated by the angel of the synagogue before and after the reading of the law; and to take care of the synagogue, and of its utensils.

The service of the synagogue was performed three times in a day, viz. in the morning, in the afternoon, and at night.

In the morning service, before the public prayers by the angel of the synagogue commenced, the people repeated several private prayers, viz. 19, of considerable length. When they were ended, the minister, public prayers, the people likewise standing, and bowing the knee and body at the rehearsal of some particular passages; and their service began and ended with the prayer "Cadich," similar to our Lord's prayer. When prayers were ended,
SYN

the chafan took out of the chest the book of the law, upon
which the whole congregation shouted, and expressed great
joy. This book consisted of several large volumes or rolls of
vellum, filled or glued very neatly together, and fastened
at one end to sticks very nicely turned. For an account of
the manner of reading the pentateuch, see PENTATEUCH
and PARASHU. After the section for the day, which
was subdivided into seven parts for so many readers, was
read and deposited by the chafan in the chest, the next part
of the service was some thanksgiving or doxology, ending
always with the prayer Cadimah. After the reading of the
law or pentateuch, which was read over once every year, there
followed that of the prophets, before which they read some
passages out of the writings of Moses. On Mondays and
Thurdays they read only the law; but on the sabbath, as
well as on fast-days and festivals, they read the prophets, and
only in the morning; for in the afternoon they constantly
read only the law. The books which the Jews meant by
the prophets were those of Joshua, Judges, Samuel, Kings,
and Chronicles, which they supposed to have been written
by prophets, denominated the "former prophets;" and they
referred to the second class Hiaiah, Jeremiah, and Ezekiel,
with the 12 lefher prophets, all of whom they called the "latter prophets." Daniel was not included among the
prophets. Accordingly, by the law and the prophets,
mentioned in the New Testament, we are to understand the
five books of Moses, and the prophetic writings above
mentioned. The same ceremonies occurred before and after
the reading of the prophets as at the reading of the law,
except that there were some additional thanksgivings then
repeated. Portions of the prophetic writings were selected,
which portions had a relation to what had been previously
read out of the law.

After the Hebrew language ceased to be the mother-
tongue of the Jews, the holy scriptures were from that
time interpreted in their synagogues, either in Greek or
Chaldee; and this practice gave rise to the Chaldean
paraphrases now extant. Some suppose that this cus-
tom was established by Ezra; others, with greater probabil-
ity, fix the commencement of it to the time of the Mac-
cabees. The mode of interpreting was as follows: the
minister, or any person appointed to read, read one
verse in the original Hebrew, if it was out of the law, and
three verses, when it was out of the prophets; then the in-
terpreter rendered the whole in the vulgar tongue. The
interpreter was esteemed by the Jews less honourable than
the reader, from respect to the original text; and very
young persons were admitted into this office. Some pas-
sages it was not lawful to interpret: such were the incest
of Reuben, of Thamar, and Amnon, the bleeding which used
be given by the priest (Num. xi. 23—26.), and the lat-
ter part of the history of the golden calf (Exod. xxil.
31—35.) The reading of the prophets, according to the
rabbins, was closed with the priest's bleeding; after which
the congregation was dismissed, unless somebody was ap-
pointed to preach.

The afternoon service consisted in singing the 8th
psalm, from v. 5, to the end, and the whole 145th, in
rehearsing the prayer Cadimah; in saying first in a low
voice, and afterwards aloud, one of the prayers that had
been said in the morning, with several other prayers and
thanksgivings; and in repeating the prayer Cadimah, which
concluded the service.

The evening service was almost the same. One of the
principal ceremonies performed in the synagogue was cir-
cumcision; though this was performed sometimes in private
houses.

There are synagogues in all the principal towns in Europe,
where Jews reside.

SYNAGRIS, in Ichthyology, a fish caught in the Archi-
pelago, and some other seas, and much resembling the
dentex. Some have used it as a synonym for that fish, and
others accounted it only a name applied to the dentex while
young; but it is properly a distinct species.

According to Arctedi, it is a species of the sparus, and is
distinguished by him by the name of the variegated sparus
with a sharp back, and with four large teeth. Linnaeus also
makes it a species of sparus; which see.

SYNALOEOPHA, ουσιναεπά, from συν, together, and λεοπά, I
aimus, in Grammar, a contraction of syllables, performed
principally by suppressing some vowel or diphthong at the
end of a word, on account of another vowel or diphthong at
the beginning of the next. As ill' ego, for ill' epo, &c.

"Conticuer omnes intensi' ora tenebant." Virg.

It is called by the Latins collisia.

SYNANCHE, in Medicine. See SYNANCHE.

SYNAPHE, in the Ancient Greek Muse, the conjunc-
tion of two tetrachords, or more exactly, the union of two
conjoint tetrachords, by the last found of the one being
the first of another. There are, therefore, three synaphes in
the Greek system: one between the hypate tetrachord and
that of the mefe; the other between the mefe tetrachord and
that of the fysmenwmen; and the third between the disjunct
chords and that of the hyperboleon. See SYSTEM and
TETRACHORD.

SYNAPHEA, in Botany, so named by Mr. Brown, from συναφή, a conuision or cohesion, on account of the peculiar
union of the stigma to one of the filaments which bears
no anther.—Brown Tr. of Linn. Soc. v. 10. 155. Prodr.
Nov. Holl. v. i. 360. Bot. of Terra Austr. 14.—Clais and
Brown.

Gen. Ch. Cal. none, unless the corolla be so denominated.
Cor. of one petal, ringent, deeply four-cleft, and at length
splitting into four parts; tube swelled; upper lip con-
cave, undivided; lower in three acute spreading segments,
the middle one smallest. Stam. Filaments four, inserted
into the tube of the corolla, and concealed within it; the
uppermost abortive, its point connected with the stigma; two
lateral ones bent forward at an acute angle; lowermost
broader, erect; anthers oblong, of one cell, two situated
back to back on the lowermost filament, one on each of the
lateral filaments, combined with the others laterally before
they burst, so that each pair forms in appearance but one
anther, bursting at the point of connection. Pfil. German
superior, inversely conical, brilly at the summit, without
any glands at the base; style club-shaped, curved, smooth,
deciduous; stigma dilated, oblique, crowned with one or
two erect horns, and strongly united behind to the abortive
filament. Seed. Nut solitary, obovate, fringed at the upper
dge with numerous spreading bristles, about its own
length.

Eff. Ch. Calyx none. Corolla four-cleft, ringent, bear-
ing the flaments. Anthers two on the lower filament.
Upper filament abortive, combined with the stigma. Nut
crownd with bristles.

This genus is separated by Mr. Brown from CONOPE:
MUM, (see that article,) chiefly on account of the very ex-
traordinary connection between the stigma, and the upper-
most filament, which is imperfect, bearing no anther. His
ideas of the flaments, in both genera, differ from ours;
but the subject is obscure, and we are guided by the analogy
of other plants in the same natural order, to consider the
authors
SYNTHROUSMUS, synarthroseus, in Rhetus, a figure which, in order to magnify a thing, whether good or bad, enumerates a great many different perfections, absurdly, so to which it relates: thus Cicero, "qui mihi venturum quod fumus, me fratri amantissimo, liberis nostris parentes, soci liberos; qui dignitatem, qui ordinem, qui fortunas, qui amplissimam rem publicam, qui patriam, qui nihil poterit e jucundius; qui denique nonmet ipnos nobis reddita." See Volf. Rhet. lib. v. p. 372.

SYNARTHROSIUS, in Anatomy, that kind of union of bones, in which no motion takes place.

SYNAULIA, the union of many musicians, who in the ancient music played on flutes in the antepalonal manner, answering each other alternately, without any mixture of voices. Rouleau observes that Malcolm, who decided whether the ancients had any music composed expressly for instruments, yet has circumcised Athenæus this account of the synaulia. He is, however, right in his first opinion: for these synaulia were nothing more than vocal music played by instruments, in a concert of unisons and octaves.

SYNEBRANCHUS, in Ichthyology, a genus of fish of the order Apodes, established by naturalists since the time of Linnaeus. The body is cell-shaped, it has no pectoral fin, and the spiracle is single beneath the neck. This genus differs from the Muraena, which feeds, in the circumstance of the spiracles or branchial orifice being single, and situated beneath the throat. There are but two species.

MARMORATUS; Olive-brown Synbranchus, marked with blackish spots; the body is yellowish beneath. The general species of this animal is that of a murrena: is about 30 inches long; the head is large, short, and thick; mouth moderately wide, and furnished with several rows of small conical teeth; the tongue is connate; lips fleshy, maxillaries simple, seated near the eyes, which are blue; the base of the body is thick and loofe; the back is of a deep ochre colour, with dusky spots; the belly and flanks are of a yellowish cast, and the spots on those parts have a tinge of violet. The dorsal or rather the caudal fin is extremely remote from the head, and surrounding the tail, unites with the vent-fin; the vent being situated at the distance of five inches from the end of the tail, which terminates acutely. It is a native of the fresh waters of Surinam.

IMMACULATUS. This is of a plain unvariegated colour: it is much allied in general form to the preceding, but is considerably smaller, and very different in colour, being nearly of a uniform brown throughout, with the exception of a few very obscure sub-tranverse dusky bars across the body, and a few whitish marblings on the fins. This, like the former, is a native of Surinam.

Dr. Shaw has mentioned another genus, denominated Spagerrachthus, which is so much allied to the latter noticed, that it may be described in this place. It has an cell-shaped body, and no pectoral fins: it has two spiracles beneath the neck.

ROSTRATUS, with the upper lip produced into a nose. This fish, as described by Dr. Bloch, measures about six inches, and is of a cylindrical form: it is situate both on the sides of the upper jaw is considerably longer than the lower, being indeed sharpened into a point: the eye is small; the teeth numerous; and the two spiracles or branchial orifices are situated at about an inch beyond the mouth, immediately beneath the neck or fore part of the body. The colour they are opposite when only equal in number to their divisions.
SYN

colour of the whole animal is of a pale brown. It is finely
figured in Dr. Shaw’s fourth volume.

SYNBRON, in Geography, a town of Germany, in the
margrave of Anspach; 6 miles S. of Feuchtwang.

SYNCAPE, formed of συν, and κατέβας, bending, a word
used by the old writers to express the joint, or flexure,
where the upper part of the arm is joined to the lower.

SYNCHRONOS, συνήθεια, in Logic, denotes a word which, signifying little or nothing of itself, yet
when joined with others, adds force to them: as all, none;
certain, &c.

SYNCAUSIS, formed of συν, and καυσίς, burning, a word
used by some medical writers to express the drying; and, as
it were, burning up of the excrements with the body by
febrile heat.

SYNCELLUS, or SINCULUS, an ancient officer in the
family of the patriarchs, and other prelates of the eastern
church.

The word in the corrupt Greek, συγκελλας, signifies a
peron who lies in the chamber with another; a chamber-
fellow, or chum.

The synkellos was an ecclesiastic, who lived with the
patriarch of Constantinople, to be a witness of his conduct;
whence it is, that the synkellos was also called the patriarch’s
eye, because his business was to observe and watch.

The other prelates had also their synkelles, who were clerks
living in the houle with them, and even lying in the same
chamber, to be witnesses of the purity of their manners.

Afterwards the office degenerated into a mere dignity;
and there were made synkelles of churches. At last it became
a title of honour, and was bestowed by the emperor on the
prelates themselves; whom they called pontificial synkelles,
and synkelles Augufitales.

There were also synkelles in the western church, particular-
lly in France. The first council of Paris speaks with a
great deal of indignation of some bishops who abolished the
office of synkelles, and lay alone; and strictly enjoins them,
that for the future, to take away all occasion of scandal,
they made the office of synkelles inseparable from that of
bishops.

SYNCELLUS, George, in Biography, a Greek his-
torian and chronicles, derived his name from his being syn-
cellus, or confidant resident with Tarasias, patriarch of Con-
stantinople. He wrote a “Chronography,” in which he
transfers the whole chronicles of Eufebius, subjoining cen-
sure and corrections of that author, though he himself
often errs both in history and chronology. Synkellos
lived in the time of Charlemagne, and began to write his
history in 792, but was prevented by death from extending
it beyond the times of Maximian and Maximin. It was
published in Gr. and Lat. by F. Goar, in 1652, fol. It is
valuable for the account of the Egyptian dynasties.

SYNCHONDROSIS, in Anatomy, the connection of
bones by the intervention of cartilage, as the ossa pubis, the
bodies of the vertebræ, &c.

SYNCHORESIS, συνήθεια, in Rhetoric, the same with
permium.

SYNCHRONISM, συνήθεια, formed of συν, and
χρόνος, time; the being or happening of several things toge-
ther, at or in the same time.

The happening or performing of several things in equal
times, as the vibrations of pendulums, &c. is more properly
called isochronism: though some authors confound the
two.

SYNCHYSIS, συνήθεια, in Rhetoric, a confused manner
of expression, where the natural order of the words is per-
verted. Horace affects it much: thus, lib. i. sat. 5.

“Pane macroดำ uist dum turbos versat igne.”

SYNCHYSIS, in Surgery, a confusion of the humours of
the eye, from blows, or violent inflammation.

SYNCOMISTERIA, συνεμπιστοσύναι, in Antiquity, the same
with thalēss.

SYNCOMISTON, formed of συν, and κατέβας, I nourish,
a name given by Atheneus, and some other authors, to the
coarser sort of bread eaten by the poor in many countries,
and made of unsifted meal, the bran being mixed up among
the rest. This is a very nourishing food, and for laborious
people, or those who use much exercise, is highly preferable
to all other sorts of bread.

SYNCOPE, and SYNCPATION, in Music, the pro-
longing of a note begun on the unaccented part of a bar, to
the accented part of the next bar. Thus every syncopated
note is what the French call contre-temps, against time; and
every succession of syncope is moving against time. It
must be remembered, that though the notes are not tied, if
they are repeated in quick notes on the same line or space,
they are as much syncope in the harmony, as if they were
united by a ligature.

Syncopeation has its use in melody for taste and the expre-
sion of words; but its principal effect is in harmony, for the
 treatment of dissonances. The first part of a syncope serves
as the preparation; the discord is continued on the second
part; and in a succession of discords, the first part of the
following syncope serves as a resolution of one discord, and
the preparation of another. The derivation of the word
syncope, or syncopeation, by Rameau and Rousseau, does
not satisy us: the first thought it came from the shock or
crash of sounds, in the dissonance; and the citizen of Geneva
derived it from συν, and σύστεται, I cut, or beat. But by the
sentation it excites, we rather think it repels in music the
effect of a syncope in medicine, in which faculty the word
implies a swoon, or fainting away.

Syncopeation is used for a driving note, that is, when some
shorter note at the beginning of a bar, or half a bar, is fol-
lowed by two, three, or more longer notes, before any
other occurs equal to that which occasioned the driving
note, to make the number even; when, for example, an odd
crotchet comes before two or three minimi, or an odd quaver
before two or three crotchets, &c.

To describe all the effects of syncopeation in melody, and
all its use in harmony, would require a book, instead of an
article for a dictionary. In quick movements, syncopeation
or driving notes expresses passion and impatience; in slow,
langouer and sorrow, sighs and despair. In harmony, all
regular discords are prepared, struck, and resolved in syn-
copeation. In the 20, the syncope is in the base; in the 4th,
7th, and 9th, in the treble. But in melody, the syn-
cope so much resembles what the French call dissonances,
linking, fainting, and swooning, that it seems to confirm
the etymology to which we incline; as a tone in syncopeation,
hower forcible and loud in the beginning, grows more and
more feeble and faint to the end; particularly on fringed in-
struments incapable of sustaining a sound.

In our Music plates, examples may be observed in the pre-
paration of all regular discords.

SYNCOPE, in Grammar, denotes an ellision, or reten-
chment of one or more letters, or syllables, from a word.

As when we say, virum for viriun, and manem altum suspi-
rum, for repulsium.

SYNCOPE, in Physiology and Medicine, fainting; a con-
side
SYNCOPE.

derable diminution, or complete interruption, of the motion of the heart, and of the function of respiration, accompanied by a suspension of action in the brain, and consequent temporary loss of sensation, volition, and the other faculties of which the brain is the organ. The complaint frequently comes on suddenly; at other times, it is more or less gradual in its approach. The following are the usual signs which indicate an impending attack: a sense of oppression and anxiety about the heart, chilliness, irregular palpitation, pain or sense of palpitations in the stomach, giddiness, feeling in the ears, dimness of sight, in which objects appear as if enveloped in mist, while a number of luminous points, or sometimes flashes of light, overspread the sphere of vision. Palmarının of the countenance, heaviness of the eyes, a general collapse of the features, and flight quivering of the lips, betray to an observer the change that is taking place in the capillary circulation; while at the same time the pulse grows exceedingly feeble, irregular, and for the most part frequent, till it ceases to be perceptible. The respiration, in these changes, becomes weak in proportion as the heart flags, and is discontinued altogether upon its ceasing to act. The blood now retires from the surface of the body, which loses its warmth as well as colour, and either contracts, or, from being moistened with cold perspiration, becomes white as snow. The extremities swell, which is often partial, and breaks out especially on the forehead and back. The functions of the brain are suspended; the patient losing all consciousness, f FaNIFN, and powers of voluntary motion; a general relaxation of the muscles takes place throughout the body; which may extend even to the sphincters, when the fainting is complete, and of long duration. If this state, indeed, should continue for any time, there may be difficulty in distinguishing it from the effects of death; for the body, under these circumstances, soon becomes cold, especially in the extremities. The joints, however, retain their flexibility; and the insensible actions of the capillary vessels, and organic texture of the body continuing to be carried on, life is still preferred, the blood retains its fluidity, and no approach is made towards putrefaction. Influences have occurred of persons continuing in a state of trance, or prolonged syncope, for many days, and yet at length recovering. The recovery from a fainting fit is always gradual, and is generally attended with more uneasy feelings to the patient than those by which it was ushered in. The sensation of anxiety about the heart is often exceedingly distressing; there is usually some nausea, discharge of sputum, and sometimes vomiting; and cold sweat very commonly occurs; together with palpitation, which is frequently violent, and sometimes the paroxysm terminates in convulsions, or an epileptic fit. Slighter attacks of epilepsy, indeed, frequently appear under the form of syncope. Sometimes one fit immediately succeeds another, for six or seven times, before the patient is tolerably recovered. Occasionally it has happened that the suspension of the animal functions has not accompanied, or at least has not been proportioned to that of the vital actions. A remarkable instance of this anomaly occurred in the case of the celebrated Mr. John Hunter, who continued for about three quarters of an hour without any sensible pulsation at the wrist, or any respiration, except what was produced by an effort of the will, while he retained all his powers of sensation, thought, and voluntary motion.

The various degrees in which this affection may occur, have given rise to a number of distinctions among theologians, which do not, however, appear to be founded. The distinction in the nature of the disease. Dr. Cullen has, therefore, with great propriety, placed the lipothymia, aphthysis, and deliquium of former authors, under the head of syncope: but it may, after all, perhaps be doubted, whether fainting, which is so constantly a secondary affection, arising from other disordered states of the system, should not rather rank as a symptom than as a distinct disease. We find it taking place from a variety of causes, some of an exciting, and others of a depressant nature. It is a symptom familiar to hypochondria and hybernic persons, and may be brought on in all those who have much mobility of nerves, by any sudden or violent emotion, passion, or even strong sensation. It is a very usual concomitance of violent pain, such as that which accompanies a surgical operation. Women are more prone to syncope than men, in consequence of greater mobility, and of greater susceptibility to impressions made on the nervous system. But we find, even among men, frequent peculiarities of constitution, which a spirit of general strength of frame, disposes them to fall from causes which appear slight, and would be inadequate to produce any effect of the kind in others. The light of blood, of a wound or sore, certain odours, or the presence of objects, such as a cat, a mouse, or a spider, in which a person has conceived an unaccountable aversion, may give rise to every degree of this affection. The ease is sometimes so great that it occurs with the sight, and at the recollection of the object to which it is referred, or even the sound of it. The removal of fluids which have collected in any part of the body, such as the hydroptic water in ascites, or the matter of a large abscess, is often followed by fainting. Cases which suddenly diminish the supply of blood to the brain tend peculiarly to produce it in those who are disposed to: this sometimes happens in consequence of remaining too long in the erect posture; or still more from rising suddenly from the horizontal position, and stretching out the arms towards an object placed above the head, as in reaching a book from a high shelf in a library. Syncope sometimes marks the termination of acute disorders, such as fever, hooping-cough, the influenza, or the exanthemata: it prevails frequently during the period of pregnancy: and is sometimes induced by alarming degrees of severe heat.

In other cases it is a symptom of some mechanical obstruction to the circulation, from organic affections of the heart itself, or the large vessels in vicinity. See CARDIOGOMUS.

This latter class of cases has been distinguished by Dr. Cullen as a distinct species, under the title of SYNCOPE CARDAINE, while the rest are included under the general head of SYNCOPE OCCASIONALE.

The pathology of syncope must depend upon the nature of the remote cause by which it has been induced. We have already endeavoured, under the article HEART, to show how it begins with an affection of the brain, and must refer our readers to what has there been said, for information on this part of the subject.

The recovery of the patient from the actual fit is, in general, easily effected by merely placing him in a horizontal position, dashing cold water on the face and hands, or clashing the temples with stimulant ammoniacal liquids, which may also be held to the nostrils when the breathing is not easily sustained. If the fit were to continue, however, it would be proper to rub the body with hot clothes, to administer Clysters, and to employ, in a word, all the aids
mean which are found expeditiously in the recovery of drowned persons. The nature of the preventive treatment must depend on that of the cause that keeps up the tendency to the complaint. A recurrence of the exciting causes should be guarded against, while the general habit is strengthened, and the mobility of the nervous system counteracted by appropriate means. Dr. Heberden observes, that when the disorder is habitual, and not complicated with any other, he has found cold bathing to be beneficial. All evacuations, especially bleeding, are manifestly hurtful to those who are subject to fainting. It should, however, be borne in mind, that frequent fainting, especially if it be found to occur certain periods, or to occur more particularly upon waking in the morning, is a very usual mode in which epilepsy commences; and when this may be insuperable, no time should be lost in applying the remedies called for by that disease.

SYNCRETISTS, formed of συνεργείον, I work together, or συνεργείον, denote in general persons who, from a variety of discordant opinions, either in philosophy or religion, form a kind of comprehensive and pacific system, with the view of uniting the several parties who maintain such opinions. The moderate men, as they are called, of every persuasion, may be comprehended under this denomination. The Platonic Syncretists, towards the close of the fifteenth century, were of this class; for they considered Plato as the supreme oracle of philosophy, and yet would by no means suffer Aristotle to be treated with indifferency or contempt; and they proposed to place, as the jarring deductions of these two famous Grecian fages, and to combine them into one system. These moderate philosophers, both in their manner of teaching, and in the opinions they adopted, followed the modern Platonic school, of which Ammoeus was the original founder. Their sect was for a long time held in the utmost veneration, particularly among the mystics; while the scholastic doctors, and all such as were infected with the itch of disputing, favoured the Peripatetics. But, after all, these reconciling Platonists were chargeable with many errors and follies: they fell into the most childish superstitious, and followed, without either reflection or restraint, the extravagant diatribes of their wanton imaginations. The Calixtins, who, in the close of the seventeenth century, endeavoured to promote union and concord among Christians in the different churches, were also called Syncretists. The principles upon which Calixtus's pacific and uniting plan was founded were, 1. That the fundamental doctrines of Christianity, by which he meant those elementary principles from which all its truths flow, were preferred pure and entire in all the three communions, (Romish, Lutheran, and Reformed,) but were contained in the ancient form of doctrine, vulgarly known by the name of the Apologists' creed; and 2. That the tenets and opinions, which had been constantly received by the ancient doctors during the first five centuries, were to be considered as of equal truth and authority with the express declarations and doctrines of scripture. Moshheim's Eccl. Hist. See Calixtins.

SYNCRISIUM, συγκρίσις, a word used by the chemical writers to express a concretion, or coagulation of any thing, effected by a spontaneous, or violent reduction of a liquid substance to a solid one, by a privation of the humid.

SYNCRISMA, a fort of ointment of the nature of the acopa, in use among the ancients.

SYNCRITICA, a name given by some writers to such medicines as are of a coercive and astringent quality, whether used externally, or given internally.

SYNDELEDFORD, in Geography, a gulf or bay in Vol. XXXIV.
SYN

second day; and by this kind of synecdoche, the plural number is sometimes put for the singular, as Matt. xxviii. 44, compared with Luke, xxiiii. 30: by the fifth kind of synecdoche, part of any material thing or quantity is put for the whole of it, as the roof for the house, fails for ships, &c.; and thus also the singular number is put for the plural, and a number less than the real number is used for any round number. Ward's Orat. vol. ii. p. 2, &c.

SYNECHES, in Medicine, is the name of a fever of the next degree to the intermittent; it also seems to be something akin to the, and is called the Catarrhal or remitting fever. It is a continual fever in regard to duration, though not in degree, continuing many days together without intermission: but then it has its diminutions and augmentations; sometimes regular, sometimes irregular, though no true intermissions. Allen's Synopsis, p. 3.

SYNECHPHONESIS, or SYMPTOMESIS, in Grammar, a coalition, by which two syllables are pronounced as one.

It is much the same thing as the synallapha, or synecphet.

SYNECTICON, a word used by the old writers to express the proximate cause of a disease; called also the cause incomatus, and always remaining closely united with the disease.

SYNEDRELLA, in Botany, a genus of Gartner's, whose name appears to be a diminutive of ovoides, a military station, or camp, but we do not perceive its application. This genus is separated from Veratrum, see that article hereafter, because the author just cited found the receptacle naked, and the radius (of only two florets) placed on the outside of the inner calyx, while the seeds of these florets are fringed with teeth. But Swartz, who gathered the plant wild, describes a single calyx, without noticing any such peculiar situation of the radius, which he says consists of four or five florets; see his Hist. Bot. 312. Whatever stress therefore, may be laid on the naked receptacle, we feel scarcely authorized to follow Gartner, who perhaps saw an imperfect or anomalous specimen only, and we have only seen a dried one, by which we can neither trace nor invalidate the particulars of his description. The habit of the plant, greatly resembling Galanthus Tetrastichus, is indeed unlike that of the genuine Veratrum.

SYNEDRIN, or SYNEDRION. See SANGREDIN.

SYNEMMENON TETRACHORD, in the Greek Music. See GREEK MUSIC, and NERE.

SYNERGASMA, formed of synergy, and syngwan, I work, a word used by Libavius, and some other authors, to express any operation in chemistry. The operations are by this author divided into two classes, the energetic, and preparatory: the first producing such bodies as are of power to act on others as menstrua, to cure diseases, and the like; and the others producing no such things, but being necessary preparatives to them.

SYNERGISTS, formed of synergy, co-operation, in Ecclesiastical History, a name given to those whose doctrine was almost the same that of the Semipelagians, and who denied that God was the only agent in the conversion of sinfull men, and affirmed, that man co-operated with divine grace, in the accomplishment of this salutary purpose. The friends and disciples of Melanchthon adopted expressions of this kind, in describing the nature of the divine agency in man's conversion; but the Lutherans considered this representation as subverlive of the true and genuine doctrine of their master, relating to the absolute servitude of the human will, and the total inability of man to do any good action, or to bear any part in his own conversion. Strigelius defended the synergetic doctrine of Melanchthon, and Flicius maintained the ancient doctrine of Luther. Mohrheim Eccl. Hist.

SYNESUSIUS, in Biography, was a native of Cyrene, in Africa, of noble extraction, who united the characters of a Christian bishop and heathen philosopher. He studied philosophy under the famous Hypatia of Alexandria; passed the chief period of his life in secular employments; and from the year 397 to 400, resided at Constantinople as deputy from his native city to the emperor Arcadius. After his conversion to Christianity, he was elected bishop of the see of Philomai in 410, though he was not then in orders, and thought himself unfit for undertaking such an office. He wrote honestly his objections in a letter to his brother; and, when he converted, he was consecrated by Theophilus, primate of Egypt, who thought that a man whose life and manners were exemplary, could not be long a bishop without being illuminated by heavenly truth. The bishop, it seems, was not mistaken; and his competence to the exercise of episcopal authority may be inferred from the following fact. In the reign of the younger Theodosius, Libya was cruelly oppressed by the president Androniconus, who invades its modes of rapine and torture, and added sacrifice to robbery. Syenesius had tried in vain mild and pious admonition, inflicted against him a sentence of excommunication, dissolving his associations and their thrones, and at the same time used his interest with the Byzantines court to bring the offender to submission; and this was at length effected. It is not known when this bishop died.

Several writings on different topics, and 155 epistles of Syenesius, all in Greek, are still extant. One of which is a free and liberal discourse, entitled "An Oration concerning the Gospel, or the Art of Receiving," another short and ingenious piece is entitled "The Praefer Babel," in his "Dion Prusius," to the praises of that city; another, which adds an account of his own studies, and a sketch of philosophical learning. He wrote also "Homilies," and a book on "Dreams," which is said to contain some curious remarks on the nature and signification of those phenomena. In his "Letters" are many historical passages, sublime notions, and moral sentiments. The style of Syenesius is characterized as lofty and dignified, inclining to the poetical and rhetorical. The best edition of all his works is that of Petaux, Gr. and Lat. Paris, 1612. Morevi. Dupin. Lardner.

SYNESTIC, formed of synexies, I render confused, is sometimes applied by physicians to express the fluids that are in a confused state, and of a confusion; such as to make them resum in their shape, in opposition to liquid ones.

SYNGE, Edward, in Biography, an Irish prelate, the Bishop of Cork, was born in 1659 at Inish- nose, near Cork, and from the diocese-school at Cork, was removed to Christ-church college, Oxford; finishing his course of education at the university of Dublin. Having preached to crowded audiences with great approbation at Dublin, he was prefected in 1714, to the see of Raphry, and as he had displayed much zeal in his attachment to the house of Hanover, he was translated, in 1716, to the archbishopric of Tuam; on which occasion he generously rendered the quarter-archiepiscopal parts of his see, and procured an act for settling them on the resident clergy of the diocese. He was made a privy-counselor; and, in the absence of the lord-chancellor, one of the keepers of the great seal. These civil offices, however, did not interfere with his ecclesiastical duties; for he composed a number of tracts, partly practical and partly controversial, which, in his piety and his attention to the concerns of his See.
SYN

fungi. Some of these kinds were very popular, and particularly his "Anwer to the Exegetes in wot coming to the Holy Commination," which had reached the 21st edition in 1752. This prelate died at Tourni in 1741, having been the son and the nephew of a bishop, and the father of two bishops. Bibliog. Brit.

SYNGENESIA, in Botany, from σύν, together, and γένεσις, generation, alluding to the combination of the male organs, or anthers, is the appellation given by Linnaeus to the 19th class of his artificial system. This great class is now, according to its general acceptance, one of the most natural possible; consisting of the compound flowers of preceeding writers, whose anthers are united into a tube. It is equivalent to Jussieu's 10th class, comprising his three orders of Cloraceae, Cinarocephala, and Caryobifera.

The essential character of the Syngenesia is, to have the anthers united into a tube, the filaments being, almost without exception, distinct; to which we now add, that the flowers are compound, consisting of several florets in one common calyx; each floret having a Stamina, and a pilt of its own, or, one of those parts, or neither; in other words, being perfect, male, female, or neuter. Linnaeus indeed admitted free flowers, with united anthers, into the present class, as Viola, Lobelia, Impatiens, &c. But this union is far from constant in such genera, whilst it occurs occasionally in others, not usually syngenesious, as Gentiana. Hence it is found most correct and commodious, as well as most natural, to abolish the Linnaean order of Syngenesia Monogynina, and to place its genera simply by their number of Stamina.

The following are the natural characters of the Syngenesia.

Common Calyx, in fact a gymnathium, containing the receptacle and florets, closing after flowering, and spreading generally when the seeds are ripe; it is either simple, surrounding the florets with a single ring of leaves; or imbricated, when the numerous leaves, or scales, are gradually shorter as they are more external, lying over the inner ones; or double, when a series of internal equal leaves, surrounding the florets, is encompassed at the base with another, more flatter, or more lax, and of a different form or aspect.

Common Receptacle, enclosed by the common calyx, supports several free florets. Its disk is either concave, flat, convex, conical, or globose: the surface being either naked, merely marked with slight dots or villous, covered with upright hairs; or chaffy, clothed with linear, awl-shaped, compressed, erect scales, variously shaped, separating the florets; or cellular, divided like a honeycomb, into angular spaces, by membranous partitions.

The Florets consist each of the following parts.

Calyx crowning the germen, in the form of a simple, sometimes oblate, border, or a series of five teeth, bristles, or hairs, becoming the pappus, or seed-down.

Corolla of one petal, with a long narrow tube, fringed on the germen; and either tubular, with a bell-shaped five-cleft limb, whose segments are spreading or reflexed; or ligulate, with a linear flat limb, directed outwards, entire, abrupt, three-toothed, or five-toothed, at the extremity; or deficient, being deftute of a limb, and often of a tube.

Stamina. Filaments five, capillary, very short, inserted into the throat of the floret; anthers as many, linear, vertical, erect, united laterally into a hollow cylinder, crowned with five teeth, on a level with the limb.

Pilif. Germen oblong, below the partial calyx and corolla, but above the common receptacle, erect, style thread-shaped, erect, the length of the Stamina, running through the cylinder formed by the anthers; Stigma in two revolving and divaricated segments or lobes.

Perianth really none, though in some instances the seed has a coriaceous crust; witness Osenpernum and Strumus.

Seed one, oblong, often quadrangular, for the most part contracted at the base, and variously crowned at the summit, either with a circular series of numerous simple, rough, or smooth hairs, or of branched coherent plumes; such a crown being in some instances fertile, in others tailed, or with five or more small scales or leaflets, originating from the partial calyx. Sometimes there is no more than a scarcely evident rim, or border, at the top of the seed, which in that case is termed naked.

The kinds of compound flowers, therefore, come under the following descriptions, and consist either

1. Of tubular perfect florets, in the disk as well as in the circumference.
2. Of tubular perfect florets in the disk, with tubular female ones in the circumference.
3. Of tubular perfect florets in the disk, with tubular neuter ones in the radius.
4. Of tubular perfect florets in the disk, with ligulate perfect ones in the radius.
5. Of tubular perfect florets in the disk, with ligulate female ones in the radius.
6. Of tubular perfect florets in the disk, with ligulate neuter ones in the radius.
7. Of tubular perfect florets in the disk, with naked female ones in the circumference.
8. Of tubular male florets in the disk, with naked female ones in the circumference.
9. Of ligulate perfect florets in the disk, as well as in the radius.

It must be observed that the first and last of these sections are the most permanently and essentially distinct. The second and third are aberrations of the fifth, and they are all capable of varying into each other. The same is the case with the fourth, fifth, and sixth, all closely allied to each other, though distinct from the fifth, second, and third. The seventh is most nearly related to the second, and they run into each other, which may also be said of the seventh and eighth.

Of these differences, however, the Linnaean Orders of the clasis Syngenesia are founded. See Polygymnia.

1. Polygymnia equilis, consists of sect. 9, 1, and 4.
2. Superfusa of 2, 5, and 7.
3. Fruticans of 5 and 6.
5. Segregata has no exclusive character of any, being distinguished by its doubly compound flowers.

However natural the class now under our consideration may be, it is not without exceptions or irregularities. Kubus, though a true compound flower in every part of its structure, has dissected anthers; which circumstance occurs, more partially, in Tufillo. A few inflorescences are found of genera in which the florets are, more or less, universally, four-cleft, with four Stamina, and in one species of Sinobezekia, they are three-cleft, with only three Stamina; see that article and Eclipta. In the generic character of the latter, line 4th, for nearly, read "nearly on the outside." A full more paradoxical exception occurs in our fifth species of Syruehina, see that article, which has solitary florets.

Linnaeus remarks, that Pluiter has not founded one new genus of compound flowers; that Tournesort fought
SYN

out the most natural genera, though he wasted the information which has been supplied by later botanists; and that Vaillant has furnished more of this than any other person.

Jullien has treated the subject with his usual skill, and has thrown new light upon it. He judiciously observes that Tournefort and Linnaeus have been led into artificial distinctions; the former by being regulated too absolutely by the form of the corolla, and the latter by the sexes of the florets; while Vaillant, from whom Jullien adopts his own three orders above-mentioned, is the most correct.

Gartner, who in the latter part of his second volume has bestowed great attention upon this tribe, being chiefly mindful of the seeds and receptacle, with their appendages, has by, that means been led, if we mistake not, to form unnatural and unstable distinctions and combinations, which require to be brought to the test of long practical observation, and perhaps cultivation. His decisions, however, are the result of intense study and great experience, and his labours form a vast and faithful florehouette for the contemplation of future systematics, who may profit by his accuracy, if they do not implicitly follow his opinion.

SYNGNATHUS, the Pipe-fish, in Natural History. The name Lyngnathus is of Graecian origin, and is formed of the word nathan, which in composition signifies the name as the Latin con, together, and gnathos, a jaw. It is given to this fish from that remarkable structure of its mouth, by which the jaws are made to grow together, and the very end of the mouth only opens. The head of this fish is very small; the snout nearly cylindrical, long, turned up at the end; mouth terminal, without teeth or tongue, and furnished with a lid; the lower jaw is movable; gill-covers are large, friate and closed; the spiracle on the nape is tubular; the body is jointed, and mailed with many-fided scales; it has no ventral fins.

The fish of this genus inhabit the ocean, near the shores; they feed on leef worms and insects, and the spawned of other fish; under the tail, commencing at the vent, is a longitudinal groove, concealing the young and the eggs; the eyes of the animal are small, covered at the sides with a membrane; the nostrils near the eyes, but scarcely to be seen; the palate is smooth; the gill-membrane is very thin, placed on the nape; the fins are small, thin, the rays undivided; it has no lateral line. Gmelin enumerates eight species, of which four are found on the coasts of our own country.

Species.

TETRAGONUS. This species has no caudal fin; the body is quadrangular; the tail is fix-fided on the fore-part, triangular behind; the lip is round. This is an inhabitant of the Indian seas; the body is brown at the sides, beneath it is varied with brown and yellow. The iris is yellow; above the eyes, on each side, is a recurved spine, and a flat, hollow between them; the snout is compressed on each side; the trunk has 17 plates, paler in the middle, triangular at the beginning; above narrow, beneath broad, and sometimes with deciduate bands; the fins are yellowish; the tail is composed of 45 plates.

* TPHE, the shorter Pipe-fish. Caudal, anal, and pectoral fins radiate; body fix-fided. This, by some writers, is considered as a variety of the tetrangainus. It is found in the northern European seas, and on our own coasts; is about 12 inches long; the body is yellow, varied with brown. The snout is slender, flat-compressed; iris yellow; trunk with 18 plates; tail with 36; the vent is nearer the head; the fins are cianecous.

* ACUS; Needle-fish. This is also called the Great Pipe-fish, and the Heptagonal whistilpipe Pipe-fish, with brown bands and pinnated tail. The caudal, anal, and pectoral fins radiate; the body is seven-fided. It is usually found from 12 to 15 inches long, but in the Northern seas it is much larger, measuring from two to three feet; it is of an extremely slender form, gradually tapering towards the extremity, and is of a pale yellowish-brown colour, and throughout its whole length with broad alternate zones; a deeper or olive-brown, with a few smaller variegations intermixed; the sides are laminae with which the joints of the body are covered, appear, if narrowly inspected, to be finely radiated from the centre by numerous lines or streaks; the dorsal fin is placed rather nearer the head than the tail, and is thin, tender, shalow, and of no great extent; the pectoral fins are small, and slightly rounded, and the tail of similar shape and size. The ova are found lying in a longitudinal channel or division at the lower part of the abdomen; they are very large in proportion to the size of the fish. From these are hatched the young, completely formed.

PELAGICUS. Caudal and pectoral fins radiate; it has anal fin; the body is seven-fided. There is a variety, in which the plates of whose trunk are 3; of the tail 3; and the dorsal fin 33 rays. It is found on the fringed tail of the Cape of Good Hope, and in the Caspian sea; the body is of a yellow-brown, marked with transverse brown lines; it is generally found swimming among sea-weeds. The iris is white; the lower jaw is the longest; it has 18 plates on the trunk; on the tail 32; the pectoral fins are of a lead-colour; the dorital and caudal are yellow.

ÆQUORUS. Caudal fin radiate; it has no pectoral or anal fin; the body is angular. It is found in different parts of the ocean.

* OPHISDON; Little Pipe-fish, or Pipe-fish with round body and finless tail. This differs from the typhe, and the acus, in having the body nearly round, or at least is obscurely cornered as to appear round; it is also entirely destitute of a tail-fin, the body terminating in a naked point; it grows to the length of two feet, and is chiefly found in the Baltic. The iris is reddish, snout short, vent near the head.

* BARBARI; Longer Pipe-fish. This has neither caudal nor anal fins; the body is fix-fided. It inhabits the European seas; it is about two feet long; the body is of an olive-brown, with numerous blueish lines pointing from the back to the belly; the tail is quadrangular.

HIPPOCAMPSUS. This species has no caudal fin; the body is seven-fided, tuberculate; the tail is fique. The fish has a very fugular appearance; it is generally from 12 to 20 inches in length; the body is much compressed; it is of a greenish-brown, varied with darker and lighter spots; the head is large and rather thick, and beak at the upper part, as well as along some of the first joints of the body, with several small, weak, lengthened spines, or cirri, which are sometimes slightly ramified; the snout is slender, the neck suddenly contracting beyond the head; the body is rather short, and suddenly contracting towards the tail, which is long, quadrangular, and terminates in a naked or finless tip. In its dry or contracted state, the animal exhibits the fancied resemblance from which it takes its name, but in the living fish this appearance is somewhat less striking; the head and tail being carried nearly flatly. It is a native of the Mediterranean, Northern, and Atlantic seas.
SYGNOME, Eudoxus, in Rhetoric, the name with connection.

SYNGRAPH. See CHIRAGRAPH.

SYNIZESIS, blindaedas from a closure of the pupil. See PUPIL, Closure of.

SYNNAS, or SYNNAUM Storum, in the Writings of the Ancients, the name of a species of marble used in the larger buildings of the Romans. It is by some confounded with the dexamium marmor, with which the temple of Jupiter, erected by Hadrian, was built; but this is erroneous, since that elegant marble was always characterized as perfectly white, without blemish; and was always spotted and clouded with black, insomuch that some writers have called it by an epithet expressing those variations, maculae freinae.

SYNNEROSIS, in Anatomy, the connexion of parts by means of tendons.

SYNOCHA, in Medicine, expresses that kind of fever which is attended with high excitement and a general inflammatory state of the system; and is more particularly used in opposition to typhus, in which an opposite state, or one of diminished action, predominates.

An account of the history and treatment of synocha is included under that of FEVER, which see.

SYNOCHUS is a term applied to those cases of fever, in which a complication of the characters of synocha and typhus takes place; those of the former prevailing in the early stages, and those of the latter in the subsequent progress of the disease. See FEVER.

SYNOD, formed from synod, convention, assembly, compounded of συν, with, and οἶκος, house, and συν, with, in Astronomy, a conjunction or concourse, of two or more stars or planets, in the same optical place of the heavens.

SYNOD, Synodus, in Church History, a council, or a meeting or assembly of ecclesiastics, to consult on matters of religion.

Of these there are four kinds; viz.

General, or ecumenical, where bishops, &c. meet from all nations.

These were first called by the emperors, afterwards by Christian princes; till in later ages the pope usurped to himself the greatest share in this business, and by his legates presided in them when called. Of this sort there was but one within the first 300 years after Christ, and that was the council of Antioch, that condemned Paulus Samofatenus; or, if this will not pass for a general council, there was not any such before that of Nice, held A.D. 325.

National, where those of one nation only come together, to determine any point of doctrine or discipline. The first of this sort which we read of in England, was that of Hereford, or Hertford, in 679, and the last was that held by cardinal Pole, in 1555.

Provincial, where they of one province only meet, now called the convocation; and

Diocesan, where those of but one diocese meet, to enforce canons made by general councils, or national and provincial synods, and to consult and agree upon rules of discipline for themselves. These were not wholly laid aside, till by a act of submissio, 25 Hen. VIII. c. 19, it was made unlawful for any synod to meet, but for the royal authority. See COUNCIL and CONVOCATION.

SYNODS, Provincial, in the Government of the Church of Scotland, are composed of several adjacent parishes, of which there are fifteen in all. The members are a minister and a ruling elder out of each parish. These synods meet twice a year, and choose a moderator, who is their proctor. The acts of the synods are subject to the review of the general assembly, which is the dernier resort of the Kirk of Scotland; and confits of commissioners from presbyteries, royal burghs, and universities. A presbytery of twelve ministers, lends two ministers and one ruling elder; a presbytery of between twelve and eighteen, lends three and one ruling elder; of between eighteen and twenty-four, lends four and two ruling elders; of twenty-four, lends five and two elders; every royal burgh lends one elder, and Edinburgh two; every university lends one commissioner, usually a minister. The general assembly meets once a year, in the month of May, and is opened and adjourned by the king's royal commissary appointed for that purpose.

SYNODAL, or Synodical rents (commuted to two shillings), paid to the bishop or archdeacon, at the time of their Easter visitation, by every parish priest.

They were thus called, because usually paid in synods; because, anciently, bishops used to visit and hold their diocesan synods at once. For the same reason, they are sometimes also denominated synodalica; but, more usually, procurations.

In all probability, this payment is the same with that which was anciently called "Cathedralicum," as paid by the parochial clergy, in honour of the episcopal chair, and in token of obedience and subjection to it. Thus it stands in the body of the canon law: "No bishop shall demand any thing of the churches but the honour of the cathedralicum, that is two shillings," at the most, says the gloss, for sometimes less is given. Synodales are due of common right to the bishop only; so that if they be claimed or demanded by the archdeacon, or dean and chapter, or any other person or persons, it must be upon the foot of composition or prescription; and if they be denied when due, they are recoverable in the spiritual court.

Constitutions made in the provincial or diocesan synods, were sometimes called synodales, which were required in many cases to be published in the parish churches.

SYNODALES TYPUS was an appellation anciently given to...
SYN

the urban and rural doves; from their informing against, and testifying, the disorder of the clergy and people in the episcopal synod.

When these sunk in their authority, in their head rose another sort of synodal witnesses, who were a kind of impampered jury, consulting of a priest, and two or three laymen, for every parish; though, at length, two for every dioceze were annually chosen; till, at last, the office came to be devolved on the churchwardens.

Some think our quechmen, who are affiants to the churchwardens, were called fidesmen, quasi synodifmen. See Sides-Men, and Quest-Men.

SYNODALE Instrumintum, a solemn oath, or engagement, that these synodical witnesses took: as our churchwardens now are sworn to the just prefements.

SYNODENDRUM, in Entomology, a genus of insects of the order Coleoptera. The generic character is as follows: antennae clavate, the club lamellate; thorax gibbous, muricate or unequal; lip sliform, horny, palpigerous at the tip. There are four species.

* CYLINDRICALON. Thorax truncate before, five-toothed; head with an erect horn. It is found in this country and other parts of Europe. The female is unarmed.

* MERICATUM. Thorax muricate, gibbous; shells two-spined before the tip. It inhabits Europe and America, in wood. The shells are dull tectateous, retuse behind, with a long hooked tooth at the future, and another shorter one at the margin; the antennae are tectateous.

* CAPECINUS. Shells entire, black; thorax rough before. It inhabits Coromandel. The thorax has numerous raised denticules before; the shells are naked, retuse at the tip.

DOMINICANUM. Smooth, black, dusky; shells fimbriate; legs pitchy. It inhabits South America, and is a very small insect. The head is black, bent under the thorax; the thorax is prominent before; shells entire, fimbriate.

SYNODICAL, something belonging to a synod.

SYNODICAL Epistles, are circular letters written by synods to the abbot prelates and churches; or even those general ones directed to all the faithful, to inform them of what had passed in the synod.

In the collection of councils are abundance of these synodical epistles.

MOMENT. Month is the period or interval of time, in which the moon, departing from the sun at a synod, or conjunction, returns to him again.

Kepler found the quantity of the mean synodical month, twenty-nine days, twelve hours, forty-four minutes, three seconds, eleven thirds.

This period is also called a lustration; because, in the course of it, the moon puts on all her phases, or appearances.

SYNONYMS. See Syndatales.

SYNODON, or SYNOD, in Ichthyology, a name given by several authors to a fish caught in the Mediterranean, and more commonly known by the name of dentex. It is a species of sbrus in the Linnaean system.

SYNONDONTIDES, in Natural History, the name of a stone described by the ancients, and said to be taken out of the head of the fish, called by them synodontes, the dentex of the moderns.

SYNOECLIA, Synoeclia, in Antiquity, a feast celebrated at Athens, in memory of Theseus's having united all the petty communities of Attica into one single commonwealth, the seat of which was Athens; where all the assemblies were to be held.

The feast was dedicated to Minerva; and, according to the scholiast of Thucydides, it was held in the mouth of the Agrippa.

SYNONYMOUS, SYNONYMOUS, is applied to a word or term that has the same import, or signification, with another. Accordingly, synonyms words agree in expressing one principal idea; but generally, if not always, they express it with some diversity in the circumstances. They are varied by some necessary idea which every word introduces, and which forms the distinction between them. Hardly in any language are there two words that convey precisely the same idea. A person thoroughly versed in the propriety of the language, will always be able to observe something that distinguishes them. In the Latin language, no two words seem to be more definitely synonymous than amare and diligere; and yet Cicero, in his Epistles, has marked a very obvious distinction between them. "Quid ergo tibi commendam eum quem tu ipse diligis? sed tuam ut scires eum non a me diligi folum, verum etiam amare, ob eam rem tibi haec scribo." Thus also tenuis and fenum, apparently synonymous and liable to be confounded as such, have nevertheles a different meaning; tenuis signifying a thing slender, and fenum free from the dread of it. Sempron (Epit. 97.) has marked the difference, "Tuta deinde & fenum, secura non fenum." In our own language, many infinities occur in which there is a difference of meaning among words reputed synonymous.

Dr. Blair has pointed out many of these. We shall find a few: e. g. astonishment, relating to the manner of acting; consternation, to that of thinking; rage, to that of punishing. In the first is opposed efficaciously, to the second, relaxation, to the third, clemency. Cursim respects the action, imibis the subject; by cursim, we mean the frequent repetition of the same act; by imibis, the effect which that repetition produces on the mind or body. Pride makes us esteem ourselves; vanity makes us desire the esteem of others; so that it is just to say with Swift, that a man is too proud to be vain. Haughtiness is founded on the high opinion we have of ourselves; disdain is on the low opinion we have of others. We invent things that are new; we discover what was before hidden; e. g. Galileo invented the telescope; Harvey discovered the circulation of the blood. A difficulty engenders us; an obstacle stops us; we remove the one and incumbe the other. Wisdom leads us to speak and act what is not proper; prudence prevents our speaking or acting improperly.

A wise man employs the most proper means for success; a prudent man, the safest means for not being brought into danger. See other infinities in Blair's Lectures, vol. i.

Some severe critics condemn all use of synonyms in the same period; but this is to condemn all antiquity: so far is the use of them from being vicious, that it is frequently necessary; as synonyms contribute both to the light and clearness of the translation. If the first word sketched out the resemblance of the thing it represents, the synonym that follows is, as it were, a second touch of the pencil, and finishes the image.

Indeed they must be used with great discretion and economy. The style must be raised and brightened, not suffused or loaded, with synonymous terms. They must be used as ornaments, and to render the expression the more forcible, without making a show of the riches of them, or heaping synonyms on synonyms.

But though synonymous words in some cases may be harmless,
SYN

SYNTAX, in Grammar, the construction, or connection, of the words of a language into sentences or phrases. See Sentence.

F. Buffier more accurately defines syntax, the manner of constructing one word with another, with regard to the different terminations of them, preferred by the rules of grammar.

Some authors, as M. Vauclus, &c. confused syntax with style; but there is a real difference.

The office of syntax is, to consider the natural suitable-ness of words with respect to one another; in order to make them agree in gender, number, declension, and mood, 

To offend in any of these points, is called to offend against syntax; and such kind of offence, when gross, is called a solecism; and when more slight, a barbarism.

The several parts of speech are, with regard to language, what materials are with regard to a building. How well prepared they may be, they will never make a house, unless they are placed conformably to the rules of architecture. It is, properly, the syntax that gives the form to language; and it is on that which turns the most essential part of grammar.

There are two kinds of syntax; the one of concord, in which the words are to agree in gender, number, case, and person: the other of regimen, or government; in which one word governs another, and occasions some variation in them. (See Conform and Regimen.) The most comprehensive rule of syntax is that which we have numbered 10 under Regimen. It will apply to many forms of sentences, which none of the other rules can be brought to bear upon; and it is calculated to prove the propriety or impropriety of many modes of expression, which other rules, less general, cannot at all, or at least, cannot so readily, determine. See this rule exemplified in a great variety of appropriate cases, in Murray's Grammar, vol. i. and ii.

SYNTENOSIS, a word used by anatomists to express an articulation of the bones when they are connected, as the osseous joints of the toes, only by a tendon.

SYNTERICE, denotes that branch of medicine which is concerned in preparing of health.

SYNTEXIS, in Medicine, an attenuation, or colliquation, of the solids of the body; such as frequently happens in atrophies, inflammations of the bowels, colliquative fevers, &c. in which a fatty and oily substance is voided with the excrements by stool. See Colliquation.

SYNTHENA, a term used by Paracelsus to express an apoplectic or epileptic disorder, attended with violent gripping pains in the bowels. This is generally mortal.

SYNTHERISMA, in Botany, so named by Mr. Walter, in his Flora Caroliniana, p. 76, from συνθεωσις, to make a crop, or barrow, of itself in allusion to its abundant produce, as well as its popular name of Crop-grass. This supposed genus, however, is the identical Diphleria of Haller, under which appellation it stands in Pursh's Flora America Septentrionalis. We have followed Linnaeus in considering it as a section of the genus PAMICUM. See that article.

SYNTHESIS, in Grammar, from συν, with, and θεωσις, composition, or the putting of several things together: as in making a compound medicine of several simple ingredients, &c. See Composition.

SYNTHESIS, in Logic, denotes a branch of method, opposite to analysis.

In the synthetica, or synthetic method, we pursue the truth by reasons drawn from principles before established or assumed, and propositions formerly proved; thus proceeding by a regular chain, until we come to the conclusion.

Such
Such is the method in Euclid's "Elements," and most demonstrations of the ancient mathematicians, which proceed from definitions and axioms, to prove propositions, &c. and from those propositions proved, to prove others.

This method we also call composition, in opposition to analysis or resolution.

SYNTHESIS, in Grammar. See SYLEPSIS.

SYNTHESIS, in Surgery, an operation by which divided parts are e-united; as in wounds, fractures, &c.

SYNTHETIC, or SYNTHETICAL, is a term given to that part of chemistry, which, after the analytical chemistry has taken bodies to pieces, or reduced them to their principles, can, from those separated principles, either recompound the same body again, or, from the mixtures of the principles of one or more bodies in various manners, form a large set of new productions, which would have been unknown to the world but for this art: such productions are brady, soap, glass, and the like.

SYNTHETICAL chemistry, taken in the strict sense for the re-composition of bodies from their own principles, is rather of philosophical than of ordinary use. This, however, is not easy, except in a few cases, nor are we to imagine, because it may be done in some, that nature has taken this way to compose them; her method of composition of bodies is a new subject, and worthy a diligent inquiry. Shaw's Elements, p. 160.

SYNTHETIC Method. See SYNTHESIS and METHOD.

SYNTHETISMUS, in Surgery, the reduction of a fracture.

SYNTHONO, or DURUM, is the epithet by which Aretinexenex expresses one of the two common diatonic genera of which the tetrachord is divided into a semi-tone and two equal tones; whereas in the molle diatonic, after the semi-tone, the first interval is three-fourths of a tone, and the second two. See GENERA and TETRACHORD.

Befides the syntonic genus of Ariftenexenex, called also Diatono-Diatonic, Ptolemy has established another, by which he divides the tetrachord into three intervals: the first is a semi-tone major; the second, a tone major; and the third, a tone minor. This durum diatonic, or syntonic of Ptolemy, is retained, and it is nearly the diatonic of Didymus, with this difference, that Didymus places the tone minor before the tone major, Ptolemy the reverse.

The difference between these two syntonic genera will be felt with a single glance, by the ratios of the intervals of which both the tetrachords are composed.

Syntone of Ariftenexenex, \( \frac{2}{3} + \frac{2}{3} + \frac{2}{3} = \frac{4}{3} \)

Syntone of Ptolemy, \( \frac{1}{3} + \frac{1}{3} + \frac{1}{3} = \frac{1}{3} \).

"There were other syntonic," says Rousseau, "of four different kinds, such as the ancient, the reformed, the tempered, and the equal; but it would be wasting our time, and abusing the patience of the reader, to drag him through all these divisions."

"SYNTHONO-LYDIAN, in Greek Music, the name of one of the ancient modes. Plato says, that the mixo-lydian mode and the syntonic-lydian, are plaintive, and proper to excite tears."

Aritides Quintilianus gives a lift, in his first book, of the different Greek modes, which we must not confound with the ecclesiastical modes that bear the same name, and which have been mentioned under the article MODE, in compliance with the practice of modern writers, which Glareanus introduced very improperly. The modes confused of different ways of varying the order of the intervals. The tones differed, as at present, in the fundamental sounds. It is in the first sense that we must understand the syntono-lydian mode mentioned by Plato, and of which we are unable to give any explanation. See PTOLEMY, and TEMPERAMENT.

SYNTHONUM DIATONUM. See GENUS.

SYNTRONIC, formed of συντρόφος, and τροφή, I nourish, an epithet used to certain dishes, which grew up with the patient. Of this kind is the epithet, which often signifies the person in infancy, and continues growing up with him, and increasing in strength as he does.

SYNULOTICA, medicines for healing of wounds.

SYNUISASTIS, SYNUISASTES, Συνυιστος, a form of συνοι, with, and συναιμφος, a sect of heretics, who maintained that there was but one nature, and one single substance, in Jesus Christ.

The Synuistais denied, that the Word assumed a body in the womb of the Virgin, but held, that part of the divine Word, being detached from the rest, was there changed into flesh and blood. Thus they taught that Jesus Christ was consubstantial to the Father, not only as to his divinity, but even as to his humanity, and very body.

SYNVMENSIS, a word used by some churlish writers to express a conjunction of two bones by means a membrane, as the bones of the incipit are connected to those of the fore-head in young children.

SYPHAR, a word used by some naturalists in the same sense as exercise, to express the skins which many roots cast off at certain times. The same, the water-cress, and all the caterpillar tribe, part with their skins during the time they remain in that state.

SYPHAK, in Geography, king of Maseylia, on the western part of Numidia, was engaged in the second Punic war on the part of the Romans against the Carthaginians, when he was defeated by Maffinia, and obliged to retire into Mauritania. He afterwards made a treaty with the Carthaginians, but a conference with Scipio, who had transferred the war to Africa, induced him secretly to enter into a negociation with that commander. Asdrubal, however, by means of his beautiful and accomplished daughter, brought him back to the interest of the Carthaginians; and an union with her was the price of a new alliance with Carthage. As soon as he found that his rival Maffinia had declared for the Romans, and that his mediation between the contending powers was of no avail, he delayed no longer to act in favour of the Carthaginians. Encamping his army apart from that of Asdrubal, both camps were in the night surprized and burned by Scipio. Afterwards, in a general engagement, the united Carthaginians and Numidian armies were defeated by Scipio; and Syphax, with the remnant of his forces, hastened back to his own country; but being pursuied by Lelius and Maffinia, he, together with his son Vermia, was taken prisoner. Maffinia then made a captive of Sophonisba, and married her, which was the occasion of a tragedy. Syphax was sent to Rome; and we learn from Polybius, that he was led to Scipio's triumph, and died a few days afterwards in prison; but other historians say that he was removed from Alba, his first place of confinement, to Tiber, where he died of grief before the return of Scipio from Africa. Univ. Hist. For other particulars, see CARTHAGINIANAE and MAFFINAE.

SYPHILIS. See LUES VENEREA.

SYPHON. See SYPHON.

SYPOMBRO, in Geography, an island on the coast of Brazil, in South America, about 7 leagues N.E. of St. John's island, and N.W. from a range of islands which form the great bay of Peru.

SYR, or ZUR, a town of Arabia; 184 miles E. of Amanzirifon.
SYRA, the ancient Syra, an island in the Grecian Archipelago, which, though mountainous, produces wine, figs, cotton, barley, and also wheat, although not so plentifully as barley. It has abundance of poultry, and fine breeds of pigs. This island has been always celebrated for the advantages it enjoys, in the excellence of its port, in its fertility, and in its fertility. It is thus extolled by Homer:

Εύβολος, μεγαλός, αντιλήπης, παλμήρος.

There is not a Turk upon the island; its inhabitants are all Greeks, and profess the Catholic religion. Also, a town is this island, built upon the summit of a lofty hill, so remarkable for its conical form, that it may be compared to a vast sugar-loaf, covered with houses. At the base of this cone is the quay, where are several warehouses for supplying vessels with the produce of the island, which is principally wine. Not far from the town are some ruins; and many ancient marbles are said to remain buried behind the magazines. Syros was the original name of the town, as well as of the island; 13 miles S. of Andros. Lat. 37° 37’. N. long. 24° 53’.

SYRA, a town of Japan, on the island of Ximo; 12 miles N. of Usumi.

SYRACUSE, a sea-port town of Sicily, in the valley of Noto, formerly a seaport city and flourishing republic; but almost totally destroyed, or at least very much reduced and diminished in extent and importance, by earthquakes, wars, and tyranny. In public and private wealth, magnificence of buildings, military renown, and excellence in all arts and sciences, Syracuse occupies a very distinguished, and, indeed, pre-eminent rank in the historical record of ancient nations: it was the most opulent, and the most powerful of all the Grecian cities, and by its own strength alone, it was able, at different times, to contend against all the power of Carthage and of Rome; and it is said to have repelled fleets of 5000 sail, and armies of 200,000 men; and to have contained within its own walls, what no city ever had before or since, fleets and armies that were the terror of the world. The great names recorded in its annals still command our veneration, though the trophies of their victories, and the monuments of their skill, have long since been swept away by the hand of time. This haughty and magnificent city is now reduced even below the consequence of the most insignificant burgh.

Syracuse was built, according to Thucydides and Strabo, by Archias, son of the Heracleid, who brought hither a colony of Corinthians, in the second year of the 11th Olympiad; and it is said to have borrowed its name from a neighbouring marble, called Syraco. This stately city contained within its walls, which were 18 miles in compass, four very considerable cities, as Strabo calls them, united into one, viz.: Acraga, Tyche, Neapolis, and the island of Ortygia.

Acraga, for an account of which, see Acraga, was situated on the sea-side, and separated from Neapolis and Tyche by a wall of an extraordinary thickness and height. The second city, called Tyche, stood between Acraga and the hill Epipole, having the former on the E. and Neapolis on the S. The chief ornaments of this division were a spacious and beautiful gymnasion, whither the youth resorted to learn all sorts of exercises; and several temples, greatly admired for their inimitable structure, especially that of Fortune, by the Greeks called Tyche, whence this division borrowed its name. The third quarter, called the Island, or Ortygia, was joined to Acraga, Tyche, and Neapolis, by a bridge. The most remarkable buildings in this part were the palace of Heron, which afterwards became the habitation of the Roman praetors; and two magnificent temples, the one dedicated to Diana, and the other to Minerva, the two tutelary goddesses of Syracuse. The temple of Minerva has been converted into the cathedral of the city, and dedicated to the Virgin. The left city was called Neapolis, or the New City, because it was built after the other three. The chief ornaments of this city were, a spacious amphitheatre and theatre, and two temples of wonderful architecture, consecrated to Ceres, and Liber and Proserpine. The statue of Apollo Temite, which was afterwards carried to Rome, is celebrated by Tully as the most valuable monument in Neapolis. Of these four cities, Ortygia alone is now remaining; it is about two miles round, and supposed to contain 14,000 inhabitants; though there are some traces, still visible, of the ancient Syracuse, in the ruins of the porticos, temples, and palaces. The famous fountain of Arethusa role in this island; but its spring is now dried up. (See ARETHUSA.) Near the city stood a hill, called Epipole, (see Epipole) exceedingly steep, and of very difficult access. When the Athenians besieged Syracuse, this hill was not inclosed by a wall, as in after-ages, but defended by a fort called Labdalon. On Epipole was the famous prison, called Latomize, which word properly signifies a "quarry." (See LATOMIZE.) Cicero has particularly described this dreadful prison, which was cut 125 paces long, and 30 feet broad, and about 100 feet below the level of the earth, cut out of the rock to an almost incredible depth. It was the work of Dionysius the tyrant, who caused those to be shut up in it, who had the misfortune to incur his displeasure. It now forms a noble subterraneous garden.

The whole city was environed by a triple wall, so flanked with towers and cisterns, at proper distances, that it was deemed impregnable. It had two harbours, at a small distance from each other, being only separated by the island; viz. the great harbour, and the small one, called otherwise Aretmus, both of which were surrounded by the same edifices. The great harbour was about 5000 paces in circumference; and the entrance of it 500 paces wide; being formed on one side by a point of the island Ortygia, and on the other by the little island and Cape Plemmynrum, which was defended by a fort of the same name. This, being reckoned six miles round, and lying on the S. W. side of the island of Ortygia, was esteemed one of the best in the Mediterranean. Diodorus says that it ran almost into the heart of the city, and was called "Marmoreo;" because it was entirely encompassed with buildings of marble; its entrance was strongly fortified, so that the Romans could never penetrate into it. The small port is on the N. E. of Ortygia, and is said to have been highly ornamented by marble edifices, reared by Dionysius and Agathocles. Fazello says, that there still remains a submarine aqueduct, that runs through the middle of it, which was intended to convey the water from the fountain of Arethusa to the other parts of the city. Near this port is shown the spot where the house of Archimedes stood, and likewise the tower from which he is said to have set fire to the Roman gallies with his burning-glasses. The catacombs, not inferior to those of Rome and Naples, and in the same style, the ear, of Dionysius, a monument of the ingenuity and magnificence, no less than of the cruelty of that tyrant, (see EAR OF DIONYSIUS,) and the remains of a great number of temples, have been objects of research and of admiration to those who have visited Syracuse. Above Acraga was a third port, called the harbour of Trogillus. The river Anapius ran about one mile and a half distant from the city, and discharged itself into the great
SYRACUSE.

great harbour. Near the mouth of the river, and about 500 paces from the city, stood a castle, called Olympia, from the temple of Jupiter Olympia, which was the chief ornament of the place. Thucydides, in his description of this city, (lib. vi), mentions only the three divisions of the island, Aegadina, and Tyche; so that Neapolis must have been added after his time.

Syracuse underwent several revolutions before it was taken by the Romans; but was always one of the most wealthy and powerful cities of those times; for Gelon, who made himself master of Syracuse in the year of Rome 260, and the other tyrants, his successors, were become equally formidable to the Greeks, Africans, and Asians. Dionysius the younger, who governed this city, kept in constant pay 100,000 foes, and 10,000 horse, besides a fleet of 400 sails.

The principal epochs of the history of Syracuse are as follow; though allowance should be made for the variations in the statements of different chronologers.

Years B.C.

736. Syracuse founded.
497. Hippocrates governed.
478. Gelon died.
467. Hiero I. died.
466. Thryphylus, 11 months.

[Sixty years of liberty.]

415. Syracuse besieged by the Athenians.
410. War against the Carthaginians.
368. Dionysius the elder died.
387. Dionysius the younger banished.
354. Dion died.
355. Calippus his fon.
354. Hypparion, son of Dionysius.
347. Dionysius returns.
333. Timoleon expelled Dionysius.
280. Agathocles died.
235. Hiero II. died.
214. Hieronymus his fon died.
212. Marcellus took the city.

It is not ascertained what kind of government first prevailed in the city of Syracuse. Atheneus and Elia mention a people named Polis, who resided there in early time, from which circumstance some have concluded, that the city was first governed by kings; but if monarchy was first introduced, it was soon changed into a democracy. A considerable obscurity involves the history of this republic for the space of 200 years; and therefore we must content ourselves with selecting a few particulars from the records that commence with the reign of Gelon, when Syracuse first made a considerable figure, and from which period it furnished many great and memorable events for an interval of above 200 years. During this time it exhibits a perpetual alternation of slavery under tyrants, and liberty under a popular government, till it was at length reduced by the Romans, and made part of their empire. For an account of Gelon, and the principal transactions of his reign, see Gelon. He was succeeded by his brother Hiero (see his biographical article); and Hiero, by his brother Tharyphylus, who was a savage and bloody tyrant, and was banished about the year 466 B.C. Upon his expulsion a popular government was introduced at Syracuse, and it was everywhere established and maintained till the reign of Dionysius the younger. The Syracusans, thus restored to their former liberty, convened a general assembly, which unanimously decreed, that a statue should be erected to Jupiter, the deliverer, of the size of a colossal; and that, on the anniversary of the happy day on which they had regained their liberty, solemn games should be exhibited, and 430 bulls sacrificed, by way of thanksgiving to the gods, and all the people entertained and feasted as a day of general rejoicing. It was also decreed, that the magistrates, according to ancient custom, should be chosen from among the chief citizens, and that none of the strangers, who had been made denizens by Gelon, should be admitted to employment of trust. This decree incensed the foreigners and was the occasion of new tumults in Syracuse. After several internal commotions and conflicts, the most important and interesting event that happened to Syracuse was the invasion of the Athenians. This brought on a war both by land and sea, which was prosecuted with alternate success and defeat and with great slaughter on both sides; till at length, after a contest of about three years, it terminated in favour of the Syracusans. See Callimiches.

When Hamilcar gained the city of Agrigentum, in a siege of eight months, the whole island of Sicily was struck with terror; and many of the inhabitants forsaking their native cities, fled to Syracuse, where they were treated with great kindness, and the chief men among them were free. However, many of these refugees were Agrigentines, and they filled the city with incitements against the Syracusan commanders, as if they had betrayed Agrigentum into the enemy's hands. These accusations caused disturbances in Syracuse, which gave Dionysius a favorable opportunity for seizing on the sovereign power, and depriving the inhabitants of that liberty which they had so abjured, and, by degrees, turned into licentiousness. For the principal events of his reign, and those of his immediate successors, we refer to the articles Dionysius I. and II. and Dion.

When Timoleon had succeeded in expelling Dionysius, and making himself master of Syracuse, it gained for Corinth and other cities of Greece a population amounting to above 10,000 persons. At the same time, great tumults of people from Italy, and other parts of Sicily, joined Timoleon, who distributed lands among them, but sold the houses, and, with the money arising from the sale, established a fund for the support of the poor and needy. He also, upon his settlement at Syracuse, appointed new magistrates, and instituted such laws as were most proper for the democracy. Among other wise institutions, he appointed a chief magistrate called Amphipolus of Jupiter Olympia; the first who followed this name and office being Callimiches. Hence arose the custom among the Syracusans of computing their years by the respective governments of these magistrates, which continued in the time of Diodorus Siculus, that is, in the reign of Augustus, above 300 years after the office of Amphipolus was first introduced. (See Timoleon.) For twenty years the Syracusans enjoyed the beneficial fruits of Timoleon's victories and conduct. At length a tyrant, exceeding all his predecessors in cruelty and all other vices, started up among them. (See Agathocles.) After his death, Syracuse underwent many revolutions, till, at length Hiero II. was declared king by the unanimous consent of the citizens, and soon after acknowledged as such by all their allies. (See Hiero II.) Hiero had formed the design of abolishing monarchy, and reforming the Syracusans to their ancient form of government, but was diverted from the execution of his purpose by one of his daughters, and her infringement bequeathed the crown to his grandson Hieron, whose vices and cruelty gave occasion to the Syracusans very much to regret the death of his grandfather. Besides their hatred, which he incurred by his misconduct,
he provoked the Romans by his contemptuous treatment of their ambassadors. The Romans commenced hostilities, and Hieronemus fell a sacrifice to a conspiracy among his subjects. Marcellus, who commanded the Roman army, besieged Syracusae both by sea and land; and though it was vigorously defended by the machines of Archimedes, which made great havoc among the Romans, it was after a three years' siege taken by assault, and the inhabitants were treated with singular clemency by the conqueror. The conduct of Marcellus ensured the lasting gratitude of the Syracusans to him, and to his posterity. (See Marcellus.) The conquest of Syracusae was soon followed by the reduction of the whole island. See Sicily.

The dioeces of Syracusae is said to produce above forty different sorts of wines; the honey of the hills is as clear as amber, and of a most delicious flavour; vegetables are here admirable in their kinds, especially broccoli, which grows to a prodigious size. The climate is singularly mild, so that it is admirably adapted for a winter's residence. In summer the marshes at the head of the port exhale vapours that infect the air, and endanger the lives of the inhabitants. A singular circumstance is mentioned by Brydone with respect to the climate, derived by tradition from the ancients, but the traveller does not vouch for the truth of it; that at noon the sun has been ever inviolate during a whole day at Syracusae; 71 miles S. of Melfi, and 115 S.E. of Palermo. N. lat. 35° 5'. E. long. 15° 14'.

SYRAU, in Geography, a town of Saxony, in the Vogtland; 4 miles N.W. of Plauen.

SYRE, a town of Norway, in the province of Christianiaand; 24 miles N.W. of Christianiaand.—Allo, a lake of Norway, in the province of Christianiaand; 50 miles N.W. of Christianiaand.—Allo, a river of Norway, which rises near the mountain Lang, runs through the vale of Syre into the lake of Lunde, in the dioeces of Christianiaand, and afterwards discharges itself into the sea, shooting like an arrow through a very contracted strait, between rocks; 20 miles W. of Syre.

SYRENS, SYRENS, in Antiquity. See SEIRENS.

SYRENIUS HIBULUS, in Ancient Geography, Illes de l'Syrene, islands of the Mediterranean, E. of the isle of Caprea, and S. of the promontory of Miserrva. They are three rocks, said to be inhabited by the Syrenae.

SYRIA, that part of Asia which, bathed by the Mediterranean on the W., had to the N. mount Taurus, to the E. the Euphrates and a small portion of Arabia, and to the S. Judea or Palestine. The Orientalists called it Aram, which see. The name, which has been transmitted to us by the Greeks, is a corruption or abridgment of Assyria, which was first adopted by the Ionians, who frequented these coasts after the Assyrians of Nineveh had reduced that country to be a province of their empire, about the year 750 B.C. By the appellation of Syria is ordinarily meant the kingdom of Syria, of which, since the reign of the Seleucidae, Antioch has been the capital.

The physical geography of this country presents to our notice some remarkable mountains and rivers. Towards the north is part of a chain of mountains denominated Taurus, which itself is included in the mountains extending from the N.E. to the S.W. On this side, and near the sea-coast, is the strait or passage called Phyle Syrie. Near Antioch, to the S., is a chain of mountains, which separates the course of the Oronites from the Mediterranean, and forces it to turn northwards to Antioch. This chain bears the name of Libanus. Farther N. one of the mountains bore the name of Laflus. The same chain is continued towards the S.W. as far as Tyre on the sea-coast. Another chain lies more to the E., and bears the name of Anti-Libanus. Among these mountains are valleys, and particularly that which is watered by the Leontes, and called Ceso-Syria; the latter including a space of about 25 leagues is one direction, and 25 in another. The most remarkable river of Syria is the Orontes, now called El-Ae. The Leontes we have already mentioned. The four ancient kingdoms comprehended in Syria, and distinguished by the Orientalists, were those which had for their capitals Damascus, Zohab, Hamath, and Geshur. After the death of Alexander, Syria was divided into five large provinces, viz. Comagene, the Seleucidae, Ceso-Syria, Phoenicia, and Judea. Adhering partly to this division, Strabo says that Syria comprehended four large nations, the Hebrews (or Jews), the Idumeans, the Gazzans, and the Assiotes. The partitions under the kings of Syria gave occasion to a greater number of provinces. Those belonging to Syria Proper, mentioned by Ptolemy, are the Comagene, Pieria, Cynorrhodica, the Seleucidae, the Cassotides, the Chalybonita, the Chalcides, the Apamea, the Laodicea, the Mediterranean Phœnia, Ceso-Syria, and the Palmyrene. By a change which took place in these divisions, a large province, formed to the E. by the Euphrates, was known under the name of Epiphraei. Comagene was the most northern part of Syria, extending N.E. between mount Amanus, from the S.W. to the E. Lus. mount Taurus to the N., and the Euphrates to the E. and S. The Euphrates extended, as we have seen, the Epiphraei, the course of which was here from N.W. to the S.E. It had a chain of mountains to the W. The Palmyrene was the eastern part of Syria, so called from the famous city of Palmyra, which see. Ceso-Syria formed the southern part of Syria, between the Libaus and Anti-Libanus. Its principal towns were Damascus, Abyla Lybar, Solani, Panas, Helipolis or Banha, &c. Phœnia of Libanus formed a part of Syria. The part called Lodiocare, or Laodicæ, lay towards the N. Here were situated Laodicæ ad Libanum, to the E. Emera, where there was a celebrated temple of the sun; to the N. Epiphanias, called Hamah; to the W. Raphanae or Rafañ, to the S., between the mountains, Lybar, N. of Lybar, and W. of Raphanae, Demetriae or Akkar; N.E. of this last place, Carion, and N.W. upon the Eleutherias, or Naher-el-Kibbir, Marriamme. The Apamea lay to the N. of Laodicæ, and was traversed by the Orontes from S.E. to N.W.; here were situated Larifia or Shizar, on the Orontes; Apamæa or Famich, on the bank of a lake to the S., and surrounded by a lake; to the N.E. of Apamæa were Marra and Andron; to the E. Caparee and Theleed. The Seleucidae comprehended the towns that lay on the sea-coast; such were Marathus or Marakia, Balana or Belena, Paltus, Gabala or Gebelich, and to the N.W., on a small promontory, Laodoceæ ad mare, or Ladikia. The tongue of land which advanced to the N.W. was called Cherefonius, having at its extremity Cape Ziaret, and upon the northern coast a small fortress called Heracles, or Meinaburg; and at a small distance towards the E. a small place called Cethela. At a small distance towards the N., on the sea-coast, at the northern extremity of a small peninsula, was Roda or Roda. On S.E. of the latter town was the island of Melibea. The second part of this division comprehended the town of Seleucia, named Pieria, from the adjoining mountain Pierius, which formed a small peninsula towards the N. At the extremity of this coast was the rock denominated Roffius Scopolus, and upon the northern coast of the peninsula was the town of Rhodus or Rofo. W. of Rhodos, and at the mouth of the Pyramus, was Aër; and between the mountains and the sea, the first called Syrie

Pylis.
SYRIA.

Pylis. The gulf bore the name of Ilicus Sinai, from the town of Ilius, situated on the northern coast, and belonging to Cilicia. On the eastern coast were Myriandrus, or Alexandria, Alexandria-Casa-Iphen, and Alexandria towards Ilius, or Alexandretta. In the midst of a valley, near a lake N.E. of Antioch, and on the course of a river, was a town called Hieracle, and more to the S., on a mountain, the temple of Gindon, and near it, the W. were Temples dedicated to the gods of the first men, of their beard and hair, which were preferred in the temple, in a vessel of gold or silver, on which was inscribed the name of the person who made the offering. The fight of a dead person rendered a person unfit to enter into the temple during the whole day.

The dynasty of Syria may be divided into two classes; those that are known to us in the first writings, or in the works of Josephus, acknowledged by the Orientalists, and the Seleucid kings, successors of Alexander, with whom we are more acquainted by Greek authors.

The first dynasty comprehends the kings of Zobah, such as Rehamos, Sabat, and Adrasa; the kings of Damascus, such as Rezen, Adad I. and II., Hazlon or Adad III., Tabrimon or Adad IV., Benhadad I., or Adad V., Benadad II. or Adad VI., Hazael or Adad VII., Benhadad III., or Adad VIII., Hazael IX., or Rezin or Haza, or Adad X.; the kings of Hamath, such as Tobi or Thah, or Adar of Joram; the kings of Gebur, such as Ammiad and Taim. The second dynasty comprehends the succession of Alexander's successors: such as Seleucus Nicator, Antiochus Soter, Antiochus Theos, Seleucus II., or Callinicus, Seleucus III., or Ceraunus, Antiochus III., or Margas, Seleucus IV., Piphilopator, Antiochus IV., or Epiphanes, Antiochus V., or Eupator, Demetrius Soter, Alexander Balas, Demetrius II., or Nicator, Antiochus, son of Balas, Diodotus Tryaneus, Antiochus VII., or Sidetes, Demetrius Nicator, Alexander Zebina, Seleucus V., Antiochus VIII., or Gemis, Antiochus IX., or Cyzicenus, Seleucus VI., son of Seleucus II., Antiochus X., son of Cyzicenus, Antiochus II., Philip, Demetrius III., Antiochus XII., Tigranes, Antiochus XIII., Tigranes, subject to the Romans, and in the year 63 B.C. Syria became a Roman province. See several biographical articles for a further account of all of these kings, and more especially of the Seleucid.

Syria, in Geography, called by the Arabians Baré Sham, a province of Asiatic Turkey, comprising the whole space contained between two lines, drawn, the one from Alexandretta to the Euphrates, and the other from Gaza to the desert of Arabia, bounded on the E. by the desert, and on the W. by the Mediterranean.

This country is, in some measure, only a chain of mountains, which divide themselves, in various directions, into one leading branch; and such, in fact, is the appearance it presents, whether we approach it from the side of the sea or by the immense plains of the desert. These mountains, as they vary their levels and situations, are also greatly changed in their form and appearance. Between Alexandretta and the Orontes, the hills, larches, oaks, beeches, laurels, yews, and myrtles, give them an air of liveliness, which delights the traveler in the several activities he meets with cypresses, envinced with figs and vines. The inferior branches, which extend to the northward of Aleppo, on the contrary, present nothing but bare rocks without verdure or earth. To the fourth of Antioch, and on the sea-coast, the hill-faces are proper for the cultivation of tobacco, olives, and vines (mount Canius excepted) on the side of the desert, the summits and declivities of the chain are almost one continued series of white rocks. To
SYRIA.

Towards Lebanon, the mountains are lofty, but are covered, in many places, with as much earth as fits them for cultivation, by industry and labour. There, amid the crags of the rocks, may be seen the not very magnificent remains of the bountiful cedars; but a much greater number of firs, oaks, brambles; mulberry-trees, figs, and vines. As we leave the country of the Druses, the mountains are no longer so high; nor so rugged, but become firmer for tillage: they rise again to the south-east of mount Carmel, are covered with woods, and afford very pleasant prospect; but as we advance towards Judea, they lose their verdure, their valleys grow narrower, they become dry and stony, and terminate at the Dead Sea in a pile of discolate rocks, full of precipices and caverns; while to the west of Jordan, and the lake, another chain of rocks, still higher, and more rugged, presents a still more gloomy prospect, and announces, afar off, the entrance of the desert, and the end of the habitable lands. A view of the country will convince us, that the most elevated point of Syria is Lebanon, on the south-east of Tripoli. See Lebanon.

The south of Syria, that is, the hollow through which the Jordan flows, is a country of volcanos. Earthquakes continue to be felt at intervals in this country. The coast in general is level and sandy, the bay of the north and south, examples of earthquakes which have changed the face of Antioc, Laodicea, Tripoli, Berytus, Tyre, Sidon, &c. In later times an earthquake is said to have devastated, in the valley of Balbec, upwards of 20,000 persons. It is remarked that, in Syria, earthquakes seldom happen but in winter, after the autumnal rains. In fo extensive a country as Syria, the soil varies. In general the land of the mountains is harsh and gritty; while that of the plains is fat and loamy, and exhibits every sign of the greatest fecundity. In the territory of Aleppo, towards Antioc, it resembles very fine sand, or Spanish sand. Everywhere, the earth is brown, and as fine as garden-mould. In the plains, such as those of Hauran, Gaza, and Balbec, it is often difficult even to find a pebble. The winter rains occasion deep quagmires; and on the return of summer, the heat produces, as in Egypt, large cracks in the earth several feet deep. The rivers, or rather rivulets, of Syria, are the Jordan, the Orontes, and the Adonis. They hardly deserve the name of rivers, as the channels of the Orontes and Jordan, the most considerable of them, are only 60 paces wide in places. The Jordan, indeed, has great depth; but if the Orontes were not impeded by successive obstructions, it would be quite dry during the summer. The obstructions that occur in several places, at the isles and in the course of the rivers, have contributed to form considerable lakes, such as those of Antioc, Aleppo, Damascus, Hauran, Tabaria, and the Dead sea.

As to the climate of Syria, it is different in different latitudes, and in different situations, such as the low and flat, or high and mountainous. While Reaumur's thermometers stand at 25 and 26 degrees upon the coast, it hardly rises to 20 or 21 among the mountains. Along the coast of Syria, and at Tripoli in particular, the lowest degrees to which the thermometer falls in winter are eight and nine degrees above the freezing point. As for the barometer, at the latter end of May, it rises at 26 inches, and never varies till October. In winter the whole chain of mountains is covered with snow, while the lower country is always free from it. In Syria we may fix two climates: one very hot, which is that of the coast and the interior plains, such as those of Balbec, Antioc, Tripoli, Acre, Gaza, Hauran, &c.; the other temperate, and almost like our own, which is the climate of the mountains, at least at a certain height. In this climate, the order of the seasons is nearly the same as in the middle provinces of France; the winter, which lasts from November to March, is sharp and rigorous. Not a year passes without snow, and the earth is frequently covered several feet deep with it for months together; the spring and autumn are mild, and the summer heat is absolutely intolerable. In the plains, on the contrary, as soon as the sun returns to the equator, the transition is rapid to oppressive heats, which continue to the end of October. But then the winter is so moderate, that the orange, date, banana, and other delicate trees, flourish in the open air; and it appears equally extraordinary and picturesque to an European at Tripoli, to behold, under his windows, in the month of January, a variety of fruit, which is the produce of Lebanon; for in the lofty head of Lebanon is a basin covered with ice and snow. It must nevertheless be observed, that in the northern parts, and to the east of the mountains, the winter is more rigorous, without the summer being less hot. At Antioc, Aleppo, and Damascus, there are several weeks of frost and snow every winter; which arises from the situation of the country, fill more than the difference of latitude. For, in fact, all the plain to the east of the mountains is very high above the level of the sea, exposed to all the wind from the north and north-east, and screened from the humid winds of the south and south-west. Befides, Antioc and Aleppo receive from the mountains of Alexandretta, which are within sight, an air which the snow, that covers them so long, must necessarily render very sharp.

Syria unites different climates under the same sky, and collects, within a narrow compass, pleasures and productions, which nature has elsewhere distributed at great distances of time and places. In spite of the barbarism of a government, which is an enemy to all industry and improvement, we are astonished at the very sight of the corn that is raised in this country. Sides wheat, rye, barley, beans, and the cotton-plant, which is cultivated every where, we find a multitude of useful and agreeable productions, appropriated to different situations. Paleikne abounds in selenium, and dourra as good as that of Egypt. Maize thrives near Balbec, and even rice is cultivated with success. They plant sugar-canes in the gardens of Saide and of Bairout, and find them equal to those of the Delta. Indigo grows, without cultivation, on the banks of the Jordan; tobacco is grown throughout all the mountains. As for trees, at Antioc and Ramla to the height of the beech; the white mulberry-tree constitutes the wealth of the whole country of the Druses, by the beautiful silks which are produced upon it; while the vine, supported on poles, or windings round the oaks, supplies grapes which afford red and white wines, that might rival those of Bordeaux. Gaza produces dates and pomegranates; Tripoli affords oranges; Bairout figs and bananas not inferior to those of St. Domingo; Aleppo enjoys the exclusive advantage of producing pashmas; and Damascus of possessing all the fruits known in the milder climates of Europe. With these numerous advantages of climate and of soil, it is not astonishing that Syria should always have been esteemed a most delicious country, and that the Greeks and Romans ranked it among the most beautiful of their provinces, and even thought it not inferior to Egypt. In more modern times, also, a pacha, who was acquainted with both these provinces, being asked to which he gave the preference, replied, "Egypt, without doubt, is a most beautiful farm, but Syria is a charming country-side.

Syria produces all our domestic animals, and, besides thefe, the buffalo, and the camel, whose utility is so well known.
SYRIA.

known. The jackals go in droves, and in uninfected places there are also hyenas and onces; but the country is free from lions and bears. Water-fowls are plentiful, but land game is less abundant.

On the mountains, and in all elevated plains which stretch to the eastward, the air is lighter, pure, and dry; while the coast, and especially from Alexandretta to Jaffa, it is muggy and heavy, and exceedingly unwholesome. In the course of a whole summer, few clouds are seen, and still less rain, which only begins about the end of October, and then is neither long nor plentiful: the husbandmen with it for to sow what they call their winter crop, that is, their wheat and barley. In December and January the rain becomes more frequent and heavier, and snow often falls in the higher country: it sometimes rains also in March and April; and the husbandman avails himself of it for his summer crop of sesame, dourou, tobacco, cotton, beans, and water-melons. The remainder of the year is uniform, and drought is more frequently complained of than too much wet.

Within 2,500 years we may reckon ten invasions, which have introduced into that country a succession of foreign nations: first, the Assyrians of Nineveh, who pawing the Ephraims about the year 750 before the Christian era, within 50 years, obtained possession of almost the whole country lying to the north of Judea; next the Chaldæans of Babylon, who having destroyed the power on which they were dependent, fought against, as heretics against, to his possessions, and completed the conquest of Syria, except the town of Tyre. The Chaldaeans were followed by the Persian, under Cyrus; and the Persians by the Macedonians, under Alexander. It then seemed as if Syria was about to cease being a vassal to foreign powers, and to obtain a distinct and independent government, according to the natural right of every country; but the people, who found in the Seleucidae only cruel despots and oppressors, fearing themselves reduced to the necessity of bearing some yoke, preferred the lightest; and Syria, yielding to the arms of Pompey, became a province of the Roman empire. Five centuries after, when the sons of Theodorus divided their immense patrimony, this country changed the capital to which it was to appertain, without changing its masters, and was annexed to the empire of Constantinople. Such was its situation, when, in the year 632, the Arabian tribes, collected under the banners of Mahomet, feigned, or rather laid it waste. Since that period, torn to pieces by the civil wars of the Fatimides and the Omrides, wracked from the caliphs by their rebellious governors, taken from them by the Turkman foldiery, invaded by the European crusaders, retaken by the Mamluks of Egypt, and ravaged by Tamerlane and his Tartars, it has at length fallen into the hands of the Ottoman Turks, who have been its masters nearly three centuries. The inhabitants may be divided into three principal classes: the poverti of the people conquered by the Arabs, that is, the Greeks of the lower empire; the poverti of the Arabian conquerors; the present ruling people, the Ottoman Turks: of these three classes, the former must be again subdivided, in consequence of several distinctions which have taken place among them. The Greeks, then, must be divided into Greeks Proper, usually called Christian, or Sephardie, from the Romish communion; Latin Greeks affiliated to that communion; Maronites, or Greeks of the sect of the monk Maron, formerly independent of the two communions, but at present united to the latter. The Arabs must be divided into the proper descendants of the conquerors, who have greatly intermixed their blood, and are considerably the most numerous; Mutuals, distinguished from these by their religion; the Druzes, distinct likewise from the same reason; the Aftarians, who are also descended from the Arabs. To these people, who are the cultivators and settled inhabitants of Syria, must still be added three oder wandering tribes, or paltors, viz. the Turkman, the Coss, and the Bedouin Arabs: such are the different races inhabited over the country, between the sea and the desert, from Gaza to Alexandretta. In this enumeration, it is remarkable that the ancient inhabitants have no meaning representative; their distinguidng character is lost and confounded in that of the Greeks, who, in fact, by a continued residence from the days of Alexander, have had a sufficient time entirely to take place of the ancient people: the country alone, and a few traits of manners and customs, preserve the vestiges of distant ages.

The Syrians are, in general, of a middling stature, and are, as in all warm countries, less corpulent than the inhabitants of the north. We find, however, in the city some individuals whose amplitude of frame proves that the influence of diet is able, in a certain degree, to counterbalance that of climate. The general language of Syria is the Arabic tongue. In Syria, as in all the Arabic countries, the dialects vary at every place. The Syriac may be, therefore, regarded as a dead language; for the Maronites, who have preferred it in their liturgy, and use it for their mafis, understand very little of it, while they use them. The Turkish language is only used, in Syria, by the military, persons of office, and the Turkmans here. The Arabic of Syria is much akin to that of Egypt.

Among the different inhabitants of Syria, some are dispersed over every part of the country, and others confine themselves to particular spots. The Greeks Proper, the Turks, and the Arabian peasants, belong to the same class, with this difference, that the Turks reside only in the towns where they are in possession of the military emoluments, and the offices of the magistracy, and when they exercise the arts. The Arabs and the Greeks inhabit the villages, and form the class of husbandmen in the country; and the inferior class in the towns. The part of the country which contains the most Greek villages is the pashalic of Damascus.

The Greeks of the Romish communion, who are not less numerous than the schismatics, are all settled in the towns, where they cultivate the arts and commerce. The protection of the Franks procured them, in the late war, decided superiority in trade, wherever there are European settlements.

The Maronites form a national body, which occupies almost exclusively the whole country comprised between Naher-el-kelb (the river of the Dog) and Mak-el-keld (the cold river), from the summits of the mountains on the coast, to the Mediterranean on the west.

The Druzes border upon them, and extend from Naher-el-kelb to the neighbourhood of Sour (Tyre), between the valley of Bekaa and the sea.

The country of the Motoufias formerly included the valley of Bekas, as far as Sour; but this people, of late years, have undergone a revolution, which has reduced them almost to nothing.

The Turks, the CURDS, and the Bedouins, have so many fixed habitations, as to be perpetually wandering with their tents and herds, in limited districts, of which they hold upon themselves as the proprietors. The Turkmans generally encamp on the plain of Antioch; the Curch is the
SYRIA.

the mountains between Alexandretta and the Euphrates; and the Arabs spread over the whole frontier of Syria, adjacent to their deserts, and even the plains of the interior part of the country, as those of Palestine, Bekas, and Gallilee.

Syria is divided into five governments, or pachalics, viz. the pachalics of Aleppo, Tripoli, Damascus, Acre, and Palestine; the whole of which is, by a modern traveller, computed to bring into the grand fiscus treasury the sum of 312,000l. sterling, and the produce of Syria is estimated at 1,281,350l. All the troops of the five pachalics united amount to no more than 5700 men. Syria is flated by the same writer as containing 452,000 square leagues, at the rate of 150 in length, and 35 in breadth; and supposing the total population to be 28 millions, we shall have, upon an average, 475 inhabitants to a square league.

The government of the Turks in Syria is a pure military despotism; that is, the bulk of the inhabitants are subject to a fraction of armed men, who dispose of every thing according to their interest or caprice. When the Ottomans, under Sultan Selim, took Syria from the Mamlouks, they considered the country only as the spoil of a vanquished enemy; as a possession acquired by the law of arms and war. Now, according to this law, among barbarous nations, the vanquished is wholly at the discretion of the victor, he becomes his slave, his life, his property, belong to his conqueror; he is held as a slave and that he is his mere property, he is sold for nothing, and grants what he leaves him as a favour. Such was the law among the Greeks and Romans; and among all these societies of robbers whom we have honoured with the name of conquerors. Such, at all times, was that of the Tartars, from whom the Turks derive their origin. On these principles, even their first social state was formed. The Turkish empire may be compared to a plantation in one of our sugar islands, where a multitude of slaves labour to supply the luxury of one great proprietor, under the inspection of a few servants, who take good care of themselves. There is no difference, except that the dominions of the sultan being too vast for a single administration, he is obliged to divide them into smaller plantations, and separate governments, administered in the same mode as the united empire. Such are the provinces under the government of the pachas. See PACHA.

The people of Syria in general, with regard to religion, are Mahometans or Christians. This difference of opinion is productive of the most disagreeable effects in their civil state. Treating each other mutually as rebels, infidels, and impious, the followers of Jesus Christ and Mahomet are actuated by a reciprocal aversion, which keeps alive a sort of perpetual war. Faithful to the spirit of the Koran, the government treats the Christians with a severity, which displays itself in varied forms. Mention has been sometimes made of the toleration of the Turks; the following is the price at which it is purchased. All kind of public worship is prohibited the Christians, except in the Kefraouan, where the government has not been able to prevent it. They cannot build any new churches; and if the old ones fall to decay, they have no right to repair them, unless by a permission which costs them very dear. A Christian cannot visit a Mahometan without risk of his life; but if a Mahometan kill a Christian, he escapes for a stipulated price. Christians must not mount on horseback in the towns; they are prohibited the use of yellow fippers, white hawals, and every sort of green colour. Red for the feet, and blue for the drabs, are the colours assigned them. The Porte has just renewed its ordinances to re-establish the ancient form of their turbans; they must be of a coarse blue muffin, with a single white border. When they travel, they are perpetually stopped at different places to pay "hafara," or tolls, from which the Mahometans are exempt. In judicial proceedings, the oath of two Christians is only reckoned for one; and if it is the partiality of the cadi, that it is almost impossible for a Christian to gain a suit. In short, they alone are subject to the capitulation, called "kaudi," the ticket of which bears these remarkable words: "Djaas-el-ram," that is, (redemption) from cutting off the head; a clear proof of the title by which they are tolerated and governed. These distinctions, so proper to foment hatred and divisions, are diffeminated among the people, and manifest themselves in all the intercourse of life.

The sultans having arrogated to themselves, by right of conquest, the property of all the lands of Syria, the inhabitants can no longer pretend to any real, or even personal property; they have nothing but a temporary possession. When a father dies, the inheritance reverts to the sultan, or his delegate; and the children can only redeem the succession by a considerable sum of money. Hence arises an indifference to landed estates, which proves fatal to agriculture. In the towns, the possession of houses is in some measure left uncertain and left ruinous; but everywhere the preference is given to property in money, as more easy to hide from the rapine of the defiat. In the tributary countries, such as those of the Drufes, the Maronites, Flanis, etc., there exists a real and a sure property, besides the rents, which are disposed of as the property which their petty princes dare not violate; on which account, the inhabitants are so attached to their estates, that it is very rare to hear of alienation of lands among them. There is nevertheless one method, even under the Turkish government, of securing a perpetual usufruct, which is by making what is called a "wakf," that is an endowment or donation of an estate to a mosque. The proprietor then becomes the irrevocable guardian of his property, on condition of a fine, and under the protection of the profilers of the law; but this act has this inconvenience, that instead of protecting the mean of the law frequently devour the property; and, in that case, to whom are they to look for redress, since the embiezars of the property are at the same time the distributors of justice? For this reason, these lawyers are almost the only landholders; nor do we fee, under the Turkish government, that multitude of small proprietors, who constitute the strength and riches of the tributary countries.

The ranks or different conditions of persons in Syria may be reduced to four or five: the cultivators or peasants, artisans, merchants, military men, and those in all the different departments of the law and juridical officers. These various classes again may be comprehended under two others; the people, which includes the peasants, artisans, and merchants; and the government composed of the military, and legal and judicial officers. According to the principles of their religion, the power should reside in the latter order; but since the disposition of the caliphs by their lieutenant, a distinction has taken place between the spiritual and temporal power, which has left only the former to the sultan, under the authority of the imam. Such is that of the grand mufle, who represents the caliph, among the Turks. The real power is in the hands of the sultan, who represents the lieutenant, or general of the army. That favourable prejudice, however, which the people entertain for dethroned powers, still presides to professors of the law a credit, of which they almost always avail themselves, to form a party of opposition. The sultan is awed by it at Constantinople; nor do the pachas venture too openly to thwart it in their provinces. In each city this party
SYRIA.

party is headed by the mufti, who derives his authority from that of Conftantinople; his employment is hereditary, and not venal; which finge circumstance has prefered more eminence in this body than in all the others. From the privilege they enjoy, the families which compose it bear a considerable refemblance to our nobility, although its true type be the army. They re semble also our magiftracy, our clergy, and even our citizens, as they are the only perfon in that country who live on their rents. From them to the pefantry, the artificers, and traders, the defcent is fudden; yet, as the condition of these three fclaves form the true standard of the police and power of an empire, we fhall felect the particulars best calculated to enable the reader to form juft ideas.

The peffants in Syria, and alfo throughout the Turkish empire, are deemed felves of the sultan, i. e. as the term imports, they are his fubjeft. Although he is maker of their lives and property, the sultan does not fell men; he does not limit them to a certain spot. If he beefows an appanage on fome grazeed, it is not faid, as in Ruflia and Poland, that he gives 500 or 1000 peffants; in a word, the peffants are opprefled by the tyranny of the government, but not integrat ed by feudal fervitude. In order to render the collection of the revenue more easy, fultan Selim, after he had conquered Syria, ettablished a fingle territorial tribute, called the "Miri," (which fce.) This he ettablished at an irrevocable rate, but the pefcians and their agents have adopted a variety of changes, which produce all the effects of an augmentation. Praefiding numerous modes of oppreffion and extortion, the poorer clafs of inhabitants cannot pay the miri, and leaving their villages fly into the cities; but the miri being unalterable, the burthen on those who remain becomes infupportable. Nothing is more def tructive to Syria, than the shameful and exorbitant uitry customary in that country. When the peffants are in want of money to purchase grain, cattle, &c. they are obliged to mortgage the whole, or part, of their future crop, greatly under its value. From these and a variety of other circumftances, which we cannot detail, the condition of the peffants is extremely wretched. They are every where reduced to a little flat cake of barley or dourra, to onions, lentils, and water. They are fo little acquainted with dainties, that they efcape from oil and rancid oil as defecrative. All Turfhan and Nabob grain is henceforth wretchedly difcouraged; his plough is often no more than the branch of a tree, cut below a bifuration, and used without wheels. The ground is tiled by affes or cows, rarely by oxen. In diftricts like Palestine, exposed to the Arabs, the countryman must fow with a mufket in his hand. The corn, before it changes colour, is reaped, but concealed in fubterraneous caverns. The whole induftry of the peffant is limited to a supply of his immediate wants; and to procure a little bread, a few onions, a wretched blue flift, and a bit of woollen, much labour is not neceffary.

The artificers and traders, whose property is more capable of concealment than that of the peffants, escape more easily from the rapacity of their rulers. Hence it is that the towns in Syria, and other parts of Turkey, are populous. Commerce, as to the mode of conducting it, is still in Syria such as it excels in barbarous ages and uncivilized countries. Along the coaf there is not a harbour capable of admitting a veque of 400 tons, nor are the roads secured by forts. In the interior parts of the country, there are neither great roads nor canals, nor even bridges over the greater part of the rivers and torrents; however necessary is water. The communication between one town and another is maintained by carriages, who have no fixed time of departing, because their safety depends on the troops that accompany them, and the number of fellow-travellers. In Syria there is neither waggon nor cart, probably because they are likely to be feized by the minions of government. Every thing is conveyed on the backs of mules, asses, or camels. The camel is chiefly ufed on the plains, because he consumes less and carries more; his usual burden being about 400 pounds, and his food, fraw, branbles, pounded dates, beans, nuts, of 40 or any thing 60 a word, which you charge to give him. With a single pound of food, and as much water in a day, he will travel for weeks in succession.

Here are no inns for the accommodation of travellers; but the cities, and commonly the villages, have a large building called a Kan, or Caravan-farai, which serves as an at lumn for all travellers. The weights and measures vary at different diftricts; but the value of the coin is more fixed; and you may travel over the whole empire, from Kothia to Afsouan, without experiencing any change in its denominations or value. The monftrous coin called also mendi, fadda, kata, or mefria: its fixe is that of an Englifh silver three-pence, and its value formerly more than a half-penny. Next to the para are pieces of 5, 10, and 20 paras; then the zollata or iolote, which is worth 30; the piaffe, called kerth-afadi, worth 40 paras, two shillings and a penny; and the abou-kelb, or pude of the dog, which is worth 60 paras. All their coins are silver, with a confiderable alloy of copper. The gold coins are the fequins, called kalb, or piece of gold, and sile, or mahalabou, or well-beloved flower; this is worth 300 paras, or 40 pounds. The rich and called faldar, is worth 170 paras, but it is very rare. Besides these coins, which belong to the whole Turkish empire, some of the European fpecies have as much currency; fuch as the silver dolar of Germany, and the gold fequins of Venice. The dolars are worth in Syria from 30 to 22 paras, and the fequins from 205 to 208. The Venetian fequins are much valued in account of the firmness of their standard, and because they are much ufed for women's trinkets. The practice of weighing money is general in Syria, Egypt, and the whole empire of Turkey. The monftrous coin of Syria is in the hands of the Franks, Greeks, and Armenians; formerly it was engrossed by the Jews. France is faid to have led the greatest trade to Syria of any European nation. The imposts confifted in five principal articles, viz. the cloths of Languedoc, cochineal from Cadiz, indigo, fugar, and Chind Indiga coffee; to which may be added hardware, callas, sheet-lead, tin, Lyons lace, foop, &c. The reft of the country is almost wholly in cottons, either linen or raw, or manufactured into coarse fluffs, in some fells of Tripoli, in gauze, in cotton, and wool. The factories ufed to be few in number, viz. Aleppo, Scandereroon, Latakia, Tripoli, Sakh, Acre, and Ramla. The arts and trades in Syria depend on a variety of circumftances. In the villages, the inhabi tants, limited to mere neceffaries, have no arts but those without which they cannot subsist. Each family manufactures the coarse cottons neceffary for clothing. Every houfe has its portable mill, with which the women grind the barley or dourra for their subsistence. The arts in this country lead our views back to ancient times. The art of manufac tur ing fluffs at Aleppo was borrowed from the Arabs, and by them probably derived from the ancient Orientals. The dyes are as old as the times of the Syrians; and the cement they ufe is, without doubt, that of the Greeks and Romans.
in making it, they take care to use the lime when boiling; they mix it with one-third of sand, and another of ashes and brick-dust. With this composition they form wells, citadels, and vaults, through which the water cannot pass. The manner of working the iron mines in Lebanon is that which is now employed in the Pyrenees, and known under the name of the "Catalonian forge." The furnace consists of a chimney formed on the side of a deep declivity: the furnace is filled with wood, which is set on fire; the bellows are applied to this fire, and the iron ore wedged in from above; the metal falls to the bottom, and is taken out by the fame mouth at which the fire is lighted. Their music does not appear to have an earlier origin than the age of the caliphs. Dancing is held in low estimation by the Arabs. The sciences are more neglected than the arts, and, it is said, totally unknown. The barbarism of Syria, as well as that of Egypt, says Volney, is complete. Education is in a very low state, and receives little encouragement. Children are taught to read the Koran, if they are Mahometans, or the Poma, if Christians; they learn a little writing, and reckoning from memory; and here their proficiency terminates. The principal cause of the ignorance and inattention to improvement that prevails is the scarcity of books. There are but two libraries throughout Syria, that of Maranah and that of Djezzar at Acre. It is impossible for books to be multiplied and for knowledge to prevail without printing and a free press. We may, however, trace the ignorance of the Orientals to the government, which does not encourage the propagation of knowledge, but exerts every effort to stifle it in its birth.

As to the manners and character of the inhabitants of Syria, we may observe in general, that they exhibit a grave and phlegmatic exterior, and almost little deportment, and a serious, even sad and melancholy countenance. These traits of character are ascribed not to the climate or soil, but principally to the nature of the government under which the Syrians live. They may also partly be ascribed to the restraints of social intercourse, and more especially that between the sexes. But we must not pursue these reflections any farther. See Volney's Travels in Egypt and Syria, in 2 vols. 8vo. Paris.

Syria, in Ancient Geography, an island on the coast of Asia Minor. Pliny reports that in his time this was part of the continent, near the town of Ephesus.

Syria Salutaris. Pompey conquered Syria in the year of Rome 689, B.C. 63; and under the reign of Theodosius the younger, it was divided into two parts, one of which, having Antioch for its capital, was called Salutaris, on account of its hot baths, which lay in the mountains situated between Orontes and the sea.

SYRIAC BIBLE. See SYRIAC BIBLES, and SYRIAC VERSION, infra.

Syriac Language, a dialect of the ancient Chaldee, which the learned divide into three different dialects, vis. that of Babylon, which is the Chaldee language in its purity; that of Jerusalem, which was used by the Jews after their return from their captivity at Babylon; and that of Antioch, which was used by the Christians of Cosamene, and some other provinces bordering upon Syria, when this was the native language of the country. This last is that which is now more particularly called the Syriac language; and into this language the Old and New Testaments were translated. The Syriac is said by Niebuhr, Maslech, and some others, to be still the vulgar tongue in some villages of the mountains in Syria. Volney, however, having interrogated several monks who were well acquainted with the country on this subject, was not able to obtain a confirmation of this fact. He was merely told, that in the towns of Maloula and Sidnaea, near Damascus, they speak a dialect so corrupted, that it is difficult to be understood. But this difficulty proves nothing, since in Syria, as in all the Arabian countries, the dialects vary at every place. The Syrian therefore, as he says, may be regarded as a dead language; for the Maronites, who have preferred it in their liturgy, and in their miscellaenae very little of it, while they reject it. The Syriac language bears a near affinity to the Hebrew and Aramaic in the number of its letters, though the form of its characters is different, and in a variety of other particulars relating to its construction and syntax. It is however, in its connection with the versions still extant, highly important and useful; and an acquaintance with it is desirable by every biblical scholar. In order to facilitate the acquisition of it, Maclellan has annexed to the second edition of his Hebrew Grammar (vol. ii.) a Syriac Grammar without points. See CHALDEE, HEBREW, LANGUAGE, and SYRIAC VERSION, infra.

SYRIAC VERSION, a version of the Old and New Testaments, which is said to have been made, if not before the death of St. John the apostle, yet very soon after that event. The translator was a Christian well skilled in the Hebrew, Greek, and Syriac languages. The learned who have examined this version, and compared it with the original, both of the Old and New Testaments, inform us, that of all the ancient versions, which are now consulted by Christians for the better understanding of the holy scriptures, as well as of the New Testament as of the Old, none can better serve this end than this old Syriac version, when carefully consulted and well understood. And to this purpose the nature of the language itself very much affords; for as it had been the mother-tongue of those who wrote the New Testament, and a dialect of that in which the old was first given to us, many things in both are more happily expressed in this version than can well be done in any other language. This Syriac version of the whole sacred scripture is still used by the Maronites, a number of Christians dwelling about mount Lebanon. (See MARONITE.) Their liturgy is also in this language. It is used also by the Nestorians (see NESTORIAN), and also by the Jacobites. (See JACOBITE.) There is also another Syriac version of the Old Testament, made from the Greek of Origen's Hexapla, which is not so much esteemed.

The old Syriac version of the New Testament, which ought to be carefully distinguished from those made in a later period, contains only the four gospels, the Acts of the Apostles, the epistles of St. Paul, including that to the Hebrews, the first epistle of St. John, the first epistle of St. Peter, and the epistle of St. James. It is called by the Syriacs "Peshito," that is, the literal, though in fact it is much less so than the new Syriac version. It has neither the form of the abstracts, in the eighth chapter of St. John's Gospel, nor the celebrated passage, John, v. 7. The epistle to the Hebrews, though contained in all the copies of the Peshito, seems not to have been translated by the same person, who also translated the other books of the New Testament, which circumstance is thus accounted for by Michaelis. The old Syriac translator made his version from the earliest collection of the books of the New Testament, in which the epistle to the Hebrews was not included, because its authority was doubted; the translation of the New Testament was followed by that of the Old, and in the mean time, the epistle to the Hebrews having been admitted into the sacred
Syr.-canon, it was afterwards translated into Syriac by a different performer: who this performer was, and in what age he lived, a total want of historical account makes it impossible to determine.

This version was first made known in Europe by Mofes of Mardin, who was sent by Ignatius, patriarch of the Maronite Christians, in the year 1552, to pope Julius III., to acknowledge on behalf of the Syrian church the supremacy of the Roman pontiff, and was commissioned to have the Syriac New Testament printed in Europe. This work was undertaken by Albert Widmanstadt, and printed at the expense of the emperor Ferdinand I., under the care of Mofes and Widmanstadt, assisted by William Poitell. It was printed in Vienna in 1555; and in this edition the two left epistles of St. John, the second of St. Peter, the epistle of St. Jude, and the Revelation of St. John, are wanting. This edition princeps will ever retain its intrinsic value. Tremelius's edition at Geneva, in 1569, fol., is a copy of the former in Hebrew, and not in Syriac letters. The Antwerp edition in the fifth volume of the Bibli Regia is referred to the year 1571. There is another Antwerp edition in 6vo., in Hebrew letters without points, which may be considered as a supplement to the Hebrew bible printed by Platina in 1573 and 1574; and there are also an Antwerp edition in 10mo., and two other Antwerp editions printed in Syriac letters, the one in 1569, and the other in 1620. The Paris edition of 1584 contains the Greek text, the vulgate, and the Syriac version, with a Latin translation over each line, different from and less literal than that in the Antwerp Polyglot. Hutter, in 1599, inserted the Syriac version in his edition of the New Testament in twelve languages: the Cothon edition by M. Troiss, in 1621, 4to., is printed in Syriac letters, with a translation and a collection of various readings, printed by Walton in the fifth volume of the London Polyglot. L. de Dieu published the Revelation of St. John in 1637, at Leyden, and reprinted it in 1643, in Syriac and Hebrew letters. Pococke published at Leyden, in 1639, the four epistles wanting in the Old Testament.

All these parts of the Syriac New Testament were collected and published in the Paris Polyglot, in Syriac letters. The Latin translations by Gabriel Slonits, the editor of the Syriac Old and New Testament, are given very inaccurately. The next edition appeared in the London Polyglot, in which was added the story of the adulteress, from a MS. in the possession of archbishop Usher, but St. John, v. 7, is faithfully omitted. The edition of Aegidius Gathier, which appeared at Hamburg in 1664, is generally used in Germany. A Syriac New Testament was published in Hebrew letters without points at Sultzbach, in 1684, by Christian Kaoroe of Rolenroth, which Schaaf says is only a reimpresion of the Antwerp edition of Plantin above-mentioned. The very best edition of the Syriac New Testament, says Michaelis, is undoubtedly that of Leyden, published by Schaaf in 1708, and reprinted in 1717. The last Syriac version of the New Testament which we shall mention, was published at Leipzig in 1715, fol. in "Christiani Reineccii Biblia quadrilingua." A new edition, says Michaelis, corrected from the most authentic MSS., is still wanting.

The learned Bengelius conjectures, that possibly the Syriac version was not taken immediately or solely from the Greek, but that the translator also made use of the Latin version. But professor Michaelis thinks this conjecture to be in the highest degree improbable; as it is hardly credible that in Syria, where Greek was the current language in all the principal cities, a translator of the New Testament would have recourse to a Latin translation rather than the Greek original; and, besides, there is reason for believing that the Syriac version was made at Edessa, where the Latin language was probably unknown. The Syriac version coincides very much with the Latin, called the Vulgate, and with those ancient Greek MSS. which are undoubtedly written in the West. This wonderful harmony between the two most ancient versions of the New Testament, one of which was spread throughout Europe and the soils of Africa, and the other propagated from Edessa to China, could have had no other cause than a similarity of the Greek MSS. in the west of Europe, and the east of Asia, which must have deviated in an equal degree from the original text, and the MSS., in which was quoted the Greek edition. The similarity of the Greek MSS. from which the two most ancient versions were taken, can be ascribed to no other cause than their high antiquity. Let us, therefore, though not seldom, does the Syriac version agree with the Coptic, and with those ancient MSS. that belong to the Alexandrine edition, sometimes when their difference from those of the Western edition. This similarity will be also ascribed to the high antiquity of those MSS., whereas the copies of the Greek edition are of a later date. Hence it appears we cannot support the undoubted authority of the Syriac, the Coptic, and the Latin verse, by a quotation of Origen, and the ancient Greek MSS. of the Alexandrine and Western editions, is not only of great importance, but may in general be regarded a genuine.

The learned are much divided in their opinions regarding the antiquity of the Syriac version; some referring to the very earliest ages, and others taking all possible pains to prove it to be modern. Professor Michaelis is of opinion that it must have been made in the first century. It is indeed barely credible, as Cranmer, who was a convert to Christianity about the year 1645, that the Christian communities in those countries should have been deficient of a translation of the New Testament in their native language; and Melito, who lived about the year 170, expressly declared, that a Syriac version of the bible at that time existed. Manes also, in his disputes with the Christians of the East, quoted the New Testament, and the public reader of the Christians of Edessa, and could have read the New Testament only in Syriac; the question, therefore, is prior to the age of Manes. Besides, it appears from the testimony of Jerom, that the Syriac bible was in his time read publicly in the churches, for he says, Ephrem, the Syrian is held in such veneration, that in writings are read in several churches immediately after the lections from the bible. A very convincing argument in favour of the antiquity of the Pehuito, is its general reception among all the sects of the Syrian Christians, a circumstance which proves it to have been in general use before the Syriac church was divided into parties. Another argument in favour is the omission of several books, which were afterwards received by the Syrians. The manner likewise in which certain words and phrases are translated in the Syriac New Testament, affords also a presumption in favour of its antiquity. In the left place, Ephrem, who lived about the year of Christ 370, quotes the New Testament, according to the version now extant. From all these considerations we may conclude, that the Syriac version was made either at the end of the first or the beginning of the second century.

The objections that have been brought against this early date are examined and refuted by professor Michaelis.
Dr. Marsh, the editor of Michaelis's *Introduction to the New Testament*, has investigated the arguments in favour of the professor's opinion, and his answers to the objections against it; and he is satisfied neither with the one nor the other. The neccessity, says Marsh, of a Syrian translation in the first century is not so obvious as Michaelis contends; for in all the great cities of Syria, Greek was at that time the current language. The testimony of Melito is questioned, as none of his works exist, except a few fragments preferred by Eusebius in his Ecclesiastical History. His evidence for the antiquity of the Pehito rests on the authority of a scholion, ascribed indeed to Melito, but probably Ipurious, and written many years after his death; and if it were genuine, it would only avail to prove, that the Syrian version of the Pentateuch existed before the close of the second century. Again, Ohannes appears, on the authority of Beaufobre, erroneously cited by Michaelis, not to have been ignorant of Greek; and therefore the argument, founded on this supposition, falls to the ground. Marsh also disputes the conclusiveness of other arguments alleged to prove, that the Syrian version was made in the first century; and he says, that positive reasons may be advanced to show that the hypothesis is wholly ungrounded. No man could think of translating the Greek Testament, before its several parts were collected and united in one volume, or before the sacred canon was formed. But Griefbach and Semler have shown, that the canon was not formed before the middle of the second century. Previously to that period, therefore, the Syrian version cannot possibly have existed.

It cannot with certainty, or even probability, be determined who was the author of the Syrian version; for though the Syrians ascribe it sometimes to the evangelist St. Mark, and at other times to Thaddeus, called by them Adabus, their accounts are confirmed by no authorities. It has been the common opinion in Europe, though it was never supposed in Asia, that Antioch, where the disciples were first called Christians, is the place where the Syrian version was made. But this opinion, says Michaelis, is not only unfounded in historical evidence, but is highly improbable in itself, and proceeds from an ignorance of that country; for Greek being the current language in all the cities to the west of the Euphrates, and especially at Antioch, no motive could have existed for making a translation of the Greek Testament in that city. Although no tradition were till extant that it was written at Antioch; if it were, it would naturally occur as the most probable place; it being a city where the Christian religion was planted in the first century, was adopted by its sovereigns, who erected churches with all the magnificence of Heathen temples, was thence early and widely propagated in the eastern parts of Asia, and a city not only whole language was Syrian, but which during many ages was the eastern metropolis of the Christian world. Michaelis commends the Pehito as the best translation of the Greek Testament which he has ever read; its language being the most elegant and pure, not loaded with foreign words, like the Philonian version and other later writings; bearing no marks of the stiffness of a translation, but written with the ease and fluency of an original; and this excellence of style is ascribed to its antiquity, and to its having been written in a city that was the residence of Syrian kings.

The translation of the second epistle of St. Peter, the second and third of St. John, that of St. Jude, and the Revelation of St. John, is undoubtedly modern, but not made by the same person who translated into Syriac the rest of the New Testament. These books are not found in any MSS. of the Syrian Pehito; neither Nestorians nor Jacobites read in their churches the Revelation of St. John. It is not certain who was the translator of the revelation; the MS. from which L. de Dieu printed it belonged to Scaliger, and was brought from the peninsula of India on this side of the Ganges. Some have ascribed it to Maraba, or Mr. Abba, or Macrejan, who was primate of the East between the years 535 and 572, and translated the Old Testament from the Greek, though a translation had been already made.

The Syrian, or Philoehian version, was so called from Philoehius, otherwise denominated Xenayas, bishop of Hieropolis, or Makbug, from the year 488 to 518; but Philoehius was only patron of the work; the translator being Polycarp, his rural bishop, who executed the work in the year 508. Of this work it was only known, before the middle of the last century, that it existed; and the conjectures formed concerning it were all confused and uncertain. Thomas of Heraclea, a Monophysite, from whom this version is sometimes called Heraclean, undertook a critical correction of it, and made a journey to Alexandria for this purpose; and it was published there in the year 616. In style this version is much inferior to the Pehito; and it is less accurate.

Besides the Pehito and Philoehian versions, it is probable that there existed other Syrian versions, with which biblical critics are at present unacquainted. The Nestorian Christians, who inhabit the mountains of Syria, whose language differs in some respects from that of the more western Jacobites, and who pronounce the dialect of Aramean as we pronounce Chalced, have a peculiar version, which we call the Karkasite. Professor Adler found at Rome a valuable Syriac or rather Chaldean version of the New Testament, though it is only a lectionarium. The dialect of this MS., known in the Vatican by the name of Codex Vaticanus, is East Aramean or Chaldean. Allman, Bib. Orient. Michaelis on the New Testament, by Marth, vol. ii. vol. iii. ed. 2. 1802.

SYRIAC YEAR. See YEAR.

SYRIACUM MARIS, in Ancient Geography, a part of the Mediterranean sea, which bathed the coasts of Syria, according to Ptolemy.

SYRIACUS LAVIS, in Natural History, a name given by Aetius, and many other authors, to the petrified stones of the aethiopes, called by us the Jews-stones, and petrified Balsam from their likeness to an olive in shape, and called by the ancients tecolithus.

It has been a common opinion that this stone was good against the gravel and stone; but Aetius limits its efficacy to a particular case, which is that where the stone matter is lodged in the kidneys and ureters; but he frankly confesses it is of no power to dissolve or break the stone in the bladder.

This is contrary to the doctrine of Dioscorides, and the other old Greeks; but more consonant to reason and experience. Some have carried its virtue so far, as to pretend, that when rubbed to powder, and mixed in water, and that mixture rubbed on the groin and perineum, it will break the stones concreted within, and bring them away in pieces by urine. This, though too good for belief, is yet given us by Pline. In most of the common editions, the words stand thus, *lignentum frangit calculeus*; but all the best copies have it *ungrentum*; and the word *lignentum* is only made by dividing the two perpendicular lines in the letter L.

SYRIE PYLAE, in Ancient Geography, a defile at the eastern extremity of the Mediterranean sea, by which they passed
paffed from the gulf of Icus into Syria, situated at the extremity of one of the branches of mount Amanus.

SYRILIANES, in Geography, a tribe of Finns, who inhabited the district of Ustya Veliko, in the governments of Vologda, of Perme, and Tobolsk. These people call themselves, as well as the Pernians, among and near whom they dwell, Komu or Kodi-mart. Their language, which they have still preserved, much resembles the Pernian, and is not, according to de Gom, the Finnish, but the older of the Slavonic family of languages, and general manners, they have approached so near to the Russians, that they are scarcely any longer distinguishable. In the 14th century, they, together with the Pernians, were converted to Christianity. Tooke's Russia, vol. i.

SYRIAS, in Ancient Geography, a promontory of Asia, in Paplagonia, upon the bank of the Euxine Sea.

SYRICON, a word used by some authors in the same sense as faunus. Pliny makes it a composition of equal parts of sphinct and faunus; and Actius gives it as the name of a collyrium, used in many disorders of the eyes.

SYRINGA, in Botany, the Lilac, was so called by Linnaeus, from ςυρίγας, ςυρίγγος, a pipe, on account of the use which the Turks, according to Clusius, make of its straight and tubular branches, when deprived of their pith, for tobacco-pipes. In Bauhin's edition of Matthiolus, p. 854, it is recorded, on the authority of Cortus, that this tree is called in Barbary Springa; which De Theia writes firi, and suppofes to be the real source of the Linnean name. It may as well be imagined that this African word came from the Greek, and originated in the resemblance of the branches to a reed, which is likewise used for various economical purposes, as well as for the simplest, most ancient, musical instruments. We have no doubt indeed that Linnaeus had both words in view; for Syringa occurs in the edition of Matthiolus which he generally used, the smaller Valgrifian one, of 1770, though not in that with the large cuts, of 1568, where much valuable matter is omitted. The Philadephus of Linnaeus and others, now commonly called Syringa in the gardens, is confounded in its nomenclature and history with the above, its branches being capable of serving the same purpofes. See Syringa in Clusius and Gerarde.—Linn. Gen. 11. Schreb. 14. Wild. Sp. Pl. v. 1. 48. Mart. Mill. Dict. v. 4. Ait. Hort. Kew. v. 1. 23. Vahl Enum. v. 1. 38. Gaertn. t. 49. (Lilac); Tourn. t. 372. Juss. 103. Lamarck Illustr. t. 7;—Clafs and order, Diandria Monogynia. Nat. Ord. Sepiaria. Linn. Jaffirica. Jaff. 2.

Gen. Ch. Cal. Perianth inferior, small, tubular, of one leaf, permanent, bordered with four ereth teeth. Cov. of one petal, funnel-shaped; tube cylindrical, several times longer than the calyx; limb in four deep, elliptic-oblong, concave, obtuse, spreading, or somewhat revolute, segments. Stam. Filaments two, very short, inserted into the tube of the corolla; anthers somewhat funnelfhaped, obtuse, ereth, enclosed within the tube. Pftp. Germen superior, oblong; style thread-shaped, riling as high as the flamen; stigma cloven, turgid. Peric. Capsule oblong, pointed, compressed, of two cells and two valves, with a contrary, fixed, double partition; from the centre of each. Seeds two in each cell, oblong, compressed, pointed at each end, with a membranous border at each margin.

1. S. vulgaris. Common Lilac. Linn. Sp. Pl. 11. Willd. n. 1. Ait. n. 1. Curt. Mag. t. 183. (S. cerulea flore; Chuf. Hift. v. 1. 56. S. cerulea; Ger. Em. 1599. Lilac; Math. Valgr. v. 2. 576. L. vulgaris; Poiteau et Turpin Pl. Paris. 7. t. 5—Leaves ovate-heart-shaped. Stem arborescent.—Said to be a native of Persia. Dr. Linsdorff found this tree wild among the shaly rocks of Mount Hennas, but not in Greece, nor its immediate neighbourhood. The Turks appear to have long cultivated the Lilac, and its common. English name is derived from them, belonging also in their language to the Privet. The first Lilac introduced into the gardens of Germany, Holland, and England, about the middle of the 16th century, appears to have come from Constantinople. At present nothing more common, or more hardy, in every garden and shrubbery, even in the smoky courts of London and other great towns, nor does any thing contribute more to adorn the country about London, than this plant and the Laburnum, vior they blossom together in May. The Lilac rite to the height of a middle-sized tree, with opposite, round, smooth branches. Leaves opposite, deciduous, flaked, smooth, a tire, pointed, veiny, of a full opaque green, without stipules; their length from two to three inches; their base heart-shaped, somewhat decurrent along the linear channeled fott-fallck. Clusters terminal, a foot long, very dense, obtuse, repeatedly compounded, of innumerable highly fragrant flowers, whose scent is too powerful for most people in a confined apartment. The corolla varies in the breadth of its extremities, as well as their hue, the narrower often being of the peculiar pale purplish-blue, popularly denominated the colour; the broader kind is more purple. A pure white variety is common. Matthiolus is charged with having imported the oriental seed, called Ben nut, to his figure of the Lilac above cited. That he confined the two plants is certain, but it seems to us that his drawing might altogether have been taken from the Syringa. See Hyperanthesia, n. 2.

2. S. chinensis. Chinefes Lilac. Willd. n. 2. Bamm. 378. Vahl n. 2. Ait. n. 2.—Leaves ovate. Stem furby. Native of China. Hardy with us, flowering in May and June. Of a much humbler stature than the former, with ovate, not at all heart-shaped, leaves, and more lax panicles of rather larger flowers. It is generally taken for a broad-leaved variety of the following, and like them bears furby well.

4. S. jacquinta. Mill. t. 164. f. 2. " Schmidt. Arb. v. 2. t. 79." (Agem Lilag Perforum; Cornut Cassud. 186.—Leaves more or less pinnatifid. Native of Persia. Introduced into our gardens about 1640; Parkinson. It is now common, and quite hardy, flowering in May, and easily forced, so as to come much earlier. This is a shrub, of a slender habit, four or five feet high, with opposite, flaked, lanceolate, pointed, entire leaves, an inch and half long; occasionally becoming deeply pinnatifid, which variety is but little increased by layers. The flowers are larger than the Common Lilac, and equally fragrant, but fewer in each branche, and less coved. Their white variety is peculiarly brilliant and elegant. This species scarcely ever forms capsulae with us.

Syringa, in Gardening, contains plants of the deciduous flowering, shrubby kind, of which the species cultivated are the common lilac (S. vulgaris), and the Persian lilac (S. persica).

In the first sort there are several varieties: as with white flowers,
flowers, with blue flowers, with purple flowers, or Scotch lilac.

The second species has also several varieties: as the common purple-flowered, white-flowered, blue-flowered, and the laciniate or cut-leaved.

Method of Culture.—These plants are mostly raised by suckers or layers, and sometimes by seeds. The suckers should be taken off in the autumn or spring, with root-fibres to them, and be planted out either in nursery-rows, to remain a year or two, or where they are to remain. The layers may be made from the young plant shoots, and be laid down in the autumn, in the usual way, when in the autumn following they may be taken off and planted out, as in the suckers. The first layer may likewise be raised from seeds sown in a bed of common earth, in the autumn or spring, keeping the plants clean when they come up. They afford variety in the large borders and other parts of shruberies.

SYRINGA OF PAN. See SYRINX.

SYRINGE, formed from syrinx, syrinx, syrinx, an instrument serving to imitate, or suck, in a quantity of any fluid, and to squirt or expel the fame with violence.

The syringe is made of a hollow cylinder, as ABCD (Plate XV. Hydraulics, fig. 8.) furnished with a little tube at the bottom E F. In this cylinder is an embolus or piston K, made, or at least covered, with leather, or some other matter that easily imbibes moisture; and so filling the cavity of the cylinder, as that no air or water may pass between the one and the other.

If then, the little end of the tube F be put in water, and the embolus drawn up, the water will ascend into the cavity left by the embolus; and, upon thrusting back the embolus, it will be violently expelled again through the same tube E F: and still with the greater impetus will the water be expelled, and to the greater distance, as the embolus is thrust down with the greater force, or the greater velocity.

This ascent of the water the ancients, who supposed a plenum, attributed to nature's abhorrence of a vacuum: but the moderns more reasonably, as well as more intelligibly, attribute it to the pressure of the atmosphere on the surface of the fluid.

For, by drawing up the embolus, the air left in the cavity of the cylinder must be exceedingly rarefied; so that being no longer a counterbalance to the air incumbent on the surface of the fluid; that prevails, and forces the water through the little tube, up into the body of the syringe.

In effect, a syringe is only a single pump, and the water ascends in it on the same principle, as in the common sucking-pump; whence it follows that water will not be raised in a syringe to an height exceeding thirty-two or thirty-three feet.

Syringes are of considerable use in medicine and surgery. By them clysters are administered: injections of medicinal waters, &c. made into wounds, &c. They also serve to inject coloured liquors, melted wax, &c. into the vesicles of the parts of animals, to shew the disposition, texture, ramifications, &c. of them.

The syringe is an instrument, that is used both in the rarefation and condensation of air. In order to understand its use in both these respects, it will be proper to explain the construction of its embolus or piston. ABCD (fig. 9.) represents a small cylinder of brass about one-fourth of an inch thick, and of such a diameter as just to move up and down in the syringe without interruption, but so close as not to admit a thin paper between it and the syringe. It has a screw at the top and bottom of the fame bigines, and of the same thread, but with this difference, that at the end C, a piece of bladder is tied on, which makes a valve, so fixed as to suffer all the air coming in the direction D C to pass by, but to stop all that endeavours to pass from C to D. The rod of the syringe, whose end is represented at R (fig. 10.), has a piece like a bell, PP H, with small holes through its upper part, and a female screw at bottom, to receive the end D of the screw of fig. 9. That piece being screwed in, as represented by the small letters a b c, must be another cylindrical piece g g, whose diameter is about one-fifth of an inch smaller than the other screwed on to c or c, serving for two uses, the one to preserve the valve at C, from being damaged against the bottom of the syringe by its thickness, and the other, (which is its principal use,) to press a soft oiled leather f f against a b. This leather will never fold upwards for want of room between A B and the sides of the syringe, but will spread against them and A B, so as to drive all the air before it. (which air is also hindered by the valve at c) forward through the nozzle in the syringe into any place where it is intended to be driven. But when the rod is driven in, as the leather f f folds easily about the smaller cylindrical plate g g, the air will easily pass by to fill the syringe that way, as well as through the valve in the direction d c. When the syringe is made use of for sucking, you must only invert the piece A B C D, so as to screw the end C with its valve into the bell P P, with the soft oiled leather f f between: and then the reverse will happen of what has been just mentioned; for then in driving down the piston, the air from any vessel coming into the syringe will slip in the direction a l b l, between the bell and sides of the syringe (the leather f f not being on now), and also through the valve-piece, and the holes near P P: but in drawing up, the valve will shut, and the leather f f will apply close to a b, so as to admit of no external air to go back into the syringe. In both cases, whether of injecting or exhausting air, such a double screw as A B C D (fig. 9.) with its valve is to be used; but with the valve towards the rod in sucking; and the other way in forcing, that no air injected into any thing may return into the syringe. De la Faye, Exp. Phil. vol. ii. p. 393.

Since the discovery lately made, as it is said, by a soldier in the French army, that light and heat are produced merely by the compresion of atmospheric air, the principle has been applied to practical purposes. Accordingly it has been found, that by adapting a moveable air-tight cap to the bottom of a common syringe, and placing within it a small piece of common tinder, and then depressing the piston with a sharp, quick action, heat will be produced sufficient to inflame the tinder. The use of the screw-cap at the end of the syringe is not only to render the instrument air-tight, but to serve for receiving the tinder or fungus placed within it. Syringes of this kind are fold by most of the philosophical instrument makers in London. Since this contrivance has been thought of, it has been proposed to make walking-sticks, furnished with similar syringes, so adapted to them, that a single stroke of the walking-stick on the ground would be sufficient to inflame the tinder, and to afford sufficient light to the person who used it in any emergency.

SYRINGE, DREW in Gardening; a fine sort of syringe, contrived for the purpose of throwing the water in a dewy manner over different fine sorts of fruit-trees. In shade-bound peach and nectarine trees, after being hard forced, the use of earth or clay paint, whenever they are pruned or tied in, will, it is said, be attended with admirable effects, especially when the dew-syringe is freely used soon after the fires are set a going, and the hose shut in: as by retaining the dewy moisture upon the bark and buds of the trees, it nourishes
SYR.

nourishes them both, makes the flowers much stronger, the fruit sets much thicker, and keeps the trees free from insects, when they are in a state most liable to be injured by them. Indeed the writer has confidently affirm, that these sorts of trees, when managed in this way with the syringing and painting, will seldom be either hide-bound or attacked by insects. The dew-syringe should of course be in every hot-house, as it is a necessary and very useful tool in all such situations and places, as well as on some other occasions.

It may also be of utility in the cultivation of some particular sorts of plants.

SYRINGITIS, a stone mentioned by Pliny, and described as being always full of cavities. Some have supposed this author meant the oboconilla by this name; but it is more probable that he meant the stone we now call fy-ringoids, or the pipe-stone.

SYRINGOIDES LAPIS, the pipe-stone, in Natural History, the name of a very beautiful foliate substance, of which there are several different kinds. The tubuli marini, or cafes of sea-worms, lodged in any solid substance of the foliate kind, constitute what is called the lapis syringoides.

The most frequent kind is made of the common matter of the ludus Helmuti, or sepias, with tubuli of different kinds and dimensions in it; but the most beautiful is that made of the bottom ofships, old boards, or piles, which, having been long in the sea, have been pierced by the sea-worms, which have made their several burrows, and left their shells behind them: the whole of these substances becoming afterwards petrified, is found in form of wood, with all the knots, veins, and other characters, but wholly of the hardness of stone. This is usually of a blackish colour, and the pipes being of a pale yellow, the whole makes a very elegant appearance.

Our clay-pits about London afford also a syringoides of this kind, but the earth there abounding with the matter of the common vitriolic pyrites, that substance by degrees gets into the pores of the wood, and the whole seems a mass of pyrites, with these pipes lodged in it in different directions. This has been called by authors pyrites syringoides.

Hill.

SYRINGOTOMUM, in Surgery, an old instrument for operating on fistula in ano.

SYRINGOTOMY, a term used for the cutting for the fistula.

SYRIX, Gr.; Fijita Pana, Lat.; Siringa, Ital.; Pan's Pipes, Eng.; an instrument composed of reeds of different lengths, tied or fastened together with wax, laid by the poets to be invented by Pan; and with respect to the syringa Pana of the ancients, it is observed by the editors of the Supplement to the first folio edition of the Encyclopaedia, that Bartholinus, De Tribus Vet. I. iii. c. 6. has related his having seen at Rome, on a monument in the Farnese palace, a syrinx with eleven pipes: the five first are of equal length, and consequently produce the same tone; with six others of equal diameter, but of different lengths from the first five. "I confess," says the author of the article, "that I am unable to conceive the use of the five first reeds or pipes of the fame length, for no two of them could be made to sound at once. If it not possible that these five pipes were half tones, and differed from each other in length, so little, as to seem all of a length; or, perhaps, they differed in diameter, and may have all produced different tones, though of equal length."

It is not a very sagacious conjecture to imagine that any ancient instrument had five semi-tones de fata. The chromatic tetrachord consisted only of one semitone major, one minor, and a minor third. We saw the syrinx mentioned by the encyclopedist at Rome, and had a drawing made of it; but reflecting on its absurdity afterwards, we made no use of it, and we have long seen that there is no truth in painters or sculptors for accurate drawings of ancient instruments of music. We have feet the syrinx, which had regular series of sounds, ascending or descending, representing four of one length, and three of another; which if course would furnish no more than two different sounds. Now the reeds that were joined together decreed is the proportion; at the top, where they received the breath, they were all of the same height; but at the bottom, where the breath escaped from the tube, they were all gradually shorter, one than the other. The cymbals, too, which were to be struck against each other, are placed in the hands of some antique figures in such a manner, that it would be impossible to bring them in contact with the necessary degree of force, without amputating, or at least violently bruising, the thumbs of the performer.

The manner of playing on the syrinx by the ancients under the title of fijita panis, is accurately described a single verse of Lucretius, lib. v.

"et supra calamos unco percurre labro."

Bianchini (De Tribus Gen. Instrum. Mus. Vet.) says the syrinx is the origin of the organ.

Bonanni (Gabinetto Armonico) calls the syrinx ciaja pfetoralis, the shepherd's whistles.

The two sets of admirable performers on Pan's pipes, at present, (1803) exalted the syrinx into a concert instrument in the open air; which is beating the ancients with their own weapons; for besides playing in different parts, they perform prettier airs, we believe, than the ancients ever heard on these rustic instruments. They have extended the scale beyond the ancient syrinx perifatum, maximum insitutum.

SYRIS, in Ancient Geography. See SIRIS.

SYRITES, in Natural History, a name used by Some for the sapphire; but by Pliny for a stone, which he says was generated in the bladder of a wolf.

SYRITTY, in Geography, a town of Bengal; 8 mays S.W. of Gorgot.

SYRIUS, a word used by some authors for a very shrill purge, a preparation of leoncy: being no other than a medicine for the ague or malady of that drug.

SYRMA, among the Greeks, a servant, or a long garment, common to both sexes, that reached to the ground. It was used in tragedies, that the perfons of the heroes and heroines might appear the taller. Pitif. in voc.

SYRMÆA, a name given by the ancients in general to a certain root, said to be of the radish-kind, and to be frequently used to promote vomiting.

Some have made it also the name of a sort of viand, prepared of honey, the fine fat of animals, and other ingredients, which was the prize bestowed at one of the Sparta games; others have used it to express a purging potion, made of salt and water, or plain brine. The Egyptians frequently purged themselves with this radish-juice and drachm, which operated gently both upwards and downwards, and these potions were called by the name name fomæus.

SYRMÆUS, a word used for a description of the games at Sparta, the prize in which was stymus, or a mixture of fat and honey.

SYRMÆUS, a word used by the ancient medical writers to express a gentle purging of the bowels, either by food or vomit, it had its name from smus, a word expressing a medicine that acted in this gentle manner.

SYRUS,
SYROS, in Ancient Geography, one of the Cyclades islands, situated S.W. of the island of Tenos, S. of that of Andros, W. of Delos, and N.W. of Paros, celebrated for its power and commerce; now Syros, which see.—Alfo, a town of the same island.—Alfo, a town of Afa Minor, in Asia.—Alfo, a river of the Peloponnesus, in Arcadia.

SYRTOS, an island situated between Sicily and the coast of Africa.

SYRTES, two gulfs on the northern coast of Africa, one called "Syrtis minor," on the coast of Byzantium; the other called "Syrtis," or "Syrtis major," on the coast of Cyrenaica, near the gulf of Sydras. The appellation "Syrtis," with a more accurate etymology, seems to be derived from the Greek σαρῶν, στραχων, and the reason is sufficiently known to those who frequent this coast, the sea continually tending to enter into these Syrtes and the adjacent coast, so that vessels are borne with it, and exposed to great danger of being lost among the rocks.

SYRYP, SYRUPUS, or SYRUPUS, in Pharmacy, an agreeable liquor, or composition of a thick consistence, made of juices, tinctures, or waters, of fruits, flowers, or herbs, boiled up, in order to preserve it from spoiling, by fermentation, or otherwise, with a more or less etherial essence, tincture, or essence, of the same bodies. Menage deriveth the word from the Arabic, صفراب, potish; formed from the root صفراب, to drink. Others derive it from the Greek σεραβος, I draw; and σεραβος, juice. Ethmus, from σεραβος, in regard these kinds of liquors were much in use among the Syrians, a very delicate people.

According to D'Herbelot, the words syrup, and sirab, or sorbat, do both come from the Arabic sirabah, which signifies any kind of drink in the general.

There are various kinds of syrups denominated from the various fruits and waters, before boiled, and from, or on their virtues; as syrup of violets, of elder, of wormwood, of poppies, &c. emetic syrups, lyeentic, and anti-nephritic syrups, and chologogue, phlegmagogue syrups, &c.

Syrups, which were formerly looked upon as medicines of considerable value, are at present regarded chiefly as vehicles for medicines of greater efficacy, and are used for sweetening of draughts, juleps, or mixtures, and for reducing the lighter powders into boluses, pills, and electuates. But as all these purposes may be answered by the simple syrup alone, there is little occasion for any other.

There seems to be no part of pharmacy in which the writers of dispensatories have more erred than in their directions about the making of syrups; which feints the more strange, because this part is particularly easy.

The whole business of syrup-making may be, however, reduced to a few short and easy rules. At first, it is matter of experience that aqueous infusions, decoctions, or other aqueous liquors, require twice their own weight of dry sugar-candy to make them into a syrup of a jiffy consistence, for keeping without candying or fermenting.

This rule, by directing the use of sugar-candy, fixes the consistence of syrups in an exact manner than any other else, because all fats require a determinate proportion of water in crystallizing; so that sugar, in the form of candy, contains always one certain proportion of water, while different kinds of sugar may hold more or less aqueous matter, according to their different manner of refining, the accidents of the weather, &c. Hence, therefore, all such infusions for syrups as are of a delicate or delectable colour, which is impaired by boiling, such as violets, clove-July flowers, &c. and all such infusions as contain any volatile parts, which would evaporate by a boiling heat, such as those of cinnamon, orange-peel, &c. should have twice their own weight of sugar added to them, and be kept close covered in the gentle heat of the balneum Mariae, till the sugar is dissolved; which, to attain the solution, should be twice the quantity.

Secondly, the decoctions of all such vegetable substances as lose no valuable parts by boiling, may be boiled down to the proper consistence with their own weight of sugar, the two being first clarified together with the whites of eggs in the usual way: but if the ingredients here contain any unctuous or balastic parts, on which their medicinal virtue depends, let the sugar be added from the very first, and boiled along with the ingredients; afterwards straining and clarifying it, before it be near the consistence of a syrup. This is founded on the property in sugar of dissolving resins and oils, so as to make them intimately mix with water.

Thirdly, all vegetable juices are to be thoroughly purified, before they are boiled into syrups. Thus the juices of lemons, oranges, &c. are first to be filtered, and then made into syrups without boiling, according to the first rule; but the juices of mulberries, and the like, will not clarify without a beginning fermentation; wherefore they must first stand a day or two, and then they will pass through a funnel; after which these are to be made into syrups and waters, &c. with an eighth part or other of the quantity of sugar that is, with one pound twelve ounces of sugar to a pint of the juice, on account of their being somewhat saccharine themselves. And wines and vinegars must be made into syrups with the same quantity. Shaw's Lectures, p. 205.

In making syrups, refined sugar should always be employed; or, if coarser sugar be used, the syrup should be clarified, by beating to a froth the white of eggs with a small portion of water, and adding it to the solution of sugar and water before boiling. The above mentioned as the syrup boils, and involving the impurities which the sugar contained, rises to the surface in the form of a scum, which must be carefully removed. If too much sugar be used, or if the syrup be too long boiled, the sugar soon crystallizes; and if it be in too small proportion, the syrup quickly ferments, and becomes accecent. The most certain test of the proper consistence of a syrup is its specific gravity, which, when cold, should be 1.385. But, however well prepared, syrups are apt to ferment, when kept in a temperature above 60°; and therefore the following direction relative to their preservation is given by the London College.

"Let syrups be preferred in a place the temperature of which never exceeds 55°."

SYRUP of Londo. Ph. is obtained by dissolving 21 lbs. of refined sugar in a pint of water, by means of a water-bath; setting it aside for 24 hours, taking off the scum, and if it has any faces, pouring off the clear part from them.

The simple or common syrup of the Edinb. Ph., is prepared by dissolving 15 parts of refined sugar powdered in eight parts of water by a gentle heat; and boiling it a little so as to form a syrup. Syrups, for which neither the weight of sugar nor the mode of dissolving it is specified, are thus prepared.
prepared; add 20 oz. of refined sugar, finely powdered by degrees, to one pint of the liquor preferred; and digest with a moderate heat, in a clove vessel, till it is dissolved, frequently stirring it; let the solution stand for 4½ hours, take off the scum, and pour off the syrup from the faces, if there be any. Simple syrup, properly prepared, should be inodorous, sweet, thickish, nearly colourless, and perfectly transparent.

Syrupus Acidis Aetigh, syrup of acetic acid, of Edinb. Ph., is prepared by boiling 3½ lbs. of refined sugar in 2½ lbs. of distilled vinegar, so as to form a syrup; as it is apt to be decomposed, it should be made in small quantities at a time. This syrup may be used for sweetening barley-water or gruels, in fevers and inflammatory diseases.

Syrupus Allii, syrup of garlic, of the Dub. Ph., is obtained by macerating one pound of garlic-root (bulb) in two pints of boiling water, in a covered vessel, for 12 hours; then adding the sugar to the strained liquor, and thus forming a syrup. This, though disagreeable, contains the virtues of garlic.

Syrupus Albae officinalis, syrup of marsh-mallows, of the Edinb. Ph., is procured by boiling 10 lbs. of water with one pound of fresh root of marsh-mallows sliced, down to one-half, and expressing it strongly, and straining; putting aside the strained liquor, and when the faces have subsided, adding 4 lbs. of sugar, then boiling it so as to form a syrup. This syrup is supposed to possess demulcent properties, which are trivial; and as it contains a small proportion of sugar, it is soon spontaneously decomposed. The lubricating virtues of this syrup may be supplied by adding to the common syrup a sufficient quantity of mucilage of gum arabic.

Syrupus Aurantis, syrup of orange, of the Lond. Ph., is prepared by macerating 2 oz. of fresh orange-peel in a pint of boiling water for 12 hours, in a covered vessel; then pouring off the liquor, and adding to it 3 lbs. of refined sugar.

Syrupus Citri Aurantis, syrup of orange, of the Edinb. Ph., is obtained by macerating 6 oz. of fresh peel of Seville oranges in 3 lbs. of boiling water for 12 hours; then adding 4 lbs. of refined sugar in powder to the strained liquor, and expelling it to a gentle heat, so as to form a syrup.

Syrupus Aurantis, syrup of orange, of the Dub. Ph., is had by macerating 8 oz. of fresh peel of Seville oranges in six pints of boiling water, for 12 hours, in a covered vessel, and diffusing as much sugar in the filtered liquor as will form a syrup.

A syrup equally agreeable and efficacious may be made by adding $\frac{1}{3}$ of tincture of orange-peel to a pint of simple syrup.

Syrupus Colchici Autumnalis, syrup of meadow-saffron, of the Edinb. Ph., may be made by macerating 1 oz. of fresh meadow saffron-root (bulb), cut into thin slices, in 16 oz. of distilled vinegar, for two days, shaking the vessel occasionally; then expressing and gently straining the liquor, and adding to it 3½ oz. of refined sugar in powder; and then boiling a little, so as to form a syrup. With the sublimation of syrup for honey, this preparation is similar to oxymel; and the dose is $\frac{1}{3}$ of a tumbler, increased gradually to $\frac{1}{2}$ or more.

Syrupus Croci, syrup of saffron. See Saffron.

Syrupus Dianthi Caryophylli, syrup of the clove-July flower, of the Edinb. Ph., is obtained by macerating 1 lb. of recent petals of the flower, freed from their claws, in 4 lbs. of boiling water for 12 hours, then adding 7 lbs. of refined sugar in powder to the strained liquor; and diffusing it with a gentle heat, so as to form a syrup.

Syrupus Caryophylli Rubri, syrup of clove-July flower, of Dub. Ph., is prepared by macerating for 12 hours, 2 lbs. of the fresh petals, freed from the claws, in six pints of boiling water, in a glazed vessel; and diffusing a sufficient quantity of sugar in the strained liquor to make a syrup. This syrup is valued for the rich colour and agreeable flavour of the flowers. Alkalies change the colour to green, and thus form a tinct of the genuineness of the syrup.

Syrupus Limonis, syrup of lemon, of the Lond. Ph., is made by diffusing 2 lbs. of refined sugar in a pint of strained lemon-juice.

Syrupus Citri Medicae, olim Syrupus Limonum, syrup of lemons, of the Edinb. Ph., is prepared by diffusing three parts of refined sugar in three parts of strained lemon-juice, after the faces have subsided, so as to form a syrup.

Syrupus Limonis, syrup of lemon, of the Dub. Ph., is made by putting two pints of expressed lemon-juice, after the faces have subsided, into a matrass, and immersing it in boiling water for a quarter of an hour; straining it through a sieve when cold, and making it into a syrup. This is an agreeable syrup for acidulating barley-water or other drinks in febrile diseases: it is also a useful adjunct for gargles in inflammatory fore-throat.

Syrupus Mori, syrup of mulberry, of the Lond. Ph., is made by diffusing 2 lbs. of refined sugar in a pint of strained mulberry juice, as for syrup. This is used for the same purposes as the syrup of lemons, and has a better colour.

Syrupus Opii, syrup of opium, of the Dub. Ph., is obtained by macerating 18 grains of the watery extract of opium in 8 oz. of boiling water, till the opium be dissolved, and then adding sugar, so as to make a syrup. This is a useful astringent for allaying the irritation which occurs cough in catarrh after the inflammatory symptoms are abated, and for procuring sleep, in the diseases of children.

Syrupus Pappionis, syrup of poppy. See Pap.

Syrupus Pectoralis, syrup pectoral, a form of medicine prescribed in the late Lond. Ph., and intended to find the place of the syrup of maiden-hair, and some others of that kind. It is to be made thus: take leaves of Equisetum maiden-hair dried five ounces, liquorice four ounces, boiling water five pints; steep the ingredients for four hours, and afterwards strain off the liquor; and when it is made thus by settling, add to it the necessary quantity of sugar to make it a syrup in the common way.

Syrupus Rhamnus, syrup of buckthorn, of the Lond. Ph., is prepared by setting apart four pints of the fresh juice of buckthorn berries for three days, that the faces may subside, and straining it: adding to the strained juice peper-root sliced, and pimento berries bruised, of each half an ounce; then macerating in a gentle heat for four hours and straining; boiling the remainder of the juice down to 2½ pints, mixing the liquors, and adding 3½ lbs. of refined sugar, so as to make a syrup. This is a brisk cathartic; but on account of the roughness of its operation, it is seldom used, except as a horrid medicine. The dose is from $\frac{1}{3}$ to $\frac{1}{2}$, drinking freely of tepid demulcent fluid during its operation. See Rhamnus.

Syrupus Rossii, syrup of rose. See Rose.

Syrupus Saporis, is an ancient medicament, the bane of which is apples, with juices of bugloa, anise, saffron, &c. Thus called from Sapor, king of Persia, who overcame the enemy.
SYSTASIS properly only denotes the confidence of any thing, as of a syrup or ointment; but authors have used it also in a different sense. Hippocrates understands by it a collection of humours about the palate; and sometimes expresses by it a contraction of any part of the body from an uneasiness, or sensation of pain.

SYSTEM, SYSTEMA, formed from σύστημα, composition, in the general denotes an assemblage or chain of principles and conclusions; or the whole of any doctrine, the several parts of which are bound together, and follow or depend on each other.

In this sense we say, a system of philosophy; a system of motions, system of fevers, &c. Divines have framed abundance of systems of grace; the system of intermediate science, and predetermination, are invented to explain that of grace.

Descartes's system is held destructive to religion. Gafendus renewed the ancient system of atoms; which was that of Democritus, followed by Epicurus, Lucretius, &c.; Sir Isaac Newton's doctrine of colours, M. Leibnitz's metaphysica, and some discourses of M. Jullié, in the Academy of Sciences, to show that there are bodies whose parts are made to be destroyed by any natural agents, are very favourable to the system of Gafendus.

Experiments and observations are the materials of systems: an infinity is required to build one.

System, in ASTRONOMY, denotes an hypothesis or supposition of a certain order and arrangement of the several parts of the universe; by which astronomers explain all the phenomena or appearances of the heavenly bodies, their motions, changes, &c.

This is more peculiarly called the system of the world, and sometimes the solar system.

System and hypothesis have much the same signification; unless, perhaps, hypothesis be a more particular system; and system a mere general hypothesis.

Some late authors, indeed, furnish another distinction; an hypothesis, say they, is a mere supposition or fiction; founded rather on imagination than reason; a system is only built on the firmest ground, and ruled by the severest rules: it is founded on astronomical observations and physical caufts, and confirmed by geometrical demonstrations.

The most celebrated systems of the world are, the PILOTMAGA and the COPERNICUS; to which may be added the EGYPTIANS and TUSCONE: the economy of each of which is as follows.

SYSTEM, PILOTMAGA, places the earth at the centre of the universe; and makes the heavens revolve round the same from east to west, and carry all the heavenly bodies, stars, and planets, along with them in twenty-four hours.

For the order, distances, &c. of the several bodies in this system, see PILOTMAGA, p. 14, in which A exhibits Pilotmagna's arrangement, and B that adopted by some other astronomers.

The principal asserter of this system are Aristotle, Hipparchus, Pilomag, and many of the old philosophers, followed by the whole world, for a great number of ages, and long adhered to in divers universities, and other places, whence free philosophizing was excluded; but the late improvements have put it out of all countenance; and we do not want even demonstration against it.

SYSTEM, COPERNICUS. See COPERNICUS System.
SYSTEM.

The planetary system, described under Copernican, is the most ancient in the world. It was the first, that we know of, introduced into Greece and Italy by Pythagoras; whence, for many ages, it was called the Pythagorean system. It is conjectured that he was acquainted with the diurnal and annual motions of the earth; but he did not publicly profess the true system of the world. This, it is said, was taught after his death by Philolaus, about the year 450 B.C. as well as by Nicetas, Plato, Archimedes, &c. but lost under the reign of the Peripatetic philosophy; till happily retrieved, above two hundred years ago, by Nic. Copernicus; whence its new appellation of Copernican system. For the economy of this system, see the scheme of it, Plate XX. Afrom. fig. 15.

System, Egyptian, was that which was taught by the Egyptians, who had the merit of discovering that Mercury and Venus revolve round the sun, and not round the earth, as it had probably been before believed: they did not, however, suppose the fame of the superior planets. See this scheme exhibited in Plate XX. Afrom. fig. 16.

System, Tychoic, was taught by Tycho Brahe, a noble Dane, who was born A.D. 1546. It supposed the earth to be fixed in the centre of the universe or firmament of stars, and that all the stars and planets revolve round the earth in twenty-four hours; but it differs from the Ptolemaic system, as it not only allows a menstrual motion to the moon round the earth, and that of the satellites about Jupiter and Saturn in their proper periods, but it makes the sun to be the centre of the orbits of Mercury, Venus, Mars, Jupiter, and Saturn, in which they are carried round the earth in their respective years; as the sun revolves round the earth in a solar year; and all these planets, together with the sun, are supposed to revolve round the earth in twenty-four hours. This hypothesis was so embarrased and perplexed, that few persons embraced it. It was afterwards altered by Longomontanus and others, who allowed the diurnal motion of the earth on its own axis, but denied its annual motion round the sun. This hypothesis, partly true and partly false, is called the Semi-Tychonic system. For the order and economy of the Tychonic system, see the scheme in Plate XX. Afrom. fig. 17.

System, Solar, or Planetary, is that which was taught by Philolaus, &c. if not by Pythagoras, revived by Copernicus (see his article), and established on an immovable foundation by Sir Isaac Newton. This is restricted to our sun, together with the planets and comets that move round him at various distances and in various periods, and occupy a limited sphere in the immensity of space, though its limits are unknown; the stars, by their hitherto unmeasurable distance, and the little relation which they seem to have to us, being reputed no part of this system. It is highly probable, however, as we have elsewhere shewn, that each fixed star is itself a sun, and the centre of a particular system, encompassed by a number of planets, &c., which, in different periods and at different distances, perform their courses round their respective suns, and are enlightened, warmed, and cherished by them: hence we are led to entertain a very magnificent idea of the world; and hence also arise the ideas of system of systems. The reader will find an ample account of this system, and of the bodies that compose it, under Comet, particularly Planet, Satellites, Sun, and Stars; and also under the appropriate names of each planet.

For a general view of the solar system, we refer to Plate II. Afromasy. and for another view of it, to Plate XII. Afromasy. fig. 1. This last cited figure comprehends the orbits of all the principal planets, and of three of the comets. The parts of the orbits represented by entire lines are set north of the ecliptic, and the dotted parts on the south; the letters A and P denote the aphelion and perihelion. The point in the centre, which ought to be only 16.66 of an inch in diameter, represents the sun. The figures of the respective planets shew their comparative magnitudes, but the sun being represented by the innermost of the graduated circles which inclose the whole: they are placed according to their actual positions on the 14th of June, 1706. The letters M D shew the mean distance of the comet of 1750, being placed at the extremity of the leper and the ellipse in which it must be supposed to revolve.

The periodical times of the different planets are represented in Plate XXI. Afromasy. fig. 2. by lines of different lengths. The comparative velocities of the different planets are represented in fig. 3. by lines which shew the number of English miles described in a second, on the scale marked the lowest line: and the places of the ascending nodes of all the planets are marked in fig. 4. on one half of the ellipse; supposed to be extended in a right line; together with the inclination of their orbits. The line marked E E E shews the situation of the fixed ecliptic.

The annexed table shews the elements of the solar system.

**SYSTEM.**

**ELEMENTS OF THE SOLAR SYSTEM.**

The sun, \( \odot \), revolves on his axis in 25.610.\(^{\circ}\). The inclination of his equator is 7\(^{\circ}\) 20\(\prime\). The place of its ascending node, \( \odot \), 2\(^{\circ}\) 18\(\prime\), or 7\(^{\circ}\) from the equinoctial point Aries. His diameter is 885,000 English miles, and his density, to use of the earth, as 155 to 1. His mean apparent diameter is 31\(\frac{1}{2}\) 57\(\prime\), his mean parallax 88.75.

SYSTEM.

Systems of Mineralogy, see Mineralogy, under which article the most eminent systematic writers on mineralogy are enumerated from Agricol to Werner and Hally; and some account is given of the principles of classification on which the different systems are founded. Notwithstanding the labour and talents which have been employed to frame systems of mineralogy conformable to natural and fixed principles of arrangement, it must be confessed that much remains which is arbitrary and uncertain in them all. Mineralogists are not yet agreed as to the principles on which a mineralogical system should be framed, whether on the external character, or the chemical composition of minerals; nor do they even agree in their definition of the essential characters which constitute mineral species.

In the classification of minerals, most mineralogists have considered the chemical composition as too important to be disregarded, wherever it would agree with the other principles of arrangement. Even the Wernerian system professes to be founded on the natural alliances and differences observable among minerals; and these are defined by Werner to depend on the quality, quantity, and mode of combination of the constituent parts; and he considers all minerals as belonging to the same species, that have the same external form and the same constituent parts. Notwithstanding this definition, minerals that differ almost entirely in their chemical composition are arranged together by Werner, and it is only when chemical results agree with the natural alliances (says Mr. Jameston), that he gives them a place in his system. This, it must be admitted, is either a departure from the principles laid down, or a very indefinite application of the terms natural alliance, which was before defined to consist in the quality, quantity, and mode of combination of the constituent parts.

According to the principal French mineralogists, the similarity of composition in minerals, forms the most important alliance which they can possibly have: if two minerals were composed of the same constituent parts, they would be of the same species. The proportion of the constituent parts which constitute the type of the species, is determined by the crystallization; for it is assumed, that the same proportions of constituent parts, give invariably the same primitive forms. On these principles Brongniart defines mineral species to be "an assemblage of individuals having the same composition and the same primitive form." (Introduction à l'Étude des Minéraux.) This principle of classification appears natural and scientific, but unfortunately it is of limited application, as a great number of minerals never occur crystallized; such must, therefore, be left out of the system, or be classified in an arbitrary manner.

In every system of classification, it is proposed either to affix the student to discover the names of minerals from their external characters, or to assign to them their proper place in nature, according to the most essential points of resemblance which they present to the minerals among which they may be classified. The first is called the artificial mode of classification; the latter, the natural. Some mineralogists regard the former as unessential in the science, being little more than a mere mechanical contrivance to recognize the name of known species; according to Berzelius, this can rank no higher compared with a proper system, than as an index to a book.

Dr. Thomson, however, has well observed, that before the chemical analysis of a mineral can lead to any useful inferences, we must be sure that a specimen belongs to the species we suppose, and also that it is unmixed with any other mineral. Now this can only be known by an acquaintance with the external characters, which must therefore serve as the basis of our mineralogical knowledge. Annals of Phil. April, 1815.

In the present state of mineralogical science, it seems highly expedient that there should be two different systems: the one which should arrange minerals according to their appearances and properties by which they may be distinguished; the other, which should be chiefly scientific, in which minerals shall be arranged according to their constituent parts, and the proportions in which they combine; the latter system must be dependent on the progress of chemistry for the state of perfection it may attain.

Both these methods of arrangement have recently been adopted; the first by Mr. Arthur Aikin, in his Manual of Mineralogy; the second by the celebrated Swedish chemist, Berzelius, in a work, intitled "An Attempt to establish a pure Scientific System of Mineralogy, by the Application of the electro-chemical Theory, and the chemical Proprieties." The views which Berzelius has disclosed are novel and highly important, and may ultimately give an entirely new form to the science. He defines mineralogy to be the science which treats of the elementary combinations of unorganic substances, found in or upon the earth, and of the various forms and the different foreign admixtures under which their bodies make their appearance. The knowledge of these combinations themselves, their composition and chemical properties, belongs to the chemistry, but that scientific mineralogy may be considered as a part of chemistry.

Hence, says Berzelius, it is clear that mineralogy can have no other scientific arrangement than a chemical one, and that every other is foreign to mineralogy as a science. The prevailing theory and arrangement of chemistry must therefore be that of mineralogy also. If this has not hitherto been the case, it may be attributed to the recent period in which chemistry has received its greatest improvements, and also to the circumstance, that the framers of systems of mineralogy, have not previously applied themselves with equal zeal and success to chemistry, and consequently have not been enabled to perceive the necessary connection between them. By the influence of electricity on the theory of chemistry, this last science has experienced a greater revolution than it did by the doctrines of Stahl or Lavoisier. The object of Berzelius is to shew that the influence of the electro-chemical theory extends to mineralogy, in the same degree as to the parent science chemistry; and also that the doctrine of definite chemical proportions is equally applicable to the elementary combinations in the mineral kingdom, and will give the same degree of mathematical certainty to the arrangements of a mineralogical system, which it has already given to chemistry. From the electro-chemical theory, we have, says he, been taught to seek in every compound body for ingredients of opposite electro-chemical properties; and we have learned from it, that the combinations cohere with a force, which is in proportion to the degree of opposition in the electro-chemical nature of the ingredients. Hence it follows, that in every compound body there are one or more electro-positive, with one or more electro-negative ingredients. By electro-positive ingredients, he designates those which have inflammable bodies, or fells for bases; and by electro-negative, the oxygen and oxides which go to the negative pole of the Voltaic battery. In other words, every substance called a basis in chemical combination, must have another which acts the part of an acid, though the latter, when uncombined, may not be distinguished by a four taste, or the property of changing vegetable blues to red. The body which, in one case, is electro-negative, may, in another case, be electro-positive, and may be united to a stronger electro-negative, that is, it may be the basis to a stronger acid.
Thus, in the union of two acids, the weaker serves as a basis to the stronger; and every combination of two or more oxides, possesthe nature of a salt, one of the oxides performing the functions of an acid. Were the combination decomposed by the voltaic battery, one oxide would be collected round the negative and the other round the positive pole. Hence in every mineral composed of oxidized bodies, whether an inorganic or organic nature, we must seek for the electro-negative and electro-positive ingredients; and after the nature and qualities of these are found, a critical application of the chemical theory will tell us what the mineral is.

The most usual mineral combinations between oxides contain three oxides, of which two are bases and one acid; and the fourth one of the two oxides in double salt is chemistry. It not infrequently happens that there are even three or four bases for one acid; but we very rarely find a chemical combination of two bases, each united with its different acid.

If with these theoretical ideas we review the productions of the mineral kingdom, what a light do they at once throw on the compounds of various metals united with sulphur, or on the compounds of various earths and metallic oxides: order at once becomes visible in this apparent chaos, and mineralogy affirms the character of a science. We immediately discover a numerous class of minerals, the similarity of which to salts had already been pointed out by chemists, though they were unable to make a more exact application of these resemblances. This class consists of minerals in which flex a part of an acid; it contains an endless variety of single, double, triple, and quadruple salts of different degrees of neutrality, or with excess of acid or base. Thus also oxide of titanium, oxide of tantalum, and several metallic oxides, not considered as acids, occasionally act the part of acids; so that the whole of the extensive range of earthy minerals may be cladded on the same principles as salts.

That flex performs the functions of an acid in the mineral kingdom, was an opinion advanced by Mr. Hume at an early as 1805; and he adduces the neutralizing effects of flex on alkalies in the formation of glasses as an illustration. (See Silicic.) Berzelius regards this new view respecting the combinations of flex with different bases, as the most important step which mineralogy has ever made towards its perfection as a science.

The circumstnaces which have contributed to conceal the existence of chemical proportions in mineralogy are, want of sufficient care in analysis, and the difficulty of meeting with mineral productions perfectly free from admixture with foreign and accidental ingredients. Even the most regular and transparent crystals are seldom entirely free from foreign admixture. The substance of which a solution contains the most, or with which it is saturated, forms the crystal; but this crystal includes parts of the solution between its plates, which not unfrequently change its colour, and render it more or less impure. Hence we find, in the analyses of most crystallized minerals, two, three, or more ingredients, which only amount to per cent., and sometimes less; these we have no reason to believe belong to the composition of the crystallized mineral, but are accidental admixtures; and these foreign substances should be subtracted from the analyses, if the results are expected to agree with the doctrines of chemical proportion.

The form, specific gravity, colour, and transparency of crystals, is also sometimes changed by the deposition of two different compounds in contact with each other; thus the aragonite owes its peculiar form to a particle of siftonite being in contact with carbonate of lime at the time of its crystallization. As the latter kind of admixture makes itself known by changing the crystalline form of a mineral, it may be more easily detected.

In determining the chemical proportions of minerals, and the distribution of the ingredients, Berzelius does not, in the first place, seek for this proportion in the relative quantities of the various elementary constituent parts; but he considers the particles of the different elements as forming binary compounds, which combine with each other in definite quantities. This he illustrates by an analogous mode of determining the distribution and proportions of the substances which compose the well-known salt alum. If, says he, we were to go no farther than to consider this salt as consisting of potash, aluminium, sulphur, hydrogen, and oxygen, we should, in a scientific view, derive but little advantage from such a statement. We come to a nearer nature of the compound, when we consider it as composed of aluminium sulphate, alumina, potash, and water. This was long regarded as the composition of alum; hence it was called a triple salt, as consisting of three principal ingredients. The next step to a more perfect knowledge of alum, was the considering it as consisting of sulhphate of potash, and sulphate of alumina, with water of crystallization. The doctrine of chemical proportions completed our knowledge of this salt, by showing that it consists of one particle of sulphate of potash, three particles of sulphate of alumina, and twenty-four particles of water of crystallization. Chemists have long considered one important class of minerals as composed of peculiar earths, without pointing out their exact combinations, or the definite proportions in the combinations, in the same manner as they have recently viewed the composition of alum. Since the development of the electro-chemical theory, and the discovery of the laws of chemical proportion, it becomes necessary to adopt an exposition of the nature of minerals, conformable to the improvements of chemical science.

Silica is the most abundant substance of which the surface of the globe is composed; and, according to Berzelius, the illustration of that order of minerals in which silica supplies the place of an acid, (being the electro-negative ingredient,) throws the greatest light over the confused mineralogy. The minerals of this order are the most numerous, and he has given to them the name of silicates. Silica, as an acid, possesses the property of forming silicates of many different degrees of saturation. The most general are those in which the flex contains the same quantity of oxygen with the base. The name silicates. When the flex contains three times the oxygen of the base, they are called trisilicates. When twice the oxygen, bisilicates. But when the base contains more oxygen than the flex, they are called fusilicates, and are designated by the terms bis, tri, &c., to announce that the base possesses twice or three times the oxygen of the flex. Of these modes of combination he has given several examples, from which we select a few as illustrative of his theory. It may be proper first to state that he calculates the oxygen in the following earths and alkalies as under:

<table>

</tbody>
</table>

In 100 parts of flex or silica
SYSTEM.

In the examples which he has given, we are not to expect the analysis to coincide exactly with the calculation, particularly in compound minerals; but must be content, he says, with such results, if the difference from the calculation does not exceed the usual errors in other analyses.

Example.—Calcareous Trifliciate, a mineral from Adefors, analysed by Hafinger.

Silica 57.77 holding 28.75 3 58.62 Sulphur. Fluoric radicle.
Lime 35.50 oxygen 9.80 1 34.58 Nitricium, or the radicle of azote. Boron.
Alumina 1.83 Oxyd of iron 1.00 3 4.35 Muriatic radicle. Carbon.
In this example, we may observe, that, according both to the analysis and the calculation, the silicium, which may be considered as the acid, contains three times more oxygen than the lime, which is considered as the base.

Calcareous Bifliciate, or Table Spar, analysed by Klaproth.

Silica 50 holding 34.83 6 50.00 Arsenic. Lead.
Lime 42 oxygen 12.6 3 44.33 Chromium. Tin.
Water 5 holding 4.4 1 4.70 Mohylbdenum. Nickel.

Aluminous Silicicate. Semmrite.

Silica 46 holding 22.83 1 46.05 Tungsten. Copper.
Alumina 49 oxygen 23.28 1 48.95 Antimony. Uranium.
Foreign ingredients, lime, 2; oxyd of iron, 1.

The above are examples of simple silicicates; but Berzelius states that silices, like other acids, forms also double silicates; and we most frequently find that the bases which have a tendency to produce double silicates with other acids do the same with silices.

Example of a double silicate. Trifliciate of Potash and Lime; the Ithyophyllalmite of Werner. Apophyllite of Italy. It contains

Silica 52 holding 25.81 18 50.83 Arsenic. Lead.
Lime 24.5 contains 6.71 5 25.4 Chromium. Tin.
Potash 8 oxygen 1.26 1 8.24 Mohylbdenum. Nickel.
Water 15 holding 13.23 10 15.89 Tungsten. Copper.

This mineral is thus a double salt, or silicate of lime and of potash, in which the former contains five times the oxygen of the latter, and the silice three times the oxygen of the bases. It is composed of one particle of trifliciate of potash, and five particles of trifliciate of lime.

Berzelius gives examples of more complex silicates, but the above may serve to shew the mode which he adopts in the distribution of the component parts of silicious minerals, and in estimating their proportions; and we may make a similar application of the same principles to other minerals.

The mineralogical arrangement propounded by Berzelius, is founded on the order of the electro-chemical properties of bodies, beginning with the most electro-negative oxygen, and terminating with the most electro-positive potassum, and placing every compound body according to its most electro-positive ingredients. But he observes, that in the present state of science, we must be content with an approximate arrangement. He divides single bodies into three classes: 1. Oxygen; 2. Simple non-metallic inflammable bodies, which he calls metalloids; 3. Metals. He arranges them in the order in which they follow one another, from the most electro-negative to the most electro-positive, in every class. This order is nearly as follows:

1. Oxygen.
2. Metalloids.

Every one of these bodies can constitute a mineralogical family, which will consist of that single body, and all its combinations with bodies that are electro-negative towards it, that is, all those which (with some few exceptions) precede it in the above series. Thus there may be as many families as there are simple substances. The families are divided into orders, according to the different electro-negative bodies with which the most electro-negative is combined. The characters, and the formula propounded by Berzelius to express in a concise manner the different mineral combinations, is it unnecessary to state, as they will probably undergo a considerable change when the system shall have attained a more complete form. It must be confessed, that the obstacles which oppose themselves to the formation of a complete mineralogical system, on the principles propounded by Berzelius, appear to be great, particularly with respect to many of the minerals that never occur crystallized, as it seems that we have no means of determining the proper constituents ingredients from the mechanical admixtures which they may contain. If, indeed, chemistry should attain that high degree of perfection which will enable us to discover the limits of all the possible combinations of the elementary parts of minerals, we may then substract from our analyses those parts which do not fall within their limits, as being in mechanical admixtures, in the same manner as the chemist is now enabled to determine, from the definitions of definite proportion alone, the quantity of uncombined acid or alkali that exists in a saline solution, when either of the ingredients is in excess.

If one class of bodies consists of salts, in which the same performs the functions of an acid, combining with them in definite proportions, the discovery of these proportions in the different combinations, is the most important step to the advancement of mineralogy as a science.
SYSTEM.

It remains that we notice the mineral system of Mr. Aikin, the principal object of which is to enable the student to ascertain the names of known minerals from certain properties joined with their external characters. The difficulty of attaining this knowledge from the systems hitherto published, is universally acknowledged, although the number of minerals, considered as species, does not exceed four hundred. Mr. Aikin arranges minerals into four classes, from their chemical characters. The orders are distinguished by properties which are supposed to be the most characteristic, or by which they may be most easily known.

CLASS I.—Non-metallic combustible minerals.
Order 1.—Combustible with flame; 2, without flame.
CLASS II.—Native metals and metaliferous minerals.
Order 1.—Volatile wholly or in part by the blowpipe, into a vapour which condenses in a pulverulent form on a piece of charcoal held over it.
Order 2.—Fixed, not volatile, except at a white heat.

The minerals of these two orders are arranged as they are more or less volatile, have a metallic or non-metallic lustre, are magnetic or non-magnetic, or are reducible to the metallic state.

CLASS III.—Earthy minerals.
Order 1.—Soluble wholly, or in a considerable portion, in dilute muriatic acid.
Order 2.—Fusible before the blowpipe.
Order 3.—Involatile before the blowpipe.

The minerals of orders 1 and 2 are arranged according to their degrees of hardness.

CLASS IV.—Saline minerals.
Order 1.—When dissolved in water afford a precipitate with carbonated alkali.
Order 2.—Do not afford a precipitate with carbonated alkali.

The different orders and subdivisions in each class are arranged without any regard to the constituent parts. But a mineralogical description of each species is also given, with an account of the component parts of those minerals of which the analysis is known.

SYSTEM OF GEOLOGY. The structure of the globe we inhabit, and the revolutions it has undergone in former ages, may justly rank among the most interesting objects of inquiry that can engage the attention of mankind in an advanced state of the physical sciences. It is scarcely half a century since geology began to be cultivated; and the various theories of the earth which appeared before that time, can only be regarded as amusing speculations, unsupported by existing phenomena. The systems of Woodward, Burnet, and Buffon, are given under the article EARTH.

Since the position and nature of the rocks and strata that compose the crust of the globe have been investigated in various parts of its surface, other theories and systems have been formed, which profess to be founded on established facts, or on legitimate inferences from them. When striking and complicated phenomena are first presented to our observation, we seek with avidity for some general principles which shall connect and elucidate the whole; and if we trace a few links of connection, which appear dependent on one and the same cause, we are too apt to consider the discovery as already completed, and to make our future observations subservient to the establishment of a system. This tendency to form premature generalizations, is the "sin which most easily befits" the first cultivators of every branch of natural science, and we are not to expect that geologists could entirely escape its influence. Fortunately, however, two systems, founded on different principles, were advanced nearly at the same time, with equal claims on public attention; the first of each not infrequently disagreed in their inferences from the same facts, and also in their explication of the facts themselves. Hence others were induced to examine nature more accurately, and new and more important facts were disclosed; thus the clouds which settled on the cradle of geology, have been blown aside by the breezes of conflicting opinions.

Every system of geology, if complete, should comprise the structure and composition of the earth's surface, the changes which it has undergone, and the changes now taking place by external or subterranean agents: it should trace, in existing phenomena, the causes by which former changes were effected, and endeavour to discover the extent of their operations, and to distinguish partial revolutions from those which have affected the whole globe.

The internal structure of the globe is concealed from human observation; the materials ejected from volcanoes come in all probability from vast depths, and are composed of similar elements to those which form its surface; but in what state those elements exist in the central recelles of the earth, or in what manner they are arranged, will perhaps for ever remain unknown.

"A great essaying the feeble efforts of his slender probation against the hide of the elephant, and attempting thereby to investigate the internal formation of that large animal, is (says Dr. Watson) no unpainted representation of man attempting to explore the internal formation of the little holes into its surface." (Chemical Essays, vol. 1.) From the fractures and dislocations of the strata, we are however enabled to make ourselves acquainted with the structure of the globe to far greater depths, than it is possible to reach in mining operations; and the subterraneous agents, of the globe, come in all probability from beds far below any which rife to the surface. Still it must be confessed that our knowledge of the inner part of our planet is nearly confined to one fact, namely, that it possesses greater density than the earth and strata, on which the surface is principally composed.

The mean density of the whole globe, as ascertained by the observations of Dr. Maclay and Mr. Cavendish confirm those of Playfair. It is at least five times that of water. The experiments of Dr. Cavendish confirm the above estimate. Hence, if the globe could be weighed in a scale, it would require five globes of water, or two and a half of common limestone, to balance it. If the diameter of the earth be 7920 miles, and it were composed of an outer spherical crust of common stone 1300 miles in thickness, it would require that the inner space, 5610 miles in diameter, should be filled with a substance equal in density to melted silver, that the whole globe might have the present mean density of the earth. If we admit the observations and experiments of Dr. Maclay and Mr. Cavendish to have established the density of the earth, as above stated, it follows that the inner part is not a hollow space, neither is it filled with air, water, or ice, as some philosophers have conjectured; and if it contain large caverns, the remaining solid parts must have greater specific gravity than many of the known metals.

The structure of the external part of our planet is exploded to observation in the interseuctions made through mountains by torrents and rivers, by the action of the sea upon the coasts, by fractures of the strata, and by the irregular
gular rise to the surface in an inclined position. It is probable that the total thickens of the crust of the globe thus exposed to our view in different districts may not be less than four or five miles. See Rock and Strata.

From the phenomena presented by the various rocks as they rise to the surface, geologists have drawn very different conclusions with respect to their formation; and two sects of geologists have been formed, the one can see in these phenomena only the agency of water, and the effects of chemical precipitations or mechanical deposits from an aqueous fluid; hence they have been called Neptunians. The celebrated professor M. Werner of Freiberg has given to these opinions a regular systematic form; hence the Neptunian theory is more frequently called the Wernerian system of geology. It has been explained at some length by the disciples of Werner, and has been warmly and ably supported by many eminent geologists. Other geologists consider subterranean heat as one of the great agents in the formation or consolidation of rocks, hence they have been called Volcanists and Plutonists, and their theory has been called the Plutonian system.

The late Dr. James Hutton, of Edinburgh, gave to this theory certain modifications, and a more comprehensive range; and it is usually designated the Huttonian system. The leading positions in which the Wernerian and Huttonian systems agree, are, that the present continents have been covered by the ocean; and that the materials of which the upper rocks and strata are composed, were deposited from an aqueous fluid. From these points of agreement they widely diverge in their explanation of the causes by which the continents were laid dry, the mountains elevated, and the materials converted into stone.

Neptunian or Wernerian System.—That part of the Wernerian system which comprises the classification of rocks, has been given under the article GEOLOGY. The speculative part of this system comprises the mode of their formation, and the original condition of the globe. According to Werner, the primeval ocean holding in solution the materials of rocks and strata, flood high over the whole earth in a calm and undisturbed state. The elementary materials began to crystallize, and fall down in this quiet state of the waters, and formed the granitic pavement of the globe. As the crystallization proceeded, elevated peaks and ridges shot up into the water, and occasioned the original inequalities of the surface. Successive deposits covered the sides and summits of the lower crystalline masses, forming the rocks denominated primary. After or during this process, the waters began to retire, and the summits of the loftiest mountains emerged from the abyss. "The waters at this period became agitated; yet this at first only prevented the perfection of the crystallization. As the water diminished in height, its motions were increased, the agitation extended down to the surface of the earth, and the crystalline florets were destroyed; thus the first mechanical productions were formed. The water still continuing to diminish, the dry land began to appear, of course the mechanical action of the water would be much increased, as also the formation of mechanical productions." The lower rocks are entirely chemical, but the crystallization becomes more and more imperfect in the newer formations, and the chemical deposits increase, the newest formations being principally mechanical productions. The Wernerian geologists conceive, that they can trace this progressive diminution of the waters of the globe, and the change which took place in the nature of the deposits. When we view the various depositions of the earliest discoverable periods to the newest, we find, says Mr. Jameson, such differences in them, as shew that the contents of the water of the globe must have changed by degrees, and that all its depositions form a beautiful connected series. The oldest rocks, which are pure chemical precipitates, are composed principally of silicious, argillaceous, and magnesian earths. These rocks, as granite, gneiss, and mica-flake, contain metals that are of contemporaneous formation with them, and that scarcely occur in new periods; these are tin, molybdena, and tungsten.

The state of the water of the globe, however, alters gradually and remarkably, as we approach the newer periods, by the abundant appearance of lime-flour, and the occurrence of coal and salt, and the disappearance of the old and the appearance of new series of petrifactions. Before the general succession discoverable in the productions of different periods, we have influences of the repetition of certain periods in considerable intervals, and in formations of different cast. In a series of this kind, all the members have general characters of agreement, and the individual members bear characters expressive not only of the period of their formation, but also of the circumstances under which they were formed. Such a series is denominated by Werner a principal formation, suite, or series of formations.

Mr. Jameson describes the lime-flour formation, as it occurs in the primary period of the crust of the earth. Amongst the first rocks denominated by Werner, are the flinty rocks, to illustrate a principal formation suite. The first member of the lime-flour suite is the white granular lime-flour, which occurs in gneiss, mica-flake, and clay-flake. The granular distinct concretions are large; but in the newest clay-flake they become more minute, and it even approaches to compact. The transition rocks contain the second member of this series, the variegated lime-flour, which has less translucence than the preceding, but more than the following members of the series. This lime-flour shows the first signs of petrifactions. The following rocks, the flints (or flint felsas), contain the third member of the series, the pure flinty lime-flour, which is scarcely translucent on the edges, and is full of petrifactions. It has some resemblance to the lime-flour of the transition period, but only a very remote one to the primitive. Chalk is the newest formation of the period: it connects the foregoing members, which have been deposited from the ocean, with the calc-tuff, the lowest link of these formations. (See TUFFA and TUFF.) We have thus a complete series from the earlist to the last period, in which we notice the gradual appearance of the crystalline, and increase of the earth's effects, corresponding with the relative age of the different members of the series, and the state of the solvant, from which they were precipitated; and all serving as proofs of the immensely gradual, but gradual, alteration of the state of the universal water.

As the waters, according to this system, covered the whole globe during the formation of the primitive and oldest transition rocks, neither land-places nor land-animals could exist; and the first traces of organic existence which appear in the transition rocks, are the remains of marine plants and animals. (See Marine Rocks.) The first relics of land-places or animals occur in the newer transition rocks, which were formed after a portion of the land was uncovered, and capable of supporting terrestrial vegetation. From this period to the newest or alluvial, the quantity and variety of vegetable remains increase, and this is further confirmed by a corresponding increase of coal. As the water diminished, it appears to have become more fitted for the support of animals and vegetables; for we find them increasing in number, variety, and perfection, and approaching more to the nature found in the present state. The same gradual increase of organic beings appears to have taken place on dry land.
SYSTEM.

As the water, according to this theory, covered the whole globe, when it first began to precipitate its contents, they were spread all over its surface, and constituted masses of stone encircling each other, like the coats of an onion. The principal rock formations are, therefore, called universal formations; besides which, there are some local formations of limited extent. The principal coal formations, according to Werner, are of this kind, and are called independent formations.

We have now to notice a remarkable feature in the Wernerian system. There are certain rocks which occur, covering other rocks and strata, without any conformity with the position of the lower beds. These rocks are principally trap, porphyry, and fiesite. (See Trap, Porphyry, and Sienite.) The nature and position of these rocks bear a similarity to that of many volcanic rocks. They are denominated in the Wernerian system varying formations. Porphyry and fiesite, according to this system, are of a far earlier date than basalt. To explain the formation of these rocks, the Wernerian geologists tell us, that after the water, which covered the whole globe, had retired to its present level, it rose again at two different periods, and covered some of the highest mountains. In the first period, it deposited the rocks of porphyry and fiesite; in the second period, it deposited the rocks of basalt, or what they call the newes flata trap. At the latter period, the water rose to the height of 11,000 feet, at least above the level of the sea.

The water of the second rising was in a very turbid and agitated state: hence its first depositions were mechanical, or composed of gravel, sand, and mud; but as it became calm, the depositions were principally chemical precipitates, forming basaltic rocks. After these labours of the ocean were completed, it retired with considerable rapidity to its former level.

According to the system of Werner, metallic and mineral veins were originally fissures in rocks, which have been subsequently filled by water, holding the contents in solution. See Veins.

The principal objections to the system of Werner are, first, that by far the greater part of the substances of which rocks are composed are insoluble in water, or require such a large proportion of it for their solution, that the capacity of the whole globe, were it a hollow sphere, would be too small to contain a sufficient quantity of the aqueous menstrum.

Nor can this objection be removed, by supposing the aqueous fluid to percolate far greater solvent powers than the ocean; for the marine organic remains found in different strata prove, that the water must have been similar in its nature to that of our present seas and lakes.

Secondly. "What has become of the immense volume of water, that once covered and filled so high over the whole earth?" To this objection, which is stated in the words of Mr. Janssen, he replies, "Although we cannot give a satisfactory answer to this question, it is evident that the theory of the diminution of the waters remains equally probable. We may be fully convinced of its trueness, and see it, although one may not be able to explain it.? To know from observation that a great phenomenon took place, is a very different thing from explaining how it happened."

Thirdly. The succession of rocks in different countries very rarely agrees with that of the universal formations, described by the disciples of Werner; nor can we trace such a regular gradation in their crystalline structure as the theory assumes: whereas if the waters, which deposited the primary rocks, covered the globe in a calm and quiescent state, the succession of deposits would be similar in the remotest districts. To this it may be replied, that though all the different orders of primary rocks, enumerated by Werner as universal formations, rarely succeed each other in any one situation, yet, wherever two or more occur together, their arrangement is generally conformable to his system; and this is as much as we can reasonably expect. Other geologists remove the objection, by modifying the system itself, assuming that the primary rocks were deposited at the same time, and are to be considered as contemporaneous formations.

Fourthly. The formation of basaltic rocks on the summits of lofty mountains cannot be satisfactorily explained by a general inundation. Indeed the cause assigned is not only at variance with existing appearances, but is contrary to the established laws of nature. "It is scarcely possible for the human mind to invent a system more repugnant to existing facts. Were basaltic rocks deposited from a solution that covered the whole globe, after the formation of the secondary strata, every part of the dry land, and every valley, must have been inundated or filled with basalt. It would be the prevailing rock of every district. On the contrary, basalt exists only in detached masses of limited extent; nor do fragments of basalt occur in any quantity, which can warrant the belief that it was ever formed over the whole globe. (Bakewell's Introduction to Geology.) Many of the basaltic rocks, to which the Wernerians attributed an aqueous origin, are now generally admitted to be volcanic; and the similarity of their composition with lava has been recently more fully established by the researches of D'Aubriéon. See Volcanic Products and Trap.

The objections made to many parts of the system of Werner, as originally announced by his followers, it would be difficult, if not impossible, to remove; but the system is susceptible of modifications, which may make it more conformable to the present state of our information; and some of its most strenuous supporters begin to perceive the necessity of adopting such modifications, in their exposition of the theory. Whatever may be the ultimate fate of the Wernerian system, it cannot be denied that its publication was of material service to the progress of geological inquiry. The striking similarity which it pointed out between many rock formations, in distant countries, if it has not proved their identity, nor the univcrsality of such formations, has at least established an important fact, that proceeds of a nearly familiar kind succeeded each other in the same order, in distant parts of the globe. To Mr. Werner we are also indebted for a knowledge of the mineral repositories peculiar to certain rocks. We have thus obtained some fixed principles to guide us in our geological investigations.

M. De Luc assumes that the strata were formed by chemical precipitations, but differs from Werner in his explanation of the caucuses that have laid dry our present continents. According to this geologist, the relative level of the continents and the sea was produced by the subidence of pre-existing continents, over which the sea immediately flowed. The broken state of the strata composing our continents was not an effect of the revolution which gave them birth; it resulted from successive catastrophes undergone by the strata, during the period of their formation at the bottom of the sea; and these catastrophes were occasioned by caverns formed beneath them. The cavities of lakes, the valleys among mountains and hills, the abrupt and shattered faces which these eminences present towards the plains, existed on our continents at the very period of their birth; being the effects of those catastrophes that fractured the strata of which these continents are composed. A succession
fion of such catastrophes was continued, till the continents were abandoned by the sea. Since that epoch, all the operations to which they have been subjected by atmospheric causes, gravitation, and defraying waters, have only tended to efface the original characters, by reducing abrupt precipices into gradual slopes, by softening down the asperities of hills, by raising, instead of excavating, the beds of valleys and by filling up the cavities of lakes. The beds of gravel and blocks of flint, found scattered in such large quantities on the surface of the earth, nay even the blocks observed in the beds of rivers, were not deposited there by running waters, but are among the original characters of our continents. The gravel composed of flints is derived from decomposed chalk flints, at some period subsequent to their formation; yet whilst they were still covered by the sea, the flints only remaining as we now find them.

The gravel formed by the attrition of fragments of the flint, as well as the blocks of flint, were projected from the interior of the earth by the expendable fluids, during the subidence of the flint, and were subsequently spread over the bottom of the sea by the agitation of the water. The naked and precipitous cliffs which border some of the coasts, are not, says M. de Luc, to be ascribed to the action of the sea; they are original characters, resulting from dissections of the flint, at the period of the vast subidence which produced the new basin of the sea; the action of which directly tends to obliterate the original characters, by forming fronds and at the feet of cliffs. Thence it is, when sufficiently raised and extended, permit the steep faces to be gradually reduced into slopes.

The quantity of loose materials brought down by rivers was at first considerable, and mixed with large fragments of rock, on account of the broken surface over which the waters descended to the coast. These transplantsations of loose materials diminished in proportion to the progress of vegetation on the surface, when its asperities were softened, and the rivers became restricted within fixed beds. Since the birth of our continents, the level of the sea has not changed. Lastly, all the operations which had a tendency to alter the original form of our continents commenced at the epoch of their birth. We still behold the causes which produced those changes, for they are still operative, and by studying them with care, we may ascertain all that they have effected in any particular place. We may even trace, says M. de Luc, what each cause has effected within known periods of time, a circumstance which supplies us with chronometers of different kinds, all independent of each other, and these chronometers agree in testifying that the age of our continents cannot exceed 4000 years. According to M. de Luc, the formation of caverns was produced by the infiltration of the primordial liquid (from which the flint was precipitated) into the interior parts of the globe; hence also refuted a cause of successive changes in the nature of the precipitates. The reader may consult the numerous travels and publications of this philosopher for a more full exposition of his system. The existence of immense caverns in the earth is assumed to explain the fractures and depressions of its surface, but is at variance with the ascertained mean density of the earth. It must be acknowledged that the theory of M. de Luc has some advantages over that of Werner, as it affirms a cause for the retiring of the water, and the elevation and depression of the flint; whereas, in the system of Werner, the present inclination of the flint is supposed to be coeval with their first formation, a supposition which seems contradicted by general appearances in almost every part of the globe. According to M. de Luc, the changes now taking place on the earth's surface will cease when all its projecting points and asperities are smoothed down or covered with vegetation; and the processes now taking place have a regular and progressive tendency to bring the solid parts of our planet into a quiescent and permanent state.

Phlyctenian or Huttonian System.—The Huttonian system of geology does not carry us back to the original formation of the globe. Dr. Hutton, in his author, supposes that the present dry land was at a former period the bed of the sea. According to this theory, the flint was not precipitated from a chemical solution, on the contrary, they exhibit proofs that the substances of which they are composed existed as the elements of other bodies that must have been destroyed before the formation of the present continents. Although the ruins of a former world are not to be found in every piece of rock, they are generally diffused, as is leave no doubt (says Dr. Hutton) that all the flint was formed from the materials of continents that previously existed, and that these materials have been carried into the sea by the same cause which are now wearing down our present continents. Every island or continent, he observes, has its extremities, the mountain-summit, and the sea-shore. On one extremity there is no increase, but a constant decay. The rocks being split into fragments by the agency of heat, frost, and moisture, these fragments are removed by rains and tides in gradual succession, from the highest stations to the lowest, and are further broken in their descent. Having reached the shore, they are dashed by the returning tides upon the coast, and serve as the instruments of its destruction, using the violence of the waves in excavating and breaking down the solid ground. Thus the present dry land is constantly diminishing, and thus the materials of former continents were carried to the ocean, and spread over its bed, either in the state of gravel, sand, mud, or impalpable cement, covering the remains of marine animals by successive deposition. According to this theory, the agent by which these materials were formed into solid flint is of terraeana fire, which is supposed to exist in the central recesses of the globe, and to have periods of increased activity, by which certain parts of its surface are heated and confounded together. The same internal fire acting with great intensity on the lower parts of the globe, the materials which form mountains of granite were then in a state of perfect igneous fluidity, and the fluid was continuing to expand, raised the flint by which it was covered from the watery abyss, and former continents were inundated or sunk down.

The new continents were immediately exposed to the last disintegrating causes by which former continents had been wrought; valleys were excavated in the softer beds by rains and water-courses, and the ocean commenced its attacks upon the coast. Thus materials are preparing for the formation of the flint of future continents to be raised from the sea by the same cause. "Here then," says professor Playfair, "we have a series of great natural revolutions in the condition of the earth's surface, of which we neither see the beginning nor the end; and this circumstance accords well with what is known concerning other parts of the economy of the world. In the continuation of different species of animals and vegetables that inhabit the earth, we discern neither a beginning nor an end; and in the planetary motions, where geometry has carried the eye so far, both into the future and the past, we discover no mark, either of the commencement or the termination of the present order. It is unreasonable indeed to suppose that such marks should exist anywhere. The Author of nature has not given laws to the material, which, like the constitutions of men, carry in themselves the elements of their own destruction; he has not permitted in
SYSTEM.

His works any symptom of infancy or old age, or any sign by which we may estimate either their future or past duration. He may put an end, as he no doubt gave a beginning, to the present system, at some determinate period of time, but we may rest assured that this great catastrophe will not be brought about by the laws now existing, and that it is not indicated by anything which we perceive.

According to the Huttonian theory, granite, which is considered by Werner as the oldest rock formation, is of more recent origin than the strata incumbent on it. It is regarded by Dr. Hutton as a subsidence which has been erupted from great depths in a state of igneous fusion, burrowing through the strata in some parts, and upheaving the whole from their subterranean situation. The original fluidity of granite is, he conceives, evinced by its crystalline structure, and also, that the fluidity was not that of the elements taken separately, but of the whole mass. It is the particular kind of granite called graphic (from the supposed resemblance of the quartz to the form of Hebrew letters), the quartz is impregnated by the rhomboidal crystals of felspar, and the felspar is highly compact and consolidated; hence this granite is not a congeries of parts, separately formed and agglutinated together. The perfect consolidation of granite may be added as a further proof of its having been rendered fluid by heat; had it crystallized from an aqueous solution, we should have found intercalations between the crystals. The view that granite has frequently been formed by incumbent schists, offers further proof that the granite must have been in a fluid state: the whole mass was also fluid at the same time. This, according to Dr. Hutton, could only have been effected by subterranean heat, which also impelled the melted matter against the incumbent beds with such force, as to raise them from their place, and give them that highly inclined position, in which they are still supported by the granite, after its fluidity ceased. See VEIN.

Thus a conclusion, rendered probable by the crystallization of granite, is established beyond all contradiction by the phenomena of granite veins. With the granite we shall, therefore, says Professor Playfair, ‘confide the proof of the igneous origin of all mineral substances as completed. Thence, whether stratified or unstratified, owe their consolidation to the same cause, though acting with different degrees of energy. The stratified have been in general only softened, whereas the unstratified have been reduced to a state of perfect fusion. In this general conclusion we discover two parts, which in their degree of certainty differ perhaps somewhat from one another. The first of these, and that which stands in the highest point of evidence, consists of two propositions, namely, that the fluidity which preceded the consolidation was simple, that is, did not arise from the combination of these substances with any solvent; and next, that after consolidation, these bodies have been raised up by an expansive power, acting from below, and have by that means been brought into their present position. These two propositions seem (says Professor Playfair) to be supported by all the evidence that is necessary to constitute the most perfect demonstration.’

The other proposition is that the sole cause of the fluidity and subsequent elevation of these mineral bodies, is, he admits, a matter of theory. ‘The cause, however, which is assigned is sufficient for the effect, and the same is not true with respect to any other known cause. This theory accounts, with singular simplicity and precision, for a system of facts, so various and complex as those which the natural history of our globe presents. Nor is the principle of subterranean heat assumed without evidence; on the contrary, it is proved by the phenomena of hot springs, volcanoes, and earthquakes; these leave no doubt of the existence of heat, and of a moving expansive power within the earth.’

It has been objected to the igneous origin of granite, that if it had been in a state of fusion when erupted from below, why did it not diffuse itself in torrents on the surface. To this objection Professor Playfair, its eloquent advocate, replies, ‘The theory of Dr. Hutton would not defer a moment’s consideration, if it were so inartificially constructed as to suppose that granite was originally fluid, and yet to point out no means of hindering this fluid from diffusing itself over the strata, and settling in an horizontal plane. The truth is, that his theory, at the same time that it conceives this fomite to have been in fusion, supposes it to have been ejected in that state among the strata already consolidated; to have heaved them up, and to have been formed in the concavity so produced as in a mould. The covering of strata thus raised up, may have been burst asunder at the summit, where the curvature and elevation were the greatest, but the melted mass underneath may have already acquired solidity, or may have been sustained by the beds of schist incumbent on its sides. This schist, forming the exterior crust, was immediately acted upon by the cauæ of want and decomposition, which have long since stripped the granite of a great part of its covering, and are now exercising their power on the central mass. We are led to think that even Mont Blanc, as well as other unstratified mountains, was once covered with fchitis, will appear to have in it nothing incongruous, when we consider the height to which the fchitis hill rises on its sides, or in the adjacent mountains; and from the appearance of want and degradation which these mountains exhibit, it is certain that the chitis mass must have reached much higher than it does at present.’

Mineral and metallic veins, that interm check rocks and strata, are supposed by Dr. Hutton to have been cracks, or fissures, originally formed by subterranean heat, and that they were filled with their contents by melted matter ejected from beneath. In some instances, the matter was sublimed in the form of vapour, which condened and crystallized on the sides of metallic veins.

The mineral veins are generally filled either with granite, porphyr, green-stone, or basalt. They are of vast extent, often traversing the whole country. As the materials which fill these large veins are frequently harder than the rocks which the veins intersect, they remain undecomposed after the surrounding rocks have perished, rising like a wall above the surface; hence in the northern parts of our island they are called dykes, the term being synonymous with a wall.

These dykes produce great changes in the position of the strata which they intersect, and are considered by Dr. Hutton as affording strong proofs of the former. The basaltic dykes bear more immediately the marks of their igneous origin, as the composition and appearance of this fomite have a great resemblance to many volcanic lavas. The changes produced on the rocks which they pass through are such as might result from contact with substances in a state of fusion. Basaltic rocks exist in countries far remote from any active volcanoes; they prove, therefore, that subterranean heat has been an important agent in the formation of our present continents.

The transition which may frequently be traced from granite to flænite, green-stone, and basalt, leads to the conclusion that they had all the same origin.

As the difference between stratified and unstratified rocks consists in the latter having been perfectly fused, and the former
former only softened by subterranean heat, so farther the strata were removed from the granite, they were less acted upon by central heat, and were left in a more earthly state; but where the materials of strata were easily fusible, such strata became more crystalline than other strata in a similar situation, but composed of refractory materials. While the strata were in a soft state, they were sometimes subjected to two forces, the one arising from the pressure of superincumbent rocks, the other from the partial depression or elevation of the earth's surface in their vicinity, which occasioned a lateral pressure, and these two forces, acting at the same time in a direction nearly at right angles to each other, produced those remarkable contortions and convolutions of the strata, which may frequently be observed in schistose rocks adjoining the granite, as represented in Plate III. Geology, fig. 6.

The theory of Dr. Hutton is distinguished from that of former Plutonists, by the aid which it derives from the introduction of compression, as a powerful agent in the formation of our present strata.

It had been objected to the system, that the present state of mineral bodies is very different from that in which we should have seen them, had they been subjected to intense heat. Lime-flint in particular is rendered caustic by heat, the carbonic acid being driven off, whereby it is converted into quick-lime. Now if the lime-flint rocks had been subjected to a great heat, they would have been left in a caustic state, like burned lime. To this Dr. Hutton replied, the circumstances under which these rocks were heated, were very different from those in which lime-flint is calcined by common fire. Under the pressure of the ocean, at a great depth, the carbonic acid would be prevented from escaping, and being confined, it would contribute to render the lime fusible; hence in cooling, it acquired its crystalline texture.

This conjecture of Dr. Hutton's could be considered as little better than an hypothesis assumed to remove a difficulty from his system, until Sir James Hall proved its accordance with nature, by a series of ingenious and most decisive experiments. He confined powdered chalk in a gun-barrel, so closely as to prevent the extraction of the carbonic acid, and then subjected it to the heat of a furnace, by which it was fused and consolidated, and converted into a substance resembling crystalline marble.

"From these experiments it appears, that a preasure of 32 atmospheres, or 1700 feet of sea, is capable of forming a lime-flint in a proper heat; that under 80 atmospheres, answering nearly to 3000 feet, or about half a mile, a complete marble may be formed; and lastly, that with a pressure of 173 atmospheres, or 5700 feet of sea, or little more than one mile, the carbonate of lime is made to undergo complete fusion, and to act powerfully on other earths." Translations of the Royal Society of Edinburgh, vol. vi. p. 149.

The igneous system has received additional support from other interesting experiments of Sir James Hall, proving that compression, and the different circumstances under which mineral bodies become consolidated after fusion, greatly modify their state, and sometimes entirely change their external appearance. Thus basalt and lava, when melted and cooled rapidly, are converted into a black glass; but if suffered to cool slowly, they acquire a texture resembling that of the original flint. See Rowley-Raige, and Trap-Rocks.

In what manner the subterranean heat is generated, or by what causes it is called into a more active state at particular periods, the supporters of this theory do not think it necessary to inquire; it is sufficient that the effects are every where discernible; nor is it more difficult to conceive that heat should be confined in the interior of planets, than that light should be constantly emitted from the surface of the sun. The extent to which volcanic fires are operative, prove that the source of heat is situated at great depth. The bed of the ocean is heated at a considerable distance from Sicily during some of the eruptions of Etna, as is proved by soundings taken at the time. The sea is constantly in a boiling state near one part of the island of Volcano, and the black sand on the shore is so hot that it cannot be held in the hand; indeed, there can be little doubt that all the volcanoes in the Lipari islands have some communication with Etna and Vefius. The connection which more distant volcanic fires appear to have with each other, will be noticed under the article Volcano. The number of submarine volcanoes which have been observed since the ocean has been more traversed, proves the existence of submarine fire under almost every degree of latitude; and the numerous volcanoes of the Andes are of sufficient magnitude and power to produce considerable changes on the surface of the globe, and overwhelm whole provinces in a single night. The craters of many extinct volcanoes exceed in fact those which are at present in a state of activity; and according to Humboldt, the most ancient volcanic lavas bear the least resemblance to primary rocks. These ancient lavas were probably erupted under the preasure of the ocean, at the period when all the present continents were covered with water.

The number and extent of ancient and existing volcanos may lead us to infer that they have an important office to perform in the economy of nature. "A volcano," says Dr. Hutton, "is not made to frighten superstitious people into fits of piety and devotion, nor to overwhelm devoted cities with destruction. A volcano should be considered as a spireacle to the subterranean furnace, in order to prevent the unnecessary elevation of land and the fatal effects of earthquakes; and we may rest assured that they in general wisely answer the end for which they were designed, without being in themselves an end for which nature had exerted such amazing power and contrivance."

We should not do justice to the theory of Dr. Hutton, in contemplating the possible effects of subterranean heat; we did not bear in mind the important difference between combustion and ignition. Most bodies exposed to heat in contact with the atmosphere undergo a chemical change, their more volatile parts are driven off, and the inflammable parts combine with oxygen; but under preasure, and confined from all access to air, the same bodies might remain for ages without undergoing any change but that of simple fusion, even at the highest degree of temperature with which we are acquainted.

According to the theory of Dr. Hutton, the different continents that now exist, may have been raised at different periods. Nor are circumstances wanting to confirm the opinion, that the American continents are of more recent formation than those of Asia or Africa; and traditions, according to Plato, seem to have preserved some memory of events that have sunk down in the Atlantic oceans. (See Atlantic.) The continents of the most recent formation may be expected to present more numerous appearances of volcanic fire, and to be more agitated by internal convulsions and earthquakes, whilst in the older continents everything is passing to a more tranquil state, and subterranean fires cease to operate on the surface. Such is nearly the present state of Asia, compared with that of South America and Africa, perhaps, may be considered as a continent newly exhausted; the secondary strata are already carried away in many parts; and the primary mountains, by their decomposition,
SYSTEM.

position, are covering with siliceous sand a great portion of
the interior of that country, and rendering it no longer
habitable.

As the greater part of the southern hemisphere is at pre-
sent covered by the sea, and three-fourths of the dry land
are on the northern side of the equator, we may, on the
Huttonian theory, indulge the speculation, that the Indian
ocean and the Southern Pacific will be the sites of future
continents, when Europe and Asia are covered by the
ocean in the next great terrestrial revolution.

Dr. Hutton supposes that the elevation of extensive
continents may require ages for its completion, and that be-
fore the rocks and strata attained their permanent level
above the ocean, they may have been subjected to partial
or more general subfurncies, by which they were again
covered with the sea, and received fresh deposits of sand,
which were formed into stone on their second elevation by
heat. This subfurnc, he thinks, is implied by many phe-
nomena which present themselves to the attentive ge-
ologist.

According to the theory of Dr. Hutton, all vallies have
been originally formed and excavated by rivers. Every
river, says professor Playfair, appears to consist of
a main trunk, fed from a variety of branches, each running
in a valley proportioned to its size, and all of them forming a
system of vallies communicating with one another, and hav-
ing such a nice adjustment of their declivities, that none of
them join the principal valley on too high a level; a circum-
crance which would be infinitely improbable, if each of
these vallies was not the work of the stream that
flows in it. In considering these circumstances, it becomes
strongly impressed upon the mind, that all these channels
have been cut by the waters themselves; that they have
been slowly dug out by washing and erosion of the land;
and that it is by repeated touches of the same instrument,
that this curious assemblage of lines has been engraved so
deeply on the surface of the ground.

If we could trace back the progress by which the ground
has been wafted, till we come in sight of the original struc-
ture, of which the remains are so vast, we might perceive
an immense mass of solid rock, as it first emerged from
the deep, naked and unshaped, and incomparably greater
than all that we now see.

The operation of rains and torrents, modified by the
hardness and tenacity of the rock, has worked the whole
into its present form, has hollowed out the vallies, and gra-
dually detached mountains from the general mass, cutting
down their sides into deep precipices at one place, and
smoothing them into gentle declivities at another. From
this has resulted a transportation of materials, which, both
for the quantity of the whole, and the magnitude of the
individual fragments, must seem incredible to every one
who has not learned to calculate the effects of continued
action, and to reflect, that length of time can convert ac-
cidental into steady causes. Hence, says professor Play-
fair, fragments of rock from the central chain are found to have
travelled into distant vallies, even where many inferior ridges
intervene; hence the granite of Mont Blanc is seen in the
plains of Lombardy, or on the sides of Jura; and the ruins
of the Carpathian mountains lie scattered over the thores
of the Baltic. These loofe blocks of stone point out the
great changes which have happened since the commence-
ment of their journey, and in particular serve to shew, that
many vallies, which now deeply intersect the surface, had
not been begun to be cut when these lofty masses were first
detached from their native rocks, as they could not
have descended from one ridge, and then ascended on the
opposite ridge.

The processes by which vallies are excavated may be seen
in many alpine districts; but it is no where more strikingly
displayed, than in the interfection of the Alleghany moun-
tains, in North America, and particularly where the Poto-
mac river has cut itself a passage through the ridge called
the Blue mountains, in Virginia. By the same process,
elevated lakes are laid dry; and by the transportation of
materials, lower lakes are gradually filled up.

The description given by the Huttonian geologists of the
formation of vallies, is accordant with existing appearances
in many situations; but will not apply to the formation of
all vallies: nor is it correct, that none of the upper vallies
join the lower at a higher level; for numerous instances of
such vallies might be cited, from which the rivers descend
in cascades from the upper to the lower valley. The strata
on the opposite sides of vallies have often a different angle
of inclination; which proves, that the valley had been ori-
originally formed by some great convulsion, that had fractured
the strata, and elevated them on one side, or depressed them
on the other. Indeed it appears consistent with the Hut-
tonian theory itself, that vallies may have been originally
formed by fractures of the strata produced by the convul-
sions to which the continents have been subjected. Through
these fractures the mountain torrents would rush down, and
smooth and widen the passage in their descent.

Many geologists, who admire Dr. Hutton that gra-
nitic and unstratified rocks and mineral dykes were formed
by the agency of fire, do not admit that stratified rocks
have been formed entirely by mechanical deposition from
the ruins of former strata, and subsequently consolidated
by subterranean heat. Nor do they admit, that the causes
assigned for the transportation of blocks of granite into dis-
tant countries are adequate to the effect.

In the seventh volume of the Transactions of the Royal
Society of Edinburgh, sir J. Hall has brought forward
several modifications of the Huttonian system, which he
conceives to be more consonant with the present appear-
ances of the globe. He supposes, that islands or continents
sometimes have been raised from the ocean by a sudden
effect of subterranean heat, analogous to the rapid form-
ation of volcanic islands in our own times. In the latter
cases, where the solid pavement, which forms the bed of
the ocean, is softened by heat and raised to the surface, it
is always accompanied with a great swell of the sea, some-
times forming a single wave of prodigious height. During
the submarine eruption of St. Erini, or Santorini, in the
Grecian Archipelago, which took place in 1650, the sea
rose to the height of 45 feet, and at such a distance
from the volcanic island, that some galleys of the grand
seignior were wrecked in the port of Candia, though it is
more than 80 miles from Santorini.

A great wave or swell of the sea has been generally ob-
served to accompany the more formidable earthquakes.
This phenomenon is in all probability occasioned by the up-
heaving of the bed on which the sea rests, though it may
not always be attended with a submarine volcanic eruption.
Professor Pallas conjectured, that some parts of Asia had
been inundated by the swell of the sea, which is supposed
to have taken place during the formation of the volcanic
islands in the Indian ocean. Sir J. Hall has given greater
extension to this speculation; he supposes, that the upheaving
of a whole continent, or large island, may have taken place
suddenly, as to drive the ocean with great impetuosity
over the highest mountains, and transport vast fragments
of
SYSTEM.

of rock into distant countries. By the sudden ruff of such an immense wave, the looser parts of the strata may have been torn away, and the surface of a whole country entirely changed. It is generally admitted, that the continents of the old world bear the marks of a mighty irruption of the waters; but geologists differ with respect to the cause; that assigned by Sir J. Hall is, we think, the most probable, being simple, sufficient for the effect, and in accordance with phenomena that occur on a smaller scale in our own times.

It may be added, that such an immense agitation of the waters, which could carry them over the Alps, and sweep round the globe, would not suddenly cease. The water, before returning to a quiescent state, would frequently revisit the same countries at a diminished level, and assist in transporting still farther the debris formed by the first irruption. The ice on the higher mountains, containing imbedded masses of stone, would be stripped off, and being specifically lighter than water, it would render the stones buoyant, and carry them to distant countries. In this manner, those blocks of granite may have been deposited which are so widely scattered over plains far removed from granitic districts.

That part of the Huttonian system which supposes all the present strata to be mechanical depositions from former continents, is exposed to many weighty objections, from an attentive consideration of these phenomena which appeared on a superficial survey to be favourable to this opinion. The organic remains found in different strata, do indeed inform us, that animals existed before their consolidation; but the occurrence of different genera and species in separate beds, without intermixture with each other, and the gradation which may be observed in the nature of these organic remains, as we ascend from the lower to the higher beds, prove that the materials were not formed and deposited from theconfused debris of former strata. If the strata were formed from the ruins of ancient continents, why do we not find the remains of land-animals in the lower beds, or why should they occur only in the strata above the chalk, or in alluvial soil? The separation of vegetable from animal remains offers a further proof, that the materials were not deposited promiscuously and mechanically; for though vegetable and animal remains sometimes occur in the same argillaceous beds, yet in strata of sand-stone and lime-stone, such intermixtures are very rare indeed.

The formation of coal by the deposition of vegetable matter in the ocean, is equally difficult to conceive. The formation of a single bed of coal might indeed be more easily explained; but a series of beds, presuming the same thickness over a vast extent, and separated from the earthy strata above and below, appear to indicate that they could not be formed by mechanical deposition. Granting the vegetable origin of coal, it would seem more probable that extensive low plains, like the swamps or fawannahs of America, had been covered with mosses and grasses, which in decaying, had settled to the flate of peat, and been buried by inundations with layers of sand or mud, that served as the soil for another vegetable crop. Successive depositions might produce a series of beds, which were by heat and pressure subsequently converted into mineral coal. Some interesting experiments of Dr. Macculloch, published in the second volume of the Transactions of the Geological Society, appear to prove, that the bituminization of vegetable matter can only be effected by moisture; but for the conversion of bituminized vegetable remains into perfect mineral coal, heat and pressure are required.

Another objection to the Huttonian system may be advanced from the recent discovery of a series of strata of siliceous and calcareous stone, perfectly formed over the chalk in the vicinity of Paris. The chalk on which they are deposited has an uneven surface, being elevated and depressed, forming hills and valleys, over which the upper strata are horizontally laid, as represented in Plate II. Geology, 4th. New it is obvious, that the chalk must have been consolidated previously to the deposition of the upper strata; and the succession of animal remains of such different genera and species in the different beds, prove that they were formed at different periods of time. If subterranean heat were necessary for their consolidation, this heat must therefore have been operative long after the formation of the chalk. If this heat had been sufficiently powerful to act on the first three or four hundred feet above the chalk, it must have been equal to fuse the chalk itself, and convert it into crystalline lime-stone, or to soften it so much, as to mould the strata upon it, or at least to shew the effects of heat on the parts most immediately in contact with the chalk. Some of these strata being of the very hardest kind (particularly the mill-stone stratum), they would require, according to the Huttonian theory, an intense degree of heat for their consolidation. See STRATA around Paris.

That fire and water are both important agents in the consolidation of different rocks, is evident from what we are in our times: of the former, we have instances in beds of compact lava; and of the latter, in the recent formation of some sand-stones. The united effects of both are seen in the indurated argillaceous beds erupted in the state of mud from the volcanoes in the Andes. See VOLCANO.

The effects of comprethion at the common temperature of the earth, have not been sufficiently attended to by geologists; nor have there been those changes which are now taking place particularly in the softer strata and beds of sand, but scarcely noticed, though there cannot be a doubt that aggregations are forming, and certain arrangements going on which, if duly investigated, might throw much light on the consolidation of strata. For further observations on the formation of strata, see STRATA.

Whatever changes the Huttonian system must undergo to adapt it to a more advanced state of the science, or whatever may be its ultimate fate, it cannot be denied that it is distinguished by characters of grandeur and simplicity. When we consider how little was generally known of geology at the time this system was first published; how extensively it applies to the various phenomena which subsequent observations have discovered; what a probable, or at least what a plausible, solution it offers to many difficulties in the science; and what confirmation it has received from chemical experiments; we must regard it as one of the most perfect efforts of speculative philosophy.

For further observations connected with the present subject, we refer to our article STRATA, where the reader will find a different theory suggested respecting the formation of stratified rocks. See also Volcan, Metamorphic, and Metalliferous System, in MINORS; and a compound interval, or interval composed, or conceived to be composed, of temporal leis intervals. Such is the octave, &c.

The word is borrowed from the ancients; who called a simple interval, diastem; and a compound one, system. As there is not any interval in the nature of things, so we conceive any given interval, as composed of, or equal to, the sum of several others. This division of intervals, therefore, only relates to practice; so that a system is properly an interval which is actually divided in practice, and where, slop
with the extremes, we conceive always some intermediate terms. (See Interval.) The nature of a system will appear plain, by conceiving it as an interval, whose terms are in practice taken either in immediate succession; or the found is made to rise and fall, from the one to the other, by touching some intermediate degree; so that the whole is a system or composition of all the intervals between one extreme and the other.

Systems of the same magnitude, and, consequently, of the same degree of concord and discord, may yet differ in respect of their composition; as containing and being actually divided into more or fewer intervals; and when they are equal in that respect, the parts may differ in magnitude. Lastly, when they consist of the same parts, or least intervals, they may differ as to the order and disposition of them between the two extremes.

System of the Ancient Greek Music. See Greek Music. In connection with which, see also Composition, Counterpoint, Harmony, Melodia, Mutations, and Rhythm.

Roman Music.——The ancient Romans, who borrowed all their music and its technics from the Greeks, as appears in Vitruvius, Martianus Capella, and Boethius, had no system of their own, yet simplified the notation; and, instead of the 1620 characters of notation, subsumed the letters of the alphabet, and thus formed a scale of two octaves, or a 15th, from the lowest A, or profissimamのある of the Greeks, to our A, in the second space in the treble.

The next partial change in the notation was made by St. Gregory, who, perceiving that after the first septenary, the octave was but a recurrence of the same found as the first note A, and that in ascending to the double octave, the intervals were the same as in the first, reduced all to the seven first letters of the alphabet, only, instead of capitals, wrote the second series in minuscules, or small letters. See St. Gregory.

At length, says Baronius, in the eleventh century, Guido Areteus, in Tuscany, a Benedictine monk of the monastery of our Lady of Pomposa, in the duchy of Ferrara, invented a new system of founds, which, with subsequent additions, is still the foundation of the general and universal system of Europe.

System of Guido. We shall not here discuss, or attempt to ascertain, several inventions included in what is called Guido's system; but specify the principal constituent parts of the system of music which has long gone under his name; such as the gamut, or diatonic scale of tones and semitones; flats, sharps, naturals, hexachords, and foliation; diaphonia, or organizing other terms for the beginning of counterpoint; intervals, diatonic, or forming a part above or below the chant, orplain-song.

The two great defects in the rude system of Guido, as far as it goes, were the want of semitones in transposed keys for harmony and modulation, and a time-table for melody. And those deficiencies occasioned by the ecclesiastical modes or tones, flopped all material improvement in secular music for many ages after the time of Guido. The want of a sharp 7th to all the modes and tones of the church in canto fermo, and their being expressed on a staff of only four lines and spaces in Gregorian notes of only two kinds, the square and lozenge, formed a new genus, and bound in chains both melody and harmony, till the invention of the time-table, and the free use of all the semitones in the modern chromatic scale, till the time of Ockenheim and his admirable disciple Josquin, in the fifteenth century. See Guido, Gamut of Scale, Hexachords, Points, and Counterpoint.

Vol. XXXIV.

System of Rameau. This system has been so amply discussed in the articles Bassa Fondamentale, Harmonics, D'Alembert, the Abbé Roussel, and M. Labarre, that we shall add but little here to what those articles contain. He was the first who arranged the scattered rules of music into a system, deducing all melody and harmony from the vibration of a single string, organ-pipe, or great bell; in short, from the harmonics of a low found, which he calls the genus. It had been discovered by C. Buirel and afterwards confirmed by Merkens, that every base or low found divides itself into its aliquot parts, 2, 3, 4, 5, 6; which divisions singly, would be the octave, the 5th of the octave, the 4th of the 5th, or the double octave, the tierce above the 15th or major 17th, minor 3d of the 17th, or 19th above the generator; between the 5th of the octave, or 12th and 17th, we have a major 6th; between the 17th and triple octave, or 8th part of a string, we have a minor 6th. So that as the string is found, we have all the concords perfect and imperfect union, 8th, 7th, and 6th, perfect; and major and minor 3d and 6th, imperfect, all given in the order of their perfection. In extending calculation beyond the minor 3d and the 4th octave, we have all the discords and small intervals in the 9th, 10th, 11th, 12th, and 13th part of a string, even to a comma. And here we have in nature all the intervals in melody, and concords and discords in harmony necessary to composition; but how to use and combine them is another enquiry.

But Rameau, before he entitled his basse fondamentale a system, and divined into harmonics and the theory of found, had published two quarto volumes on practical music, from the scale or gamut and first elements of found, to the composition of fugues, double counterpoint, and canon.

The essence of these practical works had been incorporated by d'Alembert with the theory of found and fundamental base, with clearness and geometric order; and whoever would know the merits of Rameau's system, should seek his knowledge in the great geometricalian's "Elements de Musique theorique et pratique, suivans les Principes de Rameau," to which we shall refer our readers, and to the article Basse Fondamentale.

System of Tartini. The ingenious theoretical writings of the admirable practical musician Tartini, have been reviewed and criticized in France by some, and his right to the discovery of the terno fiume diffused and claimed as his own property by M. Rameau. Rouelle, who was partial to his talents, and opposes his system to that of Rameau, has given it a long article of development and analysis at the end of his dictionary; but not with his usual clearness, feeling, and spirit in speaking of Italian music and music. He has, however, honoured his system with a very flattering eulogy, in saying "the system of the illustrious Tartini, being written in a foreign language, often profound, and always diffused, is accessible to few, and even those few are discouraged by the obscurity of the style of the work before they are acquainted with its beauties. However, this system, if not that of nature, is at least, of all those which have hitherto been published, that of which the principle is the most simple, and that in which all the laws of harmony appear to arise in a less arbitrary manner than in any other." But his theoretical treatises have never been so candidly examined as by our learned countryman Stillingfleet, in a professed commentary, under the title of "Principles and Power of Harmony," which he has rendered one of the most agreeable and amusing books on the subject of music, as well as the most instructive in our language. And to this work
work we shall refer our readers who wish to be better acquainted with Tartini.

The work in question, which Mr. Stillingfleet has commented on, was published at Padua, in 1704.

Mr. Stillingfleet probably treats St. Anthony of Padua's first violin with more respect, from having heard him perform, and being well acquainted with his compositions and character. He does not always subscribe to his opinions, and sometimes, like left partial critics, complains of the obscurity of his style, and want of found geometrical science; yet he points out so many profound and ingenious thoughts, so much refinement and feeling in melody and harmony, that whoever peruses Tartini, with Stillingfleet for his guide, will not only admire many parts of his treatise, but entirely love and reverence the author. Mr. Stillingfleet takes no notice of Tartini's second treatise, entitled "De principi dell' Armonia musicale, Contenuta nel Distantico Generale Differentationi," 4to. 1767. But Tartini himself says, that it was written only to explain the first.

The system of Tartini, as explained by Stillingfleet, has a large share of importance in the supplement to the first folio edition of the Encyclopædia, among materials with which the editors were furnished from Germany, chiefly extracted from the "General Theory of the fine Arts," by M. Sulzer of the Royal Academy of Sciences at Berlin. The author of this work was director of the philosophic clafs in the Royal Academy, and author of several works in literature and science that were much esteemed. He was particularly attached to music, which he had studied very seriously, though only a dilettante. Yet he drew up the chief music articles of his work, which was published in 3 volumes, 4to. in the form of a dictionary, under the counsel of Agricola, Schultz, and Kirnberger, who had been his music-master, and of whom he speaks in the highest terms of respect and friendship.

After analyzing the principal musical systems that have been current at different periods, in the several parts of the world, the encyclopedists introduce what is called Kirnberger's system, in the following manner.

"In all the systems which we have analyzed, we have had recourse to physical experiments, to calculations, and to analogies. The chief part of the experiments depend on the ear, as this organ is the sovereign judge of music. All the systems which we have analyzed, (a term in periodical works of criticism, at present, by which we understand reviewed,) in assigning reasons for many things, leave others in obscurity, and oblige us to abandon various harmonical combinations, to which we have been long accustomed. If, therefore, a system is found, supported on a few simple principles, which reduce all harmony to two chords only; which, however, accounts for all harmonical phrasing and transitions employed by good masters, however capricious these transitions may appear; if this system, notwithstanding its simplicity, requires no change, even in our diatonic scale, nor obliges us to abandon any harmonical practice allowed to be good by great composers in Italy, Germany, or even in France; it is, then, the system of Rameau; for it seems as if we might reasonably regard it as the only true system, and consequently that which we ought exclusively to adopt.

"We are now going to analyze such a system, which is that of M. Kirnberger, a celebrated German musician, at present (1777) in the service of her royal highness princess Amelia of Prussia. We can answer for the accuracy of the analysis, as it has been drawn up under the inspection of the said princess, who have the happiness to be particularly acquainted, and to whom we are indebted for all that appear curious and useful in harmony, throughout the different articles of this supplement. This confidence would wound our self-love, if the satisfaction of acknowledging publicly all that we owe to M. Kirnberger did not overpower every other sentiment."

This system having been adopted and explained by Mr. Kollmann, in his "Essay on Musical Harmony," published in 1796, and in his "Essay on Practical Composition," 1796; as we have referred our readers to d'Alambert's "Elements de Musique," for a clear and well-digested analysis of Rameau's system; and to Stillingfleet, for an excellent commentary on Tartini's system; we shall only point out the principles on which Kirnberger's system is founded, and refer our studious musical readers to Kollmann's full development of the system of his profound countryman.

"Since music is made for the ear, its principles ought to be founded on the judgment of that organ.

"When we speak of the judgment of the ear, we mean the judgment of the majority of the greatest musicians. If we were to be guided by the ears of every individual, we should never have done.

"Our music consists of different intervals; their name, the manner of expressing them, &c., we suppose already known.

"Intervals are considered either in succession, as melody; or in their combination, as harmony.

"With respect to melody, intervals are easy or difficult to express; with respect to harmony, they are discordant.

"A consonant and uniform expression proves the most consonant intervals are the most easy to express; for which reason it is necessary to learn the degree of consonance in each interval.

"To know the natural cause of consonance and dissonance of tones is often wished. The greatest philosophers are of opinion that the intervals, of which the ratio is the most simple, are likewise the most consonant; and experience leans to this opinion. Two strings of equal length, thicknes, and tension, produce two sounds so similar, that one cannot be distinguished from the other. To confirm, therefore, is regarded as the most perfect concert. After the concord, the ear finds the octave the most consonant interval; it has two sounds, but so united together as hardly to be distinguished. They are indeed two sounds, but not two different sounds: the length of the string, which produce an octave, or, if you please, the number of vibrations, is as 1 to 2; a ratio the most simple, after that of 1 to 1; after the octave comes the fifth, of which the ratio is 2 to 3; then the fourth, 3 to 4, &c. in the most well-known proportions," till we come to the second, which is in the proportion of 8 to 9. "The more the chord and minute the intervals," says Kirnberger, "they are always the more dissonant. The second minor, therefore, is more dissonant than the major.

"The minor third, in the ratio of 5 to 6, is generally regarded as a concord; but as it will bear a little diminution, without ceasing to be a concord, we have a right to conclude that the interval in the ratio of 6 to 7 is the last concord, and of 7 to 8 the first discord."

"This is our doctrine. More liberties have long been taken with the flat 7th, than with any of the other intervals.
The ceremony of preparing it has been long relaxed; but it has never, till lately, been numbered with concords.

"It is true," continues Kirnberger, "we do not find the interval of 6 to 7 on our keyed instruments; but the trumpet gives it. Every one knows that the trumpet and French horn give A and B♭ too low, and F too high; but few know that the tones of the trumpet and French horn are the two natural tones."

New doctrine again. We never yet met with a practical musician, or a lover of music with a good ear, who did not complain of the false intonation of the trumpet and French horn, particularly in the 4th and 6th of their scale.

"It can be proved that every string or bell gives, besides the principal tone, expressed by 1, the tones expressed by ½, ⅔, ⅔, ⅔, ⅔; all which together produce the total found: so that the tone which horn-players regard as B♭, is a true natural tone, expressed by ½, &c.; as F is by ½, and A by ½."

We should do well, therefore, to adopt the tone ½ in our musical system, which is included in the first octave ½: in calling C the fundamental found, which we call i, it would fall upon A ½, and on B♭ ½.

"The chord C, E, G, i, is literally a chord of four founds, or consonant parts, and not the chord of the flat 7th. This is proved by the use which the best composers make of the extreme sharp 6th, and of the minor 7th, which they treat as concords, doubtless because the ear takes them for the interval ½.

"As the minor 3d, ½, is the smallest concord, the major 6th, ½, which is its inversion, will be the greatest; and we have, before the union and octave, fall four kinds of concord, the tierce, the fourth, the fifth, and sixthth; or, rather, we have but two, the sixth being a tierce, and the fourth a fifth inverted.

"But we must not regard all the 3ds, 4ths, 5ths, and 6ths, as concords. Intervals have their names from their place in the diatonic scale; so that their intervals are called 3ds, 4ths, &c. on account of their situation in the scale, though they are very dissonant: thus, C, C &c., a false relation or redundant octave; a sharp 4th, or tritone, &c.

The following are the true concords, and their ratios:

| 3d minor, ½ | 6th major, ½ |
| 3d major, ½ | 6th minor, ½ |
| 4th ½ | 5th ½ |

"And if the note i or ½ be admitted, the interval is expressed by ½."

"These intervals are in their greatest purity; but experience tells us that they may be a little altered, without becoming discords. The 4th may be a semi-comma, or ½, too sharp; and, consequently, the 5th as much too flat. The major 3d may be a whole comma, or ½, too sharp; and the minor 6th as much too flat. And, finally, the minor 3d may be a comma, or ½, too flat; and the major 6th, consequently, as much too sharp. All other intervals are discords."

"In the music of the present times (1777), every melody is accompanied by different simultaneous melodies, which make but one whole with the principal: at such times we, therefore, hear many tones or founds at once. These assemblages of simultaneous founds are denominated chords; and the effect which results from them, harmony."

Then follow the usual and well-known definitions of common chord, chord of the 6th, and chord of the 5th, all arising from the triad; unison, 3d and 5th, or 3d, 5th, and 8th, to the fundamental base, or harmonic triad.

"It is probable (we are sure, from our researches, that it is certain) there was music in parts, long before discords were introduced in counterpoint."

He next gives the usual rules for preparing and resolving discords.

The origin which he gives of the minor 7th, in the chord of the 5th of the key, and to all other regular 7ths, is the same as in every other elementary book. (See Discords.) The minor 7th, and the major or sharp 7th, called by the French la note faible, have very different effects on the ear: the flat 7th tends to a defect, and, like Falstaff, "has an alacrity in sinking:" whereas the sharp 7th has a contrary disposition, and, as if charged with gas, forces its way upwards. The sharp 7th and the sharp 4th are the only discords that are resolved upwards.

It is the usual minor or flat 7th that Kirnberger calls the one essential discord. He next distinguishes three kinds of triads, or common chords: the common chord with a major 3d, with a minor 3d, and with a minor or flat 5th.

The last can only be used in the course of a passage or musical period, but never at the beginning or the end.

"In four parts there are four ways of playing or writing the chord of the 7th, which are well known to thorough-bass players."

It is by making each of these chords an appoggiatura, orfulness to it to the next base, and calling the whole chord an accidental discord.

The reducing all discords to one essential discord, is rather an evasion of the difficulty of learning all the usual discords, than a solution. The student will still have to learn what the common chord of the key-note will make to every note of the scale ascending and descending, and what the discord of the 7th will make to whatever note it is struck or applied in composition; which will not be learned the sooner for having new names, or being called accidental instead of essential. The rest must be learned, whether by their old names, or by no names at all.

The new note ½ has not yet been adopted by composers or performers.

The author of this system takes great pains to explain the difference between the accidental and essential discords. But we fear that many of these distinctions are so nearly without a difference, as not easily to be retained by a student in harmony. M. Kollmann’s plates will smooth many difficulties in this study, which the plates in the Supplement to the Encyclopédie leave in obscurity.

When the author quotes this subject, which he takes great pains to explain, he proceeds to account for many chords which appear singular.

"The chord of the superfluous 6th, as Roussel has well remarked, is only the chord of the minor 6th sharpened by accident. When our old musicians wished to make a pause on the 5th of a minor key, it was done by means of the natural 6th major, which led to the chord of the 5th of the key with a sharp 3d; which was called a semi-cadence."

We have mentioned all the singularities of this system, and what remains, though the found and good doctrine of the bent matters, is not new, and therefore needs no particular explanation.

We have enumerated all the musical systems that seem intituled to praise from their originality, or to adoption for their improvement of former principles. Many have called their publications new systems; but though some of them contain much ingenuity of arrangement, and some additions to former systems, they are not constructed on new foundations; such are those of M. Sauvage, of the great geometrician Euler, 5 B 2.
Euler, of M. Boiguelou, of M. Serre, Dr. Smith's "Harmonics, or System of Tuning by Beats." M. Jamarf, the worthy ci-devant canon of St. Genevieve, prior of Rocquefort, member of the Académie de les Belles-Lettres et Arts de Rouen, who escaped to England from Normandy during the revolution, with forty more ecclesiastics, in a leaky vessel, into which they were forced, with the intention of its being their passage-boat to the other world, published in 1769, an ingenious tract, entitled "Recherches sur la Théorie de la Musique," totally different from the practice, putting, it should seem, the ear out of the question ; and fancying the bad notes in the French horn to be the harmonics of nature, the auricular organ is not gratified by his system. And as none of the sysmes, as they have been called, are received into practice, we can only allow them to be ingenious hypotheses or speculations, sometimes correcting, and sometimes elucidating established theories.

The taking the French horn as the standard of harmonic perfection, which is so notoriously false in the two intervals of the 4th and 6th, will alarm every nice and cultivated ear, and make them fear the result of their calculations.

Here Kirnberger, an excellent practical musician, and profound contrapuntist, deserves more respect than mere speculativists; but we cannot call his an original system on a new foundation; he has refined on the old system, and proposed improvements. He is neither a blind follower of Rameau nor Tartini; but hears safely between both. There is so little nature in music, that we seize on the slightest indication of her support.

The new scale of M. Jamarf would involve music in great confusion. It was a language, in the old scales, which had only two expressions; it has, according to the venerable prior of Rocquefort, 56 in every octave.

**Chronological History of zA, a new Interval in Secular Music.**—Tartini, in 1754 and 1767; Balliere, in 1764; Jamarf, 1769; Stillingsfleet, 1771; Kirnberger the same year, in the Supplement to the folio edition of the Encyclopédie, 1777; and Kollmann, 1796, in his "Essay on Musical Harmony."

Tartini, when he first mentioned this new found in his "Trattato di Musica," p. 126, says: "Naciamo dalla diversa armonica della facque terra, o fa quarta, ed un sesto, che questo intervallo è di facilità una iniziazione fino il violino, ed è voluto dalla natura armonica perché è tale fatto dalla natura nelle trombe marine e da dato, e se così di caccia; armonica ne' quali non a luogo l'arbitrio senza nella tota fisico-armonica natura. Si aggiungano dunque in nota musicale il termine quinto e sufficiente il sestetto intervallo alla scala diatonica commune infissata dall'ellen pe4; e questa nota aggiuntesi segno con la cifra w9 a dimissione di B fa segnato con la cifra B."

Though, as Tartini says, it is in nature, and of easy production by the voice and violin, upon keyed and wind-instruments it is purely imaginary.

Tartini thinks that, with the sufficiency of this new found, the enharmonic may be recovered.

In Stillingsfleet's remarks on what Tartini says of the ancient enharmonic being contrary to the principles of harmony, the commentator tells us that he undertakes to give us an enharmonic of his own, by means of this new note, which is out of the limits of the hexachords, which he calls a conformance.

This note seems brought into use in melody, particularly in defending, though unnoticed in harmony. See Music Plate.

But the intonation of wind-instruments in general is false, particularly on the trumpet and French horn, in which the 4th and 6th differ so much from the instruments and the voice which is formed upon them, or at least is obliged to conform to them, that no composer dares use them in any thing but transient passages; in slow and sustained parts, they offend every natural ear; but the w9, or new Bb, of these instruments, if dwelt upon, or even used at all with other instruments which have no such found, would drive an audience mad, or at least out of a theatre or concert-room.

The 3ds, given by the abbé Rouffier's triple progression, and 4ths and 6ths of Balliere, Jamarf, and Kirnberger, a union with those intervals in the trumpet and French horn, we cannot reconcile our ears to, though recommended by our favourite composer Tartini.

The flat 7th, given by the last effort of the English harp, is not so offensive as that of the trumpet and French horn. But nature gives us no music; it is all a work of art. Let us, therefore, make it as pleasing as we can to that sense for which it is alone designed. There is a little pedantry in Kirnberger's treatment of the subject. To all
his other precepts we can subscribe, as they are the result of great experience, professional knowledge, and sagacity. We know not whether his treatise should be called a system, like those of Guido, Rameau, and Tartini; the first built on the Grecian system, and the two last upon physical phenomena. Kirnberger’s is but the last refinement of old doctrines. He says, that the 4th, the 5th, and flat 7th of the trumpet and French horn, should be adopted in our system, “for they are the true natural tones.” We repute nature very much; but is not nature improved very much by cultivation in fruits and flowers? and why do all professors and perfumiers of nice ears complain of the difference of wind-instruments? System of Solmisation. Dr. Wallis makes use of only four of the fix syllables ascribed to Guido: mi, fa, sol, la; which method resembles that of the ancient Greeks in naming the sounds of the tetrachords ευ, τυ, υι, το. But it appears in Cliffor’s Collection of Divine Services and Anthems, published in 1664, that the English began to discontinue the use of two of these syllables of the hexachords, the se and re, about the year 1650. Dr. Pepusch, however, in 1731, revived the ancient solmisation, and informs the vocal student, in his “Treatise on Harmony,” p. 70, that the mutations begin on the third note before Fa, which must be called re ascending, and la descending.

Let the intervals in all major keys have the same names in elementary singing, as in the key of C natural.

C D E F G A B C
Do re mi fa sol la mi fa re mi do

descending

C B A G F E D C
fa mi la sol fa re do.

In keys with minor 3rd, let the notes have the same names as in the key of A natural.

A B C D E F G A
La mi fa re mi fa sol la

descending

A G F E D C B A
la sol fa mi re fa mi la.

Such as you frequently meet with in the above diffracts. And it is still further removed from the West country downs, where, in addition to the general clean face of the country, the quagmires are converted into luxuriant water-meadows. But even these do not come up to the Leicestershire husbandry, where they do not employ sheep as dung-carriers, for the purpose of impoverishing two-thirds of their land in order to enrich the other, but, on the contrary, cultivate the whole, and, by dividing their farms into moderate-sized fields, and by raising good hedges, to afford shade from the scorching heat of the sun in the dog-days, and shelter from the nipping frosts in winter, have prepared the way for improvement in live-stock, in which they have already arrived at a degree of perfection altogether unrivalled; and both fleece and cattle are confidedly more highly conditioned than those of any of the foregoing districts.

Yet the Leicestershire husbandman, though standing very high in the scale of perfection, is much exceeded by the very superior management of the meadow and arable farmers, and likewise by the fruit and kitchen gardeners, of the county of Middlesex; since there is no land in that county, with the exception of the commons, from the well protected and healthy copses at Ryhill, to those wonderful of their kind, the gardens at the.Net-houses, but what is cultivated, and, for the most part, raised to a great degree of fertility.

And there are probably some other tracts, or districts, in which the systems of husbandry may be still superior to any of thefe, though nothing certainly will any where be found to exceed the Net-thouse culture about the metropolis. Systematical Qualities, a term used by Mr. Boyle, to express such qualities as are also called specific, and do not depend on the nature and constitution of the body itself,
SYZ

itself, but on its being a member of this general system of the universe, in which capacity it is acted upon by agents unperceived by us, which occasions great changes in it.

SYSTEMATISTS, in Botany, those authors whose works in this science are principally employed about the arranging plants into certain orders, classes, or genera. See Botany.

SYSTOLE, from συστολής, to contract, in Grammar, designates the shortening of a long syllable.

SYSTOLE, in Anatomy, contraction; it is usually applied to the heart, and denotes its contraction, for the purpose of expelling its contents.

SYSTREMMA, a word used by Hippocrates to express a collection of humours, forming a hard tumour, or tubercle, in any part of the body; called also sometimes syphrombe.

SYSTYLE, in Architecture, that manner of placing columns, where the space between the two futs consists of two diameters, or four modules. See INTERCOLUMNIATION.

SYTHERE, in Agriculture. See SYTHE.

SYXHINDEMEN, a term purely Saxon, literally signifying fixed-hundreders, or men worth fix hundred shillings a-piece. See HINDER.

SYZYGIUM, in Botany. Gertr. v. 1. 166. t. 33. (Synonym of Browne's Jamaica. 240. t. 7. f. 2.) apparently so named by the latter, from σύζυγος, a conjunction, or copulation, in allusion to its "coupled leaves and branches," is the Myrtus Synzygium of Linnaeus; but, as we conceive, rather belongs to the genus Eugenia. (See that article.) Gartner distinguishes it only by having a berry with a single seed, instead of a drupe. Jussieu however unites them. The pulp is indeed closely attached to the seed in Synygium; but the shell, or rather skin, is so thin in Eugenia, that it is hard to draw a line between these two fruits. Gartner's distinction, founded on the two cells of the genus in Synygium, does not hold good, the same being found in Eugenia, though it always becomes obliterated as the fruit ripens; just as in Olea.

Gartner enumerates four species of Synygium. 1. S. caryophyllum, a Ceylon plant, which he supposes to be Myrtus caryophyllaco of Linnaeus. 2. S. Makul, from the same country, with a more oblong fruit. 3. S. paniculata, which is Eugenia paniculata of the Bankian herbarium. 4. S. lucidum, Euginia lucida of the same collection. The original Jamaica plant of Browne is not included in this list.

SYZYGY, SYZYGIA, formed from συζύγος, which properly signifies conjunctionio in Aetymology, a term equally used for the conjunction and opposition of a planet with the sun.

On the phenomena and circumstances of the syzygies, a great part of the lunar theory depends. See Moom.

For, 1. It is shewn in the physical astronomy, that the force which diminishes the gravity of the moon in the syzygies, is double that which increases it in the quadratures; so that, in the syzygies, the gravity of the moon, from the action of the sun, is diminished by a part, which is to the whole gravity as 1 to 89.36; for, in the quadratures, the addition of gravity is to the whole gravity as 1 to 176.73.

2. In the syzygies, the disturbing force is directly as the difference of the moon from the earth, and, inversely, as the cube of the difference of the earth from the sun. And at the syzygies, the gravity of the moon towards the earth receding from its centre, is more diminished than according to the inverse ratio of the square of the distance from that centre. Hence, in the motion of the moon, from the syzygies to

the quadratures, the gravity of the moon towards the earth is continually increased; and the moon is continually retarded in its motion; and, in the motion from the quadrature to the syzygies, the moon's gravity is continually diminished, and its motion in its orbit is accelerated.

3. Further, in the syzygies, the moon's orbit or cirk round the earth is more convex than in the quadratures; for which reason the moon is less distant from the earth at the former than the latter. When the moon is in the syzygies, her apodes go backwards, or are retrograde.

When the moon is in the syzygies, the nodes now are antecedentia fasted; then flower and flower, till they become at rest when the moon is in the quadratures.

Lastly, when the nodes are come to the syzygies, the inclination of the plane of the orbit is the least of all.

Add, that these several irregularities are not equal in each syzygy, but are all somewhat greater in the conjunction than in the opposition. See Physical Cause of Moon's Motions.

SZADECK, in Geography, a town of the duchy of Wawlaw; 22 miles N.E. of Sied Infinite.

SALGEN, or Island of Serpents, a small island in the Black sea, near the mouth of the Danube. N. lat. 430; E. long. 30° 54'.

SAMAILI, a town of European Turkey, is in Babia, on the Dnieper; 45 miles S.W. of Bender.

SAMOSFALVA, a town of Transylvania, on the river Samos; 5 miles N. of Colovar. N. lat. 47° 18'. E. long. 23° 23'.

SAMOSVIVA. See SAMOSVIVAR.

SZARIGROD, a town of Poland, in the province of Podolia; 30 miles S. of Bar.

SZARNOVA, a town of Prussia, in the palatinate of Culm; 8 miles N.W. of Thorn.

SZASK, a town of Lithuania; 36 miles S. of Minik.

SASY, a town of Hungary; 4 miles E.S.E. of Czarnita.

SATHMAR. See SATMAR.

SAWLE, a town of Samogitia; 28 miles N.E. of Miedniki.

SZELENHORS, a town of Hungary, on the river Turin. In the year 1604 this town was taken by the troops of Count Botkay, and in 1655 by the Turks; 30 miles N. of Calchau. N. lat. 49°. E. long. 20° 49'.

SZEKENY, see HESSEN-NASSAU.

SZEGER. See ZGOHN.

SZEKELEY, or SZEKELEY-NID, a town of Hungary; formerly a fortification. In the year 1660, it held out against the Transylvanian peasants; in 1664, it was surrendered by the Imperial garrison to the Transylvanian prince, Abaffy; but in the ensuing year it was demolished; 7 miles N.N.W. of St. Job.

SZEKZARD, a town of Hungary, on the river Szevits, with a castle; celebrated for its wine; 18 miles N.E. of Funffkirchen.

SZELENTHA, a town of Prussia, in the palatinate of Culm; 5 miles S. of Strafsburg.

SZELEITZE, a town of Hungary, near which is a large and celebrated cavern, which is said to be extremely cold in summer, and, on the contrary, to be hot in winter: a noble wonderful account has been given of the different effects of the heat and cold, which Dr. Townson, a late traveller in Hungary, seems not willing to give credit to; 5 miles W. of Calchau.
SZERBANEST, a town of Walachia; 10 miles N.N.E. of Rucaci.
SZERBESTI, a town of European Turkey, in the province of Moldavia; 52 miles S.W. of Jaffy.
SZEREGNYE, a town of Hungary; 12 miles N. of Munkacz.
SZERESSOW, a town of Lithuania; 40 miles N.E. of Bresikie.
SZERN, a town of Prussia, in Oberland; 4 miles E. of Gardenee.
SZERWENTY, a town of Lithuania, in the palatinate of Wilna; 16 miles S.E. of Wilkomierz.
SZIGET. See Ziger.
SZINYE, a town of Hungary; 14 miles E. of Cachau.
SZISH. See Sistova.
SZITES, a town of Transylvania; 4 miles W. of Schéfburg.
SZITTEKEMEN, a town of Prussian Lithuania; 14 miles E. of Goldapp.
SZKOLYN, a town of Austrian Poland, in Galicia; 70 miles S.W. of Halicz.

SZMOLNOK. See Schmolnitz.
SZOBOTISZA, a town of Hungary, on the river Maricch; 32 miles W. of Topoltzan.
SZOBOW, a town of Poland, in Moldavia; 20 miles N.W. of Warsaw.
SZOMBOR. See Zombor.
SZOMUS, a river of Moldavia, which runs into the Siet, near Dobrata.
SZOPIA, a town of Sclavonia, on the Drave; 27 miles N. of Polesga.
SZORENY. See Severin.
SZREBERNEK, a town of Bosnia; 30 miles N.N.W. of Zwornik.
SZREDITS, a town of Croatia; 16 miles E. of Carlstadt.
SZTROPKO, a town of Hungary; 28 miles E.S.E. of Palotza.
SZYATY, a town of Lithuania, in the palatinate of Troki; 48 miles N.N.W. of Troki.
SZYDLOW, a town of Samogitia; 8 miles N.N.E. of Rofenice.

END OF VOL. XXXIV.
