The etymology, therefore, of thoſe who derive "Bethesda" from בית חסדה, the *houſe of mercy*, is much more juſt and appropriate; becauſe it expreſſed the kind deſign with which this bath was conſtructed, and the ſalutary purpoſes to which it was applied. The hiſtory informs us, that this pool had five porches, porticoes, or cloyſters, which might very reaſonably have been the caſe, notwithſtanding its oblong figure; one being on each hand of the entrance in the middle of one ſide, and three on the other ſides. Dr. Lightfoot ſuggeſts, that the baſon itſelf might be in the form of a pentagon, and that theſe cloyſters might correſpond to its five ſides. Mr. Maundrell (Journey, p. 107.) who took a view of this pool, in 1696, informs us, that it is 120 paces long, 40 broad, and 8 deep; but without water; and that at the weſt end he found ſome old arches, then dammed up, which, though only three in number, were ſuppoſed to be the five porches, in which ſat the lame, halt, and blind. This pool, he adds, is contiguous, on one ſide, to St. Stephen's gate, and on the other to the area of the temple. In theſe porticoes diſeaſed and debilitated perſons lay, "waiting for the moving of the water;" for at the time of a certain feaſt, which ſome have ſuppoſed to be the paſſover, and others the pentecoſt, or rather, according to the ſeaſon, i. e. occaſionally, at certain intervals of time, "an angel deſcended into the pool, and troubled the water; whoſoever then firſt, after the troubling of the water, ſtepped in, was made whole of whatever diſeaſe he had." Some have ſuppoſed that the miraculous cure, recorded in this hiſtory, was reſtricted to the ſeaſon of the particular feaſt mentioned in the firſt verſe of the chapter; and thus they account for the ſilence of Philo and Joſephus with regard to this miracle. But thoſe, who imagine that theſe waters had a ſanative quality on other occaſions, think the ſilence of theſe Jewiſh writers to be of little importance; as they have omitted the mention of other more important occurrences in our Lord's hiſtory, which they had an opportunity of knowing; ſuch as the variety and multitude of ſignal miracles which he performed in the courſe of his miniſtry. The majority of writers have regarded the cures wrought at this place as a ſtanding miracle among the Jews, and yet they have been ſurpriſed that Joſephus, in particular, ſhould omit to mention a fact ſo honourable to his nation. Others have, therefore, conceived, that the miraculous healing quality of theſe waters was a peculiar honour conferred on the perſonal appearance of the Son of God upon earth. To this purpoſe Dr. Doddridge (in loc.) after Calvin, obſerves, that God, to add the greater luſtre to his Son's miracles, as well as to ſhew that his ancient people were not entirely forgotten by him, had been pleaſed of late to perform ſome ſupernatural cures at this place. With reſpect to the deſcent of the angel into the pool, and the effect produced by his ſtirring the water, different hypotheſes have been propoſed. Grotius thinks, that the angel is ſaid to have deſcended, not becauſe he was ever ſeen to do ſo, but becauſe the Jews were perſuaded that God brought ſuch things to paſs by the miniſtration of angels; ſo that from the violent motion of the water, and the effect produced by it, the preſence of an angel was reaſonably ſuppoſed. Dr. Hammond (in loc.) ſuppoſes, that the blood of the great number of ſacrifices, waſhed in this pool, communicated a ſalutary efficacy to the water, upon its being ſtirred up by an angel, or meſſenger, deputed for this purpoſe by the high-prieſt; which hypotheſis Dr. Doddridge repreſents to be as unphiloſophical, as it is unſupported by hiſtory and antiquity. Mr. Fleming (Chriſtology, vol. i. p. 13—15.) in order to avoid the apparent difficulties of the literal interpretation, rejects the latter part of the *third* and the whole of the *fourth* verſe, as a ſpurious addition of ſome ignorant monk in the 8th or 9th century; becauſe that part is wanting in the Cambridge, or Beza's MS. and is written by a later hand in the margin of that in the French king's library, highly extolled by Lamy in his "Harmony." But this paſſage is found in all the other moſt celebrated MSS., in the Syriac verſion, and in the other verſions of the Polyglott. Kuſter's obſervations, relating to the genuineneſs of this text, in the preface to his edition of Mill's New Teſtament, deſerve to be conſidered. But with regard to the ſubject in diſpute, it ſhould be recollected, that the *ſeventh* verſe, which none queſtion, implies, that the water, after being troubled, had a miraculous virtue, which extended only to the firſt that went in, and cured his diſeaſe, whatever might be its nature. Dr. Doddridge ſuggeſts the following ſolution of this difficulty; the greateſt, as he acknowledges, that occurs in the hiſtory of the evangeliſts, and with reſpect to which none of the numerous writers who have replied to Mr. Woolſton had given him ſatisfaction. He ſuppoſes this pool might be remarkable for ſome mineral virtue attending the water; and this circumſtance, together with its being ſo near the temple, where a bath was ſo much needed for religious purpoſes, may account for the ſtately cloyſters erected around it. Some time before this paſſover, an extraordinary commotion had been probably obſerved in the water; and Providence ſo ordered it, that the next perſon who accidentally bathed here, being under ſome great diſorder, experienced an immediate and unexpected cure. The like phenomenon, in ſome other deſperate caſe, was probably obſerved in a ſecond commotion. Theſe commotions and cures might happen periodically, perhaps every ſabbath, for ſome weeks or months. This the Jews would naturally aſcribe to ſome angelic power, as they did afterwards the voice from heaven, (John xii. 29.) though no angel appeared. On account of their ingratitude to Chriſt for this miracle, and thoſe wrought at the former paſſover, and in the intermediate ſpace, this celeſtial viſitant probably returned no more; and therefore, it may be obſerved, that though the evangeliſt ſpeaks of the pool as ſtill at Jeruſalem, when he wrote, yet he mentions the deſcent of the angel, as a thing which had been, but not as ſtill continuing. This may account for the ſilence of Joſephus, who was not born when it happened; and who, if he heard the report of it, would oppoſe ſpeculation and hypotheſis to fact, and recur to ſome indigeſted and unmeaning harangues on the unknown force of imagination; or if he ſecretly ſuſpected it to be true, his dread of the marvellous, and his fear of diſguſting his Pagan readers with it, might as well lead him to ſuppreſs this, as to diſguiſe the paſſage through the Red ſea, and the Divine Voice from mount Sinai, in ſo mean and fooliſh a manner, as it is known he does. Beſides, the relation which this fact bore to the hiſtory of Jeſus, would make him peculiarly cautious in treating upon it, as it would have been difficult to handle it at once with decency and ſafety. The ingenious and learned biſhop Pearce, in his excellent "Vindication of Chriſt's Miracles," p. 68, &c. agrees with Dr. Doddridge in the moſt material circumſtances of his hypotheſis.

BETH-GAMUL, the *houſe of the weaned*, or *of the camel*, a city of the Moabites in the tribe of Reuben. Jer. xlviii. 23.

BETH-JESHIMOTH, the *houſe of deſolation*, or, *of poſition*, or, *of denomination*, a city of Reuben (Joſh. xiii. 20.) afterwards poſſeſſed by the Moabites. Ezek. xxv. 9.

BETH LEBAOTH, the *houſe of lioneſſes*, a city of Simeon, (Joſh. xix. 6.) ſometimes called Lebaoth. Joſh. xv. 32.

BETHLEHEM, the *houſe of bread*, a city of Judah, (Joſh. xvii. 7.) generally called "Bethlehem of Judah,"

to diſtinguiſh it from another of the ſame name in Zebulun. It is ſeated on the declivity of a hill, 6 miles ſouth from Jeruſalem, according to Euſebius and Jerom. It is likewiſe called "Ephratah," (Gen. xlviii. 7. Mic. v. 2.) This city was not very conſiderable either for its extent or riches; but it has acquired peculiar diſtinction on account of its having been the place of our Saviour's nativity. It was alſo the city of David's nativity. In and near this city travellers are ſhewn the place where our Saviour was born, which is ſaid to have been a cave ſouth of the city, and belonging to the inn, or caravanſerai, whither Joſeph and Mary retired. Jerom informs us, that Adrian, in order to eraſe the remembrance of the place where Chriſt was born, planted over the cave a grove of tall trees in honour of Adonis, ſo that when the feſtivals of this infamous deity were celebrated, the holy grotto echoed with the lamentations made in commemoration of Venus's lover. Here is alſo ſeen a large church built by St. Helena, in the form of a croſs, and ſo lofty as to command an extenſive proſpect of the adjacent country. The roof is elevated, flat, and compoſed of cedar within, and leaded without. The nave is ſupported on both ſides by two rows of marble pillars, each made of one piece, and 11 in a row, forming as it were five naves, ſeparated from each other by thoſe rows of pillars, on each of which is the picture of ſome ſaint. Over the pillars the wall is covered with moſaic work, on a gold ground. The marble which formerly overlaid the walls has been removed by the Turks for adorning their moſques. The three upper ends of the croſs terminate in three ſemicircles, having in each an altar. Over the chancel is a ſtately cupola, covered on the outſide with lead, and within adorned with moſaic work. Adjoining to the church is the monaſtery of the Franciſcans. The gardens are defended with ſtrong walls; and through the chapel is a paſſage to a ſquare cave, in which they ſay the Innocents were buried. Beyond this are paſſages to the tombs of St. Jerom, St. Paula, and Euſtochium, and of Euſebius of Cremona; and beyond theſe is a grotto or cell, called the ſchool of St. Jerom, where he is ſaid to have lodged when he tranſlated the Bible. At the end of another vault or chapel, 12 feet wide and 40 long, whoſe floor is paved and ſides lined with white marble, and roof adorned with moſaic work, now much decayed, is an arched concavity, with an altar, having over it the picture of the nativity, and under it a vault, in the middle of which is a ſtar formed of many coloured ſtones, marking the place where they ſay our Saviour was born; and near this is the manger where they pretend he was laid, which is hewn out of a rock, and new flagged with white marble. See Mount Calvary, and Jerusalem.

Bethlehem is now called *Bait-el-laham*; which ſee. The country in which it is ſituated is happy with reſpect to ſoil, air, and water. With the latter it is ſupplied by a low aqueduct, or ſtone channel, which formerly paſſed to Jeruſalem. The "fons ſignatus" is an exuberant ſpring: it is received ſucceſſively by three large ciſterns, one of which is well preſerved. In coming from the ciſterns, and at a ſmall diſtance, is ſeen what is termed the "deliciæ Solomonis," a beautiful rivulet, which flows murmuring down the valley, and waters in its courſe ſome gardens of excellent ſoil. The brinks of this brook are adorned with a variety of herbage. The convent at this place contains, under the ſame roof, the different tenets of Latins, Armenians, and Greeks. Brown's Travels in Africa, &c. p. 363.

We ſhall here obſerve, that no inconſiderable pains and ingenuity have been exerciſed to reconcile the quotation of the evangeliſt Matthew, ch. ii. 6. relating to Bethlehem, with the original text of the prophet Micah, ch. v. 2. The difficulty may be obviated, ſays an ingenious writer, or at leaſt the appearance of inconſiſtency removed, by a proper tranſlation of the latter text. "*And thou, Bethlehem Ephratah, art little in being among the thouſands of Judah;* for *out of thee will come forth unto me a ruler over Iſrael.* That is, thou haſt but little honour in being among the thouſands of *Judah*, compared with that which will accrue to thee from giving birth to the *Meſſiah.*" Thus the LXX ſeem to have underſtood it. Forms of ſpeech ſimilar to this, οὐδαμῶς ἐλαχίστη, *by no means the leaſt* for *the greateſt*, are not uncommon. (See Homer. Il. A. 277. Callim. Hym. Di. 33. Hym. Ap. 31. Eurip. Androm. 81. &c. This mode of interpretation is confirmed by Lightfoot from the Chaldee paraphraſt; and ſeems to be preferable to that of St. Jerom, or of Dr. Pococke. The former, who has been followed by ſome others, is of opinion, that Matthew produced the paſſage in Micah hiſtorically, not as it was written by the prophet, but as it had been propoſed by the prieſts to Herod, ſo that they ſhould be accuſed of falſe reading, if that were the caſe. The latter in his notes on the Porta Moſis of Maimonides, thinks, that צָעִיר, in Micah, rendered *little* in the Engliſh tranſlation, has the contrary ſignification to its uſual one of *mean* or *little*, viz. that of *noble* or *illuſtrious*, and for countenancing this conjecture he cites Jer. xlviii. 4. and the Chaldee paraphraſe upon that paſſage. Grotius, Olearius, and others, have propoſed that the Hebrew text and the Greek LXX verſion ſhould be read and tranſlated by way of interrogation. Heb. '*Art thou, Bethlehem Ephratah, the leaſt among the thouſands of Judah?* No: *out of thee ſhall he come forth to me*, &c. i.e. I will raiſe up him, &c. Greek LXX. *Art thou, Bethlehem, the houſe of Ephratah, the leaſt to be among the thouſands of Judah?* No: *out of thee*, &c. The learned biſhop Pearce has adopted this mode of tranſlation; and in favour of it he urges, that the Hebrew word צָעִיר, in Micah, rendered *little*, may be rendered *the leaſt*, as it actually is in Judges, vi. 15. 1 Sam. ix. 21. Jerem. xlix. 26. and l. 45. He alſo obſerves, that both in the Hebrew and in the Greek of the O. and N. Teſt. it is not unuſual for a ſentence to be underſtood by way of interrogation, though there is no mark placed at the beginning of the ſentence, uſed in either of the languages for a mark of interrogation. To this purpoſe he refers for the Hebrew to 2 Sam. xviii. 29. 1 Kings xxi. 7. Job. ii. 10. xli. 1. Zech. viii. 6. and for the Greek to 2 Sam. xviii. 29. Matt. xi. 3. Mark xiv. 61. He adds further, that when words are thus uſed interrogatively, there is often at the end of them an anſwer of *Yes*, or *No*, to be ſupplied in the ſenſe, though it is not expreſſed in the words. This is very common with thoſe who write in the Hebrew language, or with thoſe, who, being Hebrews, write in Greek. In the N. T. the word, *No*, is to be ſupplied in 1 Cor. x. 19, 20. The ſame mode of ſpeaking is found in 1 Cor. xii. 31. Acts viii. 31. and an inſtance, where *Yes* is to be ſupplied, is to be found in 1 Cor. ix. 20. From theſe remarks the learned prelate concludes, that, if this be the caſe, an interrogation with a *No* to be ſupplied as an anſwer to it, is the ſame as a negative not put in interrogation; or, in other words, to aſk whether any thing is *the leaſt*, and to anſwer *No*, as the Hebrew text and LXX verſion do, is the ſame as to affirm, that it *is not the leaſt*, as Matthew does. Either of the above interpretations will effectually ſuperſede the perplexity of St. Jerom, and the objections of Dr. Middleton, in his "Works," vol. ii. p. 59. See Wakefield's "New Tranſlation of the Goſpel of St. Matthew," p. 26. "Pearce's Commentary," vol. i. p. 10.

Bethlehem, a town of the tribe of Zebulun, (Joſh. xix. 15.) of obſcure and unknown ſituation.

Bethlehem, in *Geography*, a town of the Netherlands, in Brabant. N. lat. 51° 2′. E. long. 4° 40′.

Bethlehem. See Belem.

Bethlehem, a town of America, in Albany county, New York, fruitful in paſtures, and affording large quantities of excellent butter. By the ſtate cenſus of 1796, 388 of the inhabitants are electors.—Alſo, a townſhip in Berkſhire county, Maſſachuſetts, containing 261 inhabitants. It lies about 10 miles S. of E. from Stockbridge, and 130 from Boſton, and borders on the Tyringham and Loudon.—Alſo, a townſhip in Hunterdon county, New Jerſey, ſituate at the head of the ſouth branch of Raritan river, and containing 1335 inhabitants, including 31 ſlaves.—Alſo, a townſhip in Litchfield county, Connecticut, joining Litchfield county on the north, and Woodbury on the ſouth.—Alſo, a poſt town in Northampton county, Pennſylvania, which is a celebrated ſettlement of the United Brethren of the Proteſtant epiſcopal church, as they term themſelves. It is ſituate on Lehigh river, a weſtern branch of the Delaware, 53 miles northerly from Philadelphia, and 18 ſoutherly from the Wind Gap. The town ſtands partly on the lower banks of the Manakes, a fine creek, which affords trout, and other fiſh, in a healthful and pleaſant ſituation, and in ſummer is much frequented by gentry from different parts. In 1787, there were 60 dwelling houſes of ſtone, well built, and 600 inhabitants. Beſides the meeting-houſe, this place has three other public buildings, which are ſpacious; one for the ſingle brethren, one for the ſingle ſiſters, and the other for the widows. In a houſe adjoining the church is a ſchool for females, and ſince 1787, a boarding ſchool for young ladies, under the direction of the miniſter of the place, who alſo ſuperintends the boys' ſchool, kept in a ſeparate houſe. Both theſe ſchools are in high repute, and much frequented. At the lower part of the town there is an hydraulic machine of ſimple conſtruction, that raiſes the water from a ſpring to a reſervoir, at the height of 100 feet, whence it is conducted by pipes into the ſeveral ſtreets of the town. In this town are alſo a ſtore, with a general aſſortment of goods, a large tan-yard, a griſt-mill, a fulling-mill, an oil-mill, and a ſaw-mill, and on the banks of the Lehigh, a brewery. N. lat. 40° 37′. W. long. 75° 14′.

Bethlehem, *Star of*, in *Botany*. See Ornithogalum.

BETHLEHEMITES, or Bethlemites, in *Church Hiſtory*, a ſort of monks introduced into England in the year 1257, habited like the Dominicans, except that, on their breaſt, they wore a ſtar with five rays, in memory of the ſtar or comet which appeared over Bethlehem at the nativity of our Saviour. They were called at Cambridge, and had only one houſe in England.

There is alſo an order of Bethlehemites ſtill ſubſiſting in Peru, who have convents at Lima; one called of the ineurables, the other of our Lady of mount Carmel. Theſe Bethlehemites came originally from the city of Guatimala in Mexico, where they were inſtituted by the venerable Peter Joſeph of Betaneur, a native of the town of Chaſna, or Villa Fuerte, on the iſland of Teneriff, in 1626, for the ſervice of the poor. After his death, which happened in 1667, his congregation was approved of by a bull of Clement X. in 1672, and in 1674. Innocent XI. in 1687, created it into a community of regulars. Before this time it had paſſed from Guatimala to Mexico, and from thence, in 1671, to Lima. In the city of St. Miguel de Piura, they took poſſeſſion of the hoſpital of St. Ann, in 1678, and of that of St. Sebaſtian, in Truxillo, in 1680. Their probity and diligence in diſcharging theſe truſts induced other places to ſelect them as directors of their hoſpitals, and among the reſt, the city of Quito. The fathers of their order go bare-footed, and wear a habit of dark brown colour, nearly reſembling that of the capuchins, whoſe order they alſo imitate, in not ſhaving their beards. On one ſide of their cloak is an image of our Lady of Bethlehem. Every ſixth year they meet to chooſe a general, which ceremony is performed alternately at Mexico and Lima.

The Bethlehemites, though outwardly of great ſimplicity, paſs for the moſt refined politicians; inſomuch as to be called the quinteſſence of the Carmelites and Jeſuits. They are all friars. For their almoner they chooſe a ſecular prieſt, whom they hire, and who has no vote in the chapter.

BETHLEM, Gabor, in *Biography*, prince of Tranſylvania, was a deſcendant of a family of rank, but very ſmall property, and attached to the reformed religion. By his valour he obtained the favour of Gabriel Battori; but having ingratiated himſelf with the Porte, in a viſit to Conſtantinople, he obtained a force which enabled him to expel Battori, and to eſtabliſh himſelf as prince or waiwode, in 1613. He was afterwards led by ambition to extend his dominions, and under the advantage of an alliance with Frederic, the elector palatine, and newly declared king of Bohemia, he made an irruption into Upper Hungary, in 1619. Having reduced this country, he received the ſubmiſſion of Lower Hungary, and in his march towards Vienna he took Preſburg, and was acknowledged prince of Hungary. The aſſiſtance which was afforded him by the oppreſſed proteſtants, induced him to eſtabliſh liberty of conſcience throughout Hungary. At an aſſembly of the ſtates, he was declared king; but in conſequence of a treaty concluded between him and the emperor, he renounced the title and dignity of king of Hungary, and was made in return prince of the empire, with the poſſeſſion of two duchies in Sileſia, and ſeveral caſtles and diſtricts in Hungary. His reſtleſs diſpoſition however led him to violate the treaty, and, in 1624, he overran Hungary, till he was defeated by the imperial general, and obliged to take refuge in Caſſovia. Upon this a treaty of peace was negociated, by which he renounced all pretenſions to Hungary, and all connections with the enemies of the houſe of Auſtria, and was inveſted with ſeveral lordſhips in Sileſia, and with authority over Tranſylvania during life. After this period he remained quiet; and falling into a dropſy, died in 1629. He left legacies both to the emperor and grand ſeignor. Gaber married the daughter of John Sigiſmond, elector of Brandenburgh. Mod. Univ. Hiſt. vol. xxvii. p. 2, &c.

BETH-MAON, the *houſe of habitation*, or, *of iniquity*, in *Ancient Geography*, a city of the Moabites, in the tribe of Reuben. Jer. xlviii. 23.

BETH-MARCHABOTH, the *houſe of chariots*, or, *of bitterneſs extinct*, a city in the tribe of Simeon.

BETH-MAUS, a village of Galilee, between Sephoris and Tiberias, diſtant, according to Joſephus, 4 ſtadia from the latter. Lightfoot ſuppoſes it to be the Beth-meon of the Talmud.

BETH-NIMRAH, the *houſe of the leopard*, or, *of rebellion*, or, *of bitterneſs*, a city in the tribe of Gad. Numb. xxxii. 36.

BETHOANNABA, or Beth-hannabah, a town, according to Euſebius, 4 miles eaſt from Dioſpolis. The name preſerves ſome remains of the word Nob, where the tabernacle continued for ſome time, in the reign of Saul. 1 Sam. xxi. 1. According to Jerom, Nob was not far from Dioſpolis.

BETHOGLA, the *houſe of the feaſt or dance*, the name of two places: one fixed by Euſebius, 8 miles from Gaza; the other by Jerom, 2 miles from Jordan. The Bethagla of Euſebius is probably part of the tribe of Judah. Joſh. xv. 6. The Bethogla of Jerom belongs to that of Benjamin. Joſh. xviii. 21.

BETHOME, or BETHORA, was otherwiſe called *Julias*, and was the birth-place of the prophet Joel. The inhabitants of Bethome rebelled againſt Alexander Jannæus. The town was taken, and they were ſent captives to Jeruſalem.

BETHONEA, or BETH-OANEA, was ſituated 15 miles eaſt from Cæſarea, and was famous, according to Euſebius and Jerom, for its beneficial hot baths.

BETHORON, a town of Samaria. The Scriptures mention two cities of this name, the *Upper* and *Lower*, both belonging to the tribe of Ephraim, (Joſh. xvi. 3, 5.) and given by this tribe to the Levites (Joſh. xxi. 22.). They were both built by Sherah, grand-daughter of Ephraim (1 Chron. vii. 24.) and reſtored by Solomon after they had fallen to decay (1 Kings ix. 17. 2 Chron. viii. 5). Their diſtance from one another was almoſt the whole breadth of the tribe of Ephraim; the *Upper* being in the north, and the *Lower* in the ſouth of that tribe. The former was ſituated in the road from Conſtantinople to Antioch, and the ſame with *Betaron* of Antonine's itinerary; or *Betaro*, placed between Cæſarea and Dioſpolis. The latter was ſeated on a mountain, on the public road to Lydda and Cæſarea, diſtant 100 ſtadia, or about 12 miles from Jeruſalem; and hence it has been allotted by ſome to the tribe of Benjamin. Jerom ſays, that Paula paſſed through both the Bethorons in her way from Naploufe to Jeruſalem. See BITHER.

BETH-PALATH, or BETH-PELETH, *the houſe of deliverance*, or *of expulſion*, a city in the moſt ſouthern part of the tribe of Judah. Joſh. xv. 27. Nehem. xi. 26. This city was ſurrendered to the tribe of Simeon.

BETH-PAZZEZ, *the houſe of diviſion*, a city in the tribe of Iſſachar. Joſh. xix. 21.

BETH-PEOR, or BETH-PHAGOR, *the temple of Peor*, a city of Moab given to the tribe of Reuben, (Deut. iv. 46.) where the idol Baal-Peor was worſhipped. Numb. xxv. 3. It was ſituated on the other ſide of Jordan, oppoſite to mount Peor, or Phagor.

BETHPHAGE, a village at the foot of mount Olivet, between Bethany and Jeruſalem, and about 15 furlongs from the latter. See BETHANY.

BETHSAIDA, a city of the half tribe of Manaſſeh, near the deſert of the ſame name. It was ſituated, according to Pliny, on the eaſt, or on the Arabian ſhore of the lake of Gennesareth, in Batanea, and the lower Gaulonites, according to Joſephus, at the beginning of the mountainous country. It was a place of fiſhing, according to Bochart, and a place of hunting, ſays Dr. Lightfoot, ſo called becauſe it ſtood near Naphtali, where were many deer. Gen. xlix. 21. It was raiſed by Philip, the brother of Herod the tetrarch, from the rank of a village to the honour of a city, and called *Julias*, in honour of the emperor's daughter. It ſeems to have been different from Betharamphtha, called alſo Bethſaida Julias. See BETHARAMPHTHA. This latter Bethſaida, which was on the weſtern ſhore of the lake of Gennesareth (Mark vi. 45. viii. 22.) was one of the cities againſt which Chriſt denounced a woe (Matt. xi. 21.) on account of its impenitence and infidelity, after the mighty works which he had performed in it. It was alſo the city where three apoſtles dwelt, viz. Philip, Andrew, and Peter. John i. 45.

BETH-SHALISHA, or BAAL-SALISA, a town of Paleſtine, in the canton of Thamna, 15 miles north of Dioſpolis, according to Euſebius, and ſouth-eaſt of Antipatris.

BETHSAN, or BETHSEAN, a town of Samaria in the half tribe of Manaſſeh, upon the borders of Galilee, on this ſide Jordan, and about half a league from it. It was the capital of a diſtrict of the ſame name, extending to Peræa. In 2 Maccabees xii. 29. it is placed 600 ſtadia, or 75 miles from Jeruſalem. Joſephus ſays, that it was the largeſt town of the Decapolis, and that it was 120 ſtadia, or 15 miles from Tiberias. It was upon the walls of this city that the Philiſtines, after the battle of Gilboa, hung the bodies of Saul and Jonathan, which were removed in the night by the inhabitants of Jabeſh-Gilead, and honourably interred, under a grove of oaks near the city. (1 Sam. xxxi. 10, &c.) In proceſs of time it was called *Scythopolis*, which name it derived from the Scythians, who, in the reign of Joſiah, king of Judah, about 635 years before Chriſt, made an irruption into Paleſtine, and left a colony at Bethſan. Steph. Byz. and Pliny call it Nyſa. Bryant (Anal. Myth. vol. iii. p. 415.) deduces its name Bethſan, from beth, houſe or temple, and ſan, or ſhan, an ancient denomination of the ſun, under which he was worſhipped; and he ſuppoſes, that he had a temple in this city, to the walls of which the body of Saul was faſtened. Images of the ſun, under the appellation of Zanes, were peculiar to Sparta. This city, according to him, was built by the Cuthite Ophitæ, or Hivites, ſome of whom ſettled in that part of Canaan, called Galilee. As Ophitæ, they worſhipped the ſun under the figure of a ſerpent, and they were ſuppoſed to be Heliadæ, or offspring of the ſun. The ſerpent they ſtyled ſan, or ſhan; but as the Hebrew *ſhan* ſignified alſo a tooth, the Grecians, inſtead of ſaying that the Sparti had their origin from the ſerpent deity, the ſun, made them take their riſe from the teeth of a ſerpent.

BETH-SHEMESH, *the houſe of the ſun*, or, *of ſervice*, a Levitical city in the tribe of Dan, or of Judah, for it is aſſigned to the one and to the other; diſtant, according to Euſebius, 10 miles from Eleutheropolis, in the way to Nicopolis, or Emmaus. 1 Sam. vi. 12. Joſh. xiv. 41. 1 Kings iv. 5.—Alſo, a city of the tribe of Iſſachar. Joſh. xix. 22. —Alſo, a city of the tribe of Naphtali. Joſh. xix. 38. Judg. i. 33.

BETH-SUR, or BETH-ZUR, *the houſe of the rock*, or, *of the band*, a city with a ſtrong fortreſs, ſeated on a high rock, in the tribe of Judah (Joſh. xv. 38.) diſtant, according to Euſebius, 20 miles from Jeruſalem, on the road to Hebron. It was fortified by Rehoboam, to keep the Danites in awe. (2 Chron. xi. 7.) When it was beſieged by Lyſias, under Antiochus, the ſon of Antiochus Epiphanes, with an army of 60,000 foot, and 5000 horſe, Judas Maccabæus came with 10,000 men to its ſuccour, and obliged Lyſias to raiſe the ſiege, and defeated his army. B. C. 165. 1 Maccab. iv. 28. vi. 7. Bryant derives the name of this city from beth, temple, and ſur, a name given to the ſun, under which appellation he had temples and worſhip.

BETH-TAPPUA, *the apple or orchard houſe*, a city of Judah (Joſh. xv. 53.) ſaid, by Euſebius, to be the laſt city of Paleſtine in the way to Egypt; 14 miles from Raphia.

BETHUL, or BETHUEL, a city of Galilee, belonging to the tribe of Simeon, (Joſh. xix. 4.) probably the ſame with *Bethelia*, repreſented by Sozomen in his hiſtory, as belonging to the inhabitants of Gaza, well-peopled, and adorned with ſeveral temples remarkable for their ſtructure and antiquity; particularly a pantheon, or temple, dedicated to all the gods, ſeated on an eminence made of earth, which commanded the whole city. Jerom, ſpeaking of Bethelia, ſays, that from thence to Peluſium was a ſhort journey of five days. Among the biſhops of Paleſtine, we find one of Bethelia. Reland, l. i c. 35. p. 208. This was probably the ſame with *Bethulia*, celebrated on account of its ſiege by Holofernes, at which he was killed by Judith. Judith, vi. 7.

BETHUNE, in *Biography*. See Sully.

Bethune, in *Geography*, a town of France, and principal place of a diſtrict, in the department of the ſtraits of Calais, ſeated on a rock in the little river Bietre. The number of inhabitants in the town is eſtimated at 5000, and in the canton at 15,956. Its territory contains 125 kiliometres, and 17 communes. It formerly belonged to the counts of Flanders, but being taken by Gaſton, duke of Orleans, in 1645, it was united to France by the peace of the Pyrenées, and the fortifications were repaired under the direction of M. Vauban. In 1710, it was captured by the allied army, under prince Eugene and the duke of Marlborough, and reſtored to France in 1713, at the peace of Utrecht. This city and the caſtle are together of a triangular figure; but the caſtle itſelf is an irregular building. The houſes are mean, and the ſtreets are ill paved, but it contains ſeveral churches and convents, and a large handſome ſquare. In the marſhy lands, near the city, ſeveral canals are cut for the convenience of whitening linen. N. lat. 50° 32′. E. long. 2° 48′.

Bethune, a river of France in Upper Normandy, in the county of Caux.

BETHURA, in *Ancient Geography*, a town of Aſia in Aſſyria. Ptolemy.

BETIGOLA, in *Geography*, a town of Poland, in Samogitia, 10 miles S. S. E. of Roſienne.

BETIQUA, a town of Africa, in the kingdom of Congo.

BETITLO, a town of European Turkey, in the Morea, 22 miles ſouth of Miſiſtra.

BETLIS, a town of Aſia in Curdiſtan, ſituated between two high mountains, at a cannon ſhot's diſtance from each other; the reſidence of a bey, who is ſubject neither to the king of Perſia nor the Turkiſh emperor, and who commands an army of 20,000 or 25,000 horſemen, beſides infantry. It lies on the road from Tauris to Aleppo, and the paſſage is ſo narrow, that the prince can ſtop caravans whenever he pleaſes. The caſtle is on an eminence between the mountains, reſembling a ſugar-loaf, and ſo ſteep that it can only be aſcended by winding round it. The people in and near the town are ſhepherds, and are ready to take up arms at the command of their prince. It is diſtant about 110 miles E. of Diarbekir, and 100 N. of Moſul. N. lat. 37° 20′. E. long. 42° 40′.

BETOLA, a town of Italy, 16 miles S. of Placenza.

BETON, in *Architecture*. See Cements, *Calcareous*.

BETONICA, *Betony*, corrupted from *Vettonica*, which is derived from the Vettones, an ancient people of Spain, in *Botany*. Lin. gen. 718. Reich. 776. Schreb. 973. Tournef. 96. Juſſ. 114. Smith, Flor. Brit. 267. Claſs and Order, *didynamia gymnoſpermia*. Nat. Ord. *Verticillatæ*, or *Labiatæ*. Gen. Char. *Calyx*. perianth one-leafed, tubular, cylindric, five-toothed, awned, permanent. *Cor.* monopetalous, ringent; tube bent in, cylindric; upper lip roundiſh, entire, flat, erect; lower trifid; middle diviſion broader, roundiſh, emarginate. *Stam.* filaments four, ſubulate, the length of the throat; two ſhorter, inclined to the upper lip; anthers roundiſh. *Piſt.* germ four-parted; ſtyle, form, ſituation, and ſize of the ſtamens; ſtigma bifid. *Per.* none; calyx foſtering the ſeeds in its boſom. *Seeds* four, ovate.

Eſſ. Char. *Cal.* awned. *Cor.* upper lip aſcending, flattiſh; tube cylindric.

Species, 1. B. *officinalis*, wood betony. Lin. Spec. 810. Hudſ. 258. With. 530. Relh. 229. Sibth. 185. Curt. Lond. faſc. 3. t. 33. Fl. Dan. t. 726. Woodw. Suppl. t. 241. Varieties, *β*. B. alba. Bauh. pin. 235. Hall. *β*. Ger. 577. 2. *γ*. B. minima alpina helvetica. Tourn. Hall. *γ*. Lightf. *β*. Mor. f. 4. Park. 614. f. 3. Raii Hiſt. 550. "Spike interrupted; helmet of the corolla entire; middle diviſion of the lower lip emarginate; calyxes ſmoothiſh." The common wood betony has an upright ſtem, a foot high or more, not branched, or very little in its wild ſtate, hairy, channelled, the corners rounded; root-leaves on long petioles, oblong-heart-ſhaped, obtuſe, wrinkled, crenate, with few hairs, but dotted with ſmall hollow points, the edge ciliate; ſtem-leaves ſubſeſſile, lanceolate, ſerrate; bractes numerous, lanceolate, ciliate, ſhorter than the calyx; flowers in ſpikes, compoſed of ſeveral whorls; calyx coloured, ſeſſile, almoſt upright, villoſe within, having long hairs between the five long-pointed ſegments; the two upper teeth recurved; corollas purple, varying to fleſh and rarely white; tube downy, longer than the calyx, upper lip commonly entire, ſometimes cloven at the end, lower ſcalloped or crenulate; filaments villoſe; anthers blackiſh. A native of woods, heaths, and paſtures, among buſhes; perennial, flowering in July and Auguſt. The dried leaves, by their rough hairs, excite ſneezing; and it has accordingly been made an ingredient in the ſternutatory powders. But Dr. Cullen obſerves, that this, as well as marjoram, ſeems to be only uſeful, by diffuſing and giving an agreeable odour to the other errhines. Sheep eat it, but goats refuſe it. This plant dyes wool of a very fine dark yellow colour. The leaves and tops of the betony have an agreeable but weak ſmell; to the taſte they diſcover a ſlight warmth, accompained with ſome degree of aſtringency and bitterneſs. They yield very little eſſential oil. This, like many other plants formerly in great medical eſtimation, is at this time almoſt entirely diſregarded. Antonius Muſa, phyſician to the emperor Auguſtus, filled a whole volume with an enumeration of its virtues, ſtating it as a remedy for no leſs than 47 diſorders; and hence in Italy aroſe the proverbial compliments, "tu hai piu di vertu che non ha betonica," i. e. you have more virtues than betony; and "vende la tunica et compra la betonica," i. e. ſell your coat and buy betony. Simon Paulli alſo aſcribes to it powers, which may be conſidered as rather miraculous than natural, and which did not ſeem to require contradiction, from the experiments of Alſton. Modern writers, however, do not allow the betony to poſſeſs any conſiderable efficacy, and it is omitted in the catalogues of the Britiſh diſpenſatories. Scopoli indeed ſays, that he experienced its cephalic and corroborant effects; but its ſenſible qualities ſhew it to be more inert than moſt of the other verticillatæ. The roots and leaves are ſaid to be very different in quality from the other parts of the plant; and to be nauſeous, bitter, purgative, and emetic. Both this plant and eyebright enter into the compoſition of Rowley's Britiſh herb tobacco and ſnuff. The variety *β*. is not uncommon with a white flower, in ſubalpine paſtures. Gerard remarked it near Hampſtead; and Mr. Miller ſays, that he often found it in Kent. The ſmall mountainous variety *γ* is not unfrequent with a ſpike, nearly globular; the leaves and flowers are ſmaller; but all theſe differences are owing to ſituation.

2. B. *orientalis*, oriental betony. "Spike entire, middle diviſion of the lip of the corolla quite entire." The flowers are larger, and of a lighter purple than thoſe of the common ſort. It was firſt diſcovered by Tournefort in the Levant, and was cultivated in Kew garden by Mr. Miller in 1739. 3. B. *alopecuros*, fox-tail betony. Sideritis alopecuros. Scop. Carn. n. 711. t. 28. Horminum alpinum luteum, betonicæ ſpica. Raii hiſt. 547. — minus album, &c. Bauh. pin. 239. prodr. 114. "Spike leafy at the baſe, helmet of the corolla bifid." The leaves are altogether heart-ſhaped, hirſute, and ſerrate; the flowers ſmell like elder; the corollas are pale yellow; the filaments lanuginous; and the germs ſmooth and ſhining. A native of the mountains of Savoy, Piedmont, Auſtria, Carniola, Sileſia, and Provence; cultivated.

vated, in 1759, in Kew garden, by Mr. Miller. 4. B. *hirſuta*, hairy betony. B. Alpina. Miller. Dict. n. 3. B. Monierii. Obſ. 146. B. Alpina incana purpurea. Barr. ic. 340. B. fol. hirſut. flor. purpur. ampliſſimis. Mentz. pug. zanon. t. 30. p. 46. "Spikes leafy at the baſe, helmet of the corolla entire." Reſembling the foregoing, but more ſtout and hairy, with a ſhorter, thicker ſpike; a native of the Alps, Apennines, and Pyrenées, and cultivated in Kew garden by Mr. Miller, in 1739. 5. B. *heraclea*. "Spike with woolly calyxes, teeth filiform; leaves lanceolate, naked." A native of the Levant. 6. B. *ſtricta*, Daniſh betony. Ait. Hort. Kew. 2. 291. B. Danica. Miller. Dict. n. 2. "Spike oblong; helmet of the corolla entire, middle diviſion of the lower lip notch-waved; calyxes hairy." A native of Denmark, cultivated by Mr. Miller in Kew garden, in 1759. 7. B. *incana*, hoary betony. Mill. Dict. n. 5. Ait. Hort. Kew. 2. 299. "Spike interrupted; helmet of the corolla bifid, middle diviſion of the lower lip notched; tube tomentoſe bent in." A native of Italy; cultivated in Kew garden by Mr. Miller in 1759. All the ſpecies of this genus are herbaceous, fibrous-rooted, hardy, perennial plants. The ſtems are ſimple, or but little branched. The flowers are in whorls, forming a terminating ſpike.

Propagation and Culture. All the ſorts may be propagated by ſeeds, or parting the roots: they require a ſhady ſituation and a moiſt ſtiff ſoil. The beſt time for tranſplanting and ſeparating the roots is in autumn, but the ſeeds ſhould be ſown in the ſpring upon a ſhady border; and they will need no other care beſides keeping them from weeds, and thinning them when they are too cloſe. Martyn's Miller. Woodville Med. Bot. vol. ii. p. 79.

Betonica *Aquatica*. See Scrophularia.

Betonica *Pauli*. See Veronica.

BETONIM, in *Ancient Geography*, a city of Gad, towards the north of this tribe, bordering on Manaſſeh. Joſh. xiii. 26.

BETO-POULO, in *Geography*, a ſmall iſland in the Grecian Archipelago. N. lat. 37° 2'. E. long. 23° 33'.

BETOWKY, a town of Poland, in Samogitia, 16 miles weſt of Roſienne.

BETSCHKOW, a town of Bohemia, in the circle of Czaſlau, 9 miles N.W. of Czaſlau.

BETSE, or Betsetek, a town of Hungary, in the county of Beth, ſeated on the Theis, near its influx into the Danube.

BETROTHMENT, in *Law*, a mutual promiſe or compact between two parties for a future marriage. The word imports as much as giving one's troth; that is, true faith, or promiſe. Betrothment amounts to the ſame with what is called by civilians and canoniſts *ſponſalia*, or *eſpouſals*; ſometimes *deſponſation*; and by the French *fiançailles*. Betrothment is either ſolemn, made in the face of the church, or private, made before witneſſes out of the church. *To betroth by giving arrhæ*, or earneſt, is called, by *Middle Age Writers*, *ſubbarrare*. In Ruſſia, the betrothing is performed with eccleſiaſtical rites, generally eight days previous to the marriage, and is indiſſoluble. During this interval, the bride is only viſited by the bridegroom, and the girls of her acquaintance, who amuſe her with ſinging. On the laſt evening, the young women bring the bride into the hot bath, where they plait and tie up her hair, ſinging at the ſame time ballads deſcriptive of her future happineſs. Among the ancient Jews, the betrothing was performed, either by a writing, or by a piece of ſilver given to the bride, or by cohabitation and conſummation. This latter engagement, according to the Rabbins, was allowed by the law (Deut. xxiv. 1.), but it has been wiſely forbidden by the ancients, on account of the abuſes that might happen, and for preventing clandeſtine marriages. After the marriage was contracted, the young people had the liberty of ſeeing each other, which was not allowed them before. If during this time the bride ſhould treſpaſs againſt that fidelity ſhe owed to her bridegroom, ſhe was treated as an adultreſs. (Seld. Uxor. Heb. l. ii. c. 1.) The nuns of the Annunciada hold an annual feaſt, in honour of the deſponſation, or betrothment of the Virgin Mary to Joſeph.

BETTA, in *Geography*, a town of Aſiatic Turkey, 70 miles S.S.W. of Erzerum.

BETTEMBOURG, the chief place of the canton, in the diſtrict of Luxemburg, and department of Forêts; containing 812 perſons: the number in the canton amounts to 10,139. The territory comprehends 290 kiliometres, and 12 communes.

BETTERTON, Thomas, in *Biography*, a famous actor, the Engliſh Roſcius of his time, was the ſon of an under cook in the houſhold of king Charles I., born in 1635, and after a tolerably liberal education, apprenticed to a bookſeller. This bookſeller, being the publiſher of ſir William d'Avenant, introduced Betterton into an acquaintance with him, and by this means he was brought upon the ſtage, under his patronage, about the year 1656 or 1657. After the reſtoration, he engaged in the company called the Duke's company, formed in virtue of a patent granted to ſir William d'Avenant, which acted at the theatre in Lincoln's-inn fields. Betterton, whoſe talents had attracted notice, was ſent to Paris, by command of Charles I., that he might acquaint himſelf with the French ſtage, and contribute on his return to the improvement of the Engliſh theatre. A new theatre was accordingly built for d'Avenant's company, in Dorſet gardens, and the exhibitions conducted in it were attended with great ſucceſs. In 1670, Betterton married a Mrs. Saunderſon, who excelled as an actreſs on the ſame ſtage, and who contributed, in concurrence with his own exertions, to procure for them not only a comfortable ſubſiſtence, but ſuch a ſurplus as might have ſerved to maintain them in their advanced age. After the coalition of the two companies above mentioned, which took place about the year 1685 or 1686, the merit of Betterton ſhone with unrivalled luſtre; and he acquired the honour of being at the head of his profeſſion. From the account which Cibber has given of his dramatic talents, it appears that no actor entered with a more diſcriminating judgment into his part, or poſſeſſed a greater command over his audience. The leading ſtyle of his acting was the grave, dignified, and forcible. His voice, perſon, and aſpect, concurred in giving more ſpirit to terror than to the ſofter paſſions; and Cibber adds, in bearing ample teſtimony to his merit; "I never heard a line in tragedy come from Betterton, wherein my judgment, my ears, and my imagination were not fully ſatisfied." His powers, however, ſeem to have been reſtricted to a particular walk in tragedy; and Othello, Hamlet, Brutus, and Hotſpur, are enumerated among his ſtriking parts, "and in theſe the range is from calm dignity to fiery impetuoſity."

With reſpect to his private character, we are told that it was, like his theatrical, manly, decent, and elevated. Having acquired a moderate property, he embarked it, by the advice of a friend, in a commercial project, in which it was loſt; and yet that friend's daughter, when ſhe became an orphan, was maintained by him as if ſhe had been his own. In conſequence of ſome diſputes which occurred, he was compelled, by ſtage-tyranny, to quit the company, with which he had been long engaged; and a new play-houſe was opened by his efforts in Lincoln's-inn fields, in 1695. The growing infirmities of advanced age made it neceſſary for him to withdraw from the ſtage, and to acquieſce, which he did with ſelf-poſſeſſion and ſerenity of mind, in the narrow circumſtances of

his declining life. In 1709, a benefit was allowed him; and on this occaſion two eminent actreſſes, Mrs. Bracegirdle and Mrs. Barry, who had quitted the ſtage, aſſiſted him by their appearance before the public, and Mr. Rowe contributed an excellent epilogue. In April 1710, he performed again at his own benefit; but the means to which he had recourſe for repelling the gout from his feet for this purpoſe, proved fatal to him on the 28th of that month. He was buried in Weſtminſter abbey; and ſir Richard Steele devoted a paper of the Tatler (N° 167.) to record the event, and to honour his memory. His veneration for Shakeſpeare reſembled that of his great ſucceſſor, Mr. Garrick; and, like him, he derived his principal renown from an exhibition of the characters of that famous dramatic writer. The few pieces which Betterton wrote for the ſtage, owe their chief excellence to his accurate and expreſſive knowledge of theatrical effect. His widow, with whom he had lived in uninterrupted harmony, did not ſurvive him more than ſix months; nor, indeed, did ſhe live long enough to enjoy the benefit of that penſion which was ſettled upon her by queen Anne juſt before her death. We ſhall cloſe this article with the relation of an anecdote recorded by Motraye in his Travels. When Betterton was one day at dinner with the archbiſhop of Canterbury, his grace expreſſed to him his aſtoniſhment, that the repreſentation of fables on the ſtage ſhould make a greater impreſſion upon the mind than that of truth in the ſermons of the clergy; to which the actor, having obtained leave to reply, ſaid "May it pleaſe your grace, It is becauſe the clergy, in reading their ſermons, pronounce them as if they were reading fables: and we, in acting our parts, and uſing in them a proper geſture, repreſent them like matters of fact." Biog. Brit.

BETTINGEN, in *Geography*, a town of Germany, in the circle of Weſtphalia, and county of Blankenheim, 3 miles north of Geroldſtein.

BETTINI, Domenico, in *Biography*, a painter, was born at Florence in 1644, and ſtudied at Rome the works of Mario da Fiori, whoſe paintings he induſtriouſly copied, and whoſe ſtyle and manner he acquired. He painted fruit, flowers, inſects, animals, and ſtill life; his objects were well diſpoſed, and ſkilfully grouped, and had a ſtrong character of truth and nature. This artiſt died in 1705. Pilkington.

BETTON, in *Geography*, a town of France, in the department of the Ille and Villaine, and chief place of a canton in the diſtrict of Rennes; 1½ league north of Rennes.

BETTS, John, in *Biography*, born at Wincheſter, where he received the rudiments of his education, was elected one of the ſcholars of Chriſt Church Oxford, in 1642. Being of the king's party, he was ejected the houſe, in that ſeaſon of confuſion and trouble, but permitted, after a time, to return, and was made doctor in medicine, in 1654. Coming to London, he was in much requeſt, particularly by thoſe of the Romiſh church, of which he was a member. He was alſo elected one of the fellows of the college of phyſicians; and on the reſtoration of king Charles II. was made one of his phyſicians. Betts publiſhed, in 1669, "De ortu et natura ſanguinis," which was cenſured by Dr. Thompſon in his True Way of preſerving the blood in its integrity. He alſo publiſhed an account of the diſſection of Thomas Parr, who lived to the great age of 152 years and 9 months. This account was afterwards inſerted in the works of Dr. Harvey, who is ſuppoſed to have drawn it up. Wood's Athen. Ox.

BETTYAR, in *Geography*, a town of Hindoſtan, and the capital of a province, in the country of Bahar, 80 miles N.N.W. of Patna, and 124 N.E. of Benares.

BETULA, Alder, and Birch, in *Botany*. Lin. gen. n. 1052. Reich. 1147. Schreb. 1419. Tournef. 350. Juſſ. 409. Gærtn. t. 90. Claſs and Order, *monoecia tetrandria*. Nat. Ord. *amentaceæ*. Gen. Char. * *Male flowers* in a cylindric ament. *Cal.* ament imbricate on every ſide, looſe, cylindric, conſiſting of three-flowered ſcales, in each of which are two very minute ſcales, placed at the ſides; three equal floſcules fixed to the diſk of each ſcale of the calyx. Perianth in each one-leafed, ſmall, entire, three or four-parted; diviſions ovate, obtuſe. *Cor.* none. *Stam.* filaments to each four (or three, or two), very ſmall; anthers twin. * *Female flowers* in an ament of the ſame plant. *Cal.* ament cylindric or roundiſh, imbricate; with two-flowered ſcales. *Cor.* none. *Piſt.* germ proper, ovate, compreſſed, very ſmall, two-ſeeded; ſtyles two, ſetaceous; ſtigmas ſimple. *Per.* none; ament under each ſide cheriſhing the ſeeds of two florets. *Seeds*, ſolitary, ovate. Obſ. *Betula* T. has the fruits in cylindric aments; ſcales three-forked; ſeeds with a double lateral wing. *Alnus* T. has them in a roundiſh ſtrobile; ſcales roundiſh; ſeeds angular, without wings.

Eſſ. Char. *Male. Cal.* one-leafed, three-cleft, three-flowered. *Cor.* four-parted. *Fem. Cal.* one-leafed, ſubtrifid, two flowered. *Seed*, with a winged membrane on each ſide.

Species, 1. B. *alba*, common birch-tree. Lin. Spec. 1393. Hudſ. Angl. 416. Wither. 1065. Ger. 1295. Emac. 1478. Park. 1408. Raii hiſt. 1410. Hunt. Evelyn. 218. Varieties β. B. pendula, weeping-birch. γ. B. alba dalecarlica. Lin. Suppl. 416. "Leaves ovate, acuminate, ſerrate." The common birch-tree is known at firſt ſight by the ſilvery colour of its bark, epidermis, or thin outer covering of the bark; the ſmallneſs of the leaves in compariſon with other timber-trees; and the lightneſs and airineſs of its whole appearance. The branches are alternate, very flexible, covered with a reddiſh brown or ruſſet, and ſmooth bark, generally dotted with white; the leaves alternate, bright green, ſmooth, ſhining beneath, with veins croſſing like the meſhes of a net; the petioles about half an inch long, grooved above, and having at the baſe ovate green glands; the male aments or catkins, which have their ſcales tipped with brown, appear in autumn at the ends of the twigs, abide in winter, and unfold their flowers, when the female catkins appear in ſpring at the ends of the ſhorter branches, on pedicels near a quarter of an inch long; the bloſſom is egg-ſhaped, concave, and green; the germs, two or more, are compreſſed; and the ſtyles and ſtigmas are reddiſh. A native of Europe, from Lapland to the ſubalpine parts of Italy; and of Aſia, chiefly in mountainous ſituations; found with us in woods and moiſt hedges, and flowering in April and May.

Evelyn obſerves, that although the timber of birch is the worſt of any, it has its various uſes; as for the farmer's ox-yokes, for hoops, ſmall ſcrews, paniers, brooms, wands, bavin-bands and wythes for faggots, and formerly for arrows, bolts, and ſhafts. It ſerved alſo for diſhes, bowls, ladles, and other domeſtic utenſils. In New England, he ſays, our Northern Americans made canoes, boxes, buckets, baſkets, kettles, diſhes, &c. of this wood, which they curiouſly joined with threads made of cedar-roots; and out of an excreſcence from the bole, boiled, beaten, and dried in an oven, they made excellent ſpunk or touchwood, and balls for playing. They alſo conſtructed of it pinnaces, which they ribbed with white cedar, and covered with large flakes of birch-bark, ſewed with threads of ſpruce roots, and pitched; to which uſe it was anciently applied even in Britain. It ſerved alſo for fuel; birch-trees having been dug in many of the moſſes of the weſt riding of Yorkſhire, which burn and flame like fir and candle-wood; and Pliny ſays (N. H. l. xvi. c. 18.)

c. 18.) that the Gauls extracted a kind of bitumen out of birch. The inner white cuticle and ſilken bark, which ſtrips off of itſelf almoſt yearly, was anciently uſed for writing tables, before the invention of paper; and with the outward, thicker, and coarſer part are covered divers houſes in Ruſſia, Poland, and other northern tracts, inſtead of ſlates and tile; and in Sweden, the poor have even ground the bark to mingle with their bread corn. From the accounts of more modern writers we learn, that the wood of birch, which is very white, is uſed for women's ſhoe-heels and pattens, and for packing-caſes. It is planted along with hazle to make charcoal for forges; and in the northern parts of Lancaſhire, and in the vicinity of London, beſoms are made with its twigs, for home conſumption, and alſo for exportation. The twigs ſmeared with birdlime are alſo uſed by the fowlers; and in Norway they are given to horſes, when fodder is ſcarce. The bark is ſerviceable in dying wool yellow, and in fixing fugacious colours; for which purpoſe it ſhould be uſed dry, and trees of 18 or 20 years growth ſhould be diſbarked at the time when the ſap is flowing. The Highlanders of Scotland uſe the bark for tanning leather, and for making ropes; and they ſometimes burn the outer rind inſtead of candles. In Norway it is dried, ground, and mixed with meal, and boiled up with other food for ſwine, who thrive much upon it. The outer bark, as it eſcapes putrefaction in the dampeſt places, is employed for covering the roofs of houſes, uſed on a layer of turf three or four inches thick. The inner bark is applied by the Norwegians for tanning hides, for fiſhing-nets, and for ſails. With the fragments dexterouſly braided the Laplanders make ſhoes and baſkets, and they uſe large pieces of it for outer garments to keep off the rain. In Kamtſchatka, they convert it into hats and drinking cups. The wood was formerly uſed by the Scots Highlanders for their arrows, but it is now employed by the hoop-benders and wheelwrights, and for a variety of ruſtic implements. The turner uſes it for trenchers, bowls, ladles, &c.; and that which is of a proper ſize ſerves for gates, rails, &c. In France it is generally uſed for wooden ſhoes. It alſo affords good fuel, and ſome of the beſt charcoal; and the ſoot is a good lamp-black for printer's ink. The ſmall branches ſerve the Highlanders for hurdles, and for ſide-fences to their houſes. Moxa is made of the yellow fungous excreſcences of the wood, which ſometimes ſwell out from the fiſſures. The leaves afford good fodder to horſes, kine, ſheep, and goats. The ſeeds are the favourite food of the ſiſkin; and the tree ſupplies a variety of inſects with food.

The vernal ſap of the birch-tree poſſeſſes a ſaccharine quality, and has been uſed both in a fermented and unfermented ſtate, as a wholeſome diuretic wine. It was formerly in great repute againſt all nephritic diſorders; but has been diſcarded from the modern practice. Van Helmont extols a drink prepared with this juice, daucus-ſeeds and brook-lime. Mr. Boyle ſays (Work, Abr. vol. i. p. 51. vol. iii. p. 338.), that he has ſeen extraordinary medicinal effects of the juice itſelf, even when other remedies failed; and accordingly he provided himſelf with a quantity of it every ſpring. He ſays, it may be eaſily preſerved by pouring a little oil on the top of it, or by diſtillation; but the beſt way is to impregnate it with the fumes of ſulphur. The juice has been uſed for wine, and alſo for brewing, being in the latter caſe employed in lieu of water; and it is ſaid (Phil. Tranſ. N° 46. p. 963.), that a barrel of malt will afford as much, and as good ale, as four with common water. In order to obtain this juice, let holes be bored in the bodies of the larger trees, about the beginning of March, while the ſap is riſing, and before the leaves ſhoot out, and in theſe holes fix foſſets of elder ſticks, cleared of their pith, placing veſſels under them to receive the liquor. A large tree may be tapped in four or five places at a time; and from ſeveral trees may be drawn in this way ſeveral gallons of juice in a day. If a ſufficient quantity be not obtained in the day, what has been gained may be reſerved by bottling it up cloſely till more be procured; but the ſooner it is boiled the better. It has been obſerved, that in the ſpace of 12 or 14 days as much juice may be obtained from one tree, as will outweigh the whole tree, body, and roots. And Evelyn, in his "Sylva," (Hunter's edition, p. 234.) informs us, that a great difference is found between the efficacy of that liquor which diſtils from the bole, or parts of the tree nearer the roots, and that part which flows from the higher branches; the former being more crude and watery, and the latter more pure and refined. When the ſap is obtained, boil it as long as any ſcum ariſes, and well ſkim it during the operation. To every gallon of liquor add four pounds of ſugar, and boil it afterwards half an hour, well ſkimming it; then put it into an open tub to cool, and when cold turn it into a caſk. When it has done working, bung it up cloſe, and keep it three months; then either bottle it off, or draw it out of the caſk, when it is a year old.

The birch, independently of the uſes to which its various parts have been applied, merits culture in parks and ornamental woods for the ſake of variety; its ſtraight ſtem, ſmooth and white bark, and neat foliage, exhibit a picturesque appearance, when properly placed here and there in the openings, ſo as to ſhew the foliage and hanging down of the twigs, or within to diſplay its ſilvery bark through the gloom: and, beſides, its fragrant ſmell after rain, juſtly entitles it to a place in the wilderneſs. Moreover, the birch-tree deſerves cultivation, becauſe it will grow to advantage upon barren land, where better trees will not thrive. It will flouriſh in moiſt ſpungy land, in dry gravel and ſand, where the ſurface is ſhallow; and upon ground, producing only moſs, theſe trees have ſucceeded ſo well, as to be fit for cutting in ten years after planting, and to yield a conſiderable profit at a ſmall expence. Of this ſpecies there are ſeveral varieties. In the variety β, the twigs of young trees are erect, but being ſlender and pliant, they are apt to become pendent with age; and hence proceeds a variety no leſs beautiful than the weeping willow. γ, is a remarkable variety found in Dalecarlia, and deſcribed as having leaves almoſt palmate, with the ſegments toothed. Other varieties of a trifling nature, with ſlight differences in the ſhape of the leaves, are mentioned by Linnæus in his Flora ſuecica.

2. B. *nigra*, black Virginia birch-tree. Lin. Spec. 1394. Reich. 4. 126. Gærtn. fruct. 2. 54. t. 90. Gron. Virg. 188. 146. Raii Dendr. 12. n. 2. Ait. Hort. Kew. 3. 336. "Leaves rhomb-ovate, acute, doubly ſerrate, pubeſcent underneath, entire at the baſe; ſcales of the ſtrobiles villoſe, ſegments linear, equal." This ſpecies being of foreign growth, is propagated for wilderneſs and ornamental plantations; but as it now begins to be more common, it is to be hoped that it will ſoon make a figure among our foreſt trees. It is equally hardy with our common birch, and attains to a much greater magnitude, as it grows to upwards of 60 feet in height. The branches are ſpotted, and more ſparingly ſet on the trees than thoſe of the common ſort. The leaves have their larger ſerratures more deep and remote, beſides ſeveral very ſmall, fine, crowded ones; they are broader, grow on long foot-ſtalks, and add a dignity to the appearance of the tree. The twigs are pubeſcent, and the petioles villoſe. A native of Virginia and Canada; and introduced into Kew gardens in 1736, by Peter Collinſon, Eſq.

It is very deſirable in pleaſure-grounds, as it is the firſt tree in the ſpring which preſents us with leaves, which are of a light

light and lively green. Its white bark makes a beautiful variety, when intermixed with other trees. It is ſaid to be the moſt uſeful tree in North America for building both of houſes and boats; and will grow faſt in any ſoil or ſituation, whether wet or dry; and it may therefore be planted in places where few other trees will thrive, and much deſerves cultivation. There are ſeveral varieties of this ſpecies, differing in the colour, ſize of the leaves, and ſhoots; ſuch as the broad-leaved Virginian birch, the poplar-leaved Virginian birch, the paper birch, brown birch, &c.

3. B. *lenta*, Canada birch. Lin. Spec. 1394. Reich. 4. 126. Gron. Virg. 115. 146. "Leaves cordate, oblong, acuminate, ſerrate." The leaves are ſmooth, very finely and ſharply ſerrate. The female catkins are ovate, ſeſſile, with acuminate entire ſcales. This ſpecies grows to more than 60 feet in height. The liquor flowing from its wounds is uſed by the inhabitants of Kamtſchatka without previous fermentation; with the wood, and alſo with the bark, which is very light, tough, and durable, they conſtruct ſledges and canoes; and they convert the latter into food by ſtripping it off when green, and cutting it into long narrow pieces, like vermicelli, drying it, and ſtewing it with their caviar. It was cultivated by Mr. Miller in Kew garden in 1759. The varieties differ in colour, and are diſtinguiſhed by the names of duſky Canada birch, white paper birch, poplar-leaved Canada birch, low growing Canada birch, &c.

4. B. *nana*, ſmooth dwarf birch. Lin. Spec. 1394. Reich. 4. 127. Hudſ. Angl. 416. Wither. 2. 207. Hall. Helv. n. 1629. Fl. Dan. t. 91. Pallas Roſſ. 63. t. 40. D.—G. Fl. Lapp. t. 4. Lightf. Scot. 575. t. 25. "Leaves orbiculate, crenate, or circular, ſcolloped." An upright ſhrub, ſeldom riſing above two or three feet high; with a hard, ſtiff trunk, and brown, roughiſh bark, reſembling that of the ulmus campeſtris; branches expanding, ſtraight, ſcattered, tapering, woolly, ſomewhat gummy at the ends; leaves rather broader than they are long, commonly three from each bud, but frequently ſingle and alternate, generally entire at the baſe, ſcollops often pointed; catkins about half an inch long; ſtyles purple. A native of the northern parts of Europe, and of the Alps; grows on mountains and wet heaths in Scotland; and flowers in May. Here it is planted for the ſake of variety, but is of no uſe; however, Linnæus ſays, that it is very ſerviceable in the economy of the Laplanders, affording them in ſummer, when they live on the mountains, fuel for the fires, which they are obliged to keep conſtantly in their huts to defend them from the gnats; and, covered with the ſkin of the rein-deer, forming their beds. The ſeeds are the food of the ptarmigan, which ſupplies a conſiderable part of their ſuſtenance. The moxa is alſo prepared from it, which they conſider as an efficacious remedy in all painful diſeaſes. The leaves, according to Linnæus, dye a finer yellow than that afforded by the B. *alba*.

5. B. *pumila*, American, or hairy dwarf birch. Lin. Syſt. 849. Reich. 4. 127. Mant. 124. Jacq. Hort. 2. 122. B. nana. Kalm. it. 2. 263. "Leaves obovate, crenate." Reſembling the foregoing. A native of North America, and introduced into Kew garden, in 1762, by Mr. James Gordon.

6. B. *alnus*, alder. Lin. Spec. 1394. Reich. 4. 127. Hudſ. Ang. 416. Wither. 2. 206. Lightf. Scot. 576. Pallas roſſ. 64. Ait. Hort. Kew. 3. 338. Alnus. Lin. Lap. 340. Hort. Cliff. 441. Gærtn. fruct. 2. 54. t. 90. Hall. Helv. n. 1630. Hunt. Evelyn. 240. Ger. 1294. emac. 1477. Park. 1409. Raii hiſt. 1409. Cam. epit. 68. Varieties, *α. glutinoſa*, common alder, "leaves undivided." *β.* A. *laciniata*, cut-leaved alder. Ait. Hort. Kew. 3. 338. 10 *β.* Duham. Arb. 42. n. 4. "Leaves pinnatifid." "Peduncles branched; leaves roundiſh, wedge-form, very obtuſe, glutinous; axils of the veins villoſe underneath." The common alder, which appears generally as a ſhrub, ſometimes grows to the height of 35 or 40 feet. The bark is blackiſh, and in old trees full of clefts; the wood is red and brittle; the leaves are of a dark green colour, and roundiſh figure, crenate, ſmooth, viſcid to the touch; the petioles grooved above and near an inch long, with lanceolate, blunt ſtipules at their baſe; the male catkins are cylindrical, appear in autumn, and continue to the ſpring; the females are of a ſhort conical form, like a ſmall fir cone. Many botaniſts have ſeparated the alder from the birch; but Linnæus, in his latter works, has joined them in the ſame genus. Gærtner preſerves them diſtinct, alleging that they differ not only in the fruit, but in the flower. A native of Europe, from Lapland to Gibraltar; and of Aſia from the White ſea to mount Caucaſus, in wet and boggy grounds, and on the banks of rivers; flowering with us in February, March, and April. The varieties of this tree are the long-leaved American alder, the white alder, the black alder, and the dwarf alder. The laſt with a round ſerrate leaf, grows naturally on the Alps and Apennines; it is a very humble ſhrub, ſeldom riſing more than a foot high, with its branches always trailing on the ground. The firſt, or long-leaved alder from America, grows to 30 feet in height, and deſerves a place in all plantations. The branches are ſlender, ſmooth, numerous, and dark brown or purple; the leaves are long, and free from the clamminеſs of the common ſort; and ſometimes continue on the tree even in December, ſo as to give it the appearance of an ever-green.

The wood of the alder is valuable for piles, pumps, ſluices, and in general for all works intended to be conſtantly under water. It is ſaid to have been uſed under the Rialto at Venice; and we are told that the moraſſes about Ravenna were piled with this timber, in order to ſerve as the foundations of buildings. For this purpoſe it has been much cultivated in Flanders and Holland. It ſerves alſo for many domeſtic and rural uſes, as for cart-wheels, ſpinning-wheels, milk-veſſels, bowls, ſpoons, ſmall trays, trenchers, and other turnery ware, troughs, handles of tools, clogs, pattens, and wooden heels. The roots and knots furniſh a beautiful veined wood for cabinets; and the Scots Highlanders often make chairs of it, which are very handſome, and of the colour of mahogany. The wood that has lain in bogs is black like ebony. It is generally planted for coppice wood, to be cut down every ninth or tenth year for poles. The branches make good charcoal.

The bark is uſed by tanners and leather-dreſſers, and alſo by fiſhermen for ſtaining their nets. This and alſo the young ſhoots dye yellow, and with a little copperas a yellowiſh grey, uſeful in the demi-tints and ſhadows of fleſh in tapeſtry. The ſhoots cut in March dye a cinnamon colour, and a fine tawny, when dried and powdered. The freſh wood yields a dye of the colour of rappee-ſnuff. The catkins dye green. The bark is uſed as a baſis for blacks; an ounce of it dried and powdered, and boiled in three quarters of a pint of water, with an equal quantity of log-wood, with ſolution of copper, tin, and biſmuth, ſix grains of each, and two drops of ſolution of iron vitriol, will dye a ſtrong deep "boue de Paris." The leaves have been ſometimes employed in tanning leather. The Laplanders chew the bark, and dye their leathern garments red with their ſaliva. The whole tree is very aſtringent.

The alder ſerves for hedges by the ſides of ſtreams and ditches, and in all wet and moraſſy ſoils, and keeps up the banks; but if it be planted in a low meadow, it is ſaid that the ground about it will become boggy; whereas, if aſh be planted, the roots of which penetrate a great way, and run

near the ſurface, the ground will become firm and dry. The growth of graſs is not materially obſtructed by the ſhade of alder. In the highlands of Scotland, near Dundonald, Mr. Pennant ſays, the boughs cut in the ſummer ſpread over the fields, and left during the winter to rot, are found to anſwer the purpoſe of a manure. In March the ground is cleared of the undecayed parts, and then ploughed. The freſh gathered leaves are covered with a glutinous liquor, which ſome people ſtrew upon their floors to deſtroy fleas; the fleas entangling themſelves in the tenacious liquor, as birds do in bird-lime. This tree affords food to many kinds of moths, and other inſects. Horſes, cows, goats, and ſheep, eat it; but ſwine refuſe it. The tongues of horſes who feed upon it are turned black; and ſome perſons ſuppoſe that it is not wholeſome for them.

7. B. *incana*, hoary alder. Linn. Syſt. 849. Suppl. 417. Hall. Helv. n. 1631. Villars Dauph. 2. 790. Pallas Roſs. 64. Du Roy Harbecc. 1. 109. Gmelin. Sib. 1. 171. n. 24. 2. B. alnus incana. Lin. Spec. 1394. Reich. 4. 127. B. viridis. Villars Dauph. 2. 789. Alnus folio incano. Bauh. pin. 428. Raii hiſt. 1410. A. incana et hirſuta. Bauh. Hiſt. 1. P. 2. p. 154. Varieties. α. B. *glauca*, glaucous-leaved alder. "Leaves glaucous beneath; petioles red." β. B. *angulata*, elm-leaved alder. "Leaves green beneath; petioles green." "Peduncles branched; leaves roundiſh, elliptic, acute, pubeſcent underneath; axils of the veins naked; ſtipules lanceolate." This ſpecies is totally diſtinct from the common alder, both in the ſtructure of its parts, and its economical uſes. It never attains the ſize of that, and is commonly ſhrubby; the trunk is ſcarcely thicker than a man's arm; the wood is white, and of a cloſer texture. A native of the Alpine and Subalpine parts of Swiſſerland, Dauphiné, in eaſtern Siberia, in the iſlands beyond Kamtſchatka, &c. Introduced into the Kew garden, in 1780, by Mr. John Buſh. The varieties of the hoary alder are the cut-leaved, the dwarf Alpine, the long-leaved, and the roſe-flowered, with petal-like bractes produced from the male catkin.

8. B. *populifolia*, poplar-leaved birch. Ait. Hort. Kew. 3. 336. "Leaves deltoid, drawn out to a long point, unequally ſerrate, very ſmooth; the ſcales of the ſtrobiles having roundiſh ſide lobes; petioles ſmooth."

9. B. *papyracea*, paper birch. Ait. Hort. Kew. 3. 337. "Leaves ovate, acuminate, doubly ſerrate; veins hirſute underneath. Both theſe laſt ſpecies are natives of North America. Cultivated in 1750 by Archibald, duke of Argyle.

10. B. *excelſa*, tall birch. Ait. Hort. Kew. 3. 337. "Leaves ovate, acute, ſerrate; ſcales of the ſtrobiles having the ſide lobes rounded; petioles pubeſcent, ſhorter than the peduncle." A native of North America. Introduced into Kew garden, about the year 1767, by Mr. James Gordon.

11. B. *oblongata*, Turky alder. Ait. Hort. Kew. 3. 338. Miller. Dict. ed. 7. n. 2. A. fol. oblongo viridi. Bauh. pin. 428. Varieties. α. foliis oblongis, oblong-leaved Turky alder. β. foliis ellipticis, oval-leaved Turky alder. "Peduncles branched; leaves oval, obtuſiſh, glutinous; the axils of the veins naked underneath." Common in Auſtria and Hungary, whence Mr. Miller received the ſeeds. Cultivated by him in Kew garden in 1759.

12. B. *ſerrulata*, notch-leaved alder. Ait. Hort. Kew. 3. 338. "Peduncles branched; leaves obovate, acute; veins and their axils villoſe underneath; ſtipules oval, obtuſe." A native of Pennſylvania. Cultivated in Kew garden in 1759 by Peter Collinſon, Eſq.

13. B. *criſpa*, curled-leaved alder. Ait. Hort. Kew. 3. 339. "Peduncles branched; leaves ovate, acute, ſomewhat waved; veins hairy underneath; axils naked; ſtipules roundiſh-ovate." A native of Newfoundland and Hudſon's bay. Introduced into Kew garden, in 1782, by the Hudſon's bay company.

14. B. *daurica*. Pallas it. 3. 224. t. kk. f. 4. ab. fl. roſs. 60. t. 39. Gmel. Sib. 1. 167. & 2. "Leaves ovate, acuminate, ſerrate, hairy on the nerve." Scarcely diſtinguiſhable, when young, from the common birch, except by the leaves, not growing ſo tall, and the trunk not exceeding a foot in diameter; bark gray, cleft longitudinally, and dividing into brown ſcales, as if burnt; branches more ſubdivided and upright; leaves harder, commonly ſmaller, on ſhorter petioles; ſtipules lanceolate, gray, ſubpubeſcent, deciduous; male catkins at the end of the twigs of the preceding year, two or three together, larger than thoſe of the common birch; females from the ſame twigs lateral, thicker, with larger, and more rounded ſcales; the ſeed larger, ſurrounded by a narrower membrane; differing from the black American birch by having ſmaller ſtipules, and leaves leſs frequently, and never doubly ſerrate. The wood is hard, yellower than that of the common ſort, and in old trees marbled with brown and gray towards the middle; tougher, and therefore more fit for cart-timber and the uſe of the wheelwright; alſo employed in making charcoal. A native of Dauria.

15. B. *fruticoſa*. Pallas. it. 3. App. 758. n. 133. t. kk. f. 1, 2, 3. fl. roſs. 6. 2. t. 40. A. B. C. Gmel. Sib. 1. 167. var. 3. t. 36. f. 2. "Leaves rhomboid-ovate, equally ſerrate, ſmooth." Always ſhrubby, riſing with ſeveral ſtems from the ſame root, in boggy places not an inch thick, nor higher than a man's ſtature, but on mountains attaining the thickneſs of the human arm, and growing to a much loftier height; much branched from top to bottom, and of a very different habit from the common birch; the cuticle aſh-coloured with tranſverſe ſtripes; the wood not ſo white, and waved tranſverſely; the twigs almoſt covered with little reſinous dots found more or leſs in the other ſpecies; buds more copious and always alternate; two leaves commonly from the ſame bud, ſofter than thoſe of the common ſort, and decaying ſooner; having three ſeeds to each ſcale, of the ſame ſize and form with thoſe of the B. *nana*. Abundant in marſhes and on rocky mountains, and in the cold ſubalpine regions of eaſtern Siberia, eſpecially towards the lake Baikal.

Propagation and Culture. The birch-tree may be cultivated either by young plants procured from the woods where they naturally grow, or by ſeeds carefully gathered in autumn, as ſoon as the ſcales begin to open, otherwiſe they will drop and be loſt. As theſe ſeeds are ſmall, they ſhould not be buried above a quarter of an inch deep in the ground. Mr. Miller recommends autumn as the beſt ſeaſon for ſowing them; but Mr. Boutcher directs to ſpread the ſeeds thin on a floor till dry, to mix them with looſe ſand, and to keep them in an airy place till the beginning of March, when they ſhould be ſown on freſh light land, trenched or dug the preceding autumn, made very looſe, raked fine, and divided into beds three feet and a half wide. It is needleſs to throw any earth over them; but in dry and froſty weather, a ſmall quantity of peaſe-haulm may be thrown over them for three or four weeks, till the ſeeds begin to vegetate. The ground ſhould then be kept clean, and three or four gentle waterings may be given at noon in April, and repeated to the middle of June in mild evenings. In the following March they may be removed into the nurſery, and planted in rows two feet and a half diſtant, and ten, or twelve, or eighteen inches aſunder. Here they may remain two years, or, in caſes where they make little progreſs, three years; cutting after the ſecond year's growth ſuch as are leaſt thriving or crooked, cloſe to the ground in March. Mr. Miller recommends

to

to ſow the ſeeds in the ſhade, alleging that they will thus thrive better than when expoſed to the full ſun. In all places where are large trees, their ſeeds fall, and the plants ſpring up without any previous care. If theſe wild plants are taken up without any injury to the roots, they may be tranſplanted into any ground, with little or no preparation; where the land will admit of the plough, it will be beſt prepared by a crop of corn. In the ſpots where they are to ſtand, it will be ſufficient to looſen the ſoil with a ſpade or mattock; and they may then be let into holes capable of receiving their roots, which ſhould be covered with earth attached cloſely to them. After they have taken root, they require no other care beſides being kept clear of weeds, which may be cut down two or three times in a ſummer for the firſt two years; and afterwards the plants will be ſtrong enough to keep the weeds down, ſo that they can receive no injury from them. Theſe plants may be ſet any time from the middle of October till the middle of March, when the ground is free from froſt; but in dry land autumn is the beſt ſeaſon, and for a moiſt ſoil the ſpring is preferable. The diſtance at which they ſhould be placed is ſix feet ſquare, that they may ſoon cover the ground, and that by ſtanding cloſe, they may draw each other up; for in ſituations that are much expoſed, if they are not pretty cloſe, they will not thrive well. If the plants take kindly to the ground, they will be fit for cutting in about ten years; and afterwards they may be cut every ſeventh or eighth year, if they are merely deſigned for the broom-makers; but if they are intended for hoops, they ſhould not be cut oftener than every twelfth year.

As the birch is a native of Britain, it ſuits itſelf to all ſorts of ſoils. It will thrive extremely well on barren land, whether it be wet or dry, ſandy or ſtony, marſhy or boggy. It ſows itſelf, and will come up in places where hardly any other tree will grow. It may be cultivated at a moderate expence; and being eaſily diſpoſed of to the broom-makers, hoop-benders, turners, and for purpoſes of huſbandry, it will yield a conſiderable profit.

The ſecond and third ſpecies, or the American ſorts of birch, may be propagated by ſeeds in the ſame manner as the firſt, and are equally hardy. Seeds ſown in beds of fine mould, and covered about a quarter of an inch deep, will generally grow. They ſhould be conſtantly weeded and watered in dry weather; and at the age of one or two years, according to their ſtrength, they ſhould be planted in rows in the nurſery, in the uſual manner. In ſummer, weeding ſhould be obſerved, and in winter, digging between the rows; and when they are about three or four feet high, they will be of a good ſize for being tranſplanted into the wilderneſs quarters. As theſe American ſorts grow with greater vigour than the common ſort, and thrive on the moſt barren ground, they may be cultivated in England to great advantage. The varieties of the different ſpecies may be propagated by layers. For this purpoſe a ſufficient number of plants ſhould be procured, and ſet on a ſpot of double dug ground, at the diſtance of three yards from each other. In the following year, if they have made no young ſhoots, they ſhould be headed to within half a foot of the ground, to form the ſtools, which will then ſhoot vigorouſly the following ſummer; and in autumn, the young ſhoots ſhould be ſplaſhed near the ſtools, and the tender twigs layered near their ends. They will then ſtrike root, and become good plants in the following autumn; and freſh twigs will have ſprung up from the ſtools to be ready for the ſame operation. The layers ſhould then be taken up, and the operation performed afreſh. If the plants deſigned for ſtools, have made good ſhoots the firſt year, they need not be headed down, but ſplaſhed near the ground, and all the young twigs layered. An immediate crop may thus be raiſed; whilſt young ſhoots will ſpring out in great plenty below the ſplaſhed part, for the purpoſe of layering in the ſucceeding year. This work may be repeated every autumn or winter; when ſome of the ſtrongeſt layers may be planted out, if they are immediately wanted; whilſt the others may be removed into the nurſery, in order to become ſtronger plants, before they are removed to their deſtined habitations. Cuttings alſo, if ſet in a moiſt ſhady border in the beginning of October, will frequently grow; but as this is not a ſure method, and as theſe trees are ſo eaſily propagated by layers, it hardly deſerves to be practiſed.

In Sweden, the budding and leafing of the birch-tree is conſidered as a directory for ſowing barley. See FOLIATION.

The fourth and fifth ſpecies, being of no uſe with us, are not cultivated, except in botanic gardens.

The ſixth ſpecies, or alder-tree, delights in a very moiſt ſoil, where few other trees will thrive, and greatly improves ſuch lands. It may be propagated by layers, cuttings, or truncheons about three feet long. The beſt time for planting truncheons, which is the leſs eligible, though perhaps the leaſt expenſive method, is in February or the beginning of March. Theſe ſhould be ſharpened at one end, and the ground looſened with an iron crow, that when they are thruſt in, the bark may not be torn off. They muſt be planted at leaſt two feet deep, that they may not be diſturbed by ſtrong winds, and ſet at the diſtance of three feet. The plantations ſhould at firſt be cleared of all weeds; and after every fall, in the following winter, the ſtools ought to be looked over, and all the weak ſide-branches taken off. This will ſtrengthen thoſe which are already the ſtrongeſt, and will enable them to ſhoot up more vigorouſly for poles. Many of the truncheons will not grow; and Hunter, in his edition of Evelyn's Silva, ſays, that he has never ſeen a coppice, raiſed in this way, ſo luxuriant and beautiful, as when raiſed from regular plants. If the alder be raiſed by layers, this operation muſt be performed in October, and in the following October they will have taken ſufficient root for tranſplantation. They ſhould then be ſet at leaſt one foot and a half deep in the ground, and their tops ſhould be cut off to about nine inches above the ſurface, which will occaſion their ſhooting out many branches. The method of raiſing theſe trees by ſeeds, is practiſed abroad, and, ſays Hunter, (ubi ſupra) is greatly to be commended. If theſe trees are deſigned for coppices, they ſhould be placed at the diſtance of ſix feet ſquare, or they may be planted at firſt a yard ſquare, and at the end of ſeven years, when they are felled for poles, every other ſtool may be taken away; and if the ſmall lateral ſhoots be taken off in the ſpring, it will very much ſtrengthen the upright poles, provided a few ſmall ſhoots be left at certain diſtances upon the body to detain the ſap for the increaſe of its bulk. In planting alders for coppices, Hunter (ubi ſupra) ſays, it is much better to raiſe them from young trees than from truncheons. To obtain theſe in ſufficient quantity, plant ſuckers, taken out of the meadows where the alder-trees grow, on a prepared piece of ground, and afterwards head them down for ſtools; lay the ſhoots in the ſucceeding autumn, and in twelve months they will have taken root, when they ſhould be removed and planted in rows, and in one or two years they may be tranſplanted where they are to remain. If the coppice is ſituated upon boggy or watery ground, they may be removed from the nurſery, and planted three feet aſunder, in holes previouſly prepared for receiving them. Here they may ſtand for ſix or ſeven years, when every other tree ſhould be taken away, and the reſt cut down for ſtools. Every ninth or tenth year will afford a fall of theſe trees for

poles; which ſhould be taken off ſmooth and fine, ſo that the ſtool may not be damaged, or hindered from producing a freſh crop.

Theſe trees will thrive exceedingly on the ſides of brooks, and may be cut for poles every fifth or ſixth year. They may be alſo planted for hedges in moiſt ground, and trained into ſuch as are very cloſe and thick, to the height of twenty feet and upwards. The banks of rivers may be ſecured by planting truncheons very cloſe, and croſs-wiſe. As the leaves are large and of a deep green colour; theſe trees, if the beauty of aquatic plantations be regarded, ſhould be preferred to others uſually planted in ſwampy grounds.

The ſeventh ſpecies, or hoary alder, growing naturally in dry ſandy ſoils, may perhaps be cultivated with the birch, where land is of little value, as an underwood, and may be propagated either by layers or cuttings, as well as by ſeeds, where they can be obtained. Martyn's Miller. Hunter's Evelyn's Silva, p. 225, 240. Withering's Bot. Arr. vol. ii. p. 206.

Betula *Americana*. See Bursera.

BETULÆ, in *Entomology*, a ſpecies of Curculio, entirely of a golden green colour in one ſex, and blue in the other, with a ſpine on each ſide of the anterior part of the thorax of the latter. A native of Europe. Linnæus. Donov. Brit. Inſ. &c.

Betulæ, a ſpecies of Cryptocephalus, that inhabits Berlin. The colour is black; thorax ſomewhat orbicular and hairy; wing-caſes browniſh with obſcure ſtreaks. Herbſt.

Betulæ, a ſpecies of Attelabus, of a black colour, with legs formed for leaping. Linn. Fn. Succ. This is *curculio excoriato-niger* of Degeer.

Betulæ, a ſpecies of Cimex (*Acanthia membranaceus*), that lives on the white alder in the north of Europe. The thorax is denticulated; head muricated; anterior part of the wing-caſes dilated. Linn. Degeer, &c.

Betulæ, a ſpecies of Papilio (*Pleb. Rur.*), found in Europe. The wings are ſomewhat tailed, brown, yellowiſh beneath; poſterior ones with two white ſtreaks. Fabricius. Donov. Brit. Inſ. &c. The larva is green, with pale oblique lines, and white on the ſides; pupa gloſſy, and ferruginous. Feeds on the alder. The male diſtinguiſhed by a fulvous ſpot on the upper wings.

Betulæ, a ſpecies of Tenthredo, with the body red; thorax, vent, and eyes black; wings behind brown. Linn. Fn. Suec. This is *tenthredo ferruginea* of Degeer. Inhabits Europe.

Betulæ, a ſpecies of Coccus, found on the white alder. It is round, and of a bay colour. Gmel. &c.

BETULEIUS, Sixtus, in *Biography*, whoſe true name was *Birch*, was born at Memmingen, in the year 1500, and obtained the reputation of an able grammarian, as well as a good Latin poet and philoſopher. He taught the belles lettres and philoſophy; and became principal of the college of Augſburgh, where he died June 16th 1554. He publiſhed ſeveral works in proſe; and his dramatic pieces of Joſeph, Suſannah, and Judith, have been eſteemed.

BETULINUS, in *Ornithology*, a ſpecies of Tetrao, deſcribed by Scopoli. The tail is black, varied with tranſverſe rufous ſpots; rump whitiſh, faſciated with black. Scop. Ann. Latham. This is the *urogallus minor* of Aldrovandus; and *birch grous* of Latham. The body is varied with black and rufous; bill and legs black; breaſt greyiſh; quill-feathers white at the tip; eyebrows not red.

BETULUS, in *Botany*. See Carpinus.

BETUWE, Betaw, or Batavia, in *Geography*, a tract of land, in the duchy of Guelderland, in the United Netherlands, ſituated betwixt the Rhine and the Waal, and forming part of the "Inſula Batavorum," where the Batavians ſettled on their migration out of Germany. It has been divided into two bailliages, viz. the eaſtern or upper, and the weſtern or lower Betuwe. The former, by a change in the courſe of the Rhine, has been ſeparated from Betuwe, and removed into the duchy of Cleve, where the fortifications of the Schenken-Schanze, erected in 1586, by general Martin Schenk, have been gradually waſhed away by the water. The bailliage of lower Betuwe comprehends a number of villages that lie on the Rhine. See Batavi.

BETWEEN Decks, in *Sea Language*, denotes the ſpace contained between any two decks of a ſhip.

BETWHA, in *Geography*, a river of Hindoſtan, which runs into the Jumnah, 25 miles ſouth-eaſt of Calpy. This river, from its ſource ſouth of Bopal, to its confluence with the Jumnah, deſcribes a courſe of 340 miles in a north-eaſterly direction.

BETZ, the principal place of a canton, in the diſtrict of Senlis, and department of the Oiſe, containing 352 perſons; the number of the canton being 9364. Its territory comprehends 222½ kiliometres, and 29 communes.

BETZALEEL, Jehudah, or *Leo Pragenſis*, in *Biography*, a Jewiſh doctor of Prague, in Bohemia, flouriſhed about the middle of the 16th century, and was chief of the Moravian academies, and judge of the nation in that country. He left ſeveral learned works, among which is that entitled "The Redemption and Eternity of Iſrael," in which he aſſures the Jews of the certainty of the Meſſiah's advent, and of his ſettling them in a ſtate of permanent proſperity.

BETZANDORFF, in *Geography*, a ſmall town or borough of Germany, in the old mark of Brandenburg.

BETZDORF, the principal place of a canton, in the diſtrict of Luxembourg, and department of Forêts, containing 1082 inhabitants; thoſe of the canton being 8101. Its territory comprehends 212½ kiliometres and 7 communes.

BETZKO, a town of Hungary, 18 miles weſt of Topoltzan.

BETZIRVAN, or Barsan, a town of Perſia, in the province of Aiderbeitzan; 100 miles north-eaſt of Tauris.

BEVAGNA, the ancient *Mevania*, a ſmall town of Italy, in the duchy of Spoleto, ſeated on the river Tinia, or Timia.

BEVECUM, a town of Brabant, 8 miles ſouth-eaſt of Louvain. N. lat. 50° 45′. E. long. 4° 50′.

BEVEL, in *Maſonry*, and among *Joiners*, a kind of ſquare, one leg whereof is frequently ſtraight, and the other crooked, according to the ſweep of an arch or vault; being alſo moveable on a point, or centre, ſo that it may be ſet to any angle. The make and uſe of the bevel are pretty much the ſame as thoſe of the common ſquare or mitre, except that theſe latter are fixed; the firſt at an angle of ninety degrees, and the ſecond at forty-five; whereas the bevel, being moveable, may, in ſome meaſure, ſupply the office of both, and yet, which it is chiefly intended for, ſupply the deficiencies of both, ſerving to ſet off or tranſfer angles, either greater or leſs than ninety or forty-five degrees.

Bricklayers have alſo a bevel, by which they cut the under ſides of the bricks of arches ſtraight or circular, to ſuch obliqne angles as the arches require, and alſo for other uſes.

Bevel, *Graduated*, is that which has about the centre of one of its arms a ſemicircle graven, and divided into 180 degrees, whoſe diameter ſtands ſquare with the ſides of the ſame arm; ſo that the end of the other arm, being divided at right angles, almoſt to the centre, ſhews by its motion the number of degrees contained in the angle to be meaſured. This is alſo called *recipiangle*, and *pantameter*.

Bevel *angle* is uſed among the workmen, to denote any other angle beſide thoſe of ninety or forty-five degrees.

The *ſimple Bevel* (ſee *Plate* II. *Geometry*, *fig.* 35.) conſiſts of two rulers moveable on a common centre, like a carpenter's rule, with a contrivance to keep them fixed, at any required angle. The centre C muſt move on a very fine axis, ſo as to lie in a line with the fiducial edges CB, CD of the rulers, and project as little as poſſible before them. The fiducial edges of the legs repreſent the ſides of any given angle, and their interſection or centre C, its angular point. A pin, fixed in the lower ruler, and paſſing through a ſemicircular groove in the upper, ſerves, by a nut A, which ſcrews upon it, to fix the rulers, or legs, when they are placed at the deſired angle.

The uſe of this inſtrument may be illuſtrated in the following examples:

1. Let 3 points, A, B, C, be in the circumference of a circle, which is too large to be deſcribed by a pair of compaſſes; and let it be required to find any other number of points in the ſame circumference. Bring the centre of the bevel to B (*fig.* 36.), the middle point of the 3 given ones A, B, and C, and holding it there, open or ſhut the inſtrument till the fiducial edges of the legs lie upon the other two points, and fix them there by means of the ſcrew A (*fig.* 35.): this operation is called *ſetting* the bevel to the given points. Then removing the centre of the bevel to any part between B and A or C, the legs being at the ſame time kept upon A and C, that centre will deſcribe, or be always found in, the arc which paſſes through the given points, and will thus aſcertain as many others as may be required between the limits of A and C. In order to find points without thoſe limits, proceed in the following manner: the bevel being *ſet*, bring the centre to C, and mark the diſtance CB upon the left leg; remove the centre to B, and mark the diſtance BA upon the ſame leg; then placing the centre on A, bring the right leg upon B, and the firſt mark will fall upon *a*, a point in the circumference of the circle, paſſing through A, B, and C, whoſe diſtance from A is equal to the diſtance BC. Removing the centre of the bevel to the point *a* laſt found, and bringing the right leg to A, the ſecond mark will find another point *a''* in the ſame circumference, whoſe diſtance *aa''* is equal to AB. By proceeding in this manner, any number of points may be found, whoſe diſtances on the circumference are alternately BC and BA. In the ſame manner, by making ſimilar marks on the right leg, points on the other ſide, as at *c'* and *c''* are found, whoſe diſtances C*c'*, *c'c''*, are equal to BA, BC reſpectively. Intermediate points between any of the above are given by the bevel in the ſame manner with thoſe between the original points.

2. Three points, A, B, and C, being given, to draw a line from any one of them, tending to the centre of the circle, which paſſes through them all. Set the bevel to the three given points A, B, and C (*fig.* 37.); lay the centre on A, and the right leg to the point C, and the other leg will give the tangent AG'. Draw AD perpendicular to AG' for the line required. For BAE being = BCA, the angle EAC is the ſupplement to the angle ABC, or that to which the bevel is ſet; hence, when one leg is applied to C, and the centre brought to A, the direction of the other leg muſt be in that of the tangent G'E.

3. Three points being given as before, let it be required to draw from a fourth given point D, a line tending to the centre of a circle paſſing through the firſt three points. On D (*fig.* 38.), with the radius DA deſcribe an arc AK; ſet the bevel to the three given points A, B, and C, and bring its centre, always keeping the legs on A and C, to fall on the arc AK, as at H; on A and H ſeverally, with any convenient radius, ſtrike two arcs, croſſing each other at I; and the required line D*d* will paſs through the points I and D. For a line drawn from A to H will be a common chord to the circles AHK and ABC; and the line ID biſecting it at right angles, muſt paſs through both their centres.

4. Three points being given as before, together with a fourth point, to find two other points, ſuch, that a circle paſſing through them and the fourth point, ſhall be concentric to that paſſing through three given points. Draw A*c* and C*c* tending to the centre, by a former problem; ſet the bevel to the three given points A, B, and C; bring the centre of the bevel to D, and move it upon that point till its legs cut off equal parts AN, CQ, of the lines A*a* and C*c*; and N and Q will be the points required. For, ſuppoſing lines drawn from A to C, and from N to Q, the ſegments ABC and NDQ will be ſimilar ones; and conſequently, the angles contained in them will be equal.

5. Two lines tending to a diſtant point being given, and alſo a point in one of them; to find two other points (one of which muſt be in the other given line), ſuch, that a circle paſſing through theſe three points may have its centre at the point of interſection of the given lines. Draw EH (*fig.* 39.) at right angles to AB, and make FH = FE; ſet the bevel to the angle GDO, and keeping its legs on the points H and E, bring its centre to the line AB, which will give the point I.

An improved bevel is exhibited in *fig.* 40. by which the arcs of circles of any radius, without the limits attainable by a common pair of compaſſes, may be deſcribed. It conſiſts of a ruler AB, compoſed of two pieces rivetted together near C, the centre or axis, and of a triangular part CFED. The axis is a hollow ſocket fixed to the triangular part, about which another ſocket, fixed to the arm CB of the ruler AB, turns. Theſe ſockets are open in the front for part of their length upwards, as repreſented in the ſection at I, which ſhews the point of a tracer, or pin, fitted for ſliding in the ſocket. The triangular part is furniſhed with a graduated arc DE, by which and the vernier at B, the angle D*c*B may be determined to a minute. In this arc is a groove, by means of which, as well as by the nut and ſcrew at B, or ſome ſimilar contrivance, the ruler AB may be fixed in any required poſition. A ſcale of radii is put on the arm CB, by which the inſtrument may be ſet to deſcribe arcs of given circles, not leſs than 20 inches in diameter. In order to ſet the inſtrument to any given radius, the number expreſſing it in inches on CB, is brought to cut a fine line drawn on CD, parallel and near to the fiducial edge of it, and the arms are faſtened in that poſition by the ſcrew at B. Two heavy pieces of lead or braſs G, G, made in form of the ſector of a circle, the angular parts being of ſteel, and wrought to a true upright edge, as ſhewn at H, are uſed with this inſtrument, whoſe arms are made to bear againſt thoſe edges when the arcs are drawn. The under ſides of theſe ſectors are furniſhed with fine ſhort points to prevent them from ſliding. The fiducial edges of the arms CA and CD, are each divided from the centre C into 200 equal parts. This inſtrument might be furniſhed with ſmall caſtors, like the pentagraph; but little buttons, fixed on its under ſide, near A, E, and D, will enable it to ſlide with ſufficient eaſe.

The uſe of this inſtrument may be exemplified in the following problems:

1. To deſcribe an arc, which ſhall paſs through three given points.—Place the ſectors G, G', with their angular edges over the two extreme points; apply the arms of the bevel to them, and bring at the ſame time its centre C, that is, the point of the tracer, or pen, put into the ſocket, to the third

third point, and there fix the arm CB; then, bringing the tracer to the left hand ſector, ſlide the bevel, keeping the arms conſtantly bearing againſt the two ſectors, till it comes to the right hand ſector, by which the required arc will be deſcribed by the motion of its centre C. If the arc be wanted in ſome part of the drawing *without* the given points, find by caſe 1. under *ſimple bevel*, other points in thoſe parts where the arc is required; and thus a given arc may be lengthened as far as is neceſſary.

2. To deſcribe an arc of a given radius, not leſs than 10 inches.—Fix the arm CB ſo that the part of its edge, correſponding to the given radius, always reckoned in inches, may lie over the fine line drawn on CD for that purpoſe; being the centre to the point through which the arc is required to paſs, and diſpoſe the bevel in the direction in which it is intended to be drawn; place the ſectors G, G, exactly to the diviſions 100 in each arm, and ſtrike the arc as above deſcribed.

3. The bevel being ſet to ſtrike arcs of a given radius, as in the laſt inſtance, let it be required to draw other arcs, whoſe radii ſhall have a given proportion to that of the firſt arc. Suppoſe the bevel to be ſet for deſcribing arcs of 50 inches radius, and it be required to draw arcs of 60 inches radius, with the bevel ſo ſet. Say, as 50 is to 60, ſo is the conſtant number 100 to 120, the number on the arms CA and CD, to which the ſectors muſt be placed, in order to deſcribe arcs of 60 inches radius. When it is ſaid that the bevel is ſet to draw arcs of a particular radius, it is always underſtood that the ſectors G, G, are to be placed at N° 100 on CA and CD, when thoſe arcs are drawn.

4. An arc ACB (*fig.* 41.) being given, let it be required to draw other arcs concentric to it, which ſhall paſs through given points, e. g. P. Through the extremities A and B of the given arc, draw lines AB, BP, tending to its centre, by caſe 3. under *ſimple bevel*. Take the neareſt diſtance of the given point P from the arc, and ſet it from A to P, and from B to P. Hold the centre of the bevel on C, any point near the middle of the given arc, and bring its arms to paſs through A and B at the ſame time, and fix them there. Place the ſectors to the points P and P, and with the bevel, ſet as before directed, draw an arc, which will paſs through P′ the given point, and be concentric to the given arc ACB.

5. Through a given point A (*fig.* 42.) in the given line, to ſtrike an arc of a given radius, and whoſe centre ſhall lie in that line, produced if neceſſary. Set the bevel to the given radius, by caſe 2. Through A, at right angles to AB, draw CD; lay the centre of the bevel, ſet as above, on A, and the arm CA on the line AC, and draw a line AE along the edge CD of the other arm. Divide the angle DAE into two equal parts by the line AF, and place the bevel ſo that, its centre being at A, the arm CD ſhall lie on AF; while in this ſituation, place the ſectors at N° 100 in each arm, and then ſtrike the arc.

6. An arc being given, to find the length of its radius. —Place the centre of the bevel on the middle of the arc, and open or ſhut the arms till N° 100 on CA and CD, fall upon the arc on each ſide of the centre; the radius will be found on CB (in inches) at that point of it, where it is cut by the line drawn on CD. If the extent of the arc be not equal to that between the two Nos. 100. make uſe of the N° 50, in which caſe the radius found on CB, will be double of that ſought; or the arc may be lengthened by prob. 1. till it be of a ſufficient extent to admit the two Nos. 100. Adams's Geometrical and Graphical Eſſays, by Jones, 1797.

BEVELAND, in *Geography*, the name of two iſlands, formed by the ſeparate branches of the Scheldt, belonging to the ſtate of Zealand; the one, called *North Beveland*, is about 2 leagues long, and 1½ broad; it is ſouth of Schonen iſland, and on the ſouth ſide of the channel of the eaſt Scheldt, that here runs into the ſea; the other, called *South Beveland*, or *Zuid*, is near 8 leagues long, and 2½ wide, and comprehends the town of Goes and ſeveral villages; it divides the eaſt from the weſt Scheldt, and the two points of its weſt end approach to the channels oppoſite to the ports of Armuyd and Fluſhing. Both theſe iſlands have ſuffered much from inundations.

BEVELLING, in *Ship Building*, the art of hewing timber with a proper and regular curve, according to a mould which is laid on one ſide of its ſurface.

In order to hew any piece of timber to its proper bevel, it will be very expedient to make one ſide fair, and out of winding; a term uſed to ſignify that the ſide of the timber ſhould be a plane. Now if this ſide be uppermoſt, and placed horizontally, or upon a level; it is plain, if the timber is to be hewed ſquare, it may be done by a plummet and line; but if the timber is not hewn ſquare, the line will not touch both the upper and lower edge of the piece, or if a ſquare be applied to it, there will be wood wanting either at the upper or lower ſide. This is called within or without a ſquare. When the wood is deficient at the under ſide, it is called under-bevelling; and when it is deficient in the upper ſide, it is called ſtanding bevelling; and this deficiency will be more or leſs according to the depth of the piece: ſo that before the proper bevellings of the timbers are found, it will be ſometimes very convenient to aſſign the breadth of the timber; nay, in moſt caſes, it will be abſolutely neceſſary, eſpecially afore and abaft: though the breadth of two timbers, or the timber and room, which includes the two timbers, and the ſpace betwixt them, may be taken without any ſenſible error, as far as the ſquare body goes. For as one line repreſents the moulding ſide of two timbers, the foreſide of the one being ſuppoſed to unite with the aft ſide of the other, the two may be conſidered as one entire piece of timber. For further obſervations on this ſubject, and particular inſtructions with reſpect to the mode of bevelling by ribband lines, and by water-lines, ſee Murray's Treatiſe on Ship-building, p. 166, &c. See SHIP.

BEVENSEN, commonly called *Bahmſen*, a town of Germany, in the principality of Luneburgh-Zell, ſeated on the Elmenau, not far from Medingen.

BEVER, a river of Germany, which runs into the Weſer near Beverungen, in the circle of Weſtphalia.

BEVER *Head*, a cape on the ſouth-eaſt coaſt of Nova Scotia. N. lat. 44° 42′. W. long. 62° 20′.

BEVERA, a river of Italy, which paſſes by Soſpello, in the county of Nice, and runs into the Roia, 2 miles north of Vintimiglia.

BEVERAGE, in a general ſenſe, ſignifies *drink*. Hence nectar is ſaid to be the beverage of the gods. In *Writers of the Middle Age*, *beverage*, *beveragium*, or *liberagium*, denotes money given to an artificer or other perſon, to drink, over and above his hire or wages. Du-Cange.

BEVERGERN, in *Geography*, a ſmall town of Germany, in the circle of Weſtphalia, and biſhopric of Munſter, ſituate in the midſt of a moraſs, and having near it a ſalt ſpring; 21 miles north of Munſter.

BEVERIDGE, WILLIAM, in *Biography*, a learned and pious prelate of the Engliſh church, was born at Barrow in Leiceſterſhire, in 1638, and admitted in 1653 into St. John's college Cambridge, where he took his degrees of bachelor of arts in 1656, of maſter of arts in 1660, and of doctor of divinity in 1679. At the univerſity he diſtinguiſhed himſelf by his application to the learned languages, and particularly to oriental

oriental literature, in which he ſo much excelled, that at the age of 18 he wrote a treatiſe on the excellency and uſe of the oriental tongues, with a Syriac grammar. He was no leſs diſtinguiſhed at college by his early piety and exemplary ſobriety and integrity. Having taken orders in 1661, he was collated by Dr. Sheldon, biſhop of London, to the vicarage of Ealing in Middleſex, which he reſigned in 1672, upon being choſen rector of St. Peter's Cornhill, by the lord mayor and aldermen of London. In this ſituation, ſuch were his zeal and aſſiduity in the diſcharge of the duties of his office, not only in the pulpit but out of it, and ſuch was the ſucceſs that attended his labours, that he was denominated "the great reviver and reſtorer of primitive piety." His ſingular merit recommended him to the favour of his diocefan, biſhop Henchman, who, in 1674, collated him to one of the prebends of St. Paul's; and in 1681, biſhop Compton promoted him to the archdeaconry of Colcheſter, every pariſh of which he viſited in perſon. In 1684, he was inſtalled prebendary of Canterbury, and he alſo became chaplain to king William and queen Mary. Declining to accept the ſee of Bath and Wells, which was offered to him in 1691, he was conſecrated, in 1704, biſhop of St. Aſaph. In this elevated ſtation he proſecuted, with his accuſtomed zeal and diligence, every practicable meaſure for advancing the honour and intereſt of religion, both among the clergy and laity; recommending to the former the "duty of catechiſing and inſtructing the people committed to their charge, in the principles of the Chriſtian religion, to the end that they might know what they were to do, in order to ſalvation," and furniſhing them with a plain and eaſy "Expoſition upon the Church Catechiſm." After having poſſeſſed this new dignity for between three and four years, he died March, 5th, 1708, in the 71ſt year of his age, and was buried in St. Paul's cathedral. He left the greateſt part of his eſtate to the ſocieties for propagating the goſpel, and for promoting Chriſtian knowledge. Of his numerous works, thoſe publiſhed by himſelf were; 1. "De Linguarum Orientalium, præſertim Hebraicæ, Chaldaicæ, Syriacæ, Arabicæ, et Samaritanæ, præſtantiâ et uſu, cum Grammaticâ Syriacâ tribus libris traditâ," Lond. 1658, 8vo.; 2. "Inſtitutionum Chronologicarum libri duo, unâ cum totidem Arithmetices Chronologicæ libellis," Lond. 1669, 4to., 1705, 4to., and 1721, 8vo.; 3. "Συνόδικον, ſive Pandectæ Canonum S. S. Apoſtolorum, et Conciliorum ab Eccleſia Græca receptorum; necnon Canonicarum S. S. Patrum Epiſtolarum; unâ cum Scholiis Antiquorum ſingulis eorumannexis, et ſcriptis aliis huc ſpectantibus; quorum plurima et Bibliothecæ Bodleianæ aliarumque MSS. codicibus nunc primum edita; reliqua cum iiſdem MSS. ſummâ fide et diligentiâ collata, &c.," Oxon. 2 vols. fol. 1672; "4. Codex Canonum Eccleſiæ primitivæ vindicatus et illuſtratus," Lond. 1679, 4to. (See CANONS.) 5. "The Church Catechiſm explained, for the uſe of the dioceſe of St. Aſaph," Lond. 1704, 4to.: ſeveral times reprinted in a ſmaller volume. After his death, ſeveral of the biſhop's works, not intended by himſelf for publication, and in various reſpects injurious to his memory, were publiſhed by his executor. Theſe conſiſt of devotional tracts, among which are his "Private Thoughts upon Religion," a great number of ſermons, a ſyſtem of divinity, or "Theſaurus Theologicus," an "Expoſition of the 39 articles, &c." In his "Private Thoughts" the biſhop has incurred animadverſion; particularly with reſpect to his meditation upon the Trinity, in which he unreſervedly adopts the famous maxim of Tertullian, "credo, quia impoſſibile eſt." The theology of biſhop Beveridge was Calviniſtical; his extenſive learning has been univerſally allowed; his devotion inclined to myſticiſm; and as a reaſoner and writer, he has been extravagantly extolled by his admirers and panegyriſts, and no leſs ſeverely cenſured by others, for the quaintneſs and puerility of his ſtyle, the fallaciouſneſs and inconcluſiveneſs of his reaſoning, and his avowed oppoſition to rational ſentiments of religion. Theſe reflections, however, reſult from a peruſal of his poſthumous writings, the publication of which has been aſcribed to avarice or want of judgment on the part of his executor. All have concurred in allowing him the praiſe of the ſtricteſt integrity, of ſincere piety, of exemplary charity, and of great zeal for religion. Biog. Brit. Gen. Dict.

BEVERLACKE, in *Geography*, a river of Germany, which runs into the Aland, 3 miles ſouth of Seehauſen, in the old mark of Brandenburgh.

BEVERLAND, ADRIAN, in *Biography*, a man of genius and learning, who proſtituted his talents in the compoſition of ſeveral obnoxious books, was a native of Middleburgh in Zealand, about the middle of the 17th century, and ſtudied polite literature under Voſſius; and for this purpoſe he viſited Oxford in 1672. Devoting himſelf to the ſtudy of the law, he became a doctor and a counſellor; and as a philologer, he made himſelf known to the learned world. But the ſubjects of his ſelection, both for ſtudy and diſcuſſion, were principally of the impure and looſe kind; and of his licentious taſte, he gave ſome ſpecimens in his work, entitled "De jure ſtolatæ virginitatis, lucubratio academica," Leyd. 1680, 4to.; and in a treatiſe "De proſtibulis veterum," (on the brothels of the ancients), part of which was inſerted by Iſaac Voſſius in his commentary upon Catullus; but which he was diſſuaded by his friends from publiſhing. Before this time, viz. in 1678, he had rendered himſelf obnoxious by his book on original ſin, entitled "Peccatum originale κατ' ἐξοχὴν ſic nuncupatum philologicé problematicos elucubratum a 'Themidis alumno, &c.;" in which work he revived the notion of Cornelius Agrippa, that Adam's ſin conſiſted entirely in the commerce with his wife, and that original ſin is nothing but the inclination of the ſexes to each other. This book was condemned to be burnt by the magiſtrates at the Hague, and the author was committed to priſon, whence he was not liberated without paying a pecuniary fine, and taking an oath, that he would never write again upon ſuch ſubjects. He then removed to Utrecht, where his debauched manners expoſed him to freſh odium, and obliged him to withdraw to Leyden. Here he wrote a bitter ſatire againſt the magiſtrates and profeſſors under the title of "Vox clamantis in deſerto;" and at length, finding himſelf inſecure in Holland, he ſought an aſylum in England, where Iſaac Voſſius is ſaid to have procured for him a penſion upon the eccleſiaſtical revenues, which he expended in the purchaſe of ſcarce books and medals, and of obſcene pictures and prints, till he was reclaimed from his culpable mode of life by an acquaintance with the learned and worthy Dr. Edward Bernard. In token of his regret on account of his paſt conduct, and of the ſincerity of his reformation, he wrote a treatiſe "De Fornicatione cavenda admonitio, &c." publiſhed, probably, firſt at London in 1690, with a dedicatory epiſtle to Dr. Bernard, and afterwards in 1698, 8vo.; in which, notwithſtanding his pretended, or real reformation, ſome offenſive paſſages occur. After the death of Voſſius, he fell into extreme poverty, and into a ſtate of mental derangement; and probably ſoon after the year 1712, when he wandered through England, under an apprehenſion that 200 perſons had confederated together to aſſaſſinate him, he died. Gen. Dict.

BEVERLEY, or BEVERLY, in *Geography*, is a large corporate, borough, and principal town in that portion of Yorkſhire called the eaſt riding. It is ſeated at the foot of the wolds, on the banks of the river Hull, which is rendered navigable, by means of a ſhort canal, up to the town. This place appears to have been of ſome note previous to the time of Bede, whoſe preceptor, John of Beverley, archbiſhop of York,

York, founded and erected a monaſtery here, to which he retired, and wherein he died in 721. King Athelſtan having made a vow, before he proceeded againſt the Scots, inſtituted a college of ſecular canons, on his return to this town in 930, and alſo granted the freemen many immunities and privileges, which were allowed and confirmed by Henry I. and moſt of the ſucceeding monarchs to queen Elizabeth. By the laſt charter, which contains the heads of thoſe previouſly granted, the government of the town is veſted in a mayor, recorder, aldermen, and other ſubordinate officers. Though within eight miles of Hull, this town preſerves great reſpectability and commercial conſequence, from its fairs, markets, and trade. The ſeſſions for the eaſt riding of Yorkſhire are held here in a handſome hall, called the Hallgarth, which contains a regiſter office for deeds and wills, that relate to any lands in this part of the county. Beverley has ſent two members to parliament from the 26th of Edward I., except a few interminſſions in the reigns of Edward II. and III.

Here were formerly four churches, but only two remain; one of which is a large handſome edifice, and is called the Minſter. King Edward VI. and queen Elizabeth granted certain revenues for the ſupport and repairs of this edifice; but thoſe revenues being improperly applied, a Mr. Moyſer, M. P. for the town, procured a brief for the repair of it in 1708. His own contributions, with thoſe from his friends, amounted to 1500l.; which, with 800l. raiſed by the brief, were placed in the funds, and by the riſe of the South ſea ſtock, in the year 1720, he was enabled to complete the reparation and adornment of the church in his life-time. King George I. not only encouraged this work by a liberal donation of money, but gave the ſtone of the diſſolved monaſtery of St. Mary's in York towards the building; ſir Michael Warton alſo gave 500l. and bequeathed 4000l. more as a perpetual fund towards keeping it in repair. The eaſt window contains ſome fine painted glaſs; and the ſcreen between the nave and choir is much admired for its ornamental workmanſhip. The north wall of the great croſs-aiſle was at one period inclined from its perpendicular, but Mr. Thornton of York, invented a machine, which, by means of ſcrews, &c. reſtored it to its original poſition. The ancient fabric was conſumed by fire in September 1188. Here are ſeveral monuments for the Piercys, earls of Northumberland, who built a private chapel in the choir.

The principal trade of Beverley conſiſts in making of malt, oatmeal, and in the tanning of leather. The clothing trade was, at a former period, an object of much conſequence here, but at the time of Leland it was falling faſt to decay. Connected with the borough, are four large common fields, containing nearly 1000 acres, in which every burgeſs or freeman is allowed to paſture a certain number of cattle. In one of theſe fields is a mineral ſpa, which has proved ſerviceable in ſome cutaneous diſorders. There are ſeven alms-houſes in the town, and legacies left for erecting two more. Here is alſo a free-ſchool, whoſe ſcholars are allowed two fellowſhips in St. John's college Cambridge, alſo three ſcholarſhips and three exhibitions. Beverley is 183 miles north from London. It has weekly markets on Wedneſdays and Saturdays; five fairs in the year; and five annual great markets for hogs, &c. This town conſiſts of three pariſhes, called St. Martin's, St. Nicholas's, and St. Mary's; and according to the official population report in 1800, included 1228 houſes, and 5401 inhabitants.

BEVERLY, John of, in *Biography*, archbiſhop of York in the eighth century, was born at Harpham in Northumberland, and having embraced the monaſtic life, he became afterwards abbot of the monaſtery of St. Hilda. He was inſtructed in the learned languages by Theodore, archbiſhop of Canterbury, and was juſtly eſteemed one of the beſt ſcholars of his time. Some ſay that he ſtudied at Oxford, and took there the degree of maſter of arts; but as no degrees were then conferred in this univerſity, this fact has been diſputed. By Alfred, king of Northumberland, to whom his merit recommended him, he was advanced, in 685, to the ſee of Haguſtald, or Hexham, and in 687, tranſlated to that of York. Beverley was tutor to the venerable Bede, and intimate with Acca and other famous Saxon doctors, ſeveral of whom he engaged in writing comments upon the Scriptures. In 704, he founded a college for ſecular prieſts at Beverly, which, in honour of his memory, was endowed by our kings, and particularly by Athelſtane, with conſiderable immunities, ſo that it became an aſylum, or ſanctuary, for debtors and perſons ſuſpected of capital crimes. After he had governed the ſee of York 34 years, being tired with the tumults and confuſions of the church, he diveſted himſelf of the epiſcopal character, and retired to Beverly, and four years after died in *the odour of ſanctity*, on the 7th of May 721; and the day of his death was appointed a feſtival by a ſynod held at London in 1416. Bede, and other monkiſh writers, aſcribe to him ſeveral miracles. Between three and four hundred years after his death, his body was taken up by Alfric, archbiſhop of York, and richly enſhrined. He was the author of ſeveral homilies, and other religious pieces. Biog. Brit.

Beverly, in *Geography*, a townſhip, and poſt-town of America, in Eſſex county, Maſſachuſetts, ſeparated from Salem by a handſome bridge, and diſtant about 20 miles eaſt of north from Boſton, and 22 ſouth-weſt from Newbury port. It has two pariſhes, containing 3290 inhabitants. Thoſe of the pariſh next the harbour are devoted to the fiſhery, and the other branches of navigation. In the other part of the town, which is chiefly agricultural, is a cotton manufactory. lat. N. 42° 31'. W. long. 7° 50'.

Beverly's *Manor*, or *Iriſh tract*, is a tract of land, in Virginia, in N. lat. 38° 10', at the head of Maſſanutten's river, a weſtern branch of the Shenandoah, which riſes here by three branches, viz. Middle river, Lewis, and Chriſtian creeks, and lying between the Blue and the North ridge.

BEVERN, a town of Germany, in the circle of Upper Saxony, and duchy of Brunſwick, ſeated on the Weſer, 20 miles weſt of Eimbeck.

BEVERON, a river of Savoy, which runs into the Drance, 4 miles ſouth-weſt of Evian.

BEVERS, Little, lies to the weſt of point de la Hune, on the ſouthern coaſt of Newfoundland iſland, in North America, between cape de la Hune on the eaſt, and cape Raye on the weſt, being the ſouth-weſt point of the iſland.

BEVERSTADT, a town of Germany, in the circle of Lower Saxony, and duchy of Bremen, 24 miles north of Bremen.

BEVERSTONE, a village of Glouceſterſhire, England, is ſituated about two miles weſt of the town of Tetbury, and is noted for the ſtately remains of its ancient caſtle. This fortreſs is of uncertain foundation, but was undoubtedly a ſtrong place prior to the conqueſt. Earls Godwin, Swane, and Harald here met under the pretence of aſſiſting dward the confeſſor againſt the Welſh in 1048. Maurice, lord Berkeley, or de Gaunt, fortified and repaired it, and in 1227 was proſecuted by the king for doing ſo, without royal permiſſion. It was purchaſed by Thomas lord Berkely ſoon after the return of Edward III. from the battle of Poictiers. Many of the ſpoils and ranſoms from that battle were appropriated to enlarge and beautify this caſtle, which was uſed as a manſion till the great rebellion, when it was ſtrengthened, and held for the king, but beſieged by, and ſurrendered to Col. Maſſie. Great part of the caſtle, with a dwelling-houſe within its walls, was ſoon afterwards deſtroyed

ſtroyed by fire. It was originally a ſquare building, with a tower at each corner, one of which ſtill remains, with fragments of walls, and the greater part of a chapel. This has a beautiful arched roof, and on the right ſide of the altar is a ſhrine of tabernacle work, with a lavaratory, a cloſet in which is a confeſſional, and over it a priſon. The moat ſurrounding the whole, was about 200 yards in circumference. At a ſhort diſtance north of the caſtle is the pariſh church, which is a ſmall plain building. Rudge's Hiſtory of the County of Gloceſter.

BEVERUNGEN, a town of Germany, in the circle of Weſtphalia, and biſhopric of Paderborn, at the conflux of the Bever and the Weſel, near which are ſprings of ſalt water, 26 miles ſouth-eaſt of Paderborn.

BEVERWYCK, John Van, or Beverovicius, in *Biography*, not more known and eſteemed as a phyſician than as a magiſtrate, and member of the adminiſtration in his country, having attained to high honours in both thoſe capacities, was born at Dordrecht in Holland, in 1594. Being of a diſtinguiſhed family, he had the advantage of receiving inſtructions in claſſical literature from Gerard John Voſſius, and afterwards of ſtudying the different branches of medicine under the ableſt maſters in France and Italy. Returning to his own country, he took the degree of doctor in medicine at Padua, about the year 1624. His works are numerous. Thoſe moſt deſerving notice are, "Epiſtolica queſtio, de termino vitæ fatali an mobili, cum doctorum reſponſis;" 8vo. 1634, Dord. Whether there is a fixed term, beyond which life cannot be extended, he determines in the negative. "Montanus, Refutatio argumentorum, quibus medicinæ neceſſitatem impugnat;" 8vo. 1634, Dord.: in which he anſwers the cavils of the ſieur Montagne againſt phyſicians, and ſhews the neceſſity of the art. "Idea Medicinæ veterum," 8vo. 1637, Leiden. A compendium of the practice of medicine, taken from the moſt valuable writers on the ſubject. "Epiſtolicæ queſtiones cum doctorum reſponſis," 8vo. 1644, Rotter. A collection of letters on ſubjects pertaining to medicine, to which are added, the Elogia of Medicine by Eraſmus, Cardan, and Melancthon. His works, of which Haller has given a complete liſt, were publiſhed together in 4to. at Amſterdam, 1651. They have moſt of them paſſed through ſeveral editions. He died Jan. 19th 1647, and was honoured with an epitaph by his friend Heinſius. Haller Bib. Med. Gen. Biog.

Beverwyck, in *Geography*, a town of North Holland, with a ſmall harbour in the Wyckermeer, which is a continuation of the Ye, 3 leagues north of Haerlem.

BEUF, John Le, in *Biography*, a learned and laborious French writer, was born at Auxerre in 1687, and educated at Paris. After his return to his native town, he was made canon of its cathedral in 1711, and during his reſidence there frequently attended the deputies of the clergy at Sens, to aſſiſt them in reforming the liturgies of that dioceſe. In 1734, he was engaged by the archbiſhop of Paris in the compoſition of the chant in the new breviary and miſſal of that city; and from this time he chiefly reſided at Paris. He was admitted an aſſociate of the academy of belles lettres and inſcriptions in 1740, and twice obtained the prize of that academy, and five times that of the French academy at Soiſſons. He was one of the moſt indefatigable, intelligent, and ſatisfactory eccleſiaſtical antiquaries of France. The catalogue of his works from 1716 to 1741, fills 12 pages in folio in the Burgundy library: and his ſubſequent productions for the laſt 14 years of his life, are nearly as numerous. His "Traité ſur le chant eccleſiaſtic" is full of curious reſearches, and, perhaps, the ſafeſt guide on the ſubject which a muſical hiſtorian of the firſt ages of the church can conſult. This prodigy of learning died in 1760.

The beſt known of his numerous works, beſides that already mentioned, are "A Collection of various writings, tending to illuſtrate the hiſtory of France," 2 vols. 12mo. 1738; "Diſſertations on the eccleſiaſtical and civil hiſtory of Paris," 3 vols. 12mo.; "Memoir on the hiſtory of Auxerre," 2 vols. 4to. 1743; "Hiſtory of the city and of all the dioceſe of Paris," 15 vols. 12mo.; more than 200 "Memoirs," or "Hiſtorical Diſſertations," inſerted in the journals of the times; and a variety of diſſertations printed in the Memoirs of the Academy of Inſcriptions. He alſo liberally communicated a number of original pieces which he found in his aſſiduous reſearch, to learned men engaged in different works. Nouv. Dict. Hiſt.

Beuf, *Riviere au*, in *Geography*, a river of America, that diſcharges itſelf eaſtward into Miſſiſippi river, in N. lat. 39° 4', about 48 miles by the courſe of the river, above the mouth of the Illinois, and 7 miles ſouth from Riviere Oahaha.

Beuf, *Small Le*. See *Le* Bœuf.

BEVIEUX, a village of Swiſſerland, in the government of Aigle, in that part of the Valais which belongs to the republic of Berne. Bevieux is diſtant about 5 miles from the ſmall town of Bex, and is famous for its ſalt ſprings. Mr. Coxe informs us, that he went into the mountain about 3000 feet, almoſt horizontally. The gallery is 6 feet high, and 4 broad, and nicely hewn and hollowed in a black rock, veined in ſome places with white gypſum. The ſalt is procured from ſprings, which are found within a ſolid rock, perforated at a great expence; the richeſt ſource yields 28 pounds of ſalt per cent. and the pooreſt but half a pound. Near theſe ſprings are ſeveral warm ſources, which contain a mixture of ſalt, but are ſo ſtrongly impregnated with ſulphur, as to flame when a lighted candle is put into the pipe through which they flow. No ſolid ſalt, except a few cubes, has been yet diſcovered: but the mountain is replete with its particles. Rocks of white gypſum, or alabaſter, mixed with bluiſh clay, are common near the ſprings, in the ſame manner as may be obſerved in the pits of Northwich in Cheſhire. After travelling in this ſubterraneous paſſage near three quarters of a mile, Mr. Coxe obſerved a great wheel, 35 feet in diameter, which raiſes the brine from the depth of about 70 feet. From this place is a ſhaft 300 feet high, which is cut through the mountain to the ſurface, for the purpoſe of introducing freſh air. He noticed two reſervoirs hollowed in the ſolid rock for holding the brine; one was 160 feet ſquare, and 9 deep. In proceſs of time, the workmen pierced the rock 25 feet deeper, and cut a gallery 100 feet long, and they formed a third reſervoir, containing 5500 cubic feet. The brine depoſited in theſe reſervoirs is conveyed by means of 2000 pipes, about a league to Bevieux, where the ſalt is extracted. The brine pits near Aigle contain only from two to one half per cent. and yield annually about a third as much as thoſe of Bevieux, or about 5000 quintals. The ſalt is much whiter and heavier than that of Bevieux, and conſequently bears a higher price. Theſe, which are the only ſalt-works in Swiſſerland, ſcarcely yield a net yearly profit of more than 3000l., and furniſh only one-twelfth of the annual conſumption of the canton. The remainder is procured chiefly from France, at a moderate price, ſtipulated by treaty. Coxe's Travels, vol. ii. p. 105.

BEUIL, in *Geography*, the chief place of a canton, in the diſtrict of Puget-Theniers, and department of the maritime Alps, containing 468 inhabitants; thoſe of the canton amount to 2133. Its territory comprehends 225 kiliometres and 6 communes.

BEVILE', in *Heraldry*, denotes a thing broken, or opening like a carpenter's rule.—Thus he beareth argent a chief bevilé vert, by the name of *Beverlis*.

BEVIN, Elway, in *Biography*, among our eccleſiaſtical compoſers in the time of James I., juſtly deſerves to be

ranked with the muſical luminaries of that reign. He was a ſcholar of Tallis, which is diſcoverable by his works; but it is not quite ſo eaſy to diſcover how it could have been at the recommendation of his maſter, who died 1585, that he was ſworn in gentleman extraordinary of the chapel royal, in 1589, as has been ſaid. His ſervice in D minor, printed in Boyce's collection, has the true ancient caſt of modulation, the ferrugo pretioſa upon it, which gives a dignity to its effects, for which we can now hardly account. The accents, as uſual with old maſters, are often erroneouſly placed; but if that imperfection be removed, or regarded with indulgence, the compoſition muſt be allowed, in point of harmony and modulation, to be admirable. And there are ſome grand effects produced by pauſes and long notes without changing or infringing the original meaſure, that afforded us very pleaſing ſenſations. Elway Bevin was, indeed, a man of genius; and it is to be lamented that more of his compoſitions have not been preſerved. Beſides his appointment in the chapel royal, he was organiſt of Briſtol cathedral, and the maſter of Dr. Child. But notwithſtanding his abilities and great age, he was diſmiſſed from all his employments, in 1636, on being diſcovered to adhere to the Romiſh communion.

In 1631, he publiſhed a work replete with harmonical erudition, entitled "A Briefe and ſhort inſtruction of the art of muſicke, to teach how to make diſcant of all proportions that are in uſe: very neceſſary for all ſuch as are deſirous to attaine to knowledge in the art; and may by practice, if they can ſing, ſoone be able to compoſe three, foure and five parts: and alſo to compoſe all ſorts of canons that are uſuall, by theſe directions of two or three parts in one, upon a plainſong," by Elway Bevin. thin 4to. of 52 pages.

This work, however uſeleſs it may be deemed now, muſt have been of ſingular ſervice to young ſtudents in times when canons were regarded as the greateſt efforts of human intellect, and the ſolution of theſe enigmas was equally difficult with that of the moſt abſtruſe and complicated problems in Euclid. Micheli Romano publiſhed a ſimilar work at Venice, 1615, and Valentini another at Rome, 1655. See Micheli, and Valentini.

BEVIO, in *Geography*, a ſmall village of Swiſſerland, ſeated near the Julian Alps, upon the Little Rhine, in the high road leading to Coire. Bevio and Valmorara form one community, governed by 11 magiſtrates; though the number of voters, who appoint theſe magiſtrates, ſcarcely exceeds 40. The chief is called "Miniſtrale," and is confirmed every year, for which each voter receives a florin. About one-third of the merchandize from Como to Coire paſſes by Bevio; the greater part is ſent by Splugen.

BEUNTERSHEIM, a town of Germany, in the circle of the Upper Rhine, and biſhopric of Worms, 6 miles ſouth of Worms.

BEURATH, a town of Bohemia, in the county of Glatz.

BEURERIA, and Beurreria, in *Botany*. See Calycanthus, and Ehretia.

BEURRE, in *Geography*, a town of France, in the department of the Doubs, and chief place of a canton in the diſtrict of Beſançon, 2 miles ſouth of Beſançon.

BEURRY, a town of France, in the department of the Meuſe, and chief place of a canton in the diſtrict of Bar le Duc, 1¾ league weſt of Bar-le-Duc.

BEURS, William, in *Biography*, a painter, was born at Dort in 1656, and diſcovering a natural genius for drawing and deſigning, he was placed, at the age of 18, under the inſtruction of William Drillenburg. He painted in the ſtyle and manner of his maſter, almoſt equalling him in the freedom of his hand, and the clearneſs of his colouring, and ſurpaſſing him in the correctneſs of his deſign. Addicting himſelf to a diſſolute life, he obtained neither the reputation nor the wealth which his talents, diligently exerciſed, might have enabled him to acquire. He painted portraits, landſcapes, and flowers. Pilkington.

BEUS, in *Ancient Geography*, a river of Macedonia, mentioned by Livy and Steph. Byz., near which was a town called Beus, *Beue*, according to the latter.

BEUTHEN, or Nieder Beuthen, in *Geography*, a town of Germany, in the circle of Upper Saxony, and principality of Carolath, on the Oder, containing two churches; 3 miles S.W. of Ziegenbruck.

Beuthen, *Nieder*, a town of Sileſia on the Oder, in the duchy of Glogau. It has ſuffered much by war and fire; diſtant 13 miles W.N.W. from Ober Glogau. N. lat. 51° 42′. E. long. 15° 51′.

Beuthen, *Ober*, a town of Sileſia, formerly belonging to the principality of Jagerndorf, but ſince to the principality of Oppeln. It had anciently a productive mine of ſilver; diſtant 40 miles E.S.E. from Oppeln. N. lat. 50° 16′. E. long. 18° 53′.

BEUTSCHEN, a town of Poland, in the palatinate of Poſen, 44 miles weſt of Poſen.

BEUVRON, a town of France, in the department of the Calvados, and chief place of a canton in the diſtrict of Pont l'Evêque, 12 miles ſouth of Caen.—Alſo, a river of France, which runs into the Loire, 2 leagues below Blois.

BEUVRY, a town of France, in the department of the Straits of Calais, and chief place of a canton in the diſtrict of Bethune, half a league eaſt of Bethune.

BEVY, among *Sportſmen*, is uſed to ſignify a brood of quails. Thus alſo we ſay, a *covey* of partridges, a *nide* of pheaſants, and a *pack* of grouſe. *Bevy* is ſometimes uſed among foreſters to expreſs a herd of deer, though it is much leſs frequently uſed in this ſenſe than in the former.

BEUZEVILLE, in *Geography*, a town of France, in the department of the Eure, and chief place of a canton in the diſtrict of Pont-Audemer; 2½ leagues weſt of Pont-Audemer. It contains 2457 perſons, and the population of the canton amounts to 12,254. Its territory includes 192½ kilometres and 20 communes.

BEWCASTLE, a pariſh and village of Cumberland, England, is rendered intereſting to the topographer and antiquary from the Roman relics that have been diſcovered within its limits, and from the ſingular obeliſk in the churchyard. This pariſh is ſuppoſed to have included the Roman ſtation where part of the Legio-Secunda Auguſta was garriſoned to guard the workmen employed in erecting the famous Roman wall that ſeparated England from Scotland. Many veſtiges of ancient buildings are yet remaining; and numerous Roman coins, and ſome inſcribed ſtones, have been found here. The obeliſk, which has furniſhed a theme for much diſſertation, contains various ſculptured ornaments, with a Roman inſcription, and ſome figures in baſſo-relievo. The church, with the caſtle, are included within an intrenchment. The latter, now in ruins, appears to have been of a ſquariſh form, and was battered down by the parliament's forces in 1641. In this pariſh are two ſchools ſupported by ſubſcription, whoſe maſters have about ten pounds each per annum, with the privilege of a whittle gate. This was a peculiar cuſtom, formerly very common in Cumberland, and the neighbouring counties, and now prevails in ſome villages. It is a privilege given to the maſter of applying to his pupils' parents in rotation, for proviſions. Several thouſand ſheep and black cattle are fed on the hills and waſte pariſh. Hutchinſon's Hiſtory of Cumberland.

BEWDLEY, a market and borough town of Worceſterſhire in England, is pleaſantly ſituated on the banks of the river Severn, whoſe navigable ſtream has given proſperity to the place.

It was formerly included within the marſhes of Wales, but by a ſtatute of Henry VIII. was annexed to the county of Worceſter. Leland deſcribes this place as remarkable for the "wonderful height of the trees in the adjacent foreſt of Wyre," for its "beautiful ſituation," and for the palace of Tichen-hall, which Henry VII. built to be a place of retirement for prince Arthur. The ceremony of this prince's marriage in perſon, with Catharine of Arragon, by proxy, was performed here on the 19th of May 1499. King Henry VI. gave all the ſtone for building the bridge acroſs the Severn, which was erected by Edward IV. On the middle pier of this, ſtands a gate-houſe, part of which is for the corporation's priſon.

The town is in the pariſh of Ribbesford, where there is an ancient moated houſe, in which was found the manuſcript copy of the life of lord Herbert of Cherbury. Here is a chapel, which was built on the ſite of an ancient wood ſtructure in 1748. A new ſet of ſhambles was alſo erected in 1783; and the town partakes of the benefits of a free grammar ſchool, which was founded in the latter part of queen Elizabeth's reign; alſo ſome alms-houſes, and a charity ſchool. The manufactures and trades of this town were formerly very conſiderable, but they are now principally confined to tanning, horn-work, matting, and a few others. Bewdley ſeems to have been firſt incorporated by king Edward IV. whoſe charter grants the freemen great privileges and immunities by ſea and land. Theſe were confirmed by Henry VIII., and again by James I. This charter was ſurrendered in the time of Charles II.; but in the next reign another was granted, which on a trial in 1707, was determined to be void. A new one was therefore obtained from queen Anne, but this produced ſome litigation, which at length was determined in its favour. This empowers the bailiff and 12 capital burgeſſes to return one member to parliament. Here were formerly two weekly markets, on Wedneſdays and Saturdays; but the latter is only continued; which, with three fairs, annually attract much company and trade to the town.

Bewdley is 129 miles N.W. from London. It contains 840 houſes, and 3671 inhabitants. Naſh's Hiſtory of Worceſterſhire.

BEWITS, in *Falconry*, denotes a piece of leather to which a hawk's bells are faſtened, and buttoned to his legs.

BEX, in *Geography*, a ſmall town of Swiſſerland, in the canton of Berne, about 4 miles S.S.E. of Aigle, and 5 miles from the ſalt-works at Bevieux. (See Bevieux.) Between Aigle and Bex is a picturesque view of the caſtle of St. Tryphon, on the ſummit of an inſulated rock in the middle of the plain; it is quite ſurrounded with wood, and realiſes Milton's deſcription of an ancient caſtle,

"Boſom'd high in tufted trees."

It is ſaid to be built of marble, and probably of a beautiful black ſpecies in the vicinity. St. Tryphon was a Phrygian, and is ſaid to have ſuffered martyrdom at Nice in the year 251, under the perſecution of the emperor Decius.

BEXUQUILLO, in the *Materia Medica*, a name given to the white *ipecacuanha*, which the Spaniards bring from Peru, as the Portugueſe do the brown from Braſil.

BEY, or Beg, denotes a governor of a country, or town, in the Turkiſh empire.

The Turks write the word *begh* or *bek*, but they pronounce it *bey*: properly it ſignifies *lord*, but it is particularly applied to a *lord of a banner*, whom in the ſame language they call *ſangiak-beg*, or *bey*; *ſangiak*, which among them ſignifies *banner* or *ſtandard*, being the badge of him who commands in an important place of ſome province, having under him a conſiderable number of ſpahis, or horſe.

Each province in Turkey is divided into ſeven of theſe *ſangiaks*, or *banners*, each of which qualifies a bey; and theſe are all commanded by the governor of the province, whom they alſo call *beghiler-beghi*, or *beyler-bey*, i. e. *lord of the lords*, or *beys* of the province.

Theſe beys are, in a great meaſure, the ſame that *banderets* formerly were in England.

It has already been obſerved, under the article Bashaw, that when the military ariſtocracy of the Mamlouks in Egypt was aboliſhed by Selim, ſultan of the Ottomans in 1507, he eſtabliſhed a form of government, which was calculated to preſerve all the different members of the ſtate in a condition of dependence upon himſelf. With this view, he appointed, beſides a pacha, a divan, or council of regency, compoſed of the pacha and the chiefs of the ſeven military corps. At the time of this appointment it was agreed, that the 24 governors, or beys of the provinces, ſhould be choſen from the Mamlouks; and to them were entruſted the care of reſtraining the Arabs; ſuperintending the collection of the tributes, and the whole civil government of the country; but their authority was purely paſſive, and they were to be conſidered merely as the inſtruments of the determinations of the council. By this inſtitution, which is ſtill obſerved in ſome inſtances, it was ordained, that the pacha ſhould be contented to ſhare the power of the beys, and that the duration of his authority ſhould depend on their collective will. The power of the pacha was very extenſive; but it has been gradually diminiſhed, and almoſt annihilated by the intrigues and ambition of the beys. His juriſdiction was rather civil than military. He was always preſident of the divan, which was held in the caſtle where he reſided. But that council has, in later times, commonly aſſembled in the palace of one of the chief beys, except when a firmân or mandate is received from Conſtantinople, when the beys are ſummoned to the caſtle to hear the commands of the Porte. The few who attend, as ſoon as the reading is finiſhed, anſwer, as is uſual, "Eſmâna wa taâna," "we have heard, and we obey;" but on leaving the caſtle, their general voice is "Eſmâna wa awſâna," "we have heard, and ſhall diſobey." All theſe beys had been Mamlouks, or military ſlaves, who were not natives of Egypt, but imported when very young from Georgia, Circaſſia, and Mingrelia, and purchaſed for 50, or not more than 100 ſequins. Many of theſe are deſcended from Chriſtian parents, and have been ſlaves from their youth. Some few have been priſoners, taken from the Auſtrians and Ruſſians, who have exchanged their religion for an eſtabliſhment. When the ſupply obtained in this way proves inſufficient, or many have been expended, black ſlaves from Nubia, and other interior parts of Africa, are ſubſtituted in the room of the others, and if found docile, are armed and accoutred like the reſt. The Mahometans in general, and the Egyptians in particular, treat their ſlaves with great kindneſs. At Cairo, when a ſlave is legally purchaſed in the market, if he feel diſcontented with his maſter, he has only to ſay, "carry me to the market," and the maſter is legally compellable to offer him for ſale. The child of a female ſlave, begotten by her maſter, is "ipſo facto" free, and a ſlave may authorize a free perſon to purchaſe his emancipation. The Chriſtian children, bought by the beys, and the principal inhabitants of Cairo, are educated with the ſame care as their own children, in every thing neceſſary to accompliſh the character of a Mahometan lord. They are inſtructed in every neceſſary exerciſe of agility and ſtrength, and they are in general diſtinguiſhed by the elegance and beauty of their perſons. Some of them are excellent ſcribes; but many can neither read nor write. When their education is finiſhed, they procure employments in the army; and after emancipation, theſe favoured ſlaves retain the moſt lively gratitude and

affection to the generous maſters, to whom they owe their fortunes, and both their political and moral exiſtence; nor do they ever quit them in the hour of danger. Thus it often happens, that a maſter, when he finds any of his ſlaves poſſeſſed of extraordinary talents, and tried fidelity, ſpares no pains or expence to raiſe him to a more conſiderable employment than that which he himſelf occupies; and thus he at length acquires ſovereign power. In order to attain this power, it is neceſſary to be a Mamlouk, that is, the native of a foreign country, as even the children of thoſe, who riſe to offices of ſtate, do not enjoy the right of ſucceſſion. Hence it happens, that as the ſon of a bey is not honoured with any particular conſideration, the women, perhaps, procure abortions. Of 18 beys, whoſe hiſtory was known to Mr. Brown, only two had any children living. Volney obſerves, that during 550 years Mamlouks have been in Egypt, and that not one of them has left ſubſiſting iſſue; but all their children periſh in the firſt or ſecond deſcent. Hence he infers, that thoſe who are transferred from the vicinity of mount Caucaſus, to the banks of the Nile, are incapable, by the influence of the climate, of perpetuating their progeny. To this circumſtance it is owing, that the Mamlouks are replaced by ſlaves brought from their original country. From the time of the Moguls, this commerce has been continued on the confines of the Cuban and the Phaſis, in the ſame manner as it is carried on in Africa, by the wars among the numerous tribes, and by the miſery of the inhabitants, who ſell their own children for a ſubſiſtence.

Diſtinguiſhed by favouritiſm or merit, the Mamlouk becomes a caſhef, or kiaſchef, and in time a bey. The chief cauſe of preferenceariſes from political adherence to ſome powerful leader. The number of theſe beys has ſeldom or ever been complete; and the revenues of the vacant places were probably ſhared among the reſt, who were actual occupants of their office. Each of theſe beys is nominally choſen by thoſe that remain; but in fact appointed by one of the moſt powerful.

The "Yenk-tchery Aga," and ſeveral other officers, are enumerated among the 24 beys. Beſides being governors of certain diſtricts of Egypt, ſeveral of the beys receive other dignities from the Porte. Such are the "Scheik-el-belled," or governor of the city, which is an office merely civil, unaccompanied with any military power; the "Defterdar," or accountant general; the "Emir el Hadj," or leader of the ſacred caravan; and the "Emir ef Said," or governor of the Upper Egypt; which laſt two offices are annual. Theſe officers have alſo revenues allotted them by the Porte, ill-defined, and liable to much abuſe. Of the other beys, each appoints all officers and governors within his diſtrict, putting into it ſome ſlave of his own, who is compelled to render an account of the receipts; of which a part is appropriated to ſupport the grandeur of his maſter. An opulent bey may have from 600 to 1000 purſes annually; the revenue of Murad Bey more than double that ſum. The inferior beys may have 300 purſes, or 15,000l. The revenues of the beys are raiſed by a land-tax and the produce of the cuſtoms, amounting together to near two millions ſterling, of which but a ſmall proportion reaches the coffers of the Porte. Every bey ſits in judgment on caſes of equity. Theſe perſonages are very obſervant of their reſpective juriſdictions; and no bey will impriſon a man liberated by another. Although ſometimes too impetuous, they nevertheleſs diſplay great acuteneſs and knowledge of characters. This government poſſeſſes at leaſt every advantage of publicity, as every bey is a magiſtrate. But the juſtice of the rulers is ever liable to the omnipotent influence of gold. Each bey appoints his caſhefs, or lieutenants. Theſe officers preſide each over a town or village, collecting the revenues, and judging ſmall cauſes; but an appeal lies to the bey. The beys and the caſhefs are, from their ignorance, conſtrained to employ Copts as accomptants in adjuſting and receiving the revenues, that duty being of an intricate nature, and requiring great local knowledge. The authority of a caſhef is as arbitrary as that of a bey.

The beys in Egypt have been gradually acquiring an increaſe of authority and influence, and reducing the power of the Ottoman Porte to a feeble and degraded ſtate. To this ſeveral circumſtances have contributed; ſuch as the unreſtrained traffic of ſlaves; the neglect of the affairs of this province on the part of the Ottoman Porte; the extenſion of the power of the divan, and the reſtraint of that of the pachas, and the conſequent uncontroulable influence of the janizaries and Arabs. To which may be added, the change that took place in the condition of the ſoldiers, by their becoming citizens, and by the marriages they contracted, and the change alſo introduced into their diſcipline; and, more eſpecially, the permiſſion granted to the chiefs of poſſeſſing diſtinct property, lands, and villages, dependent on the Mamlouk governors, whom it became neceſſary to conciliate, in order to prevent their oppreſſion; and the aſcendancy acquired from that moment by the beys over the ſoldiers, and increaſed by the great riches accruing from their governments. Theſe riches they employed in multiplying their ſlaves; and, after emancipating them, advancing them in the army, and promoting them to various employments. By ſuch means Ibrahim, one of the kiayas or veteran colonels of the janizaries, rendered himſelf, in 1746, maſter of Egypt; for he had ſo multiplied and advanced his freedmen, that, of the 24 beys, which ſhould be their number, no leſs than eight were of his houſhold. His influence was alſo the more certain, as the pacha always left vacancies in the number, in order to receive the emoluments. On the other hand, the largeſſes he beſtowed on the officers and ſoldiers of his corps, attached them to his intereſt, and Rodvan, the moſt powerful of the Arab colonels, uniting with him, compleated his power. The pacha became a phantom, and the orders of the ſultan vaniſhed before thoſe of Ibrahim. At length, about the year 1766, Ali Bey gained a decided aſcendancy over his rivals, and under the titles of "Emir Hadj," and "Scheik el Belled," rendered himſelf abſolute maſter of the country. (See Ali Bey.) Mohammed Bey, ſurnamed "Aboudahab," or father of gold, from the luxury of his tent and capariſons, who ſucceeded him in 1773, during a reign of two years, diſplayed nothing but the ferocity of a robber, and the baſeneſs of a traitor. Upon his death in 1776, Murad, a favourite of Mohammed, was advanced to the dignity of bey; but he had a formidable competitor in Ibrahim, who had been a ſlave of Ali Bey the Great. The two rivals, however, adopted conciliatory meaſures, and entered into an agreement to divide the authority, on condition that Ibrahim ſhould retain the title of "Scheik el Belled." This union was a prudential meaſure, and neceſſary to their ſafety; for ſince the death of Ali Bey, the beys and caſhefs, who owed their promotion to his houſe, repined at ſeeing all the authority transferred to a new faction; and after ſeveral intrigues and cabals, formed a confederacy, under the denomination of the houſe of Ali Bey. The chiefs of this confederacy were Haſſan Bey, formerly governor of Djedda, and Iſmael, the only remaining bey of thoſe created by Ibrahim Kiaya; and they conducted their plot ſo well, as to oblige Murad and Ibrahim to abandon Cairo, and retire as exiles into the Said. Theſe exiles, being reinforced by the refugees, returned, and compelled the confederates, Iſmael and Haſſan, to make their eſcape

eſcape into the Said. Ibrahim and Murad have ſince ruled Egypt, the former as "Scheik el Belled," and the latter as "Defter-dàr," though not without mutual jealouſies and attempts to deſtroy each other. They, however, conſpire together to recruit the number of the Mamlouks, and to collect treaſure from all quarters. In the year 1791, Salah Aga, a ſlave of Murad Bey, was deputed, from the government of Egypt, to negociate their peace with the Porte. He carried with him preſents of horſes, rich ſtuffs, &c. He was well received, and was afterwards appointed "Waquil eſ Sultan," i. e. agent or attorney to the ſultan in Cairo. This office was probably given him to engage him in ſeconding the efforts of the court for diſuniting the beys; but it was ineffectual. Theſe had formerly experienced the evils of diviſion, and were now united by common intereſt, grown rich, and well provided with ſlaves. It is ſaid, tht no tribute has ſince that time found its way to Conſtantinople. Ibrahim and Murad are conſidered as uſurpers by the beys of Upper Egypt, who are favoured by the Porte. The moſt powerful houſe is that of Ibrahim, who has about 600 (according to Volney, but about 1000, ſays Mr. Browne,) Mamlouks. Next to him is Murad, who has not above 400 Mamlouks, ſays Volney; but according to Browne, they amounted, in 1796, to about 1700. He was originally a ſlave of Mohammed Bey, and ſucceeded in defeating and taking priſoner Ali Bey the Great. He is deteſted by the Porte. He is deſcribed by Sonnini, as handſome and martial in his appearance; his chin is covered with a buſhy black beard; his thick eye-brows deſcribe arches of ebony over his large eyes, which ſparkle with vivacity and fire. A long ſcar in one of his cheeks adds to the fierce caſt of his countenance. To great bravery, he joins ſingular addreſs and extraordinary ſtrength. He has been known, when riding by an ox, to cut off its head with one ſtroke of his ſcimitar. An intrepid warrior, capable of enduring the ſevereſt hardſhips, an excellent horſeman, dexterous and powerful in the uſe of the ſabre, courageous in adverſity, bold in enterpriſe, cool in action, but terrible in onſet. Murad, with inſtruction, might have become a great general. His proud deportment, and magnificent diſpoſition, give him the dignified appearance of a ſovereign; but injuſtice, ignorance, and cruelty, have rendered him a ferocious tyrant. Murad, ſays Mr. Browne, is one of thoſe beys who can neither read nor write. Of the profuſion of this bey, Sonnini has given the following account. In his camp were erected immenſe tents, divided into ſeveral apartments, for the accommodation of himſelf and his principal officers. The floors were covered with the moſt beautiful carpets, and the interior decorations conſiſted of the richeſt gold and ſilver ſtuffs that the manufactories of Lyons could afford. Nothing could equal the magnificence of his cavalry. Gold and ſilver ornaments, with the choiceſt embroidery on Morocco leather, glittered with a dazzling luſtre in the rays of a burning ſun; and the houſings of the ſaddles, trimmed with a broad gold lace, were made of thoſe handſome velvets, the ſmall and delicate patterns of which diſplay the elegant taſte that prevails in the productions of the manufacturers of Lyons. His profuſion is ſupplied by his rapacity. He is accuſtomed to have from the mint daily, for his pocket expences, 500 half mahbûbs, and his wife the ſame. This amounts to 1500 piaſtres, and is only a ſmall part of his diſburſements. He is married to the widow of his maſter, the daughter of the celebrated Ali Bey. Next in power to Murad, is Mohammed Bey Elfi, whoſe name imports that he was bought for 1000 patackes. His maſter was Murad Bey, juſt mentioned. He is repreſented as quick in apprehenſion, and impetuous in action. His power is great and increaſing; he has 800 Mamlouks. Ibrahim Bey, "el Uali," a name derived from the ſecond military magiſtracy in the city of Cairo, is a young man about the ſame age with the laſt mentioned, of a ſedate, but firm character, married to the daughter of the elder Ibrahim, and attached to his intereſts. He has 6 or 700 Mamlouks. Aiûb Bey, "al Zogheir," or junior, is another powerful leader, diſtinguiſhed by his ſuperior capacity, and on all occaſions conſulted by the reſt. He has not many Mamlouks; he is prudent and economical, and rarely accuſed of extortion. Fâtmé, now the aged daughter of the famous Ali, is held in much reſpect by all the beys. Even Murad, her huſband, treats her with reverence. When a bey is appointed to a government, he never fails to pay a viſit to this old lady, who lectures him on his duties, and will ſay to him, "Do not pillage the people; they were always ſpared by my father."

Of the ſyſtematic rapacity of the beys, the following inſtance is mentioned. Ibrahim Bey, at a feſtival occaſioned by the marriage of his daughter to another powerful bey in 1792, invited to his houſe a famous ſinger, who had been employed, during the preceding day and night, in the exerciſe of her profeſſion, and who had received conſiderable donations. She readily complied, expecting employment, and liberal recompence. The bey aſked her "How many half ſequins did you collect yeſterday?" She replied, "about ten thouſand." "Pay me eight thouſand then," ſaid the bey, "and I will give you a note of credit on Ibrahim Jeuhari, my ſecretary." The money was paid, but the woman was turned out of the houſe without receiving any ſecurity whatever; and is ſaid to have died of the diſappointment. Volney's Travels through Syria and Egypt, vol. i. Sonnini's Travels in Upper and Lower Egypt, p. 424, &c. Browne's Travels in Africa, &c. p. 47, &c. See Bashaw, and Mamlouk.

Bey *of Tunis*, denotes a *prince*, or *king* thereof; anſwering to what at Algiers is called the *dey*. He is choſen out of the army; each order, even the moſt inferior, having an equal right and title to that dignity with the higheſt.

In the kingdom of Algiers, each province is governed by a bey or vice-roy; who is appointed and removed at pleaſure by the bey; but has a deſpotic power within his juriſdiction; and at the ſeaſon for collecting the tribute from the Arabs, is aſſiſted by a body of troops from Algiers.

The kingdom of Tunis is not divided into provinces, like that of Algiers, and governed by provincial beys, or vice-roys; but the whole is under the immediate inſpection of the bey himſelf, who collects the tribute in perſon. For this purpoſe, he viſits, with a flying camp, once every year, the principal parts of it; traverſing, in the ſummer ſeaſon, the fertile country in the neighbourhood of Keff and Baijah; and in the winter, the ſeveral diſtricts betwixt Kairwan and the Jereed.

BEYAH, in *Geography*, anciently called *Beypaſha*, and the *Hyphaſis*, or *Haphaſis* of Alexander, a river of Hindoſtan, that riſes in the great chain of ſnowy mountains, extending from Sirinagur, to the north of Caſhmere, or the ancient Imaus; and after traverſing the Panjab, it joins the Setlege at Ferozepour; about 24 miles below the conflux, a ſeparation again takes place, and four different ſtreams are formed; the northmoſt and moſt conſiderable of which, recovers the name of Beyah, and is a deep and rapid river. The others are named Herari, Dond, and Noorney; and near Moultan they unite again, and bear the name of Setlege, until both the ſubſtance and the name are loſt in the Indus, about 80 miles, or three days' ſailing, by the courſe of the river, below the mouth of the Chunaub. Rennell's Mem. p. 102.

BEYENBERG, or Bienberg, a town of Germany, in the

the circle of Weſtphalia, and duchy of Berg, on the Wipper, 3 miles north of Lennep.

BEYERLAND, an iſland belonging to Holland, ſituated on the Meuſe, with a town of the ſame name; 4 leagues weſt of Dort.

BEYERN, a town of Germany, in the circle of Swabia, and county of Fuſtenberg, ſituated on the Danube, 4 leagues from Dutlingen.

BEYHARTING, a town of Germany, in the circle of Bavaria, 24 miles E.S.E. of Munich.

BEYKE. See Beki.

BEYLA, a town and diſtrict of Abyſſinia, in Sennar, about 11 miles weſt of Teawa, and 31½ miles due ſouth, in N. lat. 31° 42′ 4″. Between Teawa and Beyla there is no water. Imgededema, and a number of villages, were ſupplied with water from wells, and had large crops of Indian corn ſown about their poſſeſſions. But the Arabs Daveima have deſtroyed theſe places, filled up their wells, burnt their crops, and expoſed all the inhabitants to die by famine.

BEYMONT, or Beywort, a town of Germany, in the biſhopric of Liege, 8 miles ſouth of Liege.

BEYNAT, the chief place of a canton in the diſtrict of Brives, and department of Correze, containing 1462 inhabitants; thoſe of the canton being 5488. The territory comprehends 135 kiliometres and 6 communes.

BEYS, Gilles, in *Biography*, a printer at Paris, in the 16th century, who firſt introduced into his editions the diſtinction ſuggeſted by Ramus in his grammar between *j* and *v* conſonants, and the vowels *i* and *u*. He died in 1595.

BEYSZKER, (*Geſn. Thierb.*) in *Ichthyology*, a name of the *cobitis foſſilis*. Gmelin.

BEZA, Theodore, or Theodore de Beze, in *Biography*, an eminent divine among the firſt reformers in Geneva, was born of parents nobly deſcended, in 1519, at Vezelai in Burgundy, and ſent by his uncle, who was a counſellor in the parliament of Paris, to Orleans, in 1528, to be educated by Melchior Wolmar, a proteſtant and an excellent teacher. Having continued ſeven years under his tuition, he commenced the ſtudy of the law at Orleans; but his taſte led him to the cultivation of polite literature, and he compoſed ſeveral Latin poems, which were conſidered by the learned as a promiſing ſpecimen of his talents. After taking a law-degree, he returned, in 1539, to Paris, where his parents, who had intended him for the eccleſiaſtical profeſſion, had procured for him a valuable abbacy. Addicted to the delights of an eaſy and voluptuous life, he remained for ſome years at Paris; but under the influence of ſentiments imbibed in his youth from his proteſtant preceptor, he determined ſooner or later to break his fetters. A marriage contracted from conſcientious motives rendered it neceſſary for him to reſign his benefices, and haſtened in the execution of his purpoſe by the reflections attending a ſevere illneſs, he and his female companion fled, in 1548, to Geneva. In the following year he accepted the offer of a Greek profeſſorſhip at Lauſanne, in the exerciſe of which he continued with reputation for nine or ten years. Here he read lectures in French on the New Teſtament, and publiſhed ſeveral books; one of which was a tragi-comedy, in French, entitled "Abraham's Sacrifice," which paſſed through ſeveral impreſſions. Having frequent opportunities of viſiting Calvin at Geneva, he was induced by his perſuaſion to finiſh the verſion of the Pſalms, which had been begun by Marot. During his reſidence at Lauſanne, he publiſhed a treatiſe, "De Hereticis à Magiſtratu puniendis," in reply to a book written by Caſtalio, after the execution of Servetus; and in this treatiſe he maintained a doctrine no leſs dangerous in its tendency than inconſiſtent with his principles as a reformer and a proteſtant, that it was the duty of the civil magiſtrate to puniſh hereſy. He alſo wrote on predeſtination, and the euchariſt, in oppoſition to the Lutherans, and others, and in a ſtyle of raillery which a maturer judgment and after-reflection led him to correct. In 1558, he was ſelected as one of the deputies commiſſioned by the proteſtants, to engage the German princes in favour of their brethren impriſoned at Paris, and of the perſecuted inhabitants of the vallies of Piedmont. In the following year he removed to Geneva, where he became the colleague of Calvin, both in the church and univerſity, and where by his abilities, learning, and zeal, he co-operated with him in advancing the reformation. In 1561, he diſtinguiſhed himſelf by his eloquence on behalf of the Proteſtant party, at the conference of Poiſſy; although he gave offence by his declared oppoſition to the doctrine of the real preſence. Continuing in France, he attended the prince of Condé as a miniſter, when the civil war broke out, and accompanied him to the battle of Dreux. Upon his return to Geneva, in 1563, he wrote ſeveral books in theological controverſy, with an acrimony that cannot be juſtified by perſons of moderation and candour. In 1571, he officiated as moderator in the national ſynod of Rochelle, and in the following year aſſiſted in that of Niſmes. In 1586, he held a diſputation with Andreas, a Lutheran divine of Tubingen; and through the whole courſe of his life, the party to which he belonged availed itſelf, on many occaſions, of his talents and reputation. Having loſt his firſt wife in 1588, he ſoon married another. Although the infirmities of his advanced age required his withdrawing from the duties of public inſtruction, the ardour of his genius remained to the cloſe of his life, and he wrote Latin verſes a few years before his death, which happened in October 1605, after he had paſſed his 86th year. Of his ſingular natural talents and literary acquirements no doubt can be entertained; nor need we wonder that bigotted Catholics ſhould have calumniated him whilſt he lived, and reviled his memory after his death. He has indeed, by his enemies, been unjuſtly traduced as a hypocrite, and a perſon of lax morals; but charges of this kind are refuted by the uniform tenour of his life. His partial advocates, however, muſt regret that, as a diſputant, he was violent, impetuous, and dogmatical, and deficient in candour and charity. His juvenile pieces, in Latin poetry, in which critics have detected many numerous deviations from claſſical purity, were firſt printed in 1548. Some of theſe, with corrections, together with others of a more ſerious caſt, were printed by the Stephenſes at Paris, in 1597, 4to. under the title of "Theod. Bezæ Poemata varia." His French works are of an inferior kind. His theological works are numerous. Of theſe, the moſt generally read, and the moſt highly eſteemed, is his "Latin verſion of the New Teſtament," with critical and theological remarks. For an account of the MS. in his poſſeſſion, ſee Cambridge MS. Gen. Dict.

BEZABA, in *Geography*, a river of Spain, which runs into Orio, in the province of Guipuſcoa.

BEZABDA, or Gozerta, *Geziret ebn-Omar*, in *Ancient Geography*, a town of Aſia, on the right bank of the Tigris, ſouth-weſt of Tigranocerta, in the country called Zabdicana.

BEZANT, repreſents, in *Heraldry*, round flat pieces of gold. They were firſt borne by the ſoldiers of the holy wars, being the current coin of Byzantium (the modern Conſtantinople,) with which the ſtipends of the army were diſcharged, and from whence they took their name. They are always emblazoned gold, but the foreign heralds make them both gold and ſilver.

BEZANTIE, in *Heraldry*, is when the field is powdered with bezants, or when ſupporters, or creſts, are ſtrewed with them. The proper heraldic term is bezantie. When a bordure

bordure is charged with eight bezants, that being the limited number, you need not expreſs the number, but ſay, *a bordure ſable bezantie.*

BEZANTLIER, ſignifies the ſecond branch of the horn of an hart or buck, that ſhoots from the main beam, and is the next above the brow-antler.

BEZARA, in *Ancient Geography*, a town of Galilee near the ſea, ſouth of Ptolemais.

BEZDELKINO, in *Geography*, a town of Siberia, 80 miles north of Balaganſkoi.

BEZDZIEZ, a town of Lithuania, in the palatinate of Brzeſc, 24 miles weſt of Pinſk.

BEZE', a town of France, ſituate near the the ſource of a river of the ſame name, in the department of the Côte d'Or, and chief place of a canton, in the diſtrict of Is-ſur Tille, 2½ leagues E.S.E. of it.

BEZEK, or Bezaka, in *Ancient Geography*, the place where Saul reviewed his army, before he marched againſt Jabeſh-Gilead. 1 Sam. xi. 8. Euſebius mentions two cities of this name, near one another, 7 miles from Sichem, in the way to Scythopolis.

BEZENSTEIN, or Petzenstein, in *Geography*, a town of Germany, in the circle of Bavaria, and territory of Nuremberg, 19 miles N. E. of Nuremberg.

BEZER, in *Ancient Geography*, a city beyond Jordan, over-againſt Jericho, in the wilderneſs aſſigned by Moſes to the tribe of Reuben, intended by Joſhua to be a city of refuge, and given to the Levites of Gerſhom's family. Deut. iv. 43. Joſh. xx. 8. The vulgate in both places denominates it *Boſor.* Euſebius confounds it with Boſtra of Arabia, which lay much farther to the eaſt. See Bostra.

BEZETH, a city of Paleſtine, on this ſide Jordan, in the vicinity of Jeruſalem, which Bacchides ſurpriſed, and the inhabitants of which he threw into a pit; probably the ſame with Bezecath. 1 Maccab. vii. 19.

BEZETHA, or Bezeta, a diviſion or part of Jeruſalem, ſituated on a mountain, and encompaſſed with walls, being, as Joſephus ſays, a new city attached to the old one, and called in Greek Καινόπολις, Cainopolis. It lay north of Jeruſalem and the temple.

BEZETZ, in *Geography*. See Beshetsk.

BEZHLEN, a town of Tranſylvania, 12 miles N. N.E. of Biſtriz.

BEZIERS, a city of France, and principal place of a diſtrict, in the department of the Herault, ſeated on the left bank of the Orbe, not far from the grand canal. Before the revolution, it was the reſidence of a governor, and the ſee of a biſhop, ſuffragan of Narbonne; its cathedral was ſmall, but beautiful; it had beſides a collegiate church, ſeveral religious houſes, two hoſpitals, a college founded by the inhabitants in 1599, and an academy of ſciences and belles lettres. It is ſurrounded by a wall, flanked with old towers, and decayed baſtions. The number of inhabitants in both its ſections is eſtimated at 14,211, and the population is ſmall in proportion to its extent. The canton of the firſt ſection has 12,308, and that of the ſecond 13,147 perſons. The former canton has 9, and the latter 7 communes. The territorial extent of both comprehends 360 kiliometres. The ſituation is beautiful, and it commands a view of ſeveral ſluices of the grand canal of Languedoc. In the Not. Imp. it is called "Civitas Biterenſium, Bliterra Septimanorum." In the 5th century it was ravaged by the Vandals; by the Saracens, in 720; by Charles Martel, in 737; and by Simon, count Montfort, in 1209; who, in the cruſade againſt the Albigenſes, took it by aſſault, and put more than 50,000 of the inhabitants to the ſword. Since this time it has not recovered its ancient luſtre. It was re-united to the crown by S. Louis, in 1247. Its territory is fertile in corn, oil, and wine. It has alſo mineral waters. N. lat. 43° 20′ 41″. E. long. 3° 12′ 35″.

BEZIRA. See Bazira.

BEZOAR, Bezoard, primarily denotes an antidote, or counter-poiſon. The word is formed from the Perſian *pazahar*, which denotes the ſame, *pa* ſignifying *againſt*; and *zahar*, *poiſon.*

Bezoar, *Lapis Bezoardicus*, is a term applied in a general way to various ſubſtances found in the ſtomach, inteſtines, and other internal cavities of the bodies of quadrupeds.

The true bezoar, however, is a calculous concretion, uſually formed in the ſtomach of ſome of thoſe animals which ruminate, or chew the cud. There are two ſorts of the bezoar ſtone; one is brought from the Eaſt Indies, and Perſia, and thence known under the name of *Oriental* bezoar. The other kind comes from the Spaniſh Weſt Indies, or South America, and is called *Occidental* bezoar. The Oriental is conſidered by far the more valuable kind, and is exceedingly ſcarce, even in India. The larger the ſtone the more highly it is eſteemed; its price increaſing, like that of the diamond, in proportion to its ſize. A ſtone of one ounce has been ſold in India for 100 livres, and one of four ounces and a quarter for 2000 livres. The price of the ſmaller ſtones, in Germany, in the year 1600, was from 16 to 32 ducats the ounce; but it had then much declined. The larger bezoars had no regular price, being often enormouſly dear. As long as it retained its fancied reputation, as an antidote to every kind of poiſon, and as a cordial for the ſupport of life under the moſt trying circumſtances of diſeaſe, its price was advanced beyond its weight in gold, and it found a high place for many centuries among the moſt coſtly collections of precious ſtones. The ſize varied from that of a pea to a hen's egg, or even larger. Boetius relates, that in his time the emperor Rodolph II. poſſeſſed one of the ſize of a gooſe's egg, which he ordered to be hollowed out into a cup, when the nucleus was found to be a ſmall maſs of herbs ſtill ſtrongly aromatic. The moſt anciently known bezoar ſtones were procured from the ſtomachs of goats feeding in the mountains of Perſia, and thoſe from the mountain goat were in ſuch high requeſt, that the emperor Shah-Abbas (who died in 1628,) claimed all above a certain ſtandard as a royalty, and appointed collectors for the purpoſe. The Oriental bezoars paſſed through the hands of the Armenian and Perſian merchants, and were formerly brought to Europe in conſiderable quantities. In the eaſt, thoſe were the moſt eſteemed that were obtained from goats feeding in the mountains, as the aromatic herbs found there were ſuppoſed to add much to the virtues of the calculus.

Authors diſagree with reſpect to the animal in which the genuine oriental bezoar is found; ſome attribute it to a ſpecies of goat, others to the antilope genus. Moſt naturaliſts allow this ſubſtance to belong to the gazelle, (*Antilope Gazella*, Gmel.) Aldrovandus calls this ſpecies of antilope, *hircus bezoardicus*; Linnæus, *capra bezoardica*; and Pennant, the *bezoar antilope.* Pallas, however, in his Spicilegia Zoologia, gives the ſame name to the Egyptian antilope, (*Antilope Oryx*, Gmel.) Cuvier deſcribes the oriental bezoar as being found in the inteſtines of the capra ægagrus of the Linnean ſyſtem, and Gmelin aſcribes it to the *capricorne* goat. By the account of Cluſius, the animal furniſhing this concretion would ſeem to be larger than the goat, and more reſembling the Nylghau. There can be little queſtion but ſimilar ſubſtances have been occaſionally met with in each of theſe animals, and in ſeveral other ſpecies.

The bezoar ſtone, when genuine, varies much in its form; this depending upon the figure of the nucleus, upon which the calculous matter is depoſited, there being generally ſome foreign

foreign body in the centre of the bezoar. The ſubſtances which uſually ſerve for nuclei to theſe concretions are ſtraw, hair, ſmall pebbles, nuts, hard ſeeds, ſtones of fruit, &c. but the moſt frequent nucleus of the real oriental bezoar, is the pod of a fruit, much like that of the ACACIA *vera Egyptiaca:* though it at firſt ſight reſembles a *caſſia*, or tamarind ſtone. In ſome of the bezoar ſtones formed on this fruit, the outer membrane of the bean having periſhed, and the bean ſhrunk in drying, there remains a vacuity between it and the inner ſurface of the bezoar, ſo that it rattles within it, when ſhaken, in the manner of an *ætites*, or *eagle ſtone*. It is of little moment what the figure or nature of the body may be, which is to ſerve the purpoſe of a nucleus, as it cannot in the ſlighteſt degree affect the quality of the calculous ſubſtance which is to be collected on its ſurface; any extraneous matter will ſuffice for this purpoſe, which may happen by any accident to be long enough detained in the ſtomach or inteſtines. The formation of bezoars appears to be effected in a manner ſimilar to that obſerved in the production of the calculi of the urinary bladder of the human ſubject. We may preſume that the bezoar is only formed when there is a tendency in the animal to generate an extraordinary quantity of calculous matter; for if it were otherwiſe, as that theſe ſubſtances were produced by any combination of the ordinary contents of the ſtomach and inteſtines, what animal, that is liable to ſuch collections, could ever be without them? whereas, on the contrary, they are ſo ſcarce in the Eaſt Indies, that thoſe which are brought into this country are ſuppoſed to be in general artificial compoſitions; nay, ſome have doubted if we ever meet with a genuine oriental bezoar in this country.

The ſeaſon of the year alſo appears to influence their production. Camerarius remarks, that theſe bodies begin to form towards the month of November: and when the Pariſian anatomiſts diſcovered a bezoar in the ſtomach of the Chamois (*Antilope Rupicapra,*) it was the month of December.

The number of bezoar ſtones varies, in different animals, from one to ſix; hence, it is ſaid to be cuſtomary, previous to purchaſing a bezoar animal, to reckon the number of ſtones it contains, which can be aſcertained by feeling externally, and by this the price of the animal is regulated.

Velchius aſſerts, that the Bezoar is only found in the firſt or ſecond ſtomachs of ruminant animals, but the anatomiſts of the French academy ſtate, that they met with it in the third ſtomach; and others have mentioned its being ſometimes ſituated in the inteſtines.

All bezoars are made of concentric layers, or by ſtratum ſuper ſtratum, after the manner of the common urinary calculus. This proves their formation to be gradual; and as this mode of increaſe cannot be eaſily imitated, it is probably one of the beſt marks for diſtinguiſhing the genuine bezoar from that which is counterfeited.

The Oriental bezoar is ſmooth and gloſſy on the ſurface, the colour a dark green or olive; on removing the outer coat, that which lies next it appears likewiſe ſmooth and ſhining; it is generally leſs than a walnut; it is moſt eſteemed for its medicinal properties, and is the only ſort retained by the London college. The Edinburgh college, in ſome of the former editions of their pharmacopœia, directed both this and the occidental bezoar, but they now ſeem to allow them to be uſed promiſcuouſly, retaining in their catalogue only the name of *lapis bezoar*.

The imitations of this ſtone have been carried to ſuch perfection, that as far as reſpects form, colour, or other external characters, the deception cannot well be detected. Mr. Neumann ſuppoſed that thoſe which come neareſt the genuine bezoar, are a compoſition of plaſter of Paris, chalk, or other earths ſtained of the proper colour by ſome vegetable tincture. Thoſe which are palpably counterfeited, are compoſed chiefly of ſome reſinous ſubſtance, and may be eaſily diſcovered by their liquefying in the fire, and being ſoluble in ſpirits of wine; he never could diſcover any mark of an animal nature in any of theſe. Chemical works, by Dr. Lewis, p. 533, &c.

The modes of trying if bezoar be genuine are, 1ſt. To immerſe a portion of it, for ſome hours, in moderately warm water, when the water ought to remain untinged, and the ſtone undiminiſhed in its weight: 2d. to apply to it a ſharp red hot iron, which it ſhould reſiſt without frying or ſhrivelling: the 3d. which is conſidered the moſt certain experiment, is to rub the bezoar over a paper which has been previouſly ſmeared with chalk or quicklime: if it leave a yellow tint on the former, or a green one on the latter, there is no doubt of its being genuine.

The *occidental bezoar* is uneven on the ſurface; of a dirty green colour; it is heavier and more brittle than the oriental, to which it is conſidered much inferior in value; it is of a looſer texture, and when fractured, the layers appear thicker, and exhibit a number of ſtriæ curiouſly interwoven. It is alſo found of a much greater ſize; ſometimes being as large as a gooſe's egg.

The occidental bezoar has been found in ſome of the camel tribe, eſpecially the *guanaco* (*Camelus Huanacus*) and the *Vicuna* (*Camelus Vicugna,*) which are inhabitants of South America.

This kind of bezoar, Mr. Neumann apprehends, is more likely to be an animal production than the other, becauſe it yielded, on diſtillation, a ſmall portion of volatile urinous matter. Chem. Works, p. 537.

The analyſis of bezoar ſtones, as related by different chemiſts, is very contradictory, which has given riſe to the opinion of the ſpecimens which they ſubmitted to experiment, being ſpurious. Thoſe ſtones examined by Slare, as oriental bezoar, did not diſſolve in acids. Thoſe which Grew and Boyle made trial of, did. Thoſe employed by Geoffroy (in ſome experiments related in the French Memoirs, 1710,) did not ſeem to be acted on by ſpirits of wine, whilſt thoſe ſpecimens examined by Neumann, at Berlin, almoſt entirely diſſolved in ſpirits. For an account of the analyſis and chemical properties of the bezoar and ſimilar ſubſtances; ſee CALCULUS.

In the early ages, when a knowledge of diſeaſes was conſidered an occult and myſterious ſcience, rare and unknown plants, or unuſual, and what were conſidered wonderful animal productions, were chiefly employed in the way of medicines; at this period we accordingly find the bezoartic ſtone poſſeſſed great reputation as a remedy for many diſeaſes; it owed, no doubt, much of its fame to the fabulous accounts which were related with reſpect to its origin.

It was not known to the Greeks. The firſt perſon who has mentioned it was *Avenzoar*, an Arabian phyſician. He deſcribes it to be generated of the tears, or gum, of the eyes of ſtags, who, after eating ſerpents, were accuſtomed to run into the water up to the noſe, where they ſtood till their eyes began to ooze a humour, which collecting under their eye-lids, gradually thickened and coagulated, and when it became quite hard was thrown off by the animal rubbing itſelf againſt the trees. Other ſtories concerning the hiſtory of the bezoar, equally wonderful and ludicrous, were credited, until the time of Garcias al Horto, phyſician to the Portugueſe viceroy of the Indies, who gave the firſt true account of the origin of this ſubſtance. Kempfer afterwards gave a deſcription of it with ſome new particulars.

The bezoar was firſt employed to prevent the fatal conſequences of poiſon. This is expreſſed by the very name

which is derived from the Perſian word *badzcher*, or *bazcher*, *antidote*, or from *pazahar*, of which *pa* ſignifies *againſt*, and *zahar*, a *poiſon*. Others derive the term bezoar from the Perſian *pazar*, a goat.

It was afterwards given in vertigoes, epilepſies, palpitations of the heart, jaundice, colic, and a great many other diſeaſes; ſo that if its real virtues were anſwerable to its reputed ones, it was doubtleſs a *panacea*. Even later writers have beſtowed extraordinary commendations on it, as a ſudorific and alexipharmic; but there is every reaſon to doubt its poſſeſſing any ſuch virtues. It is an earthy ſubſtance, devoid of taſte or ſmell. The hiſtory of its formation proves that it is not digeſtible, or otherwiſe affected by the juices of the inteſtinal canal. If it can ever be employed as a medicine, it ſhould be on account of its abſorbent quality, which, however, it appears to poſſeſs but in a very ſlight degree. It has been adminiſtered to patients in the quantity of half a drachm, and in ſome inſtances a drachm has been taken, without producing any ſenſible effect; the doſe has been generally ſtated at a few grains, which was probably on account of its ſcarcity and great price. While it retained its medical reputation, it was ſaid to act as an antidote to every poiſon, vegetable or mineral, and to the bite or ſting of all poiſonous animals, in the doſe of about 8 grains; but it would equally prove a counter-poiſon when taken regularly in the quantity of two grains daily, in a glaſs of wine, or eſpecially of diſtilled water of carduus benedictus. To preſerve an youthful conſtitution and vigour, an oriental's recipe is to take twice a year (purging being premiſed) ten grains of bezoar daily, for five ſucceſſive days, with a cup of roſe-water. Bezoartic productions are at preſent ſo little regarded for their medicinal properties, that few druggiſts now think it neceſſary to have them in their poſſeſſion.

Bezoar, *Equinum*, is the name given to the calculous concretions occaſionally met with in horſes. They appear to be formed in the ſame manner as the bezoar of the antilope or camel genus. They grow to a conſiderable ſize; have uſually an irregular form, ſomething between a compreſſed ſphere and a rhomboidal figure; when divided they exhibit the uſual ſucceſſion of ſtrata, of which they are compoſed, but which are not ſo diſtinct as in the other bezoars; each layer is formed of excentric ſtriæ, which are in many places more evident than the diviſion into ſtrata; conſequently the ſection of the bezoar gives the appearance of its having been made of radiated, rather than concentric layers. The ſurface of the calculus bears great reſemblance to a piece of poliſhed lime-ſtone.

Bezoar, *German*, is called by ſome *cow's egg*, from the circumſtance of its being occaſionally found in the ſtomachs of cows, but the animal from which it is moſt commonly obtained is the chamois (*Antilope Rupicapra*).

The nucleus of the German bezoar is either the hair which the animal may have ſwallowed, when licking itſelf, or the fibres of undigeſted vegetables, which are rolled into a round ſmooth ball. The quantity of calculous ſubſtance which is collected upon this ball is in general very trifling, often being merely a thin pellicle.

The bezoar which was found in the chamois by the Pariſian academicians, was made up of the woody fibres of the plants the animal had eaten; it was ſmooth and beſmeared with mucus on the ſurface; and was broken at one end, expoſing a cavity in the centre of the ball, which had formerly, no doubt, been occupied by ſome ſolid ſubſtance, ſuch as a pebble, or ſtone of ſome fruit.

German bezoars have been found, according to Bartholin, and others, in horſes and ſheep, in which laſt they are chiefly compoſed of wool, which theſe animals accidentally ſwallow.

From theſe ſpecies of bezoar having little, if any, calculous matter in their compoſition, they have been called by ſome writers, with propriety, *Ægagropilæ*; which ſee, and Balls.

Beſides what have been already deſcribed, there are concretions found in the gall bladder of animals, to which the term *bezoar* has been applied; theſe appear to be no other than biliary calculi.

The *Hog* or *Boar* Bezoar, called by the Dutch *Pedra de porco*, and by the Portugueſe, who firſt brought it into Europe, *Pedro de vaparis*, is found in the gall bag of an Eaſt India boar; in form and magnitude it reſembles a filbert, though more irregular; it is moſt commonly white, with a tinge of green; the ſurface is ſmooth and ſhining, and is valued at ten times its weight in gold.

The Indians attribute extraordinary medicinal powers to this bezoar. They call it *Maſtica de ſoho*, and prefer it to that obtained from the Gazelle; they conſider it a ſovereign remedy for the *mordoxé*, a diſeaſe to which they are liable, and which is not leſs dangerous than the plague in Europe. They allow it to have great efficacy alſo in malignant fevers, ſmall-pox, and moſt diſeaſes of women not with child, it being ſuppoſed to produce abortion in thoſe who are pregnant, if they uſe it indiſcreetly. When it is to be uſed as a medicine, it is infuſed in water or wine, until it has communicated a little bitterneſs to it. To facilitate the infuſion, and at the ſame time preſerve ſo precious a ſtone, they uſually incloſe it in a gold caſe, which is pierced with holes.

The *Porcupine* and *Monkey* Bezoars, are alſo the biliary calculi of theſe animals. Tavernier aſſerts, that they are not taken from the gall bladder, but the heads of the ape and the porcupine, which is highly improbable, and contrary to general analyſis; he calls them *Malacca ſtones*, and ſays that they are held in ſuch eſtimation by the inhabitants of Malacca, that they never part with them, except as preſents to ambaſſadors, or the greateſt princes of the eaſt.

According to Neumann, ſingle ſtones, taken from the porcupine or monkey, have been ſold for ſixty and eighty pounds ſterling.

It is not impoſſible but that thoſe bezoars which are formed in the gall bladder may poſſeſs ſome power as medicines; perhaps alſo ſolutions might be employed with advantage in ſurgery, but their great reputation amongſt the Indians ſeems to ariſe altogether from ignorance and ſuperſtition.

Bezoar, *bovinum*, is a yellowiſh ſtone, found in the gall bags of the ox. It has been uſed by miniature-painters in ſeveral caſts of yellow.

Bezoar, in *Conchology*, a ſpecies of Buccinum, that inhabits China. This ſhell is ſubrotund and rugoſe: anterior part of the whorls lamellated: pillar perforated. Gmelin. The colour is dirty ochraceous, varied with brown: within yellow; coarſe, decuſſated with wrinkles, or ſtriæ; tail ſolid, bent, rugoſe with imbricated ſcales: ſpire angular with ſtraight ſides: anterior part flattiſh, plaited, or dentated above.

BEZOARA, or Buzwara, in *Geography*, a town with a fort in the peninſula of India, ſituate on the north ſide of the Kiſtna river, diſtant 40, 3 geographical miles from Maſulipatam. N. lat. 16° 33'. E. long. 80° 39' In the town is a magnificent pagoda, and another ſtands on an eminence without it; which attract a great number of pilgrims, whoſe contributions are diſtributed in alms to the poor.

BEZOARDICS. The peculiar virtue of the bezoar being that of reſiſting and expelling poiſons; the term *bezoardic* (now, however, nearly obſolete,) has come to be almoſt ſynonymous with *antidote*. Thus, when a bezoardic medicine is mentioned, it implies, with the older writers, either a

medicine into which bezoar enters, or one that refembles the bezoar in its fuppofed power of counteracting poifons, or afterwards, fimply, a cordial. A few metallic preparations have had this appellation.

BEZOARDICA Capra, Syft. Nat. *Hircus bezoardicus*, Aldr. *Animal bezoarticum*, Raj. *Bezoar Antelope*, Pennant, &c. names of the *Antilope Gazella*. Gmelin.

Bezoardica *terra*, a name ufed by fome authors for a medical earth dug in the pope's territories, and more frequently called terra *nocerlana*.

BEZOARDICUM Mineral, or *Mineral* Bezoar, is a perfect oxyd of antimony, made by adding nitrous acid to the butter of antimony, and deferibed under the article Antimony.

Bezoardicum *Joviale*, is a mixed oxyd of antimony and tin, formed by fufing together thefe metals, diftilling with corrofive fublimate to convert both metals of the alloy into a *butter*, or muriated oxyd, and adding nitrous acid to reduce them both to a perfect fimple oxyd. It is entirely difufed.

BEZOLA, in *Ichthyology*, the name of a kind of *Salmo*, called by Gefner, Albula cærulea, and fuppofed to be in no refpect different from *Salmo Lavaretus*.

BEZOUT, Stephen, in *Biography*, a celebrated mathematician of France, was born at Nemours, March 19, 1736, O. S. and notwithftanding oppofition on the part of his father, devoted himfelf to the aflidnous profecution of the mathematical fciences, to which his tafte ftrongly inclined him. In 1758, he was appointed adjunct mechanic to the Paris academy of fciences, after having communicated two memoirs on the integral calculus, and affording other proofs of his proficiency in the mathematics; in 1763, he was nominated examiner to the marine; affociate to the academy in 1768; and, in the fame year, member of the academy of marine affairs, and examiner of the pupils of the royal corps of artillery; and, in 1776, royal cenfor. His particular attention was directed to the folution of algebraic equations, and he had the honour of firft difcovering a method of refolving a particular clafs of equations of all degrees. In this work of inveftigating the roots of fuch equations, he was occafionally engaged from 1762 till 1779, when he publifhed his treatife on the fubject. To diftinguifhed talents, and elaborate refearches in the abftrufer parts of mathematics, Bezout added an aflidnous difcharge of the duties of the public ftations which he occupied, and a private character which was deftervedly efteemed. The following anecdote furnifhes a pleafing fpecimen of his regard to juftice in the exercife of his office, and at the fame time of the benignity and condefcenfion of his temper. When two of his pupils were confined by the fmall-pox, and incapable of attending for the purpofe of an examination, the want of which would have delayed their advancement for a whole year, he ventured, though he had never had that diforder, to vifit them in perfon, and to afcertain their proficiency, by which he was enabled to make a report in their favour. His conftitution was at length impaired by his unremitting application, the fatigues of his various offices, and fome perfonal chagrins; and he fell a facrifice to a malignant fever, September 27, 1783, in the 54th year of his age. His publications were "A Courfe of Mathematics for the Ufe of the Marine, with a Treatife on Navigation," 6 vols. 8vo. Paris, 1764; a "Courfe of Mathematics for the Corps of Artillery," 4 vols. 8vo. 1770; "General Theory of Algebraic Equations," 4to. 1779; with a conftderable number of Memoirs, chiefly mathematical, in the volumes of the French Academy. Montucla, Hift. des Mathem. vol. iii. p. 47. 298. Hutton's Math. Dict. Art. Bezout.

BEZOZZI, Alexander and Jerom, brothers in the fervice of the king of Sardinia, at Turin, the moft celebrated performers of their time; the one on the hautbois, and the other on the baffoon. Thefe kindred inftruments were rendered famous all over Italy during the middle of the laft century, not only by the exquifite performance, but by the amiably fingular character of thefe two brothers. Their long and uninterrupted affection and refidence together, were as remarkable as their performance. They were brothers; the eldeft, when we heard them in 1770, was 70, and the youngeft 60. The *idem velle et idem nolle* were as perfectly in tune as their inftruments; fo that they had always lived together in the utmoft harmony, carrying their fimilarity of tafte to their very drefs, which was the fame in every particular, even to buckles and buttons. They had lived fo long, and in fuch a cordial manner together, that it was thought, whenever one of them died, the other would not long furvive him; which was exactly the cafe, both dying in 1780, within a few months of each other.

The compofitions of thefe exquifite performers generally confifted of feleft and detached paffages, yet fo highly polifhed, that like apophthegms or maxims in literature, each was not a fragment but a whole; their pieces being in a peculiar manner contrived to difplay the genius of their feveral inftruments and powers of performance. The eldeft played the hautbois, and the youngeft the baffoon; but it is difficult to defcribe their peculiarities of expreffion. Their compofitions, when printed, gave but an imperfect idea of its fweetnefs and delicacy: fuch a perfect acquiefcence and agreement together, that many of the paffages feemed heart-felt fighs breathed through the fame reed. No brilliancy of execution was aimed at; all were notes of meaning. The imitations were exact; the melody equally divided between the two inftruments; each *forte*, *piano*, *crefcendo*, *diminuendo*, and *appogiatura* (fee all thefe terms in their places), were obferved with a minute exactnefs that could be attained only by a long refidence and ftudy together. The eldeft brother had loft his under front-teeth, and complained of age; and it was natural to fuppofe that the performance of each had been better; however, to me (fays Dr. Burney), who heard them now, for the firft time, it was delightful! If there was any thing to lament in fo exquifite performance, it arofe from the *equal perfection of the two parts*; which diftracted the attention, except when in dialogue, fo much as to render it impoffible to liften to both, when both had diffimilar melodies equally pleafing.

They were born at Parma, and had been upwards of 40 years in the fervice of his Sardinian majefty, without ever quitting Italy, (except one fhort excurfion to Paris, in 1755,) or even Turin, but for that journey, and another to vifit the place of their nativity. They were men of a fober, regular, and moral character; in eafy circumftances; had a town and country houfe, and in the former many good pictures by the firft maflers.

The Bezozzi family has furnifhed many admirable muficians to Italy, and other parts of Europe. Gaetano Bezozzi, a celebrated performer on the hautbois in the king of France's fervice, was born at Parma, in 1727, entered into the fervice of the king of Naples in 1736, and into that of the king of France in 1765. We heard him perform a concerto at the *concert fpiritual* at Paris in 1770, with great pleafure; and thought him fuperior to all whom we had then heard on the hautbois, except Fifcher. His father, Jofeph Bezozzi, had taught the celebrated brothers at Turin, Alexander and Jerom, his brothers, to play on the hautbois and baffoon. "M. Bezozzi of Paris," fays Laberde, "in 1780, had during 25 years merited and enjoyed the higheft reputation, as well as the efteem of all who knew him. His fon

was then lately received into the king's band, and his brother, Anthony Bezozzi, attached to the court of the king of Poland, had alſo a ſon in the ſervice of that of Dreſden, where we heard him perform in 1772, and found him a truly great performer. His *meſſa di voce*, or ſwell, was prodigious; indeed he continued to augment the force of a tone ſo much, and ſo long, that it was hardly poſſible not to fear for his lungs. His taſte and ear were exceedingly delicate and refined; and he ſeemed to poſſeſs a happy and peculiar faculty of tempering a continued tone to different baſes, according to their ſeveral relations: upon the whole, his performance was ſo capital, that a hearer muſt be extremely faſtidious not to receive from it a great degree of pleaſure.

BEZZAMA, Marcella, in *Geography*, a town of Italy, in the kingdom of Naples, and country of Otranto, 10 miles N. E. of Tarento.

BHAGNAGUR, a name formerly given to Hydrabad, which ſee.

BHAKOR. See Behker.

BHARATA, a name given in the Sanſkreet language to Hindoſtan.

BHATGAN, a city of Aſia, in the kingdom of Nepal; the capital of an independent kingdom. It contains about 12,000 families, extends towards the eaſt to the diſtance of five or ſix days' journey, and borders upon another nation, alſo independent, called "Ciratas," who profeſs no religion. See Nepal.

BHAVANI, the name of an ancient feſtival, annually celebrated on the firſt of May by the Gopas, and all other Hindoos who keep horned cattle for uſe or profit. On this feaſt, they viſit gardens, erect a pole in the fields, and adorn it with pendants and garlands. Similar rites are performed by the ſame claſs of people in England, where it is known to be a relic of ancient ſuperſtition in that country. Hence it ſhould ſeem, ſays colonel Pearſe, that the religion of the Eaſt, and the old religion of Britain, had a ſtrong affinity. Aſiatic Reſ. vol. ii. p. 333.

BHEERAH, a place in Hindoſtan, on the eaſt ſide of the Behut river, where is a paſs over it, a little to the N. of W. from Lahore, about 11 minutes north of its parallel, and diſtant from it 85½ geographical miles. N. lat. 32° 5'. E. long. 72° 13'.

BI, or Bia, a river of Ruſſia, which, by uniting with the Katunia, forms the river Oby.

BIA, in *Conchology*, a name given by the Siameſe, to a ſort of little white ſhell, brought in vaſt numbers from the Maldive iſlands, and uſed throughout moſt part of the Eaſt Indies for ſmall money. Nine of theſe are equal to the French denier; they are called coris or cowries, and belong to the Cypræa genus of Linnæus.

BIABANA, in *Ancient Geography*, a town placed by Ptolemy in the interior part of Arabia Felix.

BIACULEATUS, in *Ichthyology*, a ſpecies of Balistes, having two ventral ſpines. Bloch. Gmel. &c. This is *piſcis cornutus* of Willughby. It inhabits India, and is of an elongated form, white, cinereous above, and rough to the touch, being covered with very ſhort, hirſute, or briſtly hairs. It is a native of the Eaſt Indies, and, from the ſtructure of the mouth, is a voracious kind, feeding probably on marine worms and crabs. The Dutch call it *Hoorn-viſch*; and the French, *Baliſte à deux piquans*, in alluſion to the two ventral ſpines, which conſtitute the ſpecific character of the fiſh.

BIÆUM, from βια, *oppoſition*, in *Rhetoric*, denotes a kind of counter-argument, whereby ſomething alleged for the adverſary is retorted againſt him, and made to conclude a different way; for inſtance, "Occidiſti, quia adſtitiſti interfecto.—Immo quia adſtiti interfecto non occidi; nam ſi id eſſet, in fugam me conjeciſſem," "You killed the perſon, becauſe you were found ſtanding by his body." *(Bizum.)* "Rather I did not kill him, becauſe I was found ſtanding by his body; ſince, in the other caſe, I ſhould have fled away."

Biæum, in the *Grecian Laws*, was an action brought againſt thoſe who raviſhed women, or uſed violence to any man's perſon. Potter, Archæol. lib. i. c. 24.

Biæum alſo denotes a kind of ſaline or ſea-wine, uſed by the ancient Greeks in various diſorders. It was made of grapes gathered a little before ripe, and dried in the ſun; then preſſed, the juice put up in caſks, and mixed with a large proportion of ſea-water; though Dioſcorides ſeems to deſcribe it as made of grapes ſteeped in ſea-water, and then preſſed. Gorr. Def. Med. p. 75.

BIAFAR, or Biafra, in *Geography*, a populous and powerful kingdom of Africa, ſituate weſt of Medra and eaſt and ſouth eaſt of Benin, from which it is ſeparated by a chain of mountains; and extending beyond the fourth degree of north latitude, to the coaſt of the gulf of Guiena. It has a capital of the ſame name; and the bay on its coaſt is called the bight of Biafra. The natives of this country, the interior of which is little known, are idolaters, and much addicted to magic. They are ſaid to be zealous in their worſhip, and to ſacrifice their children to the devil. Biafra is alſo a ſmall diſtrict of Africa, extending along the ſea-coaſt, S.S.E. of the river Gambia, over-againſt the iſlands of Biſſagos.

BIAFORA, in the *Cuſtoms of the Middle Age*, a form of cry, or alarm to arms; on the hearing whereof, the inhabitants of towns or villages were to iſſue forth, and attend their prince. The word ſeems originally from Gaſcony; and the Italians even now, on a ſudden inſurrection of the people, commonly cry, *Via fora*, by an uſual change of the letter B into V.

BIAGIO, St. in *Geography*, a town of Italy, in the kingdom of Naples, and province of Calabria Ultra, 3½ miles W.S.W of Nicaſtro.—Alſo, a town in the ſame kingdom, in the county of Moliſe, 8 miles N. E. of Moliſe.

BIAJOS, the name by which the inhabitants of the iſland of Borneo are diſtinguiſhed. They are ſaid to offer ſacrifices of ſweet-ſcented wood to one ſupreme beneficent deity, and theſe ſentiments of piety are accompanied by laudable morals. See Banjermassing and Borneo.

BIALA, a part of Pruſſian Sileſia, in the circle of Zulz.—Alſo, a ſmall town in the duchy of Lithuania, belonging to Pruſſia, ſeated on the government of Johanneſburg, which obtained its privileges in 1722.—Alſo, a town and river of Poland, which runs into the Viſtula, S. W. of Cracow. N. lat. 49° 52'. E. long. 19° 20'.

BIALACERKIEW, a ſmall town of Poland, in the Ukrain, ſeated on the Roſs, a river of the palatinate of Kiov, which diſcharges itſelf into the Dnieper; diſtant 60 miles S.S.W. from Kiov. Here the Tartars were entirely defeated in 1626.

BIALAGRODKO, a ſmall town of Poland, in the palatinate of Kiov, ſeated on the Irpian, 14 miles S. W. of Kiov.

BIALLA, or Biala, a town of Poland, in the palatinate of Brzeſk or Birſetſk, 16 miles S. W. of Brzeſk or Birſetſk. N. lat. 52° 10'. E. long. 23° 25'.

BIALLISTOCK, or Bialystok, a neat and well built town of Poland, in the palatinate of Podalachia, north of Bielſk, in N. lat. 53° 5'. E. long. 23° 32'. The ſtreets are broad, and the houſes, which are in general plaſtered, ſtand detached at uniform diſtances. The ſuperior neatneſs

of this town is owing to the illuſtrious family of Braniſki, whoſe palace adjoins the town, and who have contributed to ornament their place of reſidence. This palace is a large building, in the Italian taſte, and, on account of its magnificence, generally called the Verſailles of Poland. It was formerly only a royal hunting ſeat, but given by John Caſimir, together with Balliſtock, and other eſtates, to Czarnieſki, a general highly diſtinguiſhed by his victories over the Swedes, when Poland was nearly cruſhed by her enemies. Czarnieſki left one daughter, who married Braniſki, the father of the late great general, and conveyed the eſtate into that family.

BIALOBOKY, a town of Poland, in the palatinate of Lemberg. 48 miles S. W. of Lemberg.

BIANA, a town of Hindoſtan, 20 leagues from Agra, which was formerly a large city, and included Agra among its dependencies. The town is ſtill conſiderable, and contains many large ſtone houſes. It was formerly the reſidence of a powerful rajah; but his principal city and fort were ſeated on the top of an adjoining hill, and the preſent town was only a ſuburb. The whole ridge of the hill is covered with the remains of large buildings, among which, the moſt remarkable is a fort, called "Bijey-Munder," containing a lofty pillar of ſtone, called "Bheemlat," or the Tealer or oilman's lat or ſtaff. This pillar is conſpicuous at a great diſtance. The town and diſtrict now belong to "Ramjaht Sing," the rajah of Bhirtpoor. This place is famous for its excellent indigo. N. lat. 26° 20'. E. long. 77°.

BIANCA, La, a town of Italy, in the kingdom of Naples, and province of Calabria Ultra, 12 miles N. E. of Bova.

Bianca, Ital. for the note in muſic, which we denominate a *minim*: and the Fr. *une blanche*. This, though now almoſt the longeſt note in uſe, three or four hundred years ago, was the ſhorteſt. See Time-Table, and Musical Characters.

BIANCHI, Francisco, called *Il Frari*, in *Biography*, an hiſtorical painter, was born at Modena, and was the diſciple of the celebrated Antonio Correggio. His colouring was delicately fine, his attitudes graceful, and his invention very grand. His works poſſeſſed an aſtoniſhing beauty, and are prized as highly as even thoſe of Correggio. He died in 1520. Pilkington.

Bianchi, Peter, a painter of the Roman ſchool, was born in Rome in 1694, and united with his talents as a painter the accompliſhments of literature. He painted hiſtorical ſubjects, portraits, rural and naval ſcenes, animals, plants, and flowers, in freſco, oil, and diſtemper. His reputation cauſed him to be employed in painting a picture in the church of St. Peter. He is ſaid to have been a ſevere judge of his own performances, and to have deſtroyed many of his works after they were finiſhed, becauſe they did not pleaſe him. He died at Rome in 1739. Encyclopedie.

Bianchi, John Baptist, born at Turin, Sept. 12th 1681, of an ancient and reſpectable family. After being educated with the greateſt care, and under the ableſt maſters at home, he was ſent early to the univerſity, and made ſuch progreſs in his ſtudies, that at the age of 17, he was admitted doctor in medicine, and was ſoon after made phyſician to the hoſpital, a ſituation for which he was peculiarly qualified; for being fond of anatomical purſuits, he had here opportunity, from the number of ſubjects a large eſtabliſhment of that kind neceſſarily furniſhed, of diſſecting and examining the human body at every age, and labouring under every ſpecies of diſeaſe or deformity. He had the happineſs alſo of finding his talents properly eſtimated by his brethren, and his labours rewarded, as he was advanced to be public teacher of anatomy at Turin, where his ſovereign built for him, in the year 1715, a ſpacious and convenient amphitheatre. He alſo read lectures in philoſophy, in pharmacy, chemiſtry, and on the practice of medicine. Theſe honours were not however entirely without alloy, as he had the mortification to find his doctrines cenſured by Morgagni, and by Haller, and even the exiſtence of ſome parts he ſuppoſed he had diſcovered, diſputed. The principal of his works are "Hiſtoria hepatica, ſeu de hepatis ſtructura, uſibus, et morbis," 1710, 8vo. Morgagni has publiſhed ſome ſevere ſtrictures on this work, in his "Adverſaria Anatomica." It has paſſed, however, through ſeveral editions, and in 1725, was republiſhed in 2 vols. 4to. with figures. "Ductus lacrymales novi, eorum uſus, morbi, curationes," 4to. 1715. alſo cenſured by Morgagni. "Storia de monſtro, di due corpi," 8vo. 1749, the moſt laboured and perfect, Haller ſays, of all his works. He wrote alſo an hiſtory of the generation of man, with figures, in which he attempts to delineate the fœtus in its different ſtages, but the figures, Haller ſays, are principally factitious. Many of his diſſertations are inſerted by Mangeti in his "Theatrum Anatomicum." Haller. Bib. Anat. et Chirurg. Eloy. Dict. Hiſt.

Bianchi, John, born at Rimini, Jan. 3, 1693. After receiving a liberal education, he went to Bologna, where, in 1719, he was admitted doctor in medicine. Returning the following year to Rimini, he practiſed medicine there with ſucceſs for many years. He revived the academy of Lynxes, a philoſophical ſociety, collecting the members together at firſt at his own houſe. In gratitude for this, a medal was ſtruck, with his figure on the face, and on the reverſe, a lynx, with the motto "Lynceis reſtitutis." His works are various, of which the principal are "A Treatiſe on the Cataract," 4to. 1720 in Italian; "Epiſtola anatomica, ad Joſephum Putæum," 4to. 1726. "De monſtris, et rebus monſtroſis," 4to. 1749, and in 1751, an account of an impoſtume of the right hemiſphere of the brain, occaſioning paralyſis on the oppoſite ſide of the body. Eloy. Dict. Hiſt.

BIANCHINI, Francis, a mathematician and philoſopher, was born at Verona, Dec. 13, 1662, and devoting himſelf to the church, became a doctor in theology, and diſtinguiſhed by his unfeigned piety. But his principal celebrity was acquired by his literary and ſcientific performances. In early life he contributed to the eſtabliſhment of the academy of the "Aletofoli," or the lovers of truth, and in the progreſs of his ſtudies rendered it conſiderable ſervice. His literary reputation attracted that notice to which the rank of his family alſo in ſome meaſure entitled him. Cardinal Ottoboni, afterwards pope Alexander VIII., appointed him his librarian; and he was promoted firſt to the dignity of canon in the church of Santa Maria della Rotunda, and alſo to that of St. Laurence, in Damaſo. He was alſo ſecretary to the congregation for the reform of the calendar, to which office he was nominated by pope Clement XI. The ſenate created him one of the nobility of Rome, and after his death the citizens of Verona placed his buſt in their cathedral. He died of the dropſy March 2, 1729, with a character diſtinguiſhed for the benevolence and candour of his manners, as well as for his piety and univerſal learning. Fontenelle honoured his memory with an eloge, as one of the foreign members of the academy of ſciences at Paris. His firſt work was "An Univerſal Hiſtory," on a new plan, ſerving to give perſpicuity to the chronological diſtribution. The firſt part of this work was publiſhed in 1697, under the title of "La Iſtoria Univerſale provata con monumenti et figurata con Simboli de gli Antichi." It extends, from the creation

creation of the world, to the deſtruction of the great Aſſyrian empire, and is held in high eſtimation for induſtry of reſearch, and ingenuity of diſquiſition with regard to the genuine monuments of antiquity. The ſucceeding parts were never written. On occaſion of the reform of the calendar, Bianchini wrote two learned and ſcientific treatiſes, publiſhed in 1703, and entitled "De Calendario et Cyclo Cæſaris ac de canone Paſchali Sancti Hippolyti Martyris, Diſſertationes duæ." Of his aſtronomical ſkill and labour in tracing the meridian line, in the church of the Chartreux at Rome, he publiſhed an account in a diſſertation "De nummo et gnomone Clementino." In 1727, he publiſhed "Camera ed Inſcrizioni Sepolcrati di Liberti, Servi ed Officiali della Caſa di Auguſto, &c." on occaſion of the diſcovery of a ſubterraneous ſepulchral building, in 1726, on the Appian way. His obſervations on Venus, were publiſhed in 1728, under the title of "Heſperi et Phoſphori Nova Phenomena, ſive Obſervationes circa Planetam Veneris." The reſults of his obſervations on the rotation of Venus, and the poſition of its axes, though very intereſting to aſtronomers at the time of their publication, have not, however, been confirmed by thoſe of a later date, made by Herſchel and Schroeter, with inſtruments of much greater power than any which were known in his time, and inſerted in the Philoſophical Tranſactions. The cauſe of this difference has not yet been aſcertained, and deſerves inveſtigation. (See Venus.) Bianchini was employed for eight years in preparatory meaſures for tracing a meridian line through the whole extent of Italy, but his death prevented the commencement of this enterpriſe. His edition of "Anaſtaſius's Lives of the Popes," in 4 vols. folio, with notes, diſſertations, prefaces, &c. diſplays much genius and erudition; but it is ſaid to abound with typographical errors. He left an unedited diſſertation in Latin, on the three kinds of muſical inſtruments of the ancients, which was publiſhed at Rome 1742, in 4to, under the following title: "Franciſci Bianchini Veronenſis utriuſque ſignaturæ referendarii, & prelati domeſtici, de tribus generibus inſtrumentorum muſicæ veterum organicæ diſſertatio." In dividing ancient muſical inſtruments into three claſſes, namely, wind inſtruments, ſtringed inſtruments, and inſtruments of percuſſion, the firſt claſs includes flutes, trumpets, horns, the ſyrinx, and hydraulicon; the ſecond, the monochord, the lyra trichordis, tetrachordum, the ſeven-ſtringed lyre, the chelys, the cithara, pſaltry, harp, &c.; the third claſs compriſes the tympanum, cymbalum, crotalum, ſyſtrum, and the tintinnabulum. Of all theſe, the author has given deſcriptions and repreſentations well engraven on plates. Fontenelle Eloge des Academiciens. Nouv. Dict. Hiſt.

BIANDRATE, in *Geography*, a town of Piedmont, in the Novareſe, 6 miles N. W. of Novara.

BIANDRONA, a town of Italy, in the duchy of Milan, 15 miles W.S.W. of Como.

BIANOR, in *Entomology*, a ſpecies of Papilio, nearly allied to *P. Paris*, and a native alſo of the Eaſt Indies. The wings are above and beneath of the ſame black colour, with five rufous lunules on the poſterior pair. Fabricius, &c. It may be doubted whether this is a diſtinct ſpecies from Paris; perhaps only a ſexual difference.

BIAR, a ſmall town of Valencia, in Spain, ſeated on a river which runs into the Elda, on the confines of New Caſtile. It is chiefly remarkable for its honey, which is diſtinguiſhed by its whiteneſs and ſolidity, unaffected by any change of weather; diſtant two leagues eaſt of Villena.

BIARCHUS, formed from βιος, *annona, victuals*, and αρχη, *chief*, an officer in the court of the emperors of Conſtantinople, intruſted with the care and inſpection of the proviſions of the ſoldiery. The biarchus was the ſame with what the Latins call *præfectus annonæ*. His function was called *biarchia*; by the Latins, *præfectura rei cibariæ*. He belonged to the *ſcholia agentium in rebus*. See Agentes.

BIARMIA, in *Geography*, a name given by the Scandinavian navigators, in the Middle ages, to the whole country between the White ſea and the Ural. See Permia.

BIARUM, in *Botany*, a name by which the people of Egypt at this time call the root of the *niluſar*, or *faba Ægyptia*, growing on the Nile.

BIAS, or Biass, in a general ſenſe, denotes the tendency or propenſity of a thing towards one ſide more than the other; particularly the deviation of a body, or a plane, from its rectilinear courſe, or its level. See Inclination. It ſignifies alſo the inclination of a perſon's mind to one thing more than to another. The word is French, *biais*, which ſignifies the ſame.

Bias *of a bowl*, is a piece of lead put into one ſide, to load and make it incline towards that ſide.

Bias, in *Biography*, one of the ſeven wiſe men of Greece, was a native of Priene, in Ionia, and flouriſhed in the reign of Alyattes II. king of Lydia, about 608, according to ſome, but according to Blair's tables, about 565 years before Chriſt. He was eminently diſtinguiſhed not only by his wiſdom, but by his generoſity and public ſpirit, and for theſe qualities held in the higheſt veneration by his countrymen. Alyattes was obliged by a ſtratagem of his contrivance to raiſe the ſiege of his native town, when it was reduced to the utmoſt diſtreſs by famine. He firſt ſent two fattened mules into the enemy's camp; and the king, obſerving with aſtoniſhment their good condition, ſent deputies into the city under a pretence of offering terms of peace, but with a real intention of obſerving the ſtate of the town and of the people. Bias, ſuſpecting their deſign, ordered the granaries to be filled with large heaps of ſand, and theſe heaps to be covered with corn; upon which, when the deputies returned, and reported the plenty of proviſion with which the city was furniſhed, the king no longer demurred, but concluded a treaty, and raiſed the ſiege. As an inſtance of his generoſity, it is related of him, that when ſeveral young female captives were brought from Meſſene to Priene, he redeemed them, educated them as his own daughters, and then reſtored them with a dowry to their parents. As an evidence of the low eſtimation in which he held the gifts of fortune, compared with the endowments of the mind, it is ſaid, that when Priene was once threatened with a ſiege, and the inhabitants were leaving it, loaded with their moſt valuable effects, Bias took no pains to preſerve any part of his property, alleging as a reaſon of his conduct to one who expreſſed his ſurpriſe at it, "I carry all my treaſures with me." The following maxims of wiſdom are aſcribed to him. "It is a proof of a weak and diſordered mind to deſire impoſſibilities." "The greateſt infelicity is, not to be able to endure misfortunes patiently." "Great minds alone can ſupport a ſudden reverſe of fortune." "The moſt pleaſant ſtate is to be always gaining." "Be not unmindful of the miſeries of others." "If you are handſome, do handſome things; if deformed, ſupply the defects of nature by your virtues." "Be ſlow in undertaking, but reſolute in executing." "Praiſe not a worthleſs man for the ſake of his wealth." "Whatever good you do, or do all the good you can, and aſcribe the glory of it to the gods." "Lay in wiſdom as the ſtore for your journey from youth to old age, for it is the moſt certain poſſeſſion." "Many men are diſhoneſt; therefore love your friend with caution, for he

he may hereafter become your enemy." Bias is aſſerted to have written more than 2000 verſes concerning Ionia. His death was no leſs honourable than affecting; for he expired in the arms of a grandſon, while he was pleading a cauſe for a friend. Diog. Laert. l. i. 82. Val. Max. l. iii. c. 2. vii. 2. Aul. Gell. l. v. c. 11. Cicer. de Amicit. c. 60. Plut. Conv. vii. Ariſtot. Rhet. l. ii. c. 13. Stobæus Serm. 28. Brucker's Phil. by Enf. vol. i. p. 136.

Bias, in *Entomology*, a ſpecies of Papilio (*Pleb. Rur.*), that inhabits Cayenne. The wings are entire black, gloſſed with blue; beneath brown, with a white poſterior margin. Fabricius.

BIASI, St. in *Geography*, a town of Italy, in the kingdom of Naples, and province of Principato citra, 15 miles W.N.W. of Policaſtro.

BIATHANATI, βιαθανατοι, from βια, *violence*, and θανατος, *death*; the ſame with ſuicides, or thoſe who kill themſelves.

BIB, in *Ichthyology*, the Engliſh name of a fiſh of the Gadus tribe, called *luſcus* by Linnæus.

BIBAN, in *Geography*, a town of Egypt, in Bahira, the reſidence of a kiaſchef. Once a week, on Monday, a fair for camels and other cattle is held in the fields adjoining to this place.

BIBBONA, a town of Italy, in the duchy of Tuſcany, 50 miles north of Arezzo.

BIBBS, Bibs, or Brackets, in *Naval Architecture*, are made of elm plank, and bolted to the hounds of maſts, as ſupporters to the treſtle trees. They are from three to five inches thick, and nine elevenths of the hounds in length, and in breadth ſix fifteenths their length. The after edge is firſt lined ſtraight, and the upper part ſquare from that, and the fore part tapered by a moulding to four or ſix inches of breadth at the lower ends. The after edge is fayed on the cheeks, and the upper part againſt the under ſide of the treſtle trees on the fore ſide of the maſt: viz. In the middle of the after edge, ſet up one inch and a half, and line ſtraight from that to nothing at the lower end, which makes a butt in the middle; then place the bibbs on the maſt, their thickneſs within the ſides of the cheeks, and their upper parts to the outſide of the treſtle trees; then let one inch and a half be raced by the lower edge of the bibbs upon the cheeks, and the wood taken out to that depth, and the thickneſs of the bibbs, that they may bed firm therein; they are then bolted edgeways through the cheeks with four bolts driven from the fore ſide and clenched on a ring on the aft-ſide. The bolts are to be in diameter from one inch to ſeven eighths, or three quarters in ſmall ſhips' maſts, and only three in number. The lower end of the bibb is rounded off to the ſurface of the cheek, and the edges chamfered.

BIBEN, in *Geography*, a town of Perſia, in the Irak Agemi, 140 miles eaſt of Iſpahan.

Biben, otherwiſe called *Pitſchem*, and in Latin *Pedena*, or *Petina*, a town of Carniola, ſeated in a very fertile ſpot, on a high mountain; and the ſee of a biſhop, to whoſe juriſdiction belong two towns and eleven villages, in which are fourteen pariſhes, ſuffragan to the prelate of Gorz.

Biber, a town or village of Germany, in the circle of the lower Rhine, the electorate of Mentz, and prefecturate of Steinheim, 5 miles E.S.E. of Francfort on the Main. This is one of eleven villages which are poſſeſſed in common of a wood named the "Biber Mark." At Biber, all things relating to it are managed by the ſheriffs of the Mark; and before the village, under a great lime-tree, lies the ſheriff's bench, where the Mark court is fenced in, and tranſgreſſors are openly cited and puniſhed.

BIBER, in *Zoology*, a name given by Ridinger, &c. to the *beaver*, *caſtor fiber*. Linnæus.

Biber, Henry John Francis, in *Biography*, vice-chapel-maſter to the archbiſhop of Salzburg, ſeems to have been the greateſt performer on the violin of the 17th century. Baltzar from Lubec, about the middle of that century, had ſo aſtoniſhed the Oxonians by his execution on the violin, that according to Ant. Wood, Dr. Wilſon, the muſic profeſſor, after hearing him, ſtooped down to examine his feet, whether they were not cloven; that is, "whether he was a devil, or not, becauſe his performance was beyond the faculties of man." But if we may now judge of his performance by his compoſitions that are ſtill extant, it was very inferior to that of *Biber*, who publiſhed in 1681, ſolos for a violin and baſe, the moſt difficult and the moſt fanciful of any muſic of the ſame period. One of the ſolos is written on three ſeparate ſtaves, as if a ſcore for two violins and a baſe; but the trebles are to be played in double ſtops. Others are played in different tunings of fourths and fifths, as for a treble viol. A ſecond work by this muſician, intitled *fidicinum ſacro profanum*, conſiſts of twelve ſonatas in four and five parts, to be played on three inſtruments; and a third, *harmonia artificioſo arioſa*, publiſhed at Nuremberg, conſiſting of pieces in ſeven parts, to be played on three inſtruments. In this laſt work he is ſtyled *Dapifer*. In knowledge of the finger-board, double ſtops, and uſe of the bow, as well as compoſition, he ſeems to have ſurpaſſed all preceding violiniſts.

BIBERACH, in *Geography*, an imperial city of Germany, in the circle of Swabia, ſituate in a valley, watered by the Rieſs, near the Danube. The magiſtrates and people are partly proteſtants and partly catholics; and the church, as well as the hoſpital, are common to both. The treaty of Weſtphalia requires that it ſhould have as many catholics as Lutherans in the ſenate. It is governed, as to its offices, like the city of Augſburg. It has a large manufacture of fuſtians. The number of houſes is eſtimated at 900, of inhabitants at 6,600, and of burghers at 900. This city is very ancient, and was known in the year 751, under Pepin. By the plan of indemnities agreed upon by France and Ruſſia, this imperial town was conceded to the margrave of Baden. N. lat. 48° 4′. E. long. 10° 2′.

BIBERSTEIN, a ſmall town of Swifferland, in the canton of Bern, ſeated on the north-weſt ſide of the Aar. N. lat. 47° 17′. E. long. 7° 56′.—Alſo, a bailliwick, with a caſtle, in the circle of the Upper Rhine, and biſhopric of Fulda, 8 miles eaſt of Fulda.

BIBIENA, Bernardo Da, *Cardinal*, whoſe proper name was *Dovizi*, or *Divizio*, was born of an obſcure family at Bibiena, in the Caſentine, in 1470, and entered into the ſervice of the family of Lorenzo di Medici. He attached himſelf to cardinal John, afterwards pope Leo X., whom he accompanied in his exile and ſerved with affection and fidelity. At Rome he ingratiated himſelf with pope Julius II., by whom he was employed in ſome concerns of importance, and by whom his ſervices were approved. On the death of Julius, he artfully perſuaded the cardinals, that his maſter, though only 36 years of age, was not likely to live long, and by this artifice obtained his election. Leo was not inſenſible of his obligations, and made him his firſt treaſurer, and in 1513, cardinal. In the direction of the works of the holy houſe of Loretto, in which he was employed, he encouraged men of literature, and engaged the beſt artiſts, particularly Raphael. Leo alſo deputed him as legate to the pontifical army againſt the duke of Urbino, then to the emperor Maximilian, and afterwards, in 1518, to Francis I.

cis I. king of France, for the purpoſe of forming a cruſade againſt the Turks. On this occaſion he was received with very marked diſtinction at Paris, though the event of the journey proved fatal to him. It has been generally ſuppoſed, that having a view to ſucceed Leo in the papal ſee, he had obtained the promiſe of Francis's ſupport; and that Leo, being apprized of his ambition, took him off by poiſon; or perhaps, the diſpleaſure of the pope might ſo much affect him as to occaſion a fit of illneſs, which proved mortal in November 1520.

Bibiena is diſtinguiſhed in the hiſtory of literature, as a polite writer, and particularly as the author of a celebrated comedy called "Calandra." This was the firſt comedy written in proſe in the Italian language, or at leaſt the firſt that obtained any conſiderable degree of popularity; and it is ſtill eſteemed as one of the beſt productions of the age, though the wit is not free from indelicacy, and many paſſages of it are copied from Plautus. It was repreſented in a very magnificent manner at Urbino, and afterwards at Rome. The actors were young men of rank, and the author is ſaid to have taken great pains in training the courtiers to dramatic exerciſes, which were performed under the occaſional inſpection of Leo, in the chambers of the Vatican. Gen. Biog.

Bibiena, Ferdinando-Galli, a celebrated painter and architect, was born at Bologna, in 1657; and loſing his father when very young, was placed under the direction of Carlo Cignani, who, obſerving his taſte for architecture, obtained for him the inſtruction of Paradoſſo, Aldrovandini, and Manini, the beſt maſters of that period for perſpective and architecture. In conſequence of the recommendation of Cignani, he was patronized by the prince of Parma, who employed him in executing a variety of decorations, and ſettled upon him an annual penſion. For the dukes of Parma, he painted the ſcenes for *Hiero*, tyrant of Syracuſe, in 1685; for *Thaleſtris* in love with Alexandra, 1693; for *Demetrio tiranno*, 1694; for *Eraclea*, 1700; and for *I rivali generoſo*, in 1701. From Parma he went to Milan, where, in 1704, he painted the ſcenes for *L'Anazzone Corſara*, and thence went to Vienna, and was appointed painter and architect to the emperor Charles VI., by whom he was highly honoured and rewarded. He was the inventor of thoſe wonderful and magnificent ſcenes which ſtill decorate many theatres in Italy; and publiſhed a book of inſtructions for embelliſhing theatres in general. He alſo built ſeveral palaces. He was alſo an excellent machiniſt, and the ſole inventor and director of the ſolemn feſtival machinery exhibited for the birth of the archduke of Auſtria, celebrated at *La Favorita*, near Vienna.

He had a brother, Francis, of equal genius and fame, and two ſons worthy of ſuch a father. It was Ferdinando Bibiena Galli, who, quitting mythology and fantaſtic forms, gave true repreſentations of nature; rapidity of change, intelligent diſpoſition of lights, and above all, that great help to illuſion, the leaving ſomething to the ſpectator's imagination. At length he loſt his ſight by cataracts in his eyes, and obtained leave to return to Italy, where he compoſed two volumes upon architecture for the inſtruction of young perſons. He had ſeveral children, whom he educated to his own art, and a conſiderable number of ſcholars. Bibiena died at Bologna, as ſome ſay, in 1741, and according to others, in 1743. His eaſel pictures exhibit a noble and elegant ordonnance, and an uncommonly beautiful tone of colour. His perſpectives have an aſtoniſhing effect by judicious maſſes of light and ſhadow; and the veſtiges of magnificent buildings, which he happily introduces in his compoſitions, add a richneſs and grandeur to all his performances.

Bibiena, in *Geography*, a market-town of Italy, in the duchy of Tuſcany, and diſtrict of Caſentino.

BIBIG, a town of Egypt, two miles ſouth of Feium.

BIBIO, in *Entomology*, one of the Fabrician genera of Antliata, and which in the Linnæan ſyſtem forms a ſection of the Musca genus. Fabricius defines the generical character of *Bibio* from the ſucker, feelers, and antennæ. The ſucker conſiſts of three briſtles and a ſheath of a ſingle valve; feelers very ſhort; antennæ connected at the baſe, and pointed at the tip. Ent. Syſt. See Musca.

BIBITORY Muscle. See Adductor *Oculi*.

BIBLE, a book, by way of eminence ſo called, containing the Scriptures, i. e. the writings of the Old and New Teſtament; or the whole collection of thoſe which are received among Chriſtians as of divine authority.

The word Bible comes from the Greek Βιβλια, or Βιβλιον, uſed to denote any book; but, by way of eminence, applied to the book of Scripture, which is "the book," or "book of books," as being ſuperior in excellence to all other books. Βιβλιον again comes from βιβλος, the Egyptian reed, from which the ancient paper was procured. See Biblus.

The word Bible ſeems to be uſed in the ſenſe now ſpecified by Chryſoſtom (In Col. H. 9. tom. xi. p. 391): "I therefore exhort all of you to procure to yourſelves Bibles (βιβλια). If you have nothing elſe, take care to have the New Teſtament, particularly the Acts of the Apoſtles, and the Goſpels, for your conſtant inſtructors. And Jerom ſays (In Iſ. c. 29. tom. iii. p. 246.), "that the Scriptures being all written by one Spirit, are one book." Auguſtine alſo informs us (Enarr. in Pſ. il. n. 2. tom. iv.), "that ſome called all the canonical Scriptures one book, on account of their wonderful harmony and unity of deſign throughout." It is not improbable, that this mode of ſpeaking gradually introduced the general uſe of the word "Bible" for the whole collection of the Scriptures, or the books of the Old and New Teſtament.

The Bible is known by various other appellations, as the "Sacred Books," the "Inſpired Writings," "Holy Writ," "Sacred Text," &c. By the Jews the Bible, i. e. the Old Teſtament, is called "Mikra," that is, lecture, or reading; by the Chriſtians the Bible, comprehending the Old and New Teſtament, is uſually denominated "Scripture," q. d. writing; ſometimes alſo the "Book of God," the "Canon," "Rule of Faith," &c. Theſe, and ſimilar appellations, are derived from the opinion that has been entertained, in ſucceſſive ages, of the divine original and authority of the Bible, and of its importance and utility as a rule of faith and directory of conduct. As it contains an authentic and connected hiſtory of the divine diſpenſations with regard to mankind; as it lays claim to divine inſpiration; as its chief ſubject is religion; and as the doctrines it teaches, and the duties it inculcates, pertain to the conduct of men, as rational, moral, and accountable beings, and conduce by their natural influence, as well as by a divine conſtitution and promiſe, to their preſent and future happineſs; the Bible deſerves to be held in high eſtimation, and amply juſtifies the ſentiments of veneration with which it has been regarded, and the peculiar and honourable appellations by which it has been denominated. See the ſequel of this article.

The liſt of the books contained in the Bible, is called the canon of Scripture. See Canon. Thoſe books that are contained in the catalogue to which the name of canon has been appropriated, are called canonical, by way of contradiſtinction from others called deutero-canonical, apocryphal, pſeudo-apocryphal, &c., which either are not acknowledged as divine books, or are rejected as heretical and ſpurious. See Apocryphal.

The

The firſt canon or catalogue of the ſacred books was made by the Jews; but the original author of it is not ſatisfactorily aſcertained. It is certain, however, that the five books of Moſes, called the Pentateuch, were collected into one body within a ſhort time after his death; ſince Deuteronomy, which is, at it were, the abridgment and recapitulation of the other four, was laid in the tabernacle near the ark, according to the order which he gave to the Levites. (ch. xxxi. v. 24.) Hence it appears, that the firſt canon of the ſacred writings conſiſted only of the five books of Moſes; for a further account of which, ſee PENTATEUCH. It does not appear that any other books were added to theſe, till the diviſion of the ten tribes, as the Samaritans acknowledged no others. However, after the time of Moſes, ſeveral prophets, and other writers divinely inſpired, compoſed either the hiſtory of their own times, or prophetical books and divine writings, or pſalms appropriated to the praiſe of God. But theſe books do not ſeem to have been collected into one body, or comprized under one and the ſame canon, before the Babyloniſh captivity. This was not done till after their return from the captivity, about which time the Jews had a certain number of books digeſted into a canon, which comprehended none of thoſe books that were written ſince the time of Nehemiah. The book of Eccleſiaſticus affords ſufficient evidence, that the canon of the ſacred books was completed when that tract was compoſed; for that author, in chap. xlix. having mentioned among the famous men and ſacred writers, Iſaiah, Jeremiah, Ezekiel, adds the twelve minor prophets, who follow thoſe three in the Jewiſh canon; and from this circumſtance we may infer, that the propheeies of theſe twelve were already collected and digeſted into one body. It is farther evident, that in the time of our Saviour the canon of the holy Scriptures was drawn up, ſince he cites the Law of Moſes, the Prophets, and the Pſalms, which are the three kinds of books of which that canon is compoſed, and which he often ſtyles "the Scripture," or "the Holy Scripture." Matt. xxi. 42. xxii. 29. xxvi. 54. John, v. 39. This ſhews that they were diſtinguiſhed from others, and formed a ſeparate body. The perſon who compiled this canon is generally allowed to be Ezra. According to the invariable tradition of Jews and Chriſtians, the honour is aſcribed to him of having collected together and perfected a complete edition of the Holy Scriptures. The original of the Pentateuch had been carefully preſerved in the ſide of the ark, and had been probably introduced with the ark into the temple at Jeruſalem. After having been concealed in the dangerous days of the idolatrous kings of Judah, and particularly in the impious reigns of Manaſſeh and Amon, it was found in the days of Joſiah, the ſucceeding prince, by Hilkiah the prieſt, in the temple. Prideaux ſays, that during the preceding reigns, the book of the Law was ſo deſtroyed and loſt, that, beſides this copy of it, there was then no other to be obtained. To this purpoſe he adds, that the ſurpriſe manifeſted by Hilkiah on the diſcovery of it, and the grief expreſſed by Joſiah when he heard it read, plainly ſhew that neither of them had ſeen it before. Upon this, the pious king ordered copies to be written out from this original, and to be diſperſed among the people. 2 Kings, xxii. 8—13. 2 Chron. xxxiv. On the other hand, Dr. Kennicott ſuppoſes, that long before this time, there were ſeveral copies of the Law in Iſrael, during the ſeparation of the ten tribes, and that there were ſome copies of it likewiſe among the tribes of Judah and Benjamin, particularly in the hands of the prophets, prieſts, and Levites; and that by the inſtruction and authority of theſe MSS., the various ſervices in the temple were regulated, during the reigns of the good kings of Judah. He adds, that the ſurpriſe expreſſed by Joſiah and the people, at his reading the copy found by Hilkiah, may be accounted for by adverting to the hiſtory of the preceding reigns, and by recollecting what a very idolatrous king Manaſſeh had been for 55 years, and that he wanted neither power nor inclination to deſtroy the copies of the Law, if they had not been ſecreted by the ſervants of God. The Law, after being ſo long concealed, would be unknown almoſt to all the Jews; and thus the ſolemn reading of it by Joſiah would awaken his own and the people's earneſt attention; more eſpecially, as the copy produced was probably the original written by Moſes. From this time copies of the Law were extenſively multiplied among the people; and though within a few years, the autograph, or original copy of the Law, was burnt with the city and temple by the Babylonians, yet many copies of the Law and the Prophets, and of all the other ſacred writings, were circulated in the hands of private perſons, who carried them with them into their captivity. It is certain that Daniel had a copy of the Holy Scriptures with him at Babylon; for he quotes the Law, and mentions the propheeies of Jeremiah. Dan. ix. 11. 13. ix. 2. It appears alſo, from the ſixth chapter of Ezra, and from the ninth chapter of Nehemiah, that copies of the Law were diſperſed among the people. It is unneceſſary, therefore, to ſuppoſe, with ſome of the ancient fathers, ſuch as Tertullian, Clemens Alexandrinus, Baſil, &c. that Ezra reſtored the ſcriptures by a divine revelation, after they had been loſt and deſtroyed in the Babyloniſh captivity. For this opinion they had no other authority than the fabulous relation which occurs in the 14th chapter of the ſecond apocryphal book of Eſdras; a book too abſurd for the Romaniſts themſelves to admit into their canon. The whole which Ezra did may be comprized in the following particulars. He collected as many copies of the ſacred writings as he could find, and compared them together, and out of them all, formed one complete copy, adjuſted the various readings, corrected the errors of tranſcribers, and, as ſome ſay, annexed the "Keri chetibs," which are found in the margins of the ancient MSS. He likewiſe made additions in ſeveral parts of the different books which appeared to be neceſſary for the illuſtration, correction, and completion of them. To this claſs of additions, we may refer the laſt chapter of Deuteronomy, which, as it gives an account of the death and burial of Moſes, and of the ſucceſſion of Joſhua after him, could not have been written by Moſes himſelf. Under the ſame head have alſo been included many other interpolations in the Bible, which create difficulties that can never be ſolved without allowing them; as in Gen. xii. 6. xxii. 14. xxxvi. 3. Exod. xvi. 35. Deut. ii. 12. iii. 11, 14. Prov. xxv. 1. The interpolations in theſe paſſages are aſcribed by Prideaux to Ezra; and others which were afterwards added he attributes to Simon the Juſt. Ezra alſo changed the old names of ſeveral places that were become obſolete, putting inſtead of them the new names by which they were at that time called; inſtances of which occur in Gen. xiv. 4. where Dan is ſubſtituted for Laiſh, and in ſeveral places in Geneſis, and alſo in Numbers, where Hebron is put for Kirjath Arba, &c. He likewiſe wrote out the whole in the Chaldee character, changing for it the old Hebrew character, which hath ſince that time been retained only by the Samaritans, and among whom it is preſerved even to this day. In the church of Dominic, in Bononia, there is ſaid to be a copy of the Hebrew Scriptures, preſerved with great care, which they pretend to be the original copy written by Ezra himſelf, and for which great ſums have been occaſionally borrowed by the Bononians upon the pledge of it, and which have again been paid for its redemption. This copy is written in a very

very fair character upon a ſort of leather, and made up in a roll, according to the ancient manner; but as it has the vowel points annexed, and the writing is freſh and fair, without any viſible decay, its antiquity is very juſtly denied, and its novelty is unqueſtionable. Biſhop Pocock, in his Travels, vol. i. p. 28. mentions a MS. Bible, preſerved at Cairo, in Egypt, which is ſaid to be written by Ezra.

Dupin ſays, that Nehemiah had a great hand in compiling this canon; for proof of which he refers to the letter to the Jews of Jeruſalem written to the Jews of Egypt, mentioned in the beginning of the ſecond book of Maccabees, in which, it is ſaid, that Nehemiah had collected the books of the Kings, of the Prophets, and of David. It is ſaid, that this canon was then approved by the grand ſanhedrim, the great ſynagogue or council of ſeventy, and publiſhed by its authority. It is, however, ſays Dupin, more apparent, that about that time the number of the ſacred books was fixed among the Jews by a canon, which the whole Jewiſh nation received and followed; ſo that they looked no longer upon ſuch books as ſacred and divinely inſpired, which were not contained in this canon. The canon of the whole Hebrew bible ſeems, ſays Kennicott, to have been cloſed by Malachi, the lateſt of the Jewiſh prophets: about 50 years after Ezra had collected together all the ſacred books which had been compoſed before and during his time. Prideaux ſuppoſes the canon was cloſed by Simon the Juſt, about 150 years after Malachi. But, as his opinion is founded merely on a few proper names at the end of two genealogies (1 Chron. iii. 19. & Neh. xii. 22.), which few names might very eaſily be added by a tranſcriber afterwards; it is more probable, as Kennicott thinks, that the canon was finiſhed by the laſt of the prophets, about 400 years before Chriſt. The books of the Old Teſtament having been ſettled by Ezra, Nehemiah, Haggai, Zephaniah, and Malachi, were probably left perfect; completely repaired after the injuries of time during the captivity; and corrected from ſuch errors as might have crept in from want of care in the tranſcribers. But the Hebrew text, thus left to poſterity, does not ſeem to have continued long in the ſame condition. For the celebrated text, relative to mount Gerizim, was without doubt altered ſoon after the temple upon Gerizim was built. And as that corruption has been proved upon the Jews, the Jews therefore corrupted their Pentateuch, in this inſtance, probably between the years 400 and 300 before Chriſt. See PENTATEUCH.

It is an enquiry of conſiderable importance, in its relation to the ſubject of this article, what books were contained in the canon of the Jews. In the arrangement of Ezra theſe books were divided into three parts; 1ſt. The Law; 2dly. The Prophets; and 3dly. The Cetubim, or Hagiographa, i.e. the holy writings; which diviſion our Saviour himſelf has taken notice of (Luke xxiv. 44); meaning by the Pſalms the whole third part, called the Hagiographa. In conformity to this diviſion, Joſephus (Contra Apion. i. 8. tom. ii. p. 441.) diſtributes the canonical books of the Jews into three claſſes. The firſt contains the five books of Moſes; the ſecond, thirteen hiſtorical and prophetical books, written from the time of the death of Moſes to Artaxerxes; and the third, four books of hymns and of morality; the whole number amounting to twenty-two. The firſt claſs comprehends Geneſis, Exodus, Leviticus, Numbers, and Deuteronomy; the ſecond includes Joſhua, Judges, Ruth, Samuel, Kings, Chronicles, Ezra with Nehemiah, Eſther, Iſaiah, Jeremiah with Lamentations, Ezekiel, Daniel, and the 12 minor prophets; and the third claſs contains Job, the Pſalms, Proverbs, and Eccleſiaſtes. It appears that the Song of Solomon had no place in the liſt of the ſacred writings drawn up by Joſephus. Others, however, have joined Ruth with Judges, referred Job to the ſecond claſs, and introduced the Song of Solomon into the third claſs. Origen, Athanaſius, Hilary, Gregory Nazianzen, Epiphanius, and Jerom, ſpeaking of the books that are allowed by the Jews as ſacred and canonical, agree in ſaying, that they are the ſame in number with the letters in the Hebrew alphabet, i.e. twenty-two, and reckon particularly thoſe books which we have already mentioned; with reſpect to which they all concur, except in relation to the book of Eſther. All of them place the book of Job and the Lamentations among the books contained in the canon of the Jews; but Athanaſius and Gregory Nazianzen do not reckon the book of Eſther among them, and diſtinguiſh Ruth from the book of Judges; whereas Origen, Hilary, Epiphanius, and Jerom, make only one volume of Ruth and Judges, and introduce the book of Eſther into the number of the twenty-two books reckoned by the Jews as canonical. They who diſtinguiſhed Ruth from the book of Judges, and the Lamentations from the prophecy of Jeremiah, reckoned up twenty-four of them. Theſe books are diſpoſed of in the following order: viz. 1ſt. The Law, containing Geneſis, Exodus, Leviticus, Numbers, Deuteronomy; 2dly. The writings of the prophets, divided into the former prophets and the latter prophets; thoſe of the former being Joſhua, Judges, Samuel, Kings, and the latter Iſaiah, Jeremiah, Ezekiel, and the twelve minor prophets; 3dly. The Hagiographa, which are the Pſalms, the Proverbs, Job, the Song of Solomon, or Song of Songs, or Canticles, Ruth, the Lamentations, Eccleſiaſtes, Eſther, Daniel, Ezra, and the Chronicles. Under the name of Ezra is comprehended Nehemiah. However, this order hath not always been obſerved among the Jews, neither is it ſo now in all places; for in this reſpect there has been a great variety, not only among the Jews, but alſo among the Chriſtians, Greeks as well as Latins. All theſe books were not received into the canon of the Holy Scriptures in the time of Ezra, for Malachi lived after him, and mention is made in Nehemiah of Jaddua as high prieſt, and of Darius Codomannus as king of Perſia, who lived at leaſt 100 years after his time; and in the third chapter of the firſt book of Chronicles, the genealogy of the ſons of Zerubbabel is extended to as many generations as will bring it to the time of Alexander the Great, ſo that this book could not have been inſerted in the canon till after his time. Accordingly, Prideaux ſuppoſes, that the two books of Chronicles, Ezra, Nehemiah, and Eſther, as well as Malachi, were added in the time of Simon the Juſt, when he conceives the canon of the holy Scriptures was completed. (See above).

The five books of the Law are divided into 54 ſections, which diviſion is attributed to Ezra, and was intended for the uſe of their ſynagogues, and for the better inſtruction of the people in the law of God. For every ſabbath one of theſe ſections was read in their ſynagogues. They ended the laſt ſection with the laſt words of Deuteronomy on the ſabbath of the feaſt of the tabernacles, and then began anew with the firſt ſection from the beginning of Geneſis the next ſabbath after, and ſo went round in this circle every year. The number of theſe ſections was 54, becauſe in their intercalated years (a month being then added), there were 54 ſabbaths. On other years they reduced them to the number of the ſabbaths which were in theſe years, by joining two ſhort ones ſeveral times into one. For they held themſelves obliged to have the whole law thus read over in their ſynagogues every year. Till the time of the perſecution of Antiochus Epiphanes, they read only the Law; but being then prohibited from reading it any more, they ſubſtituted in the room of the 54 ſections of the Law, 54 ſections out of

the Prophets, the reading of which they ever after continued. Thus, when the reading of the Law was reſtored by the Maccabees, the ſection which was read every ſabbath out of the Law ſerved for their firſt leſſon, and the ſection out of the Prophets for their ſecond leſſon; and this practice was continued in the time of the apoſtles. Acts. xiii. 15. xiii. 27. Theſe ſections were divided into verſes, called by the Jews "Peſukim," and they are marked out in the Hebrew Bible by two great points at the end of them, called from hence "Soph-Paſuk," i.e. the end of the verſe. This diviſion, if not made by Ezra, is very ancient; for when the Chaldee came into uſe in the room of the Hebrew language, after the return of the Jews from their captivity in Babylon, the Law was read to the people firſt in the Hebrew language, and then rendered by an interpreter into the Chaldee language; and this was done period by period. To diſtinguiſh theſe periods was an object of importance; and hence aroſe the diviſion into verſes, which was firſt applied to the Law, and afterwards to the Prophets and Hagiographa. The manner by which theſe diviſions, or verſes, are now diſtinguiſhed is by the "Soph-Paſuk;" but it is not certain that this was the ancient method. Prideaux apprehends, that the Peſukim, or verſes of the Hebrew bibles, were anciently diſtinguiſhed in the ſame manner as the "Stichi" afterwards were in the Greek Bibles. The manner of their writing theſe ſtichi at firſt was to allow a line to every ſtichus, and there to end the writing, where they ended the ſtichus, leaving the reſt of the line a void break. But this mode occaſioning a waſte of parchment, on which their books were written, and making their bulk too heavy; in order to avoid theſe inconveniences, they afterwards put a point at the end of every ſtichus, and continued the writing without leaving any blank. In the Hebrew Bibles they adopted the ſame mode, and put the two points, called "Soph-paſuk," at the place where one verſe ended, and continued the writing of the next verſe in the ſame line, without leaving any void ſpace. The diviſion of the holy Scriptures into chapters is of a much later date. The Pſalms, indeed, appear to have been always divided as they are at preſent. Acts. xiii. 33. But as to the reſt of the Bible, the preſent diviſion into chapters was unknown to the ancients. See CHAPTER and CONCORDANCE.

Beſides thoſe books which were received into the canons of the books of the Old Teſtament, and thoſe that have been deemed apocryphal, there are ſeveral others which are cited in the Old, and alſo in the New Teſtament, which ſeem either to have been loſt, or excluded by Ezra from his canon. Of ſuch books are the books "of the wars of the Lord," cited Numb. xxi. 4. but it does not appear that in this place any book is mentioned, "of the Covenant," of which it is ſaid mention is made Exod. xxiv. 7. but evidently referring to the laws received by Moſes from the hand of God, related in the preceding chapters; the "book of the Lord," mentioned If. xxxiv. 16. which does not ſeem to be any particular book; "the book of Jaſher, or the upright," cited in Joſhua. x. 13. and 2 Sam. i. 18. ſuppoſed by ſome to be an hiſtorical book, but more probably conſiſting of hymns and ſongs; and "the books of Nathan (1 Chron. xxix. 29. 2 Chron. ix. 29.) of Gad, (1 Chron. xxix. 29.) of Shemaiah, (2 Chron. xii. 15.) of Iddo, (2 Chron. ix. 29. xii. 15. xiii. 22.) of Abijah, (2 Chron. ix. 29.) and of Jehu, (2 Chron. xx. 34.), which were memoirs compoſed by thoſe prophets, or rather prophecies, which contained a part of the hiſtory. The ſame may be ſaid of the book of the "Journals or Chronicles" of the kings of Judah or of Iſrael; which are different from the Paralipomena, or Chronicles; the book of "Samuel the Seer," cited in the laſt chapter of the firſt book of Chronicles; the diſcourſes of Hoſeah, cited 2 Chron. xxxiii. 18, 19. the "Acts of Uzziah," mentioned 2 Chron. xxvi. 22. the "three thouſand Proverbs, written by Solomon, (ſee 1 Kings iv. 32.); "a thouſand and five Songs," &c. compoſed by the ſame author, and mentioned in the ſame place. Jeremiah ſpeaks of a volume of prophecies which he had dictated to Baruch, ſuppoſed by ſome to be the Lamentations. (See BARUCH). Beſides theſe books that are loſt, there are others, not included in the canon of the Old Teſtament, which are ſtill extant; ſuch as the "Prayer of king Manaſſeh, when captive at Babylon," cited 2 Chron. ch. xxxiii. "the third and fourth books of Eſdras;" "the third and fourth books of the Maccabees;" "the genealogy of Job," and "a ſpeech of Job's wife," annexed to the Greek edition of the book of Job; "a Pſalm," affixed to the Greek edition of the Pſalms; "the book of Enoch," not entire, cited by ſeveral of the fathers, and regarded by them as apocryphal, and referred to by Jude, v. 14. the book of the "Aſſumption of Moſes," and his "Teſtament," placed by St. Athanaſius among the apocryphal books; "the Aſſumption, Apocalypſe, or Secrets of Elijah," cited by Origen; and a number of others forged by the Jews, and fathered on the Patriarchs. See NEW TESTAMENT.

It may not be improper to refer, in one view, the books of the Old and New Teſtaments to their proper authors. We may ſuppoſe then, without aſcending to the region of conjecture, and tracing the origin of any books, or parts of books of the Bible to patriarchal times, that the Pentateuch conſiſts of the writings of Moſes, put together, perhaps, by Samuel, with a very few additions; that the books of Joſhua and Judges were, in like manner, collected by him; and the book of Ruth, with the firſt part of the firſt book of Samuel, written by him; that the latter part of the firſt book of Samuel, and the ſecond book, were written by the prophets who ſucceeded Samuel, viz. Nathan and Gad; that the books of Kings and Chronicles are extracts from the records of the ſucceeding prophets, concerning their own times, and from the public genealogical tables, made by Ezra; that the books of Ezra and Nehemiah are collections of like records, ſome written by Ezra and Nehemiah, and ſome by their predeceſſors; that the book of Eſther was written by ſome eminent Jew, in or near the times of the tranſactions there recorded, perhaps Mordecai; the book of Job by Moſes, or a Jew of an uncertain period; the Pſalms by David, and other pious perſons; the books of Proverbs and Canticles by Solomon; the book of Eccleſiaſtes by Solomon, or perhaps by a Jew of later times, ſpeaking in his perſon, but not with an intention to make him paſs for the author; the Prophecies by the prophets, whoſe names they bear; and the books of the New Teſtament by the perſons to whom they are uſually aſcribed. See NEW TESTAMENT. There are many internal evidences, and in the caſe of the New Teſtament, many external evidences alſo, by which theſe books may be known to belong to the authors here named. Or, if there be any doubts, they are merely of a critical nature, and do not at all affect the genuineneſs of the books, or not alter, at leaſt materially, the arguments that may be adduced in favour of their authenticity and authority. It is readily allowed, that objections have been made to the alledged authors of ſeveral of theſe books. Abenezra, followed by Hobbes, Pereira, Spinoza, and ſome others, deny the firſt five books to have been written by Moſes. F. Simon, in particular, aſſerts, that the books, as we now have them, are not the originals written by the inſpired penmen, but abridgments of them, made in after-times by a kind of college, or order, of public actuaries, or ſcribes,

ſcribes, appointed for that purpoſe. See PENTATEUCH, and each of the books of the Bible, under its proper title. See alſo NEW TESTAMENT.

The original language of the Old Teſtament was, without doubt, the old Hebrew, at leaſt the greateſt part of it; for all the books do not appear to have been written in the ſame language. Some chapters of Ezra and Daniel, (ſee EZRA and DANIEL,) are judged to have been compoſed in Chaldee; and it has been ſuppoſed, that other chapters of this latter writer, and alſo the apocryphal books of Maccabees, Wiſdom, &c. were written in Greek; Tobit and Eccleſiaſticus, either in Greek or Syriac. As for the New Teſtament, it was written in Greek, except the Goſpel of St. Matthew, which is thought by ſome to have been compoſed in Hebrew. Some few have thought that the Goſpel of St. Mark was written in Latin, and alſo the epiſtle to the Hebrews. See the Title of each Book, and TESTAMENT.

With regard to the ſtyle of the ſeveral writers of the Old and New Teſtament, there is a very conſiderable diverſity. The ſtyle of Paul may be eaſily diſtinguiſhed by its peculiarity from that of any other writer. A diſcerning reader will not eaſily confound the ſtyle of Luke with that of either of the evangeliſts, who preceded him, Matthew or Mark; nor would he be in any danger of miſtaking the apoſtle John's diction for that of any other penman of the New Teſtament. The ſame difference of ſtyle will be diſcovered by one who is but moderately converſant with the Hebrew, in the writers of the Old Teſtament. In this we have a greater variety than in the New. Some of the books are written in proſe, and ſome in verſe; and in each the differences between one book and another are conſiderable. In the book of Job, for inſtance, the character of the ſtyle is remarkably peculiar. What can be more diſſimilar in this reſpect, though both are excellent in their kind, than the towering flights of the ſublime Iſaiah, and the plaintive ſtrains of the pathetic Jeremiah? In the ſeveral books of Scripture we can ſpecify the conciſe ſtyle and the copious, the elevated and the ſimple, the aphoriſtic and the diffuſe. This diverſity in the diction of the ſacred penmen is perfectly reconcileable with the idea of their inſpiration; and in ſpeaking on this ſubject, we ſhould duly advert to the difference between the expreſſion and the ſentiment, and avoid confounding theſe two, as if they were the ſame, whereas they are widely different. The truths implied in the ſentiments are eſſential, immutable, and have an intrinſic value; the words which compoſe the expreſſion are in their nature circumſtantial, changeable, and have no other value than what they derive from the arbitrary conventions of men. That the Holy Spirit would guide the minds of the ſacred penmen in ſuch a manner as to prevent their adopting terms unſuitable to his deſign, or which might obſtruct his purpoſe; and that in other reſpects he would accommodate himſelf to their manner and diction, is both reaſonable in itſelf, and rendered unqueſtionable by the works themſelves, which have the like characteriſtic differences of ſtyle which we find in other compoſitions. Can it be accounted more ſtrange that the Holy Spirit ſhould, by the prophet Amos, addreſs us in the ſtyle of a ſhepherd, and by Daniel, in that of a courtier, than that by the one he ſhould ſpeak to us in Hebrew, and by the other in Chaldee? It is as reaſonable to think that the Spirit of God would accommodate himſelf to the phraſeology and diction, as to the tone of voice and pronunciation of thoſe whom he was pleaſed to enlighten; for it cannot be denied, that the pronunciation of one perſon in uttering a prophecy, might be more articulate, more audible, and more affecting than that of another; and in like manner, as one ſtyle has more harmony, elegance, and perſpicuity than another. Caſtalio ſays juſtly, (Def. cont. Bezam.) "Res dictat Spiritus, verba quidem et linguam loquenti aut ſcribenti liberam permittit; i. e. the Spirit dictates the things, leaving the words or language free to the ſpeaker or writer. Jerom alſo obſerved a thouſand years before, (Comment. in Epiſt. ad Gal. cap. i.) "Nec putemus in verbis Scripturarum evangelium eſſe, ſed in ſenſu;" i. e. let us not imagine that the Goſpel conſiſts in the words of Scripture, but in the ſenſe. To the ſame purpoſe is the obſervation of the ingenious and learned biſhop Lowth, (De Sacra Poeſi, Heb. Præl. xvi.) "Hoc ita ſacris vatibus tribuimus, ut nihil derogemus Divini Spiritus afflatui; etſi ſuam interea vim propriæ cujuſque Scriptoris naturæ atque ingenio concedamus: neque enim inſtinctu divino ita concitatur vatis animus, ut protinus obruatur hominis indoles: attolluntur et eriguntur, non extinguuntur aut occultantur naturalis ingenii facultates; et quanquam Moſis, Davidis, et Iſaiæ, ſcripta ſemper ſpirant quiddam tam excelſum tamque cæleſte, ut plane videantur divinitus edita, nihilo tamen minus in iis Moſem, Davidem, Iſaiam, ſemper agnoſcimus;" i. e. we ſhall detract nothing from the dignity of that inſpiration, which proceeds from higher cauſes, while we allow to the genius of each writer his own peculiar excellence and accompliſhments. The Divine Spirit by no means takes ſuch an entire poſſeſſion of the mind of the prophet as to ſubdue or extinguiſh the character and genius of the man; the natural powers of the mind are in general elevated and refined; they are neither eradicated, nor totally obſcured; and though the writings of Moſes, of David, and of Iſaiah, always bear the marks of a divine and celeſtial impulſe, we may nevertheleſs plainly diſcover in them the particular characters of their reſpective authors. See INSPIRATION.

It muſt be allowed, that many circumſtances concur to render the ſtyle both of the New Teſtament and of the Old; of the hiſtorical books, as well as of the prophetical and argumentative, generally obſcure, and often ambiguous; although we ought not to admit the exaggerated repreſentation of father Simon, (Hiſt. Crit. des V. T. liv. iii. c. 2.) with regard to the greater part of the Hebrew words, which, he ſays, are equivocal, and of courſe their ſignification altogether uncertain. The origin of this kind of ſtatement muſt be ſought in the author's attachment to tradition, rather than to that kind of ſcepticiſm with which he is charged by Boſſuet, biſhop of Meaux, and which tended to undermine Chriſtianity itſelf. To any perſon who duly reflects, this father's repreſentation muſt appear to be unfounded, or beyond all bounds hyperbolical. It is not juſt in its reference to the prophetical writings; and as to the hiſtorical books, they are, in general, remarkable for perſpicuity. The firſt quality by which the ſacred hiſtory is diſtinguiſhed is ſimplicity, which ariſes from this property of the Hebrew language, the verbs of which have not, like Greek and Latin, a variety of moods and tenſes, nor do they abound, like the modern languages, in auxiliaries and conjunctions. This quality very much conduces to the perſpicuity of its ſtyle. Of this ſimplicity we have an example in the firſt paragraph of Geneſis, conſiſting of five, not long, verſes, and containing not fewer than eleven ſentences, which are ſingularly ſimple; the ſubſtantives not being attended by adjectives, nor the verbs by adverbs, without ſynonyms, or ſuperlatives, or any effort towards expreſſing things in a bold, emphatical, or uncommon manner. In the Pentateuch, there is alſo a ſimplicity of ſentiment, ariſing from the very nature of the early and uncultivated ſtate of ſociety, about which its books are converſant, and this renders the narrative, in general, extremely clear and engaging. Beſides the ſimplicity of ſtructure, and the ſimplicity of ſentiment, there is another ſpecies of ſimplicity, for which Scripture hiſtory is more remarkable than any

other compoſitions of any language. This may be denominated ſimplicity of deſign. The ſubject of the narrative ſo engroſſes the attention of the writer, that he diſappears, as it were, from the view of the reader. He introduces nothing as from himſelf; no opinions of his own, no remarks, conjectures, doubts, or inferences; no reaſoning about the cauſe or the effects of what is related. He never interrupts his reader with the diſplay, either of his talents or his paſſions: he makes no digreſſions; he draws no characters; he ſupplies us merely with naked facts, from which we are left to collect the character. We obſerve no attempt to ſhine by means of the expreſſion, compoſition, or ſentiments. Plainneſs of language is always preferred, becauſe it is the moſt natural, the moſt obvious, and the beſt adapted to all capacities. In this laſt ſort of ſingularity, for which Xenophon among the Greeks, and Cæſar among the Latins, have been recommended, our Lord's biographers particularly excel. With reſpect to the firſt ſpecies of ſimplicity, or that of ſtructure, the difference of the genius of the Greek language from that of the Hebrew muſt, without doubt, occaſion ſome difference in the manner of Matthew, Mark, Luke, and John, from that of Moſes; but the identity of idiom ſtill occaſions a ſtrong reſemblance between them. If Geneſis, therefore, may be juſtly ſaid to poſſeſs the *firſt* rank for ſimplicity of compoſition in the ſentences, the Goſpels are certainly entitled to the *ſecond*: and John and Matthew have it in a higher degree than Mark and Luke. As to the ſecond ſpecies, or ſimplicity of ſentiment, the change of times, which is very great, as well as the difference of ſubjects, would neceſſarily confer the firſt degree of it upon the former. But in ſimplicity of object or deſign, the evangeliſts, of all writers, ſacred and prophane, appear the foremoſt. Their manner is indeed, in ſome reſpects, peculiar and unrivalled. If we divert our attention from the hiſtorical, or narrative parts of the Bible, to the writings of the poets and prophets, we ſhall diſcover the animated, elegant, and ſublime intermixed, as the ſubjects ſuggeſt, and the occaſions require, with the ſimple and perſpicuous. But for other particulars, in reference to this ſubject, ſee STYLE and TESTAMENT. See alſo the titles of the ſeveral books of the Bible, for the diſtinguiſhing character of their writers.

Having conſidered the appellations by which the Bible is diſtinguiſhed, the books of which it conſiſts, the time, and manner in which they were collected, their reſpective authors, and the language and ſtyle in which they were written, it may not be improper to ſubjoin a few obſervations on the genuineneſs and authenticity of the Scriptures, on their high original and divine authority, and on their great importance and utility.

It ſhould here be conſidered, that the genuineneſs of the Scriptures proves the truth of the principal facts contained in them; to which purpoſe we may obſerve, that it is very rare to meet with any genuine writings of the hiſtorical kind, in which the principal facts are not true, unleſs it be in inſtances where both the motives which engaged the author to falſify, and the circumſtances which gave ſome plauſibility to the fiction, are apparent; neither of which can be alledged in the preſent caſe with any colour of reaſon. As this is rare in general, it is more rare, when the writer treats of things that happened in his own time, and under his own cognizance and direction, and communicates his hiſtory to perſons under the ſame circumſtances; all which may be ſaid of the writers of the Scripture hiſtory. Beſides, the great importance of the facts mentioned in the Scriptures makes it more improbable, that the ſeveral authors ſhould either have attempted to falſify, or have ſucceeded in ſuch an attempt. This is an argument for the truth of the facts, which proves the genuineneſs of the books at the ſame time. However, the truth of the facts is inferred more directly from their importance, if the genuineneſs of the Scriptures be previouſly allowed. The ſame obſervation may be applied to the great number of particular circumſtances of time, place, perſons, &c. mentioned in the Scriptures, and to the harmony of the books with themſelves, and with each other. Theſe are arguments both for the genuineneſs of the books, and truth of the facts diſtinctly conſidered, and alſo arguments for deducing the truth from the genuineneſs. Moreover, if the books of the Old and New Teſtaments were written by the perſons to whom they have been aſcribed, i. e. if they be genuine, the moral characters of theſe writers afford the ſtrongeſt aſſurance, that the facts aſſerted by them are true. The ſufferings which ſeveral of the writers underwent both in life and in death, in attеſtation of the facts delivered by them, furniſh a particular argument in favour of theſe facts. Again, the arguments here alledged for proving the truth of the Scripture hiſtory from the genuineneſs of the books, are as concluſive in reſpect of the miraculous facts, as of the common ones. It may alſo be obſerved, that if we allow the genuineneſs of the books to be a ſufficient evidence of the common facts which they record, the miraculous facts muſt alſo be allowed, from their cloſe connection with the others. It is neceſſary to admit both or neither. We cannot conceive, that Moſes ſhould have delivered the Iſraelites from their ſlavery in Egypt, or conducted them through the wilderneſs for forty years, at all, in ſuch manner as the common hiſtory repreſents, unleſs we ſuppoſe the miraculous facts intermixed with it to be true alſo. In like manner, the fame of Chriſt's miracles, the multitudes which followed him, the adherence of his diſciples, the jealouſy and hatred of the chief prieſts, ſcribes and phariſees, with many other facts of a common nature, are impoſſible to be accounted for, unleſs we allow, that he did really work miracles. And the ſame obſervations hold, in general, of the other parts of the Scripture hiſtory. We might urge a particular argument in favour of the miraculous part of the Scripture hiſtory, that may be deduced from the reluctance of mankind to receive miraculous facts; which would put the writers and readers very much upon their guard, and would operate as a ſtrong check upon the publication of a miraculous hiſtory at or near the time when the miracles were ſaid to be performed; and thus it would ſerve as a ſtrong confirmation of ſuch an hiſtory, if its genuineneſs be previouſly granted. The converſe of the propoſition, now ſtated and explained, is alſo true: i. e. if the principal facts mentioned in the Scriptures be true, they muſt be genuine writings.

In connection with the preceding propoſition we may obſerve, that the genuineneſs of the Scriptures proves their divine authority. Porphyry in effect acknowledges the truth of this propoſition, in its reference to the book of Daniel, by being unable to deviſe a method of invalidating its divine authority implied in the accompliſhment of the prophecies which it contains, without aſſerting, that they were written after the event, or that they were forgeries. Many of the other books of the O. and N. Teſtaments have unqueſtionable evidences of the divine foreknowledge, if they be allowed genuine: ſuch are thoſe ſupplied by Moſes's propheey concerning the captivity of the Iſraelites, or of a ſtate not yet erected; Iſaiah's concerning Cyrus; Jeremiah's concerning the duration of the Babyloniſh captivity; Chriſt's concerning the deſtruction of Jeruſalem, and the captivity that was to follow; St. John's concerning the great corruption of the Chriſtian church; and Daniel's concerning the fourth empire in its declenſion; which laſt was extant in the time of Porphyry, at leaſt, that is, before the events which

it

it repreſents. The truth of the propoſition might alſo be argued from the ſublimity and excellence of the doctrines contained in the Scriptures; in no reſpect ſuiting the ſuppoſed authors, or the ages in which they lived, their education or occupation; ſo that, if they were the real authors, we are under the neceſſity of admitting the Divine aſſiſtance. The converſe of this propoſition, viz. that the Divine authority of the Scriptures infers their genuineneſs, will be readily and univerſally acknowledged. And there are ſeveral evidences for the Divine authority of the Scriptures, which are direct and immediate, and prior to the conſideration both of their genuineneſs, and of the truth of the facts contained in them. Moreover, the truth of the principal facts contained in the Scriptures proves their divine authority. Such is the frame of the human mind, that the Scripture hiſtory, allowed to be true, muſt convince us that Chriſt, the prophets, and the apoſtles, were endued with a power greater than human, and acted by the authority of a Being of the higheſt wiſdom and goodneſs. But if natural religion be previouſly eſtabliſhed, the truth of the principal facts of the Scriptures proves their divine authority in a more eaſy and more convincing manner: for the knowledge and power manifeſted by Chriſt, the prophets, and apoſtles, and alſo their good moral characters, ſhew them to be in an eminent manner the children, ſervants, and meſſengers of him, who is previouſly acknowledged to be infinite in power, knowledge, and goodneſs; and they actually lay claim to a divine miſſion, which claim cannot be thought a falſe one, if we admit their credentials: or, in other words, the truth of the principal facts mentioned in the Scriptures proves the divine miſſion of Chriſt, the prophets, and apoſtles, that is, the divine authority of the Scriptures.

By ſuch mode of reaſoning it is ſhewn, that the genuineneſs of the Scriptures, the truth of the principal facts contained in them, and their divine authority, appear to be ſo connected with each other, that any one being eſtabliſhed upon independent principles, the other two may be inferred from it. On the ſubject of the inſpiration of the Scriptures; ſee INSPIRATION.

Another argument in proof of the genuineneſs of the books of the Old and New Teſtaments, and of the truth of the principal facts contained in them, may be deduced from the manner in which they have been tranſmitted down from one age to another; reſembling that, in which all other genuine books and true hiſtories have been conveyed down to poſterity. As the writings of the Greek and Roman writers were eſteemed by theſe nations to be tranſmitted to them by their anceſtors in a continued ſucceſſion, from the times when the reſpective authors lived, ſo have the books of the Old Teſtament by the Jewiſh nation, and thoſe of the New by the Chriſtians; and it is an additional evidence in the laſt caſe, that the primitive Chriſtians were not a diſtinct nation, but a great multitude of people diſperſed through all the nations of the Roman empire, and even extending itſelf beyond the bounds of that empire. As the Greeks and Romans always believed the principal facts of their hiſtorical books, ſo the Jews and Chriſtians did more, and never ſeem to have doubted of the truth of any part of theirs. In ſhort, whatever can be ſaid of the traditional authority due to the Greek and Roman writers, ſomething analogous to this, and for the moſt part of greater weight, may be urged for the Jewiſh and Chriſtian. Now, as all ſober-minded perſons ad it the books uſually aſcribed to the Greek and Roman hiſtorians, philoſophers, &c. to be genuine, and the principal facts related or alluded to in them to be true, and that one chief evidence for this is the general traditionary one here recited; they ought, therefore, to pay the ſame regard to the books of the Old and New Teſtaments, ſince there are the ſame, or greater reaſons for it. Beſides, theſe traditionary evidences are ſufficient, and we thus obtain a real argument, as well as one "ad hominem," for receiving books thus handed down to us. For it is not conceivabl , that whole nations ſhould either be impoſed upon themſelves, or concur to deceive others, by forgeries of books or of facts. Theſe books and facts muſt, therefore, in general, be genuine and true; and it is a ſtrong additional evidence of this, that all nations muſt be jealous of forgeries for the ſame reaſons that we are. On the concluſiveneſs of this argument, as it relates to miracles; ſee MIRACLE.

We may proceed to obſerve further, that the great importance of the hiſtories, precepts, promiſes, threatenings, and prophecies contained in the Scriptures, are evidences both of their genuineneſs, and of the truth of the principal facts mentioned in them. The hiſtory of the creation, fall, deluge, longevity of the patriarchs, diſperſion of mankind, calling of Abraham, deſcent of Jacob with his family into Egypt, and the precepts of abſtaining from blood, and of circumciſion, were of ſuch concern, either to mankind in general, or to the Iſraelites in particular, and ſome of them of ſo extraordinary a nature, as that it could not be a matter of indifference to the people amongſt whom the account given of them in Geneſis was firſt publiſhed, whether they received them or not. On the ſuppoſition that this account was firſt publiſhed amongſt the Iſraelites by Moſes, and then confirmed by clear, univerſal, uninterrupted tradition, it will be eaſy to conceive, how it ſhould be handed down from age to age amongſt the Jews, and received by them as indubitable. But ſuppoſing the account to be falſe, or that there were no ſuch veſtiges and evidences of theſe hiſtories and precepts, it will be difficult to conceive how this could have happened, let the time of publication be what it may. If early, the people would reject at once the account for want of a clear tradition; if late, it would be natural to enquire how the author was informed of things never known before to others. If the account was delivered, as having been communicated to Moſes by divine revelation, which is not very conſiſtent with the numerous references that occur in Geneſis to the exiſting veſtiges of the things related, his fictitious credentials would thus be embarraſſed, and his contemporararies would be induced very particularly to examine them. As to other coſmogonies and theogonies current among Pagans, which are evident fictions; they furniſh no juſt objection againſt the Moſaic hiſtory; becauſe they were generally regarded merely as amuſing fictions; and yet they concealed in figures, or expreſſed in plain words ſome truths, which agree with the book of Geneſis, and afford a ſtrong preſumptive evidence in favour of this book. With reſpect to the law of Moſes, this was extremely burdenſome, expenſive, and ſevere, particularly in its reference to the crime of idolatry, to which mankind were then extravagantly prone; and it was abſurd, according to human judgment, in the inſtances of prohibiting their furniſhing themſelves with horſes for war, and of commanding all the males of the whole nation to appear at Jeruſalem three times a year. Nevertheleſs, it claims a divine authority, and appeals to facts of the moſt notorious kind, and to cuſtoms and ceremonies of the moſt peculiar nature, as the memorials of theſe facts. Can we then conceive, that any nation, with ſuch motives to reject, and ſuch opportunities of detecting, the forgery of the books of Exodus, Leviticus, Numbers, and Deuteronomy, ſhould yet receive them, and ſubmit to this heavy yoke? That the Jews did ſubmit to the law of Moſes in theſe circumſtances, is evident from the books of the Old and New Teſtaments, if we allow them the leaſt truth and genuineneſs, or even from profane writers; and from the preſent ob-

ſervanee of it by the Jews ſcattered through all the kingdoms of the world. Should it be ſaid, that other nations have aſcribed divine authority to their lawgivers, and ſubmitted to very ſevere laws, it may be alledged in reply, that the pretences of lawgivers amongſt the Pagans to inſpiration, and the ſubmiſſion of the people, may be aceounted for from their peculiar circumſtanees at the time, without recurring to real inſpiration; and more eſpecially, if we admit the patriarchal revelations related by Moſes, and his own divine legation, as heathen lawgivers copied after theſe, and hence we derive a ſtrong argument in their favour. Beſides, no inſtance occurs among the Pagans, of a body of laws framed at onee and remaining invariable; whereas the body politic of the Iſraelites aſſumed a complete form at once, and has preſerved it, with little variation, to the preſent time, and under many external diſadvantages; thus ſupplying us with an inſtanee altogether without parallel, and ſhewing the high opinion which they entertained of the great importance of their law. In ſhort, of all the fictions or forgeries, that can happen among any people, the moſt improbable is that of the Jewiſh body of civil laws, and it ſeems to be utterly impoſſible in the caſe of the law of Moſes.

If we further examine the hiſtory eontained in the books of Joſhua, Judges, Ruth, Samuel, Kings, Chronicles, Ezra, and Nehemiah, and extending from the death of Moſes to the re-eſtabliſhment of the Jews after the Babyloniſh eaptivity by Ezra and Nehemiah, we ſhall find a variety of important facts, moſt of which muſt be ſuppoſed to leave ſuch veſtiges of themſelves, either external and viſible, or internal in the minds and memories of the people, as would verify them if true, or cauſe them to be rejected, if falſe. The conqueſt of the land of Canaan, the diviſion of it, and the appointment of cities for the prieſts and Levites by Joſhua; the frequent ſlaveries of the Iſraelites to the neighbouring kings, and their deliverance by the judges; the creation of a kingdom by Samuel; the tranſlation of this kingdom from Saul's family to David, with his conqueſts; the glory of Solomon's kingdom; the building of the temple; the diviſion of the kingdom; the idolatrous worſhip ſet up at Dan and Bethel; the captivity of the Iſraelites by the kings of Aſſyria; the captivity of the Jews by Nebuchadnezzar; the deſtruction of their temple; their return under Cyrus, rebuilding the temple under Darius Hyſtaſpis, and re-eſtabliſhment under Artaxerxes Longimanus, by Ezra and Nehemiah;—theſe events are ſome of them the moſt glorious, and ſome of them the moſt reproachful, that can happen to any people. How can we reconcile forgeries of ſuch oppoſite kinds, and eſpecially as they are interwoven together by various complicated and neceſſary connections, which do not admit of ſeparation? The facts, indeed, are of ſuch importance, notoriety, and permanency in their effects, that no particular perſons among the Iſraelites could firſt project the deſign of feigning them, that their own people would not concur with ſuch a deſign, and that neighbouring nations would not permit the fiction to paſs. Nothing but the invincible evidence of the facts, here alleged, could induce a jealous multitude amongſt the Iſraelites or neighbouring nations to acquieſce. This muſt be acknowledged upon the ſuppoſition that the ſeveral books were publiſhed in or near the times when the facts that are recorded in them happened. But ſuppoſe all theſe hiſtorical books forged by Ezra;—the hypotheſis is evidently impoſſible. Things ſo important and notorious, ſo honourable and ſo reproachful to the people, for whoſe ſake they were forged, would have been rejected with the utmoſt indignation, unleſs there were the ſtrongeſt and moſt genuine traces of theſe things already amongſt the people. They muſt therefore, in part at leaſt, be true. If it be ſaid that additions were made by Ezra; theſe additions muſt have been either of important or trivial matters. On the firſt ſuppoſition, the difficulty already ſtated recurs; and if the important facts are true, what poſſible motive could have induced Ezra to make additions of no importance? Beſides, if any ancient writings were extant, Ezra muſt either copy after them, which deſtroys the preſent ſuppoſition; or differ from and oppoſe them, which would betray him. If there were no ſuch ancient writings, the people would be led to enquire with regard to matters of importance, for what reaſon Ezra was ſo particular in things of which there was neither any memory, nor account in writing. Should it be ſaid, that the people did not regard what Ezra had thus forged, this reduces the ſubject in queſtion to matters of ſmall, or of no importance. Beſides, why ſhould Ezra write, if no one would read, or regard? Farther, Ezra muſt have had, like other men, friends, enemies, and rivals; and ſome, or all of theſe, would have been a check upon him, and a ſecurity againſt him in matters of importance. If we ſuppoſe theſe books, inſtead of having been forged at onee, to have been forged ſucceſſively, at the interval of one, two, or three centuries after the facts related, we ſhall involve ourſelves in the ſame or ſimilar difficulties. Upon the whole, then, we may conclude, that the forgery of the annals of the Iſraelites appears to be impoſſible, as well as that of the body of their civil laws. It is needleſs to examine the books of Eſther, Job, the Pſalms, Proverbs, Eccleſiaſtes, and Canticles; and we might proceed to the Prophecies. But this ſubject will be reſumed under the article PROPHECY. For the importance of the ſubjects, comprehended in the books of the New Teſtament; ſee TESTAMENT, and CHRISTIANITY.

We ſhall here ſubjoin ſome general evidences in atteſtation to the importance of the books of Scripture. That Jews and Chriſtians have thought their ſacred books very highly important, moſt genuine, and true, appears from the perſeeutions and ſufferings which they have undergone on account of their attachment to them, and becauſe they would not be prevailed upon to ſurrender them. The preſervation of the law of Moſes, probably the firſt book written in any language, whilſt many others of a later date have been loſt, ſhews the great regard that has been paid to it; and from this circumſtance we may infer, that this and the other books of the Old Teſtament have been preſerved on account of their importance, or from ſome other cauſe, equally evincing their genuineneſs and truth. The great importance of theſe books appears alſo from the many early tranſlations and paraphraſes of them; and theſe tranſlations and paraphraſes ſeem to correct errors that are unavoidable in the lapſe of time, and to ſecure their integrity and purity. The heſitation and difficulty with which ſome few books of the New Teſtament were received into the canon, ſhew the great care and concern of the primitive Chriſtians about the canon, and the high importance of the books admitted into it; and afford a ſtrong evidence of their genuineneſs and truth. The ſame obſervation is in a degree applicable to the Jewiſh canon. Moreover, the religious hatred and animoſity which ſubſiſted between the Jews and Samaritans, and between ſeveral of the ancient ſects among the Chriſtians, convince us of what importance they all thought their ſacred books, and diſpoſed them to watch over one another with a jealous eye.

Farther, the genuineneſs of the books of the Old and New Teſtaments may be evinced from the language, ſtyle, and manner of writing uſed in them. The Hebrew language, in which the Old Teſtament was written, being the language of an ancient people, who had little intercourſe with their neighbours, would not change ſo faſt as modern languages have

have done, ſince different nations have been variouſly blended with one another by the extenſion of trade, arts, and ſciences; and yet ſome changes muſt have occurred in the interval that elapſed between the time of Moſes and that of Malachi. The Biblical Hebrew correſponds ſo exactly to this criterion, as to afford a conſiderable argument in favour of the genuineneſs of the books of the Old Teſtament. Beſides, theſe books have too great a diverſity of ſtyle to be the work of either one Jew, or of any ſet of cotemporary Jews. If they be forgeries, there muſt have been a ſucceſſion of impoſtors in different ages, who concurred in the ſame iniquitous deſign. Again, the Hebrew language ceaſed to be ſpoken, as a living language, ſoon after the time of the Babyloniſh captivity; and it would be difficult or impoſſible to forge any thing in it, after it became a dead language. Hence it appears, that all the books of the Old Teſtament muſt be nearly as ancient as the Babyloniſh captivity; and as they could not all be written in the ſame age, ſome muſt be much more ancient, and this would reduce us to the neceſſity of ſuppoſing a ſucceſſion of conſpiring impoſtors. Moreover, there is, as we have already obſerved, a ſimplicity of ſtyle, and an unaffected manner of writing, in all the books of the Old Teſtament, which is a ſtrong evidence of their genuineneſs. The ſtyle of the New Teſtament, in particular, is not only ſimple and unaffected, but perfectly adapted to the time, places, and perſons. To which we may add, that the narrations and precepts of both the Old and New Teſtament are delivered without heſitation; the writers teaching as having authority; and this circumſtance is peculiar to thoſe, who unite with a clear knowledge of what they deliver, a perfect integrity of heart.

Another argument for the genuineneſs and truth of the Scriptures, is ſupplied by the very great number of particular circumſtances of time, place, perſons, &c. mentioned in them. It is needleſs to recount theſe; but they are incompatible with forged and falſe accounts, which do not abound in ſuch particularities, and the want of which furniſhes a ſuſpicion to their diſcredit. Compare, in this reſpect, Manetho's account of the dynaſties of Egypt, Cteſias's of the Aſſyrian kings, and thoſe which the technical chronologers have given of the ancient kingdoms of Greece, which are defective in ſuch particulars, with Thucydides's hiſtory of the Peloponneſian war, and Cæſar's of the war in Gaul, in which they occur, and the difference will be ſufficiently apparent. Dr. Paley's admirable treatiſe, entitled "Horæ Paulinæ," affords very valuable illuſtrations of this argument as it reſpects the genuineneſs of the books of the New Teſtament.

The agreement of the Scriptures with hiſtory, natural and civil, is a farther proof of their genuineneſs and truth. The hiſtory of the fall agrees in an eminent manner both with the obvious facts of labour, ſorrow, pain, and death, with what we ſee and feel every day, and with all our philoſophical enquiries into the frame of the human mind, the nature of ſocial life, and the origin of evil. Natural hiſtory bears a ſtrong teſtimony to Moſes's account of the deluge. Civil hiſtory affords many evidences, which corroborate the ſame account. (See Deluge.) The Moſaic account of the confuſion of languages, of the diſperſion of Noah's ſons, and of the ſtate of religion in the ancient poſtdiluvian world, is not only rendered probable, but in a very high degree eſtabliſhed, by many collateral arguments. See Confusion *of Languages*, Dispersion *of Mankind*, Idolatry, Sacrifice, &c.

The agreement of the books of the Old and New Teſtaments, with themſelves and with each other, affords an argument both of their genuineneſs and truth. The laws of the Iſraelites are contained in the Pentateuch, and referred to, in a great variety of ways, direct and indirect, in the hiſtorical books, in the Pſalms, and in the Prophecies. The hiſtorical facts alſo in the preceding books are often referred to in thoſe that ſucceed, and in the Pſalms and Prophecies. In like manner, the goſpels have the greateſt harmony with each other, and the epiſtles of St. Paul with the Acts of the Apoſtles: and, indeed, there is ſcarcely any book of either the Old or New Teſtament, which may not be ſhewn to refer to many of the reſt, in one way or other. For the illuſtration of this argument, let us ſuppoſe that no more remained of the Roman writers than Livy, Tully, and Horace, would they not by their references to the ſame facts and cuſtoms, by the ſameneſs of ſtyle in the ſame writer, and difference in the different ones, and numberleſs other ſuch like circumſtances of critical conſideration, prove themſelves, and one another to be genuine, and the principal facts related, or alluded to, to be true? Whoever will apply this reaſoning to the preſent caſe will perceive, that the numberleſs minute, direct, and indirect agreements and coincidences, that preſent themſelves to all diligent readers of the ſcriptures, prove their truth and genuineneſs beyond all contradiction. See Acts, Epistles, and Testament.

The harmony and agreement of the ſeveral writers of the Old and New Teſtament appear the more remarkable, when it is conſidered that their various parts were penned by ſeveral hands in very different conditions of life, from the throne and ſceptre down to the loweſt degree, and in very diſtant ages, through a long interval of time; which would naturally have led a ſpirit of impoſture to have varied its ſchemes, and to have adapted them to different ſtations in the world, and to the different viciſſitudes of every age. David wrote about 400 years after Moſes, and Iſaiah about 250 after David, and Matthew more than 700 years after Iſaiah. And yet theſe authors, with all the other prophets and apoſtles, write in perfect harmony, confirming the authority of their predeceſſors, labouring to reduce the people to the obſervance of their inſtructions, and loudly exclaiming againſt the neglect and contempt of them, and denouncing the ſevereſt judgments againſt ſuch as continued diſobedient. Conſequently, as the writers of the Holy Scriptures, though they all claim a divine authority, yet write in perfect connection and harmony, mutually confirming the doctrine and teſtimony of each other, and concurring to eſtabliſh the very ſame religious truths and principles, it is a ſtrong proof that they all derived their inſtructions from the ſame fountain, the wiſdom of God, and were indeed under the direction and illumination of the ſame ſpirit. This leads us to add, that the unity of deſign, which appears in the diſpenſations recorded in the Scriptures, is an argument not only of their truth and genuineneſs, but alſo of their divine authority. In order to perceive the force of this argument, it is only neceſſary to inquire what this deſign is, and how it is purſued by the ſeries of events and divine interpoſitions, recorded in the Scriptures. (See Dispensation.) We may further add, that divine communications, miracles, and prophecies, recorded in Scripture, are agreeable to natural religion, and even ſeem to be neceſſary in the infancy of the world. (See Miracle, Prophecy, and Revelation.) It ſhould alſo be conſidered, that the hiſtorical evidences in favour of the genuineneſs, truth, and divine authority of the Scriptures, do not become leſs from age to age; but, on the contrary, it may rather be preſumed, that they increaſe. Since the three great concurring events of printing, the reformation of religion in theſe weſtern parts, and the reſtoration of letters, ſo many more evidences and coincidences have been diſcovered in favour of the Jewiſh and Chriſtian hiſtories, as may ſerve, in ſome meaſure, to ſupply the want of thoſe

thoſe that have been loſt in the preceding times; and as this improvement of the hiſtorical evidences is likely to continue, there is great reaſon to hope, that they will grow every day more and more irreſiſtible to all candid, ſerious inquirers.

The moral characters of Chriſt, the prophets, and the apoſtles, prove the truth and divine authority of the Scriptures. The characters of the perſons who are ſaid in the Scriptures to have had divine communications, and a divine miſſion, are ſo much ſuperior to the characters that occur in common life, that we can ſcarcely account for the more eminent ſingle ones, and much leſs ſo for ſo large a ſucceſſion of them, continued through ſo many ages, without allowing the divine communications and aſſiſtance, which they allege. Notwithſtanding conſiderable imperfections that pertained to many of theſe eminent perſons, and the heinous occaſional offences chargeable upon ſome of them, yet the impartial reader ſhould conſider, whether the prophets, apoſtles, &c. were not ſo much ſuperior, not only to mankind at an average, but even to the beſt men among the Greeks and Romans, as is not fairly to be accounted for by the mere powers of human nature. If this ſtatement ſhould be diſputed, their characters, however, are too good to allow the ſuppoſition of an impious fraud and impoſture, which muſt have been the caſe if they had not divine authority. Beſides, it ſhould be recollected, that the undiſguiſed and impartial manner in which the imperfections and faults of the eminent perſons mentioned in Scripture are related, furniſhes a remarkable additional evidence for the truth of ſuch parts of the Scripture hiſtory in which ſuch relations occur, beſides ſuch evidences as extend to the whole.

The excellence of the doctrine contained in the Scriptures is an additional evidence of their authority. This argument has great force independently of all other conſiderations. Suppoſe, for inſtance, that the author of the goſpel, which goes under the name of St. Matthew, was not known, and that it was unſupported by the writers of the primitive times; yet ſuch are the unaffected ſimplicity of the narrations, the purity of the doctrine, and the ſincere piety and goodneſs of the ſentiments, that it carries its own authority with it. The ſame obſervation is applicable in general to all the books of the Old and New Teſtaments: ſo that if there was no other book in the world beſides the Bible, a man could not reaſonably doubt of the truth of revealed religion. If all other arguments were ſet aſide, we may conclude from this ſingle conſideration, that the authors of the books of the Old and New Teſtament, whoever they were, cannot have made a falſe claim to divine authority. The Scriptures contain doctrines concerning God, Providence, a future ſtate, the duty of man, &c. far more pure and ſublime than can in any way be accounted for from the natural powers of men, ſo circumſtanced as the ſacred writers were. Let the reader conſider whether it can be reaſonably ſuppoſed, that Jewiſh ſhepherds, fiſhermen, &c. ſhould, both before and after the riſe of the heathen philoſophy, ſo far exceed men of the greateſt abilities and accompliſhments in other nations, by any other means than divine communications. Indeed, no writers, from the invention of letters to the preſent times, are equal to the penmen of the books of the Old and New Teſtaments in true excellence, utility, and dignity; and this is ſurely ſuch an internal criterion of their divine authority, as ought not to be reſiſted.

The many and great advantages which have accrued to the world from the Patriarchal, Judaical, and Chriſtian revelations, prove the divine authority of the Scriptures. Theſe advantages relate partly to the knowledge, and partly to the practice of religion. The internal worth and excellence of the Scriptures, as containing the beſt principles of knowledge, holineſs, conſolation and hope, and their conſequent utility and importance in a moral and practical view, fully and directly demonſtrate their divine original. The wonderful nature, and ſuperior excellence, of the attempt made by Chriſt and his apoſtles, for reforming mankind, and making them happy in a future ſtate, are evidences of their divine authority; which is farther illuſtrated and confirmed by the manner in which the love of God and of our neighbour is taught and inculcated in the Scriptures. This may alſo be inferred from the doctrine of the neceſſary ſubſerviency of pain to pleaſure, and from the mutual inſtrumentality of beings to the happineſs and miſery of each other, unfolded in the Scriptures. The divine authority of the Scriptures may be farther deduced from the ſuperior wiſdom of the Jewiſh laws, conſidered in a political light, and from the exquiſite workmanſhip manifeſted in the tabernacle and the temple. The time and manner in which the Scriptures were written and delivered to the world, furniſh arguments for their divine authority; nor is the want of univerſality in the publication of revealed religion any juſt objection to it. The excluſion of all great degrees of enthuſiaſm and impoſture from the characters of Chriſt, the prophets, and apoſtles, prove their divine authority; and it may be alſo inferred, from the reception which Chriſt, his forerunners and followers, with their doctrines, have met with in all ages. See theſe arguments ſtated, illuſtrated, and applied at large in Hartley's Obſervations on man, p. 350—421. See alſo on the ſubject of this article, Prideaux's Conn. vol. ii. 475—497, 8vo. Dupin's Hiſt. of the Canon, ch. i. and ii. Kennicott's State of the printed Hebrew text of the Old Teſtament, diſſ. ii. p. 295, &c. and Diſſertatio Generalis, annexed to the ſecond volume of his Hebrew Bible. Taylor's Scheme of Scripture Divinity, ch. 39, ch. 40.

The Jews, at firſt, were very reſerved in communicating their Scriptures to ſtrangers; deſpiſing and ſhunning the Gentiles, they would not diſcloſe to them any of the treaſures concealed in the Bible. We may add, that the people bordering on the Jews, as the Egyptians, Phœnicians, Arabs, &c. were not very curious to know the laws or hiſtory of a people, whom in their turn they hated and deſpiſed. Their firſt acquaintance with theſe books was not till after the ſeveral captivities of the Jews, when the ſingularity of the Hebrew laws and ceremonies induced ſeveral to deſire a more particular knowledge of them. Joſephus (Contr. Apion. p. 1033.) ſeems ſurpriſed to find ſuch ſlight footſteps of the Scripture hiſtory interſperſed in the Egyptian, Chaldæan, Phœnician, and Grecian hiſtories; and accounts for it from this circumſtance, that the ſacred books were not as yet tranſlated into Greek, or other languages, and conſequently not known to the writers of thoſe nations. The firſt verſion of the Bible was that of the LXX into Greek, in the time of Ptolemy Philadelphus, about 280 years before Chriſt; though ſome maintain that the whole was not then tranſlated, but only the Pentateuch; between which and the other books in the verſion of the LXX, critics find a great diverſity in point of ſtyle and expreſſion, as well as of accuracy. See SEPTUAGINT.

Various kinds of books have been compoſed on the Bible, either to explain the ſenſe, or make its doctrine more obvious, to facilitate the remembrance of it, or to eſtabliſh particular opinions from it; ſuch as Introductions, Apparatuſes, Summaries, Manuals, Hiſtories, Expoſitions, Commentaries, Harmonies, &c.

Bibles are diſtinguiſhed, according to their language, into Hebrew, Greek, Latin, Chaldee, Syriac, Arabic, Coptic, &c: ſome account of each, and their ſeveral editions, &c. we ſhall here ſubjoin.

Bibles, *Hebrew*, are either manuſcript or printed. The beſt *manuſcript* Bibles are thoſe copied by the Jews of Spain. Thoſe copied by the Jews of Germany are leſs exact, but more common. The two kinds are eaſily diſtinguiſhed from each other; the former being in beautiful characters, like the Hebrew Bibles of Bomberg, Stephens, and Plantin; the latter in characters, like thoſe of Munſter and Gryphius. F. Simon obſerves, that the oldeſt manuſcript Hebrew Bibles are not above ſix or ſeven hundred years old; nor does rabbi Menaham, who quotes a vaſt number of them, pretend that any of them exceed ſix hundred years.

Dr. Kennicott, in his Diſſertatio Generalis, annexed to his Hebrew Bible, p. 21, obſerves, that the moſt ancient MSS. were written between the years 900 and 1100: but though thoſe that are the moſt ancient are not more than 800 or 900 years old, they were tranſcribed from others of a much more ancient date. The MS. preſerved in the Bodleian library is no leſs than 800 years old. Another MS. not leſs ancient, is preſerved in the Cæſarean library at Vienna. The ſame learned writer informs us, that almoſt all the Hebrew MSS. of the Old Teſtament, which are known at preſent, were written between the years 1000 and 1457; and hence he infers, that all the MSS. written before the years 700 or 800, were deſtroyed by ſome decree of the Jewiſh ſenate, on account of their many differences from the copies then declared genuine. This circumſtance is alſo alleged by Walton (Prolegomena, 4, 8.), as the reaſon why we have ſo few copies of the age of 600 years, and why even the copies of 700 or 800 years are very rare.

The Hebrew diſtinctions and denominations of the various parts of the Hebrew Bible, as they occur in the titles of the ancient MSS. will be eaſily underſtood by the following table of diſtribution.

Pentateuch,

Prophets,
- *Prior*: Joſhua, Judges, Samuel, Kings
- *Poſterior*.
  - *Major*: Iſaiah, Jeremiah, Ezekiel
  - *Minor*: Hoſea, &c. to Malachi.

Cethubim, or Hagiographa.
- Job, Pſalms, Proverbs, Daniel, Ezr. Neh., Chronicles.
- *Megilloth*: Ruth, Eſther, Eccleſiaſtes, Lamentations, Solomon's Song.

Dr. Kennicott, by the induſtry of his reſearch, has formed a catalogue of the titles and places of above 440 different MSS. of the whole, or of parts of the Hebrew Bible: a number about three times as great as that of the Greek MSS. of the New Teſtament, which have been collected at a vaſt expence, and collated with a truly laudable zeal. (See Testament.) Of theſe MSS. 54 are preſerved in the Bodleian library at Oxford, and 13 in different colleges of the univerſity; 4 are repoſited in the public library at Cambridge, and 3 in different colleges; 27 are found in the Britiſh Muſeum; one in the Lambeth library; and one in the library of the Royal Society. The preceding MSS., with 7 copies of the Samaritan Pentateuch, amount to 110 copies, making 125 volumes. Other MS. copies are preſerved at Alcala, or Complutum in Spain, Altorf in Swabia, Amſterdam, Anhalt-Deſſau, Augſburg, Baden, Berlin, Berne, Beſançon, Bologna, Brieg in Sileſia, Cainſong-feu in China, Cairo in Egypt, Ceſena in Italy, Copenhagen, Dreſden, Erfurth, Florence, Furth in Franconia, Hague, Hall, Hamburgh, Hanover, Heidelberg, Helmſtadt, Heſſe-Caſſel, Hoba near Damaſcus, Iena, Koningſberg, Leipſic, Leyden, Lyons, Mechlin in Flanders, Milan, Modena, Nuremberg, Padua, Paris, Pekin, Rome, Schaffhauſen in Swiſſerland, Straſburgh, Toledo, Trevigio near Venice, Turin, Venice, Vienna, Ulm in Swabia, Upſal, Utrecht, Wratiſlaw, Zerbſt in Saxony, and Zurich. Beſides theſe, there are others at Fez in Africa, Theſſalonica in Greece, and Conſtantinople, Ethiopia, Malabar, and Couchin, at a ſmall diſtance ſouth of Cranganore, where are about 4000 Jews, who have a ſynagogue, in which are carefully kept their records, engraven on copper-plates, and where, it is ſaid, they can ſhew their hiſtory from Nebuchadnezzar to the preſent time. See the ſequel of this article.

The moſt ancient *printed* Hebrew Bibles are thoſe publiſhed by the Jews of Italy, eſpecially of Peſaro and Breſſe. Thoſe of Portugal, alſo, printed ſome parts of the Bible at Liſbon, before their expulſion.—This may be obſerved in the general, that the beſt Hebrew Bibles are thoſe printed under the inſpection of the Jews; there being ſo many minutiæ to be obſerved, that it is ſcarcely poſſible for any other to ſucceed in it.

The firſt printed edition of the Hebrew Bible, or at leaſt of that part of it, comprehending the prior prophets, was printed at Soncinum in 1486, according to Le Long (Biblioth. Sacra.); it contained alſo the poſterior prophets, according to Wolfius (Bib. Heb. ii. 397.); and it ſeems to have made a firſt or a ſecond part to the next we ſhall mention, or Dr. Pellet's, which is regularly the third. The edition preſented by Dr. Pellet, in 1735, to the library of Eton college, being that of a third part of the Hebrew Bible, comprehending the Cethubim or Hagiographa, was printed at Naples in 1487. This whole edition was burnt by the Jews, excepting this copy, which had the ſingular good fortune of eſcaping the flames. It is printed on vellum, in two folio volumes, and has many readings different from all the other printed copies, and contrary to the Maſora, which probably was one of the reaſons for which the whole edition was deſtroyed. This edition is mentioned by Wolfius in his "Bibliotheca Hebræa," as formerly belonging to Schræder of Gluckſtadt. The antiquity of this edition is argued from its being printed on vellum, as was the caſe with the firſt printed books, and from its having variations in the text, which are not found in any later edition. The firſt edition of the whole Hebrew Bible was printed at Soncinum in 1488, and is mentioned by Le Long, who ſays that it was printed by Abraham, the ſon of Rabbi Hhaim, or Chaim. Le Long and Wolfius affirm, that they ſaw an Hebrew Bible in 8vo. printed at Breſcia in 1494.

In the beginning of the 16th century, Dan. Bomberg printed ſeveral Hebrew Bibles in folio and quarto, at Venice, moſt of which are eſteemed both by the Jews and Chriſtians; the firſt in 1518, (the dedication being dated in 1517) which is the leaſt exact, and generally goes by the name of Felix Pratenſis, the perſon who reviſed it, and who, as Hody ſays, (p. 461.) was "ex Judæo Monachus." This edition contains the Hebrew text, the targum, and the commentaries of ſeveral rabbins. It is not known from what particular MSS. the Hebrew text of this edition was taken; but it agrees moſt with very late MSS. and ſuch as were corrected according to the Maſora. The editor, in his dedication to pope Leo, complains of the very corrupt ſtate of the Hebrew MSS., and ſpeaks of his having collated and corrected (probably by means of the Maſora) many MSS. which were

uſed for this edition. At the ſame time that this edition of the Hebrew Bible was preparing at Venice, another edition of equal fame was preparing by cardinal Ximenes, at Complutum in Spain; and as theſe two capital editions were thus in the preſs at once, neither of them could be printed from the other. But as they were both printed by men who either were, or had been Jews, (ſee Wolfius, tom. ii. p. 339.) from ſuch MSS. as were uniformly corrected by the ſame Maſora, they would exhibit almoſt univerſally the ſame text. And that the Hebrew MSS. here uſed, had ſuffered this Maſoretical caſtigation, is plain from the words of Ximenes in his dedication to pope Leo. This famous Bible was begun in 1502, and finiſhed in 1517; but not publiſhed till 1522, and not ſold publicly, ſays Michaelis, (Lect. New Teſt. § 33.) till 1524. In 1526 or 1528, the ſame Bomberg printed the folio Bible of the celebrated Rabbi Jacob Ben Chaim, with his preface, the Maſoretical diviſions, a preface of Aben Ezra, a double Maſora, and ſeveral various readings. No one who duly conſiders the preface of this editor (printed by Kennicot, Diſſ. vol. ii. p. 229.) can poſſibly doubt his having publiſhed it, according to the copies moſt exactly corrected by that Maſora, which he profoundly reverenced. In 1549, was publiſhed the ſecond edition of B. Chaim's Bible, with the famous preface at the beginning; and of this edition Le Long ſays, "præſtantiſſima eſt et omnium optima, juxta quam præſertim ſequentes prodierunt." Wolfius gives it preciſely the ſame character; but adds, that Conrade Zeltner blames B. Chaim for being ſo exceſſively devoted to the Maſora. In 1572, was publiſhed the Royal, or Spaniſh Polyglott, in 8 volumes, printed at Antwerp; principally under the direction of Arias Montanus. It is not pretended, that the leaſt correction was made in this edition of the Hebrew text; nor could it be expected from an editor who believed the perfection of the Hebrew text. The third edition of B. Chaim's Bible was printed in 1618; it is the ſame with the ſecond, but much more correct. From the former editions it was, that Buxtorf, the father, printed his rabbinical Hebrew Bible at Baſil, in 1619; which, though there are many faults in it, is more correct than any of the former. This was the fifth edition of B. Chaim's Bible, in which the Hebrew text was copied exactly from B. Chaim's ſecond edition. In 1534, Sebaſtian Munſter publiſhed a Hebrew and Latin Bible, in 2 vols. fol. at Baſil, with the commentaries of the Rabbins, and ſome notes; and Elias Hutter printed a Hebrew Bible in large letters, at Hamburgh, in 1587, fol. Robert Stephens's Hebrew Bible, with the Greek verſion from the Complutenſian edition, the Latin vulgate, and another new Latin verſion, commonly called Vatablus's Bible, was printed in 1545. In 1623, appeared at Venice a new edition of the rabbinical Bible, by Leo of Modena, a rabbin of that city, who pretended to have corrected a great number of faults in the former edition; but, beſides that it is much inferior to the other Hebrew Bibles of Venice with regard to paper and print, it has paſſed through the hands of the inquiſitors, who have altered many paſſages in the commentaries of the rabbins. The rabbinical Bible of Bomberg and Buxtorf has been ſuperſeded by that of rabbi Moſes, publiſhed at Amſterdam in 4 volumes folio, in 1724—1727. In 1641, was publiſhed, in 10 folio volumes, the Paris Polyglott, which, though it claims no merit from correcting the Hebrew text, will ever be honoured by men of true learning, for containing (beſides the Syriac and Arabic verſions) the firſt edition of the Samaritan pentateuch and its verſion, printed from MSS. brought into Europe between the years 1620 and 1630, and publiſhed by the learned Morinus, to whom the world is alſo indebted for many excellent remarks on the Hebrew text, as well as on the Samaritan pentateuch. In 1657, was publiſhed the London Polyglott, under the direction of the eminently learned Brian Walton, in which, however, the Hebrew text is printed Maſoretically; almoſt in an abſolute agreement with the many former editions, and with the lateſt and worſt MSS. Although the editor has ſhewn clearly, that the Jewiſh tranſcribers have made many miſtakes, and that the MSS. have many true readings, where the printed text is erroneous; and though he ſpeaks (Proleg. 4, 12.) of having ſupplied ſome things which were not in the Venice or Baſil editions, yet the only ſupplement which he has made is reſtoring the two verſes in Joſhua, which had been arbitrarily expelled by Maſoretic authority. See POLYGLOTT.

As to Hebrew Bibles in 4to. that of R. Stephens, in 4 vols. Paris, 1539—1544, is eſteemed for the beauty of the characters; but it is very incorrect. Plantin alſo printed ſeveral beautiful Hebrew Bibles at Antwerp: one in eight columns, with a preface by Arius Montanus, in 1571, which far exceeds the Complutenſian in paper and print, and contents; this is called the Royal Bible, *Biblia Regia*, becauſe it was printed at the expence of Philip II. of Spain: another at Geneva, in 1619; beſides many more of different ſizes, with and without points. Manaſſeh Ben Iſrael, a learned Portugueſe Jew, publiſhed two editions of the Hebrew Bible at Amſterdam; the one in 4to. in 1635, who tells us in the preface, that he had altered a few letters; and where the moſt corrected copies differed, he took refuge in grammar rules and the Maſora; the other in 8vo. in 1639: the firſt has two columns, and for that reaſon is commodious for the reader. It is printed with points, in an elegant type, and has the Keri and Chetib in the margin. The 8vo. edition has vowel points and accents, and the marginal notes. In 1639, R. Jac. Lombroſo publiſhed a new edition in 4to. at Venice, with ſmall literal notes at the bottom of each page, where he explains the Hebrew words by Spaniſh words. This Bible is much eſteemed by the Jews at Conſtantinople: in the text they have diſtinguiſhed between words where the point *kamets* is to be read with a *kamets-katuph*, that is, by *o*, and not an *a*.

Of all the editions of the Hebrew Bible in 8vo. the moſt beautiful and correct are the two of Jo. Athias, a Jew of Amſterdam. The firſt, of 1661, is the beſt paper, which, notwithſtanding its being corrected according to ancient MSS. is certainly (ſo far as letters and words are concerned) agreeable only to the lateſt, as the other printed copies were before it: but that of 1667, is the moſt exact. This was publiſhed by Leuſden, who tells the reader, "Tibi damus Biblia, impreſſa per Athiam, quibus correctiora nunquam ſol aſpexit." And yet, though the ſun never ſaw ſo much implicit obedience paid to the Maſora before, the Rabbins aſſure us, in their prefatory recommendation, that ſome whole words were here corrected "ex Maſora & a Maſoreticis, qui ſepem legis fecerunt." This ſupremely Maſoretical edition appeared to their high mightineſſes the States-general, ſo particularly meritorious, that Athias, the typographer, was preſented with a chain of gold, and a gold medal pendant. But it is ſomewhat extraordinary, that a Jew ſhould thus be rewarded for an edition, in which Leuſden (though a Chriſtian) confeſſes, that he permitted the Latin contents, here added in the margin, to explain away ſome of the prophecies relating to the Meſſiah. Le Long, in loc.

Leuſden's laſt edition of Athias, was followed in 1705, by Vander Hooght's very elegant edition. No corrections can be expected from this editor, who conſidered every letter in his book, howſoever it was introduced, as abſolutely genuine, and maintained the Maſora to be infallible.

After Athias, three Hebraizing proteſtants engaged in reviſing and publiſhing the Hebrew Bible; viz. Clodius, Jablonſki, and Opitius.—Clodius's edition was publiſhed at Frankfort in 1677, in 4to. At the bottom of the page it has the various readings of the former editions; but the author does not appear ſufficiently verſed in the accenting, eſpecially in the poetical books; beſides, as it was not publiſhed under his eye, many faults have crept in. That of Daniel Erneſt Jablonſki in 1699, in 4to. at Berlin, is very beautiful as to letter and print: but, though the editor pretends he made uſe of the editions of Athias and Clodius, ſome critics find it ſcarcely in any thing different from the 4to. edition of Bomberg. For this man of eminent learning it was reſerved to lay the foundation for a reformation of the printed Hebrew text. This he has done in the preface, by making ſeveral excellent obſervations on the nature of the preſent Hebrew MSS.; with the proper marks of their antiquity, and the great advantages to be derived from them. He has ſatisfactorily ſhewn, that the Jewiſh tranſcribers have committed many miſtakes; that the Keris are various readings ariſing from the miſtakes of tranſcribers; that the older MSS. have them in the text, but the later in the margin; and conſequently, that the Maſora, which conſiders the Keri as in the margin, muſt be founded on the later copies; that one of the Hebrew MSS. at Berlin contains ſome thouſands of various readings, and that the other old Hebrew MSS. have numerous differences from the printed text; and that theſe old MSS. have ſuffered many alterations from the late correcting Maſorets. He alſo ſtates the poſſibility of procuring, by due zeal and exertion, very ancient MSS. from ſuch of the Jews as have been ſettled for many ages in China, Ethiopia, Conſtantinople, Theſſalonica, and other diſtant parts of the world. Jablonſki is the firſt author, who, after announcing the actual exiſtence of many various readings in the Hebrew MSS., has recommended both an accurate examination of thoſe MSS. now known, and a diligent ſearch after others, at preſent unknown, through the ſeveral quarters of the world. To him, therefore, belongs the honour of having planned the noble ſcheme for correcting the many corruptions of the printed Hebrew text of the Old Teſtament; and yet not daring to practiſe what he recommends, he republiſhed the Hebrew text almoſt the ſame as it was adjuſted maſoretically in Leuſden's edition of 1667. His corrections have been confined almoſt entirely to the vowel-points and accents. The edition of Opitius was publiſhed in 4to. at Keil, in 1709; the character is large and good, but the paper bad: it is done with a great deal of care; but the editor made uſe of no manuſcripts but thoſe of the German libraries; neglecting the French ones, which is an omiſſion common to all three. Opitius copied from Leuſden's Athias, though, he ſays, he collated ſeveral MSS. in Berlin, and other places; but he idolized the Maſora, and held all readings inconſiſtent with it, however recommended by any MSS., in ſovereign contempt. Hence it follows, that if this edition was conformable to the late MSS. as regulated by the Maſora, the ſame Maſoretic influence muſt have regulated the very early copy, printed at Breſcia, in 1494; becauſe that edition is recommended by Opitius. Wolf. Beb. Heb. ii. p. 365. The three laſt mentioned editions have this advantage, however, that beſides the diviſions uſed by the Jews, both general and particular, into *paraſkes* and *peſukim*, they have alſo thoſe of the Chriſtians, or of the Latin Bibles, into chapters and verſes; the *keri ketib*, or various readings, Latin ſummaries, &c. which made them of conſiderable uſe with reſpect to the Latin editions, and the concordances. See CHAPTERS.

The little Bible of R. Stephens, in 16to. is very much prized for the beauty of the character. It was printed in 7 vols, at Paris, in 1544—1546. Care, however, muſt be taken; there being another edition of Geneva, exceedingly like it excepting that the print is worſe, and the text leſs correct. To theſe may be added ſome other Hebrew Bibles without points, in 8vo. and 24to. which are much coveted by the Jews; not that they are more exact, but more portable than the reſt; and are uſed in their ſynagogues and ſchools: of theſe there are two beautiful editions, the one of Plantin, in 8vo. with two columns, and the other in 24to. reprinted by Raphalengius at Leyden, in 1610. There is alſo an edition of them by Laurens at Amſterdam, in 1631, in a larger character; and another in 12mo. at Frankfort, in 1694, full of faults, with a preface of M. Leuſden at the head of it.

In 1720, an Hebrew Bible was publiſhed at Hall, by the learned profeſſor John Henry Michaelis; being the firſt edition, which contained any various readings, collected from Hebrew MSS. by a Chriſtian editor. The text is taken from Jablonſki's edition, with ſome few emendations. There were collated for this Bible moſt of the beſt printed editions, and alſo five Hebrew MSS. belonging to the library at Erfurth. The propriety of ſelecting various readings from Hebrew MSS. and ancient verſions, is ſet forth in the preface; and the editor has inſerted here and there ſome variations of words and letters; but the variations, chiefly noted, relate to the minutiæ of criticiſm, conſiſting only in points and accents.

Charles Francis Houbigant, one of the fathers of the oratory at Paris, publiſhed an elegant edition of the Hebrew Bible at Paris, in 1753, contained in four volumes, folio. The text is that of Vander Hooght, without points, to which he has added marginal notes, correcting that text by the Samaritan pentateuch, Hebrew MSS. and ancient verſions; and alſo a new Latin verſion, made by himſelf, expreſſive of ſuch a text as his critical emendations appeared to juſtify and recommend. This celebrated edition, (ſays Dr. Kennicott, than whom there could not be a more competent judge) ſeems to proceed upon ſo juſt a plan, as to its main principles, and to be executed (in the general) with ſo much ſkill and judgment, as to claim for its worthy author the applauſe of all the friends of religion and learning. He expreſſes, however, a wiſh, that the author had ſpared ſome of his bolder criticiſms, when they are unſupported by MSS., parallel places, or ancient verſions; eſpecially, where the propoſed emendations are not clearly and ſtrongly recommended by the context. Some learned men have wiſhed, that, inſtead of inſerting only a few ſelect various readings from the Hebrew MSS., all the various readings had been noted by the author after each chapter. But the labour of ſuch a work would have been immenſe; and we have great reaſon to be ſatisfied with what the learned and induſtrious editor has actually done. It has, indeed, been objected by Dr. Hodges, in his preface to the work entitled "The Chriſtian Plan," that Houbigant intended to alter the Hebrew text, to make it conformable to the Vulgate; whereas, it was the editor's profeſſed intention to ſet aſide the Vulgate, as being faulty, and not anſwering his purpoſe, and to publiſh a new Latin verſion of his own. F. Houbigant obtained from the pope two gold medals, in teſtimony of his approbation of this edition. Dr. Kennicott, after almoſt twenty years' laborious collation of 694 copies, manuſcript and printed, of which about 630 are MSS. either of the whole, or of particular parts of the Bible, and nine years more ſpent in examining the Hebrew MSS., and recommending a collation of them, publiſhed, in 1776, the firſt volume of his Hebrew Bible, in folio;

entitled "Vetus Teſtamentum Hebraicum, cum variis Lectionibus." The ſecond volume, with the general diſſertation, was publiſhed in 1780. The text is that of Everard Van der Hooght, in 1705, already mentioned, which is very correctly printed, with the ſimilar Hebrew letters, remarkably ſharp and well defined; differing from it only in the diſpoſition of the poetical parts, which Dr. Kennicott has printed in hemiſtichs, into which they naturally divide themſelves; however, the words follow one another in the ſame order as they do in the edition of Van der Hooght; ſo that any perſon may read theſe paſſages as proſe, if he is ſo inclined; or may divide the hemiſtichs differently, according to his own judgment. This edition is printed on an excellent type; the Samaritan text, according to the copy in the London Polyglott, is exhibited in a column parallel with the Hebrew text; thoſe parts of it only being introduced, in which it differs from the Hebrew: and the reſt of the Samaritan column being left blank, ſo that the eye perceives at once, with the utmoſt eaſe, the variations of the Hebrew and Samaritan texts. The numerous variations, both of the Samaritan manuſcripts from the printed copy of the Samaritan text, and of the Hebrew manuſcripts from the printed text of Van der Hooght, are placed ſeparately at the bottom of the page, and marked with numbers referring to the copies from which they are taken.

We ſhall ſubjoin to this article a brief account of the riſe and progreſs of that highly intereſting and meritorious undertaking, for the completion of which we are indebted to the indefatigable induſtry and perſeverance of the late Dr. Kennicott. A very general opinion ſeemed to have prevailed among learned men, till about the middle of the laſt century, in favour of the integrity of the Hebrew text: and Dr. Kennicott ingenuouſly confeſſes, that he was miſled by the common error. The Rabbins boldly aſſerted, and the Chriſtians implicitly believed, that the Hebrew text was free from error, and that in all the MSS. of it, no inſtance of any various reading of importance could be produced. The firſt perſon, who ſeems to have combated this notion in the way of a regular attack, was Ludovicus Capellus. From the differences he obſerved between the Hebrew text and the verſion of the LXX, and between the Hebrew pentateuch and the Samaritan pentateuch, from the palpable and manifeſt corruptions, which he thought he ſaw in the text itſelf, and from the many reaſons which induced him to ſuppoſe that the vowel points and the Maſora were both a modern and an uſeleſs invention, he was led to queſtion the general integrity of the text; and his enemies allowed, that in his attack upon it, he diſcovered much learning and ingenuity. Still, however, he acquieſced and admitted the uniformity of the MSS. But the matter was not brought to the teſt of an actual collation of any number of MSS. and verſions, and little was done, till Dr. Kennicott's attention was directed in 1748, by the late learned Dr. Lowth, biſhop of London, to an examination of 2 Sam. xxiii. 8. This circumſtance convinced him of his former error, and he was ſoon ſatisfied that the Hebrew text was far from being perfect, and that it was impoſſible to underſtand this ſingle verſe, without allowing that there were in it four corruptions. Kennicott's explanation of this verſe having been approved by Dr. Lowth, he was requeſted to examine the ſubſequent parts of the ſame chapter; which was likewiſe performed, and the whole was publiſhed in 1753. He proceeded to examine two parallel chapters in the firſt book of Chronicles, and the ſecond book of Samuel, and found an omiſſion in the former of no leſs than 34 Hebrew words. Although ſuch great corruptions were proved from the printed text itſelf, and from the ancient verſions, yet it had not at that time been ſuſpected, that there were now extant any Hebrew MSS. which would at all aſſiſt in correcting the faulty paſſages of the Old Teſtament. In the ſequel, however, this was found to be actually the caſe, for Dr. Kennicott, on examining ſome of the Hebrew MSS. in the Bodleian library, found that they contained, in the chapters above cited, ſeveral of the readings which he had recommended as genuine, before he had inſpected theſe MSS. A diſcovery ſo important to ſacred literature being thus begun in 1753, and extended to 70 Hebrew and Samaritan MSS. in Oxford, it was ſoon much improved by conſulting a number of others at Cambridge, and in London. The inquiry was promoted by means of a catalogue of all the other Hebrew and Samaritan MSS. which were then known to exiſt in different parts of the world, publiſhed by Dr. Kennicott in 1760, in a ſecond diſſertation on the Hebrew text. In this work he endeavoured to produce a general conviction, as to the certainty of the Hebrew printed copies being much corrupted, and the great advantages that be derived from MSS., by furniſhing many various readings of conſequence, which are the true ones; and by confirming the ancient verſion in a multitude of inſtances of little moment in themſelves, and therefore not likely to have originated from deſign. It was alſo proved, that the Samaritan Pentateuch was of great importance; that its MSS. would ſerve to correct a variety of typographical errors, which diſgraced the two printed editions; and that the Samaritan copies were frequently confirmed even by the Hebrew MSS.

In conſequence of theſe intereſting diſcoveries, Dr. Kennicott was ſolicited by the late archbiſhop Secker, and many other learned perſons, and by ſeveral ſocieties of literary men, particularly by the univerſity of Oxford, to whoſe countenance and encouragement the undertaking was recommended by the late Dr. Hunt, profeſſor of Hebrew and Arabic in that univerſity, to undertake a collation of all the Hebrew and Samaritan MSS. in our own country. Diſcouraged at firſt by the proſpect of ſo arduous an undertaking, he at laſt, in 1760, conſented to engage in it. Of his progreſs, and the circumſtances that attended it, we have a detailed account in the "Diſſertatio Generalis," publiſhed with the ſecond volume of his Bible. Having propoſed ten years as the time which, he thought, would be neceſſary for collating the Hebrew and Samaritan MSS., he was enabled by his ſingular aſſiduity to fulfil his own expectations and thoſe of the public. Patronized by his Majeſty, and by a great number of liberal friends and well-wiſhers to the undertaking, both at home and in foreign countries, in the liſt of whom are no fewer than ſeven crowned heads, ſeveral princes, cardinals, archbiſhops, and biſhops, beſides univerſities, public libraries, and many of the moſt eminent literati in various parts of Europe; Dr. Kennicott inſtituted various and extenſive inquiries after MSS. at Conſtantinople, Warſaw, Venice, Bologna, Mantua, Pavia, Genoa, Liſbon, Geneva, Utrecht, Erfurt, Berlin, Stockholm, and Hamburgh. The numerous Hebrew MSS. of the latter place were collated by the celebrated Reimarus, who not only concurred in, but applauded the undertaking. In the proſecution of this work, it was diſcovered, that the printed editions of the Hebrew Bible, which had been ſuppoſed to agree, and on the agreement of which the notion of the integrity of that text had been founded, very much differed from one another; and particularly, that the *oldeſt* editions agreed moſt with the oldeſt and beſt MSS., and the *modern* editions with the lateſt and worſt MSS. As one proof of this, it is alledged, that the variations in the firſt edition (in 1488) from Vander Hooght (in 1705) amount to twelve thouſand. In the year 1767, Dr. Kennicott derived great advantage from his own examination of the Paris MSS., both Hebrew and Samaritan, and from

Dr.

Dr. Gill's collation of all the paſſages quoted in the Talmud. An Hebrew MS., which once belonged to a ſynagogue at Jeruſalem, was at this time purchaſed by his Britannic majeſty; and our author himſelf, hoping to obtain other treaſures from the Eaſt, ſent to Canton, and had nearly ſucceeded in procuring a MS. from the Jews at Cai-fong-fu, in the province of Honan. But though he failed in China, he ſucceeded in America, and procured a complete Hebrew MS. from a Jew at New York. During the tenth and laſt year of this collation, eight Daniſh MSS. were ſent to Oxford for the author's own examination, as were alſo ſix others from Toledo, by Dr. Bayer. Collations of other MSS. were furniſhed, at the ſame time, from Sileſia, Cologne, Straſburg, Konigſburgh, Upſal, Leyden, and Ireland. The indefatigable author, having thus collected materials for his noble undertaking, an undertaking no leſs honourable to his country than to himſelf, proceeded to digeſt the variations, with which he was furniſhed, under their ſeveral books, chapters, and verſes. During this operation, he formed a plan for a more complete ſcrutiny of the beſt MSS. through Europe, by ſending ſome well-qualified perſon to re-examine the MSS. already collated, and to examine the reſt in paſſages of greater moment, and where ſucceſs ſeemed at all probable. Mr. (afterwards Dr.) Bruns, a learned German, was ſelected for this embaſſy; and he was honoured with letters from the ſecretaries of ſtate here, to all our foreign ambaſſadors, as well as from the rulers of the two ſynagogues in London. The places in which he thus examined MSS., during a tour of three years, were Paris, Louvain, Cologne, Mentz, Worms, Manheim, Nuremburgh, Augſburgh, Stutgard, Carlſruhe, Straſburgh, Baſle, Zuric, Berne, Geneva, Turin, Caſale, Verulli, Milan, Genoa, Leghorn, Sienna, Rome, Florence, Bologna, Ceſena, Modena, Reggio, Parma, Mantua, Padua, Venice, Udine, Goritia, Gradiſca, Trieſte, Vienna, Dreſden, Leipſic, Erfurt, Jena, Deſſau, Berlin, Hamburgh, Helmſtadt, Caſſel, Amſterdam, Utrecht, Leyden, and the Hague.

The variations contained in nearly 700 bundles of papers, being at laſt digeſted, including the collections made by Dr. Bruns; and the whole, when put together, being corrected by the original collations, and then fairly tranſcribed into 30 folio volumes, the work was put to the preſs in 1773; and both volumes (as we have already ſaid), with the general diſſertation, were finiſhed in July 1780.

In order to evince the neceſſity as well as the utility of this work, Dr. Kennicott has preſented us with a ſurpriſing detail of teſtimonies, which exhibit the opinions both of the Jews and Chriſtians, as to the Hebrew text, from the earlieſt times down to the preſent. The Jewiſh teſtimonies are arranged under five diſtinct periods, viz. from the time of Malachi, about 420 years before the birth of Chriſt, to the commencement of the Chriſtian æra; from Chriſt to the year 500 after Chriſt; from the year 500 after Chriſt to the year 1000; from this year to the invention of printing, about 1450; and from the invention of printing to the year 1780. The firſt Jewiſh teſtimonies are thoſe of Joſephus and Philo, who ſpeak of the Greek verſion as perfectly agreeing with the Hebrew text in their time; whereas Dr. Kennicott aſſerts the corruption of the Hebrew text before the time of theſe Jews, and alſo the very great importance of the Greek verſion. For the Pentateuch of this verſion being made about 280 years before Chriſt, and the other books being alſo tranſlated into Greek about 100 years before Chriſt (as is inferred from the prologue to Eccleſiaſticus), this verſion muſt have had many true readings, where the Hebrew was afterwards corrupted. Although in Pſ. xvi. 10. the word for "thy holy one," which is now plural in the text of every copy expreſſed maſoretically, yet in the Greek verſion it is ſingular, which is the caſe in no leſs than 180 copies, agreeably to the quotations of St. Peter and St. Paul. And becauſe the argument of theſe apoſtles urged upon the Jews, juſt after the reſurrection of Chriſt, depends on this word's being truly ſingular, Dr. Kennicott conſiders this various reading as of greater moment than any other which was ever drawn forth from MSS. He obſerves, that as the Greek verſion thus helps to prove the Hebrew text corrupted when it *differs* from it, ſo where the Hebrew text is corrupted, and that verſion *agrees*, it proves the corruption to be older than the verſion, unleſs the verſion has ſince been aſſimilated to the Hebrew. Such very early corruptions occur, as he conceives, in Deut. x. 6. Gen. xi. 32. and Gen. xxxvi. 31,—43. The third inſtance contains 13 verſes, which, not being written by Moſes, were probably inſerted from 1 Chronicles, i. 43—54. in ſome MS. of Geneſis, into the margin, and thence taken into the text. This interpolation is ſo old as to be found in all the verſions, and likewiſe in the Samaritan text. In the firſt inſtance, many words are omitted in the Hebrew text, and in all the verſions, which are preſerved only in the Samaritan text. In the ſecond inſtance, the number 145 is corrupted into 205 in the Hebrew text, and in all the verſions, and it is right only in the Samaritan text. Dr. Kennicott afterwards ſpecifies two great corruptions: one, where the Greek verſion has been aſſimilated to the Hebrew, by *addition*; and another, in which the Syriac verſion has been thus accommodated, by *change*. The firſt relates to 20 verſes, probably interpolated in 1 Sam. xvii.; and the ſecond, to the word for *body* altered to the word for *ears*, in Pſalm xl. 7.; on which word, body, the argument is grounded, in the 10th chapter of the epiſtle to the Hebrews: and a very old Syriac MS. in the royal library of Paris, tranſlated from the Hebrew, has preſerved the true word for *body*; and another has proved, that the Jews have altered their ancient copies, wilfully, from the Hebrew text and Greek verſion of Iſaiah, xix. 18. reſpecting the temple at Heliopolis; and alſo from their turning Moſes into Manaſſes, in Judges xviii. 30. Many other inſtances occur in the period now under conſideration.

In the interval between the birth of our Saviour and the year 500, Dr. Kennicott remarks, that though the preſent Maſora ſeparates our tenth commandment into two, agreeable to the diviſion now made by the Roman Catholics; yet the unity of this commandment, as made by Proteſtants, is expreſsly confirmed by Philo and Joſephus; and the Maſoretic mark of ſeparation (at Exodus xx. 17.) is abſent from at leaſt 234 Hebrew copies. Joſephus is farther cited, as confirming the ancient chronology in the Greek verſion againſt that now in the Hebrew text; and likewiſe, as having a number much more credible as to the gold and ſilver left by David. The ſame hiſtorian alſo confirms the reading in the epiſtle to the Hebrews, chap. vii. 4. from Geneſis xiv. 20. He confirms, too, the Syriac verſion, and the edition of Sixtus, reading four in 2 Sam. xv. 7., and the Vatican MS. reading four in 1 Sam. xvii. 4. And though the later Jews have taken Daniel out of their prophetical books, yet Joſephus calls him a prophet, in the ſtrongeſt terms. It appears further under this period, that the Hebrew MSS. differed at the time of the compoſition of the Talmud; and that ſome of the true readings may ſtill be found in this work. This fact is confirmed by ſeveral inſtances, and particularly by Pſalm xvi.

Under the third period Dr. Kennicott conſiders the ſubject of the *Keri*, which ſee. This period alſo includes a collection of 216 variations between the oriental and occidental MSS. Proofs of differences are likewiſe deduced from the old Jewiſh books,

books, Rabboth, Pirke Eliczer, and Cozri. Saadias, who flourished about the year 1000, is also referred to as having read differently from the printed text; and Hai, about the same period, is shewn to have followed those MSS., which were defective in Joshua, chap. xxi., where two whole verses, absolutely necessary, though expelled by the Masora, have been found in 149 Hebrew copies. At the end of this period, Dr. Kennicott introduces the Arabic version, generally ascribed to R. Saadias, which has hitherto been reputed only secondary, as if it had been always taken from the Greek or the Syriac; whereas, it is honoured with the title of a primary version in several places; because it is found to agree with the Hebrew MSS. where both Greek and Syriac differ from it. This Arabic version has some very important readings, particularly in preserving that word which expresses the cause of God's anger against Balaam, Numb. xxii. 22. It is also important where it is only secondary; because it helps to determine the true reading of the Greek version, where the Greek MSS. are now at variance; as in Psalm xviii. 14. lxviii. 9. Micah v. 1. and Zechariah xiii. 7. To the close of this period, Dr. Kennicott refers the two oldest and best Hebrew MSS. now extant, one at Oxford, and the other at Vienna. Of the Bodleian MS., supposed to be 800 years old, he observes, that it contains about 14,000 variations. In the pentateuch of this MS. the Greek version is confirmed by 109 various readings; the Syriac, by 98; the Arabic, by 82; the Vulgate, by 88; and the Chaldee paraphrase, by 42. It also agrees with the Samaritan text, against the Hebrew, in 700 instances. This, it is added, is the only one which has preserved a word of great importance for understanding, 2 Sam. xxiii. 3,—7.; which word is confirmed by the Greek version, and recovers to us a prophecy of the Messiah.

The fourth period, from 1000 to 1450, is introduced with an observation, that the oldest Hebrew MS. which has a certain date (1106), though containing only 9120 verses, has above 6000 variations. The testimonies of Aben-Ezra, Jarchi, Maimonides, and Kimchi, who all flourished between 1150 and 1250, belong to this period. After taking notice of several true readings preserved by these four Rabbies, Dr. Kennicott introduces Meir Hallevi, who died in 1244, with his pathetic lamentation over the many variations in the Hebrew MSS.

Under the fifth and last period, from 1450 to 1780, including the printed Hebrew text, Dr. Kennicott takes particular notice of the five first editions of different parts, and of the first edition of the whole together. He adds, that the Psalms, as first printed in 1477, contain about 600 variations; and that the Hebrew Bible, as first printed in 1488, contains above 12,000. These, and some other very early editions, agree with the older MSS. much more than the editions after the year 1500, but still more than that by Jacob Ben Chaim, in 1526, which has been in general the standard down to the present time. About the year 1500, began the superstitious regard for the Masora; and such MSS. as had been masoretically corrected, were preferred for the editions of Cardinal Ximenes and Felix Pratensis. But the Masora being highly venerated by Ben Chaim, he chose for his text such MSS. as had the Masora most perfect; which MSS. were the latest and the worst: and yet, unfortunately, this text became the general standard for the Antwerp, Paris, and London Polyglotts, as well as for other editions of less note afterwards. The Jews have not, however, been satisfied with the correctness of Chaim's edition. For Rabbi Lonzano was afterwards encouraged to visit many countries, and to collate ten MSS. in order to render the text more perfect; and yet this complaint of errors was again renewed in 1635, by Manasseh Ben Israel. These testimonies are concluded with the Mantuan edition, called Minchath Shai, in which are about 2000 various readings, collected from MSS. and early editions, by Solomon Menorzi, in the last century: but it was not printed till 1744. So that, at the time when Christians were generally insisting on the perfection of the Hebrew text, the Jews were labouring to correct it, and lamenting its great imperfection in the following terms: "Quis restituet decus? Quis ejiciet raphanos et spinas? Horror confredit me: quum viderem multitudinem variantium, quæ ceciderunt in libros! Editores eunt obscurati, neque lux est eis; neque est qui quærit cessationem hujus diversitatis! Ecce nos palpantes tanquam cæci, in obscuritate diversitatum! Deus auferat tenebras nostras!"

On examining the testimonies of Christian writers with regard to the state of the Hebrew text, Dr. Kennicott begins with the Evangelists and Apostles; and here he adverts to the quotations made in the New Testament from the Old: on which subject, see QUOTATION. It appears, by unquestionable evidence, that the Old Testament has been corrupted, in many instances; and that a just correction of the Hebrew text, grounded on the authorities of Hebrew MSS., the Samaritan pentateuch, and the ancient versions, will, in many places, restore to the Old Testament that harmony with the New which it has long wanted. Instances occur in Gen. ii. 24.: Psalm xvi. xxxiv. 22. compared with John xix. 36, 37, and xl. compared with Hebrews x.; Jeremiah xxxi. compared with Hebrews viii.; Amos ix. compared with Acts xv.: Isaiah vii. 14. liii. Psalm lxviii. 19. Hos. xiii. 14. Amos v. 26. Deut. xxxii. 5. and Habakkuk ii. 4. Many arguments are adduced by Dr. Kennicott to shew, that the Jews have corrupted the chronology, from the creation to Abraham, either by subtracting or by adding 1300 years; and this great corruption is not in the Greek version, but in the Hebrew text; and that it was introduced in the second century. As it was a very ancient tradition, that the Messiah was to come in the sixth chiliad, because he was to come in "the last days," (founded on a mystical application of the six days' creation), it was contrived to shorten the age of the world from about 5500 to 3760, and thence to prove that Jesus could not be the Messiah, because at the æra of his birth the time for the advent of the Messiah was not yet come. The time of this grand corruption is shewn to have between the years 175 and 200. The old Italic version, made from the Greek about the year 100, is adduced to confirm some ancient readings of the Greek version, particularly as to the more extended chronology. Dr. Kennicott, after various pertinent quotations from Ignatius, Justin Martyr, and Irenæus, refers more particularly to Tertullian, with a view of proving that, in his time, the passage in Isaiah liii. 4. expressed the sense ascribed to it in the 8th chapter of St. Matthew, where the Evangelist quotes it as foretelling, that "the Messiah should heal bodily diseases." The Hebrew words, it is shewn, admit this sense: Tertullian so expresses them; and so did the old Greek version, which has been strangely altered in this place, out of opposition to the gospel. Origen is cited, as affording many interesting particulars, with regard to the differences in the Hebrew copies, and the true readings of the Greek versions; and Eusebius, Theophilus Antiochenus, Ephraim Syrus, Jerom, Epiphanius, Augustin, and Sulpicius Severus, are quoted to the same purpose. The first period of the Christian writers terminates with the oldest MSS. of the Greek version, particularly the Vatican and Alexandrian MSS. written about the year 400, which see. Dr. Kennicott proceeds to the period that elapsed between the years 500 and 1000, and avails himself

of

of the Syriac verſions (ſee SYRIAC) for introducing ſome uſeful obſervations on ſeveral paſſages, particularly Pſalm xl. 6, 7, 9, and 2 Kings viii. 16.; in which laſt paſſage three words are now interpolated in the Hebrew text, which, though they are alſo found in the Vatican and Alexandrian MSS., are not in the Complutenſian and Aldine editions; nor are they in an ancient MS. of Kings, nor in ſome of the beſt MSS. and earlieſt editions of the Vulgate. See VULGATE. From the year 1000 to 1450, the teſtimonies of Chriſtians are very few. Yet ſoon after the Jews fled from the Eaſt into Europe, in 1040, the Hebrew language was ſtudied by ſeveral Chriſtians, particularly by Lanfranc and Anſelm, Groſthead and Roger Bacon; and this laſt learned man, with his Franciſcan brethren at Oxford, bought many Hebrew MSS. when the Jews were expelled from England in 1289. In the 13th century, Raymund Martini accuſed the Jews of corrupting the Hebrew text; and he ſpeaks of MSS. differing in Zech. xii. 10., with reſpect to which Dr. Kennicott obſerves, that forty copies have here the reading expreſſed in John xix. 37. Dr Kennicott alſo cites Nic. Lyranus, Radulphus Armachanus, Toſtatus, Perez de Valentia, and Marſilius Ficinus.

Under the laſt period, from 1450 to 1780, Zuinglius takes the lead; and he extols the Greek verſion, and remarks the corrupt addition of Jer. chap. lii. Luther is alſo mentioned; and Bibliander is celebrated on account of his excellent criticiſm on Ezekiel xiii. 21. As it is very improbable that the news of the capture of Jeruſalem ſhould be nearly eighteen months in reaching Babylon, it will be ſatisfactory to know, on the authority of the Syriac verſion and eight Hebrew MSS., that this period was not more than ſix months. Having deſcribed the editions of Sixtus and Clement, Dr. Kennicott obſerves, that the preſent Engliſh verſion frequently expreſſes, not what the tranſlators found in their Hebrew text, but what they thought ſhould have been there; and that the 14th pſalm, inſerted in the liturgy of the Church of England, contains three verſes not found at preſent in the Hebrew text of that pſalm, but which are probably genuine. We have already mentioned Capellus's opinion on this ſubject; and yet, though he proved the corruption of the Hebrew text by every argument, except that of MSS., Buxtorf, the ſon, following his father, who aſſerted the abſolute agreement of all the ancient MSS., affirmed that no Hebrew MS. in the world contained any various reading which agreed with either of the ancient verſions. It is needleſs to recite the opinions of Mede, Morinus, Beveridge, Walton, Hammond, Bochart, Huetius, Pocock, Le Clerc, &c. on this ſubject. We ſhall here only obſerve, with Dr. Kennicott, that Jablonſki was the firſt editor of an Hebrew bible who ſpoke of any Hebrew MSS.; and he names four, by the help of which he made a few corrections. Nevertheleſs, he omitted the two neceſſary verſes in Joſhua, chap. 21., though Dr. Kennicott has eſtabliſhed them, in conſequence of the examination of 149 copies. Opitius declares that he, in his edition, obeyed the Maſora, in defiance of all the MSS. and editions of the world united. Vitringa has ſhewn, according to Dr. Kennicott, how a miſtake in one MS. may afterwards have been introduced into many, from the practice of correcting many MSS. by *one* as their ſtandard. The conjectural emendation made by this eminent biblical critic, in 2 Chron. xxvi. 5., is confirmed by fifty copies; and his reading of Iſaiah xix. 18. is eſtabliſhed by the Talmud and ſixteen Hebrew copies. J. H. Michaelis, although he publiſhed ſome various readings, omitted many variations of great moment, probably from an undue deference to the advocates of the integrity of the Hebrew text. Among theſe advocates we may reckon Wolfius, who maintained that miſtakes might exiſt in ſome MS. copies, but not in all; becauſe ſome one MS., or ſome one edition, always had the true reading. Carpzovius contended, that the Hebrew text has deſcended to us in the ſame ſtate of purity in which it was firſt found; not indeed in all the copies, but in thoſe of the better ſort; nor in theſe ſeparately, but in ſuch altogether: and he thought it needleſs to collect theſe from every quarter of the world, becauſe, in his opinion, thoſe which are near at hand will be ſufficient: a conceſſion which aboliſhes his former doctrine. The learned Hallet, in his Notes on the Holy Scriptures, publiſhed in 1729, alledges, as a reaſon why the quotations in the New Teſtament differ from thoſe of the Old, that the Hebrew copies have been altered ſince the days of the apoſtles. Biſhop Hare, with whoſe teſtimonies Dr. Kennicott concludes his catalogue of Chriſtian writers, contends earneſtly for admitting the corruption of the Hebrew text. He rejects the titles of many of the pſalms, as not given by the authors of theſe pſalms. He condemns the practice of varniſhing over, inſtead of correcting, the corrupted readings; and he laments that Hebrew MSS., the chief ſupport of criticiſm, were wanting.

Dr. Kennicott cloſes his account of his laudable undertaking, with evincing the great uſe to be derived from the Hebrew MSS. and ancient verſions, for amending the printed Hebrew text; and with exhorting perſons in power to render ſuch corrections ſubſervient to the public good, by procuring a more correct and a more intelligible Engliſh tranſlation, or rather a reviſal of the preſent Engliſh tranſlation of the Old Teſtament. Theſe MSS., he ſays, ſtrongly confirm the ancient verſions, and enable us to aſcend to the times of Jerom, of the Apoſtles, and even of Ptolemy Philadelphus: and he adds, it now remains to be ſeen in what kingdom or country, through Europe, will be manifeſted the greater zeal, for correcting the modern tranſlations of the Old Teſtament.

The work of which, for the gratification of our readers, and with a view of recording and tranſmitting the honour of our country, where it was undertaken, and of the age in which we live, we have given a copious account, will appear in its pre-eminent importance and utility, whenever it ſhall be applied to the deſirable purpoſe of aiding a public and authoritative new tranſlation of the Bible, or, at leaſt, an effectual reviſion of the common verſion. In the tranſlation of particular books of Scripture, by Biſhops Lowth and Newcome, and by others of inferior rank in the church, &c. we obſerve the advantage reſulting from Dr. Kennicott's labours; but their full benefit can only be enjoyed, when the tranſlation is complete, and authoritatively introduced into common uſe. It has contributed eminently to the honour of the king of Sweden, that he has been the firſt prince in Europe who has iſſued his royal commands for executing a purpoſe of this kind: and Dr. Kennicott thinks, it would be criminal to ſuppoſe that Great Britain, which has enjoyed ſuch diſtinguiſhed bleſſings of Providence, will be backward in ſo pious a deſign. No perſons, whatever be their rank either in the church or ſtate, can more laudably teſtify their veneration for the Holy Scriptures, and their concern for the information and benefit of the world, than by adopting and accompliſhing a meaſure of this kind. It would ſerve alſo to obviate many objections againſt the truth and authority of divine revelation. It has been urged by Lord Bolingbroke, and by other writers on the ſide of ſcepticiſm or infidelity, "that if the Scriptures had been from God, they would always have been preſerved in their primitive purity." In oppoſition to ſuggeſtions of this kind, Dr. Kennicott ſhews, that neither the wiſdom nor

the goodneſs of the Supreme Being can be juſtly impeached, from the ſuppoſition that many errors have crept into the preſent text; becauſe the moſt important matters are ſtill ſecure and certain, and men have always been able to derive from the Bible a rule both of faith and practice. For the illuſtration of this poſition, he appeals to the ancient churches, both Greek and Italian, and the modern churches of both Proteſtants and Roman Catholics; ſince, amongſt all theſe, their ſacred books taught them "what they muſt do to be ſaved;" though they contained many errors, the correction of which was very deſirable. Indeed, the integrity of the ſacred books could not have been preſerved without a "miracle," perpetual as to time and univerſal as to place, which would conſequently be a greater miracle than any in the Bible: nevertheleſs, as many corruptions, in tranſcripts made from tranſcripts, ever ſince the year 400 before Chriſt, were unavoidable, it is happy that ſeveral verſions, made 1500 or 2000 years ago, will correct ſome of theſe corruptions; and that the Hebrew MSS. ſtill extant, will correct others. Upon the whole, it is of great importance, that the effect of theſe corrections ſhould appear in its whole extent, and as ſpeedily as poſſible, not only to Chriſtians in particular, but to the world in general.

The learned Dr. John Bernard Roſſi, profeſſor of divinity and the oriental languages in the Royal Academy of Parma, undertook to make a collection of the various readings of the Old Teſtament, in imitation of that of Oxford; and for this purpoſe he examined, by himſelf, or his friends, 1470 MSS. or printed copies. Of foreign MSS. 210, which had been omitted by Dr. Kennicott, were collated in the moſt important paſſages; and of ancient editions, either in his own poſſeſſion, or to which he had acceſs, the number amounted to 288, of which 230 are ſuch as had not been collated by Dr. Kennicott. M. de Roſſi announced his deſign in a tract, entitled, "Apparatus Hebræo-Biblicus," and publiſhed at Parma in 1782, 8vo.; and he propoſed to comprize the reſult of his labours in 4 vols. 4to. The firſt volume was publiſhed at Parma in 1784, under the title of "Variæ Lectiones Veteris Teſtamenti, &c." or the various readings of the Old Teſtament, drawn from an immenſe number of MSS. and printed editions, compared with the Samaritan text and the ancient verſions, and examined and appreciated by the moſt accurate rules and principles of ſacred criticiſm. This volume contains the "Prolegomena," and a clavis of the books of Geneſis, Exodus, and Leviticus. In the introduction we have ſeveral curious critical diſcuſſions, from which we learn that this collection aſcertains, as Dr. Kennicott's valuable and judicious labours had before done, inſtead of invalidating, the integrity of the ſacred text in matters of the greateſt importance; as all the MSS. notwithſtanding the diverſity of their dates, and of the places where they were tranſcribed, agree with reſpect to that which conſtitutes the proper eſſence and ſubſtance of divine revelation, namely, its doctrines, moral precepts, and hiſtorical relations. M. Roſſi charges the variations not merely on the copyiſts, but on the ignorance and temerity of the critics, who have, in all ages, been too ambitious of dictating to their authors, and who, inſtead of correcting the pretended errors of others, frequently ſubſtitute in their place real errors of their own. This author is of opinion, that the common reading of an ancient text ought never to be changed but by the authority of MSS.; and if there be any exceptions to this general rule, they are very rare: and the conjectural alterations of critics ſhould be thrown into the notes. M. Roſſi, however, obſerves, that we muſt not confound the alterations introduced into the ſacred text by the injuries of time, the negligence of tranſcribers, or the boldneſs of critics, with thoſe which have been made by public authority. The ſacred writers of ancient times left, as he ſays, their records to other writers, who were often their diſciples, as alſo to public ſcribes, and to magiſtrates, who reviſed them. In this reviſion, which was executed either by ſacred authors, or by the public authority of the ſynagogue, corrections and retrenchments were made, where they were judged neceſſary. This, M. de Roſſi thinks, appears evident from the preſent ſtate of the ſacred writings; and in confirmation of his opinion, he quotes the Syriac interpreter, who, in a note placed at the end of the pentateuch, ſays, that this work was compoſed by Moſes, but was afterwards digeſted and finiſhed by Joſhua. He alſo conjectures, that Moſes himſelf made uſe of ancient records, both in his hiſtory of the creation, and in that of the deluge. He thinks that the frequent repetitions and anachroniſms, which are diſcernible in the book of Geneſis, ought rather to be attributed to a writer anterior to Moſes, than to ſcribes in after-times; or to the confuſion of the ancient records themſelves, as ſome have imagined. This opinion was propoſed and maintained with ſingular ingenuity and erudition, before the time of Roſſi, in a French work publiſhed at Bruſſels in 1753, and entitled, "Conjectures concerning the original memoirs, which Moſes appears to have made uſe of in compoſing the book of Geneſis, together with remarks deſigned to confirm or illuſtrate the ſeveral conjectures." The reviſion, ſays Roſſi, which Ezra made of the ſacred writings, with the aſſiſtance of MSS. and according to the rules of criticiſm, both on his own authority as a ſacred writer, and that of the council of which he was a member, did not annul the MSS. that were anterior to his time, either in the hands of the Samaritans, or in thoſe of the Jews, from which thoſe of the Cuthites or Samaritans had been taken, or in the hands of the Egyptians, or in thoſe of the Babylonian Jews, who did not return to the holy land. The edition of Ezra remained entire till the deſtruction of Jeruſalem; but it underwent ſeveral alterations before the time of the Maſorites, whoſe critical labours or attempts, with a view of ſecuring the ſacred code againſt future injuries, are well known. Yet, notwithſtanding theſe attempts and labours, ſome faults, which were anterior to their time, ſtill remained; and others, though of little conſequence, afterwards crept into the ſacred text. The only ſources from which we can derive warrantable corrections of theſe faults are, according to this author, the MSS., the ancient editions, the Samaritan text, the ancient verſions, the parallel places, the analogy of the text or of the hiſtory, the teſtimonies of ancient writers, critical conjectures, and the Maſora, which De Roſſi treats with more reſpect than Dr. Kennicott, of whom he complains on that account. He ſubjoins many learned and judicious obſervations on the various ſources, from which materials are to be derived for the neceſſary corrections. As to the MSS. he lays down rules for aſcertaining their age, of which the moſt obvious is the date; and in order to underſtand their dates, he takes notice of the various methods of computing time employed by the Jews, and the different æras from which they reckon. When the dates are wanting, it becomes difficult to aſcertain the time of a MS., if it be anterior to the thirteenth century. Thoſe which are anterior to the twelfth century are very rare; and the author minutely indicates the marks that diſtinguiſh them. The rarity of the ancient Hebrew MSS. has been occaſioned by the Jewiſh cuſtom of depoſiting their books and phylacteries in public places, from whence, to make place for others, they have been taken and buried in wells, or under ground, where they ſoon rot. Thoſe of a very remote antiquity, which are no longer extant,

tant, are often reſtored, in part, by copies which ſtill ſubſiſt. With regard to ancient editions, De Roſſi diſtinguiſhes the Maſoretic from thoſe editions without the Maſora, which are anterior to the year 1525, when the rabbinical Bible of Jacob Ben Chaim was publiſhed. Of 242 which he has collected, he reckons 30 which belong to the fifteenth century, and above 60 which are anterior to the firſt Maſoretic Bible. The ancient verſions enumerated by the author are the Greek, Chaldaic, Syriac, Arabic, and Perſian; and among theſe, the Greek verſion of the Pentateuch, yet unpubliſhed, which is in the library of St. Mark at Venice, and which he ſuppoſes to have been made in the twelfth or thirteenth century, by an Helleniſt, from the Hebrew of Ezra or of Paleſtine; and not as the Septuagint, from the Egyptian or Iſraelitiſh text. The differences that are found in theſe verſions muſt not be conſidered as various readings; ſince many of theſe diverſities are to be attributed, ſays De Roſſi, to the tranſlators themſelves, who have ſometimes taken great liberties with the original text, by altering it in their verſions. For other particulars, we refer the learned reader to the work itſelf. The ſecond volume was publiſhed at Parma, in 1785, and contains the books of Numbers, Deuteronomy, Joſhua, Judges, Samuel, and Kings. The third comprehends Iſaiah, Jeremiah, Ezekiel, the twelve leſſer prophets, with the Song of Solomon, Ruth, Lamentations, Eccleſiaſtes, and Eſther. And in the fourth, or laſt, are the Pſalms, Proverbs, Job, Daniel, Ezra, Nehemiah, and Chronicles. Parmæ, 1786. The high price of Kennicott's and De Roſſi's very valuable works, induced M. Breitkopf to employ Dr. Doederlein and Profeſſor Meiſſner, to collect the moſt intereſting various readings from the above works, and to print them under the text of his new edition of Reineccius's bible, printed at Leipſic in 1725, and again in 1739, under the title of "Biblia Hebraica, olim a Chriſtiano Reineccio edita, nunc denuo, cum variis lectionibus, ex ingenti codicum copia, a B. Kennicotto & J. B. de Roſſi collatorum," Lipſiæ, 8vo, 1793.

Bibles, *Greek*. The moſt ancient Greek verſion is the Septuagint: for an account of which, the manner in which it was found, the collation of its MSS., and other circumſtances relating to it, ſee Septuagint; ſee alſo Alexandrian, and Vatican. The number of editions of the Bible in Greek is very conſiderable; but they may be all reduced to three or four principal ones, namely, that of Complutum or Alcala de Henares, that of Venice, that of Rome, and that of Oxford. The firſt or Complutenſian edition was undertaken by the divines of Complutum, under the direction and at the expence of Cardinal Ximenes, and finiſhed in 1514, but not allowed by Leo to be publiſhed till 1520; nor were the copies of it diſtributed to the world at large before the year 1522. It was inſerted in the Polyglott Bible, uſually called the "Complutenſian Bible." In this edition the Greek of the LXX. is ſaid to be altered in many places, in order to accommodate it to the Hebrew text, and to the Vulgate. For a more particular account of it, ſee Complutensian, and Polyglott. It has been reprinted in the Polyglott Bible of Antwerp, called "Biblia Regia," by Arias Montanus, in 1572; in that of the Commelines, commonly called "Vatablus's Bible," in 1599; and in De Jay's Polyglott of Paris, in 1645. See Polyglott.

The ſecond Greek Bible is that of Venice, formed from many ancient copies by Andrea Aſulanus, and printed by Aldus Manutius in 1518, and hence called the "Aldine edition." This edition approaches nearly to the Roman, and is ſaid to be purer than the Complutenſian. Maſius ſays of it, that it is a copy of the ſimple interpretation of the ancient LXX.; but not pure, nor free from all intermixture of the words of Theodotion. Uſher obſerves, that it ſometimes deviates from the LXX. and adopts the readings of Aquila; and that various gloſſes have crept into it. From this Aldine edition all the German copies have been derived, which generally adopt the words of it, but differ from it in the order of the books, chapters, and ſome verſes. The apocryphal books are printed ſeparately after the reſt. This edition was reprinted, with the Complutenſian Latin verſion, in 1520, by Aud. Cratandrus; and again, in 1550, by Rich. Brylingerus; at Straſburg, in 1526; at Hamburgh, in 1596; at Frankfort, by the Wecheliani, in 1597; and in other places, with ſome alterations, to bring it nearer to the Hebrew. The moſt commodious is that of Frankfort, in which are publiſhed, from the Complutenſian edition, the four laſt chapters of Exodus, and a great part of the 24th chapter of the Proverbs. There are alſo added little Scholia, which ſhew the different interpretations of the old Greek tranſlation. The author of this collection has not annexed his name, but it is commonly aſcribed to Francis Junius.

The third Greek Bible is that of Rome, or the Vatican (ſee Vatican), formed from the Vatican copy by cardinal Caraffa, and other learned perſons, who were employed in this work for nine years, by the order and under the auſpices of Pope Sixtus V. It was printed at Rome in 1587, with the Greek Scholia, collected from the MSS. in the Roman libraries. It was afterwards printed in Latin, with learned and uſeful notes, by Flaminius Nobilius, at Rome, in 1588. The Greek edition, with the Latin annexed, the diſtinction of verſes, according to the Vulgate, the Greek Scholia, and the Notes of Nobilius, was printed at Paris, in 1628, by J. Morin, prieſt of the Oratory. In forming this edition, Carafa made uſe of ſeveral ancient MSS. beſides the Vatican, and particularly one procured from the library of Cardinal Beſſarion, written in large letters, and another from Magna Græcia, agreeing with the Vatican; and Carafa profeſſes that it was his deſign, not to accommodate this edition to the Latin Vulgate, or the Hebrew, but to the ancient LXX. Notwithſtanding ſome few trivial objections, this edition has been extolled for its purity, its freedom from any material corruptions, and its ſuperiority to all other editions. From this all the Engliſh editions have been derived. The Greek edition of Rome, or as Grabe ſays in his Prolegomena, that of Paris, has been printed in the Polyglott Bible of London, in 1657; to which Walton has added, at bottom, the various readings of the Aldine and Complutenſian editions, and of the Alexandrian MS., as well as of Marchialanus's and Card. Barberini's. It was printed at London, in 1653, in 8vo., with ſome deviations with regard to the order of the books, the number of the pſalms, &c.; at Cambridge, in 2 vols, 12mo., with a preface by the learned Pearſon, in 1665; at Amſterdam, with the ſame preface, in 1683, by Leuſden, 8vo.; and at Leipſic, in 1697, 8vo. with the Greek Scholia of the Roman edition, the parallel places and various readings, and a preface by J. Frickius of Ulm. Another Greek Bible was publiſhed at Franequer, in 1709, by Lambert Bos, who profeſſes to adhere to the Roman edition of the Vatican copy, and to ſubjoin at the bottom of the page, beſides the Scholia of the Roman edition, all the various readings he could find, together with fragments of the verſions of Aquila, Symmachus, and Theodotion. Breitinger, however, obſerves, that Bos, inſtead of adhering to the Roman edition, has followed that of Paris by Morinus, or the text in Walton's polyglott. This edition of Bos has been long the common text-book of biblical

ſcholars, who cannnt eaſily purchaſe the Roman edition; although it is far from being a correct copy of its proto type.

The fourth Greek Bible is that done from the Alexandrian MS., begun at Oxford by Dr. Grabe, in 1707. An edition of a ſimilar kind had been undertaken by Patricius Junius, or Patrick Young, who proceeded no farther than the 17th chapter of the book of Numbers, and alſo propoſed by Voſſius, but not undertaken. In Grabe's edition, the Alexandrian manuſcript is not printed ſuch as it is, but ſuch as it was thought it ſhould be; i. e. it is altered wherever there appeared any fault of the copyiſts, or any word inſerted from any particular dialect. This ſome think an excellence, but others a fault; urging, that the manuſcript ſhould have been given abſolutely and entirely of itſelf, and all conjectures, as to the readings, ſhould have been thrown into the notes. For the plan of this work, and the mode of its execution, we refer to the author's Prolegomena. A valuable edition of this work, enriched with various readings from the Vatican copy, and other manuſcripts, and illuſtrated by critical diſſertations, was publiſhed by Joſ. Jac. Breitinger, in 4 vols, 4to., in 1730. Tigur. Helvet. A collection of the MSS. of the moſt ancient Greek verſion of the Septuagint has, within theſe few years paſt, been undertaken by Dr. Holmes, canon of Chriſt-church, Oxford; and the firſt volume was publiſhed at Oxford in 1798, folio; for an account of which, ſee SEPTUAGINT. Walton's Prolegomena. IX. Grabe's Prolegom. Hodii de Bibliorum Textibus originalibus, &c. p. 638, &c. Fabr. Bib. Græc. l. iii. c. xi. § 6. Tom. II. p. 324, &c. See SEPTUAGINT, and TESTAMENT.

BIBLES, *Latin*, how numerous ſoever, may be all reduced to three claſſes; the ancient *Vulgate*, called alſo "the old Italic," or "Vulgar Latin," (ſee ITALIC *Verſion*), tranſlated from the Greek Septuagint, for the uſe of the Latins, ſoon after their converſion to Chriſtianity: which verſion was allowed to be ſuperior to all the reſt, being, as St. Auſtin calls it, "tenacior verborum cum perſpicuitate ſententiæ": which verſion being corrupted, Jerom, between the years 370 and 380, made a new Latin verſion from the Hexaplar Greek; the *modern Vulgate*, the greateſt part of which is done from the Hebrew text; and the *new Latin tranſlations*, done alſo from the Hebrew text in the ſixteenth century. We have nothing remaining of the *ancient Vulgate*, uſed in the primitive times in the Weſtern churches, but the Pſalms, Wiſdom, and Eccleſiaſtes. Nobilius has endeavoured to retrieve it from the works of the ancient Latin fathers; but it was impoſſible to do it exactly, becauſe moſt of the fathers did not keep cloſe to it in their citations.

As to the *modern Vulgate*, there are numerous editions very different from each other. Cardinal Ximenes has inſerted one in the *Bible* of *Complutum*, corrected and altered in many places. R. Stephens, and the doctors of Louvain, have taken great pains in correcting the modern Vulgate. See VULGATE.

The beſt edition of Stephens's Latin Bible is that of 1540, reprinted in 1545, in which are added, on the margin, the various readings of ſeveral Latin manuſcripts, which he had conſulted. The doctors of Louvain reviſed the modern Vulgate after R. Stephens; and added the various readings of ſeveral Latin manuſcripts. The beſt of the Louvain editions are thoſe, at the end of which are added the critical notes of Francis Lucas of Bruges.

All theſe reformations of the Latin Bible were made before the time of pope Sixtus V. and Clement VIII. ſince which people have not dared to make any alterations, except in comments, and ſeparate notes. Sixtus V. who was advanced to the papal ſee in 1585, although the Latin Bible of Gregory XIII. was declared to have been reſtored to its primitive integrity, formed, by the aſſiſtance of learned perſons, another edition; and iſſued a bull in 1589, reſolving and declaring that this was to be deemed, without doubt or controverſy, that which was acknowledged as authentic by the council of Trent, and to be maintained as true, legitimate, authentic, and unqueſtionable; forbidding the alteration, addition, or ſubtraction of the leaſt tittle of it, and declaring ſuch a mutilated edition deſtitute of credit or authority. Nevertheleſs, after the death of Sixtus V. this edition was ſuppreſſed by ſucceeding popes, as inaccurate and imperfect. A new edition was undertaken by pope Gregory XIV. and completed and announced by Clement VIII. in 1592, which, though different from that of Sixtus, and even repugnant to it, is received as authentic, under the name of Sixtus V.; and it is now the ſtandard throughout all the Romiſh churches. That pontiff made two reformations; but it is the firſt of them that is followed. See VULGATE. From this the Bibles of Plantin were done, and from thoſe of Plantin all the reſt; ſo that the common Bibles have none of the after-corrections of the ſame Clement VIII. It is a heavy charge that lies on the editions of pope Clement, viz. that they have ſome new texts added, and many old ones altered, to countenance and confirm what they call the Catholic doctrine: witneſs that celebrated paſſage of St. John, *tres ſunt*, &c. Mr. Iames, an Engliſh proteſtant, has collected above 2000 articles, ſome of which are indeed of no great conſequence, in which Clement's edition differs from that of Sixtus. Clement has adhered more cloſely to the Hebrew text; and his edition, ſays Dupin, is much more correct than that of Sixtus. He adds, though the vulgar verſion be not altogether free from errors and defects, it muſt nevertheleſs be confeſſed that the council of Trent had ſufficient reaſon to prefer this before all the other Latin verſions, as Theodore Beza, P. Fagius, L. de Dieu, Caſaubon, Grotius, Walton, and ſome other proteſtants, have allowed. This verſion was the moſt ancient of all that were extant at the time of this council; the greater part of it was done by Jerom, a very exact and faithful interpreter. It had been uſed for many ages in the Latin church: it was written in a ſimple and natural ſtyle, and yet occaſionally heightened by noble expreſſions; and upon the whole, ſays Dupin, it was the beſt and moſt perfect verſion.

There is a great number of Latin Bibles of the third claſs, comprehending the verſions from the originals of the ſacred books made within three hundred years. The firſt is that of Sanctus Pagninus, a Dominican, under the patronage of pope Leo X. printed at Lyons, in 4to. in 1528, authoriſed by two letters of pope Adrian VI. and pope Clement VII. prefixed to it, the former dated in 1523, and the latter in 1526, and much eſteemed by the Jews. He employed 25 years in the execution of this work, and finiſhed it before the year 1518. This the author improved in a ſecond edition. In 1542, there was a beautiful edition of the ſame at Lyons, in folio, with *ſcholia*, publiſhed under the name of Michael Villanovanus, i. e. Michael Servetus, author of the *ſcholia*. Thoſe of Zurich have likewiſe publiſhed an edition of Pagninus's Bible in 4to. And R. Stephens reprinted it in folio, with the Vulgate, in 1557, pretending to give it more correct than the former editions. There is alſo another edition in 1586, in four columns, under the name of *Vatablus*: and we find it again in the Hamburgh edition of the Bible in four languages.

In the number of Latin Bibles is alſo uſually ranked the verſion of the ſame Pagninus corrected, or rather rendered literal, by Arias Montanus; which correction being approved of by the doctors of Louvain, &c. was inſerted in the Polyglott Bible of Philip II. and ſince in that of London. The chief aim of Montanus has been to tranſlate the Hebrew words by the ſame number of Latin ones; ſo that he has accommodated his whole tranſlation to the moſt ſcrupulous rules of grammar, without duly adverting to his latinity; and therefore this verſion may be conſidered rather as a grammatical commentary than a true verſion, and adapted to inſtruct young beginners in the Hebrew, rather than to be read ſeparately. There have been various editions of this in folio, quarto, and octavo; to which have been added the Hebrew text of the Old Teſtament, and the Greek of the New. The beſt of them all is the firſt, which is in folio, 1571. The tranſlation of Thomas Malvenda, a Spaniſh Dominican, is more grammatical and barbarous than that of Montanus, and not much eſteemed.

Since the Reformation, there have been ſeveral Latin verſions of the Bible from the original Hebrew by Proteſtants. The moſt eſteemed are thoſe of Munſter, Leo Juda, Caſtalio, and Tremellius: the three laſt of which have been reprinted various times. Munſter publiſhed his verſion at Baſil in 1534, which he afterwards reviſed; he publiſhed a correct edition in 1546. Without rigidly adhering to the grammatical ſignification of the words, like Pagninus and Montanus, he has given a more free and intelligible verſion; but by not deviating from the ſenſe of the Hebrew text, he has retained ſome of its idiotiſms. He has alſo availed himſelf of the commentaries of the beſt Rabbins. Huetius gives him the character of a tranſlator well verſed in the Hebrew language, whoſe ſtyle is very exact and conformable to the original. Caſtalio's fine Latin pleaſes moſt people; but there are ſome who think it too much affected, and deſtitute of that noble ſimplicity and natural grandeur, and of that inexpreſſible energy of ſtyle, belonging to the originals, and ſome other verſions: the beſt edition of it is that in 1573. Leo Juda's verſion, altered a little by the divines of Salamanca, was added to the ancient Latin edition, as publiſhed by R. Stephens, with notes, under the name of "Vatablus's Bible," in 1545. It was printed at Zurich in 1543, and is more elegantly written than Munſter's, but ſometimes recedes too far from the literal ſenſe. It was condemned by the Pariſian divines, but printed, with ſome alterations, by the Spaniſh divines of Salamanca. That of Junius and Tremellius is preferred, eſpecially by the Calviniſts, and has undergone a great number of editions. It poſſeſſes much more of the true natural ſimplicity. The chief Hebraiſms are preſerved, and the whole is exactly conformable to the Hebrew text, without the leaſt obſcurity or barbarity. Nevertheleſs, it is not without defects: relative pronouns are introduced, without attention to the Hebrew text, and they are charged with adding ſome words to expreſs their own ſenſe.

We may add a fourth claſs of Latin Bibles, comprehending the *Vulgate* edition, corrected from the originals. The Bible of Iſidorus Clarius is of this number: that author, not being contented with reſtoring the ancient Latin copy, has corrected the tranſlator in a great number of places, which he thought ill rendered, ſo as to make them conformable to the Hebrew text. Although he corrected above 8000 paſſages, he has omitted ſome to avoid giving offence to the catholics, by making too many alterations in the vulgar verſion. Some proteſtants have followed the ſame method, and, among others, Andrew and Luke Oſiander, who have each publiſhed a new edition of the "Vulgate," corrected from the originals, according to the Hebrew text. They have inſerted their emendations in a character different from the text of the vulgar verſion, inſtead of throwing them into the margin, and thus they have occaſioned ſome confuſion.

Bibles, *Oriental.* At the head of the Oriental verſions of the Bible, muſt be placed the Samaritan, as being the moſt ancient of all, though neither its age nor author have been yet aſcertained, and admitting no more for Scripture but the Pentateuch, or five books of Moſes. This tranſlation is made from the Samaritan Hebrew text, which is a little different from the Hebrew text of the Jews. This verſion has never been printed alone; nor any where but in the Polyglotts of London and Paris. See Pentateuch, and Samaritans.

Bibles, *Chaldee*, are only the gloſſes or expoſitions made by the Jews in the time when they ſpake the Chaldee tongue. Theſe they call by the name of *Targumim*, or *paraphraſes*, as not being any ſtrict verſions of the Scripture. They have been inſerted entire in the large Hebrew Bibles of Venice and Baſil; but are read more commodiouſly in the Polyglott, being there attended with a Latin tranſlation. See *Chaldee* Paraphrase.

Bibles, *Syriac.* There are extant two verſions of the Old Teſtament in the Syriac language; one from the Septuagint, which is ancient, and made probably about the time of Conſtantine; the other, called *antiqua & ſimplex*, made from the Hebrew, as ſome ſuppoſe, about the time of the apoſtles. This verſion is printed in the Polyglotts of London and Paris.

In the year 1555, Widmanſtadius printed the whole New Teſtament in Syriac, at Vienna, in a beautiful character. After him there were ſeveral other editions; and it was inſerted in the Bible of Philip II. with a Latin tranſlation. The beſt edition of the Syriac New Teſtament is unqueſtionably that of Leyden, publiſhed by Schaaf in 1708, and reprinted, much improved, at Leyden, in 1717. A new Syriac and Arabic Teſtament was printed at Rome, in 1703, by the Propaganda, for the uſe of the Maronite Chriſtians in Syria. Gabriel Sionita alſo publiſhed a beautiful Syriac edition of the Pſalms, at Paris, in 1525, with a Latin interpretation. See Syriac *Verſion*.

Bibles, *Arabic.* Although the Chriſtian religion was preached in Arabia, as well as in other countries of the Eaſt, at an early period, it never was the eſtabliſhed religion of the country, as in Syria and in Egypt; for even the temple of Mecca was a heathen temple till the time of Mahomet. A tranſlation of the Bible into Arabic was therefore wholly unneceſſary before the conqueſts of the Saracens, when the Arabic became the vernacular language of Chriſtian countries. Hiſtorical evidence on this ſubject extends no further than the tenth century, when Rabbi Saadias Gaon publiſhed an Arabic verſion of the Pentateuch; and if conjecture may be allowed (ſays Marſh, in his edition of Michaelis's Introduction, vol. iii. p. 599.), we may ſuppoſe that moſt of the Arabic verſions were made during the period that elapſed between the conqueſts of the Saracens in the 7th century, and the cruſades in the 11th, eſpecially about the middle of this period, when the Syriac and the Coptic, though they had ceaſed to be living languages, were ſtill underſtood by men of education; and Arabic literature, under the patronage of Almamon and his ſucceſſors, arrived at its higheſt pitch. The age in which the Arabic printed verſion, or verſions of the New Teſtament, were written, is wholly undecided, for we have no knowledge of the MSS. from which the Roman edition of the four Goſpels (mentioned below) was printed; and all that we know of the MSS. uſed by Gabriel Sionita in his edition of the Paris Polyglott, and by Erpenius in his edition of the Arabic New Teſtament, is, that the former uſed a MS. brought from Aleppo, and written in Egypt in the 14th century, and the latter a manu-

ſcript brought from Egypt, in which the goſpels were written in the 13th, and the Acts, Epiſtles, and Revelation in the 14th century. But we are left wholly in the dark with reſpect to the century in which the verſions themſelves were made. The Arabic verſions may be divided into four claſſes; viz. thoſe taken immediately from the Syriac, from the Coptic, from the Greek, and from the Latin. That various Arabic verſions have been made from the Latin in modern times by oriental monks reſiding at Rome, who, being inſtructed by the Romiſh clergy to regard the Vulgate as the ſtandard by which all other verſions ſhould be regulated, propoſed eſſentially to ſerve their brethren in the Eaſt, by tranſlating it into their native language, is evident from what is related by profeſſor Adler in his Biblical and Critical Journey to Rome, p. 178; and an Arabic verſion of this kind was actually publiſhed at Rome, in 1752, by Raphael Tuki, biſhop of Arſan. As for thoſe verſions which are written in parallel columns with the Syriac and Coptic, of which copies exiſt in the royal library at Paris, it is reaſonable to ſuppoſe that they were not made from the Greek, but immediately from the ancient verſions with which they are connected, as the means of underſtanding them, after the languages in which they were written had ceaſed to be ſpoken. For the ſame reaſon, thoſe annexed to the Greek text were probably taken immediately from the Greek; but of theſe Greek Arabic MSS. only one has been diſcovered, namely, that in the univerſity library at Leyden. Walton (Prolegomena, p. 96.) ſays, that there are two kinds of Arabic verſions in uſe among the eaſtern Chriſtians; one called the Syriac, and the other the Egyptian, from the countries in which they are uſed. Both theſe verſions, according to Aug. Juſtinian, biſhop of Nebo, were tranſlated from the Greek. In the year 1516, Aug. Juſtinian printed at Genoa an Arabic verſion of the Pſalter, with the Hebrew text and Chaldee paraphraſe, adding Latin interpretations, which, he ſays, were taken from the Syrian or Antiochian verſion. There are alſo Arabic verſions of the whole Scriptures in the Polyglotts of London and Paris, ſaid by Juſtinian to be taken from the Egyptian or Alexandrian verſions; and we have an edition of the Old Teſtament entire, printed at Rome in 1671, by order of the congregation *de propaganda fide;* but it is of little eſteem, as having been altered agreeably to the Vulgate edition. The Arabic Bibles among us are not the ſame with thoſe uſed by the Chriſtians in the Eaſt. Some learned men take the Arabic verſion of the Old Teſtament, printed in the Polyglotts, to be, at leaſt in the main, that of Saadias, who died in the year 942, and who tranſlated the whole Old Teſtament from the Hebrew into the Arabic, expreſſing the Arabic in Hebrew characters. Their reaſon is, that Aben Ezra, a great antagoniſt of Saadias, quotes ſome paſſages of his verſion, which are the ſame with thoſe in the Arabic verſion of the Polyglotts; yet others are of opinion that Saadias's verſion is not extant. For though the whole Hebrew Bible was thus tranſlated by him, the Pentateuch only has been, as yet, publiſhed from his verſion. The other books, now in Arabic, in the Paris and London Polyglotts, were tranſlated at different times by different authors; partly from the Greek, and partly from the Syriac verſions; and few parts, if any, excepting the Pentateuch, were tranſlated from the Hebrew text. The Arabic verſion is the lateſt of all the ancient verſions of the Old Teſtament; however, that part of it which has been tranſlated from the Hebrew, will aſſiſt in detecting ſome corruptions that have crept into the Hebrew text ſince, and thoſe parts that are made from the ancient verſions will aſſiſt in eſtabliſhing the true readings of thoſe verſions. In 1622, Erpenius printed an Arabic Pentateuch, called alſo the Pentateuch of Mauritania, as being made by the Jews of Barbary, and for their uſe. This verſion is very literal, and eſteemed very exact. The four evangeliſts have alſo been publiſhed in Arabic, without and with a Latin verſion, at Rome, in 1591, folio. The Latin tranſlation is printed under each line of the Arabic text, and is taken from the Vulgate, though the Latin text is in ſome meaſure altered, ſo as to make it correſpond to the Arabic. In a repreſentation of the baptiſm of Chriſt, annexed to it, the rite appears to be performed, not according to the oriental cuſtom of immerſion, but according to the northern practice of aſperſion; for our Saviour is placed, not in Jordan, but at the brink of the river, with his feet only immerſed, while John the Baptiſt, kneeling on a rock, pours water on his head. The MS. from which this editio princeps of the Arabic goſpels is taken, is wholly unknown. Michaelis obſerves, that upon comparing it with the catechiſm of the Druſes, the paſſages there quoted from the goſpels coincide with this edition; whence he infers that this verſion muſt have been long and generally known in Aſia. But from this coincidence no other inference can be juſtly drawn, except that the Arabic verſion of the goſpels, printed at Rome in 1591, was made before the 11th century; for to that age the origin of the Druſes is referred. Erpenius obſerves, in the preface to his Arabic New Teſtament, that this edition bears a great reſemblance to the MS. from which he printed the four goſpels, except the firſt thirteen chapters of St. Matthew. The verſion, ſays Michaelis, was certainly taken from the Greek: but father Simon (Hiſt. Crit. des Verſions du N. T. ch. 18.) ſays, that upon comparing the Arabic verſion of the four goſpels printed at Rome, and afterwards reprinted in the Polyglotts, with an Arabic tranſlation of the Coptic verſion, he found them diſſimilar; but that on comparing it with an Arabic tranſlation of the Syriac verſion, he perceived a great reſemblance. Hence he concluded, that it was taken, not from the Greek, but from the Syriac text. This verſion has been ſince reprinted in the Polyglotts of London and Paris, with ſome little alteration of Gabriel Sionita. This Gabriel Sionita, a Maronite by birth, from the neighbourhood of Libanus, and one of the principal editors of the Paris Polyglott, relates, that he made uſe of a manuſcript written in Egypt in the 14th century; but he ſeems to have been unacquainted both with the name of the author, and with the age in which he lived. Le Long relates, that it was brought immediately from Aleppo to Paris. From this MS. the Arabic verſion of the Acts and of the Epiſtles was taken, which was firſt in the Paris, and reprinted with additions in the London Polyglott. But this verſion of the Acts and Epiſtles can lay no claim to high antiquity; and though it was probably not taken from the Syriac, yet it is not certain whether it was taken from the Greek or the Coptic. Erpenius publiſhed an Arabic New Teſtament entire, as he found it in his manuſcript copy, at Leyden, in 1616, from a manuſcript written in the Upper Egypt, in 1342. From two dates, which Erpenius ſeems to have confounded, it is probable, that the manuſcript uſed by him was a compound of two different manuſcripts, one written in the 13th, and the other in the 14th century; and this is very conſiſtent with the opinion, that the goſpels in this manuſcript were tranſlated either from the Coptic or from the Greek, and the Acts and Epiſtles from the Syriac.

There are ſome other Arabic verſions of late date mentioned by Walton in his Prolegomena; particularly a verſion of the Pſalms preſerved in Sion College, London, and another of the prophets at Oxford; neither of which has been publiſhed.

The Engliſh ſociety for promoting Chriſtian knowledge publiſhed, in 1727, an Arabic New Teſtament, for the uſe of the Chriſtians in Aſia. Ten thouſand copies were printed, but none ſold in Europe, ſo that this edition is very ſcarce.

Two

Two copies are preſerved at Cambridge, one in the univerſity library, and another in the library of St. John's college. The text is taken from the Polyglotts; but the editor Soloman Negri, by order of the ſociety, altered it in thoſe paſſages which vary from the reading of our preſent Greek text. The editor, ſays Michaelis, has taken the liberty of inſerting 1 John v. 7. without cautioning the reader that it was not taken from any MS.

An Arabic Bible is ſaid to have been printed at Bukareſt, in 1700, and the goſpels at Aleppo, in 1706. Of theſe, as well as of the complete editions of the Arabic verſion, a deſcription is given in Le Long's Bibl. Sacr. ed Maſch. P. ii. vol. i. p. 110—137. For an account of the MSS. of the Arabic verſion of the N. T. preſerved in the different libraries of Europe, ſee Boerner's edition of Le Long's Bibl. Sacr. P. i. p. 234—240. or vol. 1. p. 120—122. Paris ed. 1723; Uri's Catalogue, N° 22—34 of the Arabic MSS.; and Note 11 to § 3. ch. vii. in Marſh's edition of Michaelis's Introduction to the N. T. In the univerſity library are two Arabic manuſcripts of the goſpels, which formerly belonged to Cyrillus Lucaris.

Bibles, *Coptic*. There are ſeveral manuſcript copies of the Coptic Bible in ſome of the great libraries, eſpecially in the library of Paris. The Coptic verſion of the New Teſtament muſt be regarded as a principal verſion of conſiderable antiquity, becauſe it has given birth to ſeveral others in the Arabic language; for ſince Egypt was invaded by the Saracens, who extirpated the old language, the Egyptians have generally annexed to the Coptic N. T. an Arabic tranſlation, which has almoſt ſuperſeded the original. Niebuhr, in his Deſcription of Arabia (p. 86.), relates, that though the goſpels are ſtill read in the Coptic verſion in the public ſervice, it is not underſtood even by the prieſts; and that immediately after the leſſons have been read in Coptic, the ſame are read in Arabic, which is the preſent language both of the Upper and the Lower Egypt. Thomas Marſhall had once intended to print the Coptic verſion, and had even prepared the four goſpels for the preſs, but he died before they were printed. Upon which the publication was reſerved for Dr. D. Wilkins, a native of Memel in Pruſſia, who, after having ſtudied the Coptic, made a journey to Amſterdam with this view; but induced by ſeveral advantageous circumſtances, he removed to Oxford, where his Coptic New Teſtament was printed in 1716, at the expence of the univerſity. Beſides a long preface, he added a Latin tranſlation of the Coptic text, which Jablonſki and La Croze have criticiſed with ſome ſeverity. It is ſaid, however, that Wilkins took great pains to preſent the world with a faithful copy, and that his endeavours were not unſucceſsful. He alſo printed the Pentateuch, with a Latin tranſlation, in 1731. Since his time a great variety of MSS. have been collated; and if Woide had undertaken the taſk, a more complete edition of the Coptic verſion might have been expected. The title of Wilkins's edition is "Novum Teſtamentum Ægyptium vulgo Copticum, ex MSS. Bodleianis deſcripſit, cum Vaticanibus et Pariſienſibus contulit, et in Latinum ſermonem convertit, David Wilkins, Eccleſiæ Anglicanæ Preſbyter," Oxon 1716, 4to. Maj. Montfaucon, in his Palæographia Græca (l. iv. c. 7. p. 31.), ſays, that the Coptic MSS. which remain, are not very ancient, and that he has not ſeen any older than 500 years. Wilkins, in his preface, ſupports the antiquity of the Coptic verſion by ſeveral arguments, the chief of which is drawn from Antonius, who began to lead an aſcetic life about the year 271, and who, though an Egyptian, and ignorant of Greek, read the New Teſtament. To the ſame purpoſe Woide (p. 97. of his Eſſay, mentioned below) maintains, that the Egyptian verſion uſed by Antonius in the third century, was written in Coptic, becauſe he actually read an Egyptian verſion of the Bible, and as he underſtood only the dialect of his own country, he concludes that the Coptic verſion exiſted before the middle of the third century. Ludovicus Pickius, or Louis Picques, who was acquainted with the Coptic language, refers this verſion to the fifth century. See Mill's Prolegomena, § 1509.

The readings of the Coptic have a ſtriking affinity with thoſe of the Latin verſion, and ſometimes with thoſe of the Codex Cantabrigienſis. The ſtory of the adultereſs is found in ſome copies, and omitted in others; but 1 John v. 7. is omitted in all. Wetſtein has alſo obſerved, that the Coptic New Teſtament has a very great ſimilarity to the quotations of Origen, Euſebius, Cyril, and to the Alexandrine manuſcripts. The beſt accounts of the Coptic verſion are given in Simon's Hiſtoire Critique des Verſions du Nouveau Teſtament, ed. 16.; in the Preface to Wilkins's edition of the Coptic New Teſtament; in Le Long's Bibl. Sacr. ed. Maſch. P. ii. vol. i. § 10.; and particularly by the learned Woide, in a German eſſay printed in 1778, in vol. iii. of the Kleiſche Beyträge, p. 1—100. See Coptic.

Bibles, *Sahidic*. The Sahidic verſion of the Old and New Teſtament, or that of Upper Egypt, exiſted only till of late in MS.; but in 1778, the learned Woide publiſhed propoſals for an edition of ſeveral fragments of this verſion, comprehending about a third part of the New Teſtament, under the following title, "Fragmenta Novi Teſtamenti juxta interpretationem dialecti ſuperioris Ægypti, quæ Thebaidica ſeu Sahidica appellatur, MSS. Oxonienſibus deſcripta quæ Latiné reddet, et ſimul etiam de antiquitate et variis lectionibus hujus interpretationis differet, C. G. Woide." The learned editor lived to continue the work ſo far as to print the fragments of St. Luke's goſpel, and to prepare for the preſs the manuſcript of the fragments of St. John's goſpel, but he died in May 1780. After his deceaſe, the delegates of the Clarendon preſs entruſted the completion of the work to Dr. Ford; and under his care it made its appearance, entitled, "Fragmenta Novi Teſtamenti, e verſione Egyptiacâ Dialecti Thebaidicæ, Sahidicæ, ſeu ſuperioris Egypti," Oxon. large folio. In an elaborate diſſertation prefixed to this work, Dr. Woide treats of the Coptic verſion of the Old Teſtament; of the Sahidic verſion of the Old Teſtament; and of the original texts from which thoſe verſions were made. In his opinion both the verſions were made from the Greek; they expreſs the phraſes of the verſion of the LXX.; and moſt of the additions, omiſſions, and tranſpoſitions, which diſtinguiſh the LXX. from the Hebrew, are diſcoverable in both the Coptic and the Sahidic verſion. In a ſecond ſection the author treats of the Coptic verſion of the New Teſtament, and Wilkins's edition of it; of the Sahidic verſion of the New Teſtament; and of the antiquity of the verſions of the Old and New Teſtament in both dialects. And in a third ſection, Dr. Woide gives an account of the verſions, in both dialects, of the apocryphal books of the Old and New Teſtament. From his obſervations and account, we may conclude, that the Coptic and Sahidic are diſtinct and independent verſions; that the Coptic inclines more to the Alexandrian or Weſtern edition, than the Sahidic; that no remarkable coincidence is to be found between the Coptic or Sahidic verſion and the Vulgate; and that we have no reaſon to ſuſpect the former to have been altered or made to conform to the latter; and that the age of the Sahidic verſion is not yet aſcertained. Dr. Woide ſuppoſes, that it was made in the ſecond century; and in proof of this opinion, he alleges three arguments. The firſt argument, deduced from the uſe made of an Egyptian verſion by St. Anthony, who is ſaid by St. Athanaſius to have been ignorant of the Greek language, and yet to have conſtantly read the Scripture, has been mentioned under the preceding article.

article. His ſecond argument is deduced from a Sahidic MS. which is probably of the ſecond century, and which contains various paſſages both of the Old and New Teſtaments, coinciding with ſome of the fragments of the Sahidic verſions. His third argument is founded on an apparent coincidence of ſome paſſages in the fragments, with a manuſcript containing two books of the fabrication of the Gnoſtics, and evidently written in the ſecond century. It appears then, if no objections can be made to theſe arguments, that proofs may be alleged of a higher antiquity in favour of the Sahidic verſion than can be produced in favour of any other verſion of the New Teſtament; and it muſt of courſe be of the greateſt importance in the criticiſm of the Greek Teſtament. At the ſame time it muſt be acknowledged, that the oldeſt hiſtorical evidence for the high antiquity of an Egyptian verſion is that of Epiphanius and Theodoret; the former quoted by Semler in his "Apparatus ad Novi Teſtamenti interpretationem," p. 64.; the latter by Wilkins, in the "Prolegomena" to his Coptic New Teſtament, p. 6. From an examination of the various readings furniſhed by the above-mentioned fragments, it appears, that the ſtory of the adultereſs, John, viii. 1—12. is not among them; in the Acts of the Apoſtles, ch. xx. 28. the Sahidic verſion coincides with thoſe Greek MSS. which have κυριου, not θεου; in 1 Tim. iii. 16. they coincide with thoſe which read O inſtead of θεος: and 1 John ch. v. has the ſixth and eighth verſes; but the ſeventh, which contains the teſtimony of the three heavenly witneſſes, is abſent. We have an account of the Sahidic verſion of the New Teſtament in "Friderici Münteri Commentatio de indole verſionis N. T. Sahidicæ, &c." Hafniæ, 1789, 4to. to which are annexed ſome fragments of the New Teſtament from manuſcripts in the poſſeſſion of cardinal Borgia. Some fragments of the Sahidic verſion of the goſpels of St. Matthew and St. John have been likewiſe publiſhed by Mingarelli in his "Ægyptiorum codicum reliquiæ, Venetiis in bibliotheca Naniana aſſervatæ," Bonon. 1785, 4to. MSS. or rather fragments of MSS. of the Sahidic verſion of the New Teſtament are preſerved in the libraries of Rome, Paris, Oxford, Berlin, and Venice.

Bibles, *Ethiopic*. The Ethiopians have alſo tranſlated the Bible into their language. Chryſoſtom, cited by Michaelis, ſays, that the Ethiopians had in his time a verſion of the Bible; but his evidence is unſatisfactory. Ludolf, in his hiſtory of Ethiopia, relates, that the Scripture was tranſlated into that idiom of the Ethiopic language, which was at that time more peculiar to the inhabitants of Tigré, from the Greek verſion of the LXX, according to a certain copy uſed in the church of Alexandria, which the innumerable various readings that are inſerted in the Engliſh Polyglott Bible from one of the ſame copies, plainly prove. As for the author, and time of the tranſlation, he is unable to aſcertain either; but thinks it moſt probable that it was begun at the time when the Habeſſines, or Abyſſinians, were converted, or ſoon after, and that it was gradually perfected. Mr. Bruce, in his "Travels," vol. i. p. 490, ſays, that the Abyſſinian copy of the Holy Scriptures was, in Mr. Ludolf's opinion, tranſlated by Frumentius, a biſhop in the 4th century, who firſt preached Chriſtianity in Ethiopia; but Ludolf has left the matter undecided. See Hiſt. of Ethiopia, p. 262. ed. 1682. Mr. Bruce himſelf inclines to this opinion. They divide the Old Teſtament, ſays Ludolf, containing 46 books, into four principal parts, and mix the apocryphal with the canonical. Walton, (Proleg. xv. p. 100.) ſays, that Gaulmin had an ancient MS. of the whole Ethiopic Old Teſtament, which was depoſited in the royal library of Sweden. Mr. Bruce informs us, (vol. i. p. 489.) that he brought with him a copy of the Ethiopic verſion of the O. T. which he has depoſited in the Britiſh Muſeum; but it does not appear that he brought a copy of any part of the New. Indeed he ſays, (vol. i. p. 493.) that copies of the whole N. T. are in that country very ſcarce; that, except in the churches, he had never ſeen a ſingle MS. which comprehended all the parts of it; and that even the tranſcripts of the Goſpels were in the hands only of men of the firſt diſtinction. The Ethiopic verſion of the N. T. contains the whole of it, divided, according to Ludolf, into four ſeparate parts, viz. the Goſpels, the Acts, the fourteen Epiſtles of St. Paul, and the ſeven Catholic Epiſtles. The Apocalypſe is added as an appendix, and entitled "Abukalamſis." Scaliger refers the Ethiopic verſion to the time of Juſtinian, at which period he dates the converſion of the Abyſſinians: but Walton refers it to a much earlier period, and not far diſtant from the times of the Apoſtles. Whoever was the tranſlator of it, it appears to have been taken immediately from the Greek: from the frequent confuſion of words which ſound alike in the Greek, but which have not been confounded by any other tranſlator, and from its agreement in many of its readings with the Alexandrine MS. and with the quotations of Origen. Neither of theſe circumſtances can appear extraordinary, as it was natural for the inhabitants of Abyſſinia to procure their copies of the Greek Teſtament from Egypt. The tranſlation of the Goſpels is much ſuperior to that of the Epiſtles. This verſion was firſt publiſhed at Rome, in 1548 and 1549, under the pontificate of Paul III. but the editors, who were natives of Ethiopia, had a very imperfect MS. of the Acts, the chaſms of which they were obliged to ſupply from the Vulgate. To this purpoſe, Ludolf obſerves, that the Acts of the Apoſtles, for the moſt part, were tranſlated at Rome, out of the Latin and Greek, for want of the Ethiopic original. This original ſeems to have been the ſource from which our editions of the Ethiopic verſion of the N. T. have flowed; and it is probably preſerved in the Vatican, though it has not yet been deſcribed. Walton reprinted this Roman edition in the London Polyglott; but his copy, being in ſome places illegible, the editors filled up the deficiencies according to their own judgment, ſo that the Roman edition retains the ſame value, as if no other were extant. The Latin tranſlation was made by Dudley Loftus, and corrected by Caſtell; but it is of little worth, and has led Mill, and other collectors of various readings, into error. A more accurate Latin tranſlation of the Ethiopic verſion has been publiſhed by profeſſor Bode, under the following title, "Novum Teſtamentum ex verſione Ethiopici interpretis in Bibliis polyglottis Anglicanis editum ex Ethiopicâ lingua in Latinum tranſlatum," Brunſvigiæ. 1752, 1755. 2 toms. 4to. The beſt extracts from the Ethiopic verſion, ſays Michaelis, are and muſt be uncertain, becauſe we have no accurate impreſſion of the verſion itſelf; however, his editor (Dr. Marſh) obſerves, that if the Ethiopic verſion was made immediately from the Greek, and in an early age; if its readings coincide with the quotations of Origen, and the Greek MSS. of the Alexandrine edition, it ſeems to be entitled to the ſame privileges, as other verſions of equal antiquity. The principal objection applies not ſo much to the verſion itſelf, as to our printed text, which is probably incorrect, as not being the reſult of a collation of different MSS. But the ſame objection may be made to the old Syriac verſion, in which, though various MSS. have been uſed ſince the original edition of Widmanſtad, the alterations that have been made deſerve rather the name of corruptions than of improvements. Of all the books of the O. T. there never was any printed, but the Pſalms and the Song of Solomon, in the Ethiopic language at Rome, in 1513; at Cologn, in 1518, and ſince that time, with

with corrections and emendations, by Walton, in the London Polyglott.

Bibles, *Armenian.* There is a very ancient Armenian verſion of the whole Bible, done from the Greek of the LXX, by ſome of their doctors, about the time of St. Chryſoſtom. See Armenian *verſion.* The firſt printed edition of the Armenian verſion was publiſhed in the 17th century by Uſcan, biſhop of Erivan; becauſe the Bible was at that time become ſo ſcarce in Armenia, that a ſingle copy coſt 1200 livres. Hence a council of Armenian biſhops aſſembled in 1662, ordered the Bible to be printed in Europe. Accordingly, three diſtinct editions were printed at Amſterdam; the firſt in 1666, containing both the O. and N. T. in 4to. a ſecond, in 1668, including only the N. T. in 8vo. and a third, in 1698, in 12mo. The two firſt were printed under the direction of Uſcan; but the laſt is the moſt beautiful edition. A complete deſcription, particularly of the firſt of theſe editions, is given in Le Long. Bib. ſacra, ed. Maſch. P. II. vol. i. p. 173—176, 180. A liſt of Armenian MSS. of the N. T. is given in Dr. Boerner's edition of this work, P. i. p. 280, or vol. i. p. 138, of the Paris edition of 1723; ſee alſo vol. i. p. 76, of the Catalogus MSS. Bib. Regiæ, and note 11 to § 3. chap. vii. of Marſh's Michaelis. La Croze and G. Whiſton have accuſed the editor of the above-mentioned edition of having corrupted, in ſome places, the Armenian text. It is certain, however, ſays Michaelis, that 1 John v. 7. was not in his MS.; for Sandius declares, that he had ſeen the MS. from which the Amſterdam edition was printed, and that it wanted that verſe. Sandius, in the place referred to by Michaelis, ſpeaks of one ancient MS. which he had ſeen, in poſſeſſion of the biſhop of the Armenian church, and which had been collated at Amſterdam, in which this paſſage did not occur. It is poſſible, however, and even probable, that Uſcan had more than one MS. and the words of Sandius do not imply the contrary. Nevertheleſs, we have poſitive evidence, that Armenian MSS. written before the time of the council at Cis, in 1307, have not this verſe. In like manner, John v. 4. is wanting in the Armenian MS. but inſerted in Uſcan's edition; and La Croze obſerves, that Uſcan himſelf acknowledges, in his preface, that he had altered ſome paſſages from the Vulgate; not, as he candidly allows, with an intention to deceive, but from ignorance and ſuperſtition.

Bible, *Georgian.* The Georgian verſion was firſt printed at Moſcow, in 1743, fol. and a deſcription of it is given by the learned Eichorn, in his "Allgemeine Bibliothek," or Univerſal Hiſtory of Biblical Literature, vol. i. p. 153—169. From the deſcription it appears, that the Georgian text was altered from the Slavonian, in the edition of Moſcow, and it would therefore be of little value in the criticiſm of the N. T. Two MSS. of the Georgian verſion of the Goſpels are preſerved in the Vatican. See Le Long. Bib. Sacr. tom. i. p. 140. ed. Paris, 1723.

Bibles, *Perſian.* Some of the Fathers ſeem to ſay, that all the Scripture was formerly tranſlated into the language of the Perſians; but we have nothing now remaining of the ancient verſion, which was, certainly, done from the Septuagint. The Perſian Pentateuch, printed in the London Polyglott is, without doubt, the work of Rabbi Jacob, a Perſian Jew, ſurnamed Tavoſus, Tavuſius, or Tuſius, from the city Tus, where the Jews had a famous academy. It was tranſlated from the Hebrew text, for the uſe of the Jews, who lived in Perſia, and printed in the Hebrew character, with the Hebrew text, and with the verſion of Onkelos and Saadias, at Conſtantinople, in 1551. From the collation of this, with other verſions, we may deduce a ſatisfactory explanation of the famous prophecy of Jacob concerning the advent of the Meſſiah, unperverted by the gloſſes of the Rabbins We have likewiſe two Perſic verſions of the four Goſpels, of which the moſt ancient, and that which is of courſe the moſt valued by the learned, is printed in the London Polyglott, accompanied with a Latin tranſlation by Dr. Sam. Clarke, and notes by Dr. Thomas Greaves, contained in the appendix. This Perſic verſion of the four Goſpels, which is the only part of the N. T. hitherto printed, was taken from a MS. in the poſſeſſion of Dr. Pococke, and written in the year 1341, as appears by a declaration annexed to it. A new Latin tranſlation has been publiſhed by profeſſor Bode, at Helmſtadt, in 1750, 1751, with a preface containing hiſtorical and critical remarks on the Perſic verſion. Dr. Greaves has very juſtly obſerved, that the Perſic is a tranſlation of the Syriac, for it ſometimes retains even Syriac words, and ſubjoins a Perſic interpretation; and in other places confounds the meaning of words, that have a ſimilar ſound only in the Syriac. This is likewiſe probable in itſelf; for the Chriſtians, who lived ſcattered in the Perſian empire, made uſe of Syriac as the language of the church, and as the language of literature; and it was common for the Perſians to ſtudy in the ſchools of Syria, eſpecially at Edeſſa. The principal uſe then of the Perſic verſion is in diſcovering the falſe readings that have crept, ſince that period, into the Syriac. It might be added, that the Perſic omits paſſages, that are wanting in no MS. or verſion except the Syriac; as Matth. xxvii. 46. Mark. vii. 34. There is another Perſic verſion of the Goſpels, which Abraham Wheeloc began to print in 1652, and which was finiſhed after his death by Pierſon, in 1657. It was publiſhed in London, and three MSS. were uſed by the editors. Walton, in his "Prolegomena," xvi. 9. p. 102, informs us, that he knew of only three MSS. of the Perſic Goſpels, one in the poſſeſſion of Dr. Pococke, which he uſed, and the other two in the libraries of Oxford and Cambridge, different from the other, and leſs ancient. If this be the caſe, Wheeloc muſt have uſed MSS. containing diſtinct verſions, and his text muſt be of a mixed nature, and of leſs value in that reſpect, as well as in point of antiquity, than that of the Polyglott. Wheeloc, or rather Pierſon, whoſe name is prefixed to the ſecond title page, was of opinion, that this Perſic verſion was made from the Greek; but Renaudot believed it to have been taken from the Syriac. Walton mentions two Perſian verſions of the Pſalms, that were made in the 17th century from the vulgar Latin.

Bibles, *Gothic.* It is generally ſaid, that Ulphilas, a Gothic biſhop, who lived in the fourth century, made a verſion of the whole Bible, for the uſe of his countrymen. Philoſtorgius (Hiſt. Eccles. l. ii. c. 5.) aſſerts, that Ulphilas omitted the book of Kings, from an apprehenſion, that the martial ſpirit of his nation might be roufed by the relation of the Jewiſh wars; yet this opinion has been confuted by Knittel, in his learned commentary, § 255. Michaelis, who was once a ſtrenuous advocate for the opinion, that this was a Frankiſh verſion, has ſince changed his mind, and in the laſt edition of his Int. to N. T. vol. ii. p. 130. ed. Marſh, expreſſes his conviction that it was Gothic. For an account of the author, ſee Ulphilas; and to the account already given of this verſion under the article Argenteus *Codex*, we ſhall here ſubjoin the following particulars. From the martyrology of Nicetas, preſerved by Simeon Metaphraſtes, it appears, that this verſion was made immediately from the Greek. Beſides, independently of this evidence, it is natural to conclude, that a native Cappadocian, who was biſhop of a nation in the neighbourhood of Conſtantinople, and was ſent ambaſſador to the Greek emperor, would tranſlate from the original Greek, with which he was much bet-

ter

ter acquainted than with the Latin verſion, from which ſome writers have erroneouſly ſuppoſed his verſion was taken. Moreover, from a paſſage quoted by Blanchini in the "Prolegomena," to the firſt volume of his, "Evangeliarium quadruplex," p. 8. from a MS. preſerved at Breſcia, containing the old Latin verſion of the Goſpels, we may infer, that the Gothic verſion was known in Italy, and that a diſtinction was made between it and the Italian. Of this important verſion we have few remains. The principal of theſe are contained in the *Codex* ARGENTEUS; which has the four Goſpels, though not without conſiderable chaſms. It was firſt printed in Gothic letters, at Dort, in 1665, 4to.; and reprinted at Amſterdam, in 1684, (Michaelis); and another edition was printed in Latin letters, at Stockholm, accompanied with the Iſlandiſh, Swediſh, and Latin vulgate. In 1750, it was printed at Oxford, by Lye, after the corrections and emendations of archbiſhop Benzel; and in 1752 and 1755, the learned Ihre publiſhed two ſmall eſſays, under the title of "Ulphilas illuſtratus," in which the erroneous paſſages of the former editions are correctly printed in Latin letters, accompanied with a Latin tranſlation, and notes.

BIBLES, *Muſcovite*, *Ruſſian*, or *Slavonian*. The Ruſſian or Slavonian verſion was taken from the Greek by two brothers, Methodius and Cyril, natives of Theſſalonica, and apoſtles of the Slavonians, who lived in the 9th century. According to the account given by Poletika, a learned perſon of Ruſſia, and formerly Greek tranſlator to the holy ſynod, in anſwer to inquiries propoſed by Michaelis, it appears, that the holy ſynod ordered a complete copy of the Bible to be taken, in 1499, which is preſerved in the library of that Synod; but from the ſame teſtimony it appears, that MSS. of the New Teſtament are extant from the 11th to the 14th century, ſome on vellum, others on paper, which are alſo preſerved at Moſcow, in the library of the holy ſynod. The oldeſt known edition is that of Prague, publiſhed by Francis Scorina, in 1519; but Poletika is not certain whether it contains the Bible complete. It was reviſed in 1570, altered in ſeveral paſſages from an ancient MS. written in the time of the grand duke Wladimir, given to Gamabunda, ſecretary to the duchy of Lithuania, and uſed in the edition of the Bible, printed at Oſtrog, in 1581, at the expence of Con. Baſil, duke of Oſtrog, for the common ſervice of all Chriſtians who ſpoke the Slavonic language. Other editions were printed at Moſcow, in 1663, 1751, 1756, 1757, and 1766, in folio, in 1759 in large 8vo. and in 1783, in 4to. It was alſo printed at Kiow, in 1758, folio; and at Supraſl in Poland, in ſmall folio. A copy of the edition of 1581, and another of that of 1663, both which are ſcarce, are preſerved in the univerſity library of Gottingen. A particular edition of the Acts of the Apoſtles, and the Epiſtles, was printed in 1653. The paſſage 1 John v. 7. is found neither in the Oſtrog edition, the ancient MSS. nor in thoſe editions of the Acts and Epiſtles, which are prior to 1653. That of 1653 contains it; that of 1663 has it in the margin, and that of 1751, and other modern editions, in the text. Poletika thinks this interpolation was made in the time of the patriarch Nicon, in 1653, when an edition was publiſhed of the Acts and Epiſtles. A very excellent deſcription of the Slavonian verſion has been communicated to the public by Dobrowſky, a very learned critic, in the "Neue Orientaliſche Bibliothek," vol. vii. p. 153—167. From this work the following particulars, relating to this verſion, are extracted, by Marſh, in his edition of Michaelis' notes to ch. vii. § 37. The Slavonian verſion is very literally tranſlated from the Greek, the Greek conſtruction being frequently retained where it is contrary to the genius of the Slavonian; and reſembles, in general, the moſt ancient MSS. In the Goſpels it agrees with the Codex Stephani *n* more frequently than with any other Greek MS. In the catholic epiſtles it agrees, in general, with the Codex Alexandrinus, and frequently in the Revelation. In the Acts and in the Epiſtles of St. Paul, it agrees, in general, with the moſt ancient MSS. but ſometimes with one, ſometimes with another, yet moſt frequently with Wetſtein's Codex E. Of the readings adopted by Grieſbach in the text of his Greek Teſtament, the Slavonian verſion has at leaſt three-fourths. Where the united evidence of ancient MSS. is againſt the common printed reading, the Slavonian verſion agrees with the ancient MSS. It has not been altered from the Vulgate, as ſome have ſuppoſed, though the fact is in itſelf almoſt incredible. It varies from the text of Theophylact, in as many inſtances as they agree; and their coincidence is to be aſcribed, not to an alteration from Theophylact, but to the circumſtance, that both Theophylact and the authors of the Slavonian verſion uſed the Greek edition. The Slavonian verſion has few or no readings peculiar to itſelf, or what the critics call "lectiones ſingulares."

BIBLES, *Spaniſh*. There are two tranſlations of the Bible into this language; one done by the Jews, from the Hebrew, and firſt printed at Ferrara, in 1553, and at Amſterdam, in 1661; the other by Caſſiodore Reyna, printed at Baſil, in 1569. A corrected edition of it was printed at Amſterdam, in 1602, and at Frankfort, in 1622. This tranſlation was made from the Hebrew, or rather from the verſion of Pagninus, and the New Teſtament from the Greek. There is a tranſlation of the N. T. in Spaniſh, done by Francis Enzinas, and dedicated to Charles V. of which there are ſeveral editions; and another different Spaniſh tranſlation of the N. T. printed in 1596.

BIBLES, *Italian*. There are four Italian verſions: the firſt towards the cloſe of the 13th century, by James de Voragine, archbiſhop of Genoa, who tranſlated the whole Bible into Italian, from the Vulgate; which ancient verſion is quite loſt; the ſecond by Brucciolus, in 1530, who tranſlated the Bible from the Hebrew, or rather from the verſion of Pagninus, and dedicated it to Francis I. king of France; the third by Malhermi, a Venetian and Benedictine monk, abbot of St. Michael de Lemo, tranſlated from the vulgar Latin towards the end of the 15th century; the firſt edition of which was publiſhed in 1471; one of them, in 1477, reviſed by friar Martin, a Dominican; and afterwards printed at Venice in 1541; and the 4th by Diodati, a Proteſtant, which is much eſteemed, and has been often printed. This edition, which was conformable to the French edition of Geneva, was firſt publiſhed in 1607, and again a ſecond time in 1641. The New Teſtament was tranſlated by father Zachary, a Dominican friar of Florence, and printed apart at Venice, in 1542. An Italian edition of the Epiſtles and Goſpels was printed in 1583.

BIBLES, *French*. The moſt ancient tranſlation of the Bible into French is that of Guiars de Moulins, a canon of St. Peter d'Aire, in the dioceſe of Touraine, who was employed in tranſlating the hiſtorical books of the O. and N. T. from the year 1291 till 1294. Of this tranſlation there are ſeveral editions in the Paris library. Some hiſtorians affirm, that Charles V. king of France, cauſed the Bible to be tranſlated into French by Nicholas Oreſme, ſuperior of the houſe of Navarre, and doctor of Paris. Theſe, and ſome other tranſlations of parts of the Bible, are extant in MS. in the Paris library. The firſt French Bible was printed by order of Charles VIII. and dedicated to him, and conſequently before the year 1498; being the tranſlation of Guiars de Moulins. The New Teſtament was printed in French by Colins, printer of Paris, in 1523. But the

the firſt edition of the whole Bible, tranſlated from the vulgar text into French, was printed, in 1530, at Antwerp, by Martin Lempereur, with privilege from Charles V. The firſt edition of this Bible, in 1530, is in the Paris library; and the ſecond, in 1534, which is larger, is extant in the libraries of St. Germain des Prez, and of St. Genevieve. Theſe two editions precede that of Robert Olivetan, the firſt publiſhed by the Proteſtants, in 1535. The tranſlation above-mentioned was printed the third time at Antwerp, in 1540, and is preſerved in the Jeſuits' library of the college of Lewis le Grand. This tranſlation was reviſed by the divines of Louvain, and was the foundation of all the French Bibles, ſince publiſhed either by the Catholics or Proteſtants. The firſt is that of Robert Olivetan, a kinſman of Calvin, who has copied the Antwerp tranſlation, and merely corrected ſuch paſſages as differed from the Hebrew text. A new edition was given by Calvin, which comes nearer to the vulgar Latin: and of this Bible many editions were publiſhed between the years 1550 and 1561. In 1560 was publiſhed a new edition of the Bible, reviſed by Theodore Beza. In the following year another French tranſlation of the Bible, from the Italian verſion of Diodati, was publiſhed, and held for ſome time in eſtimation by the Calviniſts. In 1588, the Geneva tranſlation was again corrected, and rendered more conformable to the Hebrew and Greek text. This was reviſed by Meſſrs. Deſmarets, miniſters of Groningen, and printed with notes at Amſterdam, in 1669. In the year 1555, Sebaſtian Caſtalio publiſhed another French tranſlation of the Bible from the Latin, the ſtyle of which is affected and obſcure.

A reformation of the French Geneva Bible, by Renatus Benedict, profeſſor of divinity in the college of Navarre, was publiſhed in 1566. This was condemned by a brief of Gregory XIII, in 1575. A new edition was undertaken ſome time after, altogether conformable to the Latin, and free from the errors of the Calviniſts, by the doctors of Louvain, who followed the old Antwerp tranſlation, and that of Olivetan, which they corrected: which was printed by privilege from the king of Spain, and under the ſanction of the licenſe of the preſs at Antwerp, in 1578; at Lyons, in 1585; and in ſeveral other places. The ſubſequent Bibles were for ſome time copies of the Louvain edition, with ſome corrections; ſuch were that of Peter Beſſe, printed at Paris, in 1608, and that of Peter Friſon, printed at Paris, in 1620. Corbin's Bible, printed in 1641, and approved by the doctors of Poictiers, recedes more than the reſt from the Bible of Louvain, and adheres more cloſely to the literal ſenſe of the text of the vulgar Latin. A new edition of the verſion of the doctors of Louvain, reviſed and corrected agreeably to the text of the ancient Vulgate, was publiſhed by father Veron, in 1647, and dedicated to the clergy of France. The tranſlation of Abbot de Marolles, is done from the Greek text, or rather from the verſion of Eraſmus, and was firſt publiſhed in 1649, again in 1653, and a third time in 1655. The edition of the N. T. called the edition of Mons, was publiſhed in 1667, under the name of Jaſper Migeot, printer at Mons. Father Amelot's tranſlation of the N. T. was firſt printed at Paris, in 1666. Godeau's tranſlation was printed at Paris, in 1668. The whole Bible was alſo tranſlated by Iſaac de Maitre, of Sacy, from the Vulgate, and partly publiſhed in his life, and afterwards continued by Peter Thomas, lord of Foſſe. Du Queſnel's tranſlation of the N. T. differs little from that of Mons, otherwiſe than by being more conformable to the vulgar Latin. Father Bonhours has alſo publiſhed a tranſlation of the N. T. and many others have in later times tranſlated either the whole or various parts of the Bible.

Bibles, *German*. Luther's tranſlation of the Bible into German, was done with the aſſiſtance of Melancthon, and others of his diſciples, the Old Teſtament from the Hebrew, and the New from the Greek, in 1524, and the publication of it, in ſeveral ſucceeding editions, very much contributed to the progreſs of the reformation. This was ſoon followed by a German tranſlation by Jerom Emſer, a catholic, who in his notes criticiſes that of Luther; and by another tranſlation, done by John of Dietenbergh, from the vulgar Latin, in oppoſition to that of Luther. Luther's edition, reformed by the Zuinglians and Calviniſts, in various editions, was publiſhed at Newſtad in 1588, and at Herborn in 1595, to the diſſatisfaction of the Lutherans. The German tranſlation of Paul Eber, a Lutheran, was printed at Wittenberg in 1564; and German tranſlations were alſo printed by Leon Juda, and John Piſcator, both Calviniſts. A new tranſlation in German, by Jaſper Ulenberg, a Catholic, not to mention many others, was printed at Cologn in 1630, and was much uſed in Germany.

Bibles, *Flemiſh*. The Catholics in the Netherlands had ſeveral Flemiſh tranſlations of the Bible in the 16th century. One was printed in 1548, which was tranſlated by Nicholas Van Winghe, who ſays that he followed a Flemiſh tranſlation printed in Holland 70 years before, i. e. long before the reformation. This Bible was reviſed by the doctors of Louvain, and printed afterwards at Antwerp in 1599, and often ſince. The Proteſtants in the Low Countries had for a long time only a tranſlation made after the German Bible of Luther, till in purſuance of an order iſſued by the ſynod of Dort, in 1618, they had a new tranſlation printed in 1637, exactly conformable to the Hebrew text of the Old, and the Greek of the New Teſtament. The Arminians, diſſatisfied with this, made another Dutch tranſlation from the Greek, which was printed at Amſterdam in 1680.

The northern nations, who embraced the doctrines of Luther, have no other tranſlations of the Bible beſides thoſe done in the vulgar tongue after the German of Luther. The Swediſh tranſlation was made by Laurence Petri, archbiſhop of Upſal, a diſciple of Luther, and printed at Stockholm in 1646. The Danes have alſo one in their language, publiſhed firſt in 1524, and ſince reviſed and reprinted in 1633. There is alſo a tranſlation of the Bible in the Iceland tongue, which ſome pretend to be the ancient language of the Norwegians or Goths: and another Finland tranſlation in 1648. The Laplanders have alſo the Pſalms, and ſome other books of the Bible, tranſlated into their own language. In the Poliſh language, the Socinians have a Bible printed in 1563, and they have likewiſe a Poliſh Bible in Lithuania, printed in 1652, done from the Greek and Hebrew by Simon Budni. Sands alſo mentions a tranſlation of the New Teſtament by Martin Czechovius, a Socinian, printed with notes in 1577. Pope Gregory XIII. employed the Jeſuit Vieki to make a new tranſlation of the Bible in the Poliſh language, which was printed at Cracow in 1599, with the approbation of Clement VIII. The Bohemians have a Bible in their language, with notes, printed in Germany from 1579 till 1601. The Hungarians have a tranſlation done by George Caldi, a Jeſuit, and printed at Vienna in 1626. They have alſo another more ancient, printed at Frankfort in 1608, and at Oppenheim in 1612.

Bibles, *Indian*. A tranſlation of the Bible into the North American Indian language, by Elliott, was publiſhed in 4to. at Cambridge, in 1685.

Bibles, *Saxon*. After the Saxon inhabitants of this country were converted to Chriſtianity, we have reaſon to believe that they ſoon had the whole Bible in the characters of their own country, and that the four Goſpels in the

ſame language were read in their religious aſſemblies. The whole ſcripture is ſaid by ſome to have been tranſlated into the Anglo-Saxon by Bede, about the year 701; though others contend that he only tranſlated the Goſpels; and others aſcribe to him only the goſpel of St. John.

We have certain books, or parts of the Bible, by ſeveral other tranſlators; as, 1. The Pſalms, by Adelm, biſhop of Shireborn, contemporary with Bede, about the year 706; though by others this verſion is attributed to king Alfred, who lived near two hundred years after, and who is ſaid by Mr. Fox (ubi infra) to have tranſlated both the Old and New Teſtament into his native language; and by others to have tranſlated the greateſt part of the New Teſtament: but the authority on which theſe aſſertions is founded is too precarious to claim any great degree of confidence. On equally uncertain authority it has been ſaid, that the whole Bible was tranſlated into the Saxon language in the reign of Athelſtan. Bale, however, "Script. Brit." cent. 2. c. 27, cites the teſtimony of Malmeſbury to this purpoſe; and archbiſhop Uſher refers this to the year 930. Some books of the Bible were tranſlated by Eadfried, or Egbert, biſhop of Lindisfarne, about the year 680, according to the conjecture of Mr. Selden. A celebrated verſion of the four Goſpels in the Saxon language, ſaid to be made by one Aldred, a prieſt, is reported to have been found in the celebrated code of biſhop Eadfried. Adelm is ſaid to have written a letter to Eadfried, extant in "Wharton's Auctarium Hiſt. Dogm. Uſſerii," p. 351; in which he exhorts him, for the common benefit and uſe of all people, to put the ſcriptures into the vulgar language, which Butler, in his book againſt the vulgar tranſlation, ſays he did. And archbiſhop Uſher, in his "Hiſt. Dogm." c. 5. informs us, that the Saxon tranſlation of the Evangeliſts, done by Eadfried, without diſtribution of chapters, was in the poſſeſſion of Mr. Rob. Bowyer. In the Cotton library is a book of the four Goſpels, ſaid by Wharton, in his "Anglia Sacra," part i. p. 695, to be written by biſhop Eadfried himſelf, and which had been adorned with pictures, gold, and jewels, by Ethelwoldf, biſhop of Wincheſter. Eadfried, or Egbert, died in 721. But ſome have doubted the exiſtence of ſuch an Anglo-Saxon MS. A verſion of the Pſalms in Anglo-Saxon was publiſhed by Spelman in 1640. 2. The Evangeliſts, ſtill extant, done from the ancient Vulgate, before it was reviſed by St. Jerom, by an author unknown, and publiſhed by Matth. Parker in 1571. This was printed from a MS. now in the Bodleian library, under the direction of archbiſhop Parker, by John Fox the martyrologiſt, with the following title, "The Goſpels of the fowre Evangeliſts, tranſlated in the olde Saxons' tyme out of the Latin into the vulgare toung of the Saxons, and now publiſhed for teſtimonie of the ſame;" at London, by John Daye, 1571. This edition has a preface by John Fox, and is dedicated to queen Elizabeth. Another edition of this verſion was publiſhed at Dort in 1665, by Dr. Thomas Marſhall, who tells us that he could aſcertain neither its author nor age. An old Saxon verſion of ſeveral books of the Bible, was made by Elfric, abbot of Malmeſbury, and afterwards, viz. in 995, archbiſhop of Canterbury; ſeveral fragments of it were publiſhed by Will. Lilly, or W. L'Iſle, in 1638, the genuine copy by Edm. Thwaites, in 1699, at Oxford.

Wm. L'Iſle obſerves, on occaſion of this publication, that if that good ordinance firſt enacted by God, Deut. x. 5. for the preſervation of the book of the law, by keeping a copy of it in the ark, had been continued, and ſtandard Bibles had been preſerved in our cathedral churches, as it has been ſince appointed by king Alfred, we might now have ſhewed the whole book of God, or the entire Old and New Teſtament in Saxon, which was the Engliſh of thoſe times, tranſlated both by that king, and the archbiſhop of Canterbury, Elfric. Elfric tranſlated the Pentateuch, Joſhua, Judges, Ruth, four books of Samuel, entitled in Latin, liber regum, a fifth book called Verba Dierum, or Chronicles, the Pſalter, three books of Solomon, viz. Proverbs, Eccleſiaſtes, the chief of all ſongs, the books of Wiſdom and Eccleſiaſticus, the prophets Iſaiah, Jeremiah, Ezekiel, Daniel, the twelve Prophets, Ezra, Job, Tobias, Eſther, Judith, and Maccabees. Hence we may conclude, with little doubt, that the books of the New Teſtament were before tranſlated into Saxon, and commonly read in that language. The Pentateuch, Joſhua, and Judges, of Elfric's tranſlation, are preſerved, ſays Uſher, in Cotton's library; where is alſo a Pſalter, with ſeveral hymns of the Old and New Teſtament, with the Apoſtles' and Athanaſian creed, with an Engliſh interlineary tranſlation. The book appears, by a note at the end of it, to have been written in the year 1049. The Anglo-Saxon verſion, above-mentioned, is divided into ſections, over each of which is placed a rubric, directing when it ſhould be read; and this circumſtance ſhews, that at this time the Holy Scriptures were read in the public ſervice of the church in a language which the people underſtood. Various readings from this verſion of the four Goſpels were firſt quoted by Mill (Proleg. § 1462.), who took them from the papers of Marſhall. With reſpect to its antiquity, the learned are not agreed: ſome have referred it to the ſixth or ſeventh century, ſince Bede died A.D. 735, but others, more generally, to ſome part of the eighth century. For an account of the MSS. of the Anglo-Saxon verſion, ſee Le Long. Bibl. Sacr. tom. i. p. 422, 423. ed. 1723; and for a complete catalogue of Anglo-Saxon MSS. in general, Wanley's Appendix to Hickes's Theſaurus, publiſhed at Oxford in 1705, folio. Lewis's Hiſt. Eng. Tranſl. of the Bible, p. 5, &c.

Bibles, *Engliſh*. The firſt Engliſh Bible we read of was that tranſlated by J. Wickliffe, about the year 1370, according to ſome, and 1380, according to others; but never printed, though there are MS. copies of it in ſeveral public and private libraries. The MS. of the Old Teſtament, ending with the ſecond book of the Maccabees, in St. John's college Oxford, is ſaid to have been written by Wickliffe himſelf. This circumſtance, though expreſſed on the top of the leaf before Geneſis, is very doubtful. This tranſlation was made from the Latin Bibles then in common uſe, not becauſe Wickliffe thought the Latin to be the original, or of the ſame authority with the Hebrew and Greek text, but becauſe he did not underſtand thoſe languages well enough to tranſlate from them. He likewiſe choſe to tranſlate word for word, as had been before done in the Anglo-Saxon tranſlation, without obſerving the idioms of the ſeveral languages, ſo that this tranſlation is in ſome places not very intelligible to thoſe who do not underſtand Latin. Before the invention of printing, tranſcripts were obtained with difficulty, and copies were ſo rare, that the price of one of Wickliffe's Engliſh New Teſtaments appears, from the regiſtry of William Alnewick, biſhop of Norwich, in 1429, to have been four marks and forty pence, or 2l. 16s. 8d. This tranſlation gave ſuch offence, that a bill was brought into the Houſe of Lords, 13 Ric. II. A.D. 1390, for ſuppreſſing it. But by the oppoſition of the duke of Lancaſter, the king's uncle, the bill was thrown out of the houſe. Wickliffe's followers were encouraged, by this favourable circumſtance, to reviſe the tranſlation of their maſter, or rather to make another not ſo ſtrict and verbal, but more free and accommodated to the ſenſe. The MS. copies of this tranſlation are more rare than thoſe of the other; but they are found in the Bodleian library, and in other libraries both of Oxford and Cambridge. J. de Treviſa, vicar of Berkley in Glouceſterſhire, who died about

about the year 1398, is alſo ſaid to have tranſlated the whole Bible; but if this be true, it does not appear that any copies of his tranſlation are now remaining. It is probable, that Treviſa merely tranſlated certain ſentences of the Bible, that occur in his writings, and ſome of which are ſaid to have been painted upon the walls of the chapel in Berkley caſtle. Another Engliſh tranſlation has been erroneouſly aſcribed to Reginald Peacock, biſhop of Chicheſter, A.D. 1450, in conſequence of his having tranſlated ſome paſſages of ſcripture, cited in his works. Rolle, an hermit of Hampole in Yorkſhire, who tranſlated the Pſalms about the year 1340, is ſuppoſed by Weever, in his "Funeral monuments," p. 151, to have been the tranſlator of the New Teſtament, which tranſlation was in reality Wickliffe's. Richard Fitz-Raiph, archbiſhop of Armagh, is ſaid to have tranſlated the Bible into Iriſh. He died in 1360. Dr. James, relying on a vague declaration of ſir Thomas More, in his account of the conſtitutions of Arundel, aſſerts, that the Bible hath been twice tranſlated into Engliſh; and that one of theſe tranſlations is much more ancient (ſome hundred years) than Wickliffe's. But Lewis has ſhewn this to be a miſtake. (Hiſt. Eng. Tranſ. p. 43.) The zealots of thoſe times were alarmed by theſe Engliſh tranſlations; and in order to prevent their increaſe, they urged the neceſſity of reſtoring the uſe of Latin Bibles; and to this purpoſe Chaucer repreſents the religious as collecting and depoſiting them in their libraries, and thus withdrawing them from ſecular prieſts and curates, and thus hindering them from preaching the goſpel to the people. In 1357, when ſome ſecular prieſts were ſent from the dioceſe of Armagh in Ireland, to ſtudy divinity at Oxford, they were obliged ſoon to return, becauſe they were not able to purchaſe a Bible. Æneas Sylvius, afterwards pope Pius II. obſerved in 1458, concerning the Italian prieſts, that they did not ſeem to have ever ſo much as read the New Teſtament; and Robert Stephens, ſpeaking of the Sorboniſts, ſays, that when they are aſked in what place of the New Teſtament any thing was written, they replied, that they had read it in Jerom, or in the Decrees, but what the New Teſtament was they did not know. (See Hody de Bibl. Textibus, p. 464.) Indeed, at that time, if copies of the Bible had been more frequent, the clergy were generally ſo ignorant as not to be able to read or underſtand Latin. The Latin Bibles were not only ſcarce, but much corrupted by the careleſſneſs of tranſcribers, and the interference of preſumptuous critics. In 1457, Wickliffe's followers were become ſo numerous, and copies of his Engliſh tranſlation of the New Teſtament ſo common, that an Engliſh Bible was ſold for 20s., whereas the price of a portuiſe, or breviary, was 6 marks. After the art of printing was introduced into England, Latin, Hebrew, and Greek Bibles, and particularly copies of the New Teſtament, became much more common; and accordingly a vicar of Croydon in Surry, is ſaid to have expreſſed himſelf to this purpoſe, in a ſermon preached at Paul's croſs about this time: "We muſt root out printing, or printing will root out us."

Bible, *Tindal's*. For the firſt printed Engliſh tranſlation of the ſcriptures we are indebted to William Tindal, who, having formed a deſign of tranſlating the New Teſtament from the original Greek into Engliſh, removed to Antwerp in Flanders, for this purpoſe. Here, with the aſſiſtance of the learned John Fry, or Fryth, burnt for hereſy in Smithfield, in 1552, and a friar, called William Roye, who ſuffered death on the ſame account in Portugal, he finiſhed it, and in the year 1526, it was printed either at Antwerp or Hamburgh, without a name, in a middle ſized 8vo. volume, and without either calendar, concordances in the margin, or table at the end. Tindal annexed a piſtil at the cloſe of it, in which he "deſyred them that were learned to amende if ought were found amyſſe." Le Long calls this "the New Teſtament tranſlated into Engliſh, from the German verſion of Luther;" but for this degrading appellation he ſeems to have no other authority beſides a ſtory related by one Cochlæus (in Actis Martini Lutheri ad an. 1526, p. 132.), with a view of depreciating Tindal's tranſlation. Many copies of this tranſlation found their way into England; and to prevent their diſperſion among the people, and the more effectually to enforce the prohibition publiſhed in all the dioceſes againſt reading them, Tonſtall, biſhop of London, purchaſed all the remaining copies of this edition, and all which he could collect from private hands, and committed them to the flames at St. Paul's croſs. The firſt impreſſion of Tindal's tranſlation being thus diſpoſed of, ſeveral other numerous editions were publiſhed in Holland, before the year 1530, in which Tindal ſeems to have had no intereſt, but which found a ready ſale, and thoſe which were imported into England, were ordered to be burned. On one of theſe occaſions, ſir Thomas More, who was then chancellor, and who concurred with the biſhop in the execution of this meaſure, enquired of a perſon, who ſtood accuſed of hereſy, and to whom he promiſed indemnity on conſideration of an explicit and ſatisfactory anſwer, how Tindal ſubſiſted abroad, and who were the perſons in London that abetted and ſupported him; to which inquiry the heretical convert replied, "It was the biſhop of London who maintained him, by ſending a ſum of money to buy up the impreſſion of his Teſtament." The chancellor ſmiled, admitted the truth of the declaration, and ſuffered the accuſed perſon to eſcape. The people formed a very unfavourable opinion of thoſe who ordered the word of God to be burned, and concluded, that there muſt be an obvious repugnance between the New Teſtament, and the doctrines of thoſe who treated it with this indignity. Thoſe who were ſuſpected of importing and concealing any of theſe books, were adjudged by ſir T. More to ride with their faces to the tails of their horſes, with papers on their heads, and the New Teſtaments, and other books which they had diſperſed, hung about their cloaks, and at the ſtandard in Cheapſide to throw them into a fire prepared for that purpoſe, and to be fined at the king's pleaſure.

When Tonſtal's purchaſe ſerved only to benefit Tindal, and thoſe who were employed in printing and ſelling ſucceſſive editions of his Teſtament, and other meaſures for reſtraining their diſperſion ſeemed to have little or no effect, the pen of the witty, eloquent, and learned ſir Thomas More, was employed againſt the tranſlator; and the biſhop granted him a licence, or faculty, dated March 7, 1527, to have and to read the ſeveral books which Tindal and others publiſhed; and at his deſire ſir Thomas compoſed a dialogue, written with much humour, and deſigned to expoſe Tindal's tranſlation, which was publiſhed in 1529. In this dialogue he alleges, among other charges, that Tindal had miſtranſlated three words of great importance, viz. the words prieſts, church, and charity; calling the firſt ſeniors, the ſecond congregation, and the third love. He alſo charges him with changing commonly the term grace into favour, confeſſion into knowledging, penance into repentance, and a contrite heart into a troubled heart. The biſhop of London had, indeed, in a ſermon, declared, that he had found in it no leſs than 2000 errors, or miſtranſlations; and ſir Thomas More diſcovered above 1000 texts by tale, falſely tranſlated. In 1530, a royal proclamation was iſſued, by the advice of the prelates and clerks, and of the univerſities, for totally ſuppreſſing the tranſlation of the ſcripture, *corrupted* by William Tindal. The proclamation ſet forth, that it was not neceſſary to have the ſcriptures in the Engliſh tongue, and in the hands of the common

people; that the diſtribution of them, as to allowing or denying it, depended on the diſcretion of their ſuperiors; and that, conſidering the malignity of the time, an Engliſh tranſlation of the Bible would rather occaſion the continuance, or increaſe of errors, than any benefit to their ſouls. However, the proclamation announced the king's intention, if the preſent tranſlation were abandoned, at a proper ſeaſon, to provide that the Holy Scriptures ſhould be by great, learned, and catholic perſons, tranſlated into the Engliſh tongue, if it ſhould then ſeem convenient. In the mean time, Tindal was buſily employed in tranſlating from the Hebrew into the Engliſh the five books of Moſes, in which he was aſſiſted by Miles Coverdale. But his papers being loſt by ſhipwreck in his voyage to Hamburgh, where he deſigned to print it, a delay occurred, and it was not put to preſs till the year 1530. It is a ſmall 8vo. printed at different preſſes, and with different types. In the preface he complained, that there was not ſo much as one *i* in his New Teſtament, if it lacked a tittle over its head, but it had been noted, and numbered to the ignorant people for an hereſy, who were made to believe, that there were many thouſand hereſies in it, and that it was ſo faulty as to be incapable of amendment or correction. In this year he publiſhed an anſwer to ſir Thomas More's dialogue, containing his reaſon for the changes which he had introduced into his tranſlation. The three former editions of Tindal's Engliſh New Teſtament being all ſold off, the Dutch bookſellers printed a fourth in this year, in a ſmaller volume and letter. In 1531, Tindal publiſhed an Engliſh verſion of the prophet Jonah, with a prologue, full of invective againſt the church of Rome. Strype ſuppoſes that before his death he finiſhed all the Bible but the Apocrypha, which was tranſlated by Rogers; but it ſeems more probable that he tranſlated only the hiſtorical parts. In 1534, was publiſhed a fourth Dutch edition, or the fifth in all, of Tindal's New Teſtament, in 12mo. In this ſame year, Tindal printed his own edition of the New Teſtament in Engliſh, which he had diligently reviſed and corrected,; to which is prefixed a prologue; and at the end are the piſtils of the Old Teſtament, cloſing with the following advertiſement, "Imprinted at Antwerp, by Marten Emperour, anno M.D. XXXIV." Another edition was publiſhed this year, in 16to. and printed in a German letter. Hall ſays, in his Chronicle, printed during the reign of Henry VIII. by Richard Grafton, the benefactor and friend of Tindal; "William Tindal tranſlated the New Teſtament, and firſt put it into print; and he likewiſe tranſlated the five books of Moſes, Joſhua, Judicum, Ruth, the books of Kings, and books of Paralipomenon, Nehemiah, and the firſt of Eſdras, and the prophet Jonas; and no more of the Holy Scriptures." Upon his return to Antwerp, in 1531, king Henry VIII. and his council, contrived means to have him ſeized and impriſoned. After long confinement he was condemned to death by the emperor's decree in an aſſembly at Augſburgh; and in 1536, he was ſtrangled at Villefort, near Bruſſels, the place of his impriſonment, after which his body was reduced to aſhes. He expired, praying repeatedly and earneſtly, "Lord, open the king of England's eyes." Several editions of his Teſtament were printed in the year of his death. Tindal had little or no ſkill in the Hebrew, and therefore he probably tranſlated the Old Teſtament from the Latin. The knowledge of languages was in its infancy; nor was our Engliſh tongue arrived at that degree of improvement, which it has ſince attained; it is not, therefore, ſurpriſing, that there ſhould be many faults in this tranſlation which need amendment. This, indeed, was a taſk, not for a ſingle perſon, but requiring the concurrence of many, in circumſtances much more favourable for the execution of it than thoſe of an exile. Nevertheleſs, although this tranſlation is far from being perfect, few firſt tranſlations, ſays Dr. Geddes (Proſpectus, p. 88.), will be found preferable to it. It is aſtoniſhing, ſays this writer, how little obſolete the language of it is, even at this day; and in point of perſpicuity, and noble ſimplicity, propriety of idiom, and purity of ſtyle, no Engliſh verſion has yet ſurpaſſed it.

Bible, *Coverdale's*. In 1535 the whole Bible, tranſlated into Engliſh, was printed in folio, and dedicated to the king by Miles Coverdale, a man greatly eſteemed for piety, knowledge of the ſcriptures, and diligent preaching; on account of which qualities king Edward VI. advanced him to the ſee of Exeter. In his dedication and preface, he obſerves to this purpoſe, that, as to the preſent tranſlation, it was neither his labour nor his deſire to have this work put into his hand; but "when others were moved by the Holy Ghoſt to undertake the coſt of it," he was the more bold to engage in the execution of it. Agreeably, therefore, to deſire, he ſet forth this "ſpecial" tranſlation, not in contempt of other men's tranſlations, or by way of reproving them, but humbly and faithfully following his interpreters, and that under correction. Of theſe, he ſaid, he uſed five different ones, who had tranſlated the ſcriptures not only into Latin, but alſo into Dutch. He further declared, that he had neither wreſted nor altered ſo much as one word for the maintenance of any manner of ſect, but had with a clear conſcience purely and faithfully tranſlated out of the foregoing interpreters, having only before his eyes the manifeſt truth of the ſcripture. But becauſe ſuch different tranſlations, he ſaw, were apt to offend weak minds, he added, that there came more underſtanding and knowledge of the ſcripture by theſe ſundry tranſlations, than by all the gloſſes of ſophiſticall doctors; and he therefore deſires, that offence might not be taken, becauſe one tranſlated "ſcribe," and another "lawyer," one "repentance," and another "penance," or "amendment." This is the firſt Engliſh Bible allowed by royal authority; and alſo the firſt tranſlation of the whole Bible printed in our language. It was called a "ſpecial" tranſlation, becauſe it was different from the former Engliſh tranſlations; as Lewis has ſhewn (Hiſt. Eng. Tranſl. p. 98.) by comparing it with Tindal's. It is divided into ſix tomes, adorned with wooden cuts, and furniſhed with ſcripture references in the margin. The laſt page has theſe words: "Prynted in the yeare of our Lorde M.D.XXXV. and fyniſhed the fourth day of October." Of this Bible there was another edition in a large 4to. 1550, which was re-publiſhed, with a new title, 1553; and theſe, according to Lewis, were all the editions of it. Coverdale, in this edition of the Engliſh Bible, prefixed to every book the contents of the ſeveral chapters, and not to the particular chapters, which was afterwards the caſe; and he likewiſe omitted all Tindal's prologues and notes. Soon after this Bible was finiſhed, in 1536, lord Cromwell, keeper of the privy-ſeal, and the king's vicar-general and vicegerent in eccleſiaſtical matters, publiſhed injunctions to the clergy by the king's authority, the ſeventh of which was, that every parſon, or proprietary of any pariſh church within this realm, ſhould, before the 1ſt of Auguſt, provide a book of the whole Bible, both in Latin and in Engliſh, and lay it in the choir, for every man that would, to look and read therein; and ſhould diſcourage no man from reading any part of the Bible either in Latin or Engliſh, but rather comfort, exhort, and admoniſh every man, to read it, as the very word of God, and the ſpiritual food of a man's ſoul, &c.

Bible, *Matthewe's*, or *Matthews's*. In 1537, another edition of the Engliſh Bible was printed by Grafton and Whit-

Whitchurch, at Hamburgh, as ſome think, or, as others ſuppoſe, at Malborow, or Marpurg in Heſſe, or Marbeck in the duchy of Wittemberg, where Rogers was ſuperintendant. It bore the name of Thomas Matthewe, and it was ſet forth with the king's moſt gracious licence. Mr. Wanley is of opinion, that, to the end of the book of Chronicles, this edition is Tindal's tranſlation: and from thence to the end of the apocrypha, Coverdale's: but Lewis (p. 107.) thinks it probable that the prophecy of Jonah ſhould be excepted, which Tindal finiſhed in his life-time, and which is the ſame in this edition, and in Coverdale's Bible of 1535. Mr. Wanley alſo obſerved, that the whole New Teſtament was Tindal's. Bale ſays, Rogers tranſlated the Bible into Engliſh, from Geneſis to the end of Revelation, making uſe of the Hebrew, Greek, Latin, German, and Engliſh (i. e. Tindal's) copies. This book contained Tindal's prologue and notes; and, as Heylin ſays (Hiſt. Ref. fol. 20.), it was no other than the tranſlation of Tindal and Coverdale ſomewhat altered. The name of Matthewe is allowed to have been fictitious, for reaſons of prudence; one of which was, that the memory of Tindal had become odious to many. It may well be admitted, that John Rogers, a learned academic, and the firſt who was condemned to the flames in the reign of queen Mary, was employed by Cranmer to ſuperintend this edition, and to furniſh the few emendations and additions that were thought neceſſary. This muſt have been the general perſuaſion in 1555, as the condemning ſentence preſerved by Fox (Acts, &c. vol. iii. 125.), is "againſt Rogers, prieſt, alias called Matthew." Cranmer preſented a copy of this book to lord Cromwell, deſiring his interceſſion with the king for the royal licenſe, that it might be purchaſed and uſed by all. There are exant two letters (Strype's life of Cranmer, p. 58.) from the archbiſhop, on the ſubject of lord Cromwell's interceſſion, expreſſing warm approbation and acknowledgement. "I doubt not," ſays he, "but that hereby ſuch fruit of good knowledge ſhall enſue, that it ſhall well appear hereafter what high and excellent ſervice you have done unto God and the king; which ſhall ſo much redound to your honour, that, beſides God's reward, you ſhall obtain perpetual memory for the fame within this realm."—"This deed you ſhall hear of at the great day, when all things ſhall be opened and made manifeſt." In the year 1538, an injunction was publiſhed by the vicar-general of the kingdom, ordaining the clergy to provide, before a certain feſtival, one book of the whole Bible, of the largeſt volume in Engliſh, and to ſet it up in ſome convenient place within their churches, where their pariſhioners might moſt commodiouſly reſort to read it. A royal declaration was alſo publiſhed, which the curates were to read in their ſeveral churches, informing the people, that it had pleaſed the king's majeſty to permit and command the Bible, being tranſlated into their mother-tongue, to be ſincerely taught by them, and to be openly laid forth in every pariſh church. But the curates were very cold in this affair (ſays Lewis, p. 108.), and read the king's injunctions and declarations in ſuch a manner, that ſcarcely any body could know or underſtand what they read. Johnſon (Hiſt. Account, &c. in biſhop Watſon's Collection, p. 94.) adds, that they alſo read the word of God confuſedly; and that they bade their pariſhioners, notwithſtanding what they read, which they were compelled to read, "to do as they did in times paſt, and to live as their fathers, the old faſhion being the beſt." Fox obſerves (Acts, &c. vol. ii. 516.), that the ſetting forth of this book much offended Gardiner and his fellow biſhops, both for the prologues, and eſpecially becauſe there was a table in the book chiefly about the Lord's ſupper, the marriage of prieſts, and the maſs, which there was ſaid not to be found in ſcripture. Strype, however, ſays, (Life of Cranmer, p. 64.), it was wonderful to ſee with what joy this book was received, not only among the more learned, and thoſe who were noted lovers of the reformation, but generally all over England, among all the common people; and with what greedineſs God's word was read, and what reſort there was to the places appointed for reading it. Every one that could, bought the book, and buſily read it, or heard it read: and many elderly perſons learned to read on purpoſe. During a vacancy in the ſee of Hereford, it was viſited by Cranmer, who enjoined the clergy to procure, by the 1ſt of Auguſt, a whole Bible in Latin and Engliſh, or, at leaſt, a New Teſtament in theſe languages; to ſtudy every day one chapter of theſe books, conferring the Latin and Engliſh together, from the beginning to the end; and not to diſcourage any layman from reading them, but encourage them to it, and to read them for the reformation of their lives and knowledge of their duty. In the courſe of the year 1538, a quarto edition of the New Teſtament, in the vulgate Latin, and Coverdale's Engliſh, bearing the name of Hollybuſhe, was printed, with the king's licence, by James Nicolſon. Of this another more correct edition was publiſhed in 1539, in 8vo., and dedicated to lord Cromwell. In 1538, an edition in 4to. of the New Teſtament, in Engliſh, with Eraſmus's Latin tranſlation, was printed, with the king's licence, by Redman. In this year it was reſolved to reviſe Matthewe's Bible, and to print a correct edition of it. With this view Grafton went to France, where the workmen were more ſkilful, and the paper was both better and cheaper than in England, and obtained permiſſion from Francis I. at the requeſt of king Henry VIII. to print his Bible at Paris. But, notwithſtanding the royal licence, the Inquiſition interpoſed, and iſſued an order, dated December 17, 1538, ſummoning the French printers, their Engliſh employers, and Coverdale the corrector of the work, and prohibiting them to proceed; and the impreſſion, conſiſting of 2500 copies, was ſeized, confiſcated, and condemned to the flames. Some cheſts, however, of theſe books, eſcaped the fire, by the avarice of the perſon who was appointed to ſuperintend the burning of them; and the Engliſh proprietors, who had fled on the firſt alarm, returned to Paris as ſoon as it ſubſided, and not only recovered ſome of theſe copies, but brought with them to London the preſſes, types, and printers, and, reſuming the work, finiſhed it in the following year.

Bible, *Cranmer's*, or the *Great*. As ſoon as the papal power was aboliſhed in England, and the king's ſupremacy ſettled by parliament in 1534, Cranmer was very aſſiduous in promoting tranſlations of the Holy Scriptures into the vulgar tongue; well knowing how much the progreſs of the reformation depended upon this meaſure. Accordingly, he moved in convocation, that a petition ſhould be preſented to the king for leave to procure a new tranſlation of the Bible. This motion was vigorouſly oppoſed by Gardiner, biſhop of Wincheſter, and his party: but Cranmer prevailed. The arguments for a new tranſlation, urged by Cranmer, and enforced by queen Anne Bullen, who had then great intereſt in the king's affections, were ſo much conſidered by him, that, notwithſtanding the oppoſition, public and private, on the part of Gardiner and his adherents, Henry gave orders for ſetting about it immediately. To prevent any revocation of the order, Cranmer, whoſe mind was intent on introducing a free uſe of the Engliſh Scriptures by faithful and able tranſlators, proceeded without delay to divide an old Engliſh tranſlation of the New Teſtament into

nine

nine or ten parts, which he cauſed to be tranſcribed into paper-books, and to be diſtributed among the moſt learned biſhops, and other; requiring that they would perfectly correct their reſpective portions, and return them to him at a limited time. When the aſſigned day came, every man ſent his appropriate portion to Lambeth, except Stokeſly, biſhop of London. This laudable deſign of the archbiſhop failed; but the buſineſs was executed by other perſons, whom he countenanced and encouraged, as we have already ſtated in the preceding articles. In April 1539, Grafton and Whitchurch printed the Bible (called the "Great Bible") in large folio, "cum privilegio ad imprimendum ſolum." A beautiful frontiſpiece, deſigned by Holben, and particularly deſcribed and exhibited in an engraving by Lewis, p. 122, &c. was prefixed to it: and in the text, thoſe parts of the Latin verſion, which are not found in the Hebrew or Greek, are inſerted in a ſmaller letter; ſuch, for inſtance, as the three verſes of the 14th pſalm, which are the 5th, 6th, and 7th, in the tranſlation of the Engliſh liturgy, and the controverted words, 1 John v. 7, 8.; and a mark is uſed to denote a difference of reading between the Hebrew and Chaldee, afterwards explained in a ſeparate treatiſe. In this edition Matthewe's Bible was reviſed, and ſeveral alterations and corrections were made in the tranſlation, eſpecially in the book of Pſalms. Tindal's prologues and notes, and the notes added by others, in the edition of 1537, were wholly omitted. Pointing hands, placed in the margin and in the text, ſhew the paſſages on which theſe notes were to have been written. Johnſon (ubi ſupra, p. 76.) calls this third edition of the Scriptures the Bible in the large or great volume, aſcribes it to the year 1539, and ſuppoſes it to have been the ſame which Graſton obtained leave to print at Paris. He ſays, that Miles Coverdale compared the tranſlation with the Hebrew, mended it in many places, and was the chief director of the work. Agreeably to this, Coverdale, in a ſermon at Paul's croſs, defended his tranſlation from ſome ſlanderous reports which were then raiſed againſt it, confeſſing "that he himſelf now ſaw ſome faults, which, if he might review the book once again, as he had twice before, he doubted not he ſhould amend; but for any hereſy, he was ſure that there was none maintained in his tranſlation." This is related by Dr. Fulk, who was one of Coverdale's auditors. A ſecond edition of this Bible ſeems to have been printed either this or the next year, by Edward Whitchurch; but the copy is imperfect, and has no date.

In the courſe of the year 1539, another Bible was printed by John Byddell, called "Taverner's Bible," from the name of its conductor, Richard Taverner, who was educated at Chriſtchurch, Oxford, patroniſed by lord Cromwell, and probably encouraged by him to undertake the work, on account of his ſkill in the Greek tongue. This is neither a bare reviſal of the Engliſh Bible juſt deſcribed, nor a new verſion; but a kind of intermediate work, being a correction of what is called "Matthews's Bible," many of whoſe marginal notes are adopted, and many omitted, and others inſerted by the editors. It is dedicated to the king. After his patron's death, Taverner was impriſoned in the Tower for this work; but he had the addreſs to reinſtate himſelf in the king's favour. Wood (Hiſt. et Ant. Univ. Oxon. fol. 1674, l. ii. p. 264.) gives a particular account of Taverner; attributes his impriſonment to the influence of thoſe biſhops who were addicted to the Romiſh religion; and informs us, that his verſion was read in churches by royal authority. In November 1539, the king, at the interceſſion of Cranmer, appointed lord Cromwell to take ſpecial care that no perſon, within the realm, ſhould attempt to print any Engliſh Bible for five years, but ſuch as ſhould be admitted by lord Cromwell; and aſſigns this reaſon for the prohibition, that the Bible ſhould be conſidered and peruſed in one tranſlation, in order to avoid the manifold inconveniences to which human frailty might be ſubject from a diverſity of tranſlations, and the ill uſe that might be made of it. In the year 1540, two privileged editions of the Bible, which had been printed in the preceding year, iſſued from the preſs of Edward Whitchurch. Lewis mentions three other impreſſions of the "Great Bible," which appeared in the courſe of this year; two printed by Whitchurch, and one by Petyt and Redman. Cranmer wrote a preface for the editions of the year 1540, from which we learn the opinions and practice of thoſe times. In May of this year, the curates and pariſhioners of every pariſh were required, by royal proclamation, to provide themſelves with the Bible of the largeſt volume before the feaſt of All-Saints, under the penalty of 40s. for every month during which they ſhould be without it. The king charged all ordinaries to enforce the obſervance of this proclamation; and he apprized the people, that his allowing them the Scriptures in their mother-tongue was not his duty, but an evidence of his goodneſs and liberality to them, of which he exhorted them not to make any ill uſe. In May 1541, one edition of Cranmer's Bible was finiſhed by Richard Grafton; who, in the November following, completed alſo another Bible of the largeſt volume, which was ſuperintended, at the king's command, by Tonſtal, biſhop of Durham, and Heath, biſhop of Rocheſter.

In conſequence of the king's ſettled judgment, "that his ſubjects ſhould be nurſed in Chriſt by reading the Scriptures," he again, on the 7th of May, publiſhed a brief, or decree, for ſetting up the Bible of the great volume in every pariſh church throughout England. However, this decree appears to have been very partially and reluctantly obſerved; and the biſhops were charged, by a writer in 1546, with attempting to ſuppreſs the Bible, under pretence of preparing a verſion of it for publication within ſeven years. After the death of Cromwell in 1540, the biſhops inclined to popery gained ſtrength; and the Engliſh tranſlation was repreſented to the king as very erroneous and heretical, and deſtructive of the harmony and peace of the kingdom. In the convocation, aſſembled in Feb. 1542, the archbiſhop, in the king's name, required the biſhops and clergy to reviſe the tranſlation of the New Teſtament, which, for that purpoſe, was divided into fourteen parts, and portioned out to fifteen biſhops; the Apocalypſe, on account of its difficulty, being aſſigned to two. Gardiner clogged this buſineſs with embarraſſing inſtructions; and Cranmer clearly perceiving the reſolution of the biſhops to defeat the propoſed tranſlation, procured the king's conſent to refer the matter to the two univerſities, againſt which the biſhops proteſted; but the archbiſhop declared his purpoſe to adhere to the will of the king his maſter. With this conteſt the buſineſs terminated; and the convocation was ſoon after diſſolved. The Romiſh party prevailed alſo in parliament, which enacted a law that condemned and aboliſhed Tindal's tranſlation, and allowed other tranſlations to remain in force, under certain reſtrictions. After the paſſing of this act, Grafton, the king's printer, was impriſoned; nor was he releaſed without giving a bond of 300l. neither to print nor ſell any more Engliſh Bibles, till the king and the clergy ſhould agree on a tranſlation. In 1544, the Pentateuch was printed by John Day and William Seres; and in 1546, the king prohibited by proclamation having and reading Wickliffe's, Tindal's, and Coverdale's tranſlations, and forbad the uſe of any other than what was allowed by parliament.

liament. From the hiſtory of Engliſh tranſlations, during the reign of Henry VIII. we learn, that the friends to the reformation conducted themſelves with zeal and prudence in the great work of introducing and improving Engliſh tranſlations of the Bible; that they encountered many difficulties from the dangerous inconſtancy of a deſpotic prince, and from the inveterate prejudices of a ſtrong Romiſh party; and that the Engliſh ſcriptures were ſought after and read with avidity by the bulk of the people.

Upon the acceſſion of Edward VI. the ſevere ſtat. 34 & 35 Henry VIII. c. 1. was repealed, and a royal injunction was publiſhed, that not only the whole Engliſh Bible ſhould be placed in churches, but alſo the paraphraſe of Eraſmus in Engliſh to the end of the four Evangeliſts. It was likewiſe ordered by this injunction, that every parſon, vicar, curate, &c. under the degree of a bachelor of divinity, ſhould poſſeſs the New Teſtament, both in Latin and Engliſh, with the paraphraſe of Eraſmus upon it; and that the biſhops, &c. in their viſitations and ſynods ſhould examine them, how they had profited in the ſtudy of the Holy Scriptures. It was alſo appointed, that the epiſtle and goſpel of the maſs ſhould be read in Engliſh; and that on every Sunday and holiday, one chapter of the New Teſtament in Engliſh ſhould be plainly and diſtinctly read at matins, and one chapter of the Old Teſtament at even-ſong. But in the year 1549, when the book of common prayer, &c. was finiſhed, what nearly reſembles our preſent cuſtom was enjoined, that after reading the Pſalms in order at morning and evening prayer, two leſſons, the firſt from the Old Teſtament, and the ſecond from the New Teſtament, ſhould be read diſtinctly with a loud voice. During the courſe of this reign, that is, in leſs than 7 years and 6 months, eleven impreſſions of the whole Engliſh Bible were publiſhed, and ſix of the Engliſh New Teſtament; beſides an Engliſh tranſlation of the whole New Teſtament, paraphraſed by Eraſmus. The Bibles were reprinted, according to the preceding editions, whether Tindal's, Coverdale's, Matthewe's, Cranmer's, or Taverner's; that is, with a different text, and different notes. But it is doubted by the writer of the preface to king James's tranſlation, whether there were any tranſlation, or correction of a tranſlation, in the courſe of this reign.

In 1562, the "Great Bible," viz. that of Coverdale's tranſlation, that had been printed in the time of Henry VIII. and alſo in the time of king Edward, was reviewed by archbiſhop Parker, and reprinted for the uſe of the church; and this was to ſerve till that projected by his grace was ready for publication. See *Biſhop's* BIBLE.

BIBLE, *Geneva*. Many of the principal reformers having been driven to Geneva during the perſecutions of queen Mary's reign, they publiſhed, in 1557, an Engliſh New Teſtament, printed by Conrad Badius; the firſt in our language which contained the diſtinctions of verſes by numerical figures, after the manner of the Greek Teſtament, which had been publiſhed by Robert Stephens in 1551. R. Stephens, indeed, publiſhed his figures in the margin; whereas the Geneva editors prefixed theirs to the beginning of minute ſubdiviſions with breaks, after our preſent manner. When queen Elizabeth paſſed through London from the Tower to her coronation, a pageant was erected in Cheapſide, repreſenting Time coming out of a cave, and leading a perſon clothed in white ſilk, who repreſented Truth, his daughter. Truth had the Engliſh Bible in her hand, on which was written "Verbum veritatis." Truth addreſſed the queen, and preſented her with the book. She kiſſed it, held it in her hands, laid it on her breaſt, greatly thanked the city for their preſent, and added, that ſhe would often and diligently read it. Upon a royal viſitation in 1559, the Bible, and Eraſmus's paraphraſe, were reſtored to churches; and articles of enquiry were exhibited whether the clergy diſcouraged any from reading any part of the ſcriptures. "Miniſters were alſo enjoined to read every day one chapter of the Bible at leaſt; and all who were admitted readers in the church were daily to read one chapter at leaſt of the Old Teſtament, and another of the New, with good adviſement, to the encreaſe of their knowledge."

During this year, the exiles at Geneva publiſhed the book of Pſalms in Engliſh, with marginal notes, and with a dedication to the queen, dated February 10. In 1560, the whole Bible in 4to. was printed at Geneva by Rowland Hare; ſome of the refugees from England continuing in that city for this purpoſe. The tranſlators were biſhop Coverdale, Anthony Gilby, William Whittingham, Chriſtopher Woodman, Thomas Sampſon, and Thomas Cole; to whom ſome add John Knox, John Bodleigh, and John Pullain; all zealous Calviniſts, both in doctrine and diſcipline: but the chief and the moſt learned of them were the three firſt. Profeſſing to obſerve the ſenſe, and to adhere as much as poſſible to the words of the original, and in many places to preſerve the Hebrew phraſeology, after the labour and ſtudy of two years and more, day and night, they finiſhed their tranſlation, and publiſhed it; with an epiſtle dedicatory to the queen, and another, by way of preface, to their brethren of England, Scotland, and Ireland. Beſides the tranſlation, the editors of the Geneva Bible noted in the margin the diverſities of ſpeech and reading, eſpecially according to the Hebrew; they inſerted in the text, with another kind of letter, every word that ſeemed to be neceſſary for explaining any particular ſentence; in the diviſion of the verſes, they followed the Hebrew examples, and added the number to each verſe; they alſo noted the principal matters, and the arguments, both for each book and each chapter; they ſet over the head of every page ſome remarkable word or ſentence, for helping the memory; they introduced brief annotations for aſcertaining the text, and explaining obſcure words; they ſet forth with figures certain places in the books of Moſes, of the Kings, and Ezekiel, which could not be made intelligible by any other deſcription; they added maps of divers places and countries, mentioned in the Old and New Teſtament; and they annexed two tables, one for the interpretation of Hebrew names, and the other containing all the chief matters of the whole Bible. Of this tranſlation, there were above 30 editions in folio, 4to., or 8vo., moſtly printed by the queen's and king's printer, from the year 1560 to 1616. Editions of it were likewiſe printed at Geneva, Edinburgh, and Amſterdam. To ſome editions of the Geneva Bible, e. g. to thoſe of 1599 and of 1611, is ſubjoined Beza's tranſlation of the New Teſtament, engliſhed by L. Tompſon. (See *Rhemiſh* BIBLE.) Dr. Geddes (Gen. Anſwer, &c. p. 4.) gives an honourable teſtimony to the Geneva tranſlation; and heſitates not in declaring that he thinks it in general better than that of king James's tranſlators.

BIBLE, *Biſhop's*. In the year 1568, the Bible, propoſed by archbiſhop Parker three years before, was completed. This edition, according to Le Long, was undertaken by royal command; and it is mentioned by Strype, to the honour of the archbiſhop, that he had reſolved to perform what Cranmer, as oppoſed by the biſhops of his days, had in vain endeavoured to accompliſh. In this performance, diſtinct portions of the Bible, at leaſt 15 in number, were allotted to ſelect men of learning and abilities, appointed, as Fuller ſays, by the queen's commiſſion; and, accordingly, at the concluſion of each part, the edition of 1568 has the initial letters of each man's name to the end of the firſt epiſtle to the Corinthians; e. g. at the end of the Pentateuch,

W. E. for William, bishop of Exeter, whose allotment ended there; at the end of Ruth, R. M. for Richard Menevensis, or bishop of St. David's, to whom pertained the second allotment; and so of the rest. But it still remains uncertain, who, and whether one or more, revised the rest of the N. T. Eight of the persons employed were bishops; whence the book was called the "Bishop's Bible," and the "Great English Bible." The archbishop employed other critics to compare this Bible with the original languages, and with the former translations; one of whom was Laurence, a man famous in those times for his knowledge of Greek, whose calligations the bishop's Bible followed exactly. His grace also sent instructions concerning the method which his translators were to observe; and recommended the addition of some short marginal notes, for the illustration or correction of the text. But the particulars of these instructions are not known. The archbishop, however, directed, reviewed, and finished the whole; which was printed and published in 1568, in a large folio size, and with a beautiful English letter, on royal paper; and embellished with several cuts of the most remarkable things in the O. and N. T. and Apocrypha, maps cut in wood, and other draughts engraven on copper. It has many marginal references and notes, and many useful tables. It has numerous insertions between brackets, and in a smaller character; which are equivalent to the italics afterwards used by James's translators. Dr. Geddes is of opinion, (Letter to the Bishop of London, p. 33.) that italic supplements were first used by Arias Montanus, who died in 1598. The several additions from the vulgar Latin, inserted in the "Great Bible," are omitted; and verse 7 of 1 John v, which was before distinguished by its being printed in a different letter, is here printed without any distinction; and the chapters are divided into verses. In the following year, 1569, it was again published in large 8vo. for the use of private families. This Bible was reprinted in 1572, in large folio, with several corrections and amendments, and several prolegomena; this is called "Matthew Packer's Bible." With regard to this Bible, Lewis (p. 61.) observes, that the editions of it are mostly in folio and 4to., and that he never heard but of one in 8vo.; for which he supposes this to be the reason, that it was principally designed for the use of churches. In the convocation of the province of Canterbury, which met in April, 1571, a canon was made, enjoining the church-wardens to see, that the Holy Bible be in every church in the largest volumes, if convenient; and it was likewise ordered, that every archbishop and bishop, every dean and chief residentiary, and every archdeacon, should have one of these Bibles in their cathedrals and families. This translation was used in the churches for forty years; though the Geneva Bible was more read in private houses. For king James's opinion of it, see *King James's* Bible.

Bible, *Rhemish.*—After the translation of the Bible by the bishops, two other private versions had been made of the New Testament; the first by Laur. Tomson, undersecretary to sir Francis Walsingham, made from Beza's Latin edition, together with the notes of Beza, published in 1576, in 8vo. and afterwards in 1599, varying very little from the Geneva Bible; the second, by the papists at Rheims, in 1582, in 4to. called the "Rhemish Bible," or "Rhemish Testament." These finding it impossible to keep the people from having the scriptures in the vulgar tongue, resolved to give a version of their own, as favourable to their cause as might be. It was printed on a large paper, with a fair letter and margin. One complaint against it was, its being translated from the vulgate Latin, and retaining a multitude of Hebrew and Greek words untranslated, for want, as the editors express it, of proper and adequate terms in the English to render them by; as the words *azymes, tunike, rational, holocaust, prepuce, pasche*, &c. whence Fuller called it, in his quaint manner, "a translation which needed to be translated," and Fuller says that "by all means they laboured to suppress the light of truth under one pretence or other." They added large annotations, to shew, as they say, the studious reader, in most places pertaining to the controversies of those times, both the heretical corruptions, and false deductions, and also the apostolic traditions, the expositions of the holy fathers, the decrees of the Catholic church, and most ancient councils. Some have said, that it was printed in a most costly manner, in order to put it out of the power of common people to purchase it; but if any of the laity secretly procured one of these Rhemish Testaments, he durst not own that he had read it, without previously obtaining from his superior a licence for this purpose. Many of the copies were seized by the queen's searchers, and confiscated; and Th. Cartwright was solicited by secretary Walsingham to refute it; but, after a good progress made therein, archbishop Whitgift prohibited his farther proceedings therein, as judging it improper the doctrine of the church of England should be committed to the defence of a puritan, and appointed Dr. Fulk in his place, who refuted the Rheimists with great spirit and learning. Cartwright's refutation was also afterwards published in 1618, under archbishop Abbot, together with the Rhemish translation. This procedure was much more agreeable to the true spirit of protestantism, than the act of seizing and burning the copies; "argument being the only weapon (says the truly excellent primate Newcome), which should be wielded to defend Christianity, or any mode of professing it." Other editions were printed at Antwerp, in 1600, and in 12mo. at the same place, in 1630, and at Paris, in 4to. in 1633. Within 30 years after their New Testament, the Roman Catholics published a translation of the Old, at Doway, hence called the "Doway Bible," in two 4to. volumes, the former in 1609, the other in 1610, from the Vulgate, with annotations. It is said that the translators were William Allyn, afterwards cardinal, Gregory Martin, and Richard Bristow; and that the annotator was Thomas Worthington. But some (Le Long. 418.) ascribe the version of the New Testament chiefly to William Raynold.

Bible, *King James's.*—The last English Bible was that which proceeded from the Hampton-court conference, in 1603, where many exceptions being made to the Bishop's Bible, king James gave order for a new one; not as the preface expresses it, for a translation altogether new, nor yet to make of a bad one a good one, but to make a good one better, or of many good one best. On the second day of this conference, Dr. Reynolds, the speaker of the Puritans, moved his majesty, that a new translation of the Bible might be undertaken; because those which were allowed in the reigns of Henry VIII. and Edward VI. were corrupt, and such versions as were extant were not answerable to the truth of the original. It has been observed by learned men with regard to the translators in the reign of Henry VIII. that they followed Erasmus and Sebastian Munster too closely; of the Geneva version, that it was formed too faithfully on the model of Beza; and of the Bishop's Bible, that it was not sufficiently exact, but full of errors, because its conductors departed from the Hebrew, and trod too exactly in the foot-steps of the Greek. In reply to Dr. Reynolds, the king said, that he had never yet seen a Bible well translated into English; though he considered the Geneva translations as the worst. On the suggestion of Bancroft, bishop of London, he forbad marginal notes; some of the Geneva

notes

notes having been, in his opinion, "very partial, untrue, ſeditious, and favouring too much of dangerous and traiterous conceits." In 1604, the king commiſſioned fifty-four learned men of the two univerſities, and of other places, to confer together, ſo that nothing ſhould paſs without a general conſent, in order to make a new and more correct tranſlation of the Bible. Such of theſe as ſurvived till the commencement of the work were divided into ſix claſſes. Ten were to meet at Weſtminſter, and to tranſlate from the Pentateuch to the end of the ſecond book of Kings. Eight, aſſembled at Cambridge, were to finiſh the reſt of the hiſtorical books, and the Hagiographa. At Oxford, ſeven were to undertake the four greater prophets, with the lamentations of Jeremiah, and the twelve minor prophets. The epiſtles of St. Paul, and the remaining canonical epiſtles, were allotted to another company of ſeven, at Weſtminſter. Another company of eight, at Oxford, were to tranſlate the four goſpels, the Acts of the Apoſtles, and the Apocalypſe. Laſtly, another company of ſeven, at Cambridge, had aſſigned to them the Apocrypha, including the prayer of Manaſſeh. The king preſcribed certain rules, which the tranſlators were required carefully to obſerve. The Biſhop's Bible was to be the ſtandard, from which as few deviations as poſſible were to be allowed; the names of the prophets, and the holy writers, with the other names in the text, were to be retained as near as poſſible to their vulgar uſe; the old eccleſiaſtical words were to be retained, as the word "church," which was not to be tranſlated "congregation," &c.; of words admitting divers ſignifications, thoſe were to be retained which had been moſt commonly uſed by the moſt eminent, or moſt ancient fathers, being agreeable to the propriety of the place, and the analogy of faith; the diviſion of the chapters was to remain with as little alteration as poſſible; no marginal notes were to be introduced, except for the explanation of Hebrew or Greek words, which could not without circumlocution be duly expreſſed; quotations were to be annexed in the margin, for the purpoſe of referring from one ſcripture to another; every particular perſon of each company was to take the ſame chapter or chapters, and having ſeparately tranſlated his appropriate part, all were to meet, to compare what they had done, and to agree as to that which ſhould remain; when any part was finiſhed by the company, it was to be referred to the reſt for their ſerious and judicious conſideration; if any doubt or difference occurred, it was to be ſettled at a general meeting; with reſpect to places of ſpecial obſcurity, the opinion of learned perſons was to be obtained by letters addreſſed to them for this purpoſe; and ſkilful perſons were requeſted to tranſmit any obſervations that might be of uſe to the company, either at Weſtminſter, Cambridge, or Oxford; the directors in each company were to be the deans of Weſtminſter and Cheſter, for that place, and the king's profeſſors in the Hebrew and Greek, in each univerſity: and the following tranſlations, if they agreed better with the text than the Biſhop's Bible, were to be uſed, viz. Tindal's, Matthewe's, Coverdale's, Whitchurch's, or the Great Bible, printed in 1539 and 1540, by Whitchurch and Grafton, and the Geneva Bible. The king alſo intimated his pleaſure, that three or four of the moſt eminent and grave divines of the univerſity, aſſigned by the vice-chancellor, upon conference with the reſt of the heads, ſhould be overſeers of the tranſlations, as well Hebrew as Greek. The tranſlation was begun in the ſpring of 1607, and the completion of it occupied almoſt three years. When the whole was finiſhed, and three copies of it were ſent to London, one from Cambridge, a ſecond from Oxford, and a third from Weſtminſter, two were choſen from the joint companies which had aſſembled at thoſe places, to review and poliſh it. The two from the Cambridge companies were Mr. John Bois, fellow of St. John's college, and Mr. Andrew Downes, profeſſor of Greek. Theſe daily met their fellow-labourers in Stationers' hall, London; where, in nine months, they completed their taſk, and received, each of them, by the week 30l. from the Company of Stationers, whereas, "before they had nothing." The whole was, at laſt, reviewed by Biſhop, biſhop of Wincheſter, and Dr. Myles Smyth, afterwards biſhop of Glouceſter, who prefixed arguments to the ſeveral books; and the latter was ordered to write the preface. This edition of the Bible, with the preface and a dedication to the king, was firſt publiſhed in London, in the year 1611; and is commonly called "King James's Bible." Several editions of it were publiſhed in 4to. and in 8vo.; and particularly one by R. Barker, in 1613. In ſome editions of this Bible, betwixt 1638 and 1685, an alteration is introduced in Acts vi. 3. where, inſtead of "*We* may appoint," is inſerted "*Ye* may appoint," which has been charged on the Independents. But as the firſt Bible in which it was obſerved is that printed at Cambridge by Buck and Daniel, in 1638, it is probably an error of the preſs, without any deſign to favour any particular party. In 1660, a beautiful edition of this Bible in folio, with chorographical cuts, engraven by Ogilby, was printed at Cambridge, by John Field; and another edition was printed in 8vo. at Amſterdam, in 1664, by John Canne, a leader of the Engliſh Browniſts, with marginal notes, ſhowing Scripture to be the beſt interpreter of Scripture. The editor has prefixed a preface; and the Apocrypha is omitted. A very fine edition of this Bible was publiſhed in a large folio, in 1701, under the direction of Dr. Teniſon, archbiſhop of Canterbury, with chronological dates, and an index, by biſhop Lloyd, and tables of ſcripture meaſures by biſhop Cumberland; but this edition abounds with typographical errors. After this tranſlation, all the other verſions dropped, and fell into diſuſe, except the Epiſtles and Goſpels in the Common Prayer Book, which were ſtill continued, according to the Biſhop's tranſlation, till the alteration of the liturgy in 1661, and the Pſalms and Hymns, which are to this day as in the old verſion.

About the time when king James reſolved on a new tranſlation of the Bible, another tranſlation was finiſhed by Mr. Ambroſe Uſher, elder brother of the learned primate of Armagh of the ſame name. It was never printed; but is preſerved in MS. in 3 vols. 4to. in the library of Trinity college at Dublin. In 1764, Mr. Anthony Purver publiſhed a new tranſlation of the Bible, at London, in 2 vols. folio. We have alſo had ſeveral tranſlations of the New Teſtament, (ſee TESTAMENT) and of particular books and parts of the Old and New Teſtament, the principal of which will be noticed in their proper places.

Learned perſons have entertained very different opinions concerning the accuracy and value of the tranſlation, made by order of king James, and now in common uſe. Biſhop Newcome, the late much reſpected primate of Ireland, has given an abſtract of theſe opinions. Selden recommends it as the "beſt tranſlation in the world." The committee for religion in the time of Cromwell, A. D. 1656, whilſt they pretended to diſcover ſome miſtakes in it, allowed it to be the "beſt extant;" Walton in his "Prolegomena," highly commends it; and Poole in his "Synopſis, &c." ſays, that "in this royal verſion occur very numerous ſpecimens of great learning and ſkill in the original languages, and of an uncommon acumen and judgment." In the "Bibliotheca Literaria," A. D. 1723, it is obſerved, that "it made its way by general conſent and approbation, without the interpoſition of authority to enforce it. A ſure argument that it is generally eſteemed the beſt we have; though it has ſtill many conſiderable

ſiderable faults, and very much needs another review." Dr. Wells, in his general preface to the O. T. profeſſes to correct it, "either where it does not give the true ſenſe of the original, or where the true ſenſe is not well expreſſed," according to the modern idiom. The author of an "Eſſay for a New Tranſlation of the Bible, &c." 1727, after ſpeaking in praiſe of this verſion, recommends the attempt to give a more exact tranſlation than any that has hitherto appeared; and he adds, "it were indeed to be wiſhed, that thoſe who are in power did employ men of true learning, and ſolid piety, free from bigotry and blind zeal, in ſo noble and neceſſary a work." "Innumerable inſtances," ſays Blackwall in his "Sacred Claſſics," might be made (in the Engliſh Bible) of faulty tranſlations of the divine original; which either weaken its ſenſe, or debaſe and tarniſh the beauty of its language." He alſo obſerves, that "a new tranſlation can give no offence to people of ſound judgment and conſideration; becauſe every body, converſant in theſe matters, and unprejudiced, muſt acknowledge, that there was leſs occaſion to change the old verſion into the preſent, than to change the preſent into a new one."—"Such an accurate and admirable tranſlation, proved and ſupported by ſound criticiſm, would quaſh and ſilence moſt of the objections of pert and profane cavillers, which chiefly proceed from their want of penetration and diſcernment of the connection of the argument, and their ignorance of the manner and phraſe, of the divine writings. It would likewiſe remove the ſcruples of many pious and conſcientious Chriſtians."—"A new diviſion of the ſacred books into chapters, ſections, and periods, might be ſo contrived and managed as to make a new edition very commodious and beautiful; which would overbalance all inconveniences which ſuperſtition and weakneſs could pretend might ariſe from alterations, and make a victorious and ſpeedy way to the favour and full approbation of the world." There is hardly one chapter in the N. T., ſays this author, that is not faultily divided, in conſequence of which, the connection and meaning of particular paſſages are rendered confuſed and obſcure; whilſt the ſtyle is materially injured. "It is, with pleaſure and juſt veneration," he continues, "to the memory of our learned and judicious tranſlators, that I acknowledge their verſion in the main, to be faithful, clear, and ſolid. But no man can be ſo ſuperſtitiouſly devoted to them, but muſt own that a conſiderable number of paſſages are weakly and imperfectly, and not a few falſely, rendered. And no wonder; for ſince their time there have been great improvements in the knowledge of antiquity, and advancements in critical learning, &c." "If ever" (ſays Dr. Waterland, Scripture Vindicated,) "a proper time ſhould come for reviſing and correcting our laſt Engliſh tranſlation, which, though a very good one, and upon the whole ſcarce inferior to any, yet is undoubtedly capable of very great improvements. &c." Doddridge, Weſley, Wynne, Pilkington, Purver, Worſley, Prieſtley, &c. &c. expreſs themſelves to the ſame purpoſe. "To confirm and illuſtrate the holy ſcriptures," ſays the eminently ingenious and learned biſhop Lowth (Viſitation Sermon at Durham, 1758.) "to evince their truth, to ſhew their conſiſtence, to explain their meaning, to make them more generally known and ſtudied, more eaſily and perfectly underſtood by all; to remove the difficulties, that diſcourage the honeſt endeavours of the unlearned, and provoke the malicious cavils of the half-learned: this is the moſt worthy object that can engage our attention; the moſt important end to which our labours in the ſearch of truth can be directed. And here I cannot but mention that nothing would more effectually conduce to this end, than the exhibiting of the holy ſcriptures themſelves to the people in a more advantageous and juſt light, by an accurate reviſal of our vulgar tranſlation by public authority. This hath often been repreſented; and, I hope, will not always be repreſented in vain." The late archbiſhop Secker delivers ſimilar ſentiments in his "Latin ſpeech intended to have been made at the opening of the Convocation in 1761, printed at the end of his charges;" London, 1769, p. 363. To the ſame purpoſe are the declarations of Dr. Durell, in his "Critical Remarks on Job, &c." Oxf. 1772. pref. p. 6.; of biſhop Lowth, in his "Prelim. Diſſ. to Iſaiah," 4to. Lond. 1778, p. 69.; of Dr. White, in his "Reviſal of the Engliſh Tranſlation of the O. T. recommended," Oxf. 1779, p. 8, 9, &c. &c. Dr. Kennicott, Green, and Blayney, excellent judges on this ſubject, have concurred in the ſame opinion, of the neceſſity and utility of either a new tranſlation or a reviſal of the old one. The late Dr. Geddes, in his "Proſpectus of a new Tranſlation of the Holy Bible," 4to. Glaſg. 1786, p. 2. expreſſes himſelf in the following language. "The higheſt eulogiums have been made on the tranſlation of James I., both by our own writers, and by foreigners; and indeed, if accuracy, fidelity, and the ſtricteſt attention to the letter of the text, be ſuppoſed to conſtitute the qualities of an excellent verſion, this, of all verſions, muſt, in general, be accounted the moſt excellent. Every ſentence, every word, every ſyllable, every letter and point, ſeem to have been weighed with the niceſt exactitude, and expreſſed, either in the text or the margin, with the greateſt preciſion. Pagninus himſelf is hardly more literal; and it was well remarked by Robertſon, above 100 years ago, that it may ſerve for a lexicon of the Hebrew language, as well as for a tranſlation. It is, however, confeſſedly, not without its faults. Beſides thoſe that are common to it with every verſion of that age, ariſing from faulty originals, and Maſoretic prepoſitions;" it has its own intrinſic and peculiar blemiſhes, which Dr. Geddes enumerates. From a ſuperſtitious attention to render the Hebrew and Greek into literal Engliſh, its authors adopted modes of expreſſion which are abhorrent from the Engliſh idiom; and perhaps from that of all other modern tongues. There is alſo a manifeſt want of uniformity in the mode of tranſlating, which is owing to the variety of perſons employed. The books called apocrypha are, in Dr. Geddes's opinion, generally tranſlated better than the reſt of the Bible; for which one reaſon may be, that the tranſlators of them were not cramped by the fetters of the Maſora. The tranſlators of this verſion miſtook the true meaning of a great many words and ſentences by depending too much on modern lexicons, and by paying too little attention to the ancient verſions. For various reaſons they encumbered their verſion with a load of uſeleſs Italics; often without the leaſt neceſſity, and almoſt always to the detriment of the text. Like other tranſlators of their day, they were too much guided by theological ſyſtems, and ſeem, on ſome occaſions, to have allowed their religious prejudices to have gotten the better of their judgment. Beſides, through the conſtant fluctuation and progreſs of living languages, there are many words and phraſes, in the vulgar verſion, now become obſolete, of which modern writers have ſelected a great variety. The conſtruction alſo is leſs grammatical than the preſent ſtate of our language ſeems to allow; and the arrangement of the words and ſentences is often ſuch as produces obſcurity and ambiguity. Dr. Campbell, in his preface to "The Four Goſpels tranſlated;" Dr. Symonds, in his "Obſervations on the Expediency of reviſing the preſent Engliſh verſion of the four Goſpels, and of the Acts of the Apoſtles;" Mr. Wakefield, in his "Tranſlation of the N. T.;" and Mr. Ormerod, in his "Short Specimen for an Improvement in ſome parts of the preſent Tranſlation of the O. T.;" unite in recommending

ing

ing a reviſal of our preſent tranſlation. Dr. Symonds, in particular, examines the grounds of an opinion, advanced by Lowth, in his "Engliſh Grammar," p. 93, and alſo by many others, which is, that the vulgar tranſlation of the Bible is the beſt ſtandard of the Engliſh language. Diſtinguiſhing between the terms *one* of the ſtandards, and the *beſt* ſtandard, which are very different, he allows that the plain and ſimple turn of expreſſion, reſulting from the choice of old Engliſh words, may entitle our verſion to the former appellation, and yet many other circumſtances muſt be united to confirm its claim to the latter. Accordingly, he ſuggeſts the following inquiries: "Are the words and phraſes, employed by our tranſlator, generally placed in their proper order? Are they ſo arranged as to preclude all obſcurity and ambiguity? Do we always find the antecedent to which the relatives refer? Hath a right attention been paid to the modes and times of verbs? And is there a due propriety obſerved in the uſe of particles, upon which the clearneſs of a ſentence chiefly depends?" The want of conformity to theſe rules, or to the greater part of them, will not allow our verſion of the Bible to lay claim to the appellation of the *beſt* ſtandard of our language. Many other opinions of very reſpectable writers, decidedly in favour of an improved verſion of the Bible, might be added to thoſe that are above cited. Objections, however, have been urged againſt it, by Dr. Viceſimus Knox, in his "Eſſays Moral and Literary," and alſo by others; and they have been examined and obviated by the late primate of Ireland, Dr. Newcome, who avows his opinion, that nothing would be more beneficial to the cauſe of religion, or more honourable to the reign and age in which it was patroniſed and executed, than an improved Engliſh verſion of the Scriptures.

It has been ſaid, that a new verſion of the Bible is quite unneceſſary. But although our Engliſh tranſlation, or any tranſlation extant, contains all things neceſſary to ſalvation, yet in common language a meaſure is ſaid to be neceſſary, when it is highly expedient. Let any competent ſcholar ſtudy the Bible in the original languages, and then pronounce whether our authorized verſion is not capable of amendment and improvement, in numberleſs places, many of which muſt be conſidered as very important. If every part of Scripture be intended to anſwer ſome important purpoſe, as it certainly is, or it would not have been given to us, every part ought to be put into the hands of Chriſtians as free as poſſible from obſcurity and error. Some miſtakes, among many that may be deemed ſmall, are ſo conſiderable as to deprive Chriſtianity of much ſolid evidence, and furniſh the Sceptic with his moſt formidable weapons. Whilſt it is acknowledged that our preſent verſion contains every thing neceſſary to ſalvation, it may be alledged, that if this be a ſufficient reaſon for not correcting thoſe faulty paſſages which admit of correction, it would be a ſufficient reaſon for throwing them out of it altogether. But as our heavenly Father has been pleaſed to favour his creatures with additional light, it would ill become us to permit any of this light to be obſcured, or to pretend that it is not wanted. If, according to the conceſſions of ſome of the objectors to a new verſion, the faith and practice of illiterate perſons are ſometimes affected by the preſent verſion, and if, in ſome inſtances, its obſcurity would be removed; religion is a matter of ſuch great concern as to demand from thoſe who watch over its intereſts, that even theſe defects ſhould be rectified. It is dangerous to retain any known errors in our national verſion; they operate differently on different minds; nor is it eaſy to eſtimate their degree or effects. The opinions and conduct not only of the unlearned, but of the learned themſelves, who do not carefully examine the Scriptures, have in fact been ſtrongly influenced in matters of acknowledged importance, by corrupt readings or miſtranſlations of a very few texts.

It has again been objected, that a new tranſlation is an extremely dangerous attempt; that nothing would more immediately tend to ſhake the baſis of the eſtabliſhment; and that it would be imprudent to ſhock the minds of ſome very devout and well-meaning people, by an innovation which they could not help conſidering as an inſult on heaven. A meaſure of this kind would tend to ſhake the faith of thouſands, to whom it were impoſſible to demonſtrate the neceſſity of a change, or the principles on which it was conducted. Perſons of this claſs would loſe their veneration for the old verſion, without acquiring ſufficient confidence in the new: and the benefits muſt be great indeed, that can compenſate even for the remoteſt poſſibility of ſuch an evil. To this mode of objecting it has been replied, that it does not immediately affect the merits of the queſtion, but it arraigns the prudence of introducing a correct verſion, as a meaſure from which dangerous effects, and not ſolid advantages, will be apt to ariſe on the whole. Whatever tends, it has been ſaid, to the perfection of an eſtabliſhment, would not ſhake it, but give it ſplendour, ſtrength, and ſecurity. An accurate verſion would reflect the higheſt honour on our national church, and may be ranked in an eminent degree among thoſe meaſures, which would fix it on a baſis as firm as truth, virtue, and Chriſtianity. Such a work would be as natural a ſubject for the praiſe of all Proteſtant countries, as king James's Bible was for the honourable teſtimony born to it by the ſynod of Dort. It ought alſo to be recollected, that after Coverdale's tranſlation had received the ſanction of authority, the Bibles of Matthewe, Cranmer, Taverner, archbiſhop Parker, and James I. were all *innovations* in their day; and yet that, conſidered as different verſions, they produced no civil or eccleſiaſtical commotion, no violent agitation in the minds of men, reſembling thoſe which are now apprehended and predicted. Beſides, a tranſlation by authority ought to ſuperſede all others from its intrinſic excellence; and it would of courſe ſuperſede them by the frequency, correctneſs, and cheapneſs of its editions, as king James's did that of Geneva, notwithſtanding the preference given to it by the Calviniſts. Moreover, it is hard to conceive, how the faith of thouſands can be ſhaken by removing ſtumbling-blocks, inſtead of retaining them. Abſurd belief and corrupt practice ariſe from an ignorance of the Scriptures; not from the beſt human inducements and aſſiſtances to ſearch and underſtand them. It is the nature of truth, and eſpecially of divine truth, to captivate thoſe who contemplate it, in proportion as the veil is withdrawn, and its genuine features appear. If ill-founded prejudices ſhould exiſt among the people, their teachers ſhould ſeriouſly labour to remove them. Theſe prejudices are ſuch, as far as they exiſt, which might be eaſily removed, or which would not deſerve to be regarded. Beſides, the public mind might be prepared for it, and diſpoſed to acquieſce in it by previous and frequent recommendations of it on the part of eccleſiaſtics, who derive weight from their rank, and, which is the higheſt of all ranks, ſays a primate of Ireland, from their reputation. A repeated diſcuſſion of the topics, that involved the neceſſity, expediency, and utility of a new verſion, in diſcourſe, in the pulpit, and from the preſs, and the concurrence of the beſt, the wiſeſt, the moſt learned, and the greateſt, in the recommendation, patronage, and conduct of an amended verſion, would give the bulk of the community as great a confidence in it as they ever repoſed in any preceding one.

Some, indeed, may ſay "Let us introduce no change; for we cannot tell what further change may be required of us." Had this kind of lukewarm and timid reaſoning been

regarded, neither the reformation, nor the revolution, could have taken place; and we ſhould have been ſtill ſubject to Romiſh ſuperſtition, and to deſpotic power. It is certainly not leſs the part of wiſdom and magnanimity to give up what is wrong, than reſolutely to maintain what is right.

It has been further argued, that the preſent tranſlation derives an advantage from its antiquity, greatly ſuperior to any which could ariſe from a correction of its inaccuracies. Hence it would follow, that the verſions of Tindal, Wickcliffe, and Jerom, riſe in excellence. But no age or preſcription can authoriſe error; and it is obſtinacy to defend in any verſion, however ancient or venerable, what cannot be rationally defended. Although it be deſirable that the grave ancient caſt ſhould prevail in an Engliſh tranſlation of the Bible, a tranſlation may neverthelefs become too antiquated; and in fact our own Bible retains words and forms of ſuch remote uſe, that ſome of them are not underſtood, even by intelligent readers, and many of them are rather harſh and uncouth, than venerable and majeſtic.

But it has been ſaid, that the preſent tranſlation ought to be retained in our churches, on account of its intrinſic beauty and excellence. The language, though ſimple and natural, is rich and expreſſive. Even in the literal tranſlation of the Pſalms, there are paſſages exquiſitely beautiful and irreſiſtibly tranſporting; and where the ſenſe is not clear nor the connection of ideas obvious at firſt ſight, the mind is ſoothed, and the ear raviſhed with the powerful yet unaffected charms of the ſtyle. Theſe beauties, it is alledged, on the other hand, are found, in an equal, or partly in a ſuperior degree, in our firſt verſion; and muſt be more or leſs found in every verſion of the Hebrew Scriptures, that is not a mere paraphraſe. King James's tranſlators found it in their prototype; the diction and phraſeology they borrowed from their predeceſſors in tranſlation. What is beautiful, what is excellent, what is melodious and raviſhing in the preſent verſion, ſhould unqueſtionably be retained by all future tranſlators; but is there any reaſon for retaining its corruptions, its miſtranſlations, its obſcurities, and its other acknowledged imperfections?

The correcting tranſlators, it will be again urged, differ among themſelves. Differences muſt neceſſarily ariſe among interpreters of the Scriptures. King James's tranſlators often diſagreed as individuals; and adopted in a body what ſeemed to be moſt agreeable to the ſound rules of interpretation. Let a like number of able judges decide, on the ſame principles, between biblical critics of the preſent age. But the new tranſlators recede too far from the common verſion. This, however, in a new verſion, is not neceſſary, nor would it be proper; whilſt they recede from its errors and imperfections; they ſhould retain its general diction and manner, nor ever allow themſelves to deviate from it without a ſatisfactory reaſon.

It has been further intimated, by thoſe who are averſe from a new verſion, that ſuch as wiſh for additional information may have recourſe to thoſe authors, who have explained obſcure and erroneous paſſages. But have all Chriſtians, who meet with difficulties, time and ability to conſult theſe writers? Or if they had, is it in any reſpect decent or fit that the public Scriptures, confeſſed to want aſſiſtance, ſhould be ſuffered to depend for ſupport on theſe extraneous props? The national Bible is the great record of our religion; it is this which the Deiſt attacks, and this muſt ſupply us with our defence.

The objectors proceed with obſerving, that no tranſlation, even of a ſingle book, has yet appeared, preferable on the whole, to the received one. Let it be conſidered, however, that the attempts of individuals neceſſarily labour under great comparative imperfections; and yet theſe ſhould be promoted by the natural patrons of ſacred learning, and parts of the Scriptures ſhould be aſſigned to ſuch as are beſt qualified for the honourable taſk of tranſlating and explaining them; becauſe theſe private verſions and expoſitions will form a moſt uſeful ground-work for a reviſed verſion of the whole Bible by public authority.

After all, it will be ſaid by ſome, who are convinced that our preſent Bible ſhould be reviſed, that this is not a proper time for the undertaking; and that we ſhould wait till, by the further increaſe of light and progreſs of improvement, we ſhall be able to carry the work to a greater degree of perfection, and, if poſſible, make future reviſals unneceſſary. This argument may be always urged; becauſe religious knowledge will encreaſe, in proportion as human learning improves, and as new light is obtained from verſions and MSS. that are already known, and that may yet be diſcovered, duly examined and compared. "But ſhall we, in the mean time, prolong the difficulties of the Chriſtian, and the fancied triumph of the Infidel? The miſtakes already diſcovered are well worthy of correction. Should others of importance be brought to light in the next, or ſubſequent generation, let them alſo be corrected. The true rule in this caſe is, to reviſe as often as reviſion is neceſſary. To defer this longer, is an injury to religion; to put it off till it can be done in ſuch a way as to preclude the neceſſity of future reviſals, is in fact to put it off for ever." "The taſte of the age for ſound logic, ſound criticiſm, and ſound philoſophy, has acquired ſufficient ſtrength to triumph over their oppoſers."

In favour of an improved verſion of the Bible, for national uſe, it has been argued, that ſuch a tranſlation becomes neceſſary by the unavoidable fluctuation of living languages. The ſtyle of Wickcliffe's verſion, and of Tindal's, very widely differs in the courſe of 148 years, and the Engliſh language underwent alſo a great change between the publication of Tindal's Bible and that of king James's, in an interval of 81 years. Since the year 1611, when the preſent verſion firſt appeared, our language has acquired a great degree of copiouſneſs, of elegance, of accuracy, and perhaps of ſtability. Many words and phraſes which occur in the reviſed verſion are become unintelligible to the generality of readers; and many, which are intelligible, are ſo antiquated and debaſed, as to excite diſguſt among the ſerious, and contempt and deriſion among libertines. Pilkington (Remarks on ſeveral paſſages of Scripture, Camb. 8vo. 1759); Purver (Tranſlation of the Bible); Dr. Symonds (Obſervations on the expediency of reviſing the preſent Engliſh verſion, &c. Camb. 4to. 1789); Dr. Wells (Pref. to Comment on the O. T.); Dr. Campbell (Four Goſpels tranſlated from the Greek, 4to. Lond. 1789); and Dr. Geddes (Proſpectus); have ſelected many words and phraſes that require correction, and that admit of obvious improvement. The ſtyle of a biblical verſion is a matter of importance; both as it invites the peruſal of a book which the Spirit of God inſpired, and as it influences the national language and taſte. Whatever merit be allowed to the verſion now in uſe, with regard both to its interpretations as well as its ſtyle, it muſt be allowed that, ſince the period in which it was executed, the biblical apparatus has been much enriched by the publications of polyglotts; of the Samaritan pentateuch; of ancient and modern verſions; of lexicons, concordances, critical diſſertations, and ſermons; books of eaſtern travels; diſquiſitions on the geography, cuſtoms, and natural hiſtory of the Eaſt; accurate tables of chronology, coins, weights, and meaſures. Many Hebrew and Samaritan MSS.; many early printed editions of the Hebrew Scriptures, have been collated by Kennicott and

and De Roſſi; the eaſtern languages, which have ſo cloſe an affinity with the Hebrew, have been induſtriouſly cultivated at home and abroad; the Maſoretic punctuation is now ranked among uſeful aſſiſtances, but no longer implicitly followed; and the Hebrew text itſelf is generally allowed to be corrupt in many places, and therefore capable of emendation by the ſame methods which are uſed in reſtoring the integrity of all other ancient books. With ſuch an acceſſion of helps, with light poured in from every part of the literary world, with ſuch important principles, and with the advancement of critical ſkill to apply them, it is natural to conclude, that many miſtakes and abſurdities may be removed from the preſent verſion, and that the preciſion, beauty, and emphaſis of the original, may be communicated to it in various places. The preſent ſtate of the Hebrew text, in its reference to a new verſion of the O. T. has been already repreſented in the commencement of this article; and that of the text of the New Teſtament will be the ſubject of a future article; See TESTAMENT.

Dr. Newcome, in his "Attempt towards an improved verſion, &c. of the Minor Prophets," publiſhed in 1785, propoſed a variety of rules for conducting a new tranſlation of the Bible. Theſe have been ſince corrected and enlarged (ubi infra); and in order to render this article, the ſubject of which is highly important and intereſting, as complete and as ſatisfactory to biblical readers as our limits will allow, we ſhall here ſubjoin the moſt material parts of them. The learned prelate propoſes, in the firſt place, that a plan, reſembling the regulations preſcribed to king James's tranſlators, ſhould be deliberately adjuſted by a large committee of judicious and learned men. A more ſelect committee, well acquainted with the original tongues in which the Bible is written, ſhould then be appointed by proper authority, who ſhould invite every ſcholar to contribute his remarks; who ſhould have their reſpective parts aſſigned them; and who, after the performance of their allotted taſks, ſhould amicably unite in advancing the whole to its proper degree of perfection. The *firſt* of his rules is, that a tranſlation of the Bible ſhould expreſs every word in the original by a literal, verbal, or cloſe rendering, where the Engliſh idiom admits of it. This rule admits of ſome few exceptions; but it excludes unneceſſary deviation from the grammatical form of the original words; unneceſſary paraphraſe, which enervates the force of the original, diſguiſes its manner, and ſometimes ſuggeſts a wrong idea; ſentential renderings; and ſuch as are defective. The *ſecond* rule directs the tranſlator, where the Engliſh idiom requires a paraphraſe, to endeavour ſo to form it as to comprehend the original word or phraſe; and to expreſs the ſupplemental part in Italics, except where harſhneſs of language reſults from the adoption of this method. The *third* rule recommends, in caſes where a verbal tranſlation cannot thus be interwoven, the ſubſtitution of one equivalent to it, and which implies the reading in the original; but the idiom in the text ſhould be literally rendered in the margin. By obſerving the ſecond and third rules, the utmoſt fidelity to the original will be ſhewn, which is the primary duty of a biblical tranſlator; the cuſtoms and manners of the eaſtern nations will be explained; the peculiar genius of the original languages will be exhibited; and the reader unſkilled in them will be beſt enabled to interpret for himſelf. The *fourth* rule requires, that the language of a biblical tranſlation ſhould be pure, or conformable to the rules of grammar. The *fifth* rule directs, that propriety ſhould be a prevailing character in the words and phraſes of a biblical tranſlation; that is, they ſhould have the ſanction of uſe, and the ſignification given to them ſhould be warranted by the beſt ſpeakers and writers. In order to preſerve the venerable turn of our preſent verſion, ſome few exceptions may be allowed under this general rule. The *ſixth* rule enjoins the tranſlators to retain the ſimplicity of the preſent verſion; for which purpoſe they ſhould exclude foreign words, and the pomp and elegance of moderniſed diction. The *ſeventh* rule inculcates perſpicuity. The *eighth* rule recommends the ſame original word, and its derivatives, according to the different leading ſenſes, and alſo the ſame phraſe, to be reſpectively tranſlated by the ſame correſponding Engliſh word or phraſe; except where a diſtinct repreſentation of a general idea, or the nature of the Engliſh language, or the avoiding of an ambiguity, or elegance of ſtyle, or harmony of ſound, requires a different mode of expreſſion. In conformity to this rule, it is propoſed, that tranſlators ſhould previouſly agree on the rendering of certain words and phraſes. Accordingly, the original word "Jehovah," which expreſſes the ſelf-exiſtence of the deity, and which, ſo far from being barbarous, is a grand and magnificent term, ſhould be retained:—that it ſhould be conſidered, by the help of concordances, whether the ſame word can always be rendered in the ſame manner; and that when an Engliſh word ſuits every place, it ſhould invariably be uſed:—that if the original word cannot always admit of the ſame rendering, of which many examples occur, the different renderings may be reduced to as few as poſſible, and thoſe the fitteſt which the Engliſh language affords:—that different words, which have the ſame, or nearly the ſame ſenſe, ſhould be diſtinguiſhed in tranſlating them, when the Engliſh tongue furniſhes diſtinct and proper terms:—and that parallel paſſages ſhould be rendered in the ſame words. The *ninth* rule requires that the collocation of words ſhould never be harſh and unſuited to an Engliſh ear. The *tenth* rule recommends to tranſlators of the Bible a ſuitable degree of beauty and elegance. This beauty, in its prevailing character, muſt be eaſy and natural, ſimple and ſevere; free from laboured ornament and artful variety of phraſe. The ſtyle, like that of the original, muſt be raiſed in the poetical parts, but not inflated, and plain in the hiſtorical parts, but not abject. "Let nothing," ſays Dr. Symonds (ubi ſupra) "be admitted into the text, which we cannot read with pleaſure, as well as with advantage." In the *eleventh* rule it is required, that dignity ſhould characterize a verſion of the Bible. The oppoſite extreme reſults from the introduction of debaſed and offenſive terms or phraſes; of which ſome are degraded by familiar uſe, others are colloquial and vulgar Angliciſms; and modern phraſeology, as ſuch, is undignified in a tranſlation of the Bible. The *twelfth* rule preſcribes energy as another characteriſtic of a biblical tranſlation. This quality is obtained, in a great degree, by ſimplicity and propriety in the terms that are ſelected to repreſent the peculiar notions conveyed by the ſacred writers, and by expreſſing the clauſes contained in the original with due conciſeneſs. The forcible ſtyle of the Scriptures is enfeebled by epithets and paraphraſe; nor does their majeſty more diſdain the defect of ornament, than the exceſs of it. A verſion of the Bible will derive much force by retaining thoſe Hebraiſms which the Engliſh language eaſily admits, or to which an Engliſh ear is now accuſtomed. Obſcure Hebraiſms, ſuch as weaken the ſignification of the original, and thoſe which miſrepreſent its meaning, ſhould be avoided. In the *thirteenth* rule it is recommended to continue the old eccleſiaſtical terms, ſuch as repentance, myſtery, elect, predeſtinated, &c. which are now part of our theological language, and of which explanations perpetually occur. Rule *fourteenth*. Metaphors are, in general, to be retained. By obſerving this rule, the genius of a language, and the nature and cuſtoms of a country, will often appear.

Rule *fifteenth*. Proper names ſhould remain as they are now written in thoſe places where they are moſt correctly repreſented. Rule *ſixteenth*. The beſt known geographical terms ſhould be inſerted in the text; and thoſe of the original in the margin; e. g. Syria, marg. Aram; Ethiopia, marg. Cuſh. Rule *ſeventeenth*. The language, ſenſe, and punctuation of our preſent verſion ſhould be retained, unleſs when a ſufficient reaſon can be aſſigned for departing from them. Rule *eighteenth*. The critical ſenſe of paſſages ſhould be conſidered, and not the opinions of any denomination of Chriſtians whatever; ſo that the tranſlators ſhould be philologiſts, and not controverſialiſts. Rule *nineteenth*. Paſſages already admitted into the common verſion, but which are allowed to be marginal gloſſes, or about the authenticity of which critics have reaſon to be doubtful, ſhould be placed in the text between brackets. Rule *twentieth*. In the beſt editions of the Bible, the poetical parts ſhould be divided into lines anſwering to the metre of the original; or ſome other method ſhould be uſed to diſtinguiſh them from proſe. But if it ſhould be thought adviſable to exclude the poetical diſtribution from our Bibles, and confine it to the proluſions of the ſcholar, ſome proper mark of diſtinction for metrical pauſe, as the Hebrew Rebhiang or two horizontal points placed over a word, may be admitted into the authorized impreſſions of the Old Teſtament; or, at leaſt, the contents prefixed may adverti ſe the reader of the paſſages generally allowed to aſſume the tone and form of poetry. Rule *twenty-firſt*. Of dark paſſages, which exhibit no meaning as they ſtand in our preſent verſion, an intelligible rendering ſhould be made on the principles of ſound criticiſm. Under this head of ſound criticiſm, Newcome includes that which is conjectural, the ſober uſe of which he frequently recommends. But it admits of doubt, whether conjecture can ever be authorized in a tranſlation which is intended for general uſe; for if it be exerciſed on ſlight occaſions, it muſt be in ſome degree ſuperfluous; if on material ones, it muſt ever be indeciſive. The learned prelate, however, lays down the following canons for this kind of criticiſm. Never ſuppoſe that the text is corrupted, without the moſt cogent and convincing reaſons. Never have recourſe to conjectural criticiſm, until every other ſource has been tried and exhauſted. Let all corrections be conſiſtent with the text, and with one another. Inſert no correction, however plauſible or even certain, in the text, without warning the reader, and diſtinguiſhing it by a proper note. For other inſtructions, more immediately deſigned for the editor of ſuch a new verſion, we refer to the author himſelf; as well as to his appendix, for a liſt of the various editions of the Bible, together with an account of the libraries public or private, in which they are to be found. Another more complete liſt of this kind is prefixed to biſhop Wilſon's Bible. See Lewis's Tranſlations of the Bible, 8vo. 1739. Johnſon's Hiſtorical Account of the ſeveral Engliſh tranſlations of the Bible, in biſhop Watſon's Collection of Theological Tracts, vol. iii. p. 60—100. Newcome's Hiſtorical View of the Engliſh Biblical Tranſactions, &c. 8vo. Dublin, 1792.

Bibles, *Welch*. There was a Welch tranſlation of the Bible made from the original in the time of queen Elizabeth, in conſequence of a bill brought into the houſe of commons for this purpoſe in 1563. The act 5 Eliz. c. 28. reciting, that in Wales the people were popiſhly inclined, and very ignorant, put the direction of this work into the hands of the biſhops of Hereford, St. David, Bangor, Landaff, and St. Aſaph, who were to inſpect the tranſlation, and take care that ſuch a number ſhould be printed as would provide every cathedral, collegiate, and pariſh-church, and chapel of eaſe, within their reſpective dioceſes, where Welch was commonly ſpoken, with one copy. It was printed in folio, in 1588. Another verſion, which is the ſtandard tranſlation for that language, was printed in 1620. It is called Parry's Bible. An impreſſion of this was printed in 1690, called Biſhop Lloyd's Bible. Theſe were in folio. The firſt octavo impreſſion of the Welch Bible was made in 1630.

Bibles, *Iriſh*. The New Teſtament having been tranſlated into Iriſh by William Daniel, archbiſhop of Tuam, Bedell, who was advanced to the ſee of Kilmore and Ardagh, in 1629, firſt procured the Old Teſtament to be tranſlated by one King; but the tranſlator being ignorant of the original languages, and having done it from the Engliſh, the biſhop himſelf reviſed and compared it with the Hebrew, the Septuagint, and the Italian verſion of Diodati. He ſupported Mr. King to the utmoſt of his ability, whilſt he was engaged in this work; and when the tranſlation was finiſhed, he would have printed it in his own houſe, and at his own charge, if the troubles in Ireland had not prevented it. The execution of his benevolent deſign was alſo impeded in conſequence of the notice that was given of it to the lord lieutenant and the archbiſhop of Canterbury, who thought it diſgraceful for a nation to have a Bible publiſhed, which had been tranſlated by ſuch a deſpicable perſon as King. However, the tranſlation eſcaped the hands of the rebels, and it was afterwards, viz. in 1685, printed at the expence of the Hon. Robert Boyle.

Bibles, *Gaelic*. The Bible was tranſlated and publiſhed by the ſociety in Scotland for promoting Chriſtian knowledge, in the Gaelic language, for the uſe of their ſchools, and of the people in the Highlands, at different periods, and in detached portions, as the funds of the ſociety allowed. In 1767, the New Teſtament in Gaelic was publiſhed by itſelf; and in various ſucceſſive years, and in ſeparate volumes, the ſeveral books of the Old Teſtament were publiſhed. In 1796, the firſt edition of the New Teſtament being exhauſted, the ſociety publiſhed another, conſiſting of 20,000 copies. And as ſome of the firſt printed volumes of the Old Teſtament have been ſo much reduced in number, as to be inſufficient to ſupply the urgent demands of the Highlands in general, and of the ſociety's own ſchool in particular, a new edition of 20,000 copies has been lately undertaken (in 1803), at an expence of 2284l. 16s. defrayed by voluntary ſubſcription. An act of charity, highly important and laudable, as the perſons, for whoſe accommodation it is deſigned, amount to no leſs than 335,000; of whom, it is computed, that 300,000 underſtand no other language than the Gaelic, or at leaſt cannot comprehend a book written, or a continued diſcourſe ſpoken, in any other.

Bible-Doctors, in *Eccleſiaſtical Hiſtory*, a denomination by which the ſchoolmen of the twelfth and thirteenth centuries were diſtinguiſhed, who made the Scriptures the chief ſubject of their ſtudies, and text of their lectures. However, in the courſe of the thirteenth century, the holy Scriptures, together with thoſe who ſtudied and explained them, fell into great neglect and even contempt. The Bible-Doctors were ſlighted as men of little learning or acumen; they had few ſcholars, and were not allowed an apartment, or a ſervant to attend them, or even a ſtated time for reading their lectures, in any of the famous univerſities of Europe. The illuſtrious Roger Bacon inveighed very bitterly againſt this abuſe; and his excellent friend, Robert Grouthead, biſhop of Lincoln, wrote a pathetic letter to the regents in theology in the univerſity of Oxford, on this ſubject; earneſtly intreating them to lay the foundations of theological learning in the ſtudy of the Scriptures, and to devote the morning-hours to lectures on the Old and New Teſtaments.

But

But all theſe remonſtrances and exhortations had little or no effect.

BIBLIA, or Biblia *petraria*, in a military ſenſe, denotes a machine uſed by the ancients for throwing ſtones or darts.

BIBLIANDER, Theodore, in *Biography*, whoſe true name was *Bouchman*, a learned proteſtant divine, was born in 1504, at Biſchoffzell near St. Gall, in Swiſſerland. He officiated as profeſſor of divinity at Zurich from 1532 to 1560, when he was declared emeritus, or paſt ſervice, not becauſe he was incapable of executing his office, but becauſe he had advanced opinions that deviated from the ſtandard of orthodoxy with regard to the doctrine of predeſtination. He died of the plague, at Zurich, in 1564. He was well acquainted with the oriental languages, and publiſhed, in 1550, an edition of the Koran; the text of which, Bayle ſays, he corrected by a collation of the Arabic and Latin copies; and he added marginal notes, pointing out and refuting its abſurdities. But others ſay, that this edition is faulty, and diſpute Bibliander's ſkill in the oriental languages. To this edition he ſubjoined the lives of Mahomet and his ſucceſſors, and prefixed an apology, by way of preface, which gave great offence by maintaining the lawfulneſs and utility of a free peruſal of books adverſe to true religion. He alſo wrote ſeveral other books on theological ſubjects, ſome of which are printed, and others remain in MS. in the library at Zurich. He likewiſe finiſhed the Bible of Leo Juda, called the "Zurich Bible," and printed in 1543, and tranſlated from the Hebrew into Latin the laſt 8 chapters of Ezekiel, Daniel, Job, Eccleſiaſtes, the Canticles, and the laſt 48 Pſalms. Gen. Dict.

BIBLIOGRAPHIA, a branch of *archæographia*, employed in the judging and peruſing of ancient manuſcripts, whether written in books, paper, or parchment. The ſenſe of it is now extended, and it ſignifies a work intended to give information concerning the firſt, or beſt editions of books; and the ways of ſelecting and diſtinguiſhing them properly. In ſhort, it is uſed for a *notitia*, or deſcription of printed books, either in the order of the alphabet, of the times when printed, or of the ſubject-matters. In which ſenſe, bibliographia amounts to much the ſame with what is otherwiſe called *bibliotheca*.

Literary journals afford alſo a kind of bibliographia.

BIBLIOMANCY, a kind of divination performed by means of the Bible. This amounts to much the ſame with what is otherwiſe called *ſortes biblicæ*, or *ſortes ſanctorum*. See Sortes. It conſiſted in taking paſſages of Scripture at hazard, and drawing indications thence concerning things future; as in Auguſtin's *tolle et lege*. It was much uſed at the conſecration of biſhops. F. J. Davidius, a Jeſuit, has publiſhed a bibliomancy, under the borrowed name of *Veridicus Chriſtianus*.

BIBLIOMANIA, an extravagant paſſion for books, to a degree of madneſs; or a deſire of accumulating them beyond all reaſon and neceſſity.

BIBLIOTHECA, from βιβλος, *book*, and θηκη, *repoſitory*, from τιθημι, *I lay up*, properly ſignifies a library, or repoſitory of books. See Library. It is alſo uſed for a compilation of all that has been written on a certain ſubject; or a digeſtion of all the authors who have treated of it. In this ſenſe, we have hiſtorical bibliothecæ, as that of Diodorus Siculus; mythological bibliothecæ, as that of Apollodorus; theological and ſacred bibliothecæ, as thoſe of Ravaneilus, &c. It is alſo uſed for a catalogue of the books in a library; ſuch are the *bibliotheca Coiſſniana*, *bibliotheca Cordeſiana*, *bibliotheca Thuanea*, *bibliotheca Bignoniana*, *bibliotheca du Boiſiana*, &c.

L'Abbe has publiſhed a *bibliotheca* of *bibliothecæ*, or a catalogue of the names of thoſe who have written bibliothecæ, which has ſince been continued and improved under another title by Teſſier, from 800 writers to the number of no leſs than 2500. Schrammius has alſo publiſhed a *programma* on the writers of theological bibliothecæ.

Bibliotheca is a name given to the books of the Old and New Teſtament, in reſpect of their excellency, and ſufficiency for the uſes of the Chriſtian life; and it is alſo a title given to divers journals, or periodical accounts in French of new books.

Bibliotheca *Patrum*, or *of the Fathers*, is a collection of the writings of the leſſer fathers, printed in one or more volumes. The firſt of this kind was publiſhed at Paris by Marg. de la Bigne in 1576.

BIBLIOTHECARIAN, a library keeper, otherwiſe called *librarian*.

The word is alſo uſed for the author of a bibliotheca, or a catalogue of books.

In this ſenſe, P. L'Abbe has given a bibliotheca, or catalogue of bibliothecarians. Geſner, Lipenius, Struvius, Fabricius, &c. are celebrated bibliothecarians.

BIBLIOTHEQUE Musicale. See Musical *Library*.

BIBLIS, in *Entomology*, a ſpecies of Papilio, with black dentated wings, and a band of ſanguineous ſpots on the poſterior ones. It is a native of America, and called *papilio hyperia* by Cramer. Gmelin. *Obſ.* This muſt not be confounded with *papilio biblis* of Cramer, which is a very different inſect, and ſeems to be a variety of *papilio pentheſilea* of Fabricius.

Biblis *Fons*, in *Ancient Geography*, a celebrated fountain of Ionia, ſituate E.S.E. of Miletus. It is mentioned by Pauſanias and Ovid.

BIBLISTS, *bibliſtæ*, an appellation given by ſome Romiſh writers to thoſe who profeſs to adhere to Scripture alone as the ſole rule of faith, excluſive of all tradition and the ſuppoſed authority of the church. In which ſenſe, all proteſtants are, or ought to be, bibliſts. Bibliſts, among Chriſtians, anſwer nearly to Caraites or Textuaries among the Jews. The Chriſtian doctors were divided, towards the cloſe of the twelfth century, into two claſſes; viz. the biblici, and the ſcholaſtics: the former were called *doctors of the ſacred page*, becauſe they explained the doctrines of Chriſtianity in their manner by the ſacred writings; however, their reputation declined, and the ſcholaſtic theology prevailed in all the European colleges till the time of Luther. See Bible-*Doctors*.

BIBLUS, in *Botany*, an aquatic plant in Egypt, called alſo *papyrus*; of the ſkin whereof the ancient Egyptians made their paper. See Papyrus, and Paper.

Hence alſo the Greeks gave the denomination βιβλος to books made of it. See Bible.

Biblus, in *Ancient Geography*, a river in the iſland of Naxia.

BIBONA, a place of Gallia Aquitanica, in the route from Burdigala to Segodum.

BIBORA River and Bay, in *Geography*, lie to the eaſt of Cartago bay, on the main land of Honduras, about N. lat. 14° 20′. W. long. 83° 45.

BIBRA, Bebra, or Biebra, a town of Germany, in the circle of Upper Saxony, in Thuringia, 10 miles weſt of Naumburg, and 8 ſouth of Querfurt.

BIBRACTE, in *Ancient Geography*, a citadel of the Ædui, according to Strabo, but according to Cæſar, a fortified town of Gaul, the capital of which was large and populous, now deſolate; about 4 miles to the north-weſt of Autun, and called Beureſt, Bevray, and Bray.

BIBRAX, Bievre, a town of Belgica, in Gaul, in the country of the Rhemi, north-weſt of Durocortorum. This town was attacked with great fury by the other Belgic nations, becauſe it had declared for Cæſar. Cæſ. Bel. Gal. l. 2. c. 7.

BIBRICH,

BIBRICH, in *Geography*, a town of Germany, in the circle of the Upper Rhine, and principality of Naſſau Saarbruck Uſingen, 3 miles S.S.W. of Wiſbaden.

BIBROCI, in *Ancient Geography*, an ancient people of Britain, who are ſuppoſed to have occupied the ſouth-eaſtern part of Berkſhire, from the Lodden on the weſt to the Thames on the eaſt. Theſe people undoubtedly came from that part of Gaul, where the town Bibrax was ſituated, and their name leads us to the diſcovery of their origin, as well as of the place of their reſidence in this iſland. It is not certainly known when this colony of the Bibroci left their native country, and ſettled in Britain, though it is probable that it was not long before Cæſar's invaſion, to whom, perhaps, they were engaged to ſubmit by the influence and example of their friends and countrymen in Gaul. As the Bibroci were but a ſmall nation, they ſeem to have been ſubdued by ſome of their neighbours before the invaſion of Claudius, and therefore they are no further mentioned in hiſtory. The name of the hundred of Bray, on the Thames, near Maidenhead, is evidently derived from the name of theſe ancient inhabitants; as the ancient Bibracte, in France, now bears the name of Bray.

BICALCARATUS, in *Zoology*, a ſpecies of Pavo, of a brown colour, with the head ſlightly creſted, and two ſpurs on each leg. Gmelin. This is *pavo Chinenſis* of Briſſon; *l'eperonnier* of Buffon; *petit paon de Malacca* of Sonnerat; *peacock pheaſant* of Edwards; and *iris peacock* of Latham.

This ſplendid bird is a native of China; in point of ſize it rather exceeds the common pheaſant, and has a blackiſh bill, with the baſe of the upper mandible red from the noſtrils; the irides are yellow; creſt ſmall, though compoſed of ſome pretty long feathers, and of a dull brown colour; the face is naked; ſides of the head white; neck brown, ſtriated acroſs with duſky; upper parts of the back, ſcapulars, and wing-coverts dull brown, dotted with pale brown, and yellowiſh: and near the end of each feather a rich and gloſſy purple ſpot, changeable to green, to blue, or gold, in different points of view; lower part of the back and rump brown, ſpotted with white, and body beneath brown, ſtriated tranſverſely with black; upper tail coverts longer than the tail, and each marked with a fine purple ſpot near the end, encircled with black and orange; legs and claws brown. This is the deſcription of the male. The female is one third ſmaller; head, neck, and upper parts brown; head ſmooth; feathers on the upper parts marked with a dull blue ſpot, encircled with dull orange; and the legs have no ſpurs.

BICARI, in *Geography*, a river of Sicily, which runs into the Termini, 2 miles weſt of Selafani.

BICARINATA, in *Zoology*, a ſpecies of Lacerta, with compreſſed tail of moderate length, and carinated above; on the back four rows of carinated ſcales. This is of a greyiſh colour, and inhabits South America and India. Gmel. &c.

BICAUDALIS, in *Anatomy*, an appellation given by ſome anatomiſts to a muſcle of the external ear, uſually denominated the *retrahens*, or *retrahentes auris*, which ſee.

Bicaudalis, in *Ichthyology*, a ſpecies of Ostracion, of a triangular form, with two ſub-caudal ſpines, and ten rays in the dorſal fin. Gmelin. There is a ſuppoſed variety of this fiſh found in India, and deſcribed by Artedi, in which the body is entirely covered with ſpots and tubercles.

BICE, or Bise, among *Painters*, a blue colour, prepared from the *lapis Armenus*, formerly brought from Armenia, but now from the ſilver mines in Germany. Phil. Tranſ. N° 179. p. 26. Doſſie, v. i. p. 95. Bice is ſmalt reduced to a fine powder by levigation. See Smalt.

The word comes from the barbarous Latin *biſus*, or *biſius*; and that, perhaps, from the French *bis*, *grey*, *griſius*; whence *biſius panis*. Vide Du-Cange, Gloſſ. Lat. tom. i. p. 565. Skin. Etym. in voc.

Bice bears the beſt body of all bright blues, uſed in common work; but is the paleſt in colour. It works indifferently well; but inclines a little to be ſandy, and therefore requires good grinding on a very hard ſtone, and ſhould be waſhed before it is uſed. It lies beſt near the eye of any blue now in uſe, except ultramarine. Its goodneſs lies in the brightneſs and coolneſs. It was formerly uſed in oil, and more frequently in water colours; but it is now much out of uſe. We have alſo a green bice, made of the blue, with the addition of orpiment; and ſeveral compoſitions of indigo and verditer, with chalk and other cheap ſubſtances, are ſold under the name of bice.

BICE, in the *Mythology of the Hindoos*, the name of one of their Caſts, proceeding from Brahma, the immediate agent of the creation, under the ſupreme power. It derives its appellation from the belly or thighs, and denotes nouriſhment, and it was deſtined by its founder to provide the neceſſaries of life by agriculture and traffic.

BICEPS, from *bis* and *caput*, in *Anatomy*, is a name common to ſeveral muſcles, which conſiſt of two diſtinct portions, called heads. Thoſe which are commonly known at preſent by that appellation are the following.

Biceps *flexor cubiti*. The longer portion, or head, of this muſcle, ariſes by a tendon from the upper part of the glenoid cavity of the ſcapula; it then paſſes through the ſhoulder joint, and deſcends in the groove in the upper part of the os brachii, afterwards the fleſhy fibres begin to be attached to it. The ſhorter portion ariſes tendinous and fleſhy from the coracoid proceſs of the ſcapula, in common with the coraco-brachialis muſcle; a little below the middle of the os brachii, the heads unite and form a bulky muſcle, the fibres of which terminate below in a ſtrong roundiſh tendon, which is inſerted into a tubercle, at the upper end of the radius, at that part which is next to the ulna. At the commencement of the lower tendon of this muſcle, an aponeuroſis is ſent off from it, which ſoon expands into the faſcia of the fore-arm.

The uſes of this muſcle are numerous, and the conſideration of them affords a good demonſtration of the impropriety of denominating a muſcle from any ſingle office which it may ſerve, as it tends to limit our ideas of its utility. The action of this muſcle tightens the faſcia of the fore arm; it turns the hand ſupine; it bends the joint of the elbow; it raiſes the arm towards the ſhoulder; and occaſionally it brings the bones of the ſhoulder to the arm.

Biceps *flexor cruris*. The long portion, or head, of this muſcle ariſes, in common with the ſemi-tendinoſus, from the upper and back part of the tuberoſity of the os iſchium; the ſhort portion ariſes from the linea aſpera on the back part of the thigh-bone. Theſe two portions having conjoined, produce a ſtrong tendon a little above the external condyle of the os femoris, which forms the outer ham ſtring, and which is attached to the upper part or head of the fibula. The chief uſe of this muſcle is to bend the leg upon the thigh, and when it is brought into that ſituation, to turn the leg outwards.

BICESTER, in *Geography*, a market-town of Oxfordſhire, England, is ſituated in a valley on the banks of a ſmall river, which falls into the Charwell, at Iſlip. It is a large reſpectable town, divided into two parts, called Market-end, a pariſh, and Kings-end, a hamlet. This place and its vicinity have been poſſeſſed by the Romans, as its name implies; and many Roman coins, and other memorials of that people, have been diſcovered here and at Alceſter, or Old Cheſter, at different times. The embankments at the latter place are nearly obliterated by the plough; but from the name, and the antiquities that have been found, it ſeems evidently

dently to have been a Roman ſtation. "Alcheſter, Al-cair, or Cair-Allect," ſays Dr. Plott, "was a walled town that ſtood in the north-eaſt parts of Oxfordſhire, built, as may be collected from many probabilities, by Caius Allectus, one of the thirty tyrants, who, by ſlaying his dear friend and emperor Caraufius, obtained the ſole government of Britain."

The Oxford canal paſſes through Lower Reyford, near this town, and conveys many articles of trade to and from it. Here are a large weekly market on Fridays, and ſix fairs annually, beſides two annual marts in ſpring and autumn for the ſale of ſheep and cattle. The town has a well eſtabliſhed charity ſchool for 30 boys; and a charity, called the feoffees. This is endowed with lands, of about 120l. yearly rent, which is applied towards the relief of decayed tradeſmen. The principal manufactory of this town is common ſlippers; and it is ſuppoſed that there are more made here than in any other town in England. Many females are employed in lace-making. The church is a large handſome building, with a lofty tower, and ornamented with many coſtly monuments. Here is a handſome meeting-houſe for the diſſenters. The pariſh of Market-end, and hamlet of Kings-end, contain 410 houſes and 1946 inhabitants. Plott's Hiſtory of Oxfordſhire. Camden's Britannia.

BICHE, Biche de Guiane, in *Zoology*, a name aſſigned by one French writer (des March. Voy.) to the *Braſilian muſk* of Pennant, *moſchus Americanus* of Gmelin. Biche *des Bois* is alſo the name of *cervus Mexicanus* (Gmelin) in Barrer. Fr. équin. 151.

BICHET, a corn meaſure, containing about a Paris *minot*, chiefly uſed in Burgundy and the Lyonnois.

Bichet denotes alſo a certain quantity of land, as much as may be ſown by a bichet of corn.

BICHNI, in *Geography*, a town of Perſia, in the province of Erivan, 30 miles N.N.E. of Erivan.

BICHON, in *Zoology*, the name given by Buffon to *canis melitæus* of Ray.

BICHONNOWY, in *Geography*, a town of Ruſſia, in the government of Mohilef, ſeated on the Dnieper, 32 miles ſouth of Mohilef. N. lat. 53° 20'. E. long. 30° 50'. This is one of the diſtricts of the government, called alſo Staroi Bykhof, or Biechov Starov.

BICINCTA, in *Entomology*, a ſpecies of Apis, deſcribed by Schranck Inſ. Auſtr. It is black and villous; mouth and abdomen gloſſy, with two white belts on the latter. Inhabits Upper Auſtria.

Bicincta, a ſpecies of Vespa, of a black colour, with a ſpotted thorax, and two yellow bands on the abdomen. A ſmall inſect, and inhabits the cape of Good Hope. Fabricius.

Bicincta, a ſpecies of Tenthredo, with a black body; belts on the abdomen, vent, mouth, and ſhanks yellow. A native of Europe. Fabricius. Abdominal yellow belts two, from which it is ſpecifically named *bicincta*.

Bicincta, a ſpecies of Musca (*Syrphus*), found in the north of Europe. It is black; antennæ elongated; ſides, dots, and two abdominal belts yellow. Linn. Fn. Suec. &c.

Bicincta, a ſpecies of Scolia, of a black colour, and hairy; abdomen with two yellow bands; wings blueiſh black. A native of America. Fabr. Gmel. &c. This inſect is *ſphex radula* of Sulzer.

BICINIUM, from *bis* and *cano*, *I ſing*, in *Church Muſic*, the ſinging of two, either together or alternately. In which ſenſe. the word ſtands oppoſed to *monody*.

BICKAGER, in *Geography*, a town of Norway, 70 miles S.S.W. of Drontheim.

BICKANEER, Bicaneer, or Beykaneer, a town of Hindoſtan, the capital of a circar or diſtrict of the ſame name in Marwar, the north diviſion of Agimere. This country is ſandy and deſert, and in great want of water. Of this country little is known; it is governed by a rajah, and inhabited by Rajpoots. The town is ſituated about 42 miles weſt of Nagore, and 80 W.N.W. of Agimere. N. lat. 27° 12'. E. long. 74°.

BICKERN *of an Anvil*, the pike, or beak-iron.

BICLINIUM, from *bis*, and κλινη, *bed*, in *Antiquity*, two beds about a table; or, as ſome ſay, rather a bed whereon two perſons lay to eat.

BICKERTON's Island, in *Geography*, a name given by Capt. Edwards, in 1791, to an iſland in the South ſea, near the Friendly iſlands, called by the natives Lattai, and diſcovered by Maurelle in 1781. It conſiſts chiefly of a vaſt conical mountain, the ſummit of which appeared to be burnt, but the ſides were covered with trees; and it is ſurrounded with a lower border, which is very fertile, and affords freſh water. This iſland ſupplies cocoa-nuts and bananas. S. lat. 18° 47' 20". W. long. 174° 48'.

BICOCCA, a town of Italy, in the duchy of Milan, near which the French were defeated by the Imperialiſts in 1552; 2 miles N.E. of Milan.

BICOLOR, in *Conchology*, a ſpecies of Donax, with an ovate ſhell marked with elevated ſtriæ, which decuſſate a few tranſverſe ones; ruſous, with a white ray on one ſide. Gualt. Gmel. &c.

Bicolor, a ſpecies of Pinna found in the Red ſea. This kind is thin, inflected at the lateral margin; yellowiſh, with black brown rays, and a few longitudinal ſtriæ. Chemnitz. This ſhell is thorny, elongated, with curved ſtriæ at the curved margin; the largeſt end rotundated.

Bicolor, in *Entomology*, a ſpecies of Apis that inhabits Denmark. The thorax villous and ferruginous; abdomen black and immaculate. Fabricius.

Bicolor, is alſo an Indian ſpecies of Apis, of a black colour, with the abdomen hairy; fulvous above, and ſnowy-white beneath. Fabricius. This bears ſome reſemblance to apis centuncularis, but is larger.

Bicolor, a ſpecies of Attelabus found in Europe. It is of a black colour, with the thorax and wing-caſes reddiſh; ſcutel, thighs, and ſhanks at the baſe, and tip black. Linnæus Fn. Suec.

Bicolor, a ſpecies of Buprestis, with pointed wing-caſes, of a braſſy-green colour, with a yellow ſpot; breaſt and abdomen yellow. Fabricius. Inhabits South America.

Bicolor, a ſpecies of Cantharis, of a yellow colour, with half of the wing-caſes blue. Thunberg. Inhabits the cape of Good Hope.

Bicolor, a ſpecies of Carabus that inhabits North America. It is black above, and ferruginous beneath. Fabricius.

Bicolor, a ſpecies of Cerambyx that inhabits Cayenne. This is ferruginous; thorax with two ſpines and tubercles; wing-caſes beyond the middle, with the abdomen black. Fabricius.

Bicolor, a ſpecies of Chrysomela, of a braſſy-green above, and violaceous beneath. Fabricius. Inhabits Alexandria.

Bicolor, a ſpecies of Cicada (*Cercopis*), of a griſeous colour, with the upper part of the thorax ſanguineous. Linn. Muſ. Leſk. A native of Europe.

Bicolor, a ſpecies of Cryptocephalus (*Eroſylus*). This inſect is of a black colour, and braſſy above. Fabricius. A native of New Holland.

Bicolor, a ſpecies of Curculio found in America.

This is of a black colour, with a rufous thorax and wing-cafes. Fabricius.

Bicolor, a fpecies of Dermestes, of an oblong form and black colour; beneath teftaceous; wing-cafes ftriated. Fabricius. Inhabits Germany.

Bicolor, a fpecies of Elater, of a browniſh ferruginous colour; head and thorax brown; wing-cafes ſtriated. Inhabits Europe. Linn. Muſ. Lefk.

Bicolor, a fpecies of Gryllus (*Locuſta*), deſcribed by Linnæus. It is griſeous, apterous, with the hinder thighs rufous beneath.

Bicolor, an African fpecies of Ichneumon, of a ferruginous colour; tip of the abdomen, breaſt, and end of the upper wings black. Gmelin.

Bicolor, a fpecies of Lampyris (*Pyrocroa*), of a ſanguineous colour, with the poſterior end violaceous. Fabricius. This is *Cantharis bicolor* of Amoen. acad. It inhabits America, and has the antennæ flattened.

Bicolor, a fpecies of Leptura, of a pale ferruginous colour, with the eyes, wing cafes, wings, and upper part of the vent black. Swederus Nov. Act. Stockh.

Bicolor, a fpecies of Leptura (*Donacia*) that inhabits Europe. It is of a golden colour, with the upper part of the thorax, and the wing-cafes green; the latter ſtriated with impreſſed dots; poſterior thighs dentated. Gmelin, &c.

Bicolor, a fpecies of Lytta, of a teſtaceous colour; wing-cafes black at the tip. Geoffroy. Inhabits France.

Bicolor, a fpecies of Mordella, deſcribed by Forſter (Nov. Inſ.). It is of a black colour; wing-cafes teſtaceous, with the tip and band in the middle black. Very ſmall. Inhabits England.

Bicolor, a fpecies of Nitidula found in Europe. This inſect is ferruginous, with black wing-cafes, having a ferruginous band at the baſe, and a ſpot of the ſame colour near the apex. Fabricius.

Bicolor, a fpecies of Phalæna (*Bombyx*) found in Saxony. The wings are white, with a large yellow ſpot, with black marks. Fabricius.

Bicolor, a fpecies of Scarabæus, with the thorax very ſlightly armed, and on the head a ſingle tubercle; wing-cafes black; abdomen rufous. Fabricius.

Bicolor, a fpecies of Silpha, of a brown colour, with rufous legs. Linn. &c. A native of Europe.

Bicolor, a fpecies of Sphex that inhabits New Holland. This is of a black colour; head, abdomen at the tip, and wings yellow; the latter brown at the tip. Gmel. This inſect was firſt deſcribed by Fabricius from a ſpecimen in the collection of ſir Joſeph Banks, under the ſpecific name *bicolorata*.

Bicolor, a fpecies of Staphylinus, of a black colour, with the antennæ, wing-cafes, and legs ferruginous. Linn. A native of Europe.

Bicolor, a fpecies of Tenthredo, of a bluciſh black, with the abdomen and baſe of the wings yellow; a band of black. Schranch. Inhabits Auſtria.

Bicolor, a fpecies of Vespa that inhabits China; and in ſize and appearance reſembles the common waſp. It is yellowiſh: antennæ above, crown, thorax, and vent brown. Fabricius, &c.

Bicolor, in *Ichthyology*, a ſpecies of Gobius, found in the Mediterranean ſea. It is of a brown colour, with all the fins black. Brün. piſc.

Bicolor, in *Ornithology*, a ſpecies of Alcedo, of a green colour, and golden rufous beneath; a black and white waved band on the breaſt; wings and tail ſpotted with white. Gmelin. This bird is a native of Cayenne. Buffon calls it *Martin pêcheur vert et roux de Cayenne*; pl. enl.; and Latham the *rufous and green kingfiſher*. Length eight inches: bill black; legs reddiſh; breaſt of the female not banded.

Bicolor, a ſpecies of Fringilla, that inhabits the woods of Jamaica and Bahama iſlands, and is called by Engliſh writers the *Bahama ſparrow*. The head and breaſt are black; back, wings, and tail, greeniſh. Gmelin. The length of this bird is four inches; its note very monotonous. Briſſon calls it *Chloris Bahamenſis*; and Buffon *Verdinere*.

Bicolor, a ſpecies of Lanius, of a blue colour; white beneath; frontlet black. Linn. &c. This is *Loxia Madagaſcarina* of Linn. Syſt. Nat. edit. 12; *Lanius Madagaſcarienſis cæruleus* of Briſſon; *Pie-griefche bleu de Madagaſcar* of Buffon; and *Blue ſhrike* of Latham. It is about ſix inches and a half in length, and, as the ſynonyms imply, is a native of Madagaſcar.

The bill, head, margin of the quill feathers, two middle tail feathers, and exterior margin of the four next blue; legs and claws black. Female, ſordid white beneath.

Bicolor, a ſpecies of Loxia found in the Eaſt Indies. Gmelin very briefly deſcribes it as being of a fuſcous colour, and red beneath. This is *Fringilla rubra minor* of Briſſon; *Brunor* of Buffon; *Little brown bulfinch* of Edwards; and *Orange-breaſted groſbeak* of Latham. There is likewiſe a variety of this kind of a browniſh colour, white beneath, and chin inclining to browniſh. About three inches and a quarter in length; bill whitiſh; legs fuſcous.

Bicolor, a ſpecies of Muscicapa, of a black colour; front, ſpace round the eyes, throat, rump, ſpurious wings, band on the greater wing-coverts, tip of the tail, and under parts of the body, white. Gmelin. Buffon calls this *Gobe mouche à ventre blanc de Cayenne*; and Edwards and Latham *Black and white fly-catcher*. A variety of this bird is white, except the hind part of the head, and neck, rump, wings, and tail, bill, and legs, which are black. The female is of an uniform grey colour. Inhabits the moiſt meadows of Guiana.

Bicolor, a ſpecies of Picus, called by Latham, after Buffon, the *Encenada woodpecker; Epeiche ou pic varié de Encénada*, Buffon. This is varied with greyiſh and white; head creſted, white on the ſides; quill feathers brown, ſpotted with white. Gmelin, &c.

The length of this beautiful bird is about ſix inches; bill lead colour; irides white; plumage browniſh-grey and white finely blended; above, the colours are intermixed tranſverſely, and beneath in a perpendicular direction; creſt on the ſides intermixed with crimſon; ſides of the head white, verging to brown; legs lead colour. The female has no creſt, and is entirely brown.

Bicolor, a ſpecies of Trochilus, of a ſmaragdine-golden colour, with the head and throat blue. Gmelin. This is of the middle ſize, and inhabits Guadaloupe. It is *Colibri* Nr. 2. of Fermin. Surin.; *Saphir-emeraude* of Buffon; and *Sapphire* and *emerald humming-bird* of Latham.

Bicolor, a ſpecies of Turdus, of a brown colour, tinged with green; abdomen and vent white. This inhabits the cape of Good Hope; and is ten inches long. Buffon calls it *Merle brun du cap de bonne eſpérance*; and Latham the *White-rumped thruſh*.

BICOLORA, in *Entomology*, an African ſpecies of Phalæna (*Noctua*). Wings yellow, with a broad brown poſterior margin.

BICOLORATA, a ſpecies of Phalæna (*Geometra*) with the wings bluciſh and ſtriated; anterior black at the tip, and ſpotted with white. Inhabits Surinam. Cramer, &c.

Bicolorata, a ſpecies of Scarabæus (*Melolontha*) found at the cape of Good Hope. It is glabrous green, beneath

beneath teſtaceous, legs tipped with gold. Fabricius, &c.

Bicolorata, a ſpecies of Phalæna (*Geometra*) with blueiſh ſtriated wings; firſt pair black at the tips, with white ſpots. A large inſect, and inhabits Surinam. Fabricius.

BICORDATA, a ſpecies of Cicada (*Ranatra*), with black wing-caſes, both ſides, and line in the middle, with the legs yellow. Scopoli. Inhabits Carniola, on the nut-tree.

BICORDATUS, in *Natural Hiſtory*, a ſpecies of Echinus, having the crown doubled. Leſke apud Klein, &c.

BICORNE Os, in *Anatomy*, is a name which has been given to the os hyoides.

BICORNES, from *bis*, and *cornu*, *horn*, in *Botany*, plants whoſe antheræ have the appearance of two horns. The term likewiſe expreſſes an order of plants of the Fragmenta Methodi Naturalis of Linnæus.

BICORNIGER, in *Mythology*, an appellation of Bacchus, who is ſometimes repreſented with horns, as ſymbols of the rays of the ſun, or of the virtue which he imparts to wine. The Arabians gave this name to Alexander the Great, either to expreſs his having added the eaſtern to the weſtern empire, or in alluſion to medals on which he is repreſented with horns, under a pretence that he was the ſon of Ammon.

BICORNIS, Musculus, in *Anatomy*, is an appellation formerly given to thoſe muſcles uſually denominated Extenſores carpi radiales; which ſee.

Bicornis, or *Tricornis pollicis manus*, are terms formerly applied to deſignate the three extenſor muſcles of the thumb.

Bicornis, in *Entomology*, a ſpecies of Scarabæus, with two horns on the thorax; a recurved, ſingle-toothed horn on the head, and rufous wing-caſes. Aubert. Jablonſky. Inhabits South America; of a middle ſize among the horned kind of Scarabæi.

Bicornis, a ſpecies of Hispa, with pectinated antennæ; thorax and wing-caſes braſſy-green; head two-horned. Inhabits North America. Fabricius.

Bicornis, a ſpecies of Curculio, with acutely dentated thighs, and two teeth on the head. Fabricius. Inhabits New Zealand, and is varied with brown and cinereous.

Bicornis, a ſpecies of Cassida that inhabits South America. It is of a cyaneous blue colour, with a truncated ſpine on the anterior angle of the wing-caſes. Linn. Fabr. &c.

Bicornis, a ſpecies of Mantis, found in South America, and it is ſaid alſo in India. The thorax is ſmooth; head bipartite and ſubulate. Linn. &c. The legs are unarmed.

Bicornis, a ſpecies of Apis, with two horns in front; head black; abdomen hirſute and rufous. A native of Europe. Fabricius.

Bicornis, a ſpecies of Aranea, with two horns on the abdomen. Lepechin. it. Found in the woods of Siberia.

Bicornis, in *Natural Hiſtory*, a ſpecies of Planaria, with an ovate-lanceolate body obtuſe at both ends, of a greyiſh aſh colour, dotted with black; and two very ſhort divergent tubes on the fore-part. Gmelin. This is *Faſciola punctata* of Pallas.

Bicornis, a ſpecies of Actinia, found in the North ſea. This kind is hemiſpherical-oval, and glabrous with two horns. Müll. Zool. Dan.

BICORPOREA *ſigna*, from *bis*, and *corpus*, *body*, in *Aſtronomy*, thoſe ſigns of the zodiac which have two bodies, or conſiſt of two figures. Such are gemini, or the twins; alſo piſces, or ſagittarius, conſiſting of a man and a horſe.

BICOSTELLA, in *Entomology*, a ſpecies of Phalæna (*Tinea*) found in Europe. This is cinereous, with a brown ſtripe on the anterior wings; feelers advanced; antennæ downy. Linn. Fabr. &c.

BICQUELY, in *Geography*, a town of France, in the department of the Meurte, and chief place of a canton in the diſtrict of Toul, 1¼ league ſouth of Toul.

BICUCULLATA, in *Botany*. See Fumaria.

BICUSPIDES, *dentes molares*, in *Anatomy*, are the two ſmall grinders, which are next the front teeth. See Teeth.

BIDA Colonia, Bleeda, in *Ancient Geography*, a town of Africa, mentioned by Ptolemy, and ſituated in the interior part of Mauritania Cæſarienſis, S.W. of Iconium. See Bleeda.

BIDACHE, in *Geography*, a town of France, in the department of the Lower Pyrenées, and chief place of a canton in the diſtrict of Uſtaritz, 5 leagues eaſt of Bayonne. The town contains 2,017 inhabitants, and the canton 9,706. Its territorial extent is 212½ kiliometres, and it has 9 communes. N. lat. 41° 31′. W. long. 10°.

BIDAL, or Bidale, in our *Ancient Cuſtoms*, denotes the invitation of friends to drink ale at ſome poor man's houſe, who, in conſideration hereof, expects ſome contribution for his relief. See Ale.

BIDALDI, an ancient kind of foot-ſoldiers mentioned by the French hiſtorians, armed with two darts.

Hence the origin of the word, which ſeems to be a corruption for "bidardi," or "á binis dardis." They are alſo called *bidarii*, *bidaus*, *bideaux*, *bidaults*, and *pitauts*.

BIDASSOA, or Vidasoa, in *Geography*, a river which riſes in the Pyrenées, and runs into the bay of Biſcay between Andaye and Fontarabia, ſeparating France from Spain. This river was for a long time a ſubject of diſpute between France and Spain, each country laying an excluſive claim to it; but in the 15th century Louis XII. of France, and Ferdinand, king of Spain, agreed, that it ſhould be common between the two nations, and that the duties paid by thoſe who paſs from Spain to France ſhould belong to the latter, and of thoſe who paſs the contrary way to the former. Buffon obſerves, that the inhabitants of the environs of this river have ears of an uncommon ſize.

BIDBURG, a town of the Netherlands, in the duchy of Luxemburgh, containing two pariſh churches, and a convent; 11 leagues N.N.E. of Luxemburg.

BIDDEFORD, or Bideford, an ancient ſea-port, market, and borough town of Devonſhire, England, is ſituated near the ſouthern coaſt on the eaſtern and weſtern banks of the river Torridge, which is of conſiderable breadth here, and at ſpring tides riſes to the height of eighteen feet. The greater part of the town is built on the declivity of a ſteep eminence, and many of the houſes being compoſed of timber, brick, cobb, or mud walls, preſent rather a poor appearance. Bideford does not appear to be noticed in the Domeſday ſurvey, but ſoon after the conqueſt it was beſtowed with Kilhampton in Cornwall, on Richard de Grenaville, a Norman knight, who accompanied the conqueror into England, and was anceſtor to the illuſtrious family of the Granvilles, who for upwards of five hundred years continued proprietors of the lordſhip. Some of this family have greatly ſignalized themſelves in the public events of England; and the names of two, ſir Richard Granville and ſir Beval Granville, are honourably noticed in the hiſtorical annals of this country. This town, though deſcribed as a borough in a

charter of Edward I. and afterwards repreſented in ſeveral parliaments, ſeems to have been greatly reduced at the time when Leland viſited it, for he merely mentions the river and the bridge. Camden, however, ſpeaks of it as "remarkable for its populouſneſs." At the time of the latter antiquary, Bideford aſſumed a commercial conſequence, and carried on ſome trade with America and Newfoundland. Queen Elizabeth granted it a charter of incorporation, which veſted the government in a mayor, five aldermen, ſeven capital burgeſſes, a recorder, town-clerk, and two ſerjeants at mace. By this charter the inhabitants are empowered to hold a weekly market, and three annual fairs. Another charter was however obtained in 1610, which confirmed the former, and granted the townſmen ſome additional powers and liberties. The patronage and reſidence of ſir Richard Granville and ſir Walter Raleigh proved highly favourable to Bideford; for after theſe worthy knights had diſcovered Virginia and Carolina, they returned to, and ſettled here. In the time of the civil wars, the inhabitants of this place declared themſelves very early in favour of the parliament; but their ſucceſs did not prove equal to their zeal, for in attempting to relieve Exeter, they experienced a ſevere and total defeat, and immediately reſigned Bideford, Barnſtable, and their appendages, to the royaliſts.

In the year 1646, Bideford was ravaged by a plague, which appears to have been occaſioned by the landing of a cargo of Spaniſh wool: an article which at that period conſtituted a principal part of the trade of the town. The credulity and ſuperſtition that characterized the Engliſh in the ſeventeenth century are ſtrikingly exemplified by an occurrence which happened here in 1682. Three poor females were accuſed of witchcraft, and ſo direct and poſitive was the evidence adduced againſt them, at ſeveral examinations before the magiſtrates, that they were committed to Exeter gaol, and ſoon afterwards tried, and executed for their alleged crime.

About the middle of the laſt century, the export trade of Bideford to Newfoundland was ſo conſiderable, that only two other ports in the kingdom employed an equal number of veſſels, and in the export trade only one port excelled it. During the unwiſe adminiſtration, and injurious wars of queen Anne's reign, theſe commercial tranſactions materially ſuffered, and the French privateers obtained ſo many valuable prizes from Bideford bay, that it was emphatically termed the *Golden bay*. The number of veſſels now belonging to this port is almoſt one hundred; theſe vary in burthen from twenty to two hundred and fifty tons, and are chiefly employed in the conveyance of coal and culm; in the exportation of oak bark to Ireland and Scotland; in the herring trade; and in the importation of fiſh from Newfoundland. The quay is conveniently ſituated near the centre of the town, and the body of the water at high tides will bring up veſſels of 500 tons burthen. The chief manufacture of this place is that of coarſe brown earthenware, which is made with clay brought from Fremington near Barnſtaple. The price of this is only two ſhillings and ſixpence per ton. The bridge at Bideford, built of ſtone, conſiſts of twenty-four irregular arches, and was conſtructed about the middle of the fourteenth century. It is 677 feet in length, and was conſtructed at the expence of ſir Theobald Granville, knt. and at the inſtigation of the biſhop of the dioceſe, who granted indulgences to ſuch perſons as gave money in aid of the work. The church, a ſpacious building, was erected in the form of a croſs about the middle of the fourteenth century. A houſe of induſtry has lately been erected here; and a free ſchool, and free grammar ſchool are ranked among the charitable foundations of the town. The market-place is ſpacious, and the town-hall is a large convenient building with two priſons beneath it. In the pariſh of Bideford are 606 houſes and 2987 inhabitants. This town is 211 miles S.W. from London.

Thomas Stucley, a deſcendant of the celebrated chaplain to Oliver Cromwell, was a native of Bideford, and was diſtinguiſhed for many eccentricities of character. John Shebbeare M.D. an author of ſome eminence, was alſo born here in the year 1709.

About five miles eaſt of this town is Tawſtock, the ſeat of ſir Bourchier Wrey, Bart. This place is mentioned by different authors as remarkable for embracing at one view "the beſt manor, beſt manſion, fineſt church, and richeſt rectory in the county." Biſhop's Tawton, near Tawſtock, is ſaid to have been the firſt ſeat of the biſhop of this dioceſe. Watkins's Hiſtory of Bideford. Maton's Tour through the weſtern counties. Prince's Worthies of Devonſhire. Beauties of England and Wales, vol. iv.

Biddeford, a port of entry and poſt-town of America, in York county, and diſtrict of Mayne, on the ſouth-weſt ſide of Saco river, on the ſea-coaſt, 14 miles S.W. from Portland, 24 N.E. from York, and 105 from Boſton. It contains 1018 inhabitants, and the county-courts are held here and at York. N. lat. 43° 26'. W. long. 70° 25'. The bay of Biddeford lies at the mouth of the river Saco, and has Black point for the N.E. point, and cape Porpoiſe for the S.W. point.

BIDDING, is uſed for proclaiming or notifying; alſo for offering a price for goods put up by auction.

Bidding *of the beads*, a charge or warning which the pariſh prieſt gave to his pariſhioners at certain ſpecial times, to ſay ſo many pater-noſters, &c. on their beads.

Biſhop Burnet (Hiſt. Ref. vol. ii. p. 20.) has preſerved the form, as it was in uſe before the reformation, which was this: after the preacher had named and opened his text, he called on the people to go to their prayers, telling them what they were to pray for; "Ye ſhall pray (ſays he) for the king, for the pope, for the holy catholic church, &c." When this was done, all the people ſaid their beads in a general ſilence, and the miniſter kneeled down and likewiſe ſaid his: they were to ſay a pater-noſter, an ave-maria, Deus miſereatur noſtri, domine ſalvum fac regem, gloria patri, &c., and then the ſermon proceeded.

BIDDLE, John, in *Biography*, a diſtinguiſhed perſon among the Socinians, and reckoned the father of the Engliſh ſect bearing this denomination, and lately aſſuming that of Unitarians, was born at Wotton-under-Edge in Glouceſterſhire, in 1615; and after a previous grammatical education, in the courſe of which he exhibited ſpecimens of his talents and improvement, admitted, in 1632, a ſtudent at Magdalen-Hall, in the univerſity of Oxford. Here he acquired great reputation for learning and prudence, both as a ſtudent and a tutor: and having taken his degrees of bachelor of arts in 1638, and of maſter of arts in 1641, he was, in this latter year, recommended by the principal perſons in the univerſity to the magiſtrates of Glouceſter, and appointed by them maſter of the free ſchool of St. Mary de Crypt, in that city. In this office he completely anſwered the expectations of his conſtituents, and gave great ſatisfaction to the parents of the young perſons who were entruſted to his care. But he did not long enjoy, without moleſtation, the advantages of this ſituation; for he was led, by a diligent ſtudy of the ſcriptures, to adopt notions that were deemed heretical, concerning the Trinity, and more particularly to deny the deity of the Holy Spirit. Failing to give ſatisfaction to the magiſtrates, before whom he was ſummoned, by his confeſſion in 1644, he drew up a more explicit account and defence

defence of his ſentiments on this ſubject in a tract, entitled, "Twelve arguments, drawn out of the ſcriptures, wherein the commonly received opinion touching the deity of the Holy Spirit is clearly and fully refuted." A copy of this treatiſe, which he had ſhewn to ſome of his friends, having been, by the treachery of an acquaintance, delivered to the magiſtrates of the city, and to the parliament committee then reſiding there, he was committed, in December 1645, to the common gaol. He was releaſed, however, on giving ſecurity for his appearance when called for. Six months after he had obtained his liberty, he was ſummoned to appear before the parliament at Weſtminſter, and examined by a committee. As he freely profeſſed his diſbelief of the commonly received opinion concerning the divinity of the holy Spirit, he was committed to the cuſtody of one of the officers, and kept in that ſtate of reſtraint for five years. In the mean while, his book entitled "Twelve arguments, &c." was publiſhed, and being declared blaſphemous againſt the divinity of Chriſt, the houſe, in 1647, ordered it to be burnt by the common hangman. In the following year, the author, perſiſting in his opinions, and avowing his ſenſe of their importance, publiſhed two other tracts of a ſimilar nature; one entitled, "A confeſſion of Faith touching the holy Trinity, according to the ſcripture;" and another entitled, "The teſtimonies of Irenæus, Juſtin Martyr, Tertullian," and of ſeveral other early writers, relating to the ſame ſubject. Theſe books excited an alarm, and were the means of procuring a ſevere ordinance of parliament, iſſued in May 1648, at the ſolicitation of the Aſſembly of divines, who acted in this inſtance in a manner that entails diſgrace on their memory, and denouncing the penalty of death againſt thoſe who held opinions contrary to thoſe that were eſtabliſhed reſpecting the Trinity, and ſome other doctrines, accounted blaſphemies and hereſies; and ſevere penalties on thoſe who differed in leſſer matters. By this infamous and execrable decree the fate of Biddle ſeemed to be inevitable. But he eſcaped in conſequence of a diſſenſion in parliament, ſupported by a party in the army, to whoſe caſe this ordinance would have extended. After the death of the king, the Independents acquired influence, and introduced a kind of general toleration, under which Biddle was allowed to go to Staffordſhire, where he was hoſpitably received by a juſtice of the peace, who, at his death, left him a legacy. From this retired aſylum, however, he was remanded by preſident Bradſhaw to cloſer confinement, in which ſtate he continued for ſeveral years, under an imputation of blaſphemy and hereſy, which deprived him of all ſociety, and reduced him to ſuch lamentable indigence, that his whole ſupport for a conſiderable time was a draught of milk morning and evening. The only divine who viſited him, during this period, was Mr. Peter Gunning, afterwards biſhop of Ely. In theſe circumſtances he obtained temporary relief by being employed in correcting the preſs for a Greek Septuagint, printed in London by Roger Daniel; and in 1651, he regained his liberty by the general act of oblivion, publiſhed by the parliament in this year. Of this liberty he availed himſelf, by inſtituting a Sunday's lecture for reading and expounding the ſcripture, and thus propagating his opinions. The Preſbyterian miniſters were rendered uneaſy by his zeal and ſucceſs, more eſpecially as they could derive no aſſiſtance for reſtraining him from the ſecular power. Not ſatisfied with the opportunities he enjoyed of diſſeminating his ſentiments from the pulpit, and in the intercourſe of private friendſhip, he had again recourſe to the preſs, and in 1654, publiſhed his "Twofold Scripture catechiſm;" one larger and more comprehenſive, and the other more brief, for the uſe of children. For this publication he was called to the bar of Cromwell's parliament, and committed to the Gate-houſe, where he was debarred the uſe of pen and ink, and the acceſs of any viſitor; and his books were alſo ordered to be burnt. Although a bill was brought into parliament for puniſhing him, he obtained his liberty after ſix months' confinement, by due courſe of law. Some time after, he had a diſpute with a baptiſt teacher; in the courſe of which he made uſe of ſome expreſſions, for which he was thrown into Newgate, and tried for his life at the next ſeſſions, on the ordinance above-mentioned. On this occaſion counſel was at firſt denied him, but afterwards granted, and the trial deferred. In the mean while Cromwell interfered, and diſapproving of this kind of intolerance, contented himſelf at firſt with detaining him in priſon; but afterwards, in order to ſilence the clamours and petitions that were preferred againſt him, baniſhed him for life to St. Mary's caſtle in the iſland of Scilly, aſſigning him an annual ſubſiſtence of 100 crowns. In this place of exile Biddle continued three years, applying himſelf to cloſe ſtudy, and particularly to that of the Apocalypſe. His friends at length prevailed with Cromwell to recall him; and in 1658, as no charge appeared againſt him, he was liberated. He then became paſtor of an independent ſociety in London, and propagated his opinions without moleſtation, till the fear of the preſbyterian parliament aſſembled by Richard Cromwell, and the advice of his friends, induced him to retire into the country. On the diſſolution of that parliament, he returned to his former ſtation. After the reſtoration of Charles II. he withdrew from public ſervice, and exerciſed his miniſtry in private aſſemblies with his ſelect friends. However, in June 1662, their meeting was diſcovered, and both he and his friends were apprehended and committed to priſon; and at length, by proceſs of law, each of his hearers was fined 20l. and Biddle himſelf 100l.; and they were ordered to remain in priſon till theſe fines were paid. The cloſe confinement and foul air of a priſon, within five weeks, brought upon him a diſtemper, which terminated his life September 22, 1662, in the 47th year of his age: and thus was his death haſtened by the intolerance which perſecuted him during the greateſt part of his life. Mr. Biddle poſſeſſed a conſiderable degree of learning; and with the Scriptures he was ſo converſant, that he could repeat the New Teſtament from memory, both in Engliſh and in Greek, as far as the 4th chapter of the revelation of St. John. He poſſeſſed alſo, with this retentiveneſs of memory, powers of reaſoning, which eminently qualified him for diſſeminating his peculiar opinions, and gaining proſelytes. In his private character he was diſtinguiſhed by his piety and devotion, by his moderation and temperance, by his condeſcenſion and benevolence, and by his irreproachable virtue. As he differed in ſome reſpects from Socinus and the foreign Unitarians, his followers were for ſome time denominated "Biddellians;" but the name did not ſubſiſt after his death Biog. Brit. Toulmin's Life of Biddle, in Unitarian tracts, vol. iv. 1791. Neal's Hiſt. of the Puritans, vol. ii. p. 470, 4to.

BIDDLES, in *Geography*, a ſettlement on a branch of Licking river, in Bourbon county, Kentucky, about 6 miles N.W. from Millers on the N.E. ſide of the ſame branch, and 32 miles N.N.E. from Lexington.

BIDENS, ſo named from the ſeed being terminated with two teeth or awns, in *Botany*. Lin. gen. n. 932. Reich. n. 1012. Schreb. 1267. Tournef. t. 262. Juſs. 188. Dill. Elth. 43. 47. Gærtn. t. 167. Ceratocephalus. Vaill. Act. Gall. 1720. ſ. 47, 48, 49. Claſs, *ſyngeneſia polygamia æqualis*. Nat. ord. *compoſitæ oppoſitifoliæ. Corymbiferæ*, Juſſ. Gen. Char. *Calyx*, common, imbricate erect; leaflets often equal,

equal, oblong, channelled, concave. *Cor.* compound, uniform, tubular; corollules hermaphrodite, tubular. Proper. one-petalled, funnel-form; border five-cleft, erect. *Stam.* filaments five, capillary, very short; anther cylindric, tubular. *Pift.* germ oblong; ftyle fimple, the length of the ftamens; ftigmas two, oblong, reflex. *Per.* none: *calyx* unchanged. *Seeds* folitary, obtufe, angular; down with two or more awns, oblong, ftraight, acute, rough-hooked backwards. *Rec.* flat, chaffy; chaffs deciduous, flattifh. *Obf.* In moft of the fpecies an expanding five-leaved calycle furrounds the compound flowers. *Verbefina* differs from *Bident* only in having a ray. Sometimes the coroila has one or two radial florets. Reich.

Eff. char. *Cal.* imbricate. *Cor.* fometimes but feldom with a flofcule or two in the ray. *Seed* crowned with erect, fcabrous awns. *Recept.* chaffy.

Species, 1. B. *tripartita*, trifid water-hemp-agrimony, or bur-marygold. Lin. fp. pl. 1165. Hudf. 355. With. 706. Hull. 181. Relh. 308. Sibth. 248. Abbot. 177. Curt. Lond. fafc. 4. t. 57. Smith. Fl. Brit. 357. 1. Verbefina feu cannabina aquatica, flore minus pulchro, elatior et magis frequens. Raii Synop. 187. Eupatorium cannabinum fœmina. Ger. em. 711. B. Conyza paluftris, fol. tripartito divifis. Loes. pruff. 53. ic. 10. "Leaves trifid, calyxes fomewhat leafy, feeds erect." Root annual; ftem from one to three feet high, with oppofite, reddifh branches, patent, leafy, obtufely quadrangular, furrowed, and fmooth; leaves oppofite, fmooth, deep ferrate, trifid or quinquefid: flowers terminating, folitary, fomewhat erect, with undivided patent leaves; leaflets of the calyx unequal, plane, fmooth, ftreaked with brown; the flofcules uniform, tubulofe, yellow; feeds compreffed, two or three-angled, the angles backward rough, two or three awns, terminating, fomewhat erect, yellow, three-cornered, prickly backward; the chaffs of the receptacle refembling the leaflets of the calyx, but narrower. It is frequent in places inundated, and on the brinks of ditches: flowers in Auguft and September. This plant dyes a deep yellow; for which purpofe the thread or yarn muft be firft fteeped in alum water, then dried and fteeped in a decoction of the plant, and afterwards boiled in the decoction. As by a chemical analyfis it is found to poffefs much the fame qualities as verbefina acmella, it may probably have the fame good effects in expelling the ftone and gravel. 2. B. *minima*, nodding bur-marygold. Lin. fp. pl. 1165. Reich. 3. 703. Hudf. ed. 1. 310. Fl. Dan. t. 312. Abbot. 178. With. 883. 7. Curt. Lond. 3. 55. B. tripartita. *β.* Hudf. 355. B. Cernua. *γ.* Smith. Fl. Br. 357. Verbefina minima. Dill. in Raii Syn. 188. t. 7. f. 2. Giff. 167. App. 66. "Leaves lanceolate feffile; flowers and feeds erect." This was firft marked by Dillenius for a diftinct fpecies. Haller thought it to be no more than a variety of the *cernua*, in which he has been followed by all our Britifh botanifts. Found in dried marfhes. 3. B. *nodiflora*, feffile-flowered bidens. Lin. fpec. 1165. Dill. elth. t. 44. f. 52. Reich. 3. 704. "Leaves oblong, quite entire, one-toothed, ftem dichotomous, flowers folitary, feffile." An annual plant, rifing with ftems eight or nine inches high, roundifh, rough, with white hairs, purple at the bafe. A native of the Eaft Indies; cultivated at Eltham by Dr. Sherard, in 1732. 4. B. *tenella*. Lin. Spec. 1166. Reich. 3. 704. Amoen. 6. afr. 47. "Leaves linear, peduncles capillary, calyxes moftly four-leaved, feeds erect five-fold." Stem filiform, purplifh, fubtrichotomous, fix or feven inches in height. An annual, and a native of the Cape of Good Hope. 5. B. *cernua*, drooping water-hemp-agrimony, or bur-marygold. Sp. pl. 1165. Hudf. 356. With. 705. Hall. 181. Relh. 309. Sibth. 248. Abbot. 177. Curt. Lond. fafc. 3. t. 55. Fl. Dan. t. 841. Smith. Fl. Brit. 357. 2. Pet. herb. t. 20. f. 6. Raii hift. 361. n. 2. 3. Verbefina pulchriore flore luteo. Raii fyn. 187. Bauh. hift. v. 2. 1074. Coreopfis bidens. Sp. pl. 1281. Chryfanthemum cannabinum bidens, foliis integris. Morif. hift. t. 6, t. 5. f. 22. Eupatorium cannabinum chryfanthemum. Barrel. ic. t. 1209. Conyza paluftris, foliis ferratis. Loes. pruff. 54. t. 11. "Leaves lanceolate, ftem-clafping, flowers nodding, feeds erect." Root annual; ftem from one to two feet high or more, upright, branched, a little hairy, purplifh, dotted with red, round at bottom, ftriated at top, with branches oppofite, nearly upright, leaves oppofite, moderately connate, undivided or with diftant ferratures, fpreading, fmooth on both fides; peduncles ftriated; flowers yellowifh-green, finally drooping, generally radiate; calyx confifting of about feven leaves, finely ferrate at the edge, ribbed, turning back, and longer than the corolla; with eight corollets in the circumference, hermaphrodite like the central ones, but with the tube more tumid and depreffed. In places overflowed for a long time, they change into ligulate neutral corollets: receptacle pyramidal, four-cornered; feeds with four awns, two of which are larger; the prickles pointing downwards. This flowers a month later than the *tripartita*; and in this ftate has a ftrong fmell, not very difagreeable. A native of moft parts of Europe. Haller obferves, that *coreopfis bidens* of Linnæus differs in no refpect from B. *cernua*, except in having radiate florets in the circumference: hence Dr. Stokes concludes, that *bidens* and *coreopfis* form one genus. Found at Ditchingham in Norfolk, and Tarporley in Cheffhire; frequent in Ireland. 6. B. *frondofa*, fmooth-ftalked bidens. Lin. Spec. 1166. Gærtn. fruct. 2. 412. Reich. 3. 704. Berkh. diff. t. 5. f. 5. Chryfanthemum, &c. Mor. hift. 3. 17. f. 6. t. 5. f. 20. "Leaves pinnate, ferrate, marked with lines, fmooth; feeds erect; calyxes leafy; ftem polifhed." The ftem rifes about three feet high, fending out many horizontal branches, from the ends of which are produced clufters of yellow flowers. It grows naturally in Virginia, Maryland, and Canada, where it is often a troublefome weed. It was cultivated by Mr. Miller in 1752. 7. B. *pilofa*, hairy bidens. Lin. Spec. 1166. Syft. 732. Reich. 3. 705. Dill. elth. t. 43. f. 51. Thunb. jap. 307. Lour. cochin. 488. Gærtn. fruct. 2. 412. *β.* B. Chinenfis. Agrimonia Molucca. Rumph. Amb. 6. 38. t. 15. f. 2. "Leaves pinnate, fomewhat hairy, ftem with bearded joints, calyxes with a fimple involucre, feeds diverging." A native of America, and of Tongataboo in the South Seas. B. of China refembles the American; but in the latter the leaflets are united, in the former they are diftinct; and the feeds of the American have from two to five awns, and in the Chinefe always four. The American fort was cultivated in 1732 by Dr. Sherard. 8. B. *bipinnata*, hemlock-leaved bidens. Lin. Spec. 1166. Reich. 3. 705. Lour. cochinch. 488. Chryfanthemum. Herm. par. t. 123. Mor. hift. 17. n. 24. f. 6. t. 7. f. 23. "Leaves bipinnate, gafhed, calyxes involucred, corollas half-radiated, feeds diverging." An annual plant; a native of Virginia; cultivated in Kew garden in 1699. Loureiro fays, it is a native of China and Cochinchina. 9. B. *nivea*, fnowy bidens. Lin. Spec. 1167. Reich. 3. 706. Dill. elth. t. 47. f. 55. Swartz obf. 296. *β.* Dill. elth. t. 47. f. 55. 3. 7. Dill. elth. t. 46. f. 54. "Leaves fimple, cordate-ovate, acuminate, branches trichotomous, ferrate, flowers hemifpherical, peduncles elongated." A native of Jamaica, in elevated paftures, and on the fea-coaft of the fouthern parts. Mr. Miller fays, it grows naturally in South Carolina, and alfo at Campeachy; cultivated at Eltham in

1732,

1732, by Dr. Sherard. 10. B. *verticillata*. Lin. Spec. 1167. Reich. 3. 706. Hort. cliff. 399. 4. "Leaves oblong. entire, lower ones entire, upper ones oppofite, flowers verticilled." A native of Vera Cruz in South America. 11. B. *leandens*. Lin. Spec. 1167. Reich. 3. 706. Hort. cliff. 399. 5. Swartz obf. 297. Brown jam. 317. 2. B. frutefcens. Mill. dict. n. 4. "Leaves oppofite, ovate, acuminate, ferrate, ftem climbing, fhrubby, flowers panicled, ovate." A native of Jamaica, on the cooler mountains, and of Vera Cruz. Miller received it from Carthagena in New Spain. 12. B. *bullata*, various-leaved bidens. Lin. Spec. 1167. Reich. 3. 706. Ard. Spec. 2. 37. t. 18. Mich. flor. 120. Hall. got. 383. "Leaves ovate, ferrate, lower ones oppofite, upper ones ternate, the middle larger." A native of America; found wild in Italy; cultivated by Miller in 1759; annual. 13. B. *hirfuta*. Swartz prodr. 110. Sloan. jam. 1. 257. Eupatorium. "Leaves oppofite, ovate-lanceolate, entire, tomentofe-hirfute, ftem-climbing fhrubby, peduncles oppofite, diverging, many-flowered." A native of Jamaica; annual. 14. B. *odorata*. Cavan. hifp. 9. n. 12. t. 13. "Stem four-cornered, branching very much, leaves connate, bipinnate, pinnules wedge-trifid, fmooth, feeds rugged." A native of Mexico; flowered at Madrid in November 1791.

Moft of the fpecies are herbaceous annuals; fome, however, are fhrubs; leaves generally oppofite, fome pinnate; flowers axillary or terminating.

Propagation and culture. The firft, fecond, and fifth, being common weeds in many parts of Europe, are feldom cultivated in our gardens, but readily propagate themfelves by feeds, in wet fituations. The third, fourth, feventh, and twelfth, muft be fown upon a moderate hot-bed in the fpring, and afterwards treated like other hardy annual plants, planting them into the full ground the latter end of May. They will flower in June; foon afterwards the plants will decay. The fixth and eighth are eafily propagated by feeds fown in the fpring, in an open fituation; where, if they be allowed to fcatter, the plants will come up the following fpring, and two or three of them may be planted where they are to grow; and after they are rooted, they will require no farther care. Being annual plants, they decay foon after the feeds are ripe. The ninth, tenth, eleventh, thirteenth, and fourteenth fpecies are propagated alfo by feeds, fown on a hot-bed in the fpring; and when the plants are fit to remove, they muft be each planted into a feparate fmall fpot, plunged into a frefh hot-bed, and treated like other tender plants from the fame hot countries. In autumn they muft be placed in the bark-ftove. Properly managed they will moftly abide for fome years.

Bidens. See Coreopsis, Elephantopus, Spilanthus, Verbesina, and Zinnia.

Bidens, in *Conchology*, a fpecies of Mytilus, with a ftriated and flightly curved fhell, having the pofterior margin inflected, and the hinge at the end bidentated. Gmelin. A native of the Mediterranean, Æthiopic, Atlantic, and Magellanic feas. The colour of this fhell under the epidermis is black or blue, about an inch in length, and ftriated longitudinally.

Bidens, a fpecies of Nerita, with a fmooth fhell, and inner lip bidentated. Linn. Muf. Lud. Ulr. Country unknown. This fhell is black or reddifh, with obfolete ftriæ, and the fize of a pea. Sometimes it is yellow, clouded with whitifh, with three black bands.

Bidens, in *Entomology*, a fpecies of Scarabæus, found in America. The head and thorax are braffy-green and downy: wing-cafes teftaceous, gloffed with green. Fabricius.

Bidens, a fpecies of Cassida, of a black colour. Wing-cafes porrected in front, with an erect fpine on the future of each. This is of a large fize, and is an inhabitant of Brafil.

Bidens, a fpecies of Curculio, that inhabits New Zealand. It is black: pofterior thighs dentated, with a fingle fpine on each of the wing-cafes. Fabricius.

Bidens, a fpecies of Cerambyx (*Lamia*), found in New Holland, and defcribed by Fabricius. It is grifeous; thorax acutely fpined; wing-cafes bidentated at the tip.

Bidens, a fpecies of Mantis, that inhabits America. The thorax is fcabrous; wing-cafes green, fafciated with black; wings brown, deep black in the difk.

Bidens, a fpecies of Cimex (*Spinofus*), the thorax of which is obtufely fpinous; inner and pofterior margin, and bidentated vent, fanguineous; wing-cafes pale. A native of Europe. Linn. and Gmelin. There is alfo another fpecies in this fection, defcribed by Linnæus and Gmelin, under the name of bidens. It is of an ovate fhape, and grifeous, with the thorax acutely fpined, and the antennæ rufous. This inhabits Europe.

Bidens, a fpecies of Sphex, of a black colour, having the head and antennæ ferruginous; four yellow fpots on the abdomen, and two fpines on the thorax. Gmelin. Inhabits Mauritania. Mouth and firft joint of the antennæ black; anterior wings pale ferruginous; pofterior ones large, tranfparent, and blueifh.

Bidens, a fpecies of Vespa, of a black colour, with two fpines on the thorax, and third fegment of the abdomen, with a yellow margin. Fabricius. It inhabits the north of Europe.

Bidens, a fpecies of Formica, that inhabits Surinam. Thorax with a bidentated tubercle; head ovate; antennæ ferruginous; lower joint black. Fabricius. Sp. Inf.

BIDENTAL, in *Antiquity*, a place ftruck with a thunderbolt, and on that account confecrated to the gods, and to Jupiter in particular, and forbidden to be trod on, and to remove its bounds was deemed facrilege. Bidental only differed from puteal, as in the latter, the thunderbolt was fuppofed to be hidden or buried with ceremony under the ground. The fall of lightning, or a thunderbolt, on any place, was judged by the Romans an indication that Jupiter demanded it for himfelf. Hence, they furrounded it with a wall, rail, ftakes, or even a rope; and expiated it, by the facrifice of a bidens, or fheep of two years old. Feftus repreſents the bidental as a temple, where fheep of two years old were offered in facrifice. But by temple, he here means no more than a place inclofed, and confecrated to the gods. The appellation was extended to thunder itfelf, and to perfons deftroyed by it.

BIDENTALES, prieſts among the ancient Romans, inſtituted for the performance of the ceremonies of a bidental. The bidentales conſtituted a college, or decury, who had the ſervice and procuration, or interpretation of thunder and lightning. The firſt, and principal part of their office was, the ſacrificing a ſheep of two years old, which, in their language, was called bidens, as having only two teeth, one on each ſide; or rather from bidennis, anciently written for biennis, two years old.

BIDENTATA, in *Conchology*, a ſpecies of Helix, found in the botanic garden at Straſburgh, and figured by Chemnitz. The ſhell is pyramidal, ſomewhat carinated, banded, and very finely ſtriated, with a reflected, bidentated lip.

Bidentata, in *Entomology*, a ſpecies of Apis, (*Andrena*) that

that inhabits America. The abdomen is brown, with five whitiſh belts; vent bidentated. Fabricius.

Bidentata, a ſpecies of Phalæna (*Noctua*). This is a native of Europe, and has brown wings; ſtigmate ſpot on the firſt wings, and inner margin white; a bidentated ſtreak in the middle. Lin. Muſ. Leſk.

Bidentata, a ſpecies of Chrysis, that inhabits Europe. This inſect is glabrous; ſhining blue; thorax armed with two teeth, and with the two firſt ſegments of the abdomen golden. Fabricius. At the vent are three very ſhort teeth.

BIDENTATUS, a ſpecies of Bostrichus, deſcribed by Fabricius, Herbſt, &c. It is black, and teſtaceous, retuſe at the extremity, and armed with two hooked ſpines.

Bidentatus, a ſpecies of Cryptocephalus (*Crioceris*), of a yellow colour: wing-caſes black, yellowiſh at the tip. Fabricius. Inhabits Africa.

Bidentatus, a ſpecies of Cerambyx, that inhabits South America. The thorax is ſlightly ſpinous; wing-caſes bidentated, rough, cinereous, and brown. Fabricius.

Bidentatus, a ſpecies of Ichneumon, that inhabits Europe. It is black, ſcutel, and poſterior part of the thorax yellow: on the latter two teeth, and the two firſt ſegments of the abdomen ferruginous. Linn. &c. The four anterior legs are rufous brown; reſt black; tips white.

Bidentatus, a ſpecies of Cimex (*Spinoſus*), found in France. This is long and brown; ſnout bent; thorax, beneath armed with two teeth on the anterior part. Geoffroy, Gmelin.

Bidentatus, a ſpecies of Tabanus, that inhabits Auſtria. This is of a ferruginous colour, with two yellow ſpots on each ſide, and ſcutel bidentated. Fabricius.

BIDENTES, in *Middle Age Writers*, denote two yearlings, or ſheep of the ſecond year. The wool of theſe bidentes, or two year old ſheep, being the firſt ſheering, was ſometimes claimed as a heriot to the king, on the death of an abbot. Among the ancient Romans, the word was extended farther to any ſort of beaſts uſed for victuals, eſpecially thoſe of that age, whence we meet with *fues bidentes*.

BIDENTI *Similis*, in *Botany*. See Siegesbeckia.

BIDET, a nag, or little horſe, formerly allowed each trooper and dragoon, for his baggage, and other occaſions. Bidets are now diſuſed, on account of the expences of them, and the diſorders frequently ariſing from thoſe who attended on them, &c.

BIDETTO, in *Geography*, a town of Italy, in the kingdom of Naples, and country of Bari, the ſee of a biſhop, ſuffragan of Bari; 118 miles eaſt of Naples.

BIDGOST, or Bigodsez, a town of Pruſſia, in Pomerelia, 64 miles ſouth of Dantziek.

BIDIÆI, in *Antiquity*, an order of magiſtrates at Sparta, five in number, whoſe buſineſs it was to ſuperintend the *ephebi*, and be preſent at their exerciſes, wreſtlings, &c.

BIDI-BIDI, in *Ornithology*, one of the ſynonymous names of the Jamaica rail, *rallus Jamaicenſis* of Latham.

BIDJIGUR, in *Geography*, a town of Hindoſtan, in the country of Benares, ſeated on the river Soane, 45 miles ſouth of Benares, and 128 S. W. of Patna. N. lat. 24° 30'. E. long. 83° 26'.

BIDIN. See Widin.

BIDIS, in *Ancient Geography*, now *S. Giovanni de Bidini*, a town of Sicily, ſouth-weſt of Syracuſe, and about 15 miles from it. It is mentioned by Cicero, and alſo by Steph. Byz. who calls it *Bidos*. The people who inhabited the eaſtern part of the iſland, at ſome diſtance from Syracuſe, were hence called *Bidini*.

BIDLOO, Godfrey, in *Biography*, a celebrated Dutch anatomiſt, born at Amſterdam, 1649, applied early to the ſtudy of ſurgery, which he practiſed ſeveral years at his native city; he was alſo ſurgeon to the army, and at length phyſician to William III. with whom he continued in great favour to the time of his death, which happened in 1702. In 1694, he was made profeſſor of anatomy and ſurgery at Leyden. He was a man of conſiderable learning, Haller ſays, but more attached to the pleaſures of the table, than to ſtudy, to which he attributes the numerous errors and inaccuracies in his otherwiſe ſplendid and valuable anatomical tables, which were criticiſed, perhaps, with too much ſeverity by Ruyſch, who had been his pupil. Our countryman, William Cowper, purchaſed 300 copies of the plates, in the life-time of Bidloo, and publiſhed them as his own, only giving new explanations, of which our author, with reaſon, complained in his "Gulielmus Cowper citatus coram tribunal," Leyden, 1700, 4to. Beſides his great anatomical work, conſiſting of 105 tables, with explanations, fol. 1685, and his controverſial papers, he publiſhed, "Obſervationes de animalculis in hepate ovillo detectis," 1698, 4to. "De oculis et viſu variorum animalium," 1712, 4to. "Exercitationes anatomico-chirurgicæ," 1780, 4to. Theſe, with various other diſſertations, were collected, and publiſhed in 1715, 4to. two years after his death. Haller. Bib. Anat. Chirurg. et Med. His nephew, Nicholas Bidloo, was phyſician to the great czar Peter I.

BIDON, a liquid meaſure of about five quarts Engliſh meaſure; ſeldom uſed except among ſhip's crews.

BIDOURLE, in *Geography*, a river of France, which paſſes by S. Hippolyte, Sauve, Sommieres, &c. and runs into the lake of Peraut, 3 leagues eaſt of Montpellier.

BIDOUZE, a river of France, which runs into the Adour, near the junction of that river with the gaves of Pace and Oleron.

BIDUMI, a country of Aſiatic Turkey, the ſouth part of Syria, bounded on the north by Paleſtine, on the weſt by Egypt, and on the eaſt and ſouth by Arabia; it is nearly deſert, and has only a few ſcattered villages.

BIE, Adrian de, in *Biography*, a painter of portraits and ornamental architecture, was born at Liere, in 1594, and after being initiated in the rudiments of his art by Wouter Abts, became the diſciple of Rodolph Schoof, a painter of conſiderable reputation at Paris. He perfected himſelf at Rome, where he ſpent ſix years in the ſtudy of the beſt maſters, and received great encouragement from perſons of the firſt diſtinction. He ſo much excelled in the neatneſs of his pencilling, and in the delicacy of his touch and colouring, that he was frequently employed to paint on jaſper, agate, porphyry, and other precious materials. The place and time of his death are not aſcertained. Pilkington. See Bye.

BIEBER, in *Geography*, a town of Germany, in the circle of the Upper Rhine, and county of Hanau Munzenberg, 16 miles eaſt of Hanau. Near this town are a mine of copper and ſilver, and ſome works of iron and cobalt, in which the latter is prepared into a beautiful ſmalt.

BIEBERICH, a ſmall but handſome town of Germany, ſeated on the borders of the Rhine, and in the vicinity of Mentz. It belongs to a prince of the ſame name.

BIEBERSBACH, a town of Germany, in the circle of Franconia, and principality of Bayreuth.

BIEBRA, a river of Poland, which runs into the Narew, near Wiezna, in Maſovia.

BIECZ, a town of Poland, in the palatinate of Cracow, ſeated on the river Waſaloke, and famous for its mines of vitriol. N. lat. 49° 50'. E. long. 21° 40'.

BIEDA,

BIEDA, a town of Italy, in the ſtate of the church, and province of Patrimonio, 10 miles W. of Sutri.

BIEDBURG, anciently *Beda*, a ſmall town of Germany, in the circle of Burgundy, and duchy of Luxemburg, which was flouriſhing till the year 1663, but ſoon afterwards laid waſte by the French.

BIEDENKOPF, or Biedencap, a ſmall town of Germany, in the circle of the Upper Rhine, and principality of Upper Heſſe, ſeated on the Ahills, 16 miles N. W. of Marburg, and formerly famous for its iron-works and foundery.

BIEFVERSKOW, a diſtrict of Zealand, belonging to Denmark, including 12 churches.

BIEKA, Bieque, Boriquen, or Crab's *iſland*, one of the Virgin iſlands in the Weſt Indies, about 23 miles in length, and not 6 in breadth, where it is wideſt. It is diſtant about 6 miles S.S.E. from Porto Rico. The ſoil is rich, and it has a good road on the ſouth ſide, called Great Harbour. It is claimed by the Spaniards, whoſe intereſt it is to let it remain deſolate. N. lat. 18° 2′. W. long. 64°. See Virgin *Iſlands*.

BIEKOW, or Jezow, a town of Poland, in the palatinate of Lenczicz, 24 miles S. E. of Lenczicz.

BIEL, a town of Spain, in Aragon, 6 leagues S. W. of Jaca.—Alſo, a river of Spain, which joins the Ores at Exea. See Bienne.

BIELA, a town of Bohemia, in the circle of Czaſlau, 6 miles N. E. of Teutſch Brod.

BIELA, or Biella, a town of Italy, in Piedmont; the capital of a ſmall country, bounded on the north by the Alps, on the weſt by the duchy of Aoſta, on the eaſt by the Vercellois and the Maſſeran, and on the ſouth by the Canavez; the town is rich and populous, containing about 7000 inhabitants, and is divided into the Upper and Lower, and has four churches and four monaſteries. It is famous for an image of the Virgin Mary; diſtant 13 miles N. from Ivrea, and 24 N. W. from Vercelli. N. lat. 45° 22′. E. long. 8° 3′.

BIELACH, a river of Germany, in the archduchy of Auſtria, which runs into the Danube, near Melck.

BIELAIA, a river of Ruſſia, which riſes in the Uralian mountains, and after traverſing the government of Ufa, diſcharges itſelf into the Kama, on the borders of the government of Caſan.

BIELASTENA, a town of Croatia, 10 miles north of Bihacs.

BIELAY, a town of Bohemia, in the circle of Konigingratz, 4 miles S. W. of Branau.

BIELBSKOI, a town of Siberia, 40 miles ſouth of Eniſeiſk.

BIELCOPOL, a town of Poland, in the palatinate of Kiov, 48 miles weſt of Bialacerkiew.

BIELEF, a town and diſtrict of Ruſſia, in the government of Tula, ſeated on the Occa, 50 miles W.S.W. of Tula.

BIELEFELD, a town of Germany, in the circle of Weſtphalia, and county of Ravenſberg, divided by the Lutterbach into the old and new town, ſeated at the foot of a mountain, and containing about 800 houſes. The inhabitants are partly Lutherans, and partly Roman Catholics. The old town has two churches, the new a convent and a chapel. This town received municipal privileges in 1287, and was formerly Hanſeatic; it is diſtant 22 miles north from Lippſtadt.

BIELGOROD, a town formerly called *Sarkel*, and diſtrict of Ruſſia, in the government of Kurſk, ſeated on the Donetz; 50 miles S.S.W. from Kurſk. N. lat. 50° 55′. E. long. 36°. This town was built in 900, by the great duke Wladimir, and is an archbiſhop's ſee; it ſubmitted to the arms of Potemkin, in 1790.

Bielgorod. See Akerman and Moscow.

BIELGRAD, a town of Croatia, 40 miles S. E. of Bihacs.

BIELIAN, a town of Ruſſian Tartary. N. lat. 43° 20′. E. long. 66° 4′.

BIELICA, or Bilizin, a town of Lithuania, in the province of Vilna, ſeated on the Niemen, 10 miles ſouth of Lida. N. lat. 53° 35′. E. long. 25° 40′.

BIELISKI, a town of Poland, in the palatinate of Kioſ, 41 miles S.W. of Kioſ.

BIELITZY. See Belitzy.

BIELLA. See Biela.

BIELLE, a town of France, in the department of the Upper Marne, and chief place of a canton, in the diſtrict of Chaumont, 6 miles E.S.E. of Chaumont.—Alſo, a town of France, in the department of the Lower Pyrenées, and chief place of a canton, in the diſtrict of Oleron, 14 miles ſouth of Oleron.

BIELOI, a town and diſtrict of Ruſſia, in the government of Smolenſko, on the ſmall river Vobiſha, falling into the Meſha or Meza, which diſcharges itſelf into the Duna; 50 miles N.N.E. of Smolenſko. N. lat. 55° 40′. E. long. 34°. —Alſo, an iſland in the Karſkoi ſea, about 70 miles in circumference, 20 miles from the continent of Ruſſia. N. lat. 73° 40′. E. long 69° 14′.

BIELOKAMESKOI, a fortreſs of Ruſſia, in Siberia, on the eaſt ſide of the Irtiſh, 12 miles S. E. of Semipolatnoi.

BIELO-OZERO, or White Lake, a lake of Ruſſia, in the government of Novgorod, about 50 verſts long, and 30 broad, which receives into it ſeveral ſmall ſtreams. The only one that flows out of it, is the Shekſna, which falls into the Volga. The water of this lake is clear, having a bottom partly of clay, and partly of ſtone. The clay is generally of a white colour, and in ſtormy weather cauſes a ſtrong white foam upon the ſurface of the water. From this circumſtance, the lake firſt obtained its name *Bielo*, or *White*. It contains plenty of fiſh and crabs. N. lat. 59° 42′. to 60° 20′. E. long. 36° 30′ to 37° 18′.

BIELOPOLIE, a town and diſtrict of Ruſſia, in the government of Karkof, ſeated on a rivulet falling into the Scim, 85 miles N.N.W of Karkof.

BIELOVITZ, a town of Croatia, 11 miles S. W. of Damianovitz.

BIELOVODSK, a town and diſtrict of Ruſſia, in the government of Voronetz, ſeated on the Derkul, which falls into the Donec, 130 miles ſouth of Voronetz. N. lat 49° 42′. E. long. 39° 10′.

BIELOW, a town of Poland, in the palatinate of Volhinia, 36 miles eaſt of Lucko.

BIELOZERSK, a town and diſtrict of Ruſſia, in the government of Novgorod, on the ſouth ſide of the lake Biclo-Ozero, near the efflux of the river Shekſna, 64 miles N. E. of Vologda. N. lat. 59° 40′. E. long. 37° 10′.

BIELSA, a town of Spain, in Aragon, 6 leagues from Ainſa.

BIELSK, a town of Poland, and capital of the palatinate of Podalachia, where the dietine for the diſtrict is held. It is little better than a miſerable village, though called in the geographical deſcriptions of Poland, a large town. N. lat. 52° 48′. E. long. 23° 28′.—Alſo, a town of Poland, in the palatinate of Ploczko, 10 miles N. E. of Ploczko.

BIELTSCH, a town of Bohemia, in the circle of Chrudim, 16 miles north of Chrudim.

BIELUGA, in *Zoology*, *Delphinus Leucas* (*Gmelin*) in Steller's Kamptſchatka, &c.

BIENAISE, Jean, in *Biography*, born in 1601, at

Mazeres, a city in France, where he practiſed ſurgery with ſuch ſucceſs, as to attract the notice of his ſovereign, Lewis XIV., by whom he was made ſurgeon to the army in Flanders. He acquired great reputation, Haller ſays, by introducing the ſuture of the tendon, and by curing a puncture of the brachial artery in a young nobleman. He gives excellent cautions, on taking up the artery, after amputating a limb, to avoid including the nerve in the ligature. He performed the paracentelis of the thorax ſucceſsfully, and appears to have been a bold and expert operator, and to have made conſiderable improvements in his art. He died 1681, aged 80 years. A few years after his death, viz. in 1688, a poſthumous work was publiſhed, containing an account of theſe operations, under the title of "Operations de Chirurgie, par une methode courte et facile," 12mo. Paris. Haller Bib. Anat. Eloy. Dict. Hiſt.

BIENENBUTTEL, in *Geography*, a town of Germany, in the circle of Lower Saxony, and principality of Lunenburg, 10 miles S.S.E. of Lunenburg.

BIENNE, a ſmall diſtrict of Swiſſerland, lies between a lake of the ſame name and a chain of the Iura mountains. It is ſurrounded by the cantons of Berne and Soleure, the biſhopric of Baſle, and the principality of Neufchatel. The biſhop of Baſle is the ſovereign of this little ſtate, but his power, even before the French revolution, was exceedingly limited; and its conſtitution was neither a limited monarchy nor an independent republic, but a kind of mixed government, partaking in ſome degree of both. The biſhop of Baſle, upon his promotion to the ſee, received the homage of the citizens and militia of the town of Bienne, with attendant tokens of abſolute ſubmiſſion, but at the ſame time he confirmed, in the ſtrongeſt manner, all their privileges and franchiſes. The mayor appointed by him was his repreſentative, to whom it belonged to convoke and preſide in the little council, as the chief court of juſtice, to collect the ſuffrages, and to declare the ſentence; but without giving any vote himſelf. Although juſtice was carried on, and executed in the name of the biſhop, yet neither that prince, nor the mayor, had the prerogative of pardoning criminals, or of mitigating the ſentence. All cauſes, civil and criminal, were brought before the council in the firſt inſtance; and in more important proceedings, an appeal lay to the ſovereign council. In both caſes, each party choſe a member of the council to act as his advocate, which office he diſcharged without fee or recompence. The ſovereign's revenue amounted only to about 300l. a year; nor did he poſſeſs the leaſt ſhare in the adminiſtration. The legiſlative authority reſided in the great and little councils combined: the former conſiſting of 40 members, and the latter, to which the executive power belonged, being compoſed of 24; and it was required that the members of each council ſhould be married men. Both councils elected their reſpective members; and therefore the conſtitution was altogether ariſtocratical. The burgo-maſter, or chief of the regency, was choſen by the two councils, and preſided at their meeting, and retained his office during life; but it was neceſſary that he, as well as the ſeveral magiſtrates, ſhould be confirmed annually by the two councils. The ſalaries annexed to theſe poſts were ſmall, and the general expences of government ſo inconſiderable, that the revenues of the ſtate were ſufficiently ample.

This republic, though a Proteſtant one, under the ſovereignty of a Catholic biſhop, enjoyed in the fulleſt extent the power of impoſing taxes, contracting alliances, declaring war and peace; and, in ſhort, of exerciſing every other act of abſolute and independent legiſlation. Its ſingular conſtitution was guaranteed by Berne, Friburg, and Soleure, with which the town was cloſely allied, having connected itſelf with the former in 1352, with the ſecond in 1496, and with the latter in 1382; in conſequence of which union it became a member of the Helvetic confederacy. This alliance between the cantons and the town of Bienne was paramount to that of the ſame cantons with the biſhop of Baſle: for the town enjoyed the right of ſending deputies to every general diet, ordinary or extraordinary, a privilege not poſſeſſed by the biſhop. The language of the country is a provincial German; but, as the territory borders on the principality of Neufchatel, the inhabitants ſpeak alſo a corrupt French. The extent of the town and territory of Bienne is eſtimated at 144 ſquare geographical miles, and its population at 5,500, or nearly 6000 perſons; the people are very active and induſtrious. Bienne forms an important paſs into the Swiſs territories; accordingly, it was occupied by the French on the 8th of February 1798, and annexed to France as ſubject to the biſhop of Baſle, whoſe rights they aſſumed in conſequence of having ſeized his territories.

BIENNE, called by the Germans *Biel*, the capital of the above diſtrict, is ſituated at the foot of mount Iura, and at a little diſtance from the lake of the ſame name. Between the town and the lake is a plain, which the ſovereign council, by a kind of Agrarian law, that was honourable to the legiſlature, allotted, by diſtinct portions, to each burgher for his own diſtinct uſe: and it is entirely laid out in ſmall kitchen gardens. Several manufactures have been eſtabliſhed in the town, which, conſidering its ſize, carries on a tolerable trade. The government, by adopting the liberal policy of conferring the burgherſhip at an eaſy rate, has contributed to increaſe the population of the town, and to extend its commerce. N. lat. 47° 8'. E. long. 1° 4'.

BIENNE, *lake of*, lies to the north-eaſt of that of Neufchatel, with which it is connected by the Thielle, which ſeparates the country of Neufchatel from the canton of Berne. It is about 9 miles long, and 4 broad; its borders are pleaſing and pictureſque, as it is ſkirted with agreeable walks and country houſes; and the town of Nidau forms a very beautiful object upon its eaſtern ſide. Towards the ſouthern extremity of this lake is the iſland of St. Peter, ſometimes called the iſland of La Motte, and ſometimes Rouſſeau's iſland, from its having been the place of Rouſſeau's retirement and reſidence, when by the violence of the populace he was obliged to withdraw from Moitier, where Frederic king of Pruſſia had enſured to him protection. Mr. Coxe, when he viſited this iſland, landed on the ſouth ſide of it, and paſſed through an agreeable meadow, ſkirted with vineyards, to a large farm-houſe, formerly a convent, and ſecularized at the reformation, but inhabited, at the time of Mr. Coxe's viſit, by the ſteward of the general hoſpital at Berne, to which the iſland belongs. "The iſland," ſays Mr. Coxe, "is about 2 miles in circumference, and richly wooded with various ſhrubs and trees, particularly with large oaks, beech, and Spaniſh cheſnuts. Its ſurface is gently undulating; the ſouthern ſhore, covered with herbage, forms a gradual ſlope to the lake; the remaining borders are ſteep and rocky; in a few places their ſummits are thinly fringed with ſhrubs; in others their perpendicular ſides are clothed to the water's edge with hanging woods. The views from the different parts of the iſland are beautiful and diverſified; that to the north is the moſt extenſive and pleaſing. It commands the lake of Bienne, which is of an oval form; its cultivated borders ſpotted with villages and caſtles, with the towns of Nidau and Bienne ſtanding on the further extremity. Agreeable walks are carried through the woods, and terminate at a circular pavilion placed in the centre of the iſland. During vintage, particularly, and on Sunday, which is the uſual day of feſtivity, the iſland is filled with parties, who take refreſhment at the farm-houſe, ſtray about the woods, or dance in the circular building, and animate theſe romantic but ſolitary

 ſcenes."

ſcenes." "Rouſſeau occupied an apartment in the farm-houſe, the only dwelling in the iſland. He lived with the ſteward and his family, who are the preſent inhabitants (1785). The woman informed me, that he paid for his board and lodgings 40 ſhillings a month; that he uſually roſe at ſix, dined with the family at twelve, and after a ſlight ſupper retired to reſt at nine. She added, he was extremely cheaiful and agreeable; converſed with the family with the greateſt eaſe and complacency, and conformed to their hours and manner of living; he amuſed himſelf entirely in wandering about the woods, and ſearching for plants, which he uſed to explain to them with ſingular ſatisfaction. Rouſſeau mentions his reſidence in this delightful iſland with the higheſt terms of rapture, and with his uſual pronenefs to exaggeration." "I was permitted," ſays he, "to remain only two months in this delightful iſland; but I could have paſſed there two years, two centuries, all eternity, without ſuffering a moment's ennui, although my whole ſociety conſiſted of the ſteward and family, good, but plain people. I eſteem thoſe two months the moſt happy period of my life; and ſo happy, that I could have paſſed my whole exiſtence without even a momentary wiſh for another ſituation." Coxe's Travels in Switzerland, &c. vol. ii. p. 152, &c.

BIENNIAL Plants, in *Botany*, denote ſuch, as the epithet imports, that are of two years' duration. Of this tribe there are numerous plants, which, being raiſed one year from ſeed, generally attain perfection in the ſame year, or within about twelve months, ſhooting up ſtalks, producing flowers, and perfecting ſeeds in the following ſpring or ſummer; and ſoon after commonly periſh, or apparently decay and dwindle, ſo that they ſoon die off. Biennials are, therefore, always in their prime the firſt or ſecond ſummer. They conſiſt both of eſculent and flower plants. Thoſe of the former ſort are the cabbage, ſavoy, carrot, parſnip, beet, onion, leek, &c.; and thoſe of the latter are the Canterbury bell, French honey-ſuckle, wall-flower, ſtock-july-flower, ſweet-william, Chinapink, common-pink, matted-pink, carnation, ſcabious, holly-hock, tree-mallow, vervain-mallow, tree-primroſe, honeſty, or moon-wort, &c.

BIENTINA, in *Geography*, a town of Italy, in the duchy of Tuſcany, on the ſide of a lake, called the "lake of Bientina," or the "lake of Seſſo;" which lake is about 6 miles long, and 5 wide; 12 miles eaſt of Piſa, and 28 weſt of Florence. The territory of Bientina lies in the middle of a marſh, in the centre of a valley, not very ſpacious, bounded by the high mountains of Piſa, and by thoſe of Lucca and Valdinievole, which interrupt the wind, and prevent a renewal of air; and it is, therefore, as one would imagine by its ſituation, peculiarly unwholeſome and unfavourable for inhabitants. It is nevertheleſs very populous, and ſufficiently healthful even in ſummer. The principal cauſes of this ſalubrity are ſaid to be, the numerous population, the extenſive commerce, and the extreme attention that is paid to the continual diſcharge of the rain-waters, but, above all, the advantage of an abundant ſpring, which deſcends from the hills of St. Colombe, by means of long aqueducts, and ſupplies the inhabitants with excellent water. The ſituation of Bientina, therefore, duly examined, ſhews how far the art of man is capable of rendering habitable, and even ſalubrious, places naturally peſtilential.

BIENVILLE, D. T. De, M.D. in *Biography*, born in France, practiſed medicine many years at the Hague, and is only known by the following works, which bear his name: "La Nymphomanie, ou Traité de la fureur uterine," Amſt. 1771, 8vo.; "Recherches theoriques et pratiques ſur la Petite verole," 1772, 8vo. "Traite des erreurs populaires, ſur la ſanté," La Hague, 1775, 8vo.

BIER, a kind of wooden carriage, on which the bodies of the dead are borne to their grave. The word comes from the French *biere*, which ſignifies the ſame. It is called in Latin *feretrum*, *a ferendo*. Among the Romans the common bier, upon which the poorer ſort were carried, was called *ſandapila*; that uſed for the richer ſort, *lectica*, *lectica funebris*, ſometimes *lectus*. The former was only a ſort of wooden cheſt, *vilis arca*, which was burnt with the body: the latter was enriched and gilded for pomp. It was carried bare, or uncovered, when the perſon died a natural and eaſy death; when he was much diſfigured or diſtorted, it was veiled or covered over.

Bier, is more particularly uſed for that on which the bodies of ſaints are placed in the church to reſt, and expoſed to the veneration of the devout. This was often enriched with gold, ſilver, and precious ſtones; and furniſhed temptations, in many inſtances, to pillage.

BIERG, in *Geography*, a herred, or diſtrict, of the dioceſe of Funen in Denmark, including 12 churches, and ſeveral noblemen's ſeats.

BIERLING, Gaspan Theophilus, in *Biography*, took his degree of doctor in medicine at Padua, about the middle of the 17th century, whence he returned to Magdeburg, his native city, where he was in conſiderable eſtimation. He publiſhed "Adverſariorum curioſorum Centuria prima," June, 1679, 4to. He deſcribes the effects of eating the hyoſcyamus (henbane,) drowſineſs, and delirium, which are cured, he ſays, by taking the extract of caſtor, and the effects from the bite of a viper, cured by eating the fleſh of one of thoſe reptiles. He had the merit of recommending the cool treatment, and even bleeding, in the ſmall-pox, contrary to the then generally received opinion. For the remainder of his works, which are numerous, but in little eſtimation; ſee Haller's Bib. Med. Elog. Dict. Hiſt.

BIERVLIET, in *Geography*, a ſmall town of Flanders, on the weſt ſide of the Scheldt, which has been much reduced by frequent inundations, and the fortifications of which were deſtroyed in 1688. William Beukeljzoon, or as others have written his name, Beukelings, who taught the Dutch the art of curing herrings, was a native of this place, and died here in 1397. The town is 7 leagues north of Ghent, and 4 E. N. E. of Sluys. N. lat. 51° 25'. E. long. 3° 42'.

BIESBOS, a large lake in the Merwe, between Dort and Gertrudenburg, formed by the irruption of the banks or dikes.

BIESE, a river of Germany, which riſes 8 miles ſouth-weſt from Stendal, in the Old Mark of Brandenburg, and purſuing its courſe to Seehauſen, changes its name to Aland.

BIESENTHAL, a town of Germany, in the circle of Upper Saxony, and middle Mark of Brandenburg, 20 miles N. E. of Berlin.

BIESIUS, Nicholas, in *Biography*, born at Ghent in Flanders, March 27, 1516, ſtudied medicine at Louvain; thence he went to Valencia in Spain, and afterwaid to Sienna, in Italy, where he took his degree of doctor. Returning to Louvain he was advanced to the chair of profeſſor in medicine, which he filled with credit ſeveral years, expounding to his pupils, as the cuſtom then was, the works of Galen. He was thence called by the emperor Maximilian II. to Vienna, and appointed his phyſician, which poſt he held until April 1572, when he was ſuddenly cut off by a fit of apoplexy. His works are, "Theoreticæ Medicinæ, libri ſex," Ant. 1558, 4to.; "In Artem medicam Galeni Commentarii," 1560, 8vo.; "De Methodo Medicinæ," 1564. 8vo.; "De Natura libri quinque," 1573, 8vo.; the two laſt works have been ſeveral times reprinted.

BIESMES, in *Geography*, a place of France, where is a paſs acroſs the Aine, from the department of the Meuſe to

that of the Marne; 3 miles from St. Menchold, and 12 from Grand Pre.

BIESNIN, a town of Poland, in the palatinate of Ploczko. N. lat. 53°. E. long. 20° 8'

BIETIGHEIM, a town of Germany, in the duchy of Wurtemberg, at the conflux of the Ens and Metterbach; 10 miles N. of Stutgartd, and 30 S. S. E. of Heidelberg.

BIEVRE, a river of France, which rifes a little to the fouth of Verfailles, and paffing towards Paris, changes its name for that of Gobelins, on account of its water being ufed in that manufacture, and foon after it joins the Seine.

BIEUZI, a town of France, in the department of Morbihan, and chief place of a canton, in the diftrict of Pontivy; 2 leagues S. S. W. of Pontivy.

BIEZOW, or Bidschow, a town of Bohemia, in the circle of Konnigingratz; 3 miles eaft of Koniagingratz.

BIFARIA, Folia, in *Botany*, denote leaves that point two ways.

BIFASCIANA, in *Entomology*, a fpecies of Phalæna (*Tortrix*). The anterior wings are teftaceous; two oblique bands, fpot, and arched mark at the apex brown. Linn. Muf. Lefk, &c. Inhabits Europe.

BIFASCIATA, in *Conchology*, a fpecies of Bulla, the fhell of which is fomewhat tapering, erect, and white, with two broad reddifh bands at the aperture. Lifter. Gmelin. Native place unknown.

Bifasciata, a fpecies of Voluta, defcribed by Lifter and Martini. This fhell is thin, tranfverfely ftriated, and flefh coloured, with two white bands and a fingle tooth on the pillar. It is rather lefs than an inch in length; and has a long narrow aperture. Native country unknown.

Bifasciata, a fpecies of Cypræa, of an oblong form and purplifh, with a ftraw-coloured band, and a narrower white one, and brown border. Gmelin. Length nearly four inches. Country unknown.

Bifasciata, a fpecies of Nerita, of a blackifh colour, with two hoary bands and white tip. A native of India. Gmelin. Chemnitz, &c.

Bifasciata, in *Entomology*, a fpecies of Silpha, found in Saxony. This is black, with two bands and a fpot at the apex of ferruginous colour. Fabricius. This is a fmall infect.

Bifasciata, a fpecies of Cassida, that inhabits South America. It is pale with two brown bands. Gmelin.

Bifasciata, a fpecies of Coccinella, of a ferruginous colour, with two bands and four dots of black. Fabricius. This infect inhabits the Cape of Good Hope; and is *Coccinella flexuofa* of Thunberg.

Bifasciata, a fpecies of Chrysomela of a large fize, that is found in Cayenne. It is teftaceous: wing-cafes braffy and fhining: two fpots and two bands of yellow. Fabricius, &c.

Bifasciata, a fpecies of Cicada (*Cercopis*), of a yellowifh colour, with brown wing cafes, and two white bands. Fabricius. This is *Cicada fufca, fafciis alarum binis albis*, of Linn. Syft. Nat. XII. and *Cicada trifafciata*, of Degeer. Inhabits the north of Europe.

Bifasciata, a fpecies of Phalæna (*Geometra*), defcribed by Linnæus as a native of Europe. The anterior wings are cinereous, clouded, with two bands; pofterior pair white.

Bifasciata, a fpecies of Libellula, that inhabits America. The wings are hyaline, with a brown fpot at the bafe, and two bands of the fame colour. Fabricius. Obf. This is *Libellula trimaculata* of Degeer; and *Libellula pulchella* of Drury.

Bifasciata, a fpecies of Tenthredo, that inhabits Europe. The general colour is brown; thorax black; mouth, fcutel, and four fpots white: on the abdomen two interrupted yellow bands: margin of the wings and legs yellow. Linnæus. Muf. Lefk.

Bifasciata, a fpecies of Mutilla, that inhabits New York. The colour is black; upper part of the head and thorax, and two bands on the abdomen red: wing violaceous-black. Swederus. Nov. Act. Stockh. Entirely downy and twice the fize of M. Europæa.

Bifasciata, a fpecies of Tipula, of a yellowifh colour, with tranfparent wings palely fafciated with brown. Schranck Inf. Auftr. Of the middle fize, with the eyes black.

Bifasciata, a fpecies of Musca, that inhabits South America. It is rufous, with two golden bands on the abdomen. Fabricius, &c.

Bifasciata, a fpecies of Scolia, that inhabits New York. This infect is of a black colour; two dots on the anterior part of the thorax, fcutel, and two interrupted bands on the abdomen ferruginous. Swederus Nov. Act. Stockh.

BIFASCIATUS, in *Conchology*, a fpecies of Conus, figured by Born. This kind is white with angulated chefnut lines, and two orange bands: fpire rather prominent: bafe furrounded with orange lines, and the intermediate fpaces with teffellated fpots. Country unknown.

Bifasciatus, in *Entomology*, a fpecies of Scarabæus, that inhabits Coromandel: on the thorax is a triple protuberance, with an erect horn on the head; wing-cafes black, with two rufous bands. Fabricius.

Bifasciatus, a fpecies of Dermestes, of a black colour, with two waved yellow bands: thorax teffellated with cinereous colour. Thunberg. A native of the Cape of Good Hope.

Bifasciatus, a fpecies of Bostrichus, found in Siberia. It is of a black colour: wing-cafes yellow, with two blueifh-black denticulated bands. Gmelin. This is *Dermeftes bifafciatus* of Lepech. it.

Bifasciatus, a fpecies of Cryptocephalus, that inhabits Africa. It is rufous, with two fpots on the thorax, and two bands on the wing-cafes of black. Fabricius.

Bifasciatus, a fpecies of Cerambyx (*Prionus*), found in South America. The thorax is denticulated: body black: wing-cafes red, with two black bands: antennæ fhort. Gronovius, Fabricius, &c.

Bifasciatus, a fpecies of Attelabus (*Clerus*), of a braffy-green and downy: wing-cafes blue, with two fcarlet lines. Fabricius. A native of Siberia.

Bifasciatus, a fpecies of Gryllus (*Bulla-Acridium*), of a fufcous brown with white fpots, and two lateral ochrey-coloured bands. *Herbft apud Fuefli.* Inhabits fandy places.

BIFASCIELLA, a fpecies of Phalæna (*Tinea*), with fufcous gloffy wings; with two bands of white, the hinder one interrupted: head rufous. Fabricius. Inhabits Denmark.

BIFERÆ, in *Botany*, denote plants that flower twice a year, or in fpring and autumn.

BIFERNO, in *Geography*, a river of Italy, which runs into the Adriatic, nor far from Termini.

BIFFA, in *Middle Age Writers*, a machine for cafting ftones and darts, having a moveable counterpoife, which turned round its yard.

BIFID Leaf, in *Botany*. See Leaf.

BIFIDUS, in *Entomology*, a fpecies of Cimex (*Reduvius*,) of a black colour: wing-cafes with a rufous band; an erect bifid fpine on the fcutel. Inhabits China, and is of a large fize. Fabricius. Donov. Inf. China.

BIFOLIUM, in *Botany*. See Ophrys.

BIFORIS, in *Natural Hiftory*, a fpecies of Echinus, having at the bafe five furrows, and ten flexuous radiated lines;

lines; and near the vent two oblong perforations. *Leſke apud Klein.* Its habitation unknown.

BIFORMIS, an appellation given to Bacchus, either becauſe he is repreſented ſometimes as a young man, ſometimes as old; ſometimes with a beard, and ſometimes without one; or becauſe wine, of which he is the ſymbol, renders men ſorrowful and frantic, or gay and pleaſant.

BIFRONS, a perſon double-fronted, or two-faced.

Bifrons is more peculiarly an appellation of Janus, who was repreſented by the ancients with two faces, as being ſuppoſed to look both backwards and forwards: though other reaſons for it are recited by Plutarch. Sometimes he was painted with four faces, *quadrifrons*, as repreſenting the four ſeaſons.

Bifrons, in *Entomology*, a ſpecies of Brentus, that inhabits Cayenne. This inſect is black, with ſtriated wing-caſes, having glabrous yellow ſpots. Fabricius.

Bifrons, a ſpecies of Ichneumon, deſcribed by Linnæus: it is an European inſect of a black colour, with the front white, with a black ſpot beneath the antennæ: tip of the petiole, and two firſt ſegments of the abdomen, with the legs reddiſh. Muſ. Leſk.

Bifrons, in *Natural Hiſtory*, a ſpecies of Nereis, deſcribed by O. Fabricius, and Müll. as a native of the north ſea. It is depreſſed: peduncles with a ſimple ſetigerous papilla, cirrated above; thoſe in the middle alſo branched. This creature is continually in motion; about an inch long, and of a fulvous or browniſh colour: head white: eyes four: cirri ſeven: body attenuated at both ends, and conſiſting of fifty-ſix joints.

BIFURCATUS, in *Entomology*, a ſpecies of Cimex (*Oblongus*), that inhabits Germany. It is blackiſh: abdomen pale yellow, and bifurcated. Schæffer. Antennæ conſiſt of four joints.

BIGA, a chariot for racing, drawn by two horſes a-breaſt. The word ought rather to be written *bigæ*, in the plural; q. d. *bijugæ*, two horſes being joined by a *jugum*, or yoke. Bigæ ſtands contradiſtinguiſhed from *trigæ*, *quadrigæ*, &c. Bigæ are of very ancient ſtanding: all the heroes in Homer, Heſiod, Virgil, &c. fought in them. The invention of bigæ is attributed by Pliny (N. H. vii. 56.) to the Phrygians; by Iſidore, (xvii. 35.) to Cyriſtenes of Sicyon, who firſt yoked two horſes together. They were firſt introduced into the olympic games in the 93d olympiad, or about the year 408, B. C. It appears, however, that the Greek heroes who celebrated the firſt Nemæan games in honour of Archemorus, were borne on bigæ. Bigæ were the chariots firſt uſed in the Circenſian games; then *trigæ*, and afterwards *quadrigæ*. The moon, night, and the morning, are by mythologiſts ſuppoſed to be carried in bigæ, the ſun in quadrigæ. Statues in bigæ were at firſt only allowed to the gods, then to conquerors in the Grecian games; under the Roman emperors, the like ſtatues, with bigæ, were decreed and granted to great and well-deſerving men, as a kind of half triumph, being erected in moſt public places of the city. Figures of bigæ were alſo ſtruck on their coins, and thoſe on which were a bigæ, and a Janus with a double face, were termed *Bigati nummi*.

The drivers of bigæ were called *bigarii*; a marble buſt of one Florus, a *bigarius*, is ſtill ſeen at Rome.

Biga, or *Bigata*, in *Writers of the Middle and Barbarous Age*, a cart with two wheels, drawn often with one horſe. It was more frequently called *birota*.

Biga, in *Geography*, a town of Aſiatic Turkey, in the province of Natolia, 16 miles S. of Artaki.

Biga, a river of North Wales, which joins the Severn in the county of Montgomery.

BIGAMY, a double marriage, or the poſſeſſion of two wives at the ſame time. Among the ancient Romans, thoſe convicted of bigamy were branded with a note of ignominy; and, in France, they were anciently puniſhed with death. See Polygamy.

Bigamy, in the *Canon Law*, is where a perſon either marries two virgins ſucceſſively; or once marries a widow. The former kind of bigamy they call *real*, and the latter *interpretative*. Each of theſe the canoniſts account impediments to be a clerk, or to hold a biſhoprick without a diſpenſation: a point of diſcipline founded on that of St. Paul, "Let a biſhop be the huſband of one wife," 1 Tim. chap. iii. ver. 2. Apoſt. Conſt. 17, 18. By a canon of the council of Lyons, A. D. 1274, held under pope Gregory X. ſuch were eſteemed "omni privilegio clericali nudati et coercioni fori ſecularis addicti." 6 Decretal, i. 12. This canon was adopted and explained in England by ſtat. 4 Edw. I. ſt. 3. c. 5.; and bigamy, in conſequence of it, became no uncommon counter-plea to the claim of the benefit of clergy. M. 40 Edw. III. 42. M. 11 Hen. IV. 11. 48. M. 13 Hen. IV. 6. Staunf. P. C. 134. The cognizance of the plea of bigamy was declared by ſtat. 18 Edw. III. ſt. 3. c. 2. to belong to the court Chriſtian, like that of baſtardy. But by ſtat. 1 Edw. VI. c. 12, §. 6. bigamy was declared to be no longer any impediment to the claim of clergy. See Dal. 21. Dyer, 201.

The Romaniſts make a third kind of bigamy, by *interpretation*; as, when a perſon in holy orders, or that has taken on him ſome monaſtic order, marries.—This the biſhop can diſpenſe withal, at leaſt on ſome occaſions.

There is alſo a kind of ſpiritual bigamy; as when a perſon holds two incompatible benefices, v. gr. two biſhopricks, two vicarages, two canonries *ſub eodem tecto*, &c.

By the eccleſiaſtical law of England, a ſecond marriage, while the former huſband or wife is living, is ſimply void, and a mere nullity; nevertheleſs, the legiſlature has thought it juſt to make it felony, by reaſon of its being ſo great a violation of the public economy and decency of a well-ordered ſtate. For the circumſtances attending this crime, and the puniſhment of it, ſee Polygamy.

BIGARELLA, in *Botany*. See Prunus.

Bigarella, in *Geography*, a town of Italy, in the duchy of Mantua, 7 miles E. N. E. of Mantua.

BIGATI, in *Antiquity*, a kind of ancient Roman ſilver coins, on one ſide whereof was repreſented a *biga*, or chariot drawn by two horſes. The bigatus was properly the Roman *denarius*, whoſe impreſſion, during the times of the common-wealth, was a chariot driven by Victory, and drawn either by two horſes, or four, according to which it was either denominated *bigatus*, or *quadrigatus*. Bigati therefore were of different values, according to the ſpecies of *denarii*, &c. Several of thoſe called conſular medals are alſo *bigati*. In lieu of horſes, the chariot is repreſented on ſome *bigati*, as drawn by two deers, eſpecially in the medals of the family of Axſia: on thoſe of the family of Crepereia, by two *hippopotami*, who draw, or rather bear Neptune on their tails.

BIGBERRY, or Bigbury *bay*, in *Geography*, lies on the ſouth coaſt of Devon, and is formed by the Bolt Tail on the eaſt, and Stoke-point on the weſt, in the direction nearly of N. W. by W. The entrance into Plymouth ſound is round Stoke point to the N. W.

BIG-BONE Creek, an American creek in Woodford county, Kentucky, which falls into the Ohio from the eaſt, in about N. lat. 39° 17′. W. long. 85° 54′. It is ſmall, but has three branches; the north-weſternmoſt interlocks with Bank Lick creek, which falls into Licking river. It is noticed on account of the large bones and ſalt licks in its vicinity.

Big-Bone *Licks* lie on each ſide of the above-mentioned creek,

creek, a little below the junction of the two eaſtern branches, about 8 miles from the mouth of the creek. Theſe, and alſo the other ſalt ſprings, in the weſtern country, are called *licks*, becauſe the earth about them is furrowed up in a very curious manner, by the buffaloes and deer which lick the earth, on account of the ſaline particles with which it is impregnated. A ſtream of brackiſh water runs through theſe licks, the ſoil of which is of a ſoft clay. The large bones found here, and in ſeveral other places near ſalt licks, and in low ſoft grounds, thought to belong to the Mammoth, have perplexed naturaliſts, in their inveſtigation of the animals to which they belong. See Bones *foſſile*, and Mammoth.

BIGEMINATE Leaf, in *Botany*. See Leaf.

BIGERRA, in *Ancient Geography*, a town of Spain, which, according to Livy, was attacked by the Carthaginians, becauſe it was allied to the Romans, but it was ſuccoured by Scipio. Ptolemy aſſigns it to the Baſtitani, in Tarragonenſis.

BIGERRONES, a people of Gaul, ſo called by Cæſar, and denominated by Pliny, *Bigerri*; and by Auſonius, *Begeritani*. M. d'Anville places them at the foot of the Pyrenees, to the weſt of the Convenæ. Their name exiſts in that of Bigorre.

BIGGAR, the name of a town and pariſh of Lanarkſhire, in Scotland. The pariſh includes an area of land, meaſuring about 6 miles, by 3½ in tranſverſe diameter. The ſurface is partly hilly, and is appropriated, in nearly equal parts, to paſture and arable. The population of the pariſh in 1790 was 937, but this was 161 leſs than when a return was made 36 years anterior. From the improved ſtate of the roads, and of agriculture, it was found to contain 1216 perſons in the year 1800. The town of Biggar has 389 inhabitants. Here are three annual fairs. At the weſt end of the pariſh are the veſtiges of a large tumulus, and three encampments. Tradition ſays, that a deſperate battle was fought here between the Scots under ſir William Wallace, and the Engliſh army, when the ſlaughter was very great. Sir John Sinclair's Statiſtical Hiſtory of Scotland.

BIGGE, a river of Germany, which runs into the Lenne, 3 miles north of Allendorn, in the duchy of Weſtphalia.

BIGGEL, in *Zoology*, *Antilope Tragocamelus* of Gmelin, in Mandelſl. it.

BIGGLESWADE, in *Geography*, is a large improving town of Bedfordſhire, England, pleaſantly ſituated in a fertile valley, on the eaſtern bank of the river Ivel. This has been rendered navigable to the town by act of parliament, and conſiderable quantities of coals, timber, corn, and ſome other commodities, are brought by this channel. An extenſive weekly market, and four annual fairs, alſo attract various merchandize to the town. The manor belongs to the king, and the pariſh includes, beſides the town, the ſmall hamlets of Stretton and Holme. Theſe together contain a population of 1650 perſons, who occupy 301 houſes. The church, an ancient and ſtrong edifice, was partly built in the year 1230, and was formerly collegiate. The inhabitants, being free tenants, have all equal rights in the church. In this town are two charity-ſchools; alſo a Baptiſt meeting-houſe; and being ſeated on a great public road, it contains ſeveral large inns. Biggleſwade ſuffered very materially by fire, which happened on the 16th of June 1785. In a few hours 150 dwelling-houſes were reduced to aſhes, beſides ſome malt-houſes, corn-chambers, &c. which were ſituated round the market-place, near the centre of the town. The damages ſuſtained by this fire were eſtimated at 24,000l. Since the conflagration ſeveral new houſes have been erected, and the town has aſſumed a more modern and improved appearance. On the 25th of February 1792, a ſhock of an earthquake greatly alarmed the inhabitants of this place, and its concuſſion was ſo powerful as to throw down ſome old houſes. It laſted ſeveral ſeconds, and was found to extend northward into Yorkſhire, and towards the ſea-coaſt of Lincolnſhire. In the manor of Stretton, at a ſhort diſtance ſouth-eaſt of Biggleſwade, as a carter was ploughing the land, he diſcovered a yellow earthen pot, which was found to contain about 300 gold coins of Henry VI. They were nearly the ſize of half crown pieces each, but being very thin did not equal the weight of a guinea.

About 4 miles weſt of Biggleſwade, are the remains of Warden-abbey, which was formerly a very extenſive and conſiderable foundation. It was founded in 1135, by Walter Eſpec, for Ciſtercian monks; and at the diſſolution its revenues were valued at 389l. 16s. 6d. per annum. Leland's Itinerary. Camden's Britannia. Beauties of England and Wales, vol. i.

BIGGS Bay, lies on the ſouth ſide of Jamaica, and to the eaſt of north from Portland-point, which is the moſt ſoutherly point of the iſland.

BIG-HILL Creek, an American creek, which runs weſt into the Kaſkaſkias river, 25 miles below Beaver creek, 17 above Blind creek, and 26 northerly from the mouth of Kaſkaſkias.

BIGGIN Swamp. See Santee *River*.

BIGHT, in the *Sea-language*, denotes any part of a rope, as it is taken compaſſing, coiled up; or the double part of a rope, when it is folded, in contradiſtinction to the end. It ſignifies alſo a ſmall bay between two points of land.

BIGINI, in *Geography*, a town of Sicily, in the valley of Mazara, 10 miles eaſt of Mazara.

BIGIS, in *Ancient Geography*, a town of Aſia, placed by Ptolemy in Drangiana.

BIGLA, in *Geography*, a town of Lithuania, in the palatinate of Wilna, 40 miles E. N. E. of Wilcomirz, near a lake from which the river Driſna iſſues. N. lat. 55° 26'. E. long. 20° 24'.

BIGLOBATUS, in *Entomology*, a ſpecies of Curculio, found at the Cape of Good Hope. This is of a black colour, with a canaliculated ſnout; thorax globoſe, very rough with punctured dots; wing-caſes with ſcabrous dots, and two rows of tubercles on each ſide. Sparrm. Nov. Act. Stockh.

BIGLUMIS, a ſpecies of Veſpa, with four dots on the ſcutel; margin of the abdominal ſegments white, with two white dots on the ſecond. Gmelin. *Veſpa Rupeſtris* of Linn. Syſt. Nat. is deemed a variety of this kind.

BIGNAN, in *Geography*, a town of France, in the department of Morbihan, and chief place of a canton, in the diſtrict of Joſſelin, 3 leagues S. W. of Joſſelin.

BIGNI, in *Conchology*, a name under which Adanſon deſcribes *Voluta Tringa* of Gmelin.

BIGNON, Jerom, in *Biography*, was born at Paris in 1590, and educated by his father, who was an advocate in the parliament of Paris, and diſtinguiſhed by his learning and character. Having made a ſurpriſing progreſs under his father's tuition, he was placed, about the age of ten years, near the perſon of the young prince of Condé, and about this period publiſhed, "A Deſcription of the Holy Land," more accurate than any extant. In 1604, he compoſed for the uſe of the young duke of Vendome, a "Treatiſe on Roman Antiquities." Theſe works were compilations; but his work on the "Election of the Popes," ſaid to be compoſed in his fourteenth year, but not publiſhed till 1608, was of a more original kind, and diſplayed a degree of erudition that ſurpriſed the moſt learned men of the age. Bignon

non was regarded by Scaliger, Caſaubon, Grotius, Pithou, de Thou, Le Fevre, and other eminent ſcholars, as a prodigy of literature, and his acquaintance was eagerly cultivated. By Henry IV., who knew his extraordinary talents and attainments, he was appointed page of honour to the dauphin, afterwards Lewis XIII.; and at court his manners were diſtinguiſhed by an eaſy politeneſs, though he unremittingly proſecuted his literary ſtudies. His next treatiſe was a refutation of Valdez, a Spaniſh writer, who publiſhed a folio volume to eſtabliſh the precedence of the kings of Spain over the other ſovereigns; it was entitled "On the Excellence of the Kings and Kingdom of France," dedicated to Henry IV. and publiſhed in 1610, 8vo. Upon the death of Henry, he withdrew from court, and acquired an additional reputation by a new edition of "The Formularies of Marculphus," publiſhed with learned notes, in 1613. In the following year he took a journey to Italy, where he was honourably received by pope Paul V., Father Paul at Venice, and other perſons, who had already heard of his fame. Upon his return he devoted himſelf to the bar, and, in 1620, was appointed advocate-general to the great council; and having acquitted himſelf with credit in this office, he was nominated by the king a counſellor of ſtate; and, in 1626, created advocate-general to the parliament. In this high ſtation he maintained the parliamentary rights with firmneſs and vigour, and manifeſted the moſt ardent zeal for juſtice. In 1641, he reſigned this honourable office to his ſon-in law, Stephen Briquet; nor did he reſume it till after his death in 1645. In 1642, cardinal Richelieu, though far from being his friend, appointed him royal librarian, which his taſte for literature induced him to accept, whilſt he declined the lucrative poſt of ſuperintendant of the finances. Queen Anne of Auſtria, during her regency, availed herſelf of his advice on many intereſting occaſions, and he was employed in many delicate negociations. Having through life maintained a character, which was univerſally reſpected and eſteemed, he terminated his courſe of uſeful ſervice in the exerciſe of thoſe ſentiments of piety by which his conduct had been governed, in the 67th year of his age, April 7, 1656. Amongſt his papers were found ſome fragments of notes on Gregory of Tours, and of a work on the origin of the French law, which he had not leiſure to finiſh. The abbé Perrault has given a good account of his life, in one volume 12mo. 1757. Nouv. Dict. Hiſt. Gen. Dict.

BIGNONIA, ſo named by Tournefort, in honour of the abbé Bignon, Eng. *trumpet flower*, or *ſcarlet jaſmine*, in *Botany*. Lin. gen. n. 759. Reich. 817. Schreb. 1018. Tourn. 72. Juſſ. 139. Gærtn. t. 52. Claſs and Order, *didynamia angioſpermia*. Nat. Ord. *Perſonatæ*. *Bignoniæ*. Juſſ. Gen. char. *Cal.* perianth one-leafed, erect, cup-form, five-cleft. *Cor.* monopetalous, campanulate; tube very ſmall, the length of the calyx; throat very long, ventricoſe beneath, oblong-campanulate; border five-parted, the two upper diviſions reflex, lower patulous. *Stam.* filaments four, ſubulate, ſhorter than the corolla; two longer than the other two; another reflex, oblong, as it were doubled. *Piſt.* germ oblong; ſtyle filiform, ſituation and form of the ſtamens; ſtigma capitate. *Per.* Silique two-celled, two-valved; partition membranaceous, parallel, thickened at the ſutures. *Seeds* very many, imbricate, compreſſed, membrane-winged on both ſides. Obſ. *Catalpa* has only two perfect ſtamens, and three very ſmall rudiments of ſtamens, with a five-leaved calyx. Four, however, and even all five perfect, have been obſerved by Cyrilli. The form of the ſilique in this genus is indeterminate. The ſeeds are always winged, though ſome on one ſide only.

Eſſ. Char. *Cal.* five-cleft, cup-form. *Cor.* throat bell-form, five-cleft, ventricoſe beneath. *Silique* two-celled. *Seeds* membrane-winged.

Species, 1. B. *Catalpa*, common Catalpa tree. Lin. ſpec. 868. Reich. 3. 155. hort. cliff. 317. 1. Ait. hort. Kew. 2. 346. Duham. Arb. 1. 104. t. 41. Cateſb. Car. 1. 49. t. 29. "Leaves ſimple, cordate; ſtem erect; ſeeds winged with membranes." A deciduous tree, with an upright ſtem, covered with a ſmooth brown bark, 30 or 40 feet high; with lateral branches, ovate leaves placed oppoſite at every joint, flowers in branching panicles towards the end of the branches, of a dirty white colour, with a few purple ſpots, and faint ſtripes of yellow on their inſide, which flowers are ſucceeded by long taper pods not yet produced in England. Found by Mr. Cateſby growing naturally on the back of South Carolina, brought into England about the year 1726, and now not uncommon in our nurſeries and plantations. In our climate the leaves come out very late; and the tree requires a ſheltered ſituation. It flowers in Auguſt, and is known in the nurſeries by its Indian name "Catalpa." The branches dye wool a kind of cinnamon colour. Thunberg mentions that the Japaneſe lay the leaves on parts of the body affected with pains, on a ſuppoſition that they are beneficial to the nerves; and that a decoction of the pods is ſerviceable in the aſthma. 2. B. *tomentoſa*. Lin. Syſt. 563. Thunb. Jap. 252. "Leaves ſimple, cordate, tomentoſe beneath; flowers axillary, panicled." A native of Japan. 3. B. *ſempervirens*, Carolina yellow jaſmine. Lin. Spec. 869. Reich. 3. 155. Gelſeminum. Park. 1465. n. 5. Raii hiſt. 1769. Cateſb. Car. 1. t. 53. Syringa. Pluk. Alm. t. 112. f. 5. "Leaves ſimple, lanceolate, ſtem twining." Riſing with ſlender ſtalks, that twiſt themſelves round the neighbouring plants, and mount to a conſiderable height, with ſingle oppoſite leaves at every joint, that remain green throughout the year; growing naturally in South Carolina, where it ſpreads over the hedges, and, at the ſeaſon of flowering, perfuming the air to a great diſtance; and alſo found in ſome parts of Virginia: called yellow jaſmine, probably from the ſweet odour of its flowers. Cultivated in 1640, in Kew garden, by Parkinſon. 4. B. *unguis*. Lin. Spec. 869. Reich. 3. 156. Apocyno affine. Sloan. jam. 1. 268. Clematis. Plum. Amer. t. 94. Pluk. Alm. t. 163. f. 2. "Leaves conjugate; tendril very ſhort, bowed, three-parted." A native of the Weſt Indies. 5. B. *æquinoctialis*. Lin. Spec. 869. Reich. 3. 156. Sabb. hort. 2. t. 85. Plum. Spec. 5. ic. 55. f. 1. "Leaves conjugate, cirrhoſe; leaflets ovate and lanceolate; peduncles two-flowered; ſiliques linear." Received by Mr. Millar from La Vera Cruz, in New Spain. 6. B. *paniculata*. Lin. Spec. 869. Syſt. 563. Reich. 3. 156. Jacq. amer. t. 116. Pict. 91. t. 175. Plum. Spec. 5. ic. 56. f. 1. "Leaves conjugate, cirrhoſe; leaflets cordate-ovate; flowers racemed; peduncles three-flowered." Sent to Mr. Miller from La Vera Cruz, by Dr. Houſtoun. Obſerved about Carthagena by Jacquin. 7. B. *crucigera*. Lin. Spec. 869. Reich. 3. 157. Vir. cliff. 60. Hort. cliff. 317. 3. Gron. virg. 1. 73. 2. 95. Plum. ic. 48. t. 58. Pſeudo-Apocynum. Mor. hiſt. 3. 612. n. 6. f. 15. t. 3. f. 16. "Leaves conjugate, cirrhoſe; leaflets cordate; ſtem muricated:" deriving its trivial name from a ſection of the ſtem which repreſents a croſs. Sent to Mr. Miller from Campeachy. 8. B. *capreolata*, four-leaved trumpet-flower. Lin. Spec. 870. Syſt. 563. Reich. 3. 157. Vir. cliff. 59. Hort. cliff. 317. Brayn. ic. 33. t. 25. Duham. Arb. 1. 104. t. 40. Cateſb. Car. 2. 82. Clematis. Bocc. ſic. 31. t. 15. f. 3. Zan. hiſt. 74. t. 2. ed. 2. 49. t. 33. Raii hiſt. 1329. "Leaves conjugate, cirrhoſe; leaflets cordate-lanceolate; bottom-leaves ſimple." Sent to Mr. Miller from Campeachy. A native of Virginia and Carolina; and cultivated

in

in Kew garden in 1730. 9. B. *pubeſcens*. Lin. Spec. 870. Reich. 3. 157. "Leaves conjugate, cirrhoſe; leaflets cordate-ovate, pubeſcent beneath." Growing naturally in Virginia, and ſeveral other parts of America. 10. B. *triphylla*, three-leaved trumpet-flower. Lin. Spec. 870. Reich. 3. 157. "Leaves ternate; leaflets ovate, acuminate; ſtem ſhrubby, erect." Sent to Mr. Miller from La Vera Cruz, by Dr. Houſtoun. 11. B. *pentaphylla*, hairy five-leaved trumpet-flower. Lin. Spec. 870. Reich. 3. 158. Hort. cliff. 497. 6 "Leaves digitate; leaflets quite entire, obovate." Sent to Mr. Miller from Jamaica, by Dr. Houſtoun; and introduced into Kew garden before 1733. 12. B. *Leucoxylon*, ſmooth five-leaved trumpet-flower, white-wood, or tulip-flower. Lin. Spec. 870. Reich. 3. 158. Swartz obſ. 233. Pluk. alm. t. 200. f. 4. Brown jam. 263. n. 1. Sloan. jam. 2. 62. n. 47. Raii dendr. 114. 2. "Leaves digitate; leaflets quite entire, ovate, acuminate." According to Sir Hans Sloane, this tree is as large as any in the iſland of Jamaica, having a large ſtraight trunk covered with a ſmooth whitiſh bark, and a very hard white wood. According to Browne, it grows in a kind ſoil to a large ſize, and is conſidered as good timber-wood; but when its growth is not luxuriant, fit only for ſmaller and ſubordinate implements. Its juice and tender buds are ſaid to be an antidote to the poiſonous juice of the manchineel. Mr. Miller ſays, that it riſes with an upright ſtem to the height of 40 feet, in the natural country of its growth; and that the ſeeds, diſperſed by the winds to neighbouring lands, ſupply plants in great plenty. Cultivated by Mr. Miller in Kew garden, in 1759; and received by him from Barbadoes under the denomination of "white wood." 13. B. *radiata*, ray-leaved trumpet-flower. Lin. Spec. 871. Reich. 3. 158. Feu. peruv. 2. 731. t. 22. "Leaves digitate; leaflets pinnatifid." Stem three inches high; corolla pale yellow, with red dots. A native of Peru, in very dry ſand. 14. B. *radicans*, rooting or aſh-leaved trumpet-flower. Lin. Spec. 871. Reich. 3. 158. Hort. cliff. 317. 4. Upſ. 178. Gron. virg. 73. 94. Duham. arb. 1. 103. 1. Sabb. hort. 2. t. 84. Pſeudo gelſeminum ſiliquoſum. Riv. mon. 101. Pſeudo-Apocynum. Mor. hiſt. 3. 612. n. 1. ſ. 15. t. 3. f. 1. Park. 1679. and 385. n. 6. Gelſeminum hederaceum Indicum. Corn. can. t. 103. Raii hiſt. 1768. β. B. fraxini fol. coccineo fl. minore. Cateſb. car. 1. t. 65. Mill. fig. 43. t. 65. Duham. arb. 103. 2. "Leaves pinnate; leaflets gaſhed; ſtem with rooting joints." Stems rough, branches trailing, faſtening by the roots, iſſuing from their joints, to the trees in their natural place of growth, and climbing to a great height; in Europe, where it is generally planted againſt walls, ſtriking into the mortar of the joints, ſo as to ſupport the branches, and riſing to the height of 40 or 50 feet: flowers produced at the ends of the ſhoots of the ſame year, in large bunches, with long ſwelling tubes, ſhaped ſomewhat like a trumpet, whence the plant has the appellation of "trumpet-flower;" corolla of an orange colour, and opening at the beginning of Auguſt. Cultivated in Kew garden in 1640. The ſeeds of β. were ſent from Carolina in 1724, by Mr. Cateſby; and ſince that time many plants have been raiſed in England, by ſeeds ſent from that country. 15. B. *ſtans*, branching-flowered trumpet-flower. Lin. Spec. 871. Reich. 3. 159. Jacq. Amer. pict. 97. t. 176. Brown. jam. 264. 3. Plum. Spec. 5. ic. 54. Sloan. jam. 2. 63 n. 49. B. frutescens. Mill. dict. n. 3. "Leaves pinnate; leaflets ſerrate; ſtem erect, firm; flowers racemed." An upright ſhrub from four to eight feet in height; flowers yellow, with red lines on the inſide of the tube; ſiliques half a foot long, with winged ſeeds. A native of all the ſugar iſlands in the Weſt Indies, chiefly in a dry, rocky, or gravelly ſoil. Mr. Miller ſays, that he received this ſort firſt in 1729, from La Vera Cruz, where Dr. Houſtoun found it in great plenty; ſince which time he obtained the ſeed from the iſland of Bermuda, by the title of "candle-wood." 16. B. *grandiflora*. Lin. Syſt. 564. Thunb. jap. 253. Kæmpf. ic. fol. 21. "Leaves pinnate; leaflets ovate, acuminate, ſerrate; ſtem twining; calyx ſemiquinquefid." Stem ſhrubby, climbing, four cornered; calyx five-cornered; corollas purple, the ſize of a roſe: differing from the *radicans* in having a ſtem not at all rooting, a larger flower, and a ſemiquinquefid calyx. A native of Japan. 17. B. *chelonoides*. Lin. Syſt. 564. Suppl. 282. Padri. Rheed. Mal. 6. 47. t. 26. "Leaves unequally pinnate; leaflets ovate, quite entire, acuminate, pubeſcent; corollas bearded, with the rudiment of a fifth ſtamen." A large tree, with a whitiſh aſh-coloured bark; leaves ſpreading, petioled; panicle terminating: pedicels oppoſite, dichotomous; flowers ſolitary, from the diviſions; calyx hoary; border of the corolla a little arched, rough with hairs, red, five-cleft; the two upper ſegments yellow, with red dots; lower ſegments rough with hairs, curled at the edge, diſk waved, white, veins red, throat rough with hairs; the rudiment of a fifth ſtamen, inſerted into the tube of the corolla, barren; ſiliques linear, flat, bent, ſtreaked. The freſh flowers, immerſed in water, give it a pleaſant odour; and in the Eaſt Indies, of which it is a native, they ſprinkle it over the temples in a morning, to correct the ſtagnant air. 18. B. *ſpathacea*. Lin. Syſt. 564. Suppl. 283. Nür Pongelion. Rheed. Mal. 6. 53. t. 29. "Leaves unequally pinnate; leaflets ovate, rough with hairs; calyx one-leafed, ſpotted; corolla ſalver-ſhaped." A large tree, differing in the ſtructure of the flower from the other ſpecies, but having didynamous ſtamens, and a pod filled with winged ſeeds. It is evidently of this genus. The timber is aſh-coloured, or red, ſmooth, and much uſed for a variety of utenſils in India. A native of Malabar, Java, and Ceylon, in woods near waters. 19. B. *peruviana*. Lin. Spec. 871. Reich. 3. 159. Hort. cliff. 317. 5. "Leaves decompound; leaflets gaſhed; ſtem with tendrils at the joints." A native of America. 20. B. *indica*, Indian trumpet-flower. Lin. Spec. 871. Reich. 3. 159. fl. zeyl. 236. Lour. cochinch. 379. Palega pajaneli. Rheed. Mal. 1. p. 77. t. 43. Raii hiſt. 1741. β. Pajaneli. Rheed. 79. t. 44. Raii hiſt. 1741. n. 2. "Leaves bipinnate; leaflets quite entire, ovate, acuminate." A large tree, with aſcending branches. A native of the Eaſt Indies, and Cochinchina. Introduced in 1795 by Dr. Solander. A variety occurs near Mozambique, in Africa. 21. B. *cærulea*. Lin. Spec. 872. Reich. 3. 160. Cateſb. car. 1. t. 42. "Leaves bipinnate; leaflets lanceolate, entire." Grows naturally in the Bahama iſlands, whence Mr. Cateſby ſent the ſeeds, in 1724; and many of the plants were raiſed in the gardens near London. In the country where it grows naturally, it riſes to the height of 20 feet. 22. B. *longiſſima*, wave-leaved trumpet-flower. Ait. Hort. Kew. 2. 347. Jacq. Amer. 182. t. 176. f. 78. Swartz Prodr. 91. Brown. jam. 264. 2. Plum. ic. 47. t. 57. B. Quercus Lamarck Encycl. 1. 417. "Leaves ſimple, oblong, acuminate; ſtem erect: ſeeds woolly." An elegant, upright tree, 40 feet high and upwards. A native of the Weſt Indies; cultivated and growing luxuriantly in many parts of Jamaica, eſpecially in the low lands and ſavannahs, where it grows to a conſiderable ſize, and is conſidered as an excellent timber-tree. Its numerous flowers, and ſlender ſiliques, add a peculiar grace to its growth. In Jamaica it is known by the name of "French oak;" and in the French Weſt India iſlands it is called "Chêne noir." 23. B. *echinata*. Gærtn. fruct. 1. 240. t. 52. Jacq. Amer. 183. t. 176. f. 52. Aublet. Guian. 2. 648. t. 263, 264.

Swartz

Swartz prodr. 91. "Climbing; lower leaves ternate; upper bijugous, cirrhoſe; fruit echinate." A rambling ſhrub climbing to the tops of trees by its very long and numerous branches. A native of the Weſt Indies, Carthagena, and Guiana. 24. B. *pentandra*. Lour. Cochinch. 379. "Leaves bipinnate; ſtamens five, with two anthers in each; calyx fleſh-coloured, five-toothed." A middle-ſized tree, with aſcending branches. A native of Cochinchina, near rivers. Loureiro has another ſpecies under the name of B. *longiſſima*, which is a native of Cochinchina, by rivers, and which is not the B. *longiſſima* of Jacquin (N° 22.); agreeing, according to Lourciro, with the "lignum equinum" of Rumphius (vol. iii. p. 73. t. 46.), or B. *ſpathacea* of the younger Linnæus, in the length and form of the corolla, but not in the ſpathaceous calyx and pinnate leaves. But Retzius obſerves, that Rumphius's plant is not the ſame with Linnæus's, and it is very different from the "Nur-Pongelion" of the Hortus Malabaricus. Loureiro alſo remarks, that the three Aſiatic ſpecies which he has deſcribed can by no means be adapted to the generic character formed by Linnæus from the American ſpecies, except in the fruit; and even that is not always two-celled in the Aſiatic ſpecies. 25. B. *alliacea*. Swartz prodr. 91. Aubl. guian. 659. 14. Barr. gall. æquin. 23. "Leaves conjugate; leaflets elliptic, entire, coriaceous; peduncles five-flowered, axillary; calyxes entire." This plant has a ſtrong ſmell of garlic, whence its trivial title, and its French name "Liane à l'Ail." A native of the Weſt Indian iſlands, and the foreſts of Cayenne and Guiana. 26. B. *caſſinoides*. Vahl. Symb. 2. 68. Lamarck. Encycl. "Leaves ſimple, elliptic, coriaceous; raceme terminating." A native of Rio Janeiro, having the appearance of an "Echites." 27. B. *bijuga*. Vahl. Symb. 2. 69. "Leaves abruptly pinnate, bijugous; leaflets elliptic, quite entire." A native of Madagaſcar.

The *Bignonias* are trees or ſhrubs, inhabitants of the hot climates, of the Eaſt and Weſt Indies, and eminently beautiful. The leaves are oppoſite; in ſome ſpecies, unequally pinnate or ternate; in others, conjugate, with a two-leaved petiole between the leaflets, frequently furniſhed with a tendril for climbing. Flowers in panicles, large and handſome, of various colours, red, blue, yellow, or white. The calyx ſhould be obſerved, whether it be ſimple or double; the corolla, whether it be regular or irregular; the ſtamens, whether they be fertile or barren; the fruit, whether it be bony or capſular, in form of a ſilique, or ovate. There are many ſpecies, particularly from Braſil, not yet ſufficiently known to admit of arrangement under this genus. B. *ſempervirens* does not belong to this genus, ſays Mr. Martyn, but to that of *liſianthus*.

Propagation and culture. Theſe are exotic trees or ſhrubs, and may be raiſed from ſeeds ſown on a moderate hot-bed in the ſpring. They ſhould be ſoon inured to the open air, to prevent their being drawn up weak. They may be alſo increaſed by cuttings, and ſome of them by layers. The ſeeds of the common Catalpa tree are annually brought over from South Carolina. The ſeedling plants ſhould be placed abroad in the beginning of June, in a ſheltered ſituation, till autumn, and then placed under a ſummer frame, to guard them from the winter froſt; expoſing them in mild weather to the open air. In the following ſpring they ſhould be taken out of the pots, and planted in a nurſery-bed, in a warm ſituation, where they may remain two years, and then planted where they are to remain. This tree may be alſo propagated by cuttings, which, in the ſpring, ſhould be planted in pots, and plunged into a moderate hot-bed, ſhading them from the mid-day ſun, and occaſionally, but ſparingly, refreſhing them with water. In about ſix weeks, when they have taken root, and made ſhoots above, they ſhould have plenty of air, and accuſtomed to bear being expoſed to the open air; and afterwards treated like the ſeedling plants. The catalpa delights in a rich moiſt ſoil, where, in a few years, it will produce flowers. The plants of the third ſpecies, not bearing cold, when young, ſhould be ſheltered in winter, planted againſt a warm wall, and protected from froſt by coverings of mats, and by tan covering the ſoil about their roots. The fourth and fifth ſpecies will live in the open air, when planted againſt a wall with a ſouth aſpect, and ſheltered in a very ſevere froſt. The ſixth, ſeventh, eighth, tenth, eleventh, and twelfth ſorts, are tender, and will not thrive in this country out of the bark-ſtove. If the ninth ſpecies be planted in the full ground againſt a wall, the roots ſhould be covered in the autumn with ſome old tanners' bark, to keep out the froſt in winter; and in very ſevere froſt they ſhould be covered with mats. The twelfth ſort will take root from cuttings planted during ſummer in pots, or plunged into a bark-bed: it has flowered ſeveral years in the Chelſea garden, in Auguſt. The fourteenth ſort is ſo hardy as to thrive in the open air; but the trailing branches ſhould be ſupported; and as they ſpread much and riſe to a great height, they will ſerve to cover unſightly buildings; and alſo trained againſt the ſtems of trees, they make a fine appearance when in flower. It is propagated by ſeeds, but the young plants thus obtained will not flower in leſs than ſeven or eight years; and therefore thoſe propagated by cuttings or layers are moſt eſteemed, becauſe they will flower in two or three years after planting. The neceſſary culture for theſe plants, after they are eſtabliſhed, is to cut away all the ſmall weak ſhoots of the former year in winter, and ſhorten the ſtrong ones to the length of about two feet; and thus young ſhoots will be obtained for flowering in the following ſummer. Theſe plants are of long duration: ſome of them remain vigorous after 60 years, and produce plenty of flowers every ſeaſon. The fifteenth ſpecies is propagated by ſeeds ſown on a hot-bed, and by tranſplanting the plants into ſeparate ſmall pots, filled with light freſh earth, and plunged into a freſh hot-bed; by removing them in autumn into the bark-ſtove, giving them but little water during winter, and in ſummer refreſhing them with it ſparingly; and they ſhould remain conſtantly in the bark-ſtove, and be treated like other tender plants from the hot countries. The third year from ſeed they will flower; but they do not produce ſeeds in England. The other ſorts have not been cultivated in England. Martyn.

BIGORNO, in *Geography*, a town of Corſica.

BIGORRE, a country of France, in the province of Guyenne before the revolution, but now forming a part of the department of the Upper Pyrenées. Its capital was Tarbes. It is bounded on the N. E. by Armagnac and the country of the four vallies, Nebouzan and Aſtarac; on the ſouth, by the Pyrenées; and by Bearn, on the weſt. It has been ſometimes divided into the country of Ruſtan, the Plain, and the Vallies; and eſtimated at 16 leagues in length from north to ſouth; and in its greateſt breadth at 7 leagues. From its general ſituation, this country might be expected to enjoy the ſame mild climate that is experienced in the neighbouring provinces, under the ſame latitude; but from local circumſtances the caſe is very different. The Pyrenées intercept the warmth of the more ſouthern country of Spain; while, from its elevated ſituation, it is expoſed to the chilling blaſts of the north. On this account, Bigorre is deprived of many fruits and vegetables, ſuch as the orange and olive; however, the laurel, fig-tree, and myrtle, are not injured by the climate. The air of the mountains is cold and chilling, but that of the plains and

vallies more mild and ſalubrious. This country produces wood in conſiderable quantities, excellent wine, rye, barley, and millet; but not much wheat. It has good paſtures, quarries of marble, and medicinal ſprings. The mountains of Bigorre conſiſt of ſchiſt, marble, and granite. See PYRENEES. The inhabitants of this diſtrict poſſeſs a peculiar and characteriſtic phyſiognomy, in which they all reſemble one another: they are healthy and active, lively and chearful, and unite impetuous courage with ſtrength and agility. The impetuoſity of their temper renders their language rapid, paſſionate, and full of proteſtations; and they ſometimes ſink the voice an octave below the natural key, that they may ſuddenly raiſe it to the ſharpeſt note. Their ideas abound with imagery: and their geſtures are quick and violent. They are diſtinguiſhed by their generoſity and beneficence. They practiſe the ſling from their infancy, and can draw a bow before they ſpeak; and thoſe perſons are regarded as the moſt accompliſhed, who are moſt ſkilled in leaping, riding, and throwing the bar. The education of the Bigorreſe, who are not huſbandmen, is conducted with a view to the church; and they boaſt of many eminent perſons in ſcience and literature.

BIGOT, a perſon fooliſhly obſtinate, or perverſely attached to an opinion. The word is formed from the German *bey*, and *Got*, or the Engliſh *by-God*. Camden relates, that the Normans were firſt called *Bigots*, on occaſion of their duke Rollo; who receiving Giſſa, daughter of king Charles, in marriage, and with her the inveſtiture of the dukedom, refuſed to kiſs the king's foot in token of ſubjection, unleſs he would hold it out for that purpoſe; and being urged to it by thoſe preſent, anſwered haſtily, "No, by God;" whereupon the king, turning about, called him *Bigot;* which name has paſſed from him to his people.

BIGOT, EMERIC, in *Biography*, an eminent promoter of literature, was born at Rouen in 1626; and forming an early attachment to literature, he declined all public buſineſs, and employed himſelf in augmenting a large library bequeathed to him by his father, and in correſpondence and converſation with perſons of learning. Few perſons conciliated, by the modeſty of his temper, by the friendſhip and ſuavity of his manners, and by his love of peace and endeavours to maintain it, a greater number of friends, who reſpected and eſteemed him. In various parts of Europe through which he travelled, he formed connections with literary men; but his moſt intimate friends of this deſcription were Menage and Nicholas Heinſius. Although he diſtinguiſhed himſelf by aiding others in their literary performances, the only work he publiſhed in his own name was the Greek text of Palladius's life of St. Chryſoſtom, found in the grand duke's library at Florence, to which he annexed a Latin tranſlation. Having entailed his valuable library on his family, in order to prevent its diſperſion, he died at Rouen in 1689. However, notwithſtanding his precaution, his library was publicly ſold at Paris in 1706. Gen. Dict.

BIGOT, in Italian *bigontia*, in *Commerce*, is uſed to denote a Venetian liquid meaſure, containing the fourth part of the *amphora*, or half the *boot*.

BIG Rock, in *Geography*, a large rock on the S.E. bank of Au Vaze river in America; about 3 miles N.E. from its mouth in the Miſſiſippi, and about 8 miles S.E. from cape St. Antonio on that river.

BIG *Rock Branch*, the north-eaſtern head branch of Alleghany river. The branch called Big Hole Town joins it, and forms the Alleghany, 85 miles N.E. from, and above, Venango fort.

BIG *Salt Lick*, a garriſon in the ſtate of Teneſſee, near the Salt lick, on Cumberland river, 115 miles from Knoxville; 80 from S.W. point on Clinch river, 32 from Bledſoe lick, and 68 from Naſhville.

BIG *Sandy River*, or *Totterwy*, riſes near the ſource of Cumberland river, and ſeparating Virginia from Kentucky, diſcharges itſelf into the Ohio, oppoſite to the French purchaſe of Galiopolis, in about N. lat. 38° 30′. Vancouver's and Harmar's forts ſtand on this river. On its banks are ſeveral ſalt licks and ſprings. *Little Sandy* is a ſhort ſmall river, which falls into the Ohio, about 20 miles weſt of Big Sandy river, in the county of Maſon, Kentucky.

BIGUBA, a town of North Africa, ſeated on the river Rio Grande. N. lat. 11° 15′. W. long. 13° 35′.

BIGUTTATA, in *Entomology*, a ſpecies of SILPHA, met with at Upſal. This is totally ferruginous, with a pale line and ſpot on the wing-caſes. Thunberg. Nov. Act. Stockh.

BIGUTTATA, a ſpecies of CASSIDA, with a yellow thorax; reddiſh wing-caſes; black margin, and two yellow ſpots. Fabricius. This inſect inhabits Cayenne.

BIGUTTATA, a ſpecies of COCCINELLA, deſcribed by Fabricius. It is rufous, with two yellow ſpots. The country is unkown. Size ſmall; thorax gloſſy and black, with the ſides yellow.

BIGUTTATA, a ſpecies of CANTHARIS, found in gardens in Europe. The thorax is black in the middle; wing-caſes ſhort, black, and yellow at the tip. Linn. Fn. Suec. Fabricius. This is *Telephorus niger, femoribus flavis, elytris apice luteis* of Degeer.

BIGUTTATA, a ſpecies of BUPRESTIS, with very entire, linear, green wing-caſes, with a white dot; abdomen blue, with three white dots. Fabricius, &c. Inhabits England.

BIGUTTATA, a ſpecies of CICADA (*Cercopis*), of a black colour, ſpotted with yellow; wing-caſes brown, with a white marginal ſpot. Inhabits Germany. Fabricius.

BIGUTTATA, a ſpecies of CICADA (*Ranatra* Fabr.) that is found in Europe. It is black, with a patch of ſanguineous red on each ſide of the thorax. Fabricius.

BIGUTTATA, a ſpecies of VESPA, of the ſmall ſize, that inhabits China. It is black, and ſpotted with yellow; margin of the ſegments, and two dots of yellow on the ſecond one. Fabricius.

BIGUTTATA, a ſpecies of SCOLIA, of a black colour, with two tranſverſe white dots on the abdomen; wings black. A ſmall ſpecies, and inhabits Spain. Fabricius.

BIGUTTATOR, a ſpecies of ICHNEUMON, deſcribed by Thunberg. It is black, with two dots on the ſcutel. Found at Upſal.

BIGUTTATUS, a ſpecies of CURCULIO, that is found in Germany. It is black, with elevated dots on the wing-caſes; abdomen and poſterior legs yellow. Fabricius.

BIGUTTATUS, a ſpecies of CRYPTOCEPHALUS, of a black colour, with the head, tip of the wing-caſes, and legs yellow. Gmelin. A native of Auſtria.

BIGUTTATUS, a ſpecies of CARABUS, that lives under the bark of trees in Sweden, and is deſcribed by Thunberg. The head is roundiſh and braſſy; wing-caſes black, with a pale ſpot at the apex.

BIGUTTATUS, a ſpecies of DYTISCUS, deſcribed by Linnæus as a native of Europe. This is black; legs, end of the abdomen, antennæ, mouth, two dots between the eyes, thorax, and wing-caſes teſtaceous, the latter ſpotted with brown; in the middle of the thorax two black ſpots.

Biguttatus, a ſpecies of Staphylinus, that inhabits ſome ſhores of the Baltic ſea. It is of a black colour, with a fulvous ſpot on each of the wing-caſes. Linn. Fabr. &c.

Biguttatus, a ſpecies of Cimex (*Rotundiditus*), deſcribed by Linnæus in his Fauna Suecica, by Scopoli, &c. It is black, with all the margins white, and a white ſpot on the wing-caſes.

BIGUTTULUS, a ſpecies of Gryllus (*Locuſta*), with a cruciate thorax; wing-caſes clouded, and marked with an oblong white ſpot near the tip. Linn. Fn. Suec. &c. This is *Acrydium biguttulum* of Degeer. Very common on ſome barren lands in the north of Europe.

BIHACS, Bihatz, Bihitz, or Vihitz, in *Geography*, a town of Croatia, ſeated on the river Unna, belonging to the Turks; 60 miles ſouth of Carlſtadt, and 180 weſt of Belgrade. N. lat. 44° 42′. E. long. 16° 20′.

BIHAI, in *Botany*. See Strelitzia.

BIHAMATA, in *Entomology*, a ſpecies of Hispa, of an oblong, depreſſed ſhape, that inhabits India. It is ſpecifically deſcribed as being unarmed, black, ſpotted with red; ſhells truncated and hooked. Gmelin.

Bihamata, a ſpecies of Formica, found in the iſland of Joanna, having four ſpines on the thorax, and two curved ones on the petiole ſcale. Fabricius, &c.

BIHAR, in *Geography*, an ancient town of Hungary, giving name to a diſtrict, in which are alſo Debretzen, Great Varadein, &c.

BIHOREAU, in *Ornithology*, the name of *Ardea nyctico-rax*, or *Night heron*, in Buffon's Hiſt. birds. *Femelle de Bihoreau* of Buffon, is *Ardea griſea*; and *Bihoureau de Cayenne* of Buff. is *Ardea cayennenſis* of Gmelin.

BIHRI, in *Geography*, a town of Perſia, in the country of Lariſſan, in the route from Iſpahan to Ormus, 30 miles N.W. of Lar.

BIJINAGUR. See Bisnagur.

BIJORE, called alſo *Bejour* and *Bajour*, the *Bazira* of Alexander, a province of Hindoſtan, bounded on the ſouth by Paiſhawur, on the north by Kuttore, on the eaſt by Sewad and Beneer, which are ſeparated from it by the Penjekoreh river, and on the weſt by Guznoorgul. This province, according to the dimenſions ſtated in the Ayen Acbaree (vol. ii. p. 192, &c.) extends 25 coſſes north and ſouth, and 10 eaſt and weſt; diſtant about 20 coſſes beyond the Cabul river, and on its weſtern extreme about 30 coſſes from the Indus. Bijore, as well as Sewad, is very mountainous, and abounds with paſſes and ſtrong ſituations; ſo that their inhabitants have not only held themſelves generally independent of the Mogul emperors, but have occaſionally made very ſerious inroads into their territories. In this province there is at this day a tribe of Afghans, denominated Yuzuf-zyes, which traces its origin to certain perſons left there by Alexander the Great, when he paſſed through this country. Both Abul Fazil, the author of the Ayen Acbaree, and Soojan Rae, an eaſtern hiſtorian of good reputation, report this tradition without any material alteration. The latter, indeed, adds, that theſe Europeans, if we may call them ſo, continued to preſerve that aſcendancy over their neighbours which their anceſtors may be ſuppoſed to have poſſeſſed, when they firſt ſettled here. Although we ſhould reject this pedigree as fabulous, yet the bare claim argues the belief of the natives, for which there muſt have been ſome foundation, that Alexander not only conquered Bijore, but alſo transferred that conqueſt to ſome of his own countrymen. The people of Bijore had likewiſe an high idea of Alexander's extenſive authority; and they denominated him the "Two-horned," agreeably to the ſtriking emblem of power in all the eaſtern languages. (Ayen Acbaree, xi. 194.) Theſe Yuzuf-zyes, ſays Mahomed Cazim, quitted their ancient habitations between Ghizni and Candahar, and after various unſucceſsful attempts to obtain a ſettlement in Cabul, at the time when Mirza Ulug Beig, ſurnamed Cabulee, ruled that kingdom, finally eſtabliſhed themſelves in Sewad and Bijore; which at this period were governed by a dynaſty of princes ſtyled "Sultani," who derived their lineage from Alexander the Great. The Yuzuf-zyes poſſeſs, in addition to Sewad and Bijore, the tracts ſituated between thoſe provinces, and the rivers of Cabul and Indus; the greateſt part of which is deſcribed as a deſert in the Ayen Acbaree, but by Bernoulli as a foreſt. In the time of Acbar, Zine Khan was ſent to chaſtiſe them; and he overran their whole territory, and even penetrated to the borders of Caſhgar, and took the ſtrong fort of Kuſhal, or Guſhal, ſeated on a mountain 17 marches north of Bijore. About the year 1670, Aurungzebe found it neceſſary to chaſtiſe theſe Yuzuf-zyes; ſince which period the return of Nadir-Shah, in 1739, again brought them into notice. To him they appeared formidable; but he reduced them to ſubmiſſion; and if they really engaged to ſupply his army with 30,000 men, the tribe muſt have increaſed ſince the time of Acbar, when Bijore contained only 30,000 and Sewad 40,000 families. Rennell's Mem. p. 159, &c.

Bijore, the capital of the above-deſcribed province, ſituated about 6 marches, or about 66 geographical miles, from Nilab or Attock, and at 50 of the ſame mile, north a little eaſt from Paiſhawur, and at the ſame diſtance eaſt a little north from Jalalabad. N. lat. 34° 7′. E. long. 70° 44′.

Bijore, the name of a river which riſes in the mountains, N.E. of Bijore, and paſſing by it, forms a junction with the Penjekoreh, Sewad, and Kameh, and falls into the Nilab, or Sinde, at Attock.

BIISK, a town and diſtrict of Siberia, in the government of Kolyvan, ſeated on the river Bi, or Biia, which, by uniting with the Katunia, forms the river Oby; 150 miles S.S.E. of Kolyvan. N. lat. 53° 31′. E. long. 84° 14′.

BIJUGUM, Folium, in *Botany*, denotes a winged leaf, bearing two pair of *foliola*.

BIKBULAKOVA, in *Geography*, a town of Ruſſia, in the government of Uſa, on the river Ik, 80 miles N.E. of Orenburg.

BIKILLAM, or Beckalen, a ſmall iſland in the Red ſea, 8 leagues from the coaſt of Arabia. N. lat. 16°. E. long. 42° 25′.

BIKOU, a town of Poland, in the palatinate of Braclaw, 50 miles north of Braclaw.

BILA, a river of Bohemia, which runs into the Moldaw near Auſſig.

Bila, *Alt*, a town of Bohemia, in the circle of Leitmeritz, 10 miles W.S.W. of Kamniz.

BILÆNA, or Bilbana, in *Ancient Geography*, a town of Arabia Felix. Ptolemy.

BILAN, in *Geography*, a town of Bohemia, in the circle of Chrudim, 5 miles weſt of Chrudim.

BILANCIIS Deferendis, in *Law*, a writ directed to a corporation, for the carrying of weights to ſuch a haven, there to weigh the wool, which perſons by our ancient laws were licenſed to tranſport. Reg. Orig. 270.

BILANDER, in *Navigation*, a ſmall merchant-ſhip with two maſts; diſtinguiſhed from other veſſels of the ſame kind by the form of the main-ſail, which reſembles a ſettee-ſail. The head is bent to a yard, ſimilar to the mizen-yard of a ſhip, and hangs to the main-maſt, as a ſhip's does to the mizen-maſt. This method of rigging has proved inconvenient, and is now ſeldom uſed, except by the Dutch.

BILANUS, in *Botany*. See CRATÆVA.

BILARIUS, PORUS. See BILIARII *Pori*.

BILATERAL COGNATION, denotes kinſhip, or kindred, on both ſides; that of the father as well as mother.

Such is the relation of brothers, ſiſters. Bilateral ſtands contradiſtinguiſhed to unilateral.

BILBA, in *Ancient Geography*, a town of Aſia, in Babylonia. Ptolemy.

BILBAO, ſometimes called *Bilboa*, in *Geography*, a port-town of Spain, in the province of Biſcay, ſeated on the banks of the river Ybaizabal, about 6 miles from the ſea. On the water-ſide is a large ſquare, well ſhaded with pleaſant walks, extending to the outlets on the banks of the river, and containing a number of houſes and gardens, which form an agreeable proſpect, particularly in ſailing up the river. The number of houſes in this town is about 800, ſome of which are built on piles; they are ſolid and lofty; the ſtreets are well paved and level; and as they may be waſhed at pleaſure, Bilboa is one of the neateſt towns in Europe. The tide that flows into the river forms a ſecure and much frequented harbour; and a conſiderable commerce is thus carried on in iron, wool, of which, it is ſaid, 60,000 bags are annually exported to Great Britain, France, and Holland, ſaffron, and cheſnuts. Towards the cloſe of the 10th century, the people of Biſcay, having maintained their independence, together with their profeſſion of Chriſtianity, even when the Moors gained poſſeſſion of the other parts of Spain, and having about this time obtained ſome advantages over them, began to direct their attention to the manufacture of their own excellent iron, not only for their own uſe, but for the ſupply of other nations; and their port of Bilboa began to have ſhipping, and to engage in foreign trade, perhaps before any other nation to the weſt of the Mediterranean ſea, at leaſt in a very conſiderable degree. In the laſt year of the 13th century, this town was refounded, or new built, by Didacus Lopez, then prince, or lord of the province; and as it was the ſtaple port for the iron and wool of Spain, its commerce rapidly increaſed; and it appears from Rymer's Fœdera, that in the reign of king Edward IV. A.D. 1474, the merchants of Guipuſcoa carried on, probably by the port of Bilboa, a conſiderable trade with England. It appears, alſo, that the Biſcayners, availing themſelves of the advantage of their ſhipping and port, were concerned in the whale-fiſhery at an earlier period than any other nation of Europe, Norway excepted. The town is ſupplied with fleſh and poultry, and alſo with fiſh of various kinds, and particularly with a ſort of eels in winter, which are ſmall, of a pale colour, about three inches long, and without a back bone, caught in prodigious quantities at low tides, and in ſummer with the cuttle-fiſh. The ſhambles are a Tuſcan building, in the centre of the town, with an open court, and a fountain in the middle, by means of which it is kept clean, and free from offenſive offals and ſcents. The environs abound in gardens, which are fertile in legumes and fruits. This town has five churches, and ſeveral religious houſes; and in its police it has one law of a peculiar kind, which renders ingratitude criminal, and ſubject to a penalty. Although the air is generally damp, the town is remarkably healthy, and the inhabitants are robuſt, cheerful, and long-lived; ſo that the hoſpital is frequently without a patient. The women are capable of enduring labour as well as the men, and are employed in unloading the ſhips, carrying burdens, and performing the buſineſs of porters. At the cloſe of the day they return to their habitations, without any appearance of laſſitude, dancing and ſinging to the pipe and tabor. Their muſic is defrayed at the expence of the town; and on holidays it is performed in the midſt of a great concourſe of perſons under the trees in the great ſquare. The women of Bilbao, though conſtantly expoſed to the air, have good complexions, lively eyes, and fine black hair, which they curiouſly braid, and which they reckon peculiarly ornamental. Married women wrap a white handkerchief round their heads, ſo knotted as to fall down in three plaits behind, and over this they wear the Montera cap. Thoſe who underſtand their language ſay it is very ſoft and harmonious, as well as energetic. N. lat. 43° 15'. W. long. 2° 45'. See BISCAY.

BILBERRY, in *Botany*. See VACCINIUM.

BILBILINÆ AQUÆ, in *Ancient Geography*, *Alhama*, mineral and medicinal waters of Spain, 24 miles from Bilbilis, according to the itinerary of Antonine. The name Alhama, given by the Arabians to this place, has the ſame meaning with the aquæ calidæ of the Latins. See ALHAMA.

BILBILIS, BAMBOLA, a town of Hiſpania Tarragonenſis, belonging to the Celtiberi, ſouth of Turiaſco; ſeated on a mountain ſurrounded by the waters of Salo or Xalon. Bilbilis was a municipal town, and bore the title of Auguſta, which is found on ſeveral medals. The poet Martial was of this city, called by Ptolemy *Bilbis*.

"Municipes Auguſta mihi quos Bilbilis acri
Monte creat, rapidis quos Salo cingit aquis."
Martial, l. 10, epig. 103.

On moſt of the medals of Bilbilis, we perceive, on one ſide a head of Auguſtus, and, on the other, a cavalier, armed with a lance and a helmet.—Alſo, a river of Spain, the waters of which were famous for tempering iron; called alſo *Salo*.

BILBOWS, in *Sea-phraſe*, a puniſhment anſwering to the ſtocks at land.

They conſiſt of long bars, or bolts of iron, with ſhackles ſliding on them, and a lock at the end, uſed to confine the feet of priſoners, in a manner ſimilar to the confinement of the hands in handcuffs. See STOCKS.

BILCOCK, in *Ornithology*, one of the ſynonymous Engliſh names of *Rallus aquaticus*, or water-rail.

BILDERWERTSCHEN, in *Geography*, a town of Pruſſia, in the province of Lithuania, 4 miles W.N.W. of Stalluponen.

BILDESTON. See BILSTON.

BILDGE, or BILGE *of a Ship*, denotes the bottom of her floor; or the breadth of that part which ſhe reſts on, when ſhe is a-ground.

Hence, when a ſhip receives a fracture in this place, by ſtriking on a rock, or otherwiſe, ſhe is ſaid to be *bilged*, or *bulged*.

BILDGE-*Water*, is that which, by reaſon of the flatneſs of the ſhip's bottom, lies on her floor, and cannot go to the well of the pump. This water is always, if the ſhip does not leak, of a dirty colour, and diſagreeable ſmell.

The Dutch, whoſe ſhips are often of this form, uſe a ſort of pumps, called "bildge-pumps," or, as we call them "burr-pumps," to carry off the bildge-water.

BILE, in *Phyſiology*, is the fluid prepared from the blood by the liver of animals. The colour of healthy bile in the human ſubject is probably of a deep yellow brown. In oxen, it is frequently of a yellowiſh green. In the gall bladder, it is of a thickiſh conſiſtence, of an unctuous feel, or like that of mucus, of a bitter taſte, and peculiar ſmell. Its ſpecific gravity is about 1.027. It readily mixes with water, but will not incorporate with oil, yet it takes greaſe out of cloths. Albumen may be precipitated from it by alcohol and acids; and Cadet aſcertained its proportion in 100 parts of ox bile to be about 0.52. (Cadet, Mem. Par. 1767.) If a ſolution of bile in muriatic acid be concentrated by heat, a copious precipitate takes place, and the ſolution changes its colour from a

graſs

graſs green to a brown. This precipitate has the properties of a reſin. From 100 parts of bile, 1.87 of cryſtallized ſoda has been obtained, and ſome was probably loſt in the proceſs. Cadet alſo obtained from bile a ſalt of a ſweetiſh taſte. There are other ſubſtances found in bile in ſmall quantities: ſulphurated hydrogen gas, which is emitted on the addition of muriatic acid; a little muriate of ſoda, phoſphate of lime, and phoſphate of ſoda and of iron. Of courſe water is the vehicle for all theſe ſubſtances, and forms the largeſt ſhare of the ingredients in the compoſition of bile. For an account of the ſecretion of bile, ſee the article LIVER, *functions of*.

BILE, in *Chemiſtry*. This fluid may juſtly be conſidered as equally important to the chemiſt as to the phyſiologiſt; and accordingly it has been examined with extreme minuteneſs by a great number of eminent chemiſts, in various countries, with a general parity of reſult which is highly ſatisfactory. Indeed the analyſis of bile, as far as relates to the detection of its leading conſtituent parts, is neither very complicated nor remarkably difficult.

Chemiſts have not been able to detect any conſiderable difference between the bile immediately ſecreted from the liver, and that which is found in the gall-bladder, excepting that the latter appears on the whole to be ſomewhat leſs watery, more bitter and more viſcid than the former. The age of the animal makes a greater difference, the bile or gall of oxen being more viſcid than that of calves. On account of the eaſe with which ox-gall is procured in conſiderable quantity, this has generally been ſelected for experiment; but its analyſis does not eſſentially differ from that of the bile of any other animal.

Bile is a homogenous fluid, in ſome animals of a deep yellowiſh brown, in others of various ſhades of green, ſo viſcid as not to pour by drops; of a peculiar faint ſmell, but not ungrateful when freſh, and not from a diſeaſed animal; intenſely bitter to the taſte, even when very largely diluted with water, and ſomewhat pungent. It is conſiderably heavier than water; its ſpecific gravity being from about 1.02 to 1.025, varying according to the age and health of the animal, and probably to the time that it has remained within the gall-bladder. When agitated, bile lathers like ſoap water.

When bile is gently heated, an aqueous vapour ariſes, which, when condenſed, appears by the moſt delicate reagents to be nothing but water, ſtrongly impregnated however with the odorous part of this fluid, and ſomewhat fœtid. Bile loſes about ſeven eighths of its bulk of mere water by this evaporation; and the reſidue gradually thickens into the conſiſtence of a tenacious extract, which, on carefully drying, becomes a hard brittle ſhining reſin-like maſs, of a dark colour, and intenſely bitter.

If this extract of bile be ſlowly heated in a retort to decompoſition, the products are, a watery fluid fœtid with ſulphuretted hydrogen gas, a brown fœtid liquor containing ammonia, a tenacious ſtinking empyreumatic oil, with more carbonated ammonia, and a copious emiſſion of carbonic acid, and carburetted with ſulphuretted hydrogen. The maſs in the retort ſwells up prodigiouſly in the proceſs, and leaves a puffy coal eaſy to incinerate, the aſhes of which contain a notable quantity of carbonated ſoda, with ſome muriated ſoda, phoſphat of ſoda and lime, and a little iron. Fontana obtained from a pound of ox-gall 43 grains of carbonated ſoda, and 6 grains of common ſalt.

The reſidue, therefore, of calcined bile contains alkali in exceſs; and hence water, with which it has been lixiviated, readily turns ſyrup of violets green. The ſame teſt of an alkali is given with freſh bile, diluted with water, that the change of colour may be more apparent.

The action of acids on bile throws much light on its compoſition. Muriatic acid, ſtrong or dilute, added to bile, immediately produces a coagulation, and, at the ſame time, renders the whole liquor of a fine light green. The coagulum, however, is partly rediſſolved, if the acid is concentrated. Examined chemically, it is found to be albumen, but intenſely bitter. In the clear green liquor, though retaining the muriatic acid, the bitter taſte alſo ſtrongly predominates. Evaporated ſlowly, it depoſits in about an hour's time another precipitate, very green, intenſely bitter, and ſoft and tenacious like turpentine. The clear liquor is now yellowiſh, and, on further evaporation, yields a number of cubical cryſtals of muriated ſoda, formed chiefly, if not entirely, by the ſoda originally contained in the bile and the acid added. As a proof that this is the caſe, if the experiment is made with nitrous or ſulphuric acid, inſtead of the muriatic, the ſalt will be nitrated or ſulphated ſoda. The above decompoſition is more perfect, if bile and dilute muriatic acid are at firſt boiled together for a few minutes; the reſult then is a total ſeparation of a dark green glutinous bitter maſs, and a liquid now colourleſs and ſcarcely bitter, from which the muriated ſoda may be procured by evaporation.

This glutinous coagulum, when dry, burns like a reſin. Alcohol heated upon it diſſolves one part, and leaves another untouched, thus entirely ſeparating it into two diſtinct principles; the inſoluble, which is albumen; and the ſoluble, which retains the colour and taſte of bile, is totally precipitated from the ſpirit by water, is highly inflammable, inſoluble in water, and has been conſidered as a ſpecies of reſin or concreſcible oil, and is termed by ſome the *reſin of bile*. Fourcroy, however, ſuppoſes it to be more of the nature of *adipocire*.

Alcohol alone is another important re-agent for the analyſis of bile. When theſe two fluids are mixed together, a coagulum is immediately formed of a whitiſh tenacious ſubſtance, ſcarcely bitter when well waſhed, and exhibiting all the properties of albumen. The remaing liquor is green, and contains, mixed with the alcohol, the reſinous, ſaline, and colouring matter of the bile. Alcohol equally ſeparates albumen from bile, inſpiſſated by evaporation, and diſſolves the remainder. The alcoholic ſolution of bile, not previouſly treated by an acid, differs conſiderably from that which has undergone this treatment. In the latter caſe, as before mentioned, the ſolution is decompoſable by mere water, and by evaporation is converted into a very reſinous product. In the former caſe, the ſolution mixes uniformly with water, yields by evaporation a tranſparent extract like gum-arabic, of a ſweetiſh taſte, a little mixed with the natural bitterneſs of bile, and eaſily ſoluble in water. The reaſon of this difference is doubtleſs owing to the ſeparation of the ſoda from the reſin of bile by the oxyd in one inſtance, whereas in the other they remain united in the form of a natural ſoap. Hence it is that the affuſion of an acid upon the latter alcoholic ſolution decompoſes it, and ſeparates an unctuous ſubſtance, which again diſſolved in alcohol is *now* precipitable from this ſolvent by ſimple water, and reſembles a pure reſinous ſolution.

Some chemiſts have thought that they could alſo detect a ſaccharine matter in bile, but the experiments to this purpoſe are not concluſive.

The oxygenized muriatic acid gas paſſed through bile diluted with a little water, ſoon deſtroys its yellow green colour, and precipitates the albumen in white flocculi; the ſaponaceous reſin

refin continues in folution without colour or fmell; but the bitternefs remains. A further quantity of this acid feparates the refinous oil as the muriatic acid does, but white and concrete. Any acid poured upon bile already bleached by the oxymuriatic acid, feparates unctuous white concrete matter much refembling *adipocire*, but the precife nature of the change produced by the oxymuriatic acid has not been properly afcertained.

Bile therefore may be inferred from the prefent ftate of chemical analyfis to contain,

1. A large proportion of water.
2. A fubftance clofely refembling animal albumen.
3. A peculiar refinous inflammable matter, naturally and intimately with
4. Soda, into a kind of foap, or faponaceous extract.
5. Some neutral falts.
6. A fmall quantity of oxyd of iron.

Befides thefe conftituents, there is a colouring and odorant matter, but it is not yet afcertained whether thefe are properties of any of the above-mentioned ingredients, or whether they belong to a peculiar fubftance.

Some chemifts have alfo fuppofed a kind of faccharine mucilage, refembling the fugar of milk, but the exiftence of this, in recent unaltered bile, is very doubtful.

Bile has been fuppofed to be a powerful antifeptic, and its effects in the animal economy have been attributed to this quality, but without much foundation. Bile, left to itfelf in a moderate temperature foon becomes putrid (though not fo fpeedily as blood); it then exhales a very fœtid odour, but after this point it decompofes but very flowly, and at laft aflumes a ftrong, not very unpleafant mufky fmell. This partial refiftance to putrefaction is probably owing to the refinous ingredient, which laft, when feparated by acids and alcohol, in the way already mentioned, is abfolutely incapable of putrefaction. M. Cadet afferts, that at no time during this procefs is any acid generated.

The *faponaceous* quality of bile, which is very characteriftic, and is owing to the intimate union of its refin with foda, renders it mifcible with milk, with oil, myrrh, aloe, and other gum-refins, by trituration, without curdling, or ready decompofition. It is alfo owing to an intimate mixture with this natural foap that the albumen which bile contains is not coagulable by heat; even if an additional quantity of albumen (white of egg for example) is mixed with bile, heat will not coagulate it. Hence too, alcohol only partially feparates the albumen, unlefs an acid is previoufly applied to engage the foda, and the alcoholic folution of the refin retains the foda fo as to render the refin not feparable by mere water.

Bile, or ox-gall, is employed in various ways as a cleanfer of wool, cloth, &c. to get out greafe fpots, to take off the greafinefs of ivory in preparing it for receiving colours; and in China it is mixed with fome of their varnifhes. Gall a little putrid may be preferved a long time from further alteration by being boiled for a few minutes.

M. Fourcroy afferts, that he has obtained a fubftance, refembling bile in every property, by mixing blood with a third of water, coagulating it by heat, and flowly evaporating the ferum. This experiment has, however, been repeated by others without fuccefs. See Cadet in the Mem. de l'Acad. des Sciences, for 1767 and 1769. Van Bochante, Profeffor at Louvain, in the Jour. de Phyf. tom. 13. Suppl. An. Chim. tom. 4, 5, and 6. Fourcroy Syfteme de Conn. Chim. &c.

Bile, in *Medicine*, a yellowifh-green fluid, more or lefs vifcid, and of a bitter tafte, fecreted in the liver, and conveyed from that vifcus, by the focalled ductus communis choledochus, into the duodenum. It is a very compound fluid, being refolved by chemical analyfis into a variety of ingredients; fuch as water, albumen, refin, foda, muriate of foda, phofphate of foda, phofphate of lime and iron, befides a fweetifh matter analogous to fugar of milk. In its general properties, it may be faid to partake of the nature of a foap, although it will not intimately mix with oil. The cyftic bile, or that which is contained in the gall-bladder, poffeffes more vifcidity and bitternefs, (i. e. is more concentrated) than that which flows directly from the biliary ducts into the duodenum, and which is termed hepatic bile.

When we fee an organ of fuch magnitude as the liver, appropriated to the fecretion of the bile, we are naturally led to infer that the fluid fo fecreted, muft anfwer fome ufeful purpofes in the animal economy; but refpecting the number and kind of purpofes which it anfwers, phyfiologifts do not exactly agree. It may, perhaps, concur with the pancreatic juice, to the feparation of the refufe part of the alimentary pulp (chyme) from the proper chyle; but, as Dr. G. Fordyce has remarked, in his treatife on the digeftion of food, the bile does not unite with the chyle itfelf, and pafs along with it, through the lacteals into the blood. Mixed with the feculent matter, and colouring it, the bile feems to prevent that matter from running into fermentation, by virtue of its alkaline nature; and perhaps, alfo, in confequence of the bitter principle which it contains, it may, in fome degree, refift putrefaction; but its principal and moft obvious ufe is, as a ftimulus to the inteftines, ferving to keep up a due degree of periftaltic action, and thereby to produce a regular and natural evacuation of their contents. Hence a diminifhed fecretion, or obftructed paffage of the bile, is always accompanied with coftivenefs.

From this view of the nature and compofition of the biliary fecretion, and of its action upon the living body in a ftate of health; we proceed to the confideration of its morbid conditions, which may be reduced to four heads; viz. 1. *Deficiency*. 2. *Obftruction*. 3. *Excefs*. 4. *Vitiation*.

1. *A deficiency of Bile*. This is known by a pale and languid habit of body, indigeftion, flatulency, acidity, coftivenefs, and pale or clay-coloured ftools. It is occafioned by a fedentary mode of life, by intemperance, and by depreffing paffions of the mind. It occurs in chlorofis, hypochondriafis, and chronic hepatitis. (See what is faid of thefe diftafes under their refpective titles.) To whatfoever caufe it may be owing, it is always attended with indigeftion and coftivenefs; two fymptoms which fhould be efpecially attended to in the cure. A well regulated diet fhould be prefcribed, wherein fpirituous drinks, high-feafoned meats, flatulent vegetables, and crude and acid fruits, fhould be forbidden. Much ftrefs fhould at the fame time be laid on a plan of regular exercife; and the injurious effects of cold and damp upon the gaftric and hepatic fyftems, fhould be counteracted by fuitable cloathing. As a further aid to digeftion, bitters and chalybeates (efpecially the chalybeate mineral waters), fhould be prefcribed; and coftivenefs fhould be remedied by occafional dofes of rhubarb, neutral falts, and aloetics; and fome times by the ftronger cathartics. Acidity fhould be counteracted by alkalies, among which, foda or natron præparatum anfwers beft. Where the diminifhed fecretion of bile has appeared to be connected with a difeafed ftructure of the liver, and particularly where fuch a change of ftructure has arifen from inflammation, mercury (Dr. Saunders obferves), has been found ufeful, even carried to the degree of producing a flight falivation; moderating the violence, however, of its operations by plentiful dilution, with

with gum arabic, and other vegetable demulcents. In theſe caſes, the ſame author has found a tepid bath, of 90 degrees of Fahrenheit, to produce manifeſt good effects.

2. *Obſtruction of Bile.* After it is ſecreted, the bile is ſometimes prevented from paſſing into the duodenum. This may happen from various cauſes; viz. from an obliteration of the cavities of the biliary ducts, either by a thickening of their coats, or by a tuberculous ſtate of the liver, the conſequences of inflammation; from preſſure produced by enlargements of the neighbouring parts; and from a too viſcid and conſiſtent ſtate of the bile itſelf; but, more than all, from gall-ſtones impacted in the common duct. Whenever in any of theſe ways, the bile, after being ſecreted, is hindered from paſſing into the duodenum, it is either taken into the circulating ſyſtem by what is termed regurgitation, or by abſorption; producing great langour and oppreſſion, together with a yellowneſs of the ſkin, and tunica conjunctiva of the eyes, &c. i. e. giving riſe to *jaundice*. (See Gall-Stones and Jaundice.) The treatment muſt be varied, according to the variety of conditions on which the obſtruction depends. In this place, it will be ſufficient to remark, that ſaline purgatives, mercurials, ſaponaceous and alkaline medicines, with tepid dilution, and warm bathing, will be found ſuited to the majority of theſe caſes.

3. *Exceſs, or redundancy of Bile*, is a morbid affection, of very frequent occurrence. Among its exciting cauſes may be mentioned intemperance of living, the ſummer and autumnal heats of our own latitudes, and more eſpecially the high temperatures of the tropical climates; in a word, whatever produces a hurried circulation, or irritates the vaſcular and ſecreting ſyſtem of the liver. A redundancy of bile makes itſelf known by "a general languor of the body, together with nauſea, foul tongue, loſs of appetite, and indigeſtion: or, by being directed to the inteſtines, excites a painful diarrhœa, ultimately tending to weaken their tone, and diſturb their regular periſtaltic motion. It generally happens, that, during the exceſs and prevalence of bile in the firſt paſſages, ſome abſorption of it takes place into the habit, ſo that the ſkin becomes yellow, and the urine is ſenſibly impregnated with it. The pulſe is quicker than natural, and there is a conſiderable degree of thirſt, with an increaſe of heat; the uſual ſymptoms of fever. The body becomes emaciated, and the general aſpect of the patient is extremely unhealthy." It may be added, that moſt of the fevers of hot climates, whether intermittent, remittent, or continued are accompanied by an an overflow of bile. (See Fevers.) When the increaſed ſecretion of bile affects the ſtomach and bowels in ſuch manner as to excite both vomiting and purging to a violent degree, it gives riſe to that form of diſeaſe which is termed *cholera*; of which a particular deſcription will be found under that title; when it produces vomiting, joined with conſtipation and acute pains about the umbilical region, the diſeaſe is termed *bilious colic* (ſee Colic); and laſtly, when the evacuation of bile is frequent and copious by ſtool only, without frequent vomiting, it conſtitutes *bilious diarrhœa*. (See Diarrhoea.) It is the remark of that judicious writer to whoſe work we have more than once referred in this account of bilious diſorders, that it is more difficult to ſupply a deficiency of bile, than to carry off its exceſs. In fact, little more is required for the fulfilment of this laſt intention, than to promote the diſcharge of the redundant bile by gentle ſaline evacuants, (for the bile has generally of itſelf a purgative tendency), and to prevent freſh accumulations, by diluting freely with water heated to a proper temperature. For this purpoſe, the patient ſhould drink every morning (according to the excellent directions of Dr. Saunders), from half a pint to a pint of water, of a temperature from 90° to 114° of Fahrenheit's thermometer, and uſe moderate exercife before breakfaſt. With the ſame view, the Bath and Buxton waters, (provided their uſe be not contra-indicated by viſceral diſeaſe), and the Cheltenham water alſo may be recommended. At the ſame time, a proper diet ſhould be preſcribed, conſiſting of food that is eaſy of digeſtion, not over-ſtimulating, and free from flatulency; and ſpirituous drinks and malt liquors ſhould be forbidden. Paſtry is particularly improper. Water, or wine and water, will be the beſt beverage. When the bile has been ſufficiently evacuated, bitters and chalybeates may be given with advantage. But where theſe complaints are the conſequence of reſiding in the tropical regions, the only effectual remedy is to remove to a temperate climate. People, who have ſuffered in theſe reſpects from the heat of climate, and to whom it is neceſſary to return to this country for the recovery of their health, ſhould endeavour (as Dr. Lind has ſuggeſted), to arrive in the beginning of ſummer, as they will find the winters of Great Britain, on their firſt arrival, too piercing and ſevere for their conſtitutions.

4. *Vitiation of the Bile.* In almoſt all caſes wherein the ſecretion of bile exceeds the natural quantity, it is at the ſame time vitiated in its quality. Thus in bilious fevers, bilious diarrhœas, bilious colic, and cholera morbus, it is often vitiated both in colour and taſte, appearing wholly of a pure green colour, and poſſeſſing a ſharpneſs or acidity which ſets the teeth on edge, and produces a burning and corroding ſenſation in the ſtomach, œſophagus and fauces, and at the ſame time violent twitchings in the inteſtinal canal. Such vitiations of the bile are common to infants, as well as to adults. The remedial treatment conſiſts in evacuating the offending bile by the means ſpecified under the preceding diviſion (3), and correcting its vitiated qualities by the employment of alkalies, and by copious dilution with aqueous and mucilaginous liquors. After due evacuations, the ſtomach and bowels may be protected from the irritating action of the remaining bile by opiate medicines. Lind, Clark, Winterbottom, and other writers on the diſeaſes of hot climates, may be referred to for many excellent obſervations on bilious diſorders; but the beſt and moſt comprehenſive treatiſe on this ſubject is that of Dr. Saunders.

BILEDGIK, in *Geography*, a town of Aſiatic Turkey, in the province of Natolia, 32 miles N. W. of Eſki-Shehr.

BILEDULGERID, a country of Africa, comprehending, according to ſome geographers, the ſouthern part of Algiers, together with the whole tract of land that lies in this direction between the Atlantic ocean and Egypt, and in this extent, including eight large tracts or provinces, viz. Barca, Biledulgerid proper, Segelmeſſa, or Sijilmiſſa, Tafilet, Tigorarin, Zeb or Zab, Darka or Darah, and Teſſel, beſides ſeveral inferior diſtricts, mentioned under the names of Oguela, or Augela, Faſſan or Fezzan, and Gudamis or Gadamis, &c. It was known to the ancients under the name of *Numidia*. But in a more confined and proper ſenſe, according to the arrangement of De Liſle, and ſeveral modern geographers, Biledulgerid includes that tract of land which lies ſouth of Algiers and Tunis, and is bounded on the eaſt by a ridge of lofty mountains, which ſeparates it from Tripoli and part of Gadamis, on the weſt by the countries of Zab and Mezzab, and on the ſouth by the province of Verghela, or Wergela. Its dimenſions are not accurately aſcertained; but it is ſomewhat of a ſquare form, ſuppoſed to extend about 60 or 80 leagues, every way, or from about 31° 15′ to 34° 15′. N. lat.; and from 5° 30′ to 10° E. long. Some have derived the appellation Biledulgerid from *Bekd el jerid*, or the "land of dates," under which denomination it is diſtinguiſhed in Rennell's map of North Africa; but others, with

Dr.

Dr. Shaw, deduce it from *Blaid el jeride*, or the "dry country." The whole province of Biledulgerid, bordering to the ſouth on Sahara, or the Great Deſert, is mountainous, ſandy, and barren, producing little or no ſuſtenance but dates, which grow in ſuch abundance, that various parts of it are covered with palm-trees bearing this fruit. The climate is hot and unhealthy; the people are meagre, ſwarthy, and ſhrivelled in their complexions, and their eyes are inflamed by the reflection of the ſun-beams, from the white hard ſoil, and by clouds of duſt and ſand driven by the high winds at ſome ſeaſons in ſuch abundance, as to bury men and cattle under their collected maſſes. They are alſo ſubject to a ſcorbutic complaint, of which they can aſſign no probable cauſe, but ſo inveterate, that their teeth drop out, and their bodies become loathſome. In other reſpects they are healthy and vigorous, and live without ſickneſs or diſeaſe to a great age. The plague of Barbary is ſcarcely ever heard of in this province, notwithſtanding the contiguity of the two countries, and the frequent intercourſe of their inhabitants. Biledulgerid, properly ſo called, has few rivers and towns. The natives of Biledulgerid are repreſented as a lewd, treacherous, thieviſh, and ſavage people, that delight in murder, blood, and rapine. They are, in general, a mixture of old Africans and wild Arabs; the former of whom lived with ſome degree of regularity and civil order, in a kind of villages compoſed of a number of little huts, whilſt the latter inhabited moveable tents, and ranged from place to place in queſt of food and plunder. Theſe Arabs value themſelves on their ſuperiority with regard to birth and talents above the primitive inhabitants; and whilſt they are wholly independent and free, they occaſionally hire themſelves to ſerve in the wars of the neighbouring princes, and hence ariſes the chief part of their public revenue; the reſt purſue no other occupations beſides plundering and hunting, and particularly hunting oſtriches, the fleſh of which they dreſs for food, and the feathers they barter for corn, pulſe, and other neceſſaries. The other parts of theſe birds they uſe in their religious rites, as ornaments of dreſs, or as pouches and knapſacks. Beſides dates and oſtriches, they likewiſe ſubſiſt on the fleſh of goats and camels; and for their drink, they uſe either the broth in which the fleſh is boiled, or the milk of their camels, for they ſeldom taſte water, which is not only ſcarce, but brackiſh and unwholeſome. For the character and manners of thoſe who inhabit that part of Biledulgerid, taken in its former extent, and bordering on the Atlantic ocean; ſee Monselemines and Mongearts.

BILEFELD. See Bielfeld.

BILGE. See Bilge.

BILGUER, John Ulrick, in *Biography*, born at Coire, in the country of the Griſons, in Switzerland; after paſſing through the uſual courſe of education, practiſed ſurgery at Berlin, where he ſoon acquired ſuch reputation, as to engage the attention of king Frederic the Great, who made him ſurgeon to one of his regiments, and, in progreſſion, ſurgeon-general to the Pruſſian army. In the courſe of an extenſive practice in this poſt, he had an opportunity of obſerving how very ſmall a proportion of the men recovered from fractures, where the ſoft parts were greatly bruiſed, and the bones ſhattered, when the limb had been amputated, which in ſuch caſes was the general practice. This induced him to try more lenient methods, which he practiſed with ſuch ſucceſs, as to enable him to reduce the caſes in which amputation ſhould be declared to be neceſſary to a very ſmall number. In 1761, he was admitted to the degree of doctor in medicine, by the univerſity of Hall, in Saxony, when he read for his theſis "De membrorum amputatione rariſſime adminiſtranda, aut quaſi abroganda." This work was tranſlated into French, and highly commended by Tiſſot, then in the zenith of his reputation, which gave the work ſuch credit, and ſo quick a circulation, that it was ſoon naturalized in every country of Europe, and its diffuſion has been attended with the moſt beneficial conſequences. The methods recommended by the author for preſerving fractured limbs, even in caſes that have been before thought hopeleſs, ſucceeded ſo often, as very much to diminiſh the frequency of the operation. He alſo publiſhed at Glogau, in 1763, "Inſtructions for Surgeons of Hoſpitals," in German. In this work, he further defends and illuſtrates the doctrine contained in the theſis. In caſes where amputation cannot be avoided, he adviſes leaving a portion of the integuments, a practice now become general. There are alſo other works publiſhed by this author on the practice of ſurgery, for the titles and accounts of which, ſee Haller's Bib. Chirurg. Eloy. Dict. Hiſt.

BILGHY, in *Geography*, a town of Hindoſtan, in the Myſore country, and in that diſtrict ceded to Britain in 1799, 58 miles W.S.W. from Harponully, and 35 N.N.W. from Bednore. N. lat. 14° 8′. E. long. 74° 50′.

BILIARY *Calculi*. Some of the concretions found in the gall bladder or ducts, and which are generally of an oval form, are compoſed of a white ſubſtance like ſpermaceti, cryſtallized in brilliant plates or ſtriæ. Theſe concretions float in water, and are inflammable. They diſſolve in heated alcohol, in oil of turpentine, and in alkalies; in the latter caſe, the ſolution has the properties of a ſoap.

Other biliary concretions are of a polygonal form, and generally very numerous; they are of a browniſh colour, and are formed of concentric layers, of a ſubſtance reſembling inſpiſſated bile.

In ſome biliary concretions, there is a mixture of both the ſubſtances above deſcribed.

There are alſo ſometimes found in the gall bladder dark-coloured ſmall brittle concretions, which are inſoluble in alcohol, or oil of turpentine, and which are not inflammable. (See Gall-Stones.) For a detail of experiments relative to Bile and theſe calculi, conſult Cadet, Mem. Par. 1797. Fourcroy, Ann. de Chimie. Gren & Vauquelon, ibid. Ramſay in the Theſaur. Med. Edin. and Maclurg. See Calculi, *Biliary*.

BILIARII *Pori*, the excretory ducts of the liver, now commonly termed *vaſa biliaria*. See Liver.

BILICH, a town of Siberia, 8 miles S.E. of Vercholenſk.

BILIHAN, a town of Perſia, in the province of Irac, 100 miles S.S.W. of Amadan.

BILIKOWKN, a town of Poland, in the palatinate of Kiov, 50 miles weſt of Kiov.

BILIMBI, in *Botany*, a ſpecies of the Averrhoa (ſee Averrhoa); which is carefully cultivated in the gardens of the Eaſt Indies, where it flowers throughout the year. The juice of the root is drank as a cure for fevers. The leaves boiled, and made into a cataplaſm with rice, are famed in all ſorts of tumors, and the juice of the fruit is uſed in almoſt all external heats, dipping linen rags in it, and applying them to the parts. It is drank, mixed with arrack, to cure diarrhœas; and the dried leaves, mixed with betel leaves, and given in arrack, are ſaid to promote delivery. The fruit is pleaſant to the taſte when fully ripe, and is commonly eaten; when ſmaller, and unripe, it makes a very pleaſant pickle.

BILIN, in *Geography*, a town of Bohemia, in the circle of Leitmeritz, 14 miles weſt of Leitmeritz. This place has a fine citadel, and a ſpring of acid water; and holds annual fairs.

BILINEATA, in *Entomology*, a ſpecies of LEPTURA, of a blackiſh-brown, with two lines on the thorax, and ſcattered dots on the wing-caſes yellowiſh. Scopoli, Gmelin. Inhabits Carniola.

BILINEATA, a ſpecies of CANTHARIS, with a yellow thorax, with a ſpot, and four brown dots; wing-caſes yellow, with a fuſcous line. Thunberg, &c. This is a native of the cape of Good Hope.

BILINEATA, a ſpecies of CHRYSOMELA, that inhabits Scandinavia. It is green, gloſſed with gold; anterior part of the thorax excavated; and a double blue line on the wing-caſes. Gmelin.

BILINEATA, a ſpecies of PHALÆNA (*Geometra*), with yellowiſh teſtaceous wings, waved, with a broad ſtripe acroſs, having a brown and a white margin. Linn. Fn. Suec. &c. A very common inſect in hedges during the ſummer months; and is called in England ſometimes the *elm moth*.

BILINEATA, a ſpecies of PHRYGANEA, of a blackiſh colour, with brown wings, and two white lines on each margin. Inhabits the north of Europe.

BILINEATUM, in *Conchology*, a ſpecies of BUCCINUM, deſcribed by Liſter. The ſhell is tranſverſely ſtriated; ſpire obtuſe; the whorls with a ſpotted band and two lines. Its native country is unknown.

BILINEATUM, in *Entomology*, a ſpecies of PHALANGIUM, of a pale colour, with two dorſal lines and black dots. Fabricius. Inhabits Norway.

BILINEATUS, a ſpecies of CURCULIO. This inſect is brown, with two white lines on the wing-caſes. Inhabits Germany.

BILINEATUS, a ſpecies of CERAMBYX (*Prionus*), with crenated thorax, marked with two white lines; wing-caſes ferruginous, ſpeckled with white, and bordered with yellow. Inhabits America. Fabricius, &c.

BILINEATUS, a ſpecies of CRYPTOCEPHALUS, of a minute ſize, that is found in Europe. This inſect is black, with two yellowiſh lines on the wing-caſes, and ferruginous legs. Gmelin. A native of Europe, and deſcribed by Linnæus as *chryſomela bilineata*.

BILINEATUS, a ſpecies of ICHNEUMON. It is black, with two yellow lines in front; abdomen depreſſed; legs red; tips of the poſterior ones brown. Linn. Muſ. Leſk.

BILINEATUS, in *Ichthyology*, a ſpecies of PLEURONECTES, found in China. It is thin, long, above yellow, with a brown margin; beneath reddiſh-white; entirely covered with very ſmall ſcales. This is ſpecifically diſtinguiſhed by having the lateral line double. Bloch.

BILINEATUS, in *Zoology*, a ſpecies of COLUBER, of a rufous colour, with two yellowiſh ſtripes; *la double-raie* of count de Cepede, and *bilineated ſnake* of Dr. Shaw. This kind, according to the former writer, meaſures two feet one inch in length, of which the tail is ſix inches and a half; colour rufous, each ſcale bordered with yellow; and from the back of the head are two bright golden-yellow ſtripes extending to the end of the tail; ſcales on the head large, thoſe on the body ſmooth; native country unknown; abdominal ſcuta 205, ſubcordal ſcales 99.

BILINGUIS, in *Law*. See MEDIETAS *Linguæ*.

BILINGUIS, properly denotes a perſon who has two tongues in his mouth; an inſtance of which is given by Dolœus. It is alſo uſed for a perſon who ſpeaks two languages.

BILIOUS *Complexion*. See COMPLEXION, and TEMPERAMENT.

BILIOUS *Colic*. See COLIC.

BILIOUS *Diarrhœa*. See DIARRHŒA.

BILIOUS *Fever*. See FEVER.

BILIRIANS, in *Geography*, a denomination given to a claſs of inhabitants of the ſouthern parts of Ruſſia. In their origin they are Sarmates, who ſettled in their preſent habitations, and now exiſt under the name of Tſchuvaſches. See BOLGARIANS.

BILITZ, a town of Sileſia, in the principality of Teſchen, ſeparated from Biala by the river of the ſame name, and at a ſmall diſtance from it. N. lat. 49° 51′. E. long. 19° 6′.

BILIZIN, a town of Poland, in the palatinate of Novogrodek, about 18 miles N. E. of Novogrodek. N. lat. 53° 55′. E. long. 25° 45′.

BILL, in *Agriculture*, denotes an edge-tool, of the ax kind, with a hooked point, fitted to a handle, and uſed to lop boughs of trees, &c. When ſhort, it is called a "hand-bill;" when long, a "hedge-bill."

BILL, in *Common Language*, denotes a written or printed paper, poſted up in ſome public place, for the purpoſe of advertiſing the ſale of any merchandize, ſhip, &c. or the ſailing of any veſſel, &c.

BILL is alſo uſed among tradeſmen and workmen for an account of goods ſold and delivered, or of work done, with the charge annexed.

BILL, in *Commerce*, denotes a ſecurity for money under the hand, and ſometimes ſeal of the debtor, without any condition or forfeiture, in caſe of non-performance.—In which it is diſtinguiſhed from a bond or obligation. See BOND.

It has been uſually defined a writing, wherein one man is bound to another to pay a ſum of money, on a day that is future, or preſently on demand, according to the agreement of the parties at the time when it is drawn, and the dealings between them.

BILL, in *Law*, denotes a declaration in writing, expreſſing a wrong or grievance, which the complainant hath ſuffered by the party complained of; or elſe ſome offence committed by him againſt ſome law or ſtatute of the realm. This bill is commonly addreſſed to the lord chancellor, eſpecially for unconſcionable wrongs done to the complainant; and ſometimes to others having juriſdiction, according as the law directs. It contains the fact complained of, the damages ſuſtained, and the petition of proceſs againſt the defendant for redreſs. This is uſed as well in criminal as in civil matters. In criminal caſes, when the grand jury upon a preſentment or indictment find the ſame to be true, they indorſe on it "billa vera;" upon which the offender is ſaid to ſtand indicted of the crime, and is bound to make anſwer to it; and if the crime touch the life of the perſon indicted, it is then referred to the jury of life or death, viz. the petty jury, by whom, if he be found guilty, then he ſhall ſtand convicted of the crime, and is by the judge condemned to death.

Many of the proceedings in the king's bench are by bill; it is the ancient form of proceeding, and was, and yet ſhould be, filed in parchment, in all ſuits, not by original. The declaration is a tranſcript of it, or ſuppoſed to be. See AMENDMENT.

In Scots law, every ſummary application in writing, by way of petition to the court of ſeſſion, is called a "bill."

BILL *of Appeal*. See APPEAL.

BILL *of Attainder*. See ATTAINDER.

BILL, *Croſs*. See CROSS-*Bill*, and SUIT in *Equity*.

BILL *in equity*, is a kind of petition addreſſed to the lord chancellor, with which a ſuit in chancery commences. This, in the nature of a declaration at common law, or a libel and allegation in the ſpiritual courts, ſets forth the circumſtances of the caſe at length, "in conſideration of which," (for this is the uſual language of the bill) "and for that your orator

is wholly without remedy at the common law," relief is therefore prayed at the chancellor's hands, and alſo proceſs of ſubpœna againſt the defendant, to compel him to anſwer upon oath to all the matter charged in the bill. See SUIT in *Equity*.

BILL *of Exception to Evidence.* See EXCEPTION.

BILL *of Exchange*, in *Commerce* and *Law*, a ſhort note, or writing, ordering the payment of a ſum of money in one place, to ſome perſon aſſigned by the drawer, or remitter, in conſideration of the like value paid to him in another place. (See REMITTANCE.) Or, it is an open letter of requeſt from one man to another, deſiring him to pay a ſum of money named in it to a third perſon, on his account, or to any other to whom that third perſon ſhall order it to be paid; or it may be made payable to bearer. This kind of negociable ſecurity for money, invented among merchants in different countries, ſerves to facilitate the remittance of money from the one to the other, and of courſe the conduct of commercial tranſactions; ſo that, ſince its firſt introduction, it has extended itſelf to almoſt all pecuniary negociations.

Bills of exchange were unknown in the ancient Roman commerce, as well as juriſprudence. According to the common opinion, they are ſaid to have been brought into general uſe by the Jews and Lombards, when baniſhed for their uſury and other vices; who found means to withdraw their effects, which they had lodged in the hands of friends, both in France and England, by ſecret letters and bills conceived in ſhort preciſe terms, like the modern bills of exchange, which they negociated by the aſſiſtance of merchants and travellers. The Jews were baniſhed out of France by Philip Auguſtus, in 1143, and out of England, in 1290; but the uſe of paper credit was introduced in the Mogul empire in China, in 1236. It further appears, that bills of exchange were negociated at Hamburgh, in 1188; and it has been ſaid, that the faction of the Gibellins, being expelled Italy by the Guelphs, towards the cloſe of the 13th century, retired to Amſterdam, and uſed the ſame means for the recovery of their effects in Italy as the Jews had done; and hence, as ſome have thought, the Dutch merchants took the hint of negociating bills of exchange, and ſoon ſpread the practice throughout Europe. The ſame Gibellins are ſaid to be the inventors of the re-change, or re-exchange, on account of damages, charges, and intereſt, when bills of exchange, which they called "polizzo di cambio," are not paid, but returned on proteſt. In 1307, bills of exchange ſeem to have been in uſe in England, though their nature was not well underſtood at a much later period; and the firſt reference to them in an act of parliament, occurs in 1381, when they were forbidden to be uſed without the king's licence. In 1394, an ordinance was iſſued by the city of Barcelona, that bills of exchange ſhould be accepted within twenty-four hours after they were preſented, and that the acceptance ſhould be written on the back of the bill. Moreover, in 1404, the magiſtrates of Bruges requeſted thoſe of Barcelona to inform them what was the common practice, in regard to bills of exchange, when the perſon who preſented a bill raiſed money on it in an unuſual manner, in the caſe of its not being paid, and by theſe means increaſed the expences ſo much, that the drawer would not conſent to ſuſtain the loſs. The form of the bill, ſuch as is now uſed, is ſeen in the memorial, which alſo ſpeaks of uſance; and it alſo appears, that firſt and ſecond bills were at that time drawn, and that when bills were not accepted, it was cuſtomary to proteſt them. Anderſon's Hiſt. Com. vol. i. Beckman's Hiſt. of Invent. vol. iii. p. 462.

In common ſpeech, a bill of exchange is frequently called a "draught;" but the former is the more legal, as well as mercantile expreſſion. The perſon who makes or draws the bill is called the "drawer," and he to whom it is addreſſed is denominated the "drawee;" and when he undertakes to pay the amount, he is called the "acceptor." The perſon to whom it is ordered to be paid is called the "payee;" and if he appoint another to receive the money, this other is called the "indorſee," as the payee is, with reſpect to him, the "indorſer;" and any one who happens for the time to be in poſſeſſion of the bill is called the "holder" of it. The time at which the payment is limited to be made is various, according to the circumſtances of the parties, and the diſtance of their reſpective places of reſidence. Sometimes the amount is made payable at ſight; ſometimes at ſo many days after ſight; at other times at a certain interval from the date. See USANCE.

Where the time of payment is limited by months, it muſt be computed by calendar, not lunar months; and where one month is longer than the ſucceeding, it is a rule not to go in the computation into a third. Thus on a bill dated the 28th, 29th, 30th, or 31ſt of January, and payable one month after date, the time expires on the 28th of February, in common years, and in the three latter caſes, in leap year, on the 29th; to which are to be added the "days of grace." Where a bill is payable at ſo many days after ſight, or from the date, the day of preſentment, or of the date, is excluded. Thus, where a bill payable 10 days after ſight is preſented on the firſt day of a month, the 10 days expire on the 11th; where it is dated the firſt, and payable 20 days after date, theſe expire on the 21ſt. (Ld. Raym 281. Stra. 829.) It is a cuſtom among merchants, that a perſon to whom a bill is addreſſed, ſhall be allowed a few days for payment, beyond the time mentioned in the bill, called "days of grace." In Great Britain and Ireland, three days are allowed; in other places more. If the laſt of theſe three days happens to be Sunday, the bill is to be paid on Saturday; but theſe days of grace are not allowed on bills payable at ſight. If bills become due on Sunday, or on ſuch holidays, when the law forbids buſineſs to be done, payment muſt be demanded or proteſt made for non-payment on the preceding day.

Bills of exchange are either "foreign" or "inland;" the firſt being thoſe which paſs from one country to another, and the latter ſuch as paſs between parties reſiding in the ſame country: and by the conſent of merchants, certain cuſtoms are eſtabliſhed with regard to foreign bills, which have been adopted as part of the law in every commercial ſtate. Inland bills of exchange do not ſeem to have been very frequent in England before the reign of Charles II. (6 Mod. 29); and foreign bills were much more regarded by the law than inland ones, as being thought of more public concern in the advancement of commerce. But at length the legiſlature, by two ſtatutes, viz. 9 & 10 W. 3. c. 17. and 3 & 4 Ann. c. 9. has ſet both ſorts of bills nearly on the ſame footing; ſo that what was the law and cuſtom of merchants, with regard to the one, is now, in moſt reſpects, the eſtabliſhed law of the country, with regard to the other.

Promiſſory notes, or notes of hand, are a plain and direct engagement in writing to pay a ſum ſpecified at the time limited in it, to a perſon therein named, or to his order, or to the bearer at large. Theſe notes were at firſt conſidered merely as evidence of a debt; and it was held that a promiſſory note was not aſſignable or indorſible, within the cuſtom of merchants; and that if ſuch a note had been indorſed or aſſigned over, the perſon to whom it was ſo indorſed or aſſigned, could not maintain an action within the cuſtom againſt the drawer of the note; nor could even the perſon, to whom it was in the firſt inſtance made payable, bring ſuch

action. (1 Salk. 129. 2 Ld. Raym. 757, 9.) But at length the legiſlature recognized them and put them upon the ſame footing with inland bills of exchange; by ſtatute 3 & 4 Ann. c. 9. made perpetual by ſtat. 7 Ann. c. 25. § 3.; which enacts that promiſſory notes, payable to order or bearer, may be aſſigned and indorſed, and action maintained on them, as on inland bills of exchange. By ſtats. 15 Geo. III. c. 51, and 17 Geo. III. c. 30. made perpetual by ſtat. 27 Geo. III. c. 16. all negotiable notes and bills for leſs than 20s. are declared to be null and void; and notes or bills between that ſum and 5l. muſt be made payable within 21 days after date, muſt particularize the name and deſcription of the payees, muſt bear date at the time and place in which they are made, muſt be atteſted by a ſubſcribing witneſs, and the indorſement of them muſt be attended with the ſame ſtrictneſs in all reſpects, and made before the notes or bills become due. The omiſſion of any one of theſe regulations and formalities vacates the ſecurity, and is penal to him that utters it. Bills of exchange and promiſſory notes muſt now be drawn on ſtamped paper; and the ſtamp is proportioned under ſtat. 31 Geo. III. c. 25. 37 G. III. and 41 G. III. c. 10. to the amount of the bill from ſixpence to three ſhillings for ſuch as are payable on demand; and for thoſe payable after date from one ſhilling to four ſhillings. If foreign bills are drawn here, the whole ſet muſt be ſtamped; but bills drawn abroad are not liable to any ſtamp duty.

As bills of exchange were firſt introduced for the convenience of commerce, it was formerly thought that they could neither be drawn nor negociated by any perſon who was not actually a merchant; but it has been ſince decided, that any perſon capable of binding himſelf by a contract, may draw or accept, or negociate a bill of exchange, and by ſtat. 3 & 4 Ann. c. 9. be a party to a promiſſory note. However, an infant cannot be ſued on a bill of exchange, nor a feme-covert, except in ſuch caſes as ſhe is allowed to act in as a feme-ſole. If a bill is drawn on two joint traders, the acceptance of one binds the other, if it concern the joint trade; but it is otherwiſe, if the bill concern the acceptor only, in a diſtinct intereſt and reſpect. On the ſubject of procuration with regard to bills; ſee PROCURATION.

A promiſſory note, when indorſed, begins to reſemble a bill of exchange, for the indorſer of the note correſponds to the drawer of the bill; the maker to the drawee or acceptor, and the indorſee to the payee: and this reſemblance being fixed, the law is preciſely the ſame in bills of exchange and promiſſory notes. It is now a decided point of law, that bills and notes made payable to bearer are equally transferrable with thoſe payable to order; and the transfer in both caſes equally confers the right of action on the *bona fide* holder. But the mode of transfer is different; as bills and notes payable to bearer are transferred by mere delivery, the others by indorſement.

There are other bills and notes which differ from thoſe already deſcribed, and which are ſecurities for money, becauſe they are conſidered as money itſelf. Theſe are "Bank-notes," "Banker's caſh-notes," and "drafts on Bankers," payable on demand. Bank-notes are regarded in ordinary tranſactions by common conſent as caſh, and they have the credit and currency of money to every effectual purpoſe, and ſeem to be as lawful a tender. (Stat. 5 W. & M. c. 20. § 28. 3 Term Rep. 554.) Banker's caſh-notes, and drafts on bankers, are conſidered among merchants as money, and received in payment as ready caſh; and if the party receiving them do not, within a reaſonable time, demand the money, he muſt bear the loſs in caſe of the banker's failure. The preciſe time is not abſolutely determined; but it is held moſt adviſeable to carry ſuch drafts on bankers, as are payable on demand, for payment on the day in which they are received, if the ſituation of the parties admit of it.

Bills of exchange and promiſſory notes, which, according to the general principles of law, are to be conſidered only as evidences of a ſimple contract, are however in one reſpect regarded as ſpecialties, and on the ſame footing with bonds; for they are preſumed, unleſs the contrary be ſhewn by the defendant, to have been made on a good conſideration; nor is it incumbent on the plaintiff either to ſhew a conſideration in his declaration, or to prove it at the trial.

Bills of exchange, and alſo notes, are aſſignable or negotiable without any fiction; and every perſon to whom they are transferred may maintain an action in his own name againſt any one, who has before him in the courſe of their negociation rendered himſelf reſponſible for the payment of them. But the inſtrument, or writing, which conſtitutes a good bill or note, muſt have certain eſſential qualities. One of theſe is, that the bill or note ſhould be for the payment of money *only*, and not for the payment of money *and* the doing of ſome other act. Another requiſite quality is, that the inſtrument muſt carry with it a *perſonal* and certain credit, given to the drawer or maker, not confined to credit on any particular fund. But in the application of this principle, there is a material diſtinction between bills and notes. With regard to the former, where the fund is ſuppoſed to be in the hands of the drawee, the objection holds in its full force, not only becauſe the productiveneſs of the fund is contingent and precarious, but becauſe the credit is not given to the *perſon* of the drawer; but where the fund, on account of which the money is payable, either is in the hands of the drawer, or he is accountable for it, the objection will not hold, becauſe the credit is perſonal to him, and the fund is only the conſideration of his giving the bill. With reſpect to a note, if the drawer promiſe to pay out of a particular fund, then within his power, the note will be good under the ſtatute; the payment does not depend on the circumſtance of the fund's proving unproductive, or not, but there is an obligation upon his *perſonal* credit; the bare making of the note being an acknowledgment that he has money in his hands. Another eſſential quality of a good bill or note is, that it muſt be abſolutely payable at all events, and not depend on any particular circumſtances which may or may not happen in the common courſe of things. No preciſe form of words is neceſſary to make a bill of exchange or a note under the ſtatute; any order, which cannot be complied with, or promiſe, which cannot be performed, without the payment of money, will make a good bill or note. As the words "value received," have been uſually inſerted in bills or notes, ſome doubt has occurred, whether they are eſſential. It is now underſtood, as a decided point, that theſe words are not neceſſary; for inſtruments of this kind are preſumed to have been made on a valuable conſideration; and therefore words, which import no more, cannot be eſſential. It has been queried, whether it be eſſential to the conſtitution of a bill of exchange, that it ſhould contain words which render it negotiable, as "to order," or "to bearer;" and the point has not yet received a judicial deciſion. With regard to notes that have not theſe words, the perſon to whom they are made payable, may maintain an action on them, within the ſtatute, againſt the maker. With regard to the acceptance of bills of exchange. See ACCEPTANCE. Forging the acceptance of any ſuch bill, or the number or principal ſum of any accountable receipt, is made felony by ſtat. 7 Geo. 2. c. 22.

The mode of transferring bills and notes is different according to the expreſſions which render them negotiable. Such as are payable to bearer, are transferred by de-

livery; if payable to A. B. or bearer, they are payable to bearer, as if A. B. were not mentioned. But to the transfer of thoſe payable to order, it is neceſſary, in addition to delivery, there ſhould be ſomething, by which the payee may appear to expreſs his order. This additional circumſtance is called an "indorſement." See INDORSEMENT.

By the very act of drawing a bill, the drawer comes under an implied engagement to the payee, and to every ſubſequent holder, fairly entitled to the poſſeſſion, that the perſon on whom he draws is capable of binding himſelf by his acceptance; that he is to be found at the place where he is deſcribed to be, if that deſcription be mentioned in the bill; that if the bill be duly preſented to him, he will accept in writing on the bill itſelf, according to its tenor; and that he will pay it when it becomes due, if preſented in proper time for that purpoſe. In default of any of theſe particulars, the drawer is liable to an action at the ſuit of any of the parties beforementioned, on due diligence being exerciſed on their parts, not only for the payment of the original ſum mentioned in the bill, but alſo in ſome caſes for damages, intereſt, and coſts; and he is equally anſwerable, whether the bill was drawn on his own account, or on that of a third perſon; for the holder of the bill is not to be affected by the circumſtances that may exiſt between the drawer and another; the perſonal credit of the drawer being pledged for the due honour of the bill. If a man write his name on a blank piece of paper, and deliver it to another, with authority to draw on it a bill of exchange to any amount, at any diſtance of time, he renders himſelf liable to be called on as the drawer of any bill ſo formed by the perſon to whom he has given the authority. If acceptance be refuſed, and the bill returned, this is notice to the drawer of the refuſal of the drawee; and then the period, when the debt of the former is to be conſidered as contracted, is the moment when he draws the bill; and an action may be immediately commenced againſt him, though the regular time of payment, according to the tenor of the bill, be not arrived; for the drawee, not having given credit, which was the ground of the contract, what the drawer had undertaken has not been performed. When a bill of exchange is indorſed by the perſon to whom it was made payable, as between the indorſer and indorſee, it is a new bill of exchange; as it is alſo between every ſubſequent indorſer and indorſee; the indorſer, therefore, with reſpect to all the parties ſubſequent to him, ſtands in the place of the drawer, being a collateral ſecurity for the acceptance and payment of the bill by the drawee; his indorſement impoſes on him the ſame engagement that the drawing of the bill does on the drawer; and the period when that engagement attaches, is the time of the indorſement. Nor will any thing diſcharge the indorſer from his engagement, but the abſolute payment of the money; not even a judgment recovered againſt the drawer or any previous indorſer; neither is his engagement diſcharged by an ineffectual execution againſt the drawer, or any prior or ſubſequent indorſer. The engagement of the drawer and indorſers depends on certain conditions to be performed by the holder of the bill, and without the performance of which he has no remedy againſt them.

When the payment of the bill is limited to a certain time after ſight, the holder muſt preſent it for acceptance, otherwiſe the time of payment will never come. Although it has never been directly determined, whether the holder of a bill, payable at a certain time after date, be bound to preſent it for acceptance immediately on receiving it, or whether he may wait till it become due, and then preſent it for payment; yet in practice it often happens that a bill is negotiated and transferred through many hands, without acceptance, and not preſented to the drawee till the time of payment; and no objection is ever made on that account. If, however, on the holder preſenting the bill for acceptance, this be refuſed, he is bound to give regular notice to all the preceding parties to whom he intends to reſort for non-payment; and if on account of the holder's delay, any loſs be incurred by the failure of any of theſe parties, he muſt bear this loſs. It is alſo the duty of the holder of a bill, whether accepted or not, to preſent it for payment within a limited time; otherwiſe the law will imply that payment has been made, and it would be prejudicial to commerce, if a bill might be produced to charge the drawer at any diſtance of time, when all accounts might be adjuſted between him and the drawee. A preſentment either for payment or acceptance muſt be made at ſeaſonable hours, which are the common hours of buſineſs in the place where the party, to whom the bill is preſented, reſides. If acceptance or payment be refuſed, or the drawee of the bill, or the maker of the note, has become inſolvent, or has abſconded, notice from the holder himſelf muſt be given to the preceding parties, and in this notice it muſt be added, that the holder does not intend to give him credit. What may be conſidered as a reaſonable time, within which notice ſhould be given, either of non-acceptance or non-payment, has been ſubject to much doubt and uncertainty. It was once held, that a fortnight was a reaſonable time; but that period is now much contracted. With reſpect to acceptance, it is uſual to leave a bill for that purpoſe with the drawee till the next day; but if he, when called upon the next day, delay or refuſe to accept according to the tenor of the bill, it is now an eſtabliſhed rule, where the parties, to whom notice is to be given, reſide at a different place from the holder and drawee, that notice ſhould be ſent by the next poſt; and the ſame rule obtains in caſe of non-payment. Alſo in caſe of the drawee of the bill, or maker of the note, having abſconded, or not being found, notice of theſe circumſtances, in caſe either of non-acceptance or non-payment, muſt be ſent by the firſt poſt. Conſiderable difficulty has occurred in eſtabliſhing a general rule in this reſpect, where the party entitled to notice reſides in or near the place in which the holder lives. The court, however, has on ſeveral occaſions laid it down as a principle, that what ſhall be conſidered as a reaſonable time in caſe of notice, and alſo of demand of payment, is a queſtion of law; and this ſeems to have been fully eſtabliſhed, and it is underſtood generally, that a demand muſt be made, and notice given, as ſoon as under all the circumſtances it is poſſible to do ſo. As to the manner in which notice is given, either of non-acceptance or non payment, there is a remarkable difference between inland and foreign bills. In the former no particular form of words is neceſſary to entitle the holder to recover againſt the drawer or indorſers, the amount of the bill, on failure of the drawee or acceptor; it is ſufficient if it appear that the holder means to give no credit to the latter, but to hold the former to their reſponſibility. But in foreign bills, other formalities are required. If the perſon to whom the bill is addreſſed, on preſentment, will not accept it, the holder is to carry it to a perſon veſted with a public character, who is to go to the drawee and demand acceptance; and if he then refuſe, the officer is there to make a minute on the bill itſelf, conſiſting of his initials, the month, the day, and the year, with his charges for minuting. He muſt afterwards draw up a ſolemn declaration, that the bill has been preſented for acceptance, which was refuſed, and that the holder intends to recover all damages which he, or the deliverer of the money to the drawer, or any other, may ſuſtain on account of the non-

accept

acceptance. This minute, in common language, is termed the "noting" of the bill; the folemn declaration, the "proteſt;" and the perſon whoſe office it is to do theſe acts called a "public notary;" and to his proteſtation all foreign courts give credit. If no ſuch notary be reſident in the place where the bill is negotiated, proteſt may be made by any ſubſtantial inhabitant in the preſence of two credible witneſſes. For the circumſtances attending this proteſt, and the difference in this reſpect between inland and foreign bills, ſee PROTEST.

When a bill is once accepted abſolutely, it cannot in any caſe be revoked, and the acceptor is at all events bound, though he hear of the drawer's having failed the next moment, even if the failure was before the acceptance. The acceptor may however be diſcharged by an expreſs declaration of the holder, or by ſomething equivalent to ſuch declaration. But no circumſtances of indulgence ſhewn to the acceptor by the holder, nor an attempt on his part to recover of the drawer, will amount to an expreſs declaration of diſcharge. Neither will any length of time ſhort of the ſtatute of limitations, nor the receipt of part of the money from the drawer or indorſer, nor a promiſe by indorſement on the bill by the drawer to pay the reſidue, diſcharge the holder's remedy againſt the acceptor. Although the receipt of part from the drawer or indorſer be no diſcharge to the acceptor, yet the receipt of part from the acceptor of a bill, or the maker of a note, is a diſcharge to the drawer and indorſers in the one caſe, and to the indorſers in the other, unleſs due notice be given of the non-payment of the reſidue; but where due notice is given, that the bill is not duly paid, the receipt of part of the money from an acceptor, or maker, will not diſcharge the drawer or indorſers; becauſe it is for their advantage, that as much ſhould be received from others as may be. So the receipt of part from an indorſer is no diſcharge of the drawer or preceding indorſer. If the drawer of a note, or the acceptor of a bill, be ſued by the indorſee, and the bail pay the debt and coſts, this abſolutely diſcharges the indorſer as much as if the principal had paid the note or bill; and the bail cannot afterwards recover againſt the indorſer in the name of the indorſee. On the principles of ſeveral caſes it has been finally ſettled, that to entitle the indorſee to recover againſt the indorſer of an inland bill of exchange, it is not neceſſary to demand the money of the firſt drawer.

By the ſtat. 3 & 4 Ann. c. 9. § 7. it is enacted, that if any perſon accept a bill of exchange for and in ſatisfaction of any former debt or ſum of money formerly due to him, this ſhall be accounted and eſteemed a full and complete payment of ſuch debt; if ſuch perſon, accepting any ſuch bill for his debt, do not take his due courſe to obtain payment of it, by endeavouring to get the ſame accepted and paid, and make his proteſt according to the directions of the act, either for non-acceptance or non-payment.

Where a privity exiſts between the parties in a bill of exchange, an action of debt, or of "indebitatus aſſumpſit," may be maintained; but where it does not exiſt, neither of theſe actions will lie. A privity exiſts between the payee and the drawer of a bill of exchange; the payee and drawer of a promiſſory note; the indorſee and his immediate indorſer of either the one or the other; and perhaps between the drawer and acceptor of a bill; provided that, in all theſe caſes, a conſideration paſſed reſpectively between the parties. But no privity is ſuppoſed to exiſt between the indorſee and acceptor of a bill, or the maker of a note, or between an indorſee and a remote indorſer of either.

The action which is now brought on a bill of exchange, is a ſpecial action on the caſe, founded on the cuſtom of merchants. This cuſtom was not at firſt recognized by the court, unleſs it was ſpecially ſet forth; but when this cuſtom was recognized by the judges as part of the law of the land, and they declared they would take notice of it "ex officio," it became unneceſſary to recite the cuſtom at full length; a ſimple allegation that "the drawer, mentioning him by his name, *according to the cuſtom of merchants*, drew his bill of exchange, &c." was ſufficient. If the plaintiff, adhering to former precedents, thought proper to recite the cuſtom in general terms, and did not bring his caſe within the cuſtom ſo ſet forth; yet if by the law of merchants, as recognized by the court, the caſe as ſtated, entitled him to his action, he might recover; and the ſetting forth of the cuſtom was reckoned ſurpluſage, and rejected. Whether the drawer of a bill, or the indorſer of a bill or of a note, receiving the bill or note in the regular courſe of negotiation before it has become due, can maintain an action on it againſt the acceptor or maker, in the character of indorſee, ſeems undecided; but there is a caſe which clearly ſhews that a drawer or indorſer cannot maintain an action in the character of indorſee, "where the indorſement is after the refuſal of payment;" becauſe when a bill is returned unpaid, either on the drawer or indorſer, its negotiability is at an end. The action, therefore, in which the drawer or indorſer, after payment of the money in default of the acceptor, may recover, the firſt againſt the acceptor, and the latter againſt any of the preceding parties, muſt be brought in their original capacity as drawer or indorſer, and not as indorſee. If the drawee, without having effects of the drawer, accept and duly pay the bill without having it proteſted, he may recover back the money in action for money paid, laid out, and expended to the uſe of the drawer. Inſtead of bringing an action on the cuſtom, or on the ſtatute, the plaintiff may in many caſes uſe a bill or note only as evidence in another action; and if the inſtrument want ſome of the requiſites for making it a good bill or note, the only uſe he can make of it is to give it in evidence.

The holder of the bill or note may ſue all the parties who are liable to pay the money; either at the ſame time, or in ſucceſſion; and he may recover judgment againſt all, if ſatisfaction be not made by the payment of the money before judgment obtained againſt all; and proceedings will not be ſtaid in any one action, but on payment of the debt and coſts in that action, and the coſts in all the others in which he has not obtained judgment. But though he may have judgment againſt all, yet he can recover but one ſatisfaction; and though he be paid by one, he may ſue out execution for the coſts in the ſeveral actions againſt the others. To this action the defendant may plead the ſtatute of limitations; and by the expreſs proviſion of the ſtatute of queen Anne, all actions on promiſſory notes muſt be brought within the ſame time as is limited by the ſtatute of James, with reſpect to actions on the caſe. And to this plea it is no good replication, that it was on account between merchants, where it appears to be for value received.

As the action on a bill of exchange is founded on the cuſtom of merchants, ſo that on a promiſſory note is founded on the ſtatute 3 & 4 Ann. c. 9. In both caſes, however, it is neceſſary, that all thoſe circumſtances ſhould be expreſsly ſtated, or clearly and inevitably implied, which, according to the characters of the parties to the action, muſt neceſſarily concur, in order to entitle the plaintiff to recover. In ſtating the bill or note, regard muſt be had to the legal operation of each reſpectively. It has been decided, that the legal operation of a bill or of a note, payable to a fictitious payee, is, that it is payable to the *bearer*; and therefore it is proper in the ſtatement of ſuch a *bill*, to allege that the drawer thereby requeſted the drawee to pay ſo much money to the

bearer

bearer; and in the ſtatement of ſuch a *note*, that the maker thereby promiſed to pay ſuch a ſum to the bearer.

As to the *proof* that is neceſſary in actions on bills or notes, we may obſerve, that the plaintiff muſt, in all caſes, prove ſo much of what is neceſſary to entitle him to his action, and of what muſt be ſtated in his declaration, as is not, from the nature of the thing, and the ſituation of the parties, neceſſarily admitted. In an action againſt the acceptor, it is a general rule that the drawer's hand-writing is admitted; that of the acceptor muſt of courſe be proved; and that of every perſon, through whom the plaintiff, from the nature of the tranſaction, muſt neceſſarily derive his title. On a bill payable to *bearer*, in an action againſt the acceptor, he has only to prove the hand-writing of the acceptor himſelf; but in caſe of a bill payable to *order*, the plaintiff muſt prove the hand-writing of the very payee who muſt be the firſt indorſer. In caſe of a transfer by delivery, the plaintiff may be called upon to prove that he gave a good conſideration for the bill or note, without the knowledge of its having been ſtolen, or of any of the names of the blank indorſers having been forged. In an action by the indorſee againſt the drawer, the ſame rules obtain with reſpect to proof of the hand-writing of the indorſers, as in an action againſt the acceptors. That of the drawer himſelf muſt of courſe be proved; and it muſt alſo be proved that the plaintiff has uſed due diligence. From the rule, that in an action againſt the drawer or acceptor of a bill payable to order, there muſt be proof of the ſignature of the payee, firſt indorſer, and all thoſe to whom an indorſement has been ſpecially made, aroſe the queſtion, which long and greatly agitated the commercial world, on the ſubject of indorſements in the name of "fictitious payees." A bill, payable to the order of a fictitious perſon, and indorſed in a fictitious name, is not a novelty among merchants and traders. But in the years 1786, 7, and 8, two or three houſes, having connection in trade, and entering into engagements far beyond their capital, under an apprehenſion that the credit of their own names would not be ſufficient to procure currency to their bills, adopted, to a very extenſive degree, a practice which had before been found convenient on a ſmaller ſcale. For a conſiderable time, whilſt money could be procured for the payment of theſe bills by the acceptors or drawers, and they had ſufficient credit with the holder to have them renewed, the ſubject of theſe fictitious indorſements was not queſtioned. But when credit failed, and a commiſſion of bankruptcy became neceſſary, the other creditors felt it their intereſt to reſiſt the claims of the holders of theſe bills, and inſiſted that they ſhould not be allowed to prove their debts, becauſe they could not conform to the general rule of law, requiring proof of the hand-writing of the firſt indorſer. The chancellor, when the queſtion came before him by petition, directed trials at law. From the deciſions in conſequence of theſe trials, the principal of which was affirmed in the Houſe of Lords, and which have ſettled that ſuch bills are to be conſidered as payable to *bearer*; it follows, that proof of the acceptor's hand only is ſufficient to entitle the holder to recover on the bill; and in a particular caſe, where the bill was drawn by the defendant and others on the defendant, it was determined that a *bonâ fide* holder for a valuable conſideration might recover the amount againſt the acceptor in an action for *money paid*, or *money had and received*. The effect of the determination of the judges in the Houſe of Lords, with reſpect to the principal caſe above alluded to, is as follows. If a bill of exchange be drawn in favour of a fictitious payee, with the knowledge as well of the acceptor as the drawer; and the name of ſuch payee be indorſed on it by the drawer, with the knowledge of the acceptor, which fictitious indorſement purports to be to the drawer himſelf or his order; and then the drawer indorſes the bill to an innocent indorſer for a valuable conſideration, and afterwards the bill is accepted; but it does not appear that there was an intent to defraud any particular perſon; ſuch innocent indorſee for a valuable conſideration may recover againſt the acceptor, as on a bill payable to bearer. Perhaps alſo, in ſuch caſe, the innocent indorſee might recover againſt the acceptor, as on a bill payable to the order of the drawee, or on a count ſtating the ſpecial circumſtances. On other caſes, afterwards brought before the Houſe of Lords on demurrers to evidence, the judges gave their opinion, that it was not competent to the defendants to demur; and that on the record, as ſtated, no judgment could be given. The whole diſcloſed a ſyſtem of bill-negotiation to the amount of a *million a year*, on fictitious credit, which ended in the bankruptcy of many; but which had at leaſt the good effect of ſhewing that the obligations of law are not ſo eaſily eluded as thoſe of honour and conſcience.

In an action by an indorſee againſt an indorſer, it is not neceſſary to prove either the hand of the drawer or of the acceptor, or of any indorſer before him againſt whom the action is brought, every indorſer being, with reſpect to ſubſequent indorſees or holders, a new drawer. Where an action is by one indorſer, who has paid the money, proof muſt be given of the payment. In an action by the drawer againſt the acceptor, where the bill has been paid away and returned, it is neceſſary to prove the hand-writing of the latter, demand of payment by him, and refuſal, the return of the bill, and payment by the plaintiff. In an action on the caſe by the acceptor againſt the drawer, the plaintiff muſt prove the hand-writing of the defendant, and payment of the money by himſelf; or ſomething equivalent, as his being in priſon on execution. Where a bill is accepted, or a bill or note is drawn or indorſed, by one of two or more partners, on the partnerſhip's account, proof of the ſignature of the party accepting, drawing, or indorſing, is ſufficient to bind all the reſt. When a ſervant has a general authority to draw, accept, or indorſe bills or notes, proof of his ſignature is ſufficient againſt the maſter; but his authority muſt be proved, as that it was a general cuſtom for him to do ſo, &c. An action on a bill of exchange being by an executor, and upon a debt laid to be due to teſtator, it was held neceſſary to prove that the acceptance was in the life-time of the teſtator. Where the defendant ſuffers judgment by default, and the plaintiff executes a writ of inquiry, it is ſufficient for the latter to produce the note or bill, without any proof of the defendant's hand; and on ſuch judgment, a writ of inquiry ſeems now to be unneceſſary.

As to the different ſubjects of *defence*, with regard to bills of exchange and notes, the moſt uſual are thoſe which ariſe either from the total want of conſideration, or from the illegality of the conſideration for which the bill or note was given. See CONSIDERATION.

If a bank-bill, payable to A. B. or bearer, be loſt, and it is found by a ſtranger, payment to him would indemnify the bank; yet A. B. may have trover againſt the finder, though not againſt his aſſignee for valuable conſideration, which creates a property. If the poſſeſſor of a bill accidentally loſes it, he muſt cauſe intimation to be made by a notary public before witneſſes, that the bill is loſt or miſlaid, and requiring that payment be not made of the ſame to any perſon without his privity. And by ſtat. 9 & 10 W. III. c. 17. if any inland bill of exchange for 5l. or upwards ſhall be loſt, the drawer of the bill ſhall give another of the ſame tenor, ſecurity being given to indemnify him, in caſe the bill ſo loſt be found again. If a bill loſt by the poſſeſſor ſhould

ſhould afterwards come into the poſſeſſion of any perſon, who pays a full and valuable conſideration for it, without knowledge of its having been loſt, the drawer and acceptor, if the bill was accepted, muſt pay it when due to ſuch fair poſſeſſor, ſo that the proviſions of the ſtatute may, in many caſes, be uſeleſs to the loſer of the bill. But againſt the perſon who finds the bill, the real owner may maintain an action of trover. Stealing bills of exchange, notes, &c. is felony in the ſame degree as if the offender had robbed the owner of ſo much money, &c. And the forging of bills of exchange, or notes of money, indorſements, &c. is felony, by ſtat. 2 Geo. II. c. 25, 9 Geo. II. c. 18. See alſo ſtat. 31 Geo. II. c. 22. §. 78. Blackſt. Com. vol. ii. p. 466. Jacob's Law Dictionary, by Tomlins, vol. i. art. *Bill*.

Bill of *Indictment*. See Bill above, and Indictment.

Bill of *Interpleader*. See Interpleader, and Suit *in Equity*.

Bill of *Middleſex*, which was formerly always founded on a "plaint" of treſpaſs *quare clauſum fregit*, entered on the records of the court, is a kind of "capias," directed to the ſheriff of that county, and commanding him to take the defendant, and have him before our lord the king, at Weſtminſter, on a day preſixed, to anſwer to the plaintiff of a plea of treſpaſs. This bill of Middleſex muſt be ſerved on the defendant by the ſheriff, if he finds him in that county; but if he returns "non eſt inventus," then there iſſues out a writ of "latitat" to the ſheriff of another county, as Berks; which, in the court of king's bench, is ſimilar to the "teſtatum capias" in the common pleas, and recites the writ of Middleſex, and the proceedings thereon; and that it is teſtified, that the defendant "latitat et diſcurrit," lurks and wanders about in Berks; and therefore commands the ſheriff to take him, and have his body in court on the day of the return. But, as in the common pleas, the "teſtatum capias" may be ſued out upon only a ſuppoſed, and not an actual, preceding "capias;" ſo, in the king's bench, a "latitat" is uſually ſued out upon only a ſuppoſed, and not an actual, "bill of Middleſex:" ſo that, in fact, a "latitat" may be called the firſt proceſs in the court of king's bench, as the "teſtatum capias" is in the common pleas. Yet, as in the common pleas, if the defendant lives in the county wherein the action is laid, a common "capias" ſuffices; ſo, in the king's bench likewiſe, if he lives in Middleſex, the proceſs muſt ſtill be by "bill of Middleſex" only.

Bill, *Navy*. See Navy.

Bill, in *Parliament*, denotes a paper containing propoſitions offered to the houſes, to be paſſed by them, and then to be preſented to the king to paſs into an act or law: for the mode of preſenting and conducting of which, ſee Parliament.

Bills, *Lumbard*, are inſtruments of an uncommon kind and figure, uſed in Italy and Flanders, and alſo in France; conſiſting of a piece of parchment, cut to an acute angle about an inch broad at top, and terminating in a point at bottom; chiefly given where private perſons are concerned in the fitting out a ſhip for any long voyage.

The manner is this: the party who is deſirous to be concerned in the cargo or venture, carries his money to the merchant, who fits out the ſhip, where it is entered down in a regiſter. At the ſame time, the merchant writes down on a piece of parchment, upwards of an inch broad, and ſeven or eight inches long, the name of the lender, and the ſum lent, which being cut diagonal-wiſe, or from corner to corner, each party retains his half. On the return of the veſſel, the lender brings his moiety to the merchant, which being compared with the other, he receives his dividend accordingly. Much the ſame is practiſed in Holland by thoſe who lend money on pledges: the name of the borrower, and the ſum, are written on a like ſlip of parchment, which is cut in two, and half given to the borrower, and the other half ſtitched to the pledge; that, upon comparing them together again, the borrower may receive his goods, on paying the money ſtipulated.

Bill, *to note a*. See Note, and Bill of *Exchange*.

Bill, *to proteſt a*. See Protest, and Bill of *Exchange*.

Bills, *bank*, are notes or obligations ſigned on behalf of the company of the bank, by one of their caſhiers, for value received. See Note, and Bill of *Exchange*.

Bill *of credit*. See Credit.

Bill *of entry*, an account of goods entered at the cuſtom-houſe, both inward and outward; in which are expreſſed, the name of the merchant importing or exporting, the quantity, number, and mark of the goods, and place from or to which they are imported, or to be exported.

Bill *of lading*, an inſtrument ſigned by the maſter of a ſhip, acknowledging the receipt of a merchant's goods, and obliging himſelf to deliver them at the place to which they are conſigned, in good condition. Of ſuch bills there are uſually three: the *firſt*, kept by the merchant; the *ſecond*, ſent to the factor to whom the goods are conſigned; and the *third*, kept by the maſter of the ſhip. See Charter-party.

Bills *of mortality*, are weekly liſts compiled by the pariſh-clerks in and about London, containing the numbers of ſuch as die of each diſeaſe, as well as of thoſe that are born every week. See Mortality.

Bill *of parcels*, an account of the particular ſorts and prices of goods bought, given by the ſeller to the buyer.

Bill *of rights*. See Rights.

Bill *of ſale*, is an inſtrument or writing which a perſon, wanting a ſum of money, and delivering goods as a ſecurity to the lender, gives to him, impowering him to ſell the ſaid goods, in caſe the ſum borrowed is not repaid, with intereſt, at the time appointed. See Sale.

Bill *of ſtore*, a licence granted at the cuſtom-houſe to merchants, to carry ſuch ſtores and proviſions as are neceſſary for their voyage, cuſtom-free.

Bill *of ſufferance*, a licence granted at the cuſtom-houſe to a merchant, to ſuffer him to trade from one Engliſh port to another, without paying cuſtom.

Bill, or Beak, *roſtrum*, in *Ornithology*, the elongated horny proceſſes or mandibles of birds. The form of the bill varies ſo greatly in different kinds of birds, that they afford the moſt permanent character by which theſe creatures may be arranged. In the diſtribution of families, Linnæus firſt notices the ſtructure of the bill, the tongue, and noſtrils; and theſe parts conſtitute almoſt excluſively (with the legs) the diſtinction of the genera likewiſe. See Ornithology, and *Anatomy of* Birds.

The phoenicopter's bill is a true *hyperbola*, pointed at the end like a ſword; and what is remarkable, the upper bill of this bird moves in eating, the lower being fixed, which is the contrary of what is found in all other kinds. The wood-pecker's bill is ſtrong, and ſharp enough to dig holes, and build in the heart of the hardeſt timber. See Phoenicopterus and Picus. Phil. Tranſ. N° 211, p. 155. N° 350, p. 509.

In the iſland of Ferro, a fixed reward is given for the bills of ravenous birds. All watermen are obliged to bring a certain number yearly to the country courts, at the feaſt of St. Olaus; when they are thrown into a heap, and burnt in triumph. Plott gives divers inſtances of monſtrous irregularities

gularities in the bills of birds; particularly of a raven, whoſe mandibles croſſed each other, the lower chap turning upwards, and the upper downwards. Plott's Nat. Hiſt. Staffordſh. ch. vii. § 4.

BILLA VERA, *the bill is true.* The grand jury indorſing a bill whereby any crime puniſhable in that court, is preſented to them, with the words *billa vera*, ſignify thereby, that the preſenter has furniſhed his preſentment with probable evidence, and worthy of farther conſideration; whereupon the party preſented is ſaid to ſtand indicted of the crime, and bound to make anſwer thereto, either by confeſſing or traverſing the indictment. See BILL in *Law*, *ſupra*.

BILLANCOURT, in *Geography*, a town of France, 4 miles S.W. from Paris.

BILLARD, or BILLET, in *Ichthyology*, an Engliſh name, in ſome places, for the young coal-fiſh, *gadus carbonarius*, when a year old; meaſuring at that time from 8 to 10 or 15 inches in length.

BILLAU, in *Geography*, a river of Sileſia, which runs into the Neyſs, near the town of Neyſs.

BILLE', a town of France, in the department of the Ille and Vilaine, and the chief place of a canton, in the diſtrict of Fougeres, 1¼ league ſouth of Fougeres.

BILLEKA, a town of Poland, in the palatinate of Lemberg, 10 miles eaſt of Lemberg.

BILLERBEECK, a town of Germany, in the circle of Weſtphalia, and biſhopric of Munſter, 5 miles N.N.E. from Coesfeld.

BILLERICA, a townſhip in Middleſex county, Maſſachuſetts, in America, incorporated in 1655, containing 1200 inhabitants, lying 20 miles north of Boſton, and watered by Concord and Shawſheen rivers, which run north-eaſterly into Merrimack river.

BILLERICAY, in *Geography*, a market-town of Eſſex, England; is built on a fine eminence, commanding a view of a rich vale between the town and the river Thames. Though enjoying the advantage of a weekly market on Tueſdays, it is only a hamlet in the pariſh of Great Burſtead, the church of which is ſituate about one mile and a half ſouth of this place. For the accommodation of the inhabitants, a chapel is endowed and ſupported in the town. Here are two annual fairs: and the whole pariſh contains 250 houſes, and 1472 inhabitants. Billericay is 23 miles N.E. from London. Morant's hiſtory of Eſſex.

BILLESDON. See BILSTON.

BILLET. See HATBOROUGH.

BILLET, or BILLETTÉE, in *Heraldry*, ſignifies a figure whoſe length exceeds its breadth; when the arms are charged with ſeveral of them, they are then called *Billettée*. The royal arms of Naſſau, prince of Orange, is *Jupiter Billettée ſol, a lion rampant of the laſt.* Authors differ much in regard to the antiquity of the billet, which was evidently a piece of wood cut in the form of a parallelogram, and retains that name and ſhape to this day.

BILLET, *Billette*, in the *French Cuſtoms*, a little ſign in form of a caſk, hung up at places where toll is to be paid, to advertiſe paſſengers and carriages, that before they advance farther, the dues are to be paid to the king, or the lord who is charged with the care of repairing the highways.

BILLETS *for fuel*, are ſmall pieces of wood, which muſt be 3 feet 4 inches long, and 7½ in compaſs, &c. Juſtices of peace ſhall enquire, by the oaths of ſix men, of the aſſize of billets; and thoſe which are under ſize are forfeited to the poor. Stat. 43. Eliz. c. 14. 9. Ann. c. 15. 10. Ann. c. 6. See FUEL.

BILLETS *of gold*, denote wedges or ingots of gold, mentioned in the ſtat. 27. Ed. 3. c. 27.

BILLETING *of ſoldiers*, in *Military language*, is the lodging or quartering of them in the houſes of the inhabitants of a place. This is done by a ticket, called a *billet*, which entitles each ſoldier, by act of parliament, to candles, vinegar, ſalt, and either ſmall beer or cyder, not exceeding five pints per day, gratis; with the uſe of fire, and the neceſſary utenſils for dreſſing and eating their meat.

BILLETING, among *Sportſmen*, denotes the ordure and dung of a fox.

BILLETINS. See BROTHERS of *Charity*.

BILLI, JAMES DE, in *Biography*, a French Jeſuit, was born in Compiegne in 1602, and entered the ſociety of Jeſuits in 1619. He taught philoſophy for three years, and was a preacher for more than twenty years. He was rector of Chalons, Langres, and Sens; but he is beſt known by his mathematical writings, which are as follow: "Nova Geometriæ Clavis Algebra," Paris, 1643, 4to.; "Tabulæ Lodoicæ de doctrina eclipſeon," Dijon, 1658, 4to.; "Tumulus Aſtrologiæ Judiciariæ," Paris, 1659, 4to.; "Diophantus Geometra," Paris, 1660, 4to.; "Opus Aſtronomicum, &c." Dijon, 1661, 4to.; "Décours de la Comete qui a paru l'an 1665, au mois d'Avril," Paris, 1665, 4to.; "Criſis Aſtronomica de motu Cometarum," Dijon, 1666, 8vo.; "Doctrinæ analyticæ inventum novum," Toulouſe, fol. Moreri.

BILLIARDS, an ingenious kind of game played with two ſmall ivory balls, on an oblong table, covered with green cloth, and placed exactly level; which balls are driven, by ſticks made on purpoſe, alternately againſt each other, with a view to puſh the paſſive ball into hazards, or holes, on the edges and corners, according to certain laws or conditions of the game.

The word comes from the French *billiard*, of *bile*, the ball made uſe of; and that from the Latin *pila*, a *ball*.

This game was invented by the French, and practiſed by the Germans, Dutch, and Italians; and is now a favourite diverſion among perſons of the firſt rank in many parts of England. The table on which it is played is about 12 feet long, and 6 wide; and not only covered with green cloth, but ſurrounded with cuſhions to prevent the balls from rolling off, and to make them rebound. It has ſix holes, nets, or pockets, which are fixed on the four corners, and in the middle, oppoſite to each other, for receiving the balls, which, when put into theſe holes, are called hazards. The making of a hazard, or putting the adverſary's ball into the hole at the uſual game, is reckoned for two in favour of the player.

The game is played with ſticks, called maces, or with cues. The mace is a long ſtraight ſtick, with a head at the end, and is the moſt powerful inſtrument of the two: the cue is a thick ſtick decreaſing gradually to a point of about half an inch in diameter: this inſtrument is played over the left hand, and ſupported by the forefinger and thumb. This is the only inſtrument in vogue abroad, and is uſed with aſtoniſhing addreſs by the Italians, and ſome of the Dutch; but in England the mace is the prevailing inſtrument, though regarded with ſome degree of contempt by foreigners, as the uſe of it does not require ſo much addreſs as the cue; however, the mace is uſed for the peculiar advantage of "trailing," as it is called; or of following the ball with it to ſuch a convenient diſtance from the other ball as to make it an eaſy hazard. The ſeveral degrees of trailing are variouſly denominated by the connoiſſeurs; e. g. the ſhove, the ſweep, the long ſtroke, the trail, and the dead

trail

trail or turn up, all which ſecure certain advantages to a good player; and even the butt-end of the cue becomes very powerful, when it is made uſe of by a good trailer. The varieties of this game are denominated the "white winning game," the "white loſing game," the "red or carambole winning game," and the "red loſing game." The game uſually played is the firſt of theſe, and 12 is the number. The rules for this game are as follow; 1. String for the lead and choice of balls; the perſon who does this muſt ſtand within the limits of the corner of the table, and not place his ball beyond the ſtringing nails or ſpots; the lead is won by him who brings his ball neareſt the cuſhion. 2. If after the firſt perſon has ſtrung for the lead, the adverſary ſhould make his ball touch the other, he loſes the lead; and if the player holes his own ball in ſtringing or leading, he loſes the lead. 3. If the leader follows his ball with either mace or cue beyond the middle hole, it is no lead; and it is at the option of his adverſary to make him lead again. 4. The ſtriker who plays at the lead muſt ſtand with both his feet within the limits of the corner of the table, and not place his ball beyond the ſtringing nails; and his adverſary (only) is bound to ſee that he ſtands and plays fair; otherwiſe the ſtriker wins all the points he made by the ſtroke. 5. When a hazard has been loſt in either of the corner holes, the leader is obliged, if his adverſary require it, to lead from the end of the table, where the hazard was loſt; but if the hazard was loſt in either of the middle holes, it is at the leader's option to lead from either end of the table. 6. If the ſtriker does not hit his adverſary's ball, he loſes one point; and if by the ſaid ſtroke his ball ſhould go into a hole, over the table, or on a cuſhion, he loſes three points; and he alſo loſes the lead. 7. If the ſtriker holes his adverſary's ball, or forces it over the table, or on a cuſhion; or if he holes both balls, or forces them over the table, or on a cuſhion; in either caſe he loſes two points. 8. No perſon has a right to take up his ball without permiſſion from his adverſary. 9. If the ſtriker ſhould touch or move his own ball, without intending to make a ſtroke, it is deemed an accident; and his adverſary, if he require it, may put the ball back in the place where it ſtood. 10. If the ſtriker force his adverſary's ball over the table, and his adverſary ſhould chance to ſtop it, ſo as to make it come on the table again, the ſtriker wins two points; if the ſtriker ſhould force his own ball over the table, and his adverſary ſhould chance to ſtop it ſo as to make it come on the table again, the ſtriker loſes nothing by the ſtroke, and has the lead; but if the ſtriker miſſes the ball and forces it over the table, and it ſhould be ſtopped by his adverſary, he loſes one point, and has the lead, if he chuſes. 11. If the ſtriker, in playing from a cuſhion or otherwiſe, by touching the ball, makes his mace or cue go over or beyond it, he loſes one point; and, if his adverſary require it, he may put the ball back, and make him paſs the ball. 12. If the ſtriker, in attempting to make a ſtroke, doth not touch his ball, it is no ſtroke; and he muſt make another trial; but if when the balls are near each other, the ſtriker ſhould accidentally make his ball touch the other, it is a ſtroke, though not intended. 13. If the ſtriker who plays the ſtroke, ſhould make his adverſary's ball go ſo near the brink of a hole, as to be judged to ſtand ſtill, and afterwards fall into it, the ſtriker wins nothing; and the ball muſt be put upon the ſame brink where it ſtood, for his adverſary to play from the next ſtroke. 14. If the ſtriker's ball ſhould ſtand on the brink or edge of a hole, and if in playing it off he ſhould make the ball go in, he loſes three points. 15. If a ball ſhould ſtand on the brink or on the edge of a hole, and ſhould fall into the hole, before or when the ſtriker has delivered his ball from the mace or cue, ſo as to have no chance for his ſtroke, in that caſe the ſtriker and his adverſary's ball muſt be placed in the ſame poſition, as nearly as poſſible, and the ſtriker muſt play again. 16. The ſtriker is obliged to paſs his adverſary's ball, more eſpecially if he miſſes the ball on purpoſe; and it is at the option of his adverſary to oblige him to place the ball where it ſtood, and play until he has paſſed. 17. If the ſtriker plays both balls from his mace or cue, ſo that they touch at the ſame time, it is deemed a foul ſtroke; or if the adverſary diſcover it, and a diſpute ſhould ariſe, an appeal may be made to the company preſent; and the marker, if required, muſt go round the table to each perſon ſeparately, and aſk if he has any bet depending, and if he underſtands the game and the diſputed ſubject; and if the company and marker determine it to be a foul ſtroke, it is at the adverſary's option (if not holed) either to play at the ball, or to take the lead; but if the adverſary doth not diſcover it to be a foul ſtroke, the ſtriker may reckon all the points he made by the ſaid ſtroke, and the marker is obliged to mark them: and no perſon has a right to diſcover to the player whether a ſtroke be fair or foul, unleſs he is aſked. 18. If by a foul ſtroke the ſtriker ſhould hole his adverſary's ball, he loſes the lead; but if by ſuch a ſtroke he holes his own or both balls, or forces his own or both over the table, or on a cuſhion, he loſes two points. 19. If the ſtriker plays on a ball when it is running or moving, it is deemed a foul ſtroke; and if he plays with both feet off the ground, without leave of his adverſary, it is a foul ſtroke: if he plays with a wrong ball, he loſes the lead, if his adverſary require it. 20. If the ball ſhould be changed in a hazard, or on a game, and it is not known by which party, the hazard muſt be played by each party with their different balls and then changed. 21. If the ſtriker plays with his adverſary's ball, and hole, or forces the ball at which he played over the table, &c. it is deemed a foul ſtroke. 22. If the ſtriker plays with his adverſary's ball, and holes, or forces the ball with which he played over the table, &c. he loſes two points; and if he miſſed the ball, three points. 23. If the ſtriker plays with his adverſary's ball and miſſes it, he loſes one point; and if his adverſary diſcovers that he hath played with the wrong ball, he may part the balls, and take the lead if he pleaſes. 24. In all theſe caſes of the ſtriker's playing with the wrong ball (if diſcovered), his adverſary muſt play with the ball, at which the ſtriker played throughout the hazard, or part the balls and take the lead. 25. Whoever ſtops a ball when running with hand, ſtick, or otherwiſe, loſes the lead, if his adverſary does not like the ball he has to play at the next ſtroke. 26. Whoever retains his adverſary's ſtick when playing, it is deemed foul. 27. If the ſtriker ſtops, or puts his ball out of its courſe, when running towards either of the holes, and, if adjudged by the marker and company to be going into a pocket, if he miſſes the ball he loſes one point, and if going into a hole by the ſame ſtroke, three points. 28. If the ſtriker ſtops or puts his adverſary's ball out of the courſe, when running towards or into a hole, or puts it into a hole, it is deemed a foul ſtroke. If the adverſary does the ſame, as in the foregoing caſes, he is ſubject to the ſame penalties as the ſtriker. 29. He who ſhakes the table when the ball is running, or throws his ſtick acroſs the table, ſo as to occaſion any detriment to his adverſary, or blows on the ball when running, makes in either caſe a foul ſtroke; and if his own ball was running towards or near the hole, when he blows on it, he loſes two points. 30. He who leaves the game before it is finiſhed, and will not play it out, loſes the game. 31. Any perſon, whilſt playing, may change his mace or cue; and neither party has a right to object to either mace or cue being played within the ſaid game; but when the parties agree to play mace againſt

cue, the mace-player hath no right to uſe a cue, and vice verſâ, without leave of the adverſary. 32. When a perſon agrees to play with the cue, he muſt play every ball within his reach with its point, and if he agrees to play with the butt of the cue, he muſt not uſe the point, without permiſſion; when the parties agree to play point and point of the cue, neither has a right to uſe a butt during the match, without permiſſion; but they have a right to play with a long cue over a mace, &c. and when they agree to play all points with the ſame cue, they have no right to uſe any other during the game. 33. If it be propoſed to part the balls, the propoſer, if the adverſary agree to it, loſes the lead. 34. Two miſſings do not make a hazard, unleſs the contrary is previouſly ſettled. 35. The betters are to abide by the players on the determination of the hazard, or on the game; and they have a right to demand their money, when their game is over, to prevent diſputes. 36. The ſtriker has a right to command his adverſary not to ſtand facing him, or near him, ſo as to annoy or moleſt him in the ſtroke. 37. Each perſon is to attend to his own game, without aſking queſtions. 38. No perſon in the room has a right to lay more than the odds on a hazard or game; and in queſtionable caſes appeal ſhould be made to the marker, or to the table of odds hung up in the room. 39. When four perſons play, the game is fifteen in number; and each party has a right to conſult with and direct his partner in any matter reſpecting the game, &c.

The "white loſing-game" is the common winning-game, and twelve is the number. This depends entirely upon the defence, and the knowledge of the degree of ſtrength with which each ſtroke ſhould be played, either to defend or make a hazard; for if a perſon who has a competent knowledge of the game ſhould not have a hazard to play at, he muſt endeavour to lay his own ball in ſuch a poſition, that his adverſary may not have one to play at the next ſtroke. In this game, if the ſtriker miſſes the ball, he loſes one, and if by the ſame ſtroke his ball goes into a hole, he loſes three points; if he ſtrikes his adverſary's ball he loſes two points; if either or both balls be forced over the table, or on a cuſhion, nothing is reckoned and the ſtriker loſes the lead, but if he miſſes his adverſary's ball, and forces his own over the table, &c. he loſes one point and the lead; if either of the parties forces either or both balls over the table, he reckons nothing, and the ſtriker loſes the lead; if the ſtriker holes his own ball, he wins two points; if he holes both balls, he wins four points; if he holes either ball, and forces the other over the table, &c. he only loſes the lead. The "winning and loſing game" is a combination of both games; in which all balls that are put in by ſtriking firſt the adverſary's ball, reckon towards game; and holing both balls reckons four. At this game and the loſing, knocking over, or forcing the balls over the cuſhion, goes for nothing; the ſtriker only loſing the lead. The "choice of balls" is chooſing each time which ball the player pleaſes, which is without doubt a great advantage, and is generally played againſt loſing and winning.

"Bricole," is being obliged to hit a cuſhion, and make the ball rebound or return to hit the adverſary's ball, otherwiſe the player loſes a point. This is a great diſadvantage, and is reckoned between even players to be equal to receiving about eight or nine points.

"Carambole," is a game newly introduced from France. It is played with three balls, one being red, which is neutral, and is placed upon a ſpot on a line with the ſtringing nail, (*i. e.* that part of the table from whence the player ſtrikes his ball at firſt ſetting off, and which is generally marked with two braſs nails). Each antagoniſt at the firſt ſtroke of a hazard, plays from a mark which is upon a line with it at the other end of the table. The chief object at this game is, for the player to hit with his own ball the two other balls: which is called a *carambole*, and by which the player wins two. If he puts in the red ball he gets three, and when he holes his adverſary's ball he gets two; ſo that ſeven may be made at one ſtroke, by caramboling and putting in both balls. This game reſembles the loſing, depending chiefly upon particular ſtrengths, and is generally played with the cue. The game is ſixteen up; nevertheleſs it is reckoned to be ſooner over than the common game. The next object of this game, after making what we have diſtinguiſhed by the *carambole*, is the *baulk*; that is, making the white ball, and bringing the player's own ball and the red one below the ſtringing nail, from whence the adverſaries begin. By this means the opponent is obliged to play bricole from the oppoſite cuſhion; and it often happens that the game is determined by this ſituation.

"The Ruſſian carambole," is a game that has ſtill more lately been introduced from abroad, and is played in the following manner: The red ball is placed as uſual on the ſpot made for that purpoſe; but the player, when he begins, or after having been holed, never places his ball on any particular place or ſpot; being at liberty to put it where he pleaſes. When he begins to play, inſtead of ſtriking at the red ball, he leads his own gently behind it, and his antagoniſt is to play at which he thinks proper; if he plays at the red ball and holes it, he ſcores three as uſual towards the game, which is twenty-four inſtead of ſixteen points; and the red ball is put upon the ſpot again: at which he may ſtrike again, or take his choice which of the two balls to puſh at, always following his ſtroke till both balls are off the table. He is entitled to two points each time that he caramboles, the ſame as at the other game; but if he caramboles and puts his own ball into any hole, he loſes as many as he might have got had he not holed himſelf; for example, if he ſtrikes at the red ball, which he holes, and at the ſame time caramboles and holes himſelf, he loſes five points; and if he holes both balls when he caramboles, and likewiſe his own, he loſes ſeven, which he would have got if he had not holed his own ball. In other reſpects it is played like the common carambole game.

"The Bar-hole," is ſo called from the hole being barred which the ball ſhould be played for, and the player ſtriking for another hole; when this game is played againſt the common game, the advantage for the latter, between equal players, is reckoned to be about ſix.

The player at the *one-hole*, though it ſeems to thoſe who are not judges of the game to be a great diſadvantage, has in fact the beſt of it; for as all balls that go into the one hole reckon, the player endeavours to lay his ball conſtantly before that hole, and his antagoniſt frequently finds it very difficult to keep one or other ball out, particularly on the leads, when the one player lays his ball (which he does as often as he can) on the brink of the hole; leading for that purpoſe from the oppoſite end, which in reality he has no right to do; for the lead ſhould be given from the end of the table at which the hazard is made; but when a perſon happens to be a novice, this advantage is often taken.

"The four game," conſiſts of two partners on each ſide, as the common winning game; who play by ſucceſſion after each hazard, or two points loſt. The game is fifteen up; ſo that the point or hazard is an odd number, which makes a miſs at this game of more conſequence than it is at another; being as much at four, ſix, or eight, as it is at five, ſeven, or nine, at the ſingle game.

"Hazards," are ſo called becauſe they depend entirely upon the making of hazards, there being no account kept

of

of any game. Any number of perſons may play by having balls that are numbered; but the number ſeldom exceeds ſix, to avoid confuſion. The perſon whoſe ball is put in, pays ſo much to the player according to what is agreed to be played for each hazard; and the perſon who miſſes, pays half the price of a hazard to him whoſe ball he played at. The only general rule is, not to lay any ball a hazard for the next player, which may be in a great meaſure avoided, by always playing upon the next player, and either bringing him cloſe to the cuſhion, or putting him at a diſtance from the reſt of the balls. The table, when hazards are played, is always paid for by the hour.

BILLIAT, in *Geography*, a town of France, in the department of the Ain, and chief place of a canton, in the diſtrict of Nantua, 2¾ leagues S. E. of Nantua.

BILLICHA, in *Ancient Geography*, a river of Aſia in Meſopotamia, which riſes in the mountains of Oſroène, ſouth of Edeſſa, and purſuing a ſouth-eaſterly courſe, diſcharges itſelf into the Euphrates, at the town of Nicephorum.

BILLIGHEIM, in *Geography*, a town of Germany, in the palatinate of the Rhine, 4 miles S. of Landau, and 16 S. W. of Spire.

BILLIGRATZ, a town of Germany, in the duchy of Carniola, 4 leagues N. of Laubach.

BILLINGEN, a town of the Netherlands, in the duchy of Luxemburg, 20 miles E. of Spa.

BILLINGSGATE, a fiſh-market of London, kept every day, and the toll of which is appointed by ſtatute. All perſons buying fiſh in this market may ſell the ſame in any other market by retail, but none but fiſh mongers are allowed to ſell it in ſhops: and if any perſon ſhall buy any quantity of fiſh at Billingſgate for others, or any fiſhmonger ſhall engroſs in the market, they incur a penalty of 20l. Fiſh imported by foreigners ſhall be forfeited, and the veſſel &c. 10 & 11 Wil. III. c. 24. 1 Geo. I. ſtat. 2. c. 18. § 1. &c.

BILLINGSPORT, a place on the river Delaware, in America, ſituate 12 miles below Philadelphia, which was fortified in the late war, for the defence of the channel, and oppoſite to which were ſunk frames of timber, headed with iron ſpikes, called chevaux-de-frize, in order to prevent the Britiſh ſhips from paſſing. After the war they were raiſed by a curious machine, invented at Philadelphia for this purpoſe.

BILLIS, in *Ancient Geography*, a ſmall river of Aſia Minor, on the frontiers of Paphlagonia, on the borders of which was ſeated the town of Teium, mentioned by Salluſt.

BILLITON, in *Geography*, one of the Sunda iſlands in the Indian ocean, N. E. of the lower part of Sumatra, and E. of Banca. (See *Straits* of Banca.) S. lat. between 2° 30′. and 3° 30′. E. long. between 107° 45′. and 108° 26′.

BILLOM, a town of France, and principal place of a canton, in the diſtrict of Clermont, and department of Puy-de-Dome, 4 leagues E. S. E. from Clermont. The town contains 5,110 inhabitants, and the canton 13,711. The territorial extent comprehends 115 kiliometres, and 10 communes. N. lat. 45° 43′. E. long. 3° 14′.

BILLON, Billio, in *Coinage*, a kind of baſe metal, either of gold or ſilver, in whoſe mixture copper predominates.

The word is French, formed according to Menage, from the Latin *bulla*, or *bullo*, *billion*. According to M. Bouteroue, billon of gold is any gold beneath ſtandard, or twenty-one carats; and billon of ſilver, all below ten penny-weights. But, according to others, and among the reſt, M. Boizard, gold and ſilver beneath the ſtandard, as far as twelve carats, and ſix penny-weights, are properly baſe gold and ſilver, and all under thoſe billon of gold, and billon of ſilver, becauſe copper is the prevailing metal. The writers on numiſmatic ſcience appropriate the term billon to ſignify metals of copper alloyed with a very ſmall quantity of ſilver.

BILLS, in *Geography*, a rock in the Atlantic, near the weſt coaſt of Ireland, 6 miles N. W. from the iſland of Clare, and 6 S. S. E. from Achill-head.

BILLY, James De, in *Biography*, was born in 1535, at Guiſe in Picardy, and devoting himſelf to ſtudy, he entered the church, in which he poſſeſſed ſome beneſices. After ſuffering conſiderably in the civil wars, he retired to Paris, and died in the houſe of his friend Gilbert Genebrard, in 1581. His works, both in proſe and verſe, were numerous; but the moſt valuable are his Latin tranſlations of the Greek fathers: ſuch are, "S. Gregorii Nazianzeni opera omnia," fol. 1569 and 1583; "Interpretatio Latina 18 priorum libri S. Irenæi adv. Hæreſ. capitum," fol. 1577; "S. Joh. Damaſceni opera," fol. 1577; "Iſidori Peluſiotæ Epiſtolæ, Gr. & Lat. (3 firſt books,) fol. 1587;" and tranſlations of ſome pieces of St. Chryſoſtom, inſerted in the Paris editions of his works, in 1581, &c. Moreri.

Billy, in *Geography*, a town of France in the department of the Allier; 4½ leagues N. E. from Gannat.

BILMA, a deſert country in the north of Africa, being a part of the Great Deſert, or Sahara, and a prolongation of the Libyan deſert to the S. W. bounded on the N. by the Tibeſti mountains, and the deſert of Berdoa, on the E. by Kawar or Kuar, on the S. by Bornou, and on the W. by Zegzeg, Agades, Aſouda, Ganat, &c. N. lat. about 23° to 25°. W. long. about 20°. The ſalt lake of Dumboo, the Chelonides Palus of Ptolemy, is ſaid to be ſituated in the deſert of Bilma.

BILOBUS, in *Entomology*, a ſpecies of Scarabæus, with two prominent lobes on the thorax; a ſimple horn on the head, and wing-caſes ſtriated. Inhabits the ſouth of Europe. Fabricius.

Bilobus, a ſpecies of Dytiscus, of an oblong-ovate form and black; mouth, vertical two-lobed ſpot, thorax, futural line, baſe, and margin of the wing-caſes yellow. Linn. Muſ. Leſk.

Bilobus, a ſpecies of Cimex (*Spinoſus*), with an obtuſe-dentated thorax; wing-caſes greyiſh or reddiſh; vent with two lobes. Linn. Muſ. Leſk. A native of Europe.

Bilobus, in *Ornithology*, a ſpecies of Charadrius, called the *Wattled Plover*, by Latham. It is an inhabitant of the coaſt of the Malabar. The bill and legs are yellow; frontal ſkin naked, and pendulous in two pointed lobes; body above yelloviſh grey; beneath white. Gmelin, &c. The crown, band on the tail, and quill feathers are black; band acroſs the eyes, greater wing-coverts, and ſome of the tail feathers at the end white. This is *Pluvier à lambeaux* of Buff. Hiſt. Oiſ. and *Pluvier de la côte de Malabar* of Pl. enl. of the ſame author. Length nine inches and a half.

BILOCULAR, in *Botany*, a term applied to a *capſule*, having two cells.

BILOIYAR, in *Geography*, a town of Ruſſia, in the government of Simbirſk, on the eaſt ſide of the Volga, 16 miles S. E. of Simbirſk.

BILS, or BILSIUS, Louis de, of Rotterdam, in Holland, in *Biography*, acquired much fame for a time, about the middle of the 17th century, for a ſuppoſed new method of preſerving bodies from putrefaction, and of diſſecting them without occaſioning an effuſion of blood. By his method of preparing the bodies, they were ſaid to preſerve their flexibility as well as freedom from putridity for ages; ſo that they

they might be diſſected during the ſummer, and remain under the demonſtrator's hands for weeks, months, or years, if neceſſary, without emitting any offenſive ſmell. De Bils had the art of gaining ſo much credit to his profeſſions, that he is ſaid, by Haller, to have ſold his ſecret to the univerſity of Louvain for 22000 florins. He had demanded a much larger ſum, and certainly had his preparations anſwered the high elogia beſtowed on them by his favourers, the ſecret would have deſerved it. Prior to the ſale he had ſent one of his bodies to the theatre at Leyden, at which Deuſingius, one of his warmeſt admirers ſays, "ſed fidem ſuperat omnem, exſiccatum hominis cadaver, recenter mortuum dicores, tanto theatro digniſſimum opus." De admiranda anatome, nobiliſſimi viri L. D. Bils, p. 362. But not contented with the fame, and money acquired by his ſecret, for he ſold his prepared bodies at high prices, he pretended to have made diſcoveries in the ſtructure of the liver, and in the lymphatics, by which he expoſed himſelf to deſerved contempt, it appearing that he was totally ignorant of the art of anatomy, in which he affected to be a maſter. He is ſaid to have died phthiſical from the effects of the putrid air inhaled while preparing his bodies, and in a few years his preparations, which were to have laſted for ages, were totally deſtroyed. His productions, which were numerous, and excited much intereſt at the time, were collected and publiſhed in 1692, in 4to. under the title of, "De Bils inventa anatomica antiquo-nova cum clariſſimorum virorum epiſtolis, et teſtimoniis, ubi adnotationes Joannis ab Hoorne, et Pauli Barbette, refutantur, interprete Gedeone Buenio. Amſt.

BILSAH, in *Geography*, a city of Hindoſtan, and capital of a circar in the Malwa country; 416 miles S. W. of Benares, 867 N. W. of Calcutta, by Gurry Mundlah, 560 N. W. of Hydrabad, 367 S. W. of Lucknow, 249 N. W. of Nagpour, 140 nearly E. of Ougein, and 496 N. E. of Poonah. Bilſah, which is almoſt in the heart of India, affords tobacco of the moſt fragrant and delicious kind throughout that whole region, and which is diſtributed accordingly. N. lat. 23° 30'. E. long. 77° 53'.

BILSEN, a town of Germany, in the circle of Weſtphalia, and biſhopric of Liege, chief place of a canton in the diſtrict of Maeſtricht, and department of the Lower Meuſe, ſeated on the Demer, poſſeſſing the privileges of a city, but of no great conſideration, 14 miles N. of Liege. The town contains 1925 perſons, and the population of the canton includes 9388. The territory comprehends 170 kiliometres, and 16 communes.

BILSKOI, a town of Siberia, on the Bilaia, 90 miles N. W. of Irkutſk.

BILSON, Thomas, in *Biography*, a learned prelate of the Engliſh church, was born at Wincheſter, and educated at Wykeham's ſchool near his native city. In 1565, he was admitted fellow of New College, Oxford, after having ſerved two years of probation. He took in due courſe his ſeveral degrees of bachelor and maſter of art, and alſo of bachelor and doctor of divinity; the laſt of which was conferred on him in 1580. In his earlier years he was fond of poetry, philoſophy, and phyſic; but after having entered into orders, he confined himſelf wholly to divinity, and became an excellent preacher. His firſt preferment was the maſterſhip of Wincheſter ſchool; and he afterwards became prebendary of Wincheſter, and at length warden of the college, in which office he was inſtrumental in preſerving the revenues of it, when they were likely to have been loſt by forgery. In 1585, he publiſhed a treatiſe entitled "The true Difference between Chriſtian Subjection and unchriſtian Rebellion," dedicated to queen Elizabeth, and compoſed for the purpoſe of confuting thoſe catholic writers who attacked her right to the throne, and to the allegiance of her ſubjects. In this treatiſe paſſages occur that are favourable to reſiſtance in certain caſes, and which have not eſcaped the cenſures of later advocates of paſſive obedience. This was ſucceeded, in 1593, by his "Perpetual Government of Chriſt's church, &c." deſigned to ſhew, that from the Moſaic inſtitution to the modern ages of Chriſtianity, the church has been governed by paſtors and teachers of different ranks, ſuperior and ſubordinate, and eſteemed one of the beſt books in favour of epiſcopacy. In conſequence of this publication he was promoted to the ſee of Worceſter in 1596, from which he was tranſlated in 1597 to that of Wincheſter, when he was alſo appointed a privy counſellor. About this time he delivered a courſe of ſermons at Paul's croſs, againſt ſome of the tenets of the Puritans, on the ſubject of redemption, and the deſcent of Chriſt into hell, which occaſioned a controverſy with the leaders of that ſect. In the courſe of this controverſy the biſhop maintained the actual deſcent of Chriſt into hell, or the place of the damned, an opinion which was then deemed orthodox, but which has ſince been rejected by the beſt expoſitors of the 39 articles, and by every rational divine. This prelate took a lead in the Hampton-court conference, where he was diſtinguiſhed by his learning; and in general he was one of the moſt able advocates in favour of the church of England. To him, in conjunction with Dr. Smith, afterwards biſhop of Glouceſter, was committed the care of reviſing and finiſhing the new verſion of the Scriptures, called king James's Bible. He was alſo one of the delegates who pronounced the ſentence of divorce between the earl of Eſſex and his counteſs. This learned biſhop, whoſe life was a courſe of inceſſant labour for the public good, and whoſe private character uniformly correſponded with his high ſtation, died in 1616, and was buried in Weſtminſter Abbey. Biog. Brit.

BILSTEIN, in *Geography*, a town of Germany, in the circle of the Lower Rhine, and capital of a bailiwick, in the duchy of Weſtphalia, ſeated on a mountain; 42 miles E. of Cologn.

BILSTON, a large village, or chapelry, of Staffordſhire, England, is remarkable for the number of its houſes and inhabitants, without having the advantage of a chartered market or fair. From its proximity to Birmingham and Wolverhampton, and having the advantage of a navigable canal near it, Bilſton abounds with manufactures, among which thoſe for japanned and enamelled goods are the principal. Furnaces for ſmelting iron ore, forges and ſlitting mills, moſtly worked by ſteam engines, alſo abound here. In the vicinity of the town are ſeveral coal mines, which produce great quantities of that foſſil. An orange coloured ſand is alſo abundant, and is in much requeſt by the artizans, as a ſand to caſt metals in. Here is a quarry of remarkable ſtones, lying horizontally in twelve ſtrata, each progreſſively increaſing in thickneſs from the top downwards. The ſtone is moſtly appropriated to the making of ciſterns, troughs, &c. Bilſton is in the pariſh of Wolverhampton, but is a diſtinct townſhip for all parochial proceedings. There is a chapel of modern erection; alſo two meeting-houſes, and a free-ſchool. This chapelry is within the exempt juriſdiction of the dean of Wolverhampton, and is a perpetual curacy. Bilſton is 127 miles N. W. from London: it contains 1305 houſes, and 6914 inhabitants. Shaw's Hiſtory of Staffordſhire.

Bilston, or Bildston, is a ſmall manufacturing town of Suffolk, England. The making of blue cloths, blankets, and yarn, give employ to moſt of the inhabitants. Here was formerly a conſiderable market on Wedneſdays, but it

is

is nearly deſerted, and the whole town is much reduced. Here are two annual fairs. The pariſh contains 121 houſes, and 744 inhabitants.

BILUR, in *Natural Hiſtory*, a name given by many of the Arabian writers to a gem, which though they often mention, yet they have no where given us a deſcription of. Some have imagined it the *onyx*, and others the *beryl*; but it appears more probable to have been a ſpecies of cryſtal; probably the pebble-cryſtal of the Eaſt Indies, which is conſiderably finer than the common ſprig-cryſtal, and is often ſold under the name of the white ſapphire; though conſiderably inferior, both in luſtre and hardneſs, to the true white ſapphire.

BIMA, in *Geography*, a river of Hindoſtan, ſo called by Mr. Pennant. See BEEMAH.

BIMACULARIS, in *Entomology*, a ſpecies of PHALÆNA (*Pyralis*, Gmel.), found in Europe. The anterior wings are griſeous brown, with two brown ſpots. Linn.

BIMACULATA, in *Conchology*, a ſpecies of TELLINA, found in the European and American ſeas. This ſhell is of a ſomewhat rotundated triangular ſhape, rather broad, ſmooth, whitiſh, with two ſanguineous ſpots within. It is a ſmall ſhell, being uſually half an inch in length, and ſometimes, though rarely, of a yellowiſh colour. Linnæus, Donovan Brit. Shells, &c. On the Engliſh coaſts this is a ſcarce ſpecies.

BIMACULATA, in *Entomology*, a ſpecies of SILPHA, found in Barbary. It is ovate and black; head of the antennæ, globoſe; legs ferruginous. Gmelin. The margin of the thorax is rather ferruginous, and the middle of each wing-caſe is marked with a red ſpot.

BIMACULATA, a ſpecies of CHRYSOMELA, of an oblong ſhape, and black; wing-caſes teſtaceous, with a black ſpot on each. Inhabits America. Fabricius.

BIMACULATA, a ſpecies of LEPTURA, of a rufous colour, with cylindrical thorax; wing-caſes dotted, with a ſpot and undulated ſtreak of white on each. Schæffer, &c.

BIMACULATA, a North American ſpecies of CANTHARIS, with a ferruginous thorax, having a black ſpot; wing-caſes teſtaceous, with a black ſpot at the tip. Fabricius.

BIMACULATA, a ſpecies of MORDELLA, of a large ſize, that is found in Hungary. It is ferruginous, with the breaſt black; wing-caſes teſtaceous, with a black ſpot on each. Fabricius. Mant. Inſ.

BIMACULATA, a ſpecies of BUPRESTIS, that inhabits India. The wings are very entire, ſtriated, with a red ſpot; body browniſh, green. Linn. Fabr. &c.

BIMACULATA, a ſpecies of SPHINX (*Zygæna*), of the middle ſize, that inhabits America. The wings are above and beneath black, with two yellow ſpots on the anterior wings. Gmel. Fabr. &c.

BIMACULATA, a ſpecies of PHRYGÆNEA, deſcribed by Degeer. The wings are brown, with a double yellow lateral ſpot. Linn. &c.

BIMACULATA, a ſpecies of TIPULA, found in Europe. The wings are hyaline, with two brown ſpots; abdomen ſpotted, with ferruginous in the middle; antennæ feathered. Linn. Fn. Suec. Obſ. This ſpecific character is liable to ſome exception, for it is only the female which has the abdomen ſpotted with ferruginous; that of the male is immaculate.

BIMACULATA, a ſpecies of MUSCA, found in New Holland, and deſcribed by Swederus, Nov. Act. Stockh. The colour is light blue, with a whitiſh ſpot on each ſide of the breaſt: abdomen green, and blue at the baſe.

BIMACULATA, a ſpecies of SCOLIA, deſcribed by Fabricius. It is black, hairy, with two pale yellow ſpots; antennæ yellow. A variety of this inſect with fulvous, inſtead of yellow ſpots, is mentioned by Pelagn. Inſ. Calabr. The former inhabits North America.

BIMACULATA, a ſpecies of ARANEA, of a ſmall ſize, that is found in Europe. The abdomen is ſubrotund, cheſnut, with two white ſpots. Gmelin. Abdomen rather depreſſed.

BIMACULATA, a ſpecies of TENTHREDO, of a pale colour, with the eyes, baſe of the abdomen above, and two ſpots on the breaſt, black. Linnæus Muſ. Leſk.

BIMACULATA, in *Zoology*, a ſpecies of LACERTA, deſcribed by Sparmann. Nov. Act. Stockh. The tail is carinated, toothed, and twice the length of the body; all the toes lobated. Inhabits the woods of St. Euſtace and Pennſylvania, living under ground, or in the hollows of trees, and depoſiting its eggs in the earth. The body is blue, tinged with green, and thickly ſpotted with black, but having two larger than the reſt on the ſhoulders, from whence it is ſpecifically named *bimaculata*; on each foot are five toes.

BIMACULATUM, in *Entomology*, a ſpecies of PHALANGIUM, with the abdomen black, and two white ſpots. A native of England and Norway. Gmelin.

BIMACULATUS, a ſpecies of SCARABÆUS, with three ſlight tubercles on the head; wing-caſes ſtriated, with two red ſpots at the baſe. Inhabits Germany. Fabricius.

BIMACULATUS, a ſpecies of HISTER, of a black colour, with the poſterior end of the wing-caſes red. Linn. Fn. Suec. Found in the dung of oxen. This is *Hiſter fimetarius* of Scopoli; and *Attelabus totus niger; elytris lævis nonnihil ſtriatis*; *l'eſcarbot noir* of Geoffroy.

BIMACULATUS, a ſpecies of CURCULIO, of a brown colour; wing-caſes dotted with cinereous; ſnout and legs black. Inhabits Saxony; and reſembles *Curculio colon*, but is rather ſmaller.

BIMACULATUS, a ſpecies of CRYPTOCEPHALUS, of a duſky black, with fulvous thorax, and teſtaceous wing-caſes, with two ſpots of black. Fabricius. Obſ. This is *Chryſomela melanocephala* of Schaller, &c. A native of Italy and Saxony.

BIMACULATUS, a ſpecies of CARABUS, of a black colour, with a common interrupted band; antennæ and feet teſtaceous. Mant. p. 532. Gmel. Inhabits India. The thorax of this inſect is yellow, or black, and ſometimes ſpotted in different ſpecimens.

BIMACULATUS, a ſpecies of DYTISCUS, of a teſtaceous colour, with a blackiſh ſpot on the wing-caſes. Inhabits France. Size of a grain of rice. Gouan. Gmelin, &c.

BIMACULATUS, a ſpecies of GRYLLUS (*Bulla acridium*) found in Europe, and deſcribed by Herbſt. The thorax is brown, with an ochraceous lunule on each ſide.

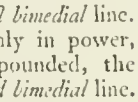
BIMACULATUS, a ſpecies of ICHNEUMON. Colour black; front, legs, antennæ beneath, anterior part of the thorax, two ſpots on the wings, and poſterior margin of the abdominal ſegments, except the ſecond, yellow. Linn. Muſ. Leſk. Breeds in the larva of phalæna fimbria. Scutel raiſed behind. Inhabits Europe.

BIMACULATUS, is alſo a ſpecies of ICHNEUMON, that inhabits Auſtria, and is deſcribed by Schranck. It is black, with a yellowiſh ſcutel; two laſt ſegments of the abdomen with a ſingle gypſeous ſpot on each above.

BIMACULATUS, in *Ichthyology*, a ſpecies of SALMO, the body of which is compreſſed, and marked with two ſpots; anal fin with thirty-two rays. Gmelin. This is a native of South America. Seba calls it *Tetragonopterus*; and Artedi *Coregonoides Amboinenſis*.

BIMACULATUS, a ſpecies of LABRUS, found in the Mediterranean

diterranean ſea. The dorſal fin is filamentous, body marked with a brown ſpot in the middle, and another near the tail. Gmel. &c.



BIMACULOSA, in *Entomology*, a ſpecies of Coccinella, with ſulvous wing-caſes, having two obſolete white ſemilunar patches. Herbſt. apud Fueſsli, &c.

Bimaculosa, a ſpecies of Phalæna, that inhabits Germany. Colour whitiſh grey; anterior wings rather clouded; poſterior ones with two black ſpots. Fabricius, &c.

BIMATRA, in *Ancient Geography*, a town of Aſia in Meſopotamia. Ptolemy.

BIMBELE' *ou fauſſe Linotte*, in *Ornithology*, a name given by Buffon to a ſpecies of motacilla, ſince called by Latham the *palm warbler*, and *motacilla palmarum* by Gmelin.

BIMEDIAL, in *Mathematics*. When two medial lines, as AB and BC, commenſurable only in power, and containing a rational rectangle, are compounded; the whole AC ſhall be irrational, with reſpect to either of the two, and is called a *firſt bimedial* line.

But if two medial lines, commenſurable only in power, and containing a medial rectangle, be compounded, the whole will be irrational, and is called a *ſecond bimedial* line. Euc. lib. x. prop. 38 and 39.

BIMINI, in *Geography*, one of the Bahama iſlands on the weſt ſide of the great Bahama bank, near the gulf of Florida. Its compaſs is about twenty miles, and it has a good harbour. N. lat. 25°. W. long. 79° 34′.

BIMLIPATAM, or Bimlipatan, a ſea-port town of Hindoſtan, on the weſtern ſide of the bay of Bengal, in the circar of Cicacole, 35 miles S.S.W. of Cicacole. N. lat. 18° 10′. E. long. 83° 15′.

BIMUCRONATUS, in *Entomology*, a ſpecies of Scarabæus, that inhabits Amboyna. It is teſtaceous; ſhanks of the anterior legs large, and bearded; ſhield of the head mucronated on both ſides, and bordered with fine hairs.

BINA, in *Geography*, a town of Italy, in the Cremoneſe, 10 miles N.E. from Cremona.

BINACLE, in *Sea-Language*. See Bittacle.

BINAGARA, in *Ancient Geography*, a town of India, on this ſide the Ganges. Ptolemy.

BINARD Island, in *Geography*, a long and narrow iſland on the north coaſt of France, to the eaſt of Roteneuf point, having entrances at both the eaſt and weſt end, and within it a ſound or bay. It lies to the eaſt of St. Maloes, towards Cancale.

BINAROS, or Vinaros, a town of Spain in Valencia, on the confines of Catalonia, near the coaſt of the Mediterranean, at the mouth of a river, which forms a ſmall harbour, with anchorage at about a cannon ſhot from the town, in 6 to 9 fathoms. It is ſurrounded with walls, and defended by ſome cannon; 5 miles north of Penniſcola, and 20 ſouth of Tortoſa.

BINARY Number, that which is compoſed of two units.

Binary *Arithmetic*, a method of computation firſt propoſed by M. Leibnitz; wherein, in lieu of the ten figures in the common arithmetic, and the progreſſion from 10 to 10, he has only two figures, and uſes the ſimple progreſſion from two to two.

Joſ. Pelican, of Prague, has more largely explained the principles and practice of the binary arithmetic, in a book entitled, "Arithmeticus perfectus, qui tria numerare neſcit," 1712.

All his characters uſed in this arithmetic are 0 and 1; and the cipher, here, multiplies every thing by 2, as it does in the common arithmetic by 10. Thus, 1 is one; 10, two; 11, three; 100, four; 101, five; 110, ſix; 111, ſeven; 1000, eight; 1001, nine; 1010, ten, &c. being founded on the ſame principles with the common arithmetic. Hence immediately appears the reaſon of the celebrated property of the duplicate geometrical proportion in whole numbers; viz. that one number of each degree being had, we may thence compoſe all the other whole numbers above the double of the higheſt degree. It being here, v. gr. as if one ſhould ſay 111 is the ſum of 4, 2, and 1, which property may ſerve aſſayers to weigh all kinds of maſſes with a little weight; and may be uſed in coins, to give ſeveral values with ſmall pieces. This method of expreſſing numbers once eſtabliſhed, all the operations will be eaſy: in multiplication particularly, there will be no need for a table, or getting any thing by heart. The author, however, does not recommend this method for common uſe, becauſe of the great number of figures required to expreſs a number; adding, that if the common progreſſion were from 12 to 12, or from 16 to 16, it would be ſtill more expeditious: but its uſe is in diſcovering the properties of numbers, in conſtructing tables, &c. What makes the binary arithmetic the more remarkable is that it appears to have been the ſame with that uſed 4000 years ago among the Chineſe, and left in *ænigma* by Fohi, the founder of their empire, as well as of their ſciences. M. Lagny has propoſed a new ſyſtem of logarithms, on the plan of the binary arithmetic; which he finds ſhorter, more eaſy, and natural than the common ones.

111	7

Binary, a time in *Muſic*, conſiſting of two crotchets or two minims in a bar.

BINASCO, in *Geography*, a town of Italy, in the Milaneſe, 10 miles ſouth of Milan.

BINATED Leaf, in *Botany*. See Leaf.

BINCHE, in *Geography*, a town of the Netherlands, in the county of Hainaut, ſituated in a fertile country, on the river Haiſne; and, according to the French diſtribution, a place and canton in the diſtrict of Charleroy and department of Jemappe. The town contains 3798 perſons, and the population of the canton is eſtimated at 13,908. The extent of the territory comprehends 125 kiliometres and 16 communes. Binche was burned by Henry II. of France in 1554, and ſoon after rebuilt. In 1578, it was taken by John duke of Auſtria, and retaken in the ſame year by the duke of Alençon. The Spaniards regained poſſeſſion of it, and ceded it to France at the peace of Aix-la-Chapelle, but the peace of Nimeguen reſtored it, together with its juriſdiction, including 51 towns and villages, to Spain. It is diſtant 8 miles E.S.E. from Mons.

BIND, in *Commerce*, contains 10 ſtrikes of eels; each ſtrike including 25.

Bind-*Weed*, in *Botany*. See Convolvulus.

Bind-*Weed*, *black*. See Tamus.

Bind-*Weed*, *rough*. See Smilax.

Bind-*With*. See Clematis.

BINDEN, in *Geography*, a town of Swiſſerland in the Valais, near the river Binna. N. lat. 46° 13′. E. long. 7° 58′.

BINDER-Ooze, the weakeſt kind of tan-ooze. See Tanning.

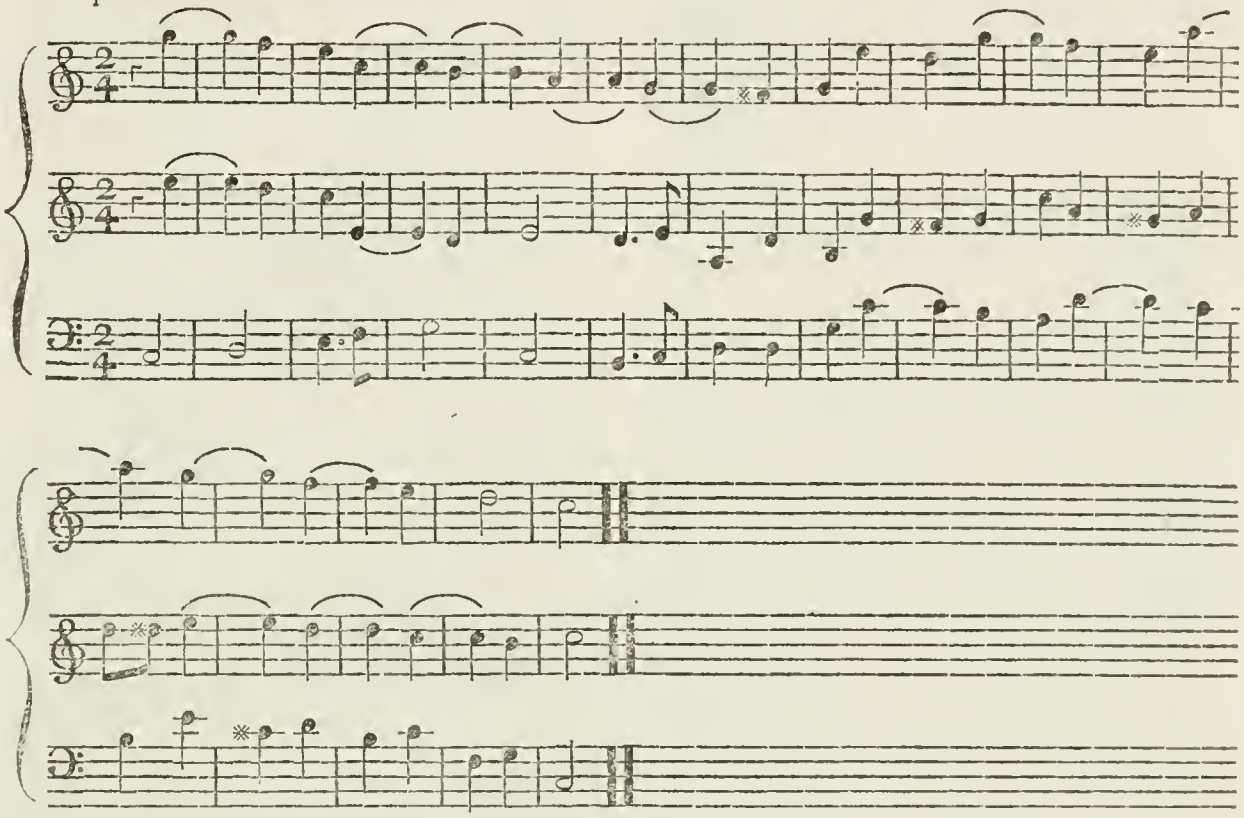
BINDING Joists, in *Architecture*. See Joists.

Binding, in the *Art of Defence*, a method of ſecuring or croſſing the adverſary's ſword with a preſſure, accompanied with a ſpring from the wriſt. See Beating.

Unleſs a man, by ſome kind of croſs, ſecure, as it were, or render his adverſary's ſword incapable to find him during the time of his performing a leſſon upon him, it is impoſſible for him to be certain but that he may receive from his adverſary, either a fortuitous *contretemps*, or an exchanged thruſt,

thruſt, before the recovery of his body, or going off after a thruſt.

The great objection made by ſome people, particularly thoſe time-catchers, againſt the frequent uſe of *binding*, is, that when a man, in performing it, cleaves too much to his adverſary's ſword, he is liable to his adverſary's ſlipping of him, and conſequently of receiving either a plain thruſt, or one from a feint.



Binding is a term in *Falconry*, which implies tiring, or when a hawk ſeizes.

Binding *Books*. See Book-*Binding*.

Binding-*Notes*, in *Muſic*, imply two or more ſounds on the ſame line or ſpace, that are linked together by a ſemi-circle; and which, though written or printed twice, are not to be ſeparated, but ſuſtained like a ſingle ſound.

The firſt of theſe tied or binding-notes, as in preparing diſcords, is uſually ſtruck on the unaccented part of a bar, and continued on the accented part. See Ligature, and Syncopation.

Example.

BINETTA, in *Geography*, a town of Italy, in the kingdom of Naples, and country of Bari, 4 miles W.S.W. of Bidetto.

BINGAZI. See Bengasi.

BINGE, a town of France, in the department of the Cote d'Or, and chief place of a canton in the diſtrict of Dijon, 10 miles eaſt of Dijon.

BINGEN, a town of Germany, in the circle of the Lower Rhine, and electorate of Mentz or Mayence, and by the French arrangement, the principal place of a canton, in the diſtrict of Mayence, and department of Mont-Tonnerre. The town is ſaid to contain 2663 inhabitants, and the canton 5638. It includes 10 communes. The town is ſeated at the conflux of the Nahe and Rhine. The ſtone bridge over the former is a noble ſtructure, and the adjoining country is delightful. Bingen is a very ancient town, and was once imperial. The fortifications were deſtroyed by Lewis XIV. in 1689. A great part of the corn, which is carried into the Rhinegau, the neighbouring palatinate, comes through this place, which, on the other hand, ſupplies the palatinate with drugs, and various foreign commodities. Beſides this traffic, it has in its vicinity very fruitful vineyards, which produce excellent wine. Near this town the Rhine is compreſſed into a narrow channel, between two rocks; about a mile and a half below it is a kind of whirl-pool, called the "Bingen-loch," the paſſage of which is dangerous. At a ſmall diſtance is alſo an iſland on the Rhine, denominated "Mauſtburn," or tower of rats; from a tradition, that an archbiſhop of Mentz was there devoured by theſe animals, in the tenth century, as a judgment executed on him for his cruelty to the poor, whom he compared to rats eating up the ſubſtance of the rich. Bingen is 19 miles W. of Mentz, 30 S. of Coblentz, and 54 E. of Treves. N. lat. 49° 54'. E. long. 7° 33'.

BINGENHEIM, a town of Germany, in the circle of the Upper Rhine, and principality of Heſſe, 16 miles N.N.E. from Frankfort on the Mayne.

BINGHAM, Joseph, in *Biography*, a learned Engliſh divine, was born at Wakefield, in Yorkſhire, in 1668. Having acquired the rudiments of claſſical learning at a ſchool in his native town, he was admitted in 1683, into Univerſity-college at Oxford, and in 1687, became fellow. Having taken

taken his maſter's degree in 1690, he was ſoon after preſented by Dr. Radcliffe, the celebrated phyſician, to the rectory of Headbourn-Worthy, near Wincheſter; a preferment, which, though not exceeding in value 100l. a year, afforded him acceſs to the valuable library at Wincheſter, and enabled him to proſecute the arduous undertaking, to which, in this retirement, he devoted much of his time and labour. Accordingly, the firſt volume of his learned work, entitled "Origines Eccleſiaſticæ, or the Antiquities of the Chriſtian Church," appeared in 1708. It was completed in ten volumes, 8vo. and contains a judicious and candid, as well as ample account of the Chriſtian clergy and churches from the earlieſt times. Beſides this work, which was the reſult of much reading and indefatigable application, he publiſhed, in 1706, "The French Church's Apology for the Church of England; or, the Objections of the Diſſenters againſt the Articles, Homilies, Liturgy, and Canons of the Engliſh Church, conſidered and anſwered upon the principles of the Reformed Church of France, &c." 8vo. His avowed deſign in this work was to reaſon diſſenters "into union upon ſuch principles as are common to all the churches of the reformation." However laudable the deſign, uniformity of ſentiment is not likely to be produced by any reaſoning, as long as men are allowed to exerciſe the right of private judgment, and the only practicable union ſeems to be that which reſults from mutual forbearance and benevolence. Mr. Bingham likewiſe publiſhed "A Scholaſtic Hiſtory of Lay-Baptiſm," in two parts, 1712, 8vo.; and "A Diſcourſe concerning the Mercy of God to Penitent Sinners." All his works were collected and publiſhed in 2 vols. fol. Lond. 1725. Notwithſtanding the acknowledged learning and meritorious ſervices of Mr. Bingham, he had no other preferment beſides that above-mentioned, till the year 1712, when he was collated to the rectory of Havant near Portſmouth. He died in 1723, and was buried in the church-yard of Headbourn-Worthy, without any monument, of which he declared his diſlike in his laſt will. Biog. Brit.

Bingham, in *Geography*, a town of Nottinghamſhire, in England, ſtands nearly in the centre of the vale of Belvoir. It conſiſts principally of two ſtreets, running nearly parallel to each other, with ſome ſmaller ſtreets branching from them. Near the centre of the town is a ſpacious market-place, where a weekly market is held every Thurſday; it has alſo three annual fairs, and a large ſtatute fair yearly, for hiring of ſervants. Bingham is ſtated by Thoroton to be much reduced ſince the reformation, as, previouſly to that event, it contained three chapels, excluſive of the pariſh church. The latter was collegiate, and is ſtill a large handſome ſtructure, with a tower and ſpire, ſide ailes and chancel. It contains numerous monuments, among which is a plain one inſcribed to the memory of Robert White, a native of this place, where he died, in 1773, at the advanced age of eighty. He was author of an annual publication, entitled "The cœleſtial Atlas, or New Ephemeris." The rectory of Bingham is eſteemed one of the moſt valuable in the county of Nottingham, and is in the gift of lord Cheſterfield, who is lord of the manor. This town is 124 miles north from London. It contains 220 houſes, and 1082 inhabitants.

At Aſlaſton, about two miles eaſt from Bingham, archbiſhop Cranmer was born. About two miles north from Bingham is Eaſt-Bridgeford, where are the remains of an entrenchment, and where ſome coins, urns, &c. have been found. Horſley places the Roman ſtation, Margidunum, "near Eaſt Bridgeford," from its ſituation near the foſs-road, and from the agreement of diſtances, between this and the other ſtations named in the Itinerary. Thoroton's Hiſtory of Nottinghamſhire.

BINGIUM, in *Ancient Geography*, a town of Gaul, in Germania Prima, weſt of Mogentiacum; now *Bingen*, which ſee.

BINGLESTEIN, in *Geography*, a town of Germany, in the circle of Weſtphalia, and biſhopric of Paderborn, 3 miles ſouth of Buren.

BINGO, a ſmall country of Japan, in the iſland of Nipon, ſituate in N. lat. about 34° 30'. E. long. 134°.

BINGUM, a town of Germany, in the circle of Weſtphalia, and county of Eaſt Frieſland, one mile north-weſt of Ort.

BINGUT Cape and Bay, lie about E. by N. from Algiers, on the coaſt of Africa, in the Mediterranean. The town of Bingut is at the bottom of the bay of its name, about 12 or 13 leagues from Algiers.

BINIESZKY, a town of Lithuania, in the palatinate of Wilna, 44 miles S.E. of Wilna.

BINN, *binna*, a ſort of cheſt or cupboard, wherein to lock up bread, meat, or other proviſions.

The word is alſo uſed for a place boarded up to put corn in. The peaſe and oatmeal, uſed at ſea, are apt to ſpoil in caſks. Dr. Hales propoſes to prevent this by putting them into large binns, with falſe bottoms of hair-cloth laid on bars, whereby freſh air may be blown upwards through them, at proper times, with ſmall ventilators.

BINNA, in *Ancient Geography*, a town of Aſſyria, according to Ptolemy.

BINNINGER, John Nicholas, in *Biography*, born at Montbelliard, in 1628, ſtudied medicine at Padua, and then went to Baſle, where he was admitted to the degree of doctor in that art in 1652. Returning to his own country, he ſoon acquired ſo much fame for his ſkill in his profeſſion, that he was appointed profeſſor of medicine, and phyſician to the family of the duke, his ſovereign. He left "Obſervationum et Curationum medicinalium, centuriæ quinque," 8vo. 1673, Montb. containing ſome curious and valuable obſervations. Haller. Bib. Med. Eloy. Dict. Hiſt.

BINNIGUET, in *Geography*, a ſmall iſland near the weſt coaſt of France, about a league ſouth-weſt of Le Conquet, and ¾ weſt of St. Matthew's point. N. lat. 48° 19'. E. long. 1° 5'.

BINN-NA-BAIRD, and Binn-na-Muick-duidh; are the names of two lofty mountains, in the pariſh of Crathy, Aberdeenſhire, in Scotland. Theſe eminences are conſtantly covered with ſnow, and extending in the ſame ridge with the Cairngoram mountain, contain the ſame ſpecies of topaz, which bears the name of Cairngoram ſtones. Emeralds have been ſometimes diſcovered here; alſo a ſpecies of brown ſiliceous ſtone, which bears a very fine poliſh.

BINOCLE, or Binocular *Teleſcope*, from *binus*, *double*, and *oculus*, *eye*, in *Optics*, that to which both the eyes may be applied, and conſequently the ſame object be obſerved at the ſame time by both. It conſiſts of two tubes, with two ſets of glaſſes of the ſame power, and adjuſted to the ſame axis; and ſome have pretended that it repreſents objects much larger and clearer than a ſingle or monocular glaſs. But this is perhaps only an illuſion, occaſioned by the ſtronger impreſſion, which two equal images alike illuminated make upon the eyes. This method of conſtruction was invented by father Rheita, and brought into uſe by father Cherubin of Orleans. There are alſo microſcopes of the ſame kind, but very ſeldom uſed.

BINODIS, in *Entomology*, a ſpecies of Formica, deſcribed by Fabricius as a native of Egypt. It is black; head

head large and rufous; with two tubercles on the petiole.

BINOMINAL, or BINOMIAL, from *bis*, *twice*, and *nomen*, *name*, in *Algebra*, a quantity conſiſting of two terms or members, connected by the ſign + *plus*, or − *minus*.

Thus $a+b$ and $5-3$ are binomials, conſiſting of the ſum or difference of thoſe quantities; though the latter is often called *reſidual*, and by Euclid, *apotome*.

The terms binomial and reſidual are ſaid to have been firſt introduced by Robert Recorde. See ALGEBRA.

The powers of a binomial are found by a continual multiplication of it by itſelf, as often as an unit is contained in the index of the power required. Thoſe of a reſidual, $a-b$, are obtained in the ſame manner, only with this difference in the reſult, that the terms in which the exponent of b is an odd number, will be negative.

If a root have three parts, as $a+b+c$, it is called a trinomial; if more, a multinomial.

BINOMIAL, *impoſſible*, or *imaginary*, in *Algebra*, is uſed for a binomial, one of the terms of which is an impoſſible or imaginary quantity: as $a\pm\sqrt{-bb}$ is an impoſſible binomial.

Dr. Maſkelyne, the aſtronomer royal, has given (in his Introduction to "Taylor's Tables of Logarithms," p. 56.) the following method of finding any power of an impoſſible binomial, by another ſimilar binomial. The logarithms of a and b being given, it is required to find the power of the impoſſible binomial $a\pm\sqrt{-b^2}$ whoſe index is $\frac{m}{n}$, that is to find $(a\pm\sqrt{-b^2})^{\frac{m}{n}}$ by another impoſſible binomial; and thence the value of $(a+\sqrt{-b^2})^{\frac{m}{n}}+(a-\sqrt{-b^2})^{\frac{m}{n}}$, which is always poſſible, whether a or b be the greater of the two.

Solution. Put $\frac{b}{a}=$ tang. z. Then

$(a\pm\sqrt{-b^2})^{\frac{m}{n}}\ (=a^2+b^2)^{\frac{m}{2n}}\times(\text{cof. }\frac{m}{n}z\pm\sqrt{-1}\text{ ſin. }\frac{m}{n}z)$.

Hence $(a+\sqrt{-b^2})^{\frac{m}{n}}+(a-\sqrt{-b^2})^{\frac{m}{n}}=(a^2+b^2)^{\frac{m}{2n}}\times 2$ cof. $\frac{m}{n}z=a\times\text{ſec. }z)^{\frac{m}{n}}\times 2$ coſin. $\frac{m}{n}z=(b\times\text{coſec. }z.)^{\frac{m}{n}}\times 2$ coſin. $\frac{m}{n}z$, where the firſt or ſecond of theſe two laſt expreſſions is to be uſed, according as z is an extreme or mean arc; or rather, becauſe $\frac{b}{a}$ is not only the tangent of z but alſo of $z+360°$, $z+720°$, &c.; therefore the factor in the anſwer will have ſeveral values, viz.

$2\text{ cof. }\frac{m}{n}z$; $2\text{ cof. }\frac{m}{n}(z+360°)$; $2\text{ cof. }\frac{m}{n}(z+720°)$; &c.; the number of which, if m and n be whole numbers, and the fraction $\frac{m}{n}$ be in its leaſt terms, will be equal to the denominator n; otherwiſe infinite.

By Logarithms. Put log. $b+10-$ log. $a=$ log. tan. z. Then log. $\left((a+\sqrt{-b^2})^{\frac{m}{n}}+(a-\sqrt{-b^2})^{\frac{m}{n}}\right)=\frac{m}{n}\times(\text{l. }a+10-\text{l. cof. }z)+\text{l. }2+\text{l. cof. }\frac{m}{n}z-10=\frac{m}{n}\times(\text{l. }b+10-\text{l. ſin. }z)+\text{l. }2+\text{l. cof. }\frac{m}{n}z-10$; where the firſt or ſecond expreſſion is to be uſed, according as z is an extreme or mean arc. Moreover, by taking ſucceſſively, l. cof. $\frac{m}{n}z$; l. cof. $\frac{m}{n}(z+360°)$; l. cof. $\frac{m}{n}(z+720°)$, &c. there will ariſe ſeveral diſtinct anſwers to the queſtion, agreeably to the remark above.

BINOMIAL *ſurd*, is uſed for a binomial, the terms of which are ſurds; as $\sqrt{a}+\sqrt{b}$, or $a^{\frac{m}{n}}+b^{\frac{m}{n}}$, if m and n be fractions. The term binomial ſurd is alſo applied to any quantity having a rational part and a ſurd part, as $25+\sqrt{968}$. Euclid enumerates ſix kinds of binomial lines or ſurds in the 10th book of his "Elements," which are exactly ſimilar to the ſix reſiduals or apotomes, of which he has alſo treated in the ſame place. See APOTOME. Theſe apotomes become binomials by merely changing the ſign of the latter term from *minus* to *plus*, and they are as follow: 1ſt. $3+\sqrt{5}$; 2d. $\sqrt{18}+4$; 3d. $\sqrt{24}+\sqrt{18}$; 4th. $4+\sqrt{3}$; 5th. $\sqrt{6}+2$ 6th. $\sqrt{6}+\sqrt{2}$.

For the extraction of roots of binomial ſurds, ſee Newton's Arithmetica Univerſalis; St. Graveſande's Commentary; and Mac Laurin's Algebra, p. 114—130. See SURD.

BINOMIAL *Curve*, is uſed for a curve, the ordinate of which is expreſſed by a binomial. Thus, if the ordinate of a curve be of this form $\overline{x+e+fx^{\frac{1}{n}}}^{\lambda}$, the curve is called a binomial curve. Stirling. Method. Diff. p. 58.

BINOMIAL *Theorem*, is a general algebraical expreſſion, or formula, by which any power or root of a quantity, conſiſting of two terms, is expanded into a ſeries.

It is alſo frequently called the Newtonian theorem, or Newton's binomial theorem, on account of his being commonly conſidered as the inventor of it, as he undoubtedly was, at leaſt in the caſe of fractional indices, which includes all the other particular caſes of powers, diviſions, &c.

This celebrated theorem, as propoſed in its moſt general form, may be exhibited in a manner nearly ſimilar to that of Newton, as follows:

$\overline{a+x}^{\frac{m}{n}}=a^{\frac{m}{n}}\times:1+\frac{m}{n}\left(\frac{x}{a}\right)+\frac{m}{n}\cdot\frac{m-n}{2n}\left(\frac{x}{a}\right)^2+\frac{m}{n}\cdot\frac{m-n}{2n}\cdot\frac{m-2}{3n}\left(\frac{x}{a}\right)^3+$ &c. Or, $\overline{a+x}^{\frac{m}{n}}=a^{\frac{m}{n}}\times:1+\frac{m}{n}\text{ A}\left(\frac{x}{a}\right)+\frac{m-n}{2n}\text{ B}\left(\frac{x}{a}\right)+\frac{m-2n}{3n}\text{ C}\left(\frac{x}{a}\right)+\frac{m-3n}{4n}\text{ D}\left(\frac{x}{a}\right)+$ &c.

Where a, x, are the two terms of the binomial, $\frac{m}{n}$ the index, and A, B, C, D, &c. each preceding term, including their ſigns + or −, the terms of the ſeries being all poſitive when x is poſitive, and alternately poſitive and negative when x is negative, independently however of the effect of the coefficients made up of m and n, which may be any numbers whatever, poſitive or negative.

A few eaſy examples, in the extraction of roots, will be ſufficient to ſhew the application of the theorem in all ſimilar caſes. For this purpoſe, let it be required to find the ſquare root of $a+b$, or $\overline{a+b}^{\frac{1}{2}}$, and the cube root of $a-b$, or $\overline{a-b}^{\frac{1}{3}}$; in the firſt of which $\frac{m}{n}=\frac{1}{2}$ and in the ſecond $\frac{m}{n}=\frac{1}{3}$.

Then $\overline{a+b}^{\frac{1}{2}}=a^{\frac{1}{2}}\left[1+\frac{1}{2}\left(\frac{b}{a}\right)-\frac{1}{2.4}\left(\frac{b}{a}\right)^2+\frac{3}{2.4.6}\left(\frac{b}{a}\right)^3-\frac{3.5}{2.4.6.8}\left(\frac{b}{a}\right)^4\right.$, &c.

And $\overline{a-b}^{\frac{1}{3}} = a^{\frac{1}{3}}\left[1 - \frac{1}{3}\left(\frac{b}{a}\right) - \frac{1}{3^2}\left(\frac{b}{a}\right)^2 - \frac{5}{3\cdot 3^3}\left(\frac{b}{a}\right)^3 - \frac{5\cdot 8}{4\cdot 3^4}\left(\frac{b}{a}\right)^4\right.$, &c.

And, in the same manner, if 1, divided by the cube root of the square of $a \pm b$, be converted into a series, we shall have $\frac{1}{\overline{a \pm b}^{\frac{2}{3}}} = \frac{1}{a^{\frac{2}{3}}}\left[1 \mp \frac{2}{3}\left(\frac{b}{a}\right) + \frac{2\cdot 5}{2\cdot 3^2}\left(\frac{b}{a}\right)^2 \mp \frac{2\cdot 5\cdot 7}{2\cdot 3^3}\left(\frac{b}{a}\right)^3\right.$, &c.

But these series are only commodious in calculation, in proportion to their degree of convergency. For if N be made to represent the rank which any term holds in the series arising from the binomial $a-b$ being raised to the mth power, then that term will be to the following one as 1 to $\frac{b}{a} \times \frac{m-N+1}{N}$; from which it is evident, that for the terms of the series to go on decreasing, $b \times \overline{m-N+1}$, taken positively, must be always less than aN.

With respect to the history of this theorem, the prevailing opinion, till within these few years, has been, that it was not only invented by Newton, but first given by him in that state of perfection, in which the terms of the series, for any assigned power whatever, can be found, independently of the terms of the preceding powers; viz. the second term from the first, the third from the second, the fourth from the third, and so on, by a general rule. But it has since been found, that in the case of integral powers, the theorem had been described by Briggs, in his "Trigonometrica Britannica," long before Newton was born; and that, by the general law of the terms, independently of those of the preceding powers. For, as far as regards the generation of the coefficients of the terms of one power from those of the former ones, successively one after another, it was remarked by Vieta, Oughtred, and many others; and was not unknown to much more early writers on arithmetic and algebra, as will be manifest by a slight inspection of their works, as well as the gradual advance the property made, both in extent and perspicuity, under the hands of the latter authors, most of whom added something more towards its perfection.

The knowledge, indeed, of this property of the coefficients of the terms of the integral powers of a binomial, is, at least, as old as the practice of the extraction of roots, of which it is both the foundation and principle. And as the writers on arithmetic became acquainted with the nature of the coefficients in the higher powers, they extended the extraction of roots accordingly, still making use of this property. At first, they appear to have been only acquainted with the nature of the square, the coefficients of which are the three terms, 1, 2, 1; and, by their means, extracted the square roots of numbers, but went no farther. The nature of the cube next presented itself, which consists of the coefficients, 1, 3, 3, 1; and, by means of these, they extracted the cube roots of numbers, in the same way as is practised at present. And this was the extent of their extractions, in the time of Lucas de Burgo, who, from 1470 to 1500, wrote several tracts on arithmetic, containing the substance of what was then known of this science.

It was not long, however, before the nature of the coefficients of all the higher powers became known, and tables formed for constructing them indefinitely. For, in the year 1543, Michael Stifelius, a German, published an excellent work on arithmetic and algebra, under the title of *Arithmetica Integra*, in which he gives the following table, for constructing both figurate numbers and the coefficients of the terms of the various powers of a binomial, which, since his time, has been often used for these and other purposes; and, more than a century after, was, by Pascal, otherwise called the arithmetical triangle, and of which he has commonly been called the inventor, though he only mentioned some of its additional properties.

17	136	680	2380	6188	12376	19448	24310	24310

In this table Stifelius observes, that the horizontal lines furnish the coefficients of the terms of the correspondent powers of a binomial; and teaches how to use them in extracting the roots of all powers whatever. The same table was also used, for a similar purpose, by Cardan, Stevin, and other writers on arithmetic; and it is highly probable that it was known much earlier than the time of Stifelius, at least as far as regards the progressions of figurate numbers, which had been amply treated of by Nicomachus, who lived, according to some, before Euclid, but not till long after him, according to others; and whose work on arithmetic was published at Paris in 1538, and is supposed to have been chiefly copied in the treatise on the same subject by Boethius.

The contemplation of this table has also, probably, been attended with the invention and extension of some of our most curious discoveries in mathematics, both with respect to the powers of a binomial, the consequent extraction of roots, the doctrine of angular sections by Vieta, and the differential method of Briggs, and others. For a few of the powers or sections being once known, the table would be of the greatest use in discovering and constructing the rest; and accordingly it appears to have been used, on many occasions of this kind, by Stifelius, Cardan, Stevin, Vieta, Briggs, Oughtred, Mercator, Pascal, &c.

But although the nature and construction of this table were thus early known, and employed in raising powers and extracting roots, it was yet only by raising the numbers from one another, by continual additions, and taking them from the table, for use, when wanted; till Briggs first pointed out the way of raising any horizontal line in the table, by itself, without any of the preceding lines; and thus teaching to raise the terms of any integral powers of a binomial, independently of any other powers; which was, in fact, giving the substance of the binomial theorem in words, but wanting the notation in symbols.

It may, however, be fairly questioned, whether Briggs knew how, even in the case of an integral exponent, to exhibit the law of the formation of the coefficients, under the form $\frac{m(m-1).(m-2)....(m-n+1)}{1.2.3....n}$; for, though his method of forming the successive coefficients amounts to nearly

nearly the same thing, yet the advancement in analysis depended on the circumstance of the law which they observe, being expressed by means of a general symbol (m); without which, its extension would never have been made to those cases in which the index is negative or fractional: so that Briggs, even in the case of integral powers, does not appear to be fully entitled to the invention of the binomial theorem, properly so called.

But however this may be, it is universally agreed that no one before Newton had ever thought of extracting roots by means of infinite series. He was the first who happily discovered, that, by considering roots as powers having fractional exponents, the same binomial series would equally serve for them all, whether the index should be fractional or integral, or the series finite or infinite; and from this extension of the theorem, some of the most important improvements, in the higher departments of mathematics, have arisen; particularly in the construction of logarithms, and the doctrine of series in general, which have since been carried to a great degree of perfection, and now form some of the most curious and interesting branches of analytics.

It may also be farther observed, with respect to the claim of Newton as an original inventor of this highly useful theorem, that he had probably never seen the *Arithmetica Logarithmica* of Briggs; for it is well known that he was not an extensive reader of mathematical works, depending more on the powers of his own genius than upon any helps of this kind: so that there can be but little doubt of his having made the discovery himself, without receiving any light from what had been done by Briggs; and that he conceived the theorem to be new for all powers in general, as it was for roots and quantities with fractional indices.

But though this appears to be the case with respect to Newton, it is yet surprising that Dr. Wallis, who was a general reader of most mathematical works, and who had actually seen Briggs's *Arithmetica Logarithmica*, as he mentions it in page 60. chap. xii. of his Algebra, should not have attended enough to this curious treatise, to know that it contained such a new and excellent theorem, as it fully appears he did not; since, in the 85th chapter of the above-mentioned work, he ascribes the invention entirely to Newton; and adds, that he himself had sought after such a rule, but without success. It is also no less singular, that John Bernoulli, not half a century since, should first dispute the invention of this theorem with Newton, and afterwards give the discovery of it to Pascal, who was not born till long after it had been taught by Briggs. (See Bernoulli's works, vol. iv. p. 173).

Dr. Wallis's Algebra was published in the year 1685; and it was here, for the first time after Newton's discovery of it, that the binomial theorem, according to his general manner of expressing it, appeared in print, and was made known to the learned world; though Leibnitz, and probably Dr. Barrow (who was Newton's great friend and patron in his youth), as well as some other mathematicians of that time, had seen it, in a letter addressed to Mr. Oldenburgh, of October 24th 1676, (which was given in the *Commercium Epistolicum*), soon after the said letter was written. But he no where tells us his manner of investigating it; nor is any demonstration of it to be found, even in the case where the index is a whole number, in any part of his works. He says, indeed, in his next letter to Oldenburgh, to be found in the same work, that the occasion of its discovery was as follows:

"Not long (he observes) after I had ventured upon the study of the mathematics, whilst I was perusing the works of the celebrated Dr. Wallis, and considering the series of universal roots, by the interpolation of which we exhibit the area of the circle and hyperbola: for instance, in this series of curves, whose common base or axis is x, and the respective ordinates $\overline{1-x^2}^{\frac{0}{2}}$, $\overline{1-x^2}^{\frac{1}{2}}$, $\overline{1-x^2}^{\frac{2}{2}}$, $\overline{1-x^2}^{\frac{3}{2}}$, $\overline{1-x^2}^{\frac{4}{2}}$, $\overline{1-x^2}^{\frac{5}{2}}$, &c. I observed that if the areas of the alternate curves, which are x, $x-\frac{1}{3}x^3$, $x-\frac{2}{3}x^3+\frac{1}{5}x^5$, $x-\frac{3}{3}x^3+\frac{3}{5}x^5-\frac{1}{7}x^7$, &c. could be interpolated, we should by this means, obtain the areas of the intermediate ones, the first of which $\overline{1-x^2}^{\frac{1}{2}}$ is the area of the circle. In order to this it was evident, that in each of these series the first term was x, and that the second terms $\frac{0}{3}x^3$, $\frac{1}{3}x^3$, $\frac{2}{3}x^3$, $\frac{3}{3}x^3$, &c. were in arithmetical progression; and consequently the first three terms of the series to be interpolated must be $x-\frac{1}{3}\left(\frac{1}{2}x^3\right)$, $x-\frac{1}{3}\left(\frac{3}{2}x^3\right)$, $x-\frac{1}{3}\left(\frac{5}{2}x^3\right)$, &c.

"Now, for the interpolation of the rest, I considered that the denominators 1, 3, 5, 7, &c. were, in all of them, in arithmetical progression; and consequently the whole difficulty consisted in discovering the numeral co-efficients: but these, in the alternate areas which are given, I observed were the same with the figures of which the several ascending powers of the number 11 consist, viz. 11^0, 11^1, 11^2, 11^3, 11^4, &c. that is, the first, 1; the second, 1, 1; the third, 1, 2, 1; the fourth, 1, 3, 3, 1; the fifth, 1, 4, 6, 4, 1, &c.

"I applied myself, therefore, to discover a method by which the first two figures of this series might be derived from the rest; and I found, that if for the second figure, or numeral term, I put m, the rest of the terms would be produced by the continual multiplication of the terms of this series, $\frac{m-0}{1}\times\frac{m-1}{2}\times\frac{m-2}{2}\times\frac{m-3}{4}\times\frac{m-4}{5}$, &c.

"For instance, if the second term be put for 4, there will arise $4\times\frac{m-1}{2}$, that is 6, which is the third term; the fourth term will be $6\times\frac{m-2}{3}$, that is 4; the fifth term will be $4\times\frac{m-3}{4}$, that is 1; and the sixth term will be $4\times\frac{m-4}{5}$, that is 0, which shews the series is here terminated, in this case.

"This being found, I applied it, as a rule, to interpolate the above-mentioned series. And since, in the series which expresses the circle, the second term was found to be $\frac{1}{3}\left(\frac{1}{2}x^3\right)$, I therefore put $m=\frac{1}{2}$, and there was produced the terms $\frac{1}{2}\times\frac{1}{2}\left(\frac{1}{2}-1\right)$ or $-\frac{1}{8}$; $-\frac{1}{8}\times\frac{1}{3}\left(\frac{1}{2}-2\right)$ or $+\frac{1}{16}$; $\frac{1}{16}\times\frac{1}{4}\left(\frac{1}{2}-3\right)$ or $-\frac{5}{128}$, and so on *ad infinitum*. Hence I found that the area of the segment of the circle sought is $x-\frac{1}{2}\left(\frac{1}{3}x^3\right)-\frac{1}{8}\left(\frac{1}{5}x^5\right)-\frac{1}{16}\left(\frac{1}{7}x^7\right)-\frac{5}{128}\left(\frac{1}{9}x^9\right)$ &c.

"In the same manner, the areas to be interpolated of the other curves might be produced; as also the area of the

hyperbola, and the reſt of the alternate curves in the ſeries $\overline{1+x}^{0}$, $\overline{1+x}^{\frac{1}{2}}$, $\overline{1+x}^{\frac{2}{2}}$, $\overline{1+x}^{\frac{3}{2}}$, &c.; and in a ſimilar way might other ſeries be likewiſe interpolated, and that even if they ſhould be taken at two or more intervals.

"This was the way by which I firſt opened an entrance into theſe ſpeculations, which I ſhould not have remembered, but that, in turning over my papers, a few weeks ago, I, by chance, caſt my eyes upon thoſe relating to this matter.

"After I had proceeded ſo far, it immediately occurred to me that the terms $\overline{1-x^2}^{0}$, $\overline{1-x^2}^{\frac{1}{2}}$, $\overline{1-x^2}^{\frac{2}{2}}$, $\overline{1-x^2}^{\frac{3}{2}}$, &c. that is, 1, $1-x^2$, $1-2x^2+x^4$, $1-3x^2+3x^4-x^6$, &c. might be interpolated in the ſame manner as I had done in the caſe of the areas generated by them: and for this, there required nothing more than to leave out the denominators, 1, 3, 5, 7, &c. in the terms that expreſs the areas; then the coefficients of the terms to be interpolated ($\overline{1-x^2}^{\frac{1}{2}}$, $\overline{1-x^2}^{\frac{3}{2}}$, or univerſally $\overline{1-x^2}^{\frac{m}{2}}$) will be had by the continual multiplication of the terms of the ſeries $m \times \frac{m-1}{2} \times \frac{m-2}{3} \times \frac{m-3}{4}$ &c.

"Thus, for example, $\overline{1-x^2}^{\frac{1}{2}} = 1-\frac{1}{2}x^2-\frac{1}{8}x^4-\frac{1}{16}x^6$ &c.; and $\overline{1-x^2}^{\frac{3}{2}} = 1-\frac{3}{2}x^2-\frac{3}{8}x^4-\frac{3}{16}x^6$ &c.; and $\overline{1-x^2}^{\frac{1}{3}} = 1-\frac{1}{3}x^2-\frac{1}{9}x^4-\frac{5}{81}x^6$ &c.

"Thus, I diſcovered a general method of reducing radical quantities into infinite ſeries, by the binomial theorem, which I ſent in my laſt letter, before I obſerved that the ſame thing might be obtained by the extraction of roots.

"But after I had diſcovered this method, the other way could not long remain unknown; for, in order to prove the truth of theſe operations, I multiplied $1-\frac{1}{2}x^2-\frac{1}{8}x^4-\frac{1}{16}x^6$ &c. by itſelf, and found the product to be $1-x^2$, all the terms after theſe *ad infinitum* vaniſhing: in like manner $1-\frac{2}{3}x^2-\frac{1}{9}x^4-\frac{5}{81}x^6$ &c. being twice multiplied into itſelf, produced $1-x^2$. And as this was a certain proof of the truth of theſe concluſions, I was thereby naturally led to try the converſe of it, viz. whether theſe ſeries, that were now known to be the roots of the quantity $1-x^2$, might not be produced by the rule for extraction of roots in arithmetic; and, upon trial, I found it ſucceed to my wiſhes.

"This being found, I laid aſide the method of interpolation, and aſſumed theſe operations, as a more genuine foundation to proceed upon. In the mean time, I was not ignorant of the way of reduction by diviſion, which was ſo much eaſier."

From this account, as given by Newton himſelf, it appears that his diſcovery of the law for the areas, with irrational ordinates, preceded that of the law for the expanſion of thoſe ordinates; although the latter, as Montucla obſerves, might have been expected to precede the former, if inventive genius always purſued the moſt eaſy method. But, in tracing the progreſs of the human mind, it may generally be obſerved, that a collection of diſcoveries, in any branch of ſcience, is ſeldom found to be a ſeries of regular deductions; but, on the contrary, we often diſcern therein many anticipations, and ſometimes even a reverſion of the natural and logical order of ideas.

It is worth while here to remark, that Newton had made theſe diſcoveries, as well as many others, ſeveral years before Mercator had publiſhed his "Logarithmotechnia," which contains a particular caſe of this theory; but, from an exceſs of modeſty and indifference for theſe fruits of his genius, he delayed making them known to the world: and, even after the above-mentioned work had appeared, which would have operated as a powerful motive with moſt other men, in exciting them to ſhare in the glory of theſe brilliant inventions, he was ſtill more confirmed in the reſolution he had taken, of not making himſelf known as an author till he was of a more mature age. He conceived, that Mercator having diſcovered, as it was ſaid, the ſeries for the hyperbola, would not be long before he extended his method to the circle, and other curves; or, if this ſhould not be done by him, the invention would be readily perceived by others. In ſhort, it appears rather ſingular, that as Mercator had converted the expreſſion $\frac{1}{1+x}$ into an infinite ſeries, by the ordinary method of diviſion, he ſhould not have tried to diſcover the ſeries for $\sqrt{1\pm x^2}$ by the known method of extracting the ſquare root; but this, though extremely obvious, eſcaped his notice: and many circumſtances, of a ſimilar kind, are to be found in the hiſtory of the ſciences.

Newton, as has been already obſerved, left no demonſtration of this theorem; but appears to have formed it merely from an induction of particular caſes; and though no doubt can be entertained of its truth, having been found to ſucceed in all the inſtances in which it has been applied; yet, agreeably to the rigour that ought to be obſerved in the eſtabliſhment of every mathematical theory, and eſpecially in a fundamental theorem of ſuch general uſe and application, it is neceſſary that as regular and ſtrict a proof ſhould be given of it as the nature of the ſubject, and the ſtate of analyſis, can afford.

One of the firſt demonſtrations of this kind that appears to have been given, is that of James Bernoulli, which is to be found, among ſeveral other curious things, in a ſmall treatiſe of his, entitled "Ars Conjectandi," which has been very improperly omitted in the collection of his works, publiſhed by his nephew, Nicholas Bernoulli. But this is only applied to the caſe of integral and affirmative powers, and is nearly the ſame with that which was afterwards given by Mr. John Stewart, in his commentary on ſir Iſaac Newton's quadrature of curves. It is founded on the doctrine of combinations, and the properties of figurate numbers, which are there ſhewn to involve in them the generation of theſe coefficients; and in the inſtance before mentioned, where the index of the binomial is a whole poſitive number, it is clearly and ſatisfactorily explained.

Since that time, many attempts have been made to demonſtrate the general caſe, or that where the index of the binomial is either a whole number or a fraction, poſitive or negative; but moſt of theſe demonſtrations having been conducted, either by the method of increments, the multinomial theorem of De Moivre, or by fluxions, are commonly thought to be unſatisfactory and imperfect; and it ſhould ſeem not without reaſon; as, independently of other objections, it appears contrary to the principles of ſcience, as well as to juſt reaſoning, to employ, in a matter purely algebraical, notions and doctrines derived from other branches, or from an analyſis which is in ſome ſort tranſcendental.

For theſe reaſons, ſeveral eminent mathematicians have endeavoured to inveſtigate this formula on pure analytical principles,

ciples, in a more natural and obvious way; one of the firſt of theſe attempts being that of Landen, in his "Diſcourſe concerning the reſidual analyſis," and the next that of Epinus, in the eighth volume of the "New Peterſburg Memoirs." But the legitimacy of the former may be objected to, as depending upon vaniſhing fractions, and other conſiderations of too difficult and abſtract a nature to be regarded as ſufficiently convincing; and the latter, though very ingenious, is not leſs difficult and embarraſſing; at leaſt, ſuch is the opinion of Euler, who having himſelf firſt given a demonſtration of this theorem, in which, like Maclaurin, he employed the differential calculus, or method of fluxions, was afterwards led to deduce it from the principles of algebra alone; though he does not appear to have been much more ſucceſsful than either of the former.

S. Lhuilier of Geneva, perceiving the defects and obſcurity of theſe methods, has made a new demonſtration of this formula in one of the preliminary articles of his excellent work, entitled, "Principiorum calculi differentialis et integralis, &c." which is purely elementary; and abating from its length, and a fatiguing detail of particulars, which the nature of the ſubject does not ſeem to require, he appears to have accompliſhed his object; at leaſt as far as the method he adopted would allow; for it muſt be confeſſed, that neither this, nor any other inveſtigation, that had hitherto appeared, have been attended with the ſimplicity and ſtrictneſs which could be deſired.

The reaſon of this, as Dr. Woodhouſe properly obſerves, in his "Principles of Analytical Calculation," ſeems to be, that moſt mathematicians appear to have ſought for ſome high origin of this theorem, diſtinct from the ſimple operations of multiplication, diviſion, extracting of roots, &c.: and inſtead of conſidering the nature of the operations it was known to comprehend, hoped to ſuperſede them by deductions drawn from abſtruſe and fine theories; whereas, it is clear, that whatever imperfections theſe fundamental operations are attended with, are alſo attached to the binomial theorem, which, in a certain ſenſe, may be ſaid to be a method of trial and conjecture. For, as this formula is only meant to expreſs, in general terms, the algebraical rules above mentioned, it cannot poſſeſs a greater degree of certainty than is poſſeſſed by the ſimple operations themſelves.

To avoid entering into a too prolix inveſtigation of the well known and ſimple elements upon which the general formula depends, it is ſufficient to obſerve that it is clearly manifeſt from ſome of the firſt and moſt common rules of algebra, that whatever is the operation which the index (m) in $\overline{a+x}^m$ directs to be performed upon the binomial $a+x$, whether of continued multiplication, or elevation, or of diviſion, or of extraction of roots, the terms of the reſulting ſeries will neceſſarily ariſe by regular and whole poſitive powers of x; and that the two firſt terms of this ſeries will always be $a^m + ma^{m-1}x$; ſo that the entire expanſion of it may be repreſented under the form $a^m + ma^{m-1}x + px^2 + qx^3 + rx^4$, &c.

For, omitting the practical part of the proceſs, which is taught by the above mentioned rules, it will conſtantly be found, by performing the operations at length in the uſual way, that

$$\overline{a\pm x}^2 = a^2 \pm 2ax + x^2$$
$$\overline{a\pm x}^3 = a^3 \pm 3a^2x + 3a^2x^2 \pm x^3$$
$$\overline{a\pm x}^4 = a^4 \pm 4a^3x + 6a^2x^2 \pm 4ax^3 + x^4$$
&c. &c.

$$\frac{1}{\overline{a\pm x}} = a^{-1} \mp a^{-2}x + a^{-3}x^2 \mp a^{-4}x^3, \text{ &c.}$$

$$\frac{1}{\overline{a\pm x}^2} = a^{-2} \mp 2a^{-3}x + 3a^{-4}x^2 \mp 4a^{-5}x^3, \text{ &c.}$$

$$\frac{1}{\overline{a\pm x}^3} = a^{-3} \pm 3a^{-4}x + 6a^{-5}x^2 \pm 10a^{-6}x^3, \text{ &c.}$$
&c. &c.

$$\overline{a\pm x}^{\frac{1}{2}} = a^{\frac{1}{2}} \pm \frac{1}{2}a^{-\frac{1}{2}}x - \frac{1}{8}a^{-\frac{3}{2}}x^2 \pm \frac{1}{16}a^{-\frac{5}{2}}x^3 \text{ &c.}$$

$$\overline{a\pm x}^{\frac{1}{3}} = a^{\frac{1}{3}} \pm \frac{1}{3}a^{-\frac{2}{3}}x - \frac{1}{9}a^{-\frac{5}{3}}x^2 \pm \frac{5}{81}a^{-\frac{8}{3}}x^3, \text{ &c.}$$

$$\overline{a\pm x}^{\frac{2}{3}} = a^{\frac{2}{3}} \pm \frac{2}{3}a^{-\frac{1}{3}}x - \frac{1}{9}a^{-\frac{4}{3}}x^2 \pm \frac{2}{81}a^{-\frac{7}{3}}x^3, \text{ &c.}$$
&c. &c.

$$\frac{1}{\overline{a\pm x}^{\frac{1}{3}}} = a^{-\frac{1}{3}} \pm \frac{1}{3}a^{-\frac{4}{3}}x + \frac{2}{9}a^{-\frac{7}{3}}x^2 \pm \frac{7}{81}a^{-\frac{10}{3}}x^3 \text{ &c.}$$

$$\frac{1}{\overline{a\pm x}^{\frac{2}{3}}} = a^{-\frac{2}{3}} \pm \frac{2}{3}a^{-\frac{5}{3}}x + \frac{5}{9}a^{-\frac{8}{3}}x^2 \mp \frac{20}{81}a^{-\frac{11}{3}}x^3, \text{ &c.}$$
&c. &c.

In all the inſtances here given, it is apparent, that the firſt term of the ſeries, in each of them, is the ſame as the power or root of the firſt term of the binomial quantity to which it belongs; and that the coefficient of x in the ſecond term is always had by multiplying the index of the firſt term into that term, having its index diminiſhed by 1; and as theſe caſes are of the ſame kind with thoſe that are deſigned to be expreſſed, in univerſal terms, by the general formula, it is in vain, as far as regards the two firſt terms of the expanſion, to look for any other origin of them, than what may be derived from theſe and ſimilar operations.

Aſſuming, therefore, $\overline{a+x}^m = a^m + ma^{m-1}x + px^2 + qx^3 + rx^4$, &c. it only remains to determine the value of the coefficients p, q, r, &c. and to ſhew the law of their dependence on the index (m) of the operation by which they are produced.

For this purpoſe, let m denote any number whatever, integral or fractional, poſitive, or negative; and let the coefficients of the 3d, 4th, 5th, &c. terms of the mth power of any binomial be denoted by p', q', r', &c.

Then for x, in the above form, put $y+z$, and there will ariſe $\overline{a+y+z}^m = \overline{\overline{a+y}+z}^m = \overline{a+\overline{y+z}}^m$; which are all identical expreſſions; and when expanded according to the proper forms, muſt be equal to each other.

But $\overline{a+y+z}^m = a^m + ma^{m-1}(y+z) + p(y^2+2yz, \text{&c.}) + q(y^3+3y^2z, \text{&c.})$ &c. (omitting to ſet down the higher powers of z, which are not wanted in the demonſtration) $= a^m + ma^{m-1}y + py^2 + qy^3$ &c. $+ ma^{m-1}z + 2pyz + 3qy^2z$, &c.

And $\overline{a+y+z}^m = \overline{a+y}^m + m.\overline{a+y}^{m-1}z$, &c. $= \overline{a+y}^m + mz(a^{m-1} + m-1.a^{m-2}y + p'y^2 + q'y^3, \text{&c.}) = a^m + ma^{m-1}y + py^2 + qy^3$, &c. $+ ma^{m-1}z + m.m-1.a^{m-2}yz + mp'y^2z + mq'y^3z$, &c. Hence the two ſeries being identical, $a^m + ma^{m-1}y + py^2 + qy^3$ &c. $+ ma^{m-1}z + 2pyz + 3qy^2z$, &c. $= a^m + ma^{m-1}y + py^2 + qy^3$ &c. $+ ma^{m-1}z + m.m-1.a^{m-2}yz + mp'y^2z + mq'y^3z$, &c. or, leaving out the terms common to each, $2pyz + 3qy^2z$ &c. $= m.m-1.a^{m-2}yz + mp'y^2z$, &c.

And ſince the coefficients of the terms involving the ſame powers of the arbitrary quantities y and z muſt be the ſame, we ſhall have $2p = m.m-1.a^{m-2}$, or $p = \frac{m.m-1}{2}a^{m-2}$; and hence $p' = \frac{m-1.m-2}{2}a^{m-3}$. Alſo $3q = mp' = \overline{m.m-1.}$

$\frac{m.\overline{m-1}.\overline{m-2}}{2}a^{m-3}$, or $q = \frac{m.\overline{m-1}.\overline{m-2}}{2.3}a^{m-3}$; and so on.

From which it follows, that $\overline{a+x}|^m = a^m + m.a^{m-1}x + \frac{m.\overline{m-1}}{2}a^{m-2}x^2 + \frac{m.\overline{m-1}.\overline{m-2}}{2.3}a^{m-3}x^3$ &c. universally, whatever may be the value of *m*, whether integral or fractional, positive or negative, as was to be shewn.

The demonstration here given (which is similar to that in vol. ii. of Manning's Algebra) is founded upon the principles first laid down by la Grange, in his "Theorie des Fonctions Analytiques;" to which admirable work the reader is referred for farther information on this subject, as well as for whatever regards the doctrine of expanded functions in general, which is there treated of in a way worthy the genius of the author.

BINOMIUS, from *bis* and *nomen*, *name*, in *Middle Age Writers*, denotes a person with two names.

Most Christians anciently were called binomii, as having had other names in their heathen state, which they changed at their conversion. Besides, it was an ancient custom for parents to give names to their children immediately after they were born, and sometimes other different ones afterwards at their baptism; one of which frequently became a *cognomen*, or furname. In reality, it was a constant practice to assume a new name at baptism, as the religious still do in the Romish church, on their reception into the monastic state; or the Jewish proselytes at their circumcision.

BINOTATA, in *Entomology*, a species of Chrysomela, found in Denmark. This is testaceous, with the wing-cases ferruginous at the base. Gmelin.

Binotata, a species of Cicada (*Membracis Foliacea*). This insect inhabits New Holland; the thorax is slightly armed, and produced behind; abdomen short and testaceous; with a black spot at the base of the wing-cases. Fabricius, &c.

BINOTATUS, an European species of Carabus, of a black colour, with two red spots in front of the head, and the antennæ yellow at the base. Fabricius.

Binotatus, a species of Cimex (*Reduvius*), found in Surinam. It is black above, with a rufous dot at the apex of each of the wing-cases. Fabricius.

BINTAM. in *Geography*, one of the chief towns of the kingdom of Yohor or Jor. See Malacca.

BINTAN, one of the small islands at the south end of the straits of Malacca, and nearly north from Lingan island.

BINTHA, in *Ancient Geography*, a town of Libya interior, near the Niger, according to Ptolemy.—Also, a place in Asia, in Osrhoene, according to the Notitia Imperii.

BINTSCHAY, in *Geography*, a town of Bohemia, in the circle of Boleslaw, 7 miles north-east of Turnau.

BINWY Head, a cape of Ireland, on the north-west coast of the county of Mayo. N. lat. 54° 20'. W. long. 9° 36'.

BIOBIO, or Vinvio, a river of Chili, in South America. Its source is among the silver mines, in the mountains called *Sierra bel'uda*; it receives the streams of the Huequen and Tolpan, before it reaches Santa Fee, where it first becomes navigable, and from whence, to its mouth, for the distance of 33 leagues, its course is nearly from east to west.

The new city of Mocha, peopled by inhabitants who removed from Conception twelve years ago, is situated on its north bank, about twelve miles from the sea, and is a depot for the silver from the mines of Nimino, and for the gold with which its sands abound.

The mouth of this river is in S. lat. 36° 45', W. long. 73° 28'; and its entrance known by two remarkable hills, called the Teats of Biobio, which are situated at the north, betwixt it and the bay of Conception, and serve to both as land-marks for navigators.

The river is about one mile across at the mouth, has good depth of water in the middle, and the tide rises about seven feet and a half at the full and change of the moon.

BIOCOLYTÆ, in the *Byzantine Empire*, an order of officers appointed to prevent the violences frequently committed by the soldiers. The word is compounded of βιος, *vis*, *violence*, and κωλυω, *I hinder*; and should rather be written *biscolytæ*.

The biocolytæ appear to have been much the same with the French archers of the Marshalsea. They were suppressed by the emperor Justinian.

BIOCULATA, in *Entomology*, a species of Ephemera, described by Geoffroy, Linnæus, &c. The wings are white, reticulated; on the head two yellow tubercles. Fabr. Inhabits wet places in Europe. The tail of this kind is furnished with two bristles as long as the body.

Bioculata, in *Natural History*, a species of Hirudo, of an elongated form and cinereous colour, with two eyes. Gmel. Müll. This is *hirudo stagnalis* of Linnæus. Fn. Suec. &c. Found in wet hollows and rivulets very common. Length of this creature is nine lines. The female bears about forty eggs at a time, which are surrounded by a pellucid circle; at first these are cinereous, afterwards brown; and the young, after exclusion, adhere by their tails to the belly of the female. Gmel.

Bioculatus, in *Entomology*, a species of Cryptocephalus (*Crioceris*), found at the cape of Good Hope. It is testaceous; thorax immaculate; on the wing-cases two ocellar white spots. Fabricius.

BIOCZ, in *Geography*, a town of Poland, in the palatinate of Cracow, north of the Carpathian mountains. N. lat. 49° 48'. E. long. 21° 40'.

BIOEA, in *Ancient Geography*, a sea-port in the southern part of the island of Sardinia, according to Ptolemy.

BIOGLIO, in *Geography*, a town of Italy, in the lordship of Vercelli, 23 miles N.W. of Vercelli.

BIOGRAPHER, formed from the Greek βιος, *life*, and γραφω, *I describe*, an author who writes a history, or life, of one or more persons. Such were Plutarch, Corn. Nepos, &c.

BIOGRAPHY, the art of describing or writing lives, is a branch or species of history more entertaining, as well as more useful in many respects, than general history, as it represents great men more distinctly, unincumbered with a crowd of other actors, and descending into the detail of their actions and character, their virtues and failings, gives more light into human nature, and leads to a more intimate acquaintance with particular persons than general history allows. A writer of lives may descend, with propriety, to minute circumstances and familiar incidents. From him it is expected to give the private as well as the public life of those whose actions he records; and it is from private life, from familiar, domestic, and seemingly trivial occurrences, that we often derive the most accurate knowledge of the real character. The subjects of biography are not only the lives of public or private persons, who have been eminent and beneficial to the world in their respective stations, but those also of persons notorious for their vice and profligacy; which may serve, when justly characterized, as warnings to others, by exhibiting the fatal consequences which, sooner or later, generally follow licentious practices. As for those, who exposed their lives, or otherwise employed their time and labours for the service

ſervice of their fellow-creatures, it ſeems but a juſt debt, that their memories ſhould be perpetuated after them, and that poſterity ſhould be made acquainted with their benefactors. This was no ſmall incentive to virtue in the pagan world; and no one can be ignorant, on due reflection, how natural this paſſion is to mankind in general. For this reaſon, as Dr. Ward preſumes (Orat. vol. ii. p. 252.), Virgil has placed not only his heroes, but alſo the inventors of uſeful arts and ſciences, and other perſons of diſtinguiſhed merit, in the Elyſian fields, where he deſcribes them (Æn. l. vi. v. 661.):

"Here patriots live, who, for their country's good,
In fighting fields were prodigal of blood;
Prieſts of unblemiſhed lives here make abode,
And poets worthy their inſpiring god;
And ſearching wits of more mechanic parts,
Who grac'd their age with new invented arts;
Thoſe who to worth their bounty did extend,
And thoſe who knew that bounty to commend:
The heads of theſe with holy fillets bound,
And all their temples were with garlands crown'd."

In the lives of public perſons, their public characters are principally, but not ſolely, to be regarded. The world is inquiſitive to know the conduct of princes and other great men, as well in private as in public: and both may be of ſervice, conſidering the influence of their examples. But to be over-inquiſitive in ſearching into the weakneſſes and failings of the greateſt or beſt men, is, to ſay no more of it, a needleſs curioſity.

In this ſpecies of writing Plutarch has no inconſiderable merit; and to him we are indebted for much of the knowledge which we poſſeſs concerning ſeveral of the moſt eminent perſonages of antiquity. His matter, however, is better than his manner; as he cannot lay claim to any peculiar beauty or elegance. His judgment too, and his accuracy, have ſometimes been taxed; but whatever may be his defects of this kind, his lives of eminent men will always be conſidered as a valuable treaſure of inſtruction. He is remarkable for being one of the moſt humane writers of all antiquity; leſs dazzled than many of them are, with the exploits of valour and ambition; and fond of diſplaying his great men to us, in the more gentle lights of retirement and private life.

It has been a matter of diſpute among the learned, whether any one ought to write his own hiſtory. No one, it may be ſaid, can be ſo much maſter of the ſubject as the perſon himſelf; and beſides, there are many inſtances, both ancient and modern, to juſtify this practice. But, on the other hand, it muſt be owned, that it is attended with many inconveniences, ſome of which are mentioned by Cicero: "If," ſays he (Ad Famil. l. v. epiſt. 12.) "there is any thing commendable, perſons are obliged to ſpeak of themſelves with greater modeſty, and to omit what is blameable in others. Beſides, what is ſaid is not ſo ſoon credited, and has leſs authority; and after all, many will not heſitate in cenſuring it." To the ſame purpoſe it is well obſerved by Pliny (l. viii. ep. 1.): "Thoſe who proclaim their own virtues, are thought not ſo much to proclaim them, becauſe they did them, as to have done them, that they might proclaim them. Hence, what would appear great, if told by another, is loſt, when related by the party himſelf. For when men cannot deny the fact, they reflect upon the vanity of its author. Wherefore, if you do things not worth mentioning, the actions themſelves are blamed; and if the things you do are commendable, you are blamed for mentioning them." The juſtice of theſe reflections will be allowed; and yet, conſidering how natural it is for men to love themſelves, and to be inclined in their own favour, it ſeems to be a very difficult taſk for any one to write an impartial hiſtory of his own actions. There is ſcarcely any treatiſe of this kind that is more celebrated than Cæſar's "Commentaries;" and yet Suetonius tells us (In Vit. c. 56.), that "Aſinius Pollio, who lived at that time, thought that they were written neither with due care nor integrity; that Cæſar was too often credulous in his accounts of what was done by other perſons, and miſrepreſented his own actions, either deſignedly, or through forgetfulneſs; and therefore he ſuppoſes he would have reviſed and corrected them." At ſome times, however, it may without doubt be juſtifiable for a perſon to be his own hiſtorian. Plutarch mentions two caſes, in which it is allowable for a man to commend himſelf, and to be the publiſher of his own merits. Theſe are, "when the doing of it may be of conſiderable advantage, either to himſelf, or to others." "Anciently," ſays Tacitus (Vit. Agric. c. 1.), "many wrote their own lives, rather as a teſtimony of their conduct, than from pride;" remarking, "that the more virtue abounds, the ſooner the reports of it are credited." But the ancient writers had a method of diverting the reader's attention from themſelves, when they had occaſion to record their own actions, and of thus rendering what they ſaid leſs invidious, which was by ſpeaking of themſelves in the third perſon: thus Cæſar never ſays, "I did," or "I ſaid this or that," but always "Cæſar did," or "ſaid, ſo and ſo." Dr. Johnſon has given an excellent paper on the ſubject of biography in the collection of papers called the "Idler." Volney, in his "Lectures on Hiſtory," remarks, that biography is the only kind of hiſtory that is proper for young people. See HISTORY.

Dr. Prieſtley has conſtructed and publiſhed a "Biographical Chart," which is very uſeful to ſtudents in chronology, hiſtory, and biography. This chart, which is about three feet in length, and two feet in breadth, repreſents the interval of time between the year 1200 before the Chriſtian æra and 1800 after Chriſt, divided by an equal ſcale into centuries. It contains about 2000 names of perſons the moſt diſtinguiſhed in the annals of fame, the length of whoſe lives is here repreſented by lines drawn in proportion to their real duration, and terminated in ſuch a manner as to correſpond to the dates of their births and deaths in univerſal time. Theſe names are diſtinguiſhed into ſeveral claſſes by lines running the whole length of the chart, the contents of each diviſion being expreſſed at the end of it. The chronology is noted in the margin on the upper ſide, by the year before and after Chriſt, and on the lower by the ſame æra, and alſo by the ſucceſſion of ſuch kings as were the moſt diſtinguiſhed in the whole period.

BIOLLE, La, in *Geography*, the chief place of a canton, in the diſtrict of Chambery, and department of Mont Blanc. The population of the place is eſtimated at 1038, and of the canton at 5625 perſons; the territorial extent contains 92⅛ kiliometres, and 10 communes.

BIOLYCHNIUM, formed of βιος, *life*, and λυχνος, *light*, a name given by ſome phyſicians to a ſuppoſed principle of vitality inherent in the heart, or blood, and remaining there as long as life continues. Of this principle, or innate heat, different accounts have been given by different writers; as Gaſp. Hoffman, Conrigius, &c.

Beguinus has deſcribed a proceſs for preparing from human blood a vital balſam under this denomination; and J. Ern. Burgravius has written a treatiſe upon it.

BION, in *Biography*, a native of Proconneſus, was contemporary with Pherecydes, and flouriſhed about the 59th olympiad, or 544 years B. C. Clemens Alexandrinus informs us, that he copied the titles, and abridged the works

of Cadmus the Milesian, who is said to have been the first writer of history in prose, and to have lived before the Trojan war.

Bion, the *Philosopher*, was a native of Borysthenes, and flourished in the reign of Antigonus Gonatas, king of Macedon, and died about the last year of the 134th olympiad, or the 241st year B.C. He was a person of mean extraction, being the son of a Lacedæmonian harlot; and when young, was sold as a slave to an orator, who afterwards gave him his freedom, and left him large possessions. Thus endowed he went to Athens, and devoted himself to the study of philosophy. He was first the disciple of Crates, then of the Cynics, afterwards of Theodorus, and last of all of Theophrastus; but he adopted and maintained the opinions of Theodorus, called the atheist. He was skilled in geometry and music, and also in poetry and rhetoric; and went about from one city to another, displaying his talents. Several of his repartees, for which he was famous, are preserved; and Horace is supposed to allude to him in his

"Ille Bionæis sermonibus, et sale nigro." Epist. 2. lib. ii. To a great talker, who asked him a favour, he said, "If you would have me grant it, let some other person ask it for you." Being on board a ship belonging to pirates, which was chased by another, the pirates exclaimed, "We are undone, if they discover who we are;" "and I," says Bion, "if they discover who I am." He ridiculed the contradiction of burning the dead as if they were insensible, and lamenting them as if they were still sensible. Some of his jests were offensive to morals and decency; for to neither of these did he pay much regard. Notwithstanding his avowed irreligion, he recurred, when sick, to the practice of puerile superstitions, and submitted to death with great reluctance. Brucker's Hist. Phil. by Enfield, vol. i. p. 189. Gen. Dict. Laertius, lib. iv. tom. i. Ed. Meib. p. 253, &c.

Bion, a celebrated Bucolic poet, was a native of Smyrna, and a contemporary of Ptolemy Philadelphus, about 280 years B.C. In Sicily or Magna Græcia, where he is supposed to have spent the last part of his life, Moschus was his pupil; and from the beautiful elegy of this poet, we are led to infer, that he lost his life in prison, and that the perpetrators of this deed did not escape just punishment. As a poet he was highly esteemed; and his performances that are extant, though inconsiderable, serve as examples of the excellence to which the Greeks had attained in similar compositions. Nothing can be more sweet and tender than his "Elegy on the death of Adonis," nor any thing more elegantly ingenious than his "Cupid instructed." The works of Bion are usually printed with those of Moschus; and the best editions are those of Paris, in 1686; of Venice, in 1746; Heskin's, at Oxford, in 1748; Scheir's, at Leipsic, in 1752; and Wakefield's, Lond. 1795. Gen. Dict. Gen. Biog.

Bion, M. mathematical instrument maker to the French king, died at Paris, in 1733, at the age of 78 years, and is known to mathematicians as the author of two works; one, "On the construction and principal uses of mathematical instruments," translated into English with additions, by Mr. Edmund Stone;" and another, "On the use of the Globes;" the fifth edition of which was published at Paris, in 1728.

BIONCOURT, in *Geography*, a town of France, in the department of the Meurthe, and the chief place of a canton, in the district of Chateau-Salins, 2 leagues W.S.W. of Chateau-Salins.

BJÖRKNA, in *Ichthyology*, a species of Cyprinus, having thirty-five rays in the anal fin. Found in the lakes of Sweden. Linnæus. This is *Cyprinus quinquncialis*, pinna ani officulorum 25, of Artedi.

BIONDO, Flavio, (Lat. *Blondus*), in *Biography*, an antiquary and historian, and one of the first who illustrated the Roman antiquities, was born at Forli in 1388, and studied at Cremona. Being deputed in his youth on public business to Milan, he there made the first copy of Cicero's treatise on famous orators. At Rome he became secretary to pope Eugenius IV., and served the three succeeding popes in the same office. He was employed in various delegations to Venice, where he had an opportunity of cultivating an acquaintance and friendship with many learned persons in that republic. Debarred by his marriage from enjoying any church preferments, and devoted to study more than to the pursuit of wealth and honour, he preferred retirement to any public station, and prosecuted his literary labours till his death in 1463. His long residence at Rome enabled him accurately to describe its chief relics of antiquity in 3 books entitled "Roma instaurata;" which were followed by 10 books on the laws, government, customs, religion, &c. of the Romans, under the title of "De Roma triumphante." Another work, on its history, antiquities, and geography, was intitled "Italia illustrata." All these works display great reading and diligent research, though they are not free from many errors to which his ignorance of Greek literature must have contributed. Having undertaken to write a general history from the decline of the Roman empire to his own time, he finished three decads of it, and the first book of the fourth. He also wrote a book "De Origine et Gestis Venetorum," and had planned an entire history of the Venetian republic; but he afterwards chose to insert the substance of it in his general history. He left several other writings in MS., which it is needless to mention. His style wants purity and elegance, and his judgment in collecting materials was superior to his taste in using them. A collection of his works was published at Basil, in 1531, fol. Nouv. Dict. Hist. Gen. Biog.

BIORKO, in *Geography*, a town of Sweden, in the province of Upland.

BIORNEBORG, a town of Finland, on the east side of the gulf of Bothnia, seated on a lake, 80 miles north of Abo. N. lat. 62° 6′. E. long. 22° 35′.

BIORNSE, a small island of Denmark, near the south coast of the island of Funen.

BIÖRNSTAHL, James Jonas, in *Biography*, a learned Swedish traveller, was born at Rotarbo in 1731, and having finished his education in the university of Upsal, he became, in 1766, tutor to the son of baron Rudbec, with whom he travelled for eight years through France, Italy, part of Germany, Holland, and England. At Paris, where he improved himself in the oriental languages, he was elected, in 1770, a member of the academy of sciences, and upon the baron's return to Sweden, in 1775, Biörnstahl received orders from the king to travel at his expence through the Ottoman empire, Syria, Egypt, and the northern part of Africa, and in the same year he was appointed extraordinary professor of philosophy at Upsal. In the following year he commenced his travels; and having arrived at Constantinople, he continued there two years, improving himself in the eastern languages. In 1779, he was appointed professor of the oriental languages at Lund; but he died this year of a putrid fever at Salonichi. The result of his observations in the course of his travels was communicated in a series of letters to C. C. Giörwell, librarian to the king at Stockholm; and a complete collection of them appeared at Stockholm, in 1778, in three volumes, 8vo. under the title of "J. J. Biörnstahl's Bref rörande des utländska Resa til utgifvaren C. C. Giörwell." A German translation of this work was published at Stralsund and Rostock, in 1783, in six volumes, 8vo. The principal object of Biörnstahl's research was oriental MSS., from which he made many important and useful extracts. Gen. Biog.

BIOT, in *Geography*, a town of France, in the department of the Var, and chief place of a canton, in the diſtrict of Graſſe, 3 miles north of Antibes.

BIOTA, in *Zoology*, a name introduced by Dr. Hill for the Polype genus called *Hydra*, by Linnæus, as it is believed from the reproduction or repullulation of the parts when cut off; and this name *biota* is likewiſe given it on the ſame account, being derived from βιος, *life*. See Hydra.

BIOTHANATI, from βια, *violence*, and θανατος, *death*, in ſome *Medical Writers*, denote thoſe who die a violent death. The word is alſo written, and with more propriety, *biathanati*; ſometimes *biæothanati*.

In a more particular ſenſe, it denotes thoſe who kill themſelves, more properly called *autothanati*. See Suicide. In this ſenſe it is that the word is uſed both by Greek and Latin writers. By the ancient diſcipline of the church, they were puniſhed by denying them burial, and refuſing all commemoration of them in the prayers and offices of the church.

Biothanati, ſuppoſed by ſome to be derived from βιος, *life*, and θανατος, *death*, and alluding to the belief of a future life after death, was alſo a name of reproach given by the heathens to the primitive Chriſtians, for their conſtancy and forwardneſs to lay down their lives in martyrdom.

Biothanatos is alſo uſed in ſome writers of the barbarous age for wicked, damnable, or accurſed. Du-Cange.

BIOUAC, Bivouac, or Biovac, in the *Military Art*, a nightly guard performed by the whole army, when there is an apprehenſion of danger from the enemy. The word is formed by corruption from the German *weywacht*, a *double watch* or *guard*. See Guard.

BIOULLE, in *Geography*, a town of France, in the department of the Lot, and chief place of a canton, in the diſtrict of Montauban, 3 leagues N.E. of Montauban.

BIPARTIENT, in *Arithmetic*, is a number that divides another into two equal parts without a remainder. Thus 2 is a bipartient to 4, &c.

BIPARTITA, in *Entomology*, a ſpecies of Leptura, that inhabits Upper Auſtria. It is of a black colour; thorax ferruginous, with a longitudinal black line; a common ferruginous ſpot on the wing-caſes.

BIPARTITE Leaf, in *Botany*. See Leaf.

BIPARTITION, ſignifies a diviſion into two equal parts.

BIPED, in *Zoology*, an animal furniſhed with only two legs. Men and birds are bipeds. Apes occaſionally walk on their hind legs, and ſeem to be of this tribe, but that is not a natural poſition for them, and they reſt upon all their legs like other quadrupeds. The jerboas are alſo of the latter deſcription, jumping and leaping on their hind legs, but reſting on the fore legs likewiſe.

Plato, we are told, once defined a man to be a biped without feathers; and Diogenes, in order to ſhew what he deemed the abſurdity of this definition, plucked all the feathers off a cock, and placing it in the midſt of the Academic ſchool, exclaimed, "there is one of Plato's men!"

Biped, Bipède, Bipes, a genus of reptiles that belongs to the lizard family, in the ſyſtem of La Cepede. Theſe have, according to the character eſtabliſhed by that author, a very long body covered with ſcales; and the toes of the two little feet, which are placed anteriorly, are armed with nails. La Cepede deſcribes only one ſpecies of this genus, which he calls *le cannelle*; it is a native of Mexico, and preſerved in the muſeum at Paris. La Cepede, it appears, was the firſt writer who deſcribed this creature; but Dr. Shaw noticed it afterwards in the Naturaliſt's Miſcellany, under the name of *lacerta lumbricoides*, lumbricoid lizard, which ſee; and a ſpecimen of it, about half the ſize of that in the muſeum at Paris, is preſerved in the Britiſh muſeum. This muſt not be confounded with *lacerta bipes* of Linnæus. Pallas has deſcribed another kind of biped lizard, which is called *lacerta apus*, but in that the legs are very ſmall, monodactylous, and placed far behind: ſome have almoſt doubted whether theſe may not rather be part of the organs of generation than legs; and in general appearance the creature approaches rather to the ſnake than lizard tribe. It is a native of the ſouthern parts of Siberia, and alſo of Greece, and is of a ferruginous colour.

BIPENNIS, in *Roman Antiquity*, a two edged ax, uſed anciently by the Amazons in fight: as alſo by the ſeamen, to cut aſunder the ropes and cordage of the enemy's veſſels. The bipennis was a weapon chiefly of the oriental nations, made like a double ax, or two axes joined back to back, with a ſhort handle. Some compare it to a figure of a pen, and ſuppoſe it hence to have acquired the name *bipennis*; the tube or barrel of the pen repreſenting the handle, and the point or nib the head. Modern writers uſually compare it to our halbard, or partizan; from which it differed in that it had no point, and that its ſhaft or handle was much ſhorter. See Halbard.

BIPES, in *Zoology*, a ſpecies of Lacerta, with the body ſubequal, round, imbricated, and pale; on each ſcale a brown dot; no anterior feet; poſterior feet with two toes unarmed. Gmelin. *Anguis bipes*, with 100 abdominal, and 60 ſubcaudal plates. Linn. Muſ. Ad. Frid. A native of South America and India. Length about ſix inches; body cylindrical and ſlender; colour pale yellow. Biped Lizard.

Bipes, a ſpecies of Coluber, deſcribed by Gmelin on the authority of Scopoli, as an inhabitant of the Tyroleſe waters, where it is ſaid to feed on frogs and fiſhes; it has two feet, fulvous eyes, whitiſh under-jaw, elliptic, marginate, dorſal ſcales; ſides ſpotted with white; abdominal plates whitiſh, with a brown ſpot in the middle. Gmelin deſcribes it ſpecifically as having 116 plates on the belly, and 58 ſubcaudal ſcales.

BIPINNULA, in *Botany*. See Arethusa.

BIPLICATA, in *Conchology*, a ſpecies of Voluta, figured by Martini only. It is of a tapering ſhape, ſmooth, white ſpotted with yellow, and dotted with black; lip acute; pillar with two plaits.

BIPUNCTARIA, in *Entomology*, a ſpecies of Phalæna (*Geometra*), the anterior wings of which are cinereous, undulated with brown; a duſky band in the middle, and two black dots. Fabricius, &c.

BIPUNCTATA, a ſpecies of Apis, that inhabits Siberia. This inſect is hairy and black, with two yellow belts; the firſt with two lateral black dots. Lepechin. it. Gmel.

Bipunctata, a ſpecies of Aranea, with a black, globoſe abdomen, marked with two excavated dots. Linn. Fn. Suec.

Bipunctata, a ſpecies of Cantharis, with two black ſpots on the thorax; wing-caſes black at the tip. Fabricius. Inhabits Leipſic.

Bipunctata, a ſpecies of Cassida, of a yelloviſh colour, with two black dots on the wing-caſes. This is a native of India. Fabricius.

Bipunctata, a ſpecies of Chrysomela, deſcribed by Fabricius as a native of the cape of Good Hope. It is teſtaceous, with a brown ſpot on each of the wing-caſes.

Bipunctata, a ſpecies of Cicada, deſcribed by Linnæus. It is yellow, with two brown ſpots in front; wing-caſes white, veined with yellow. A native of Europe.

Bipunctata, is alſo a ſpecies of Cicada (*Deflexa*), found in South America. The colour is whitiſh; wing-caſes deflected, and griſeous, with two impreſſed dots on the anterior part of the margin of the thorax. Fabricius, &c.

Bipunctata, a ſpecies of Coccinella, of a red colour, with two black dots. Linn. Fn. Suec. &c.

Bipunctata, a ſpecies of Forficula, that inhabits Italy. This is black; hind part of the head and legs rufous; a white ſpot on the wing-caſes. Fabricius. It has eleven joints in the antennæ.

Bipunctata, a ſpecies of Leptura, of a black colour, and villous; wing-caſes livid; future, ſpot in the middle, and tip black. Inhabits Siberia.

Bipunctata, a ſpecies of Nitidula, of a teſtaceous colour, with five black ſpots. Gmelin.

Bipunctata, a ſpecies of Tenthredo, with ſomewhat ſetaceous antennæ, of nine joints; black; ſcutel black, and marked with two white dots. Inhabits the woods of Luface.

Bipunctata, a ſpecies of Vespa, with a ſpotted thorax; abdomen with four yellow bands, and two dots of the ſame colour on the firſt ſegment. Fabricius. Inhabits Germany.

BIPUNCTATUM, a ſpecies of Opatrum, of a brown colour, with ſomewhat cylindrical, immarginate thorax, with two hollows; two extreme joints of the antennæ diſtant and larger Herbſt. Gmel. &c.

BIPUNCTATUS, a ſpecies of Bruchus, that inhabits Helvetia. It is cinereous; wing-caſes brown with an ocellar, black dot at the baſe of each. Fabricius.

Bipunctatus, a ſpecies of Carabus, of a ſomewhat braſſy colour, with two impreſſed dots on the wing-caſes. Linn. Fn. Suec. This is deſcribed by Fabricius as being braſſy, with black antennæ, and pale ſhanks. This inhabits Europe.

Bipunctatus, a ſpecies of Cimex (*Rotundatus*,) of a pale griſeous colour, with a white dot on each ſide of the ſcutel near the baſe. Linnæus. Inhabits Syria.

Bipunctatus, a ſpecies of Cryptocephalus, of a gloſſy black; wing-caſes red with two black dots; antennæ length of the body. Fabricius. Gmelin, &c. *Chryſomela punctata.* Linn. Inhabits the northern parts of Europe; on the Nut.

Bipunctatus, a ſpecies of Curculio, found in Europe. This is cinereous, with a black ſpot on the wing-caſes; ſhanks yellowiſh. Linnæus. Fn. Suec.

Bipunctatus, is likewiſe a ſpecies of Curculio, with the thorax ſcabrous; wing-caſes clouded, with two gloſſy black ſpots near the apex. Lepech. it. A native of Siberia.

Bipunctatus, a ſpecies of Gryllus (*Acrida. Truxalis*,) of a browniſh colour; ſcutel as long as the abdomen. A native of Europe.

Bipunctatus, a ſpecies of Hemorobius, found in Europe. It is variegated with yellow and brown, and has two black ſpots on the wings. Fabricius.

Bipunctatus, a ſpecies of Ichneumon, found in Europe. This inſect is black; baſe of the antennæ brown; thighs at the baſe, and face yellow, with two black marks on the latter; abdomen, ſhanks, and tips of the poſterior feet ferruginous. Linn. Muſ. Leſk.

Bipunctatus, a ſpecies of Papilio (*Pleb. Urb.*). The wings are entire, brown; on both ſides of the firſt pair an oblique band, and two dots of ſilvery; at the baſe of the poſterior ones beneath a band and ſtriæ of yellowiſh.

Bipunctatus, a ſpecies of Scarabæus, having a black thorax, bordered with red; and red wing-caſes with a black ſpot on each. Lepech. it. Fabricius. This is the inſect which Pallas names *Scarabæus coccinelloides*; it is found in the ſouthern parts of Ruſſia under horſe-dung.

Bipunctatus, in *Ichthyology*, a ſpecies of Cyprinus, deſcribed by Bloch. The lateral line is red, with a double ſeries of black ſpots; and ſixteen rays in the anal fin. This kind is found in the ſandy rivers of Germany.

BIPUNCTELLA, in *Entomology*, a ſpecies of Phalæna (*Tinea*), wings cinereous brown, with a marginal white ſpot. Fabricius.

Bipunctella, a ſpecies of Phalæna (*Tinea*), with fuſcous wings, with a common dentated white ſtripe; thorax ſnowy-white with two black ſpots. Fabricius. This is *Tinea echiella* of Schmetterl.

BIPUSTULATA, a ſpecies of Cantharis (*Malachius*,) of a braſſy-green colour with the apex of the wing-caſes red. Linn. Fn. Suec. Geoffroy. This is *Thelephorus viridiæneus nitidus*, of Degeer. A very common inſect in moſt parts of Europe.

Bipuſtulata, a ſpecies of Caſſida, of a green colour; wing-caſes with two lateral ſanguineous ſpots. Inhabits Cayenne. Linn. Fabr. &c.

Bipuſtulata, a ſpecies of Chryſomela, deſcribed as a Swediſh inſect by Thunberg. The wing-caſes are black, ſpot at the tip, head and ſides of the thorax yellow.

Bipuſtulata, a ſpecies of Coccinella, of a black colour, with red ſpots, and ſanguineous abdomen. Linn. Fn. Suec.

Bipuſtulata, a ſpecies of Hiſpa, with ſerrated antennæ; black and hairy, with a rufous ſpot at the baſe of the wing-caſes. This kind inhabits Italy. Fabricius.

Bipuſtulata, a ſpecies of Leptura, that inhabits Upſal. The wing-caſes are black, ſtriated with dots, and two teſtaceous ſpots. Thunberg, &c.

Bipuſtulata, a ſpecies of Nitidula, of an ovate form, and black colour, with a red ſpot on each of the wing-caſes. Fabricius and Gmelin. This is *Silpha oblonga nigra*, &c. of Linn. Fn. Suec. and Syſt. Nat. *Silpha*, of Degeer; *Dermeſtes*, of Geoffroy; and *Oſtoma bipuſtulata*, of Laichart. Inhabits Europe, and feeds on carcaſes, meat, bacon, &c.

BIPUSTULATUM, a ſpecies of Opatrum, that inhabits Pomerania, and is about the ſixth part of an inch in length. Its form is narrow and elongated; colour ferruginous; wing-caſes ſlightly grooved.

BIPUSTULATUS, a ſpecies of Attelabus, met with in North America. It is black, with a rufous ſpot at the baſe of each of the wing-caſes. Fabricius.

Bipuſtulatus, an inſect of the genus Carabus, in Gmelin's edition of the *Syſtema naturæ*. This is the true *Carabus crux major* of Linnæus, which Fabricius miſconceiving, deſcribes as a new ſpecies, in his work entitled "Species Inſectorum," under the name of *Bipuſtulatus*. By retaining at the ſame time the Linnæan character of *Carabus crux major* under the proper name, he conſtitutes two ſpecies of the ſame inſect. In the *Entomologia ſyſtematica* of Fabricius, this error is continued, and Gmelin, reſting on the authority of this writer, deſcribes them alſo as diſtinct ſpeceis. See Crux major (*Carabus.*)

Bipuſtulatus, a ſpecies of Cimex, the general colour of which is black; thorax ſpinous; wing-caſes livid; and two ſcarlet dots on the head. Fabricius, Gmelin, &c. *Cimex balteatus* of Degeer. Inhabits South America.

Bipuſtulatus, a ſpecies of Cryptocephalus, deſcribed by Fabricius as being of a black colour, with a rufous ſpot at the tip of the wing-caſes. Obſ. The figure referred to in Schæffer *Vierzehender Fallkäfer*, is not black, but of a light

light or azure blue, rufous at the apex of the wing-cafes; and the antennæ of the fame colour. It is an European inſect, and inhabits the flowers of the chryſanthemum. Gmelin conſiders it as *Crytocephalus podæ* of Laichart.

Bipustulatus, a ſpecies of Dermestes, that is black and gloſſy, with the head, thorax, and ſpot at the baſe of the wing-cafes red. Thunberg. This is *Ips humeralis* of Fabricius. Country unknown.

Bipustulatus, a ſpecies of Dytiscus, deſcribed by Fabricius.. It is ſmooth and black, with two red ſpots on the poſterior part of the head. This inhabits the north of Europe.

Bipustulatus, a ſpecies of Dytiscus, that inhabits Germany. This kind is black; thorax yellow, with two black ſpots; wing-caſes yellow, varied with brown. Fabricius.

Bipustulatus, a ſmall ſpecies of Elater, found in woods in England and other parts of Europe; the colour is black and ſhining, with a red ſpot at the baſe of each of the wing-caſes. Linn. Marſh, &c. Obſ. By miſtake this inſect is thus deſcribed by Gmelin, *Niger nitidus, elytris puncto baſeos nigro*, with reference to the Fabrician Species Inſectorum, in which the dot at the baſe of the wing-caſes is ſaid to be red. This is *Elater punctatus* of Panzer; and *Le Taupin noir à taches rouges* of Geoffroy.

Bipustulatus, a ſpecies of Gryllus, in the ſection *locuſta*, of a pale brown colour; ſword at the extremity of the abdomen, and two ſpots on the thorax black; wing-caſes yellowiſh, teſſellated with black, and ſhorter than the wings. Gmelin, &c. This inſect is rather leſs than an inch in length according to Schaeffer's figure, excluſive of the antennæ, which are rather longer than the body. Inhabits Europe.

Bipustulatus, a ſpecies of Scarabæus, of a black colour, with a rufous ſpot on each of the wing-caſes. A native of New Holland. Fabricius.

Bipustulatus, a ſpecies of Staphylinus, that inhabits the northern parts of Europe. Colour black, with a ferruginous dot on each of the wing-caſes. Linn.

BIQUADRATE, or Biquadratic *power*, in *Algebra*, and *Arithmetic*, is the next power above the cube, or the ſquare multiplied by itſelf. Thus 16 is the biquadrate, or 4th power of 2, or it is the ſquare of 4, which is the ſecond power of 2: for $2\times2=4$, and $4\times4=16$.

BIQUADRATIC *Equation*, an equation raiſed to the fourth power, or where the unknown quantity of one of the terms has four dimenſions: thus $x^4+ax^3+bx^2+cx+d=0$ is a biquadratic equation. See Equation.

Biquadratic *parabola*, in *Geometry*, a curve line of the third order, having two infinite legs tending the ſame way. See Parabola.

Biquadratic *root of any number*, is the ſquare root of the ſquare root of that number: thus the biquadratic root of 81 is 3: for the ſquare root of 81 is 9, and the ſquare root of 9 is 3: the biquadratic root of 16 is 2.

BIQUALAR, in the *Cuſtoms of the Algerines*, a cook of the divan. The janizaries, whom the Algerines call *oldachis*, after ſerving a certain time as common ſoldiers, are preferred to be biqualars, or cooks of the divan, which is the firſt ſtep towards arriving at higher preferments. Biqualars have the care of furniſhing the officers and commanders of the Algerine ſoldiery with meat and drink in the camp, in garriſon, &c. From biqualars they are made *odebachis*; that is, corporals of companies, or commanders of ſquadrons.

BIQUINTILE, an aſpect of the planets, when they are 144 degrees diſtant from each other. It is thus called, becauſe they are diſtant from one another by twice the fifth part of the 360 degrees. See Aspect.

BIR, or Biraidschik, in *Geography*, a town of Aſiatic Turkey in Meſopotamia, ſeated on a mountain near the eaſt coaſt of the Euphrates, in a very fertile country, the reſidence of a bey; 100 miles S. W. of Diarbeck.

BIRABETANE, in the *Botanical Writings of the Ancients*, a name given to *verbena*, or vervain, and to other herbs uſed in ſacrifices. It is only the word *hierobotane*, as altered by the Æolic manner of writing and ſpeaking it. Hierobotane is the common Greek name of vervain, and other ſacrifical herbs, and it is probable that the Latin name verbena came from the Æolic manner of ſpeaking this word. All thoſe herbs, which were laid upon the altars on ſolemn occaſions, ſuch as making of peace, and other ſolemn contracts, and were to be taken up by the contracting parties as part of the ceremony, were called by the Greeks *hierobotanæ*, that is, ſacred plants, and verbenæ; but as the plant we now particularly know by the name verbena was more frequent in uſe than any other on this occaſion, it was afterwards diſtinguiſhed by that name. See Verbena.

BIR-AL-CADHI, in *Geography*, a town of Perſia, in the province of Segeſtan, 80 miles weſt of Zareng.

BIRBOOM, a town of Hindoſtan in Bengal, 56 miles W. S. W. of Moorſhedabad, 100 N. N. W. of Calcutta. N. lat. 24°. E. long. 87° 40'.

BIRBUSCA. See Birviesca.

BIRCH, Thomas, in *Biography*, an Engliſh hiſtorical and biographical writer of extenſive and induſtrious reſearch, was born in London, November 23, 1705. His parents were Quakers; and he was intended for his father's trade, which was that of a coffee-mill maker; but ſo ſtrong was his inclination to literature, that he requeſted leave to indulge it on the condition of providing for himſelf. Accordingly he became aſſiſtant to the maſter of a ſchool belonging to the Quakers at Hemel-Hempſted; and after a ſimilar employment in other ſituations, he at length deſerted the profeſſion of his parents, and though he had not enjoyed the advantage of an univerſity education, took orders in the church of England. In 1732, having been ordained deacon in 1730, and prieſt in 1731, he was preferred under the patronage of lord chancellor Hardwicke, who was then attorney-general, to the living of Ulting, in the county of Eſſex. Some time before he took orders, he married the daughter of a clergyman; but ſhe died within 12 months after their marriage. In 1735, he was admitted into the royal ſociety, and alſo into the ſociety of antiquaries; and of the former ſociety he became ſecretary in 1752, which office his declining health obliged him to reſign in 1765. In 1753, the degree of doctor in divinity was conferred upon him by the Mariſchal college of Aberdeen, and in the ſame year he received the ſame honour from Dr. Herring, archbiſhop of Canterbury. He was alſo a director of the ſociety of antiquaries, and a truſtee of the Britiſh muſeum. His church preferments were various, and rapid in their ſucceſſion; but the laſt of theſe was the rectory of Depden in Eſſex, which he held, together with the united rectories of St. Margaret Pattens and St. Gabriel, Fenchurch-ſtreet, till his death. This melancholy event happened in conſequence of a fall from his horſe betwixt London and Hampſtead, January the 19th 1766. Having, in the courſe of his life, generouſly aſſiſted his relations, he bequeathed his library of books and MSS. to the Britiſh muſeum, and the reſidue of his property, amounting to little more than 500l. for the purpoſe of augmenting the ſalaries of the aſſiſtant librarians.

Dr. Birch was diſtinguiſhed by the ſimplicity of his manners, and the friendlineſs and benevolence of his diſpoſition. He was eminently active and zealous in promoting literary and laudable undertakings of various kinds; and though he devoted much of his time and attention to purſuits of literature, he gained leiſure by early riſing for indulging himſelf

in the pleaſures of ſocial intercourſe with perſons the moſt diſtinguiſhed for their attachment to letters and ſcience. With reſpect to theological ſubjects, his ſentiments were rational and liberal, and he was a zealous friend to religious and civil liberty. In this reſpect his views and principles were conformable to thoſe of the truly excellent biſhop Hoadly.

In literary labour few perſons have been more diligent and indefatigable than Dr. Birch. The firſt great work in which he engaged was, "The General Dictionary, Hiſtorical and Critical," comprehending a new tranſlation of that of Mr. Bayle, and ſeveral thouſand new lives, never before publiſhed. This valuable work was completed, principally by himſelf, with the co-operation of the reverend Mr. John Peter Bernard, Mr. John Lockman, and Mr. George Sale, in 10 volumes, folio. The firſt volume appeared in 1734, and the laſt in 1741. In 1737, he publiſhed "Profeſſor Greaves's Miſcellaneous Works," 2 vols. 8vo.; and in 1742, "Thurloe's State Papers," in 7 vols. folio, with a dedication to lord chancellor Hardwicke. In 1743, he edited "Cudworth's Intellectual Syſtem," his "Diſcourſe on the Lord's Supper," and "Two Sermons," with a life of the writer, in 2 vols. 4to. His "Life of the Hon. Robert Boyle," 8vo. which has been ſince prefixed to the 4to. edition of that eminent philoſopher's works, appeared in 1744; and in the ſame year he began a ſeries of biographical ſketches of diſtinguiſhed perſons, deſigned to accompany their engraved portraits by Howbraken and Vertue. The firſt volume of this work was completed in 1747, and the ſecond in 1752. In 1747, he publiſhed in 8vo. "An Inquiry into the ſhare which king Charles I. had in the Tranſactions of the Earl of Glamorgan, &c." a fact which, however overlooked, or diſputed by ſome of our hiſtorians, was confirmed by the evidence adduced in this intereſting publication, and has been ſince further corroborated by the Clarendon ſtate papers. In 1748, Dr. Birch was the editor, in 2 vols. 8vo. of the "Miſcellaneous Works of Sir Walter Raleigh," to which is prefixed a life of the author. His next publication was "An Hiſtorical View of the Negotiations between the Courts of England, France, and Bruſſels, from the year 1592 to 1617; extracted chiefly from the MS. ſtate papers of ſir Thomas Edmondes, and of Anthony Bacon, eſq.; to which is added, a relation of the ſtate of France, with the character of Henry IV. and the principal perſons of his court, by ſir George Carew," 8vo. 1749. To this volume Dr. Birch has prefixed a diſcourſe on the utility of deducing hiſtory from the original letters and papers of the perſons who were the principal actors in public affairs, followed by a biographical account of the three negotiations above-mentioned. Mrs. Cockburn's "Theological, moral, dramatic, and poetical works," 2 vols. 8vo. with the life of that ingenious lady, were edited by Dr. Birch in 1751; and he alſo publiſhed an edition of "Spenſer's Fairy Queen," in 3 vols. 4to. One of his moſt popular works, which was "The Life of Archbiſhop Tillotſon, compiled chiefly from his original papers and letters," and dedicated to archbiſhop Herring, in one volume, 8vo. appeared in 1752; and in the following year he reviſed an edition of "Milton's Proſe Works," in 2 vols. 4to. to which is prefixed a new life of the author. In 1754, he publiſhed in 2 vols. 4to. "Memoirs of the reign of Queen Elizabeth, from the year 1581 till her death, &c. from the papers of Anthony Bacon, eſq. and other MSS. never before publiſhed;" in which, beſides a full diſplay of the temper and actions of the earl of Eſſex, much light is thrown on the characters of the Cecils, Bacons, and other eminent perſons of that period. Dr. Birch's next publication was "The Hiſtory of the Royal Society of London, from its firſt riſe; in which the moſt conſiderable of thoſe Papers communicated to the Society, which have hitherto not been publiſhed, are inſerted in their proper order, as a Supplement to the Philoſophical Tranſactions." The two firſt volumes of this work appeared in 1756, and the other two volumes in 1757; and they bring down the hiſtory to the end of the year 1687. This is unqueſtionably an uſeful book of reference, and contains many particulars which may be of occaſional ſervice both to the philoſopher and the biographer. In 1760, Dr. Birch publiſhed "Letters between Colonel Robert Hammond, Governor of the Iſle of Wight, and the Committee of Lords and Commons at Derby-houſe, &c. concerning the King's deportment at Hampton Court, and in the Iſle of Wight," 8vo.; and he cloſed his voluminous labours with "Letters, Speeches, Charges, Advices, &c. of Francis Bacon, lord viſcount St. Alban's, &c. in one volume, 8vo. Soon after his death, Dr. Maty publiſhed, "The Life of Dr. Ward," which he had juſt lived to finiſh; and he had alſo prepared for the preſs, "Hiſtorical Letters, written in the reign of James I. and Charles I." which Mr. Ayſcough propoſed to publiſh. In the liſt of his printed works we might alſo comprehend ſome papers communicated to the Royal Society, and ſome accounts of books in the works of the learned; but beſides theſe, ſuch was his unwearied aſſiduity in collecting every fragment pertaining to literature, and deemed by him of importance, that he left behind him 24 volumes 4to. of various papers copied by himſelf from the Lambeth library. Upon the whole, whatever may be thought of Dr. Birch's judgment in his ſelection of materials, of the minuteneſs of his reſearches, of the juſtice and ſagacity of his inferences from the facts which he produces, and of the want of elegance and animation in his ſtyle, it muſt be allowed, that literature has already derived, and may yet further derive, great benefit from his labours. Biog. Brit.

Birch *tree*, in *Botany*. See Betula.

Birch, *bark*, *fungus*, *leaves*, *twigs*, *wine of*. See Betula.

Birch *bay*, in *Geography*, a bay on the coaſt of New Albion, ſituate in N. lat. 48° 53′ 30″. E. long. 237° 33′.

BIRCK, in *Geography*, a town of Germany, in the circle of Weſtphalia, and duchy of Berg; 3 miles N. E. of Siegberg.

BIRD, Birds, *Aves*, in *Ornithology*. See Avis, and Ornithology.

Bird, or *fowl-mead graſs*, in *Agriculture*, a ſpecies of graſs, which has been lately cultivated with a particular attention. It is a fine, ſweet, ſilky graſs, with a durable verdure; throws out a great crop, and produces a large quantity of ſeed. One rood of ground yielded a hundred weight of ſeed, and a very large load of hay. It is moſt proper for upland meadow: the ſeed ſhould be left uncovered on the ground.

Birds, *Anatomy of*. The regard which has been beſtowed upon this tribe of animals, by different deſcriptions of mankind, renders their organization one of the moſt intereſting branches of general anatomy. The immenſe catalogue of the ſpecies of birds, and the variety and beauty of their external characters, have made them favourite objects of inveſtigation with the natural hiſtorian. The extraordinary degree of inſtinct diſplayed in all their habits and economy, more eſpecially in the attachment of the ſexes, the conſtruction of their neſts, the care of their young, and the conduct of their migrations, have called forth the admiration of the philoſopher and the lover of nature. The ſplendid colouring of their plumage, the powers of melody, and the livelineſs and docility of many ſpecies, have given them value as objects of beauty or entertainment; whilſt others

are as highly prized from furniſhing occupation to the ſportſman, or a delicacy to the epicure.

The anatomical characters of this claſs of animals, are not leſs deſerving of attention than their other properties. In the ſcale of animated exiſtence, birds can ſcarcely be conſidered inferior to mammalia; and yet many of their functions are exerciſed upon a very diſſimilar plan, and almoſt conſtantly by organs differently conſtituted. It is in birds that we perceive the firſt general deviations from the ſcheme of organization purſued in the human ſubject: this will be found moſt remarkably exemplified in the apparatus for the preparation and digeſtion of food, the ſecretion of urine, the mode of generation, and the growth and economy of the young animal, the anatomy of the brain, the ſtructure of the eye and ear, the mechaniſm of the organs of ſound, and the conſtruction of the inſtruments of loco-motion.

The anatomy of birds has been much proſecuted both by the older authors and in modern times, as the means of phyſiological knowledge, and in aid of the ſeveral purpoſes for which theſe animals are ſo much eſtimated. The information, however, communicated in this way, falls far ſhort of a ſyſtematic account of the ſubject; to ſupply which, therefore, much original matter is neceſſarily introduced into the preſent article, more particularly in the deſcriptions of the blood-veſſels, of the organs of motion, and of the minute ſtructure and uſes of parts. Many errors of the older writers are alſo corrected; and wherever the deſcriptions of others are followed, they have been, as far as it has been practicable, reviſed by a compariſon with the recent ſubject or authentic preparations.

Organs concerned in the Exercise of the vital Functions.

The Mouth and its contained Parts.

In the other claſſes of animals, theſe parts are conſtructed to effect the diviſion of the food previous to its paſſage into the ſtomach, but in birds the proceſs of maſtication is either imperfectly performed, or carried on by a peculiar mechaniſm to be afterwards deſcribed. Birds are unprovided with thoſe ſoft and flexible parts called lips; the aperture of their mouth is made by the prolongation of the two jaws, which are covered with a hard and horny ſubſtance. Theſe are named the upper and the lower *mandibles*, and together form the *beak* or *bill*. The bones which enter into the compoſition of the bill, will be conſidered along with the other parts of the ſkeleton. The external or horny part is produced, like other ſimilar ſubſtances, from a vaſcular and ſpongy membrane, which is interpoſed between it and the bones; it correſponds exactly in ſhape with the jaws, which ſerve it as a mould.

The bill is deſigned for many different purpoſes, and conſequently is ſubject to great variety in its conformation. In the birds of prey it is ſtrong, hooked, ſharp, and furniſhed with a tooth-like proceſs on its edge, to enable them the better to ſeize and lacerate their prey; thoſe birds which ſubſiſt on ſmall grain, are provided with ſhort, pointed, ſharp-edged bills for picking up and breaking their food; the parrots alſo uſe their bills for dividing their meat; in thoſe inſtances, therefore, the bill may be conſidered analogous to the teeth of other animals; but it is only the inciſors with which it can be compared, as it is incapable both from its thin edges, and from the nature of the articulation of the lower jaw, of performing any thing like the grinding motion in which properly maſtication conſiſts.

The *piſcivorous* birds have commonly large and extended bills, which become neceſſary to them, in order to ſecure their prey; theſe birds almoſt always ſwallow their food without dividing it.

Swallows and *goat-ſuckers* have ſhort bills, but opening very wide, ſuitable to their mode of procuring their food, which conſiſts in taking flies while the bird is on the wing.

The *wood-peckers*, *wry-necks*, *nut-hatches*, &c. uſe the bill as an inſtrument for perforating the bark of trees, and breaking nuts; for which purpoſe it is conſtructed like a wedge.

It may, in fine, be given as a general obſervation, that the form and ſtructure of the bill indicate the proper habits and economy of the birds; they have therefore been always employed by naturaliſts as claſſific diſtinctions, and to their works we refer the reader for a more detailed account of the peculiarities obſerved in the bills of birds.

In conſequence of a particular mechaniſm, ariſing from two additional bones, the upper jaw of birds is capable of a certain degree of motion. In general this is very confined, but the *parrot* tribe are able to move the upper jaw with conſiderable freedom. The bones and muſcles upon which this peculiarity depends, will be deſcribed with the organs of motion.

The *cavity of the mouth* is lined with a thick vaſcular membrane, behind which are placed a great number of follicular glands, which diſcharge a mucous liquor upon every part of the ſurface of the mouth. They are, however, moſt abundant in thoſe parts which ſuſtain moſt friction, as the commencement of the œſophagus, and ſurrounding the aperture of the nares, in the upper and back part of the mouth.

A cuticular tunic is ſpread over the glandular membrane, which is as uſual ſo ſoft and delicate, that it cannot without difficulty be detected.

The *tongue of birds* can hardly be conſidered an inſtrument of manducation; its motions are very limited, in conſequence of its containing a bone which runs through its whole length, and the lingual bone being articulated behind with the os hyoides, which determines the extent of its movements. The only birds, in which the tongue is immediately concerned in the diviſion of the food, are thoſe *paſſeres* living upon ſeeds that are incloſed by a ſhell. In ſuch the tongue is employed to convey the ſeed between the edges of the bill, and ſecure it there until it is broken, which is not unlike the action of the tongue of mammalia during maſtication.

The tongue of the *wood-peckers* and *wry-necks* is an organ of curious ſtructure, and enables theſe birds to tranſfix their prey at ſome diſtance from the mouth; the mechaniſm by which this is accompliſhed, and the bones and muſcles which belong to the tongue in general, will be particularly deſcribed, with the other organs of motion. The varieties in external form, and the ſtructure and integuments of the ſubſtance of the tongue, will be conſidered under the head of the organ of taſte.

Salivary glands have been aſcribed by moſt authors to birds; but as it would appear, without duly conſidering the uſes of theſe parts. Birds, as already obſerved, do not comminute their food by maſtication in the mouth, for which purpoſe the ſaliva is employed by other animals; and the glandular bodies, which have been deſcribed as ſalivary, appear to yield a fluid of rather a mucous than an aqueous nature. The internal ſurface of the mouth of birds is beſmeared with mucus, in order to facilitate the paſſage of the food, which would not be neceſſary, if the aliments were ſoftened by ſaliva.

The reputed ſalivary glands of birds are ſituated within the angle formed by the anterior part of the lower jaw, and between the ſkin and the inner membrane of the mouth. They are two in number, and appear to be compoſed of granular maſſes, or follicles, cloſely connected to each other. They diſcharge their ſecretion into the lower part of the mouth, by means of ſome foramina arranged on each ſide of the

the tongue. They would ſeem to be of the greateſt ſize in proportion to the bird, where the food is hard and dry grain; they are larger in the *common fowl* than in the *gooſe*.

The Pariſian academicians obſerved theſe glands in almoſt every bird they diſſected. In the *oſtrich* they deſcribe them as being ſituated towards the pharynx; and in the *buſtard*, they found ſeveral glandular bodies.

Oeſophagus.

The tube, which conveys the food into the ſtomach of birds, is not ſituated exactly on the fore part of the neck, but a little on the right ſide. It is partially covered by the trachea, and it is connected to all the neighbouring parts by looſe cellular ſubſtance; in conſequence of which, and its inclination to one ſide, when the neck is much bent, it does not take the ſame degree of flexure, but falls a little off to the right ſide. This effect is beſt obſerved in ſome of the birds which have long and flexible necks, as the *grallæ* and *water birds*.

The form of the œſophagus varies according to the habits of the bird, and the nature of its food. In the rapacious birds, and thoſe which ſubſiſt on fiſh, it is of great capacity throughout its whole length, generally exceeding in width the ſtomach itſelf. The magnitude of the œſophagus not only enables thoſe birds to ſwallow their prey whole, but anſwers the purpoſe of a repoſitory for their food, and thus counterbalances the diſadvantages ariſing from their precarious means of ſubſiſtence.

Herons, the *cormorant*, the *ſpoon-bill*, &c. will devour as much fiſh at once as will be ſufficient to ſupport them for a conſiderable time; and an *owl* is often obliged to exiſt for days or weeks upon a rat or mouſe, which being ſwallowed, is conveyed by degrees into the ſtomach, until the whole is digeſted.

All the *piſcivorous* birds have the œſophagus moſt capacious at its commencement, or next the fauces, for the more convenient ſwallowing of their prey, which is always gulped down.

The *pelican* furniſhes a moſt remarkable inſtance of a dilatation of the fauces, in the pouch which is placed beneath the lower jaw. This bag, if full, is very conſpicuous externally; but when it is empty, the bird has the power of contracting it very conſiderably; when completely diſtended, it is ſaid to be capable of containing ten quarts of water. The internal part of the pouch appears to poſſeſs the ſame ſtructure as the reſt of the œſophagus; the ſkin covering it externally, is clothed with a ſhort down, ſmooth and ſoft, like ſilk.

The *pelican* derives a double advantage from this enlargement of the fauces; it enables it to provide a ſupply of food and water for future neceſſity, and to tranſport nouriſhment to its young, until they can acquire it for themſelves: in diſgorging the food for her family, the parent preſſes the bottom of the ſack againſt her breaſt, and thus diſcharges its contents; from which probably aroſe the abſurd fable of her opening her breaſt, and feeding her young with her blood.

A very remarkable proviſion of this kind has been deſcribed in the *buſtard*, by Dr. James Douglas. In this animal there is a membranous bag, extending for ſome way down the fore-part of the neck, capable of containing ſeven quarts of water; it communicates with the mouth by an aperture beneath the tongue. See *Plate* I. *fig.* 1. in the *Anatomy of Birds*, in which this part is repreſented, as it has been figured in Edwards's Natural Hiſtory of Birds, vol. ii. p. 73. *a* the pouch, upon which a ligature is faſtened near its connexion with the mouth, *b* the trachea, and *c* the œſophagus.

The pouch of the buſtard is confined to the male bird, according to moſt authors; ſome have, however, aſcribed it to the female, and others have doubted its exiſtence altogether. The Pariſian academicians diſſected ſix buſtards, and do not deſcribe the throat ſac, although all their ſubjects were males.

The buſtard is ſaid to uſe the pouch, as a temporary reſervoir of water, from which it ſupplies the female during the period of incubation, and likewiſe the young brood, until they can move from the neſt. It has been alſo occaſionally employed as the means of defence. Barrington relates in his Miſcellanies, p. 553. that at Morocco, where it is uſual to fly the hawk at the buſtard, the latter has been known to eject the water contained in the ſack againſt his aſſailant, who is not uncommonly by this means baffled in the purſuit.

The *crop*, or *craw*, is a term applied to another ſpecies of dilatation of the œſophagus of birds.

When this enlargement is ſingle, it is ſituated upon the right ſide of the œſophagus, and placed ſo low on the neck, that a portion of the bag is accommodated in the ſpace left at the upper part of the thorax, within the fork-ſhaped bone. Its form is in general globular, but rendered ſomewhat irregular, from its connexion with the œſophagus, which enters at the ſuperior part, and appears again on the middle, by which means the greater part of the crop is formed into a cul de ſac.

It is obvious, that the effect of this ſtructure is not only to receive a greater quantity of food than can be digeſted, but alſo to detain it in the craw until it has ſuffered ſome change.

The birds in which the craw is found of the figure juſt deſcribed, feed uſually upon grain or other hard ſubſtances, which require to be ſoftened by maceration in the mucous ſecretion of the œſophagus. Of theſe we may mention as inſtances, the *pheaſants*, the *common fowl*, the *pintado*, the *turkey*, the *Indian cock*, the *pea-fowl*, &c.

Fig. 2. of *Plate* I. in the *Anatomy of Birds*, exhibits the crop of the *pheaſant*, *a* the œſophagus above the craw, *b* the ſame going on to the ſtomach, *c* the dilated part forming the crop.

The Pariſian anatomiſts found the œſophagus very much enlarged in the *oſtrich*, but ſo cloſe to the gizzard that theſe two parts appeared to be confounded with each other; ſo that it was difficult to mark the ſuperior orifice of the ventricle; the ſituation of the bag alſo was very unuſual, being lower than the gizzard, into which the entrance was by the bottom, and thus what is commonly called the ſuperior orifice, was really the inferior.

It is ſomewhat remarkable, that the *buſtard*, which is a graminivorous bird, and in moſt reſpects reſembles thoſe which have crops, ſhould be quite without this proviſion, its œſophagus conſiſting of an equal and regular tube.

The *parrot* has a dilatation of the lower part of the œſophagus, which is commonly reckoned to be a crop, though perhaps improperly, as the enlargement is neither ſo ſuddenly produced, nor in ſuch a degree, as to obſtruct the paſſage of the food into the ſtomach; the craw of the parrot is only calculated, therefore, to afford a temporary accommodation to its food.

Some *carnivorous* birds are furniſhed with a craw, which only ſerves the purpoſe of a reſervoir, as their food does not ſtand in need of maceration to ſoften it, which is ſo neceſſary with hard and dry grain.

The moſt ſingular kind of crop is that found in the *pigeon* genus. The œſophagus in theſe birds is of great capacity, from its very commencement, and at its lower part it ſwells out into two large ſacks, between which and the ſtomach it ſuffers a conſiderable contraction. See *Plate* I. of the *Anatomy of Birds*, *fig.* 3. *a* the upper portion of the œſophagus,

b, *b*,

b, *b*, the two crops, *c* the contracted part of the œsophagus.

In some species, as the *pouting pigeon*, the œsophagus above the crops, is of such great dimensions, that the latter are hardly discernible; these birds also have the power of distending their œsophagus with air, which gives them that grotesque appearance from whence they derive their name. A capacious crop is more necessary to the pigeon than other birds, both because its food requires long maceration, and because the young, and even, on some occasions, the female, draw their subsistence from this repository. The extraordinary change which occurs in the structure of the inner membrane of the crops of the pigeon, by which a milky fluid is secreted, for the nourishment of the young birds, will be described in its proper place.

Although there is all the variety in the form of the œsophagus we have described, the internal structure appears to be the same in all birds. Besides the external cellular covering, by which it is connected to the adjacent parts, it possesses a muscular coat, an internal vascular tunic, and a cuticular lining. The muscular coat consists of two layers of fibres; in the external layer these are transverse, or more properly circular; the other stratum is composed of longitudinal fibres. The muscular coat is most strongly marked at the top of the tube, where the actions of deglutition commence, and upon the crops, where support and motion are required. The internal coat resembles in structure that which is usually met with upon the inner parts of cavities, with this difference that it is provided in birds with an extraordinary number of follicular glands, which pour out their fluid through numerous foramina, resembling pin-holes, upon the internal surface. These glands secrete a quantity of mucus, which is employed in macerating the food, while it is detained in the œsophagus, or crop. This secretion is remarkably copious. Spallanzani introduced a piece of sponge into the crop of a *pigeon*; and after it had remained there twelve hours, he expressed from it above an ounce of mucus, and the quantity obtained from a *turkey*, amounted to seven ounces in ten hours. The follicular glands are most numerous at the commencement of the œsophagus, and towards the termination of this tube in the stomach, the inner surface of the craw is but sparingly supplied with them. See *Plate* I. of the *Anatomy of Birds*, *fig.* 2. in which the œsophagus and crop are inverted, for the purpose of exhibiting the orifices of the mucous follicles, and in *fig.* 3. they assume a beautiful and regular appearance below the dilated parts of the œsophagus. It is very common for the mucous glands to be assembled in a regular and marked manner round the very termination of the œsophagus, as *a* in *Plate* II. *fig.* 2. of the *Anatomy of Birds*.

The cuticle, which invests the œsophagus, is generally so thin and tender, that it might escape observation. It is, however, sufficiently plain in many large birds, and almost always visible, upon the inside of the crop or the other dilated parts, which are more exposed to friction from extraneous substances. The insensible lining of the œsophagus terminates abruptly at the zone of gastric glands.

It may be remarked with respect to the œsophagus of birds, that its chief peculiarities consist in the great size, occasional enlargements, and number of mucous glands. These circumstances necessarily depend upon the very singular structure of the stomach, which we shall next describe.

Stomach.

The organ of digestion in birds consists of two parts; one for producing the digestive fluid; the other the receptacle in which the conversion of the food is effected. The apparatus for the secretion of the gastric juice is called,

The Bulbus glandulosus, or the Zone of Gastric Glands.—This part is situated at the termination of the œsophagus, and appears in most instances to be the continuation of that tube. It has the same cellular and muscular coats, which obscure its real structure, when perceived externally, especially in the graminivorous birds, which have strong muscles upon the œsophagus. When the outer tunics are removed, a number of small glandular bodies are exposed, arranged with the most perfect regularity, and closely applied to each other. They assume an indistinct granular appearance in small birds generally, and even still more so in those which subsist on animal food, as the *accipitrine* and *piscivorous* birds; but in the *gallinæ*, and the large *graminivorous water* birds, as the *swan*, the *goose*, &c. the gastric glands, when divested of their coats, are readily discovered, by the naked eye, to be small cylinders, or tubes, placed horizontally with respect to the parietes of the stomach; the external end is close and of a round figure; the internal extremity of the tube is somewhat concave, and contains a small foramen, which is applied to a corresponding hole in the internal membrane of the bulbus glandulosus. See *Plate* II. in the *Anatomy of Birds*, *fig.* 1. *a* represents a number of the gastric glands, with their external extremity exposed, by a portion of the muscular coat being removed; and in *fig.* 2. *b* shews the orifices of these glands upon the internal coat of the stomach, and *c* the cut edge of the bulbus, with the cylinders as they are placed between the muscular and internal coats. The subject of both the figures is the *wild swan*.

The gastric glands commonly encircle the beginning of the stomach as a perfect and equal zone. In some instances, however, where they are not large, as in the *rapacious* and *piscivorous* birds, they are more numerous at one part of the stomach than another; see *Plate* III. *fig.* 2. which exhibits the stomach of the *heron*, *b b* the gastric glands.

The form of the bulbus is not quite regular in the *ostrich*; the structure of the glands also is not the same as in other birds: instead of being placed in regular and close order, they are disposed in masses of an unequal form and size, separated for some distance from each other. On making a section of the masses, they are found divided or interrupted, by processes of strong white cellular substance; from which it would seem, that they are composed of several glands, although there is but one foramen belonging to each mass on the internal tunic of the bulbus. The magnitude of the orifices of the gastric glands, even exceeds the proportion to be expected from the size of the bird; being capable of receiving the head of a large pin, they stand at the distance of about the $\frac{1}{3}$ of an inch asunder, and do not open with perfect regularity upon the internal surface of the stomach, being most crowded towards the centre, where also their apertures are largest; the internal tunic of the ostrich, from these circumstances, exhibits a worm-eaten appearance.

The gastric glands in all birds, like other parts, which produce an important secretion, are endowed with an extreme degree of vascularity.

Some authors have described a cuticular coat, on the internal surface of the bulbus glandulosus, which they have compared to velvet on account of its soft and spungy texture; it appears, however, very doubtful, whether this covering should be considered a tunic or not; we have observed that it is readily detached, and soluble in water; it certainly bears no resemblance to the epidermis of the œsophagus, and still less to the substance which invests the remaining portion of the stomach, or gizzard.

No very satisfactory experiments have yet been made upon the nature of the digestive fluid of birds. When it is expressed from the gastric glands, which is the only mode of obtain-

obtaining it pure, it is obſerved to be of an aſh or pale yellow colour, turbid, and of a tenacious conſiſtence, like mucus. Spallanzani found it in ſeveral birds to have a bitter and ſalt taſte, which he attributed to admixture with ſome of the fluids contained in the inteſtines; he diſcovered alſo, that the turbidity and the colour were produced by the exiſtence of a number of yellow particles, too minute to be diſtinctly ſeen without the aid of the microſcope, and which in a few hours ſubſiding to the bottom, left the ſupernatant liquor as tranſparent as water. He has remarked the yellow tinge to vary in intenſity, according to the ſpecies; in the *eagle*, for inſtance, it is cineritious, and in the *crow* a reddiſh yellow colour, like the yolk of an egg.

A number of the experiments performed by Spallanzani, although in ſome inſtances he failed, ſhew that the gaſtric fluid of *carnivorous birds* will act upon vegetable matters and upon the other hand, that graminivorous birds can digeſt animal food: but his moſt intereſting and important experiment on the properties of the gaſtric fluid, is that made to determine its powers of reſiſting the operation of cold. "On "a very cold day in winter," he ſays, "I expoſed a ſmall "quantity (of the gaſtric juice of the eagle) in a glaſs, on a "window, along with two other glaſſes containing water, in "one of which was diſſolved a quantity of common ſalt, ſuf- "ficient to give it a ſtronger taſte than the gaſtric fluid had. "The thermometers ſet beſide the glaſſes ſtood at five degrees "below o (twenty and three-fourths, Faren.). Of the three "liquors, the firſt that was frozen, was the common water, "the next was the ſalt water, and the laſt was the gaſtric fluid. "When I carried them into my apartment, where the tempe- "rature was three and an half deg. above o. the firſt that "thawed was the gaſtric fluid, next the brine, and laſtly the "water." The concluſion which neceſſarily reſults from this experiment is, that the gaſtric juice of birds, and from analogy, that of other animals, is capable of reſiſting the effects of cold more than common fluids, or even thoſe impregnated with a great quantity of ſalt; and therefore it may be conſidered as poſſeſſing ſome degree of vitality. If this ſuppoſition be admitted, it determines the nature of the digeſtive proceſs, ſo long a queſtion in phyſiology.

The gaſtric fluid of the *crow* has been ſubmitted to chemical examination by Scopoli, by which he diſcovered that it contained a quantity of gelatine and ſaponaceous ſubſtance, ſome muriate of ammonia, and phoſphate of lime, with a large proportion of water.

The ſecond part of the organ of digeſtion of birds, is not leſs ſingular than the ſtructure juſt deſcribed; it immediately ſucceeds the zone of gaſtric glands, and when in the natural ſituation, occupies the left region of the abdominal cavity, in which poſition it is retained by the ſeveral reflexions of peritoneum, which conſtitute the air cells. From being the part into which the food is received in order to undergo the proceſs of digeſtion, it has commonly received the diſtinctive appellation of *ſtomach*: but it would ſeem more conſiſtent, not only with the form of the digeſtive organ in ſome birds, and with its functions in other animals, to apply the term *ſtomach*, both to the gaſtric glands, and to the muſcular bag which immediately receives their ſecretion, and the food; or for the greater convenience and clearneſs of deſcription, the lower portion of the ſtomach might be diſtinguiſhed from the bulbus glanduloſus, by the name of *ventricle*.

The greateſt variety exiſts with reſpect to the ſtructure of this part of the organ of digeſtion in birds: when it poſſeſſes a certain degree of muſcularity, it is well known under the name of the *gizzard*; and when its muſcles are ſo thin as to give it the appearance of a ſimple bag, it is commonly, though erroneouſly, called a membranous ſtomach.

Fourcroy attempted to eſtabliſh two claſſes of birds, according to the formation of their ſtomachs, calling the one *myogaſtriques*, and the other *hymenogaſtriques*, but theſe terms were only applicable to the two extremes.

Vic d'Azir has admitted three diſtinctions in the ſtructure of the ventricle; the firſt that of the true gizzard, of which he gives inſtances in the *gallinæ*, the *ſwan*, the *gooſe*, &c.; the ſecond where the muſcles which compoſe the gizzard are not diſtinct from the other parts, nor very ſtrongly marked, as in the *thruſh* and *jay*; the third is the membranous ſtomach, as it is called, which is found in the *heron*, *eagle*, *cormorant*, &c. See the introduction to Vic d'Azir's great Syſtem of Anatomy.

Theſe diſtinctions are not, however, juſt; the gradation from the moſt muſcular gizzard to the thinneſt ventricle, is regular and uninterrupted; in order to underſtand which, and the other variations in ſtructure, it is neceſſary that the true gizzard, or muſcular ſtomach, be firſt deſcribed.

The external form of this organ is uſually an irregular oval, the two ends of which are made of the great *lateral* or *digaſtric* muſcle.

This muſcle conſtitutes the principal maſs of the gizzard; its attitude with reſpect to the bulbus glanduloſus is oblique. The two fleſhy portions are united by means of a ſtrong flat tendon, on each ſide of the gizzard, which in the centre is diſtinct from the parietes of the ventricle.

The portion of the ſtomach, which appears between the two fleſhy maſſes of the digaſtric muſcle, and which is croſſed by the tendon, belongs to the cavity of the ventricle; it is compoſed of fleſhy fibres, paſſing in ſeveral directions, as may be moſt convenient for diminiſhing the cavity. Many of theſe fibres are continued into the ſubſtance of the digaſtric muſcle, and others run in its outer margin, thus giving integrity and connexion to theſe two portions of the ventricle. See *Plate* II. *fig.* 1. in the *Anatomy of Birds*, which repreſents the external appearance of the ſtomach of the *wild ſwan*, *b b*, the fleſhy parts of the digaſtric muſcle, *c*, the tendon connecting them to each other, *d*, the parietes of the ventricle on the ſuperior part, *e*, the ſame, inferiorly, *f*, the margins of the digaſtric muſcle, with fibres paſſing along them.

The diſpoſition of the fibres in the interior of the digaſtric muſcle is exceedingly curious. They appear, upon a ſuperficial view, to be arranged in thin concentric laminæ, ſeparated from each other by the moſt delicate tendon. Theſe layers paſs to the lateral tendons on the circumference, ſo that their force is exerted upon them. See *Plate* III. *fig.* 1. which is the ſection of the gizzard of the *gooſe*, *a a*, the two great maſſes of the muſcular ſubſtance, *b*, *b*, the tendons by which they are connected to each other. But if another ſection be made, parallel to the ſides of the gizzard, or acroſs the concentric layers, we have found each of the laminæ to be divided by a great number of delicate tendinous proceſſes which form with each other ſquares and triangles of various ſhapes, producing a reticulation, not unlike a honeycomb. The extraordinary multiplication of muſcular faſciculi, which ariſes from the lamellated and reticulated ſtructure of the gizzard, creates a force which almoſt ſurpaſſes calculation.

On laying the gizzard open by cutting through the tendon, which is the thinneſt part, it is obſerved to be covered internally with a rude, callous ſubſtance, of a dark brown colour; this is thin and pliable upon the portion of the ventricle, not incloſed by the digaſtric muſcle, and partakes of the motions of the cavity; but when it covers that muſcle, it becomes as tough and inflexible as the hoof of a quadruped; two oval ſurfaces are ſeen to project beyond the other parts; they are raiſed upon the interior of the thickeſt portions of the digaſtric muſcle, and the horny integument

when

when paſſing over them acquires nearly the thickneſs of an eighth of an inch. *Plate* II. *fig.* 2. in the *Anatomy of Birds*, ſhews the gizzard of the *wild ſwan* laid open, *d* the divided tendon, *e* the cuticular or horny covering of the gizzard, ending decidedly at the commencement of the inteſtine, and below the zone of gaſtric glands; at the latter place the edge is ſhewn detached, *f f* the two prominent oval ſurfaces, *g g* the origin of the inteſtine, which being cut off ſhort on the outſide permits the light to appear through it.

The cavity of the gizzard differs very much in ſhape and extent from what might be expected, from the external figure of that organ. When all foreign matters have been expelled, the two prominent oval ſurfaces approach each other, leaving only a ſlit between them: any thing that deſerves the name of a cavity, is ſituated above and below the place where the tendons croſs (ſee *Plate* II. *fig.* 2.), for juſt within the tendon there is not cavity ſufficient to contain the end of a finger. See *Plate* III. *fig.* 1. which ſhews a ſection in which the two oval ſurfaces are applied to each other, leaving at either end the appearance of a round hole, by means of which the ſuperior and inferior cavities of the ventricle have communication.

When the horny or inſenſible lining is removed, there appears another coat to the gizzard. This is ſoft, ſomewhat ſpongy, and endowed with vaſcularity; it is intimately united to the muſcular ſubſtance of the ventricle, on one ſide, and on the other affords a ſurface for the adheſion of the horny coat; the connexion with which appears to depend upon the mutual inſertion of villous proceſſes, too fine to be diſtinctly perceived by the naked eye.

Such is the deſcription of the muſcular ventricle, or *true gizzard*, as it exiſts in the *ſwan*, the *gooſe*, the *duck*, the *pheaſant*, and *common fowl*, the *pintado*, the *turkey*, and a few others. In by far the greater number of birds, there is a deviation from the ſtructure of the gizzard. The digaſtric muſcle is leſs powerful, its tendon is incorporated with the parietes of the ventricle; the oval, or grinding ſurfaces are little or not at all diſtinguiſhable from the reſt of the cavity, which is therefore of larger capacity; and, laſtly, the ſubſtance lining the ventricle is leſs tough, thick, and hard, approaching more to the nature of cuticle. It would be endleſs to enumerate all the different inſtances of intermediate ſtructure, which we and others have obſerved; ſuffice it to ſay, that it exiſts in almoſt all the *paſſeres*, or ſmall birds which ſubſiſt upon a mixed food, ſuch as grain, worms, inſects, and fruits; alſo in moſt of the order *ſcanſores*, and in many of the *grallæ* and *anſeres*, which are purſued as game. In all which inſtances the deviation from the true ſtructure of the gizzard varies in degree according to the nature of the food uſed by the bird; nay, differs from this cauſe in the ſame individual. Thus the *gull* has a ſtrong muſcular ventricle, when fed upon grain, which, if the bird be ſupported by fiſh, becomes ſo thin as to approach the membranous ſtomach.

It is remarkable, that many birds which live upon grain and hard ſubſtances, have neither a very muſcular ventricle, nor the horny integument very thick. This is the caſe with all the *ſtruthious* birds, and ſome *gallinæ*, as the *buſtard*.

The ſtomach of the *oſtrich* is capacious; the digaſtric muſcle is thin, conſidering the ſize of the bird, and the nature of its food; and the cuticular coat is ſo ſoft, that it has been aptly compared by ſeveral authors to flannel. The Pariſian anatomiſts deſcribe the ſtomach of the *caſſowary* as being thinner than that of the *oſtrich*, and divided into two parts by a valvular projection of the inner coat.

When the digaſtric muſcle becomes ſo thin as to form a mere layer of fibres, in cloſe union with the other coats of the ſtomach, and its tendons only fine aponeuroſes, expanded on each ſide, the ventricle is termed *membranous*; an improper appellation, inaſmuch as the very ſame parts exiſt, which belong to the powerful and maſſy gizzard, although in a diſguiſed and diminiſhed form, and unequal to the ſame functions; affording thus a curious example of the uniformity with which nature copies her own works.

This ſpecies of ſtomach is almoſt confined to the *accipitrine*, or rapacious birds, and thoſe amongſt the *grallæ* and *anſeres*, which feed on fiſh. The *woodpeckers* alſo poſſeſs it, and probably it may be found in ſome foreign birds, which live on inſects and ſoft fruits.

The ſubſtance lining the membranous ſtomach is much thicker than common cuticle. It is occaſionally ſoft, and almoſt of a gelatinous conſiſtence, and eaſily detached from the internal coat of the ventricle.

The ſhape of this kind of ſtomach is uſually a ſemi-oval, or the ſection of an egg. Several of the *piſcivorous* birds, as the *heron*, *bittern*, *pelican*, &c. have, however, a ſecond chamber, through which the food paſſes in its way to the inteſtine. See *Plate* III. in the *Anatomy of Birds*. *Fig.* 2. is the ſtomach of the *heron*; *a* the lower part of the œſophagus, appearing ſmaller than it really is, from being thrown into folds; *b* the zone of gaſtric glands, diſtinctly ſeen through the coats of the ſtomach, in conſequence of the cavity being diſtended with a tranſparent fluid, and afterwards placed againſt the light. If Spallanzani had employed the ſame expedient, he could not have denied the exiſtence of a diſtinct glandular ſtructure to the *heron*; *c* the inferior part of the ſtomach, chiefly compoſed of muſcular fibres, ſpreading in a radiated manner from the lateral aponeuroſis; *d*, which ſupplies the place of the great tendons of the digaſtric muſcle; *e* the ſecond ſtomach, furniſhed with circular muſcular fibres; *f* the firſt inteſtine ariſing from the additional ventricle. The communication between the two ſtomachs is very ſtrait in the *pelican*.

Having deſcribed the ſtructure of the digeſtive organ of birds, it remains to conſider its functions. In thoſe caſes where the muſcular power of the ſtomach is inconſiderable, and the cuticular coat thin and ſoft, digeſtion is carried on in the ſame way as in man and other animals, with this difference only, that the gaſtric fluid is furniſhed by a diſtinct apparatus of glands, inſtead of being ſecreted by the whole ſurface of the cavity. In the true gizzard, however, we perceive an extraordinary departure from the common ſtructure of the organs of digeſtion. This part ſupplies the place of the teeth of other graminivorous animals. In its mechanic powers and action it reſembles a mill: the upper part ſerves as the receptacle for the grain; the two internal projecting oval ſurfaces correſpond to the mill ſtones, and the firſt inteſtine receives the ſubſtances in the ground or divided ſtate. The experiments made at the academy of Cimento, and thoſe of Reaumur, Spallanzani, and others, ſhew that the gizzard is a machine of no ordinary powers. Theſe experiments conſiſted in compelling birds to ſwallow hard and unyielding ſubſtances, and, after ſome hours, examining what were the effects produced upon them.

When balls of glaſs, or other brittle ſubſtances, were employed, they were ſpeedily reduced to powder: metals and precious ſtones were indented or abraded. Spallanzani introduced into the gizzard of the turkey, and common fowl, leaden balls, armed in one inſtance with twelve ſharp needles, one quarter of an inch long; and in another, ſet with as many lancet points. Upon deſtroying the birds 18 hours afterwards, the needles and lancets were found broken off, and marks of impreſſion appeared even upon the balls themſelves; and, what he conſidered more extraordinary, the coats of the gizzard were perfectly unhurt. When we con-

ſider the immenſe ſtrength which is obtained by the arrangement of the muſcular fibres in the gizzard, and the horny conſiſtence of its inner coat, there appears nothing incredible in theſe effects. And there is ſtill another circumſtance, not before mentioned, which fully accounts for ſuch extraordinary powers of trituration: every muſcular ſtomach or gizzard contains a number of ſmall ſtones or pebbles; the ſize of the ſtones is proportioned to that of the bird. Their number is ſubject to vary from many accidental cauſes. Two hundred have been reckoned in a *turkey-hen*, and above a thouſand have been taken from the gizzard of one *gooſe*.

Spallanzani denied that theſe ſtones were at all required for the comminution of the food. He has endeavoured to ſupport his opinion by ſeveral experiments, which are, however, not clear or conſiſtent with each other, and in contradiction to general obſervation; for it is well known, that birds do not thrive when they cannot obtain ſmall ſtones, and that it is part of the duty of the parent to provide them for their young, before they leave the neſt. Spallanzani acknowledges that he could not procure any bird ſo young, that it had not ſome ſtones in its gizzard; and therefore he was obliged to rear pigeons and turkeys even from the ſhell, before he was able to ſucceed. Birds, ſo far from ſwallowing ſtones from keenneſs of appetite, or in miſtake for food, ſeek out and ſelect thoſe moſt ſuitable to their purpoſe, which are almoſt all bits of quartz, of an equal ſize, and a roundiſh figure, with many ſmall ſharp angles.

Large birds, as the *ſtruthious* kind, the *buſtard*, &c. are in the habit of ſwallowing coins and pieces of metal, which neceſſarily ſuffer a reduction by the friction to which they are expoſed; and hence has ariſen the ridiculous notion of the *oſtrich* digeſting iron.

We have no heſitation in deciding, that the extraneous bodies found in the gizzard are abſolutely required for the perfect diviſion of the food uſed by thoſe birds that employ them. In further proof of which opinion it may be mentioned, that they are proportioned in quantity to the degree of muſcularity poſſeſſed by the ventricle, and the nutritive quality of the food; and that thoſe birds which have thin ſtomachs, and live upon animal food, never deſignedly ſwallow ſtones, or other indigeſtible ſubſtances.

In order to aſcertain the mode of operation of the gizzard in the living body, Reaumur opened ſeveral fowls during the proceſs of digeſtion. One inſtance alone ſhewed any motion in the part, which conſiſted in alternate contractions and dilatations, ſlowly and gradually performed. Spallanzani inſtituted ſimilar experiments upon ſeveral birds, with no better ſucceſs, being ſeldom able to detect the leaſt motion; and when he did perceive any, it was irregular, partial, and indiſtinct. This he attributed to the violence committed by opening the animal's body, which no doubt cauſes the motions to be leſs ſtrong and regular; but the gizzard's exhibiting externally ſo little action, depends upon the diſpoſition of the fibres in the interior of the digaſtric muſcle, which are calculated, not for performing extenſive motions, but for exerting an immenſe concentrated force upon whatever may come within their influence.

The moſt ſatisfactory, as well as convenient mode of examining the actions of the living gizzard is, to provide a very lean, young bird, which has thin parietes to the abdomen. The ſide of the belly being deprived of feathers, all the motions of the gizzard can be both felt and ſeen. We have thus aſcertained them to conſiſt in alternate contractions of the digaſtric muſcle, and of the intermediate parts of the ventricle. When the muſcle acts, its figure is not perceptibly changed, but it feels as hard as a ſtone: upon its relaxation, the parietes of the ventricle urge their contents again between the two grinding ſurfaces, when the muſcle repeats its powerful contraction, by which the ſubſtances interpoſed are ſubmitted to a preſſure like that of a vice, accompanied by a ſlight rolling motion of the ſurfaces upon each other. Theſe alternate actions ſucceed each other very ſlowly, but with regularity.

When the food and ſtones roll under the preſſure of the digaſtric muſcle, a ſound is heard exactly like what is produced by the tide coming upon a ſhore, where there are many looſe ſtones. This occurs with the ſame intervals of time, alſo, which are obſerved between the flux and reflux of the tide; and if the ear be applied to the body of the bird, during the time that the gizzard is in action, the ſound of the ebbing and flowing of the tide is imitated ſo perfectly in loudneſs, and every other reſpect, that it is difficult to conceive it is occaſioned by any other cauſe.

During the time that the food is undergoing a very minute diviſion, in the manner deſcribed, the gaſtric juice is diſtilled from the bulbus glandulоſus in greater quantity than uſual, and a more intimate mixture is formed of the digeſtive fluid and the triturated food, than could be accompliſhed under any other circumſtances; and therefore we may look upon the proceſs of digeſtion in graminivorous birds, as not only more complicated, but more perfect than it is in animals in general.

Inteſtines.

Theſe are divided in birds, as in other animals, into great and ſmall, although the terms are not very appropriate; there not being in general any material difference in the magnitude of each.

The *ſmall inteſtines* exceed the large very much in length; they are ſituated chiefly in the anterior and right ſide of the abdomen, where they are ſtrictly confined by the proceſſes of peritoneum, which form the air-cells. The convolutions of the inteſtines are very regular, and conſiſt in ſucceſſive doublings one ſhorter than another, which give the appearance, on opening the abdomen, of a coil of rope, particularly in thoſe birds which have the ſmall inteſtines of conſiderable length. This effect depends upon the figure of the meſentery, which is not compoſed in quite the ſame manner as in mammalia.

The diſtinction of the ſmall inteſtines into duodenum, jejunum, and ilium, is at all times to a certain degree arbitrary, and is ſtill leſs allowable in birds. The only portion which deſerves to be diſtinguiſhed from the reſt of the tube, is the firſt coil; which aſcends on the right ſide of the ſtomach, including in its reflection the pancreas, and receives the biliary and pancreatic ducts.

The length of the inteſtines is determined uſually according to the nature of the food upon which the bird lives; they are longeſt in the *graminivorous*, and very ſhort in the *accipitres*. Many birds, however, which uſe a mixed food, or even live altogether upon fiſh, have the ſmall inteſtines of great length; this is the caſe with the *heron*, and ſeveral others. The whole of the inteſtines of the *cormorant*, according to the Pariſian anatomiſts, meaſured ſeven feet long; and what is difficult to explain, thoſe of the *buſtard* and *caſſowary*, although large and graminivorous birds, were only four feet in length. The different *oſtriches* diſſected by the Academy, varied materially with reſpect to the length of the inteſtinal canal, one ſubject meaſuring fifty feet, another forty-two, a third thirty-three, and a fourth twenty-nine feet.

There is very little peculiar to be noticed in the ſtructure of the ſmall inteſtines. They are, as in other animals, covered externally by peritoneum, have two layers of muſcular fibres, and their internal ſurface is furniſhed with thoſe innumerable fine vaſcular proceſſes called *villi*. The *graminivo-*

rous

rous birds have commonly the longeſt villi; in the *gooſe* and *ſwan* they are ſingularly beautiful, floating a conſiderable way into the cavity of the inteſtine. The birds of prey, and thoſe which feed on fiſh, have the villi in general ſo ſmall and indiſtinct, that on a ſlight inſpection, the inner ſurface of the inteſtine appears quite ſmooth. The *owl*, however, forms a remarkable exception to this obſervation in having long and pendulous villi.

The vaſcular proceſſes upon the internal ſurface of the ſmall inteſtines of the *oſtrich* do not poſſeſs the uſual villous or hair-like form, but conſiſt of very thin plates, or lamellæ. Theſe are ſhort, with the edges ſomewhat round, and placed not in ſucceſſion, but alternately one with reſpect to another, ſo that each lamella ſtands oppoſite to the interſpace of the two adjoining, by which means the ſurface of the inteſtine puts on very exactly the appearance of twilled cloth. The ſtructure producing this effect cannot be ſeen completely, as may be ſuppoſed, without a magnifying glaſs.

We have not obſerved in birds any thing analogous to thoſe projections of the internal coat of the ſmall inteſtines, which in other animals are called *valvulæ conniventes*. The Academicians, however, relate that they found in the *buſtard* the inner tunic of the ilium folded longitudinally, in the manner of the laſt ſtomach of ruminating animals, and that towards the extremity of this inteſtine there were ſome tranſverſe wrinkles, which ſupplied the place of the valve of the colon.

Throughout the tract of the inteſtinal tube, we have diſcovered ſeveral cluſters of mucous glands: where theſe are ſituated, the internal coat appears as if ſlightly ulcerated, or not unlike a dyſenteric inteſtine, inſtead of that regular dotted figure which the mucous glands commonly exhibit in mammalia.

The *great inteſtines*, as they are called, bear no ſort of proportion to the ſmall, in point of length: in many inſtances, even where the latter are of conſiderable extent, they do not exceed a few inches. They only admit of diviſion into two parts; the cœcal appendages, and the continuation of the tube until it terminates at the anus. The firſt correſpond with the inteſtinum cœcum of mammalia; and the other takes the place of the colon and rectum; but which from its extreme ſhortneſs and direct courſe to the anus, would appear to deſerve only the name of rectum.

The *cæcal appendages* are ſubject to as much variety as perhaps any other part of the ſtructure of birds. Generally, they are two in number; in which caſe, they ariſe rather abruptly from oppoſite ſides of the inteſtinal tube, about the place where the convolutions ceaſe, and the inteſtine becomes ſtraight.

It may be received as a general rule, to which, however, there are ſome ſtriking exceptions, that the magnitude of the cœca is in proportion to the muſcularity of the ſtomach; we accordingly meet with this organ of the greateſt ſize, and the ſtrongeſt characters in the *gallinæ* and other *graminivorous* birds, from which it will be found moſt convenient firſt to take the deſcription.

The cœca in theſe birds commonly aſcend for ſome way quite cloſe to each ſide of the inteſtine, from which they ariſe; during which they are leſs than the other parts of the inteſtinal canal; they then make a ſlight curve outwards, and become ſomewhat enlarged, and towards the ſuperior extremity they again diminiſh before their termination in the cul de ſac. Theſe parts reach up in the abdomen to near the liver, and often make a ſlight curve round the ſpleen; they are connected to each other, and to the inteſtine between them, and alſo retained in their relative ſituation in the abdomen, by reflections of peritoneum, of which ſome are analogous to the meſo-colon and meſo-rectum, and others contribute to the formation of the air-cells. See *Plate* III. in the *Anatomy of Birds*. *Fig.* 3. repreſents thoſe parts in the *pintado*, or *guinea-hen*; *a* the laſt portion of the ſmall inteſtine placed between the two cœca, *b b* the cœca, *c* the rectum, *d d d* the peritoneum connecting thoſe parts, *e* a proceſs of peritoneum paſſing acroſs from the top of one cœcum to another. If the cœca be ſlit open, it is found that they communicate with the rectum by an aperture which is ſmaller than their own cavity at the place; and conſequently, any ſubſtance will paſs with difficulty into them from the other inteſtines, and likewiſe be obſtructed in its return.

Juſt within the entrance of each cœcum, there is a cluſter of mucous glands, which appear like two ſpots of ulceration. Theſe are particularly uſeful in this ſituation to ſmooth the paſſage of ſubſtances in and out of the cœca.

The contracted parts of the cœca are in ſome degree villous on the inner ſurface, and reſemble in ſtructure the reſt of the inteſtinal canal; but the dilated parts are deprived of villi, poſſeſs very little vaſcularity, appear to have few, if any, muſcular fibres, are without mucous glands, and are little better than ſimple membranous tubes. Theſe parts contain the exuviæ of the food.

All the uſes which the cœca ſerve to animals are certainly not yet known; and the functions of theſe organs in birds are amongſt the leaſt underſtood. The magnitude of their cœca is not always in proportion to the apparent neceſſity for ſuch reſervoirs; often, where they might be expected large, they are ſmall, or abſent altogether, and ſometimes, where the nature of the food would not ſeem to need theſe repoſitories, they are of conſiderable ſize. With the view of determining their uſes, they were removed from the living hen, and the conſequence is ſaid to have been, that the animal would not admit any food from the crop into the gizzard, from which it might be inferred, that their organs ſerve other and more important purpoſes in the animal economy, than mere reſervoirs of excrement; that, however, they are employed as a ſort of temporary ſewers, to receive the undigeſted parts of the food, is obviouſly true; and that in doing ſo, they anſwer an uſeful purpoſe, appears to be proved, in deſpite of many exceptions, by the more numerous inſtances of their bearing a decided relation to the digeſtive organs, and the quality of the food.

The ſame ſtructure which has been deſcribed in the *guinea hen*, or *pintado*, is to be found with little variation in all the *gallinæ* except the pigeon, and in the *herbivorous anſeres*, ſuch as the *ſwan*, the *gooſe*, &c.

Daudin deſcribes the cœca of the *heath-cock* (*tetrao urogallus*), and of the *white grous* (*tetrao lagopus*), as grooved or fluted longitudinally.

The cœca of the *oſtrich* are different from thoſe of other birds; they are large where they commence, and diminiſh gradually towards their termination; they ſuffer many convolutions in conſequence of a longitudinal band upon the poſterior ſide, which is only two thirds of their length; they are ſacculated, or divided into loculi, throughout their whole extent, by means of a valvular projection of the internal coat, which winds in a ſpiral manner, ſimilar to the valve of the cœcum in the *hare* and *rabbit* in mammalia, or the *ray* and *ſhark* kind amongſt fiſh.

The ſpiral lamina is about five lines in breadth, but becomes ſomewhat leſs towards the extremities of the cœca. This lamellated ſtructure is continued for ſome way into the other great inteſtine, and even into the ſmall inteſtines; not, however, as one ſpiral valve, but in ſeveral tranſverſe projections, which have a ſemilunar figure, and are placed alternately, ſo that one lamella is received between two others, in the manner of the denticuli of the bivalve ſhells. *Plate* III. *fig.* 4. is a portion of the firſt part of the great inteſtine

or colon of the *oſtrich*, repreſented of the natural ſize and cut acroſs to ſhew the ſemicircular lamina on the inſide.

The *effect* of this ſtructure is obviouſly the retention of the excrementitious part of the food for a longer time in the cœca; which is accompliſhed in other inſtances by the ſmallneſs of the aperture through which theſe parts communicate with the other inteſtines. This organ is not ſimilar in the other *ſtruthious* birds. According to the Pariſian diſſectors, the *caſſowary* is not provided with any cœcum. In the *caſſowary*, or (with more propriety) *oſtrich*, of New Holland, we have found two cæcal appendages, which opened into the rectum by orifices not much larger than pin-holes. The internal ſurfaces had none of the laminæ, or valvular projections, but were furniſhed with fine vaſcular floccuſi, ſimilar to thoſe of the ſmall inteſtines of the *oſtrich*; with this difference, that in the New Holland bird, they are placed longitudinally, and are more looſe and pendulous, looking ſomewhat like lacerated portions or ſhreds of the inner coat of the inteſtine.

In by far the greater number of birds the cœcal appendages are too ſmall to ſerve any purpoſe, and appear only as uſeleſs imitations of the ſtructure deſcribed in the *graminivorous* kinds. Many, that live on a mixt food, and whoſe ſtomachs are of an intermediate ſtrength, amongſt the larger *paſſeres*, the *picæ* of Linnæus, the *grallæ*, and the *anſeres*, have two cœca meaſuring in length uſually about twice or thrice the width of the inteſtine from which they take their origin. See *Plate* III. *fig.* 5. which exhibits theſe parts in the *gull*. Cœca of this ſize have hardly any cavity, and ſeldom receive any of the contents of the other inteſtines; in the ſmall *paſſeres*, which feed upon ſeeds, as the *ſparrow* and *finch* tribes, the cœca bear a ſtill leſs proportion to the ſize of the reſt of the inteſtinal canal; ſee *fig.* 6. of *Plate* III. in which the cœca are repreſented as they are commonly found in thoſe birds.

In the *pigeon* the cœcal proceſſes are ſo ſmall, that they eſcaped the notice of ſo accurate an anatomiſt as Severinus, who deſcribed the pigeon as wanting them altogether. *Fig.* 7. of *Plate* III. exhibits their appearance in the *dove*.

The carnivorous birds of all others have the cœca of the ſmalleſt dimenſions; ſo much ſo, in many inſtances, that their exiſtence has been often denied. *Fig.* 8. of *Plate* III. is copied from the Memoirs of the Royal Academy of Paris; it ſhews the ſlight dilatation which was found in the *bald buzzard (falco haliætus*, Linn.) in place of the cœcal proceſſes. On the internal ſide, however, this enlargement was furniſhed with a valvular membrane, by which a pouch was formed on each ſide.

The *owl* appears a very remarkable exception to the common ſtructure of the *accipitres*, with reſpect to the formation of the cœca, which both in figure and magnitude are ſimilar to thoſe parts in the *gallinæ*. It is difficult to account for this ſingularity, unleſs it be ſuppoſed neceſſary to receive the indigeſtible parts of the animals, which this bird ſwallows entire.

Some of the *piſcivorous* birds, as the *heron*, &c. have only one cœcal proceſs; it is very ſhort, and in the *heron* terminates in a pointed manner. See *Plate* III. *fig.* 9.

There are inſtances of the cœcal appendages being altogether wanting. They have not been found in the *caſſowary*, the *cormorant*, the *bittern* (*ardea ſtellaris*), the *parrot*, and the *wood-pecker*.

That portion of the inteſtinal canal which correſponds to the colon and rectum of mammalia, as already obſerved, is very ſhort in birds. In its external characters, it reſembles the reſt of the inteſtinal canal, of which it appears to be ſimply the continuation. The internal ſurface is provided with villi, which, however, are not ſo long and delicate as thoſe of the ſmall inteſtines. They are rather very minute eminences than villous proceſſes, eſpecially towards the termination of the rectum, at which place they often aſſume a decided granular appearance. The inner ſurface of the rectum in the *New Holland oſtrich*, however, preſents an exception to this obſervation; it is covered with fine and truly hair-like proceſſes; in this bird alſo the internal coat of the great inteſtine is ſlightly folded or wrinkled tranſverſely, in a manner ſomewhat ſimilar to the valvulæ conniventes of the ſmall inteſtines of the human ſubject.

The termination of the rectum in birds is very uſually called the *cloaca*, on account of its receiving, as a common ſink or ſewer, both the excrements of the inteſtines and the urine. There is at this place a dilatation of the gut, which is often only a ſlight and gradual enlargement juſt within the margin of the anus; but ſometimes it ſwells out ſuddenly into a pouch or ſack. A remarkable example of which occurs in the parrot; ſee *Plate* IV. in the *Anatomy of Birds*, *fig.* 1. *a* the rectum, *b* the pouch.

The cloaca of the *buſtard* has been found large enough to contain an egg. It is of an oval form; it is ſituated about an inch from the anus, and the rectum again experiences a contraction previous to its termination in the vent. See *fig.* 2. of *Plate* IV. in the *Anatomy of Birds*; *a*, the rectum before it enters the pouch; *b*, *b*, the pouch laid open to expoſe its interior; *c*, the contraction within the anus.

In the *oſtrich*, this dilatation is of great ſize; being capable of receiving one's two fiſts, according to the report both of the anatomiſts of the French academy, and of Mr. Warren, who publiſhed a diſſection of this bird, in the Philoſophical Tranſactions, ſee N° 394. p. 113.

The uſe which the anal pouch anſwers is almoſt too obvious to be mentioned, which is that of a temporary accommodation to the excrements of the bird, by which their ejection is rendered leſs frequent.

The cloaca is furniſhed with ſomewhat ſtronger muſcular fibres than the reſt of the inteſtine, and is inveſted with a reflection of cuticle, which in the larger birds is very palpable. Connected with the cloaca, there is a bag, or purſe, which, taking the name of the anatomiſt who firſt deſcribed it, is called *burſa Fabricii*.

The *purſe of Fabricius* is uſually of an oval or round figure, depreſſed on the anterior and poſterior ſides, and thence always appearing empty. It is furniſhed with a narrow proceſs, or neck, which is moſt contracted about its middle. Its ſituation is on the back part of the cloaca, to which it is cloſely connected, being incloſed in the ſame reflection of peritoneum which envelopes the rectum. When the peritoneum is diſſected off, it is found to be a diſtinct bag or ſack, united only to the rectum by means of its neck, which paſſing obliquely in the coats of the cloaca, opens into the inteſtine by a ſlit-ſhaped aperture. The internal coat of the cloaca projects over the opening like a penthouſe, and performs the office of a valve, readily allowing the contents of the bag to paſs out, but ſtanding in the way of any regurgitation from the inteſtine. See *Plate* IV. of *fig.* 2. and the purſe of Fabricius in the *buſtard*, which is of an oblong ſhape in this bird; *e*, the ſlit by which it communicates with the cloaca.

The ſize of this bag is in general fairly proportioned to that of the bird in which it is found. In the *buſtard* it has been ſtated to be two inches long; in the *gooſe*, it meaſures about an inch and a quarter in length, and half an inch in breadth; and in the *ſparrow*, it is about a quarter of an inch long, and half as broad.

The external ſide of the burſa is ſmooth and equal, but the internal part is thrown into deep rugæ. The folds are diſpoſed in an arboreſcent form, and branch off with great regu-

regularity from a ſtem which is lodged in the neck of the bag. See *Plate* IV. *fig.* 3. in which the purſe of the *gooſe* is delineated, with its cavity laid open, to exhibit the folds upon the inner ſurface.

When more cloſely examined, the ſtructure of this part is very curious. Under the peritoneal covering, it is ſurrounded by a very delicate expanſion of muſcle, the fibres of which take a tranſverſe direction. The internal tunic of the purſe is made of a thin pellucid membrane, and the folds which have been deſcribed, conſiſt entirely of glandular bodies, which are too minute to be diſtinguiſhed with the naked eye. By employing a lens of common magnifying powers, we have diſcovered them to bear a great reſemblance to the gaſtric glands, being, like them, little cylinders, which are perforated at one extremity to give paſſage to their ſecreted fluid; indeed, the only difference which appears between them, is, that the glands of the purſe are ſhorter, being ſo much compreſſed in ſome inſtances, that they are nearly of an annular form. *Fig.* 4. of *Plate* IV. exhibits a portion of the burſa of the *gooſe*, highly magnified; *a*, *a*, the glands compoſing the folds; *b*, *b*, the ſpaces left between the folds, which conſiſt only of the tunics of the purſe.

The fluid produced by theſe glands, and of which the purſe always contains a greater or leſs quantity, appears to differ in no reſpect from common mucus. The neceſſity, however, for ſo ample a ſupply of mucus, as theſe glands are capable of furniſhing, does not ſeem very plain, eſpecially when it is conſidered that the purſe of Fabricius is not met with in all birds. Amongſt others, the *parrot* is without it, as appears by *fig.* 1. of *Plate* IV. in the *Anatomy of Birds*; and yet the parrot has a very large cloaca, and might thence be ſuppoſed to need this glandular apparatus, even more than many birds, admitting its uſe to be the ſecretion of a mucous fluid, to ſheath the cloaca againſt the acrimony of the excrement and urine.

Although the functions of the purſe of Fabricius cannot be ſtated with certainty, it may be conjectured that they are not unimportant, from the delicacy of its organization, and its being ſo rarely wanting. There are a number of black points to be ſeen within the anus of the *parrot*, which appear like the orifices of mucous glands: may not theſe ſuperſede the neceſſity of the purſe in this bird?

The *excrements* of birds have been aſcertained by Vauquelin and others, to poſſeſs an acid. This is increaſed by fermentation, into which feculent matters rapidly tend, and as it proceeds, the acid gives place to ammonia, which is evolved, towards the end of the proceſs, in great abundance. The dung of the *pigeon* is found to contain an acid of a peculiar kind, which is increaſed by the mixture of the fæces with water. It is from its chemical properties that the dung of pigeons becomes ſo ſerviceable as a manure, and that it is employed in the proceſs of ſome manufactures, and for domeſtic purpoſes, ſuch as cleanſing clothes, &c.

Vauquelin has alſo analyſed the fixed parts of the excrements of fowls, which being compared with thoſe of the food, afforded ſome very ſingular and important reſults.

For this purpoſe he fed a *hen* for ten days upon oats, of which ſhe conſumed during that time 11,111,843 grains troy weight; theſe contained

136,509 grains of phoſphate of lime,
219,548 ſilica,

356,057.

In the courſe of theſe ten days the hen laid four eggs; the ſhells of which yielded 98,776 grains of phoſphate of lime, and 453,417 grains of carbonate of lime. The whole quantity of excrement ejected during the ten days contained 175,529 grains of phoſphate of lime, 58,494 grains of carbonate of lime, and 185,266 grains of ſilica. The amount, therefore, of the fixed parts diſcharged from the ſyſtem during this period were as follows:

274,305 grains of phoſphate of lime,
511,911 grains of carbonate of lime,
185,266 ſilica,

Given out	971,482
Taken in	356,057
Surplus	615,425

Hence it appears, that the quantity of ſolid matter parted with by the ſyſtem during ten days, exceeded the quantity taken in by 615,425 grains.

The amount of the ſilica received was 219,548 grains,
The quantity given out was only 185,266 grains,

Deficient 34,282 grains.

Conſequently there diſappeared, during ten days, 34,282 grains of ſilica.

The quantity of phoſphate of lime
taken in was - - 136,509 grains,
That given out was - - 274,305 grains,

137,796

There muſt have been formed, by digeſtion in this fowl, no leſs than 137,796 grains of phoſphate of lime, as well as 511,911 grains of the carbonate of lime. It may thence be preſumed, that lime (and perhaps phoſphorus) is not a ſimple ſubſtance, but compounded of ingredients which exiſt in oats, water, and air, which were the only matters that could be introduced into the body of this fowl; as a quantity of ſilica had diſappeared, it might be ſuppoſed, that it had contributed to the formation of the additional products; but if ſo, it muſt have entered into combination with a great quantity of ſome other ſubſtance. See Annal. de Chim. xxix. 16.

Notwithſtanding theſe experiments were conducted by the ableſt chemiſt of the age, they ought not perhaps to be aſſented to without being repeated under every circumſtance which could lead to the detection of any error that might poſſibly ariſe.

This is not only neceſſary on account of the extraordinary nature of the reſults, which could only be produced by a creative power in the aſſimilating organs of the animal; but from other analogous experiments yielding reſults of a contrary kind. Dr. Fordyce, for inſtance, found that a certain quantity of calcareous matter was required by birds during the period of laying; and if the bird was deprived of this, the ſhell never was formed, and the bird frequently died from the eggs not coming properly forward. The method he adopted to prove this was ſimple and ſatisfactory: he took a number of canary birds, when about to lay; ſome he incloſed, ſo that they could have no acceſs to any calcareous matter; and to others he gave a piece of old mortar, which they ſwallowed with avidity, and they laid their eggs as uſual; whilſt, on the other hand, thoſe birds he had not furniſhed with the mortar were unable to produce eggs, and in ſeveral inſtances died. See Fordyce on Digeſtion, p. 25 & 26.

Liver.

This viſcus is ſituated about the middle of the common cavity of birds. Its form, as in other animals, is much influenced by the ſhape of the parts which are immediately adjacent. The left ſide lies on the ſtomach, the right covers the

the inteſtines, and the apex of the heart is accommodated in the middle, and wherever the liver comes into contact with theſe parts, it receives in a degree an impreſſion of their form.

Vic d'Azir, in his great ſyſtem of anatomy, ſays, that the liver of birds is divided into only two lobes; and Cuvier has repeated the aſſertion in his Tableau Elementaire de l'Hiſtoire Naturelle. The obſervation, nevertheleſs, is not in all caſes ſtrictly true. In many birds there is a third lobe, ſituated at the back of the liver, between the right and left lobes: this appears to be analogous to the lobulus ſpigelii of the human ſubject, both from its moſt uſual figure, and from its poſition. See *Plate* IV. of the *Anatomy of Birds*. *Fig.* 5. repreſents the liver, &c. of the *gooſe* reviewed on the poſterior or reverſe ſide; *a* the right lobe reaching lower down than the other, and exhibiting impreſſions correſponding to the convolutions of the inteſtines; *b* the left lobe, with two prominent parts, and a depreſſion extending along the lobe between them; *c* the third, or intermediate lobe. In the *common fowl*, the left lobe is cleft on the anterior part ſo deeply as almoſt to form two lobes on the left ſide. The French academicians allow three lobes to the liver of the *cormorant*; they are all very ſmall. A third lobe has been deſcribed alſo in the *pigeon* by Borrichius, and in the *ſwan* by Bartholine. The liver of the *oſtrich* conſiſts of four imperfect lobes.

There is conſiderable variety in the ſhape and relative ſize of the two principal lobes; generally the right lobe much exceeds the other in bulk, and is ſomewhat longer. This character of the lobes is to be ſeen in the liver of the *gooſe*, *Plate* IV. *fig.* 5. but is more remarkable in the *caſſowary*, and even ſtill more ſo in the *buſtard*, in which the right lobe deſcends to the bottom of the belly; both lobes are ſhort in the *eagle*, the *Indian cock*, the *parrot*, the *owl*, and many others; and in the *eagle* the left lobe has the greater bulk.

The two lobes are nearly of equal ſize in the *heron* kind, and both long ſhaped. However much the livers of birds may differ in external forms, the internal ſtructure is the ſame in all caſes, as we have proved by numerous obſervations. The ſecretory veſſel is produced from the veins of the neighbouring viſcera, as in mammalia, and after entering the liver by the depreſſion or fiſſure on the lower ſurface, which correſponds to the *portæ* or *gates* of the human liver, it is diſtributed throughout the ſubſtance of the organ, and terminates in the ſame manner as the *vena portæ*, i. e. in fine radii, or penicilli towards the ſurface of the liver.

As there is no muſcular ſeptum between the thorax and abdomen of birds, their liver has not the advantage of that mode of connection, which is called in mammalia the coronary ligament: it is however amply ſupplied by the duplicature of peritoneum, which correſponds to the falciform ligament; this proceſs divides the two principal lobes, paſſing deeply between them; it is connected to the peritoneum, which forms the air cells, in the ſides and back part of the abdomen, is incorporated with the pericardium, and joins the ſternum and the linea alba on the fore part of the abdomen, and then becomes reflected on each ſide of the common cavity, which is thus divided almoſt for its whole extent, in the ſame manner as the mediaſtinum divides the thorax in mammalia. The extended attachment, which is in this way procured for the liver, renders this viſcus more ſteady in its ſituation than it is in other animals, which birds require on account of the rapid and violent motions of their bodies during the act of flying. As the falciform ligament goes on to the fore part of the cavity, the margin which forms the round ligament is neceſſarily wanting, but the remains of the umbilical vein may be traced running between the duplicature of the peritoneum.

The *gall-bag*, or reſervoir of the ſecreted fluid of the liver, in almoſt every inſtance where it exiſts, is ſituated upon the lower ſurface of the right lobe, ſomewhat nearer its central than its external edge. It is commonly received into a ſlight depreſſion of the liver, ſo that about one half of the bag is brought into contact with that viſcus, nothing being interpoſed between them but the connecting cellular ſubſtance. The ſurface of attachment is occaſionally leſs extenſive; thus in the *eagle*, *buſtard*, and *cormorant*, the bag ſtands out from the liver being only united to it by one end.

The form of this bag is commonly that of an egg, or a globe, or often ſomething between theſe two figures. In a few inſtances it is elongated, as in the *buſtard* and *caſſowary*; it meaſured in the latter bird only one inch in diameter, although it is ſeven inches in length.

The ſtructure of the *gall-bag* appears to differ in no reſpect from that deſcribed in mammalia; its coats diſcover no trace of muſcular fibres, and its internal ſurface exhibits the ſame kind of reticulation or net-work which is found in the gall-bladder of the human ſubject. See *Plate* IV. and *fig.* 5 in the *Anatomy of Birds*; the letter *d* indicates the gall-bag of the *gooſe* viewed particularly in its natural poſition; the reticulated ſtructure is viſible on the outſide, but to bring it more perfectly into view the cavity is expoſed by the removal of a portion of the bag.

The bile does not flow into the gall-bag by regurgitation from the common duct, but is conveyed directly thither by means of a particular tube deſigned for that purpoſe. This duct ariſes from the right lobe, paſſes on the ſide of the bag which is in contact with the liver, then becomes involved in the coats of the cyſt, which it perforates about the diſtance of one-third from the poſterior end.

The orifice by which the duct opens into the cavity of the bag, is very ſmall, and is ſurrounded by a ſmooth projection of the inner membrane, which added to the obliquity of the duct, affords the effect of a valve, and entirely prevents any return of the fluid upon the liver; for the more the cyſt is diſtended, the more preſſure will be laid upon the duct, in its paſſage.

It would ſeem that the cyſto-hepatic duct is ſituated nearly in the ſame way in all birds, where it exiſts, but the preſent deſcription is taken from the *gooſe*. See *Plate* IV. and *fig.* 5. in which *e* points out the termination of the duct in the gall-bag, upon the papilla above-mentioned, and the courſe of the duct alſo is to be indiſtinctly ſeen behind the tunics of the cyſt.

The *ducts* which carry the bile to the inteſtines, are two in number, the *hepatic* and the *cyſtic*. The firſt ariſes by two branches, generally from the right and left lobes of the liver, and while within the fiſſure or portæ of the liver, they unite to form the trunk which proceeds to its inſertion in the inteſtine, and uſually croſſes the duct of the gall-bag in its way thither.

The *cyſtic duct* comes forth abruptly from the moſt poſterior part of the gall-bag, which is not prolonged into a neck, as in other animals. The duct makes a turn round the end of the bag, along the ſide of which it then proceeds ſo cloſely applied, that upon a ſlight examination it might be ſuppoſed to commence from that part, or even from the anterior end of the cyſt.

The cyſtic and hepatic ducts never unite to form the ductus communis, as in many animals; but proceed diſtinctly to the inteſtine, into which they always enter ſeparately; ſometimes very near each other, and at others removed to a little diſtance. Two hepatic ducts have been

found in the *Indian cock*, or *curaſſow*, which alſo had a diſtinct inſertion in the inteſtine.

The part of the inteſtines where the biliary ducts penetrate, is commonly at the concluſion of the firſt doubling or convolution, which occurs after the origin of the inteſtine from the ſtomach; or, in other words, it might be ſaid to be at the termination of the duodenum. The bile duct of the *oſtrich* is very large and enters the inteſtine near the ſtomach.

As in mammalia, the paſſage of the ducts through the coats of the duodenum is ſomewhat oblique, and they open upon a papilla or prominence of the internal coat, thus gaining the effect of a valve, and preventing the regurgitation of their fluid. In addition to which, the *buſtard* is deſcribed as having a fold of the inner coat of the inteſtine projecting over the orifices of the biliary and pancreatic ducts.

Plate IV. and *fig.* 5. in the *Anatomy of Birds*, exhibits the origin, courſe, and termination of the biliary ducts in the *gooſe*; *f* the hepatic duct, formed of two branches in the fiſſure of the liver: *g* the origin of the cyſtic duct from the end of the bag, appearing internally like a puckered hole; *h* its courſe behind the hepatic duct, beyond which it terminates in the inteſtine; *i i* the firſt convolution of the inteſtine; *k* the portion from which the gizzard has been cut away; *l* the commencement of the ſecond fold of the inteſtines, or the beginning of the jejunum.

Both the cyſtic and hepatic ducts of the *gull* become ſlightly enlarged juſt at their inſertion in the inteſtine, which is produced not ſo much from a dilatation of their cavity as a thickening of their coats. The more minute ſtructure and the functions of the bile ducts are in every reſpect analogous moſt probably to thoſe of the ſame parts in other animals. A very curious obſervation has been made on this ſubject by Borrichius, which deſerves to be mentioned. He opened a pigeon while yet alive, and diſcovered in the hepatic duct a pulſatory motion, by which it was alternately diſtended and emptied of its contents, the intervals between each contraction were ſomewhat longer than they occur between the ſyſtole and diaſtole of the heart. If this had been related by a leſs accurate anatomiſt than Borrichius, one would be led to ſuſpect that a blood-veſſel had been miſtaken for the biliary duct; but he watched the moment that the action of the heart ſubſided, and ſtill the duct was alternately emptied and diſtended with a green fluid as before.

The gall-bag is occaſionally wanting in birds, and it ſhould be remarked, that this irregularity is not governed by any general rules of ſtructure, as two ſpecies which agree in every other reſpect, are obſerved to differ in this; nay, according to the French academicians, the gall-bag is not conſtantly found even amongſt the individuals of the ſame ſpecies; thus in diſſecting ſix *demoiſelles of Numidia* (*ardea virgo*), it was abſent in two of them, and the others had it very ſmall. Amongſt ten *pintados*, alſo, they only met with the gall-bag twice, and differing very much both in ſize and ſhape; and in theſe inſtances where the bag was abſent the hepatic duct was found very large.

The ſpecies known to be deprived of the gall-bag, are the *oſtrich*, the *parrot*, the *pigeon*, the *bittern*, the *crane*, and the *cuckow*; in ſome of theſe, dilatations of the ducts have been obſerved which may be ſuppoſed to ſupply in a degree the office of the gall-bag, which appears from this, as well as other circumſtances, to be ſimply a reſervoir for the bile, and not an organ for working any change in the properties of that fluid. Being, therefore, a convenient, rather than a neceſſary ſtructure, its abſence need not be expected to be marked with any clear relation to the other functions of the animal economy.

No experiments have yet been inſtituted with the deſign of procuring a chemical analyſis of the bile of birds; it is, moſt probable, however, that theſe would diſcover nothing peculiar, as in ſenſible properties, ſuch as colour, taſte, &c. it perfectly reſembles the bile of mammalia.

The Pancreas

Conſiſts of two diſtinct glands, for the moſt part, in birds. Their common ſituation is between the coil of the firſt inteſtines, to which they are very firmly bound by their peritoneal coat; they have a very elongated figure, furniſhed with decided ſides, angles, and edges, which are irregularly notched or indented. Theſe clefts mark out imperfectly the original lobules of which the glands are compoſed. They appear to poſſeſs the ſame internal ſtructure which is deſcribed in mammalia, though not ſo palpably as to be diſcovered without ſome pains; to a ſlight obſervation their ſubſtance ſeems to be a white homogeneous maſs, inſtead of that congeries of lobules, cells, blood-veſſels, and ducts, which really enter into its compoſition. Each of the glands produces a principal duct, which ſeparately runs in the reflection of peritoneum, into which inteſtine they are inſerted, at a variable diſtance from each other, in the manner of the two biliary ducts. Their entrance is, with ſcarce an exception, adjacent to that of the bile ducts, and often ſo near that one projection of the internal coat of the inteſtine ſerves for the termination of all the ducts.

See *Plate* IV. in the *Anatomy of Birds*, in *fig.* 5. the letters *mm* indicate the two pancreatic glands of the *gooſe*, a little ſeparated from each other, and their other peritoneal connections, to exhibit more clearly their figure; *n n* the ducts from each gently curved in their paſſage to the inteſtine. The pancreatic and biliary ducts are at a conſiderable diſtance in the *oſtrich* and the *gull*. In the firſt, as already mentioned, the hepatic duct enters the inteſtine near the ſtomach; but the pancreatic duct paſſes as uſual into the laſt portion of the duodenum. The pancreatic ducts of the *gull* penetrate the duodenum at its commencement, whilſt the biliary preſerve nearly the common ſituation. It is not very unuſual for theſe ducts to enter the inteſtine alternately, or for the two pancreatic to paſs between the two biliary; this may be obſerved in the *eagle*, the *heron*, &c.

Conſiderable varieties have been deſcribed in the number, external figure, and magnitude, &c. of the pancreas in different birds. The French academicians have repreſented it as a ſingle gland, with only one duct in the *oſtrich* and *caſſowary*. In the latter it was extremely ſmall in proportion to the ſize of the bird, being only two inches long, and its duct a line and a half in length. In the *eagle* it appeared to be ſingle, although in one inſtance it ſent forth two ducts, and in another three; it was enlarged and round at the head, at which place it was perforated by the hepatic duct in its way to the inteſtine. They alſo deſcribe that this gland varies in different individuals of the ſame ſpecies; thus in one *curaſſow* they found the pancreas double, and in another ſingle. De Graef in moſt *fowl* found three pancreatic ducts, and alſo in the *pigeon*, and Bartholin obſerved only one pancreatic duct in the *peacock*.

The Spleen

Has been deſcribed as occupying different ſituations by different authors. Thus Cuvier, and other anatomiſts, have ſtated its common poſition to be the middle of the meſentery. The French academicians found it cloſely adhering to the ſide of the ventricle, in one ſpecies of eagle (*falco chryſaëtos*); and in another (*falco haliaëtos*), it was met with under the right lobe of the liver; and Severinus mentions the ſpleen of the *crow* being ſituated upon the firſt inteſtine. In every bird, however, which we have examined with the view of aſcer-

aſcertaining the ſituation of the ſpleen, it has been uniformly diſcovered underneath the left lobe of the liver, placed a good deal backwards, and on the right ſide of the zone of gaſtric glands. Its peritoneal connections to the neighbouring parts are looſe and permit it to be diſplaced, when the other viſcera are removed from their ſituations, which circumſtance may have occaſioned ſome difference in the obſervations made upon the ſubject. The ſituation we have deſcribed is the moſt convenient for its being ſupplied with blood, which it receives from the gaſtric artery, and is beſides conſiſtent with general analogy.

The figure of the ſpleen is moſt commonly round; it is, however, in ſome birds, a little different in form. The moſt uſual deviation is the oval or kidney ſhape, which has been obſerved in the *cormorant*, the *eagle*, the *pintado*, the *common fowl*, &c. In the *oſtrich* it is cylindrical, and in the *caſſowary* it has been likened in figure to a ſoal fiſh. In the *gull* it is much elongated, and pointed at both ends, as it is ſhewn in *Plate* IV. in the *Anatomy of Birds*, and *fig.* 6.

The ſpleen aſſumes rather an irregular form in the *gooſe*; it is ſlightly compreſſed and round on the one ſide, and flat on the other. The outline preſented on either ſide is triangular, and one of the angles is prolonged as a mamillary proceſs, which is diſtinguiſhed from the reſt of the ſpleen by a ſlight cleft or fiſſure. This is repreſented in *fig.* 7. of *Plate* IV. of the *Anatomy of Birds*; *a* the body of the ſpleen viewed on the flat ſurface; *b* the papilla-ſhaped proceſs; *c* the entrance of the ſplenic artery, upon the edge; *d* the vein penetrating the flat ſurface.

The texture of the ſpleen is ſo much more cloſe and firm in birds than mammalia, that one might be eaſily led to ſuppoſe its ſtructure was different; but when prepared by being injected with coloured ſubſtances, and ſubmitted to examination through a lens, we have diſcovered, as in mammalia, the ſplenic artery to terminate in numerous minute branches, and the veins to take their riſe from cells. The only difference which exiſts, is with reſpect to the magnitude of the cells, which are extremely minute; and thence ariſe the peculiar compactneſs and denſity of the ſpleen of birds.

The ſtructure of this organ being ſo very ſimilar to that of the ſpleen in mammalia, it is fair to conclude that their functions are alſo analogous. The ſituation of the viſcus in birds might be conſidered, therefore, as affording an objection to that theory, which ſuppoſes this organ was deſigned to regulate the quantity of blood employed by the arteries of the ſtomach during the ſecretion of the gaſtric fluid; for, in birds, the ſpleen receives no preſſure as occurs in mammalia by the introduction of food into the ſtomach, and conſequently, cannot affect the diſtribution of the blood in the collateral arteries, more under the circumſtance of a full ſtomach than an empty one. In order to put the ſpleen of birds in the ſame conditions to which it is ſubject in man and quadrupeds, it ſhould be placed under the crop in the graminivorous tribe, or between the ventricle and the ribs in the other kinds.

Although it would be often wrong to determine the uſes of an organ in one claſs of animals, from the circumſtances in which it may be placed in another; yet no theory can be conſidered as well founded, unleſs it be framed in the contemplation of all the varieties of comparative ſtructure.

Abſorbents.

One of the moſt remarkable and inexplicable circumſtances in the anatomy of birds is, that the nutritious fluid of the inteſtines, or the chyle, is as tranſparent as the lymph which is taken up from the common interſtices, or the ſurface of the body. The abſorbents of the inteſtines, therefore, do not deſerve to be called *lacteals*, an appellation they have received in man and quadrupeds, in conſequence of the opacity and milky appearance of their contents.

The diſcovery of the lymphatic ſyſtem in birds may be reckoned amongſt the modern improvements in anatomy. Before Mr. Hunter, about the middle of the laſt century, deſcribed the abſorbents of the neck, it was generally ſuppoſed that the office of theſe veſſels was fulfilled in birds by the minute branches of veins. This opinion was rendered the more probable as ſeveral able anatomiſts had fought in vain for thoſe white veſſels, and their glands, which are ſo eaſily detected in the meſentery of the ſmalleſt quadruped. It was not then known, however, that the lymphatic veſſels of the inteſtines were always pellucid in birds, and unprovided with glands, and accordingly Mr. Hunter's diſcovery was not generally admitted as deciſive on the queſtion, until ſome years afterwards the whole of the lymphatic ſyſtem had been deſcribed by Mr. Hewſon; he employed for this purpoſe a young and very lean gooſe, which had been recently fed, and having ſecured it upon a table, he opened the abdomen whilſt the bird was yet alive, and paſſing a ligature round its meſenteric veſſels, as near to the root of the meſentery as poſſible, the lymphatics of this part became apparent in a few minutes. The ſame method alſo was purſued to expoſe the abſorbents of the neck. A ligature was placed round the jugular vein at the lower part of the neck; and to be more certain of incloſing the lymphatics which are near it, a ſufficient quantity of the ſurrounding ſubſtance was included by the ligature. In this way he ſucceeded in tracing the lymphatic ſyſtem, in more inſtances than one, after having filled the veſſels with quickſilver. He publiſhed a deſcription of the abſorbents, illuſtrated by two drawings, in the Philoſophical Tranſactions for the year 1748, and in his Experimental Inquiries into the lymphatic ſyſtem.

As no accounts or figures of the abſorbents of birds have been offered to the public ſince Mr. Hewſon's time, we cannot do better than adopt the deſcription, and copy the repreſentation left to us by that indefatigable anatomiſt; in doing which, we ſhall tranſcribe his own words.

"This ſyſtem conſiſts in birds, as it does in the human "ſubject, of three parts, viz. the lacteals, the lymphatic "veſſels, and their common trunk, the thoracic duct. The "lacteals indeed, in their ſtricteſt ſenſe, are in birds, "the lymphatics of the inteſtines, and like the other lym"phatics, carry only a tranſparent lymph; and inſtead of "one thoracic duct there are two, which go to the two "jugular veins. In theſe circumſtances, it would ſeem, "that birds differ from the human ſubject, ſo far at leaſt "as I may judge from the diſſection of a gooſe, which was "the bird I choſe as moſt proper for this inquiry, and from "which I took the following deſcription, after previouſly "injecting its lymphatic ſyſtem with quickſilver.

"The lacteals run from the inteſtines upon the meſenteric "veſſels. Thoſe of the duodenum paſs by the ſide of the "pancreas, and probably receive its lymphatics: afterwards "they get upon the cœliac artery. Whilſt they are upon "this artery they are joined by lymphatics from the liver. "Here they form a plexus, which ſurrounds the cœliac "artery: at this part they receive a lymphatic from the "gizzard; and a little farther, another from the lower "part of the œſophagus (or zone of gaſtric glands). Hav"ing now got to the root of the cœliac artery, they are "joined by the lymphatics from the glandulæ renales, or "renal capſules; and near the ſame part, by the lacteals "from the other ſmall inteſtines, which veſſels accompany

" the meſenteric artery. Theſe laſt mentioned lacteals, " before they join thoſe from the duodenum, receive from " the rectum a lymphatic, which runs with the blood-veſſels " of that gut. Into this lymphatic ſome ſmall branches " from the kidneys ſeem to enter, which, coming from " thoſe glands upon the meſentery of the rectum, at laſt " open into its lymphatics. At the root of the coeliac " artery, the lymphatics of the lower extremities probably " join thoſe from the inteſtines. The former," he ſays, "I " have not yet traced to their termination, though I have " diſtinctly ſeen them on the blood-veſſels of the thigh; " and in one ſubject which I injected, ſome veſſels were " filled, contrary to the courſe of the lymph, from the net- " work near the root of the coeliac artery. Theſe veſſels " ran behind the cava, and down upon the aorta, near " to the origin of the crural arteries; and I preſume they " were the trunks of thoſe branches which I had ſeen in the " thigh. At the root of the coeliac artery, and upon the " contiguous part of the aorta, a net-work is formed by " the lacteals and lymphatics above-deſcribed. This net- " work conſiſts of three or four tranſverſe branches, which " make a communication between thoſe which are lateral. " In the ſubject from which this deſcription was taken " there were four. From this net-work ariſe the two " thoracic ducts, of which one lies on each ſide of the ſpine, " and runs upon the lungs obliquely up towards the jugular " vein, into which it opens, not indeed into the angle be- " tween the jugular and ſubclavian vein, as in the human " ſubject, but into the inſide of the jugular vein, nearly " oppoſite to the angle. The thoracic duct of the left ſide " is joined by a large lymphatic which runs upon the œſo- " phagus, and can be traced as far as the lower or glan- " dular part of that canal, from which part, or from the " gizzard, it ſeems to iſſue. The thoracic ducts are joined " by the lymphatics of the neck (and probably by thoſe of " the wings), juſt where they open into the jugular veins.

" The lymphatics of the neck generally conſiſt of two " pretty large branches on each ſide of the neck, accom- " panying the blood-veſſels. Thoſe two branches join near " the lower part of the neck; and the trunk is in general " as ſmall, if not ſmaller, than either of the branches. " This trunk runs cloſe to the jugular vein, gets on its in- " ſide, and then opens into a lymphatic gland. From the " oppoſite ſide of this gland a lymphatic comes out, which " pours the lymph into the jugular vein. On the left ſide, " the whole of this lymphatic joins the thoracic duct of the " ſame ſide; but, on the right, one part of it goes into " the inſide of the jugular vein a little above the angle, " whilſt another joins the thoracic duct, and, with that " duct, forms a common trunk, which opens into the in- " ſide of the jugular vein, a little below the angle which " that vein makes with the ſubclavian.

" To this deſcription it may be neceſſary to add, that " though it be taken from one ſubject, yet in three others " of the ſame ſpecies, which I examined carefully, I ſaw " nothing which diſagreed with it. I particularly attended " to the number of the thoracic ducts, ſuſpecting that " poſſibly in this ſubject the two that I had ſeen might be " only a variety, which is a circumſtance that, as we are " told, has occurred even in the human body. But in " three others of this ſpecies, which I likewiſe ſucceſsfully " injected, I ſtill ſaw two ducts; and therefore I am in- " clined to believe, that this is the conſtant number. I " likewiſe carefully attended to the veſſels coming from the " gland on the right ſide; and in the only two ſubjects in " which the lymphatics of the neck were properly filled, " I obſerved that one part of it opened immediately into " the vein, and the other joined the thoracic duct. In all " the four ſubjects I evidently ſaw that the thoracic ducts " opened into the inſide of the jugular veins.

" This ſyſtem in birds differs moſt from that of quad- " rupeds, 1ſt, In the chyle being tranſparent and colour- " leſs; 2dly, In there being no viſible lymphatic glands, " neither in the courſe of the lacteals, nor in that of the " lymphatics of the abdomen, nor near the thoracic ducts; " 3dly, In the ſeveral parts of this ſyſtem in birds being " more frequently enlarged, or varicoſe, than in quadrupeds. " In particular, this appears to be the caſe of the veſſels " which conſtitute the net-work at the root of the cœliac " artery, in that ſubject from which the drawing was " taken. The lacteals are frequently enlarged in ſome " places; ſo are the thoracic ducts; and the lymphatics on " each ſide of the neck are commonly, when taken to- " gether, larger than their trunk, which opens into the " lymphatic gland. In one ſubject, when, inſtead of two " lymphatics on the left ſide, I found only one, that veſſel " was as large as a crow quill, whilſt the lower part of it, " which entered the gland, was much ſmaller."

The figures which explain the foregoing deſcription are to be found in *Plate* V. of the *Anatomy of birds*. *Fig.* 1. ſhews the abſorbents in their natural ſituation, with reſpect to the other parts of the body; A, the neck; B, B, the clavicle divided near its middle; C, the left ſubclavian artery; D, D, the jugular veins; E, E, the pulmonary arteries; F, F, the two branches of the trachea; G, G, the lungs; H, the aorta; I, the cœliac artery; L, the œſophagus turned to one ſide; M, M, the renal capſules; N, a ſmall part of the liver fixed to a rib by a thread; O, O, O, inteſtines; P, the duodenum; Q, the pancreas fixed to a rib by a thread; R, the gizzard. *Fig.* 2. exhibits the abſorbents, and their more immediate connexions with the veſſels, in outlines: *a*, the lacteals, or more properly lymphatics, which come from the *duodenum*; *b*, the lymphatics of the liver, N; *c*, *c*, a plexus formed by the above-mentioned lacteals and lymphatics, which ſurrounds the cœliac artery, I; *d*, a lymphatic from the gizzard; *e*, a lymphatic from the lower part of the *œſophagus*; *f*, *f*, a net-work formed by the lymphatics upon the *aorta*, H; *g*, *g*, the two thoracic ducts; *i*, *i*, the trunks of the lymphatics of the neck; *k*, *k*, the glands through which the lymphatic veſſels of the neck paſs: that of the left ſide is oblong, and could not well be repreſented in a Figure; *l*, the thoracic duct of the left ſide, and the lymphatic veſſel of the neck, opening together into the inſide of the jugular vein; *m*, a part of the lymphatic of the right ſide of the neck, opening into the jugular vein, D; *n*, the thoracic duct of the right ſide, joined by a part of the lymphatic veſſel of the right ſide, and then opening into the inſide of the jugular vein.

Heart.

This organ occupies the centre of the ſuperior portion of the common cavity of birds. It is placed uſually in the line of the body, as in quadrupeds; the heart, however, is inclined in the ſlighteſt degree to the left ſide in ſome inſtances, and in others a little to the right ſide. The apex of the heart is commonly received between the two chief lobes of the liver, which are hollowed out for its accommodation.

The membranous bag, which contains the heart, is formed like the pericardium of other animals, and is reflected in the common manner upon the origin of the great veſſels, and the heart. The pericardium of birds is generally conſiderably larger than the heart, and eſpecially at the lower part,

which is often prolonged for ſome way between the lobes of the liver. It deſerves remark, that notwithſtanding the great ſize of the pericardium, the air, which pervades almoſt all the cavities of birds, is not admitted into this. The Pariſian academicians, it is true, obſerved the pericardium to ſwell when they inflated the lungs and air-cells of the *pintado*, and thence concluded that the air had admiſſion to the heart, for which they aſſigned ſome curious reaſons; ſuch as the heart requiring compreſſion and evaporation from its ſurface. They appear, however, to have been equally in error with reſpect to the fact and the reaſoning; for, in a great number of ſpecies we have examined for the purpoſe, the pericardium was uniformly found to contain a certain quantity of water, and had not the leaſt communication with either the lungs or air-cells. The Pariſian anatomiſts muſt have been led into this miſtake by the diſtenſion of the air-cells around the pericardium.

The heart is of a longer figure in birds than in other animals; and the outline of the right ſide is ſlightly concave, in conſequence of the parietes of the right ventricle being relatively thin. In the *oſtrich*, the heart has been deſcribed as nearly round; meaſuring ſix inches from the baſe to the apex, and five inches acroſs.

Birds have, like mammalia, four diſtinct cavities in the heart, which bear the uſual proportions in magnitude with reſpect to each other. The auricles however, and eſpecially the right, are commonly more muſcular than in other animals; and the left ventricle is always much ſtronger than the right.

The internal ſurface of the auricles is very irregular, in conſequence of the ſhape and ſize of the muſcular faſciculi. There is one very ſtrong portion of muſcle, which enters into the compoſition of the auricular part of both cavities, from which other faſciculi proceed in a regular and radiated manner, at leaſt in the right auricle. See *Plate* V. in the *Anatomy of Birds*. *Fig.* 3. ſhews the heart of the *gooſe*, with the auricle and ventricle of the right ſide laid open, *e* the principal muſcular faſciculus of the auricular portion of the cavity paſſing backwards towards the left auricle; *f* the leſſer faſciculi, which depart from the other as branches from a trunk; *g g* the deep foſſæ which exiſt on each ſide of the large faſciculus.

The blood of the viſcera and lower limbs is conveyed into the right auricle by a vein correſponding to the inferior vena cava of mammalia. There is, however, no vein ſtrictly analogous to the ſuperior cava, the veins of the right wing and that ſide of the head and neck, form a diſtinct trunk, which enters the upper part of the auricle; while thoſe of the oppoſite ſide alſo produce another trunk, which paſſes along the poſterior ſurface of the left auricle, to which it is cloſely united, and opens into the right auricle beſide the inferior cava.

The anatomiſts of the French academy obſerved, in moſt of the birds they diſſected, a valvular projection of the inner membrane of the heart, over the entrance of the inferior vena cava into the right auricle. This valve reſembles in form that of the coronary vein of the human heart, and by its means, the oriſice of the cava, which is really very large, puts on the appearance of a narrow ſlit. A ſimilar valve hangs over the entrance of the veins which return the blood of the wings and head to the auricle. See *Plate* V. in the *Anatomy of Birds*, *fig.* 3. *a a a* point out the veins, which terminate in the right auricle with their valvular orifices, into each of which a briſtle has been introduced.

The analogy between the valves of the veins entering the right auricle of birds, and the Euſtachian valve of the human heart, is very obvious, and demonſtrates, as far as analogous ſtructure can, that the latter ſerves the purpoſe of a valve to the vena cava in the human ſubject.

There are commonly two or three orifices for the coronary veins in birds, one is always larger than the reſt, and tranſmits the blood of the principal vein of the heart. They are each provided with a ſlight projection of the inner membrane, which acts imperfectly as a valve.

The right ventricle is of a triangular figure, and is quite ſmooth on the internal ſurface; there being none of thoſe proceſſes of muſcle which are called *carneæ columnæ*.

The valve, which is placed at the mouth of the right ventricle, is of a peculiar ſhape and ſtructure in birds. Inſtead of thoſe thin and membranous folds, which uſually ſurround the orifice of the ventricle, and are moved by means of their connexion with the carneæ columnæ, and which from their figure in the human ſubject are called the *tricuſpid valve*; there is a ſingle projection of the fleſh of the heart, of a triangular figure, and nearly as thick as the parietes of the cavity in which it is contained. The triangular valve is joined by its ſuperior edge to the margin of the oriſice of the ventricle, and is united by another of its edges to the right ſide of the cavity almoſt to the bottom. The third edge is unconnected, except by a ſmall proceſs, which goes off near one of the ſuperior angles to the parietes of the ventricle on the left ſide. See *Plate* V. in the *Anatomy of Birds*, *fig.* 3. *b* the triangular valve, expoſed by means of the anterior parietes of the right ventricle being cut off, a briſtle is paſſed under the valve from the auricle; *d d d* the external ſurface of the heart; *c* the proceſs connecting the floating edge of the valve to the parietes of the ventricle, with a briſtle lying under it.

The triangular valve, from its thickneſs and muſcularity, would ſeem to operate chiefly by means of the contraction of its own fibres changing its figure, and thus obſtructing the return of the blood into the auricle. Borrichius diſcovered a foramen in the ſeptum of the heart of the *pigeon*, large enough to admit a briſtle, by which the two ventricles had a direct communication with each other. See Act. Dan. anni 1. obſerv. 96.; and we have obſerved the ſame foramen at the upper part of the ſeptum of the heart of the *gooſe* in one inſtance; it was of ſufficient ſize to receive a crow quill. Such a communication does not appear, however, to be an uniform or natural ſtructure, as we failed to diſcover it in other *geeſe*, and in different ſpecies of birds examined for the purpoſe. Indeed, a ready communication between the ventricles of an adult bird, would be inconſiſtent with the mode in which the functions of reſpiration and circulation are carried on in this claſs of animals.

The pulmonary artery is provided with three ſemicircular valves, as in mammalia. It divides alſo, as uſual, into a veſſel for each lung, and that of the right ſide paſſes under the arch of the deſcending aorta.

The blood is returned from the lungs by two pulmonary veins, which open very near each other into the upper and poſterior part of the left auricle.

The mechaniſm of the cavities of the left ſide of the heart more nearly reſembles that which exiſts in mammalia. The ſinus, or membranous part of the left auricle, is however very ſmall, and of an oblong ſhape; and at the place where the pulmonary veins enter into the auricle, there appears to be a projection of the internal membrane, which performs the office of a valve to their orifices.

The valve of the left ventricle is thin and membranous, and reſembles ſo much the *mitral* valve of the human heart, that the ſame name might with propriety be given to it.

The

The tendinous cords, however, which are attached to the margins of the valve, are not moved by diſtinct muſcular faſciculi, or *carneæ columnæ*, but proceed immediately to be loſt in the ſides of the ventricle. The lower part of the cavity is faſciculated, although not ſo remarkably as the internal ſurface of the ventricle of man or quadrupeds.

The aortic or ſemicircular valves are to be found at the origin of the great arterial trunk from the left ventricle.

The above account of the mechaniſm of the heart of birds ſhews that this organ is calculated to exerciſe its functions preciſely in the ſame manner in theſe animals as in mammalia; and that the pulmonary and general circulations are maintained by different chambers of the heart; conſequently every particle of blood is expoſed to the influence of the air in the lungs, previous to its diſtribution throughout the ſyſtem for the purpoſes of nutrition, excretion, &c. Before the deſcription of the veſſels of general circulation is entered upon, it is in order therefore to treat of the organs of reſpiration, or the

Lungs.

Theſe bodies are ſituated on each ſide of the dorſal ſpine, upon the ſurface of the ribs and intercoſtal ſpaces, uſually reaching in length from the ſecond rib to the laſt intercoſtal ſpace but one, and extending in breadth from the ſpine to about that part of the ribs, where the proceſſes are ſent from one to the other. In the *oſtrich*, the lungs were found to meaſure ten inches long, and three and an half broad, and were one inch and an half in thickneſs.

The lungs of birds never move from their poſition, as they adhere to the inſide of the cheſt, and are covered over by a ſtrong membrane or aponeuroſis.

They are ſmooth and even on the anterior part; but their figure poſteriorly exactly correſponds with that of the parts upon which they are laid. The ribs and intercoſtal ſpaces ſerve as a mould, of which the lungs are the perfect caſt, preſenting a remarkable projection for each depreſſion between the ribs. Theſe eminences are of courſe moſt ſtriking next the ſpine; and towards the anterior edge of the lungs, which is very thin, they are ſcarcely viſible.

The lungs have two coverings; one is ſomewhat analogous to the *pleura*, though not exactly ſimilar to it in ſtructure, being more like condenſed cellular ſubſtance. It cloſely inveſts each lung, and appears to be floculent on ſome parts of its ſurface, and to adhere to the parietes of the cheſt. The other coat is common to both lungs; it is extended from each ſide of the cheſt to the dorſal ſpine acroſs the anterior ſurface of the lungs. It is connected in a degree to the fore-part of the ſpine, and incloſes at this place the trunk of the deſcending aorta, ſuffering the cœliac artery to paſs through it. It has no intimate union with the proper tunic of the lungs except at the openings of the air-cells, and around the entrance of the great veſſels of the lungs. The texture of this coat appears to be tendinous; its fibres all run in the tranſverſe direction; and in large birds they are evidently white. This aponeuroſis is not equally ſtrong upon every part of the lungs; at the upper part, and eſpecially above where the veſſels enter, it is ſo weak as often to be hardly viſible.

In all birds there would appear to be ſome muſcular fibres paſſing from the ſide of the cheſt upon the aponeuroſis of the lungs. Theſe are very diſtinctly to be ſeen in the larger ſpecies, in ſome of which the muſcles of the lungs are of conſiderable ſtrength. The anatomiſts of the French academy obſerved ſix ſtrong ſlips of muſcle on each ſide of the body in the *oſtrich* and *caſſowary*. They aroſe from the ribs which come from the ſpine, near their junction with thoſe which belong to the ſternum, and terminated in the aponeuroſis which covered the lungs. Mr. Ranby diſcovered eight muſcular faſciculi to each lung of the *oſtrich*. See Phil. Tranſ. N° 386. p. 223. We have noticed only four broad thin ſlips of muſcle in the *gooſe*, which proceed from the articulation of as many vertebral ribs with the ſternal; in the common *fowl*, the muſcles of the lungs do not preſent the appearance of diſtinct ſlips, as in other inſtances, but are ſpread as a ſingle layer upon each lung.

It is difficult to ſpeak with certainty of the uſes of the pulmonary muſcles. The effect of their contraction appears to be the tenſion of the aponeuroſis, and conſequently the elevation of it into a flat ſurface which is ordinarily concave or depreſſed. This would neceſſarily produce ſome dilatation of the lungs; and therefore theſe muſcles might be reckoned amongſt the agents of inſpiration, although their operation in this way would be very trifling.

The Pariſian anatomiſts attributed ſeveral uſes to them; they ſuppoſed that theſe muſcles had the power of depreſſing the anterior part of the thorax, in conſequence of their attachment to the moveable angle of the ribs, and their oblique courſe upward to the ſpine. If they be allowed to perform this effect, they muſt be conſidered as muſcles of expiration.

They imagined alſo that they cauſed, when in action, a conſtriction of the foramina through which the air is admitted into the great air-cells of the thorax or upper part of the body, and thus enabled the bird to maintain a continued diſtenſion of theſe cells, in order to diminiſh the ſpecific gravity of its body during the time it remained on wing; or (what the academicians thought more probable) furniſhed the bird with a ſupply of common air to carry with it into the regions of the atmoſphere, in which the air would be too thin and light for reſpiration; in the laſt conjecture, however, they ſeem to have forgotten the effect that the temperature of the bird's body would produce in the rarefaction of the air contained in the cells.

When the lungs of birds are ſtripped of their coverings, there are ſtill found to be a connected, uniform ſubſtance, and not reducible into lobes or lobules as in mammalia; they appear, to a ſuperficial view, ſolid and fleſhy, but if examined more clearly, are ſeen to be made up of the ramifications of the great blood-veſſels, the bronchiæ, and very minute air-cells.

When the bronchiæ enter the lungs, their chief branches, inſtead of being regularly and equally diſtributed, paſs directly to certain points upon the ſurface of the lungs, and there terminate in ſeveral foramina, which communicate with the great air-cells of the body; theſe branches alſo of the bronchiæ retain in their ſtructure, almoſt throughout their extent, ſome cartilaginous rings. The ramifications of the air tube which really ſupply the ſubſtance of the lungs, are but branches of thoſe which go to the cells. They are comparatively ſmall, and entirely compoſed of membranes. This ſtructure accounts for the fleſhy appearance and ſolid feel of the lungs, and explains why birds are able to fill their air-cells with ſo much eaſe and rapidity.

Air-Cells.

Although phyſiologiſts are not agreed with reſpect to the uſes which theſe parts ſerve in birds, yet as they are immediately connected with the lungs, it ſeems moſt proper to deſcribe them in this place. It is one of the moſt remarkable and peculiar circumſtances in the anatomy of birds, that the atmoſpheric air has a ready paſſage to almoſt every part of the interior of their bodies.

The air-cells, according to their ſituation, may be divided

into three kinds. 1. Thoſe of the great cavity of their body which takes the place of the thorax and abdomen. 2. Thoſe ſituated amongſt the muſcles; and laſtly, thoſe in the interior of their bones.

It has been already ſtated, that the body of birds is not divided into two parts by a tranſverſe muſcular partition or diaphragm. This common cavity is interſected by a great number of membranes, ſome of which ſimply encloſe the ſeveral viſcera, but the greater number form cells, which are filled from openings upon the ſurface of the lungs.

Theſe membranes are in moſt birds extremely fine and delicate, often ſo much ſo, that the viſcera are perfectly viſible through them; they are almoſt impoſſible to be diſſected unleſs when kept continually inflated, by blowing into the trachea; it is ſaid, however, that in the *oſtrich* and *caſſowary*, they are as ſtrong as a hog's bladder.

The anatomiſts of the academy deſcribe the heart and liver of the *oſtrich* as contained in one cavity, which was unfurniſhed with air, and was ſeparated from the air-cells on the ſide by two longitudinal membranes, and from the ſtomach and inteſtines below, by a tranſverſe membrane, ſituated like the diaphragm of mammalia, and covered on its inferior ſurface by a layer of fat, of the thickneſs of a finger; in all the birds, however, which we have examined, we have found a membrane incloſing the pericardium, in the manner of the mediaſtinum, and afterwards reflected upon the liver, and then forming two ſacks, of which one contained the right lobe of the liver, and the other included the left lobe, along with the anterior ſurface of the gizzard; and in the *gooſe*, and ſome other birds, the membranous ſack of the left ſide of the liver only admitted into it the upper half of the anterior part of the gizzard; in general, no air is found in the cells which encloſe the liver and the anterior part of the gizzard; we, however, once inflated them from the trachea in the *gooſe*, in which they had a communication with the cells of the abdomen, by means of three large holes; but it is probable, that this was from mal-conformation of the membrane.

The *air cells of the great cavity* of birds, according to the academicians, who take their deſcription from the *oſtrich* and the *caſſowary*, are five on each ſide of the body. The four ſuperior cells are immediately next the aponeuroſis of the lungs, and are ſeparated from the reſt of the cavity by a ſtrong membrane which deſcends from the top of the thorax upon each ſide to be joined to the tranſverſe membrane which divides the heart and liver from the ſtomach and inteſtines. The inferior cells are by much the largeſt, and are kept diſtinct from the inteſtines by a ſtrong membrane, ſimilar to the other partitions of the cavity, they come in contact with the aponeuroſis of the lungs, only at their ſuperior part, where they receive their air. The uppermoſt cell is the ſmalleſt, and derives its air from an opening at the ſuperior part of the lungs. The next cell is of a ſquare figure, and is filled by means of two foramina ſituated upon the external edge of the lungs. The third cell of each ſide is not a regular ſquare, being of greater extent where it joins the lungs than at the oppoſite ſide; it has but one communication with the bronchia, which is placed upon the internal margin of the lungs. The fourth cell is of a very irregular elongated form, reaching down to the bones of the pelvis; it is leſs extenſive in the *caſſowary* than in other birds. The air-hole of this cell is ſituated at the loweſt part of the lungs. The laſt or inferior cells are long, and ſomewhat of an oval ſhape; they communicate with the moſt inferior point of the lungs.

The Pariſian anatomiſts deſcribe all theſe cells as being formed of diſtinct tunics, ſo that each is a ſeparate bag, inſtead of being made by continuous and reflected membranes. They repreſent the bags to be diſtinct alſo from the great membranous partitions of the cavity. See *Plate* V. in the *Anatomy of Birds; fig.* 4. is copied from the memoirs of the French academy, and exhibits the air cells, &c. of the *oſtrich; a* the trachea; *b b* the two bronchiæ paſſing to the lungs; *c* the heart; and *d d* the liver, ſeen in the ſuperior diviſion of the cavity; *e* the tranſverſe membrane which ſeparates, like the diaphragm, the common cavity into two parts; *f* the ſtomach; and *g g g* the convolutions of the inteſtine, ſeen in the lower or abdominal portion of the cavity; *h h h h* the lateral partitions which incloſe the four ſuperior cells; 1 2 3 4 5 indicate the different cells; the air holes are apparent in each, except the inferior or abdominal cells, which cannot be brought into view, as they lie behind the fourth cells.

The air-cells of birds in general do not exactly accord with the deſcription given of the *oſtrich* and *caſſowary*, by the members of the Royal Academy; we ſhall therefore proceed to give an account of what we have obſerved on this part of the anatomy of birds in the *gooſe*, *duck*, *common fowl*, *pigeon*, &c.; and in order to make this deſcription more intelligible, we ſhall take the liberty of naming the cells according to their ſituation with reſpect to other parts, although ſome of the terms muſt be adopted upon the ſtrength of analogy, as the diſtinctions of thorax and abdomen do not with ſtrictneſs belong to birds.

The firſt is the *ſuperior thoracic*, or *jugular air cell*. When it is diſtended with air, it becomes evident upon the outſide of the thorax, between the two branches of the fork; it is large enough in the *gooſe* to contain an apple in its anterior part, and poſteriorly it extends on each ſide of the baſis of the heart, over the lungs. This cell contains the diviſions of the trachea into the bronchiæ, and the trunks and primary branches of the blood-veſſels which ſupply the wings and head. A great number of membranous ſepta paſs through it in various directions, which ſerve to connect and keep ſteady the different veſſels, and alſo divide this cell into ſeveral chambers, which, however, have all a free communication with each other. The air is tranſmitted from the ſuperior part of each lung by two openings which are placed in the poſterior chambers of this cell. Theſe chambers do not appear to extend ſo far upon the lungs in other birds as they do in the *gooſe*; it is from this cell that the air paſſes into the cells of the axilla, and under the fork-ſhaped bone, into the deep ſeated cells of the neck, and to thoſe about the ſhoulder.

The next cells may be called the *intermediate thoracic*. They are generally two in number, one to each ſide; they lie immediately upon the lungs, and are in a degree covered by the anterior thoracic cell. That of the right ſide is uſually larger than the one on the left; the latter is particularly ſmall in the *gooſe*, being almoſt concealed by the two adjoining cells, and extending under the poſterior part of the liver. The cell of the right ſide is of an oblong ſquare figure, and is prolonged under the termination of the inferior vena cava in the right auricle, as far as the left ſide of the bulbus glandulofus. The intermediate thoracic cells receive their air through a large foramen, ſituated upon the inner edge of each lung, juſt at the baſis of the heart. At the upper and inner angle of theſe cells alſo there is an opening which appears to lead to ſome ſmall cells under the pericardium and œſophagus, and to communicate indirectly with the anterior thoracic cell.

The

The *lateral thoracic cells* are amongſt the largeſt of the body. They are of a pyramidal figure, their baſis being applied to the intermediate thoracic cells, and their point reaching as far down as the bones of the pelvis; they cover the inferior portion of the lungs, and occupy a ſpace between the ribs and the lobes of the liver. They have a very free communication with the branches of the bronchiæ, at the external edge of the lungs.

As the intermediate thoracic cells are ſmall on the left, and large on the right ſide, theſe cells are larger on the left ſide than on the right: this diſproportion is moſt obſervable in the *gooſe*, and very trifling in the *duck*, in which the two intermediate thoracic cells are nearly of an equal magnitude.

The air-cells, which are found in the lower or abdominal portion of the cavity of birds, are compoſed of thinner membranes than the others; in ſome parts they are ſo tender, that they are ruptured with the ſlighteſt touch, from which they become very difficult to examine.

Underneath the lateral thoracic cells, at the very loweſt part of the lungs, on each ſide of the ſpine, the branches of the bronchiæ open into the cavity of the abdomen, by which means air is conveyed directly into the two great *lateral abdominal cells*, and from theſe it would appear that it paſſes into the others.

The *lateral abdominal cell* of the right ſide is by much the largeſt in the body; it reaches from the laſt ribs to the anus, and lies over and includes almoſt all the ſmall inteſtines, the renal capſule, and the kidney. It appears in the *gooſe* to be divided from the oppoſite cell by a membrane which paſſes obliquely from the right ſide of the anus to the lower part of the gizzard.

The *left lateral abdominal cell* contains the inteſtines of that ſide; it is attached to the margin of the gizzard, under which it is prolonged as far as the lungs, where it is ſupplied with air, as already mentioned.

The lateral abdominal cells tranſmit air to the inguinal cells, and to ſeveral chambers formed by the moſt delicate membrane, amongſt the inteſtines. One of theſe being ſomewhat ſtronger than the others, there was an opportunity of obſerving it more diſtinctly. It makes a circuit around the right ſide of the gizzard to which it is attached, and incloſes the duodenum and pancreas; it might thence receive the name of the *duodenal cell*.

Interpoſed between the parietes of the belly and the lateral cells there is frequently found a conſiderable quantity of tender fat; eſpecially in aquatic birds, ſuch as the *gooſe*, &c. By this means a ſoft cuſhion is provided for the ſmall inteſtines to preſs and move upon, thus ſupplying the uſe of the *omentum*, which is a part not met with in birds.

The ſtructure of the air-cells of birds in general does not appear to be the ſame deſcribed in the *oſtrich* and *caſſowary* by the academicians. The membranes compoſing them inſtead of being diſtinct bags, as they relate, reſemble rather the pleura or the peritoneum, and like them, ſeem to produce all the different cavities by the means of reflection. It muſt be confeſſed, however, that the membranes of the cells, eſpecially in the abdomen, are very eaſily ſeparable into different lamina, or layers, which, it might be ſuppoſed, could be ultimately reſolved into diſtinct ſacks.

It deſerves to be mentioned, that each of the air-holes in the ſurface of the lungs opens obliquely into the air-cells; there being a ſlight projection of thin membrane over the aperture. The Pariſian anatomiſts aſcribed a valvular effect to this ſtructure, which they ſuppoſed of great conſequence, as it would ſerve to continue the diſtenſion of the air-bags, after they were once inflated. The projection of the membrane over the air-holes does not however appear to be ſufficient to cauſe any obſtruction to the regreſs of the air from the cells; nor would it ſeem neceſſary or convenient to interrupt in the leaſt degree the expulſion of the air contained in the cells.

The membranes of which the air-cells are compoſed, are reflected into the apertures of the air-holes, and are there perforated by a great number of ſmall foramina, which correſpond to the termination of the ramification of the bronchiæ, through which the air has a ready paſſage. When theſe foramina are brought into view, by diſſecting of the coverings of the lungs, they give the anterior ſurface an appearance of being pricked by pins.

The air-cells which are found amongſt the muſcles and integuments of the external parts of the body, vary in number and magnitude, according to the ſtructure and economy of the bird. In every inſtance, perhaps, the anterior thoracic or jugular cell is continued along with the veſſels and nerves into the axilla, making what may be called an *axillary cell*, and in moſt birds others go off from this anteriorly under the pectoral muſcle, and backwards under the muſcles of the ſcapula, forming *pectoral* and *ſubſcapular cells*. In the *eagle*, *hawk*, *ſtork*, *lark*, and other high flying birds, theſe cells are very large, and in many of thoſe birds there are ſtill larger cells, aſcending under the integuments of the neck, and paſſing beneath the ſkin of the inſide of the arm, and the back of the ſhoulder. In the *ſtork* we found theſe cells large enough to admit the finger to paſs a conſiderable way down upon the inſide and the back of the wing. They are alſo large in the *owl* and other birds of prey.

Moſt birds of flight have a number of cells placed under the lateral muſcles of the neck. Theſe are oppoſite to the bodies of the cervical vertebræ, and communicate with one another. It is from the different cells about the axilla and neck, that the bones of the ſhoulder, the humerus, and the vertebræ, receive the air which they contain.

The *inguinal* and *gluteal cells* are filled from the great lateral cells of the abdomen, with which they have a communication, where the blood veſſels of the lower extremities paſs out of the pelvis. The inguinal and gluteal cells furround the neck of the femur; they are in moſt birds very ſmall, but in thoſe which are much employed in flight, eſpecially if the thigh bones receive air, they are larger, extending for ſome way amongſt the muſcles behind the joint. Camper obſerved two air bags between the glutæi muſcles of the genus *ſpoonbill* (*platalea*), although no air was tranſmitted into the femur.

The ſubcutaneous air-cells of the *pelican* are very large, and were deſcribed long ago by Mery, in the early Memoirs of the Academy of Sciences of Paris.

Several means have been employed to prove that the air is permitted to enter the cavity of the bones in birds. The air-cells and the lungs have been inflated from the bones, and injection being thrown into the trachea, was found, after diſtending the air-cells, to have paſſed into the interior of the bones. A ſtill more deciſive experiment (although a cruel one) is to cut the humerus acroſs in a living bird, and introduce the extremity of the divided bone into water, in which ſome ſoap has been diſſolved, when it is perceived that bubbles are produced by the exit of the air from the end of the bone. This expedient not only aſcertains the exiſtence of air in the bone, but ſhews that there is a motion or circulation of it, which is the effect of the actions of inſpiration and expiration.

This ſubject has been very extenſively inveſtigated by Cam-

per;

per; he diſcovered the communications between the cavities of the bones and the air-cells of the ſoft parts, and aſcertained in a great number of ſpecies what bones were filled with air.

The reſult of both his obſervations and our own tends to ſhew, that the bones of birds are ſupplied with air, according as they are employed in the locomotion of the animal's body. In birds of flight, therefore, almoſt all the bones are hollow, and receive air; thus in the *eagle* Camper found the air-cells communicated with the thigh bones, thoſe of the pelvis and coxyx, all the vertebræ, the ſternum, clavicles, ſcapulæ, and fork-ſhaped bone, and the bones of the wing. The air was alſo admitted into the bones of the head from the cavity of the tympanum. We have obſerved the bones in the *hawk* and *ſtork* to want marrow in the ſame manner as thoſe of the eagle. Moſt of the bones are hollow in the *owl*; but the os femoris is filled with marrow. The *pigeon* kind in general alſo have no air in their thigh bones, although the *crown pigeon* has been obſerved by Camper to poſſeſs it.

Birds even of moderate powers of flight, receive ſome air into the ſternum and other bones of the trunk, and between the plates of their cranium; and all birds, whoſe wings are not incapable of flight, have the humerus filled with air, with the exception of the *woodcock*, which has been obſerved to poſſeſs marrow in the humerus; but to counterbalance this impediment to the velocity of its motion, it is provided with pectoral muſcles of unuſual ſtrength.

Thoſe birds which are unable to tranſport themſelves for any diſtance by the effort of their wings, are deprived of air in the humerus; of theſe may be inſtanced all the *ſtruthious* kind, the *penguin*, the *puffin*, &c. It is worthy of remark, however, that the *ſtruthious* birds, which run with great rapidity, have moſt of their other bones hollow; Camper diſcovered the air to paſs into the thigh bones and lower jaw of the *oſtrich*, and we have obſerved that it fills not only theſe bones, but the ſternum, the ribs, the vertebræ, and the bones of the pelvis, in both the common *oſtrich* and that from New Holland.

The internal ſurface of thoſe bones which contain air have been deſcribed by Camper as being in ſome caſes lined with perioſteum, and in others entirely deprived of it; thus he ſtates the internal part of the femur of the *eagle* to be cancellated and furniſhed with a perioſteum, upon which ſeveral blood-veſſels are ramified, and the humerus of the ſame bird to be a ſimple oſſeous tube, without membrane, veſſels, or cancelli. It appears to us, however, that the membranes of which the air-cells are compoſed, are continued in every inſtance into the interior of the bone, to which they may ſerve, it is true, the purpoſe of a perioſteum, although in ſtructure they are much more fine and delicate, and when theſe membranes ceaſe to be vaſcular, they become dry, and adhere ſo cloſely to the ſurface of the bone, that they are not eaſily perceived.

The internal parts of the bones of birds which are filled with air conſiſt of cells, like thoſe of other animals; the only difference that can be obſerved is, that the cancellated ſtructure is leſs cloſe, and that the tube of the cylindrical bodies, ſuch as the humerus and femur, is larger than uſual.

It has been already mentioned, that the bones derive their air in general from thoſe cells which are placed next them amongſt the muſcles. Some, however, are filled immediately from the lungs, or the large internal air-cells, and the bones of the head and jaws have communications with the Euſtachian tube, the cavity of the tympanum, and the ſinuſes of the noſe.

The humerus is ſupplied with air by the axillary cell, by means of an opening ſituated at the inner and back part of the head of the bone. See *Plate* VI. in the *Anatomy of Birds*; *fig.* 1. repreſents the ſuperior half of the humerus of the *American turkey* (*meleagris*); *a* the air hole, which like the air-holes of the lungs, does not open immediately into the cavity of the bone, but contains a number of ſmaller foramina, that are produced by the cancelli, and have a direct communication with the internal part of the humerus.

The fork-ſhaped bone is filled from the jugular air-cell, from which alſo the ſuperior dorſal, and the loweſt cervical vertebræ, receive ſome air, through ſeveral ſmall holes ſcattered upon their lateral and anterior parts. The air-hole of the fork is placed upon the ſide of its ſcapular extremity, next the ſpine. See *Plate* VI. in the *Anatomy of Birds*; *fig.* 2. is the one half of the fork-ſhaped bone of the *ſtork* viewed upon the inſide, *a* the air-hole.

The clavicle appears to obtain its chief ſupply of air from the cells which are continued from the jugular air-cells backwards upon the ſhoulder joint.

The principal foramen is found on the inſide of the clavicle, where that bone is connected to the branch of the fork. There are beſides this, ſome very minute holes upon the outſide of the clavicle, immediately above the ſhoulder joint; and on each ſide of the ſternal extremity of the bone, there is a hole large enough to admit a briſtle. See *Plate* VI. in the *Anatomy of Birds*. *Fig.* 3. ſhews an internal view of the clavicle of the *ſtork*; *a*, the larger air hole at the joint of the ſhoulder; *b*, one of the ſmall foramina which opens into the cheſt, containing a briſtle.

The ſcapula derives air alſo from the proceſs of the jugular cell behind the joint. It is tranſmitted through ſeveral holes upon the very extremity of the bone. See *fig.* 4. of *Plate* VI. of the *Anatomy of Birds*, *a* the air holes.

We have diſcovered the openings by which the air is conveyed into the ſternum, to be exceedingly numerous. The principal foramina are ſituated all along the middle line of the bone, upon the internal ſurface, which appears reticulated, or made of cancelli. Towards the anterior part there is one hole much larger than any of the reſt; and in addition to thoſe of the middle of the bone, there are many others paſſing into the edges of the ſternum to which the ribs are articulated. All theſe foramina would appear to communicate with the thoracic cells. See *Plate* VI. in the *Anatomy of Birds*; *fig.* 5. exhibits the internal ſurface of the ſternum of the *ſtork*; *a a a* the ſmall foramina in the middle of the bone, *b* the principal air-hole near the top of the ſternum, *c c c c* many little foramina ſeen between the ſternal ribs which lead to the lateral parts of the bone.

The vertebræ of the back ſeem to procure air immediately from the lungs; the foramina are numerous, and placed along the ſides of the bodies of the vertebræ and at the roots of their tranſverſe proceſſes. The foramina which conduct the air into the cervical vertebræ, occur with as little regularity; the three firſt have their largeſt holes upon the ſides of their bodies, and in the reſt they are to be found within the canal of the tranſverſe proceſs for lodging the vertebral artery, and along the courſe of the ſpinal canal, at leaſt ſo they have appeared in the *ſtork*. See *Plate* VI. in the *Anatomy of Birds*. *Fig.* 6. ſhews one of the cervical vertebræ of that bird, *a* the body of the bone, *b* the ſpinous proceſs, *c c* the tranſverſe proceſſes forming a portion of the vertebral canal, on the inſide of which are perceived ſeveral foramina leading into the ſubſtance of the bone, *d* the tube behind the body of the vertebra for containing the ſpinal marrow, exhibiting many ſmall holes upon its internal

nal ſurface. The foramina of the cervical vertebræ have communication with the lateral air-cells of the neck.

The air-holes of the anterior ribs are placed upon the ends of theſe bones, where they are joined to the ſternum. They are ſupplied from the intermediate and lateral thoracic air cells. See *Plate* VI. in the *Anatomy of Birds*, *fig.* 5. *dddd* refer to the opening upon the ſternal ribs.

The air paſſes into the poſterior or vertebral ribs by a number of foramina, ſituated upon the internal ſurface of their extremities next the ſpine. Theſe foramina appear to have from their ſituation a direct communication with the poſterior ſurface of the lungs. See *Plate* VI. in the *Anatomy of Birds*. *Fig.* 7. is a vertebral rib of the *ſtork* ſeen upon its inner ſide, *a* the proceſs which articulates with the bodies of the dorſal vertebræ, *b* the part joined to the tranſverſe proceſſes, *c c* the ſeveral air-holes.

The air-holes of the bones of the pelvis are ſo numerous, and occur with ſo much irregularity, that they do not admit of a particular deſcription. They are all ſituated upon the internal ſurface of the bones, and appear to be confined to that ſpace covered by the kidnies, under which the air muſt inſinuate itſelf from the abdominal cells, in order to reach them.

The paſſage of the air into the femur of the *eagle* and *ſtork* is through an opening upon the fore part of the bone, juſt within the proceſs correſponding to the great trochanter. It is a round depreſſion, under the edge of which the apertures leading to the cavity of the bone are ſituated. See *Plate* VI. and *fig.* 8. of the *Anatomy of Birds*, which repreſents the femur of the *eagle* ſeen upon the anterior ſide; *a* the air hole, *bb* the cavity of the bone laid open, exhibiting a number of oſſeous proceſſes, paſſing in all directions, dividing the bone on the inſide into many irregular cells; theſe are moſt numerous towards the extremities of the femur, and are hardly to be ſeen in the centre; *c* an artery diſtributing its branches to the membrane which lines the internal part of the bone. The air-hole of the femur in theſe birds communicates with the gluteal cells.

In the *ſtruthious* birds the air-holes of the femur are placed upon the poſterior part, and are found upon both the upper and lower portions of the bone. See *Plate* VI. in the *Anatomy of Birds*. *Fig.* 9. ſhews the poſterior ſurface of the femur of a *young oſtrich*; *a* a depreſſion on the upper part of the bone, containing a number of air-holes, *b* the inferior depreſſion with only three foramina.

The air-holes of the lower jaw have been obſerved in the *African* and *New Holland oſtriches*, the *ſtork*, the *buceros naſutus* and *buceros rhinoceros*, and the *crow*; and in all theſe they conſiſt of two holes ſituated upon the two extremities of the jaw behind the articulation. See *Plate* VI. in the *Anatomy of Birds*. *Fig.* 10. is the lower jaw of the *crow*; *a a* the two air-holes. Theſe foramina communicate by a tube with the cavity of the ear.

The air does not penetrate the bones of the head and jaws in *water fowls*.

Having deſcribed the diſtribution of air, which takes place throughout the bodies of birds, it remains to aſſign an uſe to this moſt curious and peculiar circumſtance in their anatomy. It has been already ſtated, that the opinions of anatomiſts upon this ſubject are different. The members of the French academy ſuppoſed that the air-cells were neceſſary to carry on the actions of reſpiration in birds. Camper thought that air was admitted into the bodies of birds for the purpoſe of diminiſhing their gravity in relation to their bulk, and thus facilitate their motions; while Mr. Hunter, the greateſt phyſiologiſt of this or any other country, felt unwilling to confine the functions of the air cells to any one purpoſe, and ſuſpected they might be uſeful in giving tone and ſtrength to the ſong of birds.

The obſervations of the academicians appear to us perfectly ſatisfactory with reſpect to the connection between the exiſtence of the air-cells, and the office of the lungs. They have related, that during the act of inſpiration the ſternum was elevated, and the thoracic air-cells diſtended at the ſame moment with the lungs, and that when the air was expelled from the lungs and thoracic cells, by the depreſſion of the ſternum, one portion of it was expired by the trachea in the uſual way, and the reſt was urged into the cells of the abdomen, the two parts of the cavity thus becoming alternately enlarged and diminiſhed. In order to aſcertain with the more certainty the condition of the air-cells during reſpiration, the academicians ſubjected ſeveral large birds, ſuch as the *turkey*, *gooſe*, &c. to the experiment of having the parietes of the belly diſſected off without injuring the air-cells, while the animal was ſtill alive, by which they had an opportunity of obſerving, that the air-cells below the ſternum were rendered tenſe during the time the thorax was diminiſhed for exſpiration, and that as ſoon as the ſternum was raiſed to increaſe the capacity of the thorax, the abdominal air-bags become flaccid. We have made an experiment of a ſimilar kind, with the ſame reſult; the abdomen of a living *gooſe* was laid open, from which no air proceeded during inſpiration, but while the air was diſcharged from the lungs, it paſſed into the abdominal cells and through the opening of the belly with ſo much force as to blow out a candle. The neceſſity of having the cavity filled with air in birds, obviouſly ariſes from the circumſtance of the lungs being confined to the poſterior part of the thorax, and conſequently not capable of ſuffering any compreſſion from the contraction of the cheſt, but by the interpoſition of ſome other parts.

Many have ſuppoſed that the air-cells were not only mechanically ſubſervient to the actions of reſpiration, but anſwered another important purpoſe by collecting a quantity of air, which in repaſſing the lungs effected a further change upon the blood, thus producing a ſort of double reſpiration; but the free communication which exiſts between the lungs and the cells, renders it probable that the air on its return paſſes directly by the air-holes into the branches of the bronchiæ, and, conſequently, is never brought into contact with the blood. It would therefore appear that the only part the cells perform in the proceſs of reſpiration is to ſupply an elaſtic medium, by means of which the motion of the ſternum and ribs, equally and regularly affect every part of the lungs.

The air-cells making part of the mechaniſm of the organs of reſpiration, does not preclude them from anſwering other purpoſes in the animal economy. It is plain to demonſtration that the bodies of birds loſe much of their relative weight by containing air in their cavities, and ſtill more from its admiſſion into the external parts and the bones; the advantages of which in tranſporting themſelves through ſo light a medium as the air, or even in locomotion upon a ſolid ſurface, are too obvious to be inſiſted upon.

The air while it remains in the body, neceſſarily acquires the temperature of the living bird, which renders it much lighter even than atmoſpheric air, and therefore it acts like that contained in the ſwimming bladder of fiſhes.

A compariſon of the ſtructure of one bird with another proves that the quantity of air is in proportion to the rapidity and continuance of the animal's motion, all other circumſtances being the ſame; and that the air is diſtributed always in preference to thoſe members which are moſt employed in locomotion, as has been already pointed out.

It might be offered in objection to this opinion of the uſe of the air-cells in birds, that the *bat*, which is an animal very remarkable for the velocity of its flight, and its long continuance on the wing, is unfurniſhed with any apparatus except its lungs for containing air. The anſwer to this, however, is very eaſy; the extent of the wing of the *bat* is ſingularly large for the animal, and its membranous ſtructure enables it to give impulſe to a larger volume of air than could be produced by a wing compoſed of feathers, even of an equal extent; and further, the pectoral muſcles of the *bat* are larger in proportion to the animal than they are found in any ſpecies of birds, even thoſe of the higheſt flight; ſo that the ſtructure of the *bat*, inſtead of proving any objection to the uſes aſſigned to the air-cells in birds, affords the ſtrongeſt confirmation of the theory.

Notwithſtanding the reſpect which is due to every phyſiological opinion of Mr. Hunter, we cannot perceive that there is the leaſt relation between the air-cells and the organs of voice in birds. With a view of determining this, we have compared the ſtructure of different birds, and have not found the air-cells larger in ſinging birds, than others. The *nightingale*, ſo eminent for its loud and protracted notes, is formed, with reſpect to the air-cells, exactly like the *common ſparrow*.

Animal Heat.

Although it is not yet proved that the vital temperature of animals is the reſult of that proceſs which is called reſpiration; yet, as it is generally ſuppoſed to be ſo, it would appear moſt proper to notice the animal heat of birds, immediately after the deſcription of the lungs and their appendages. It is remarkable, that birds poſſeſs a higher ſtandard of vital temperature than all other animals. Camper ſtates it to vary from 104 to 107 degrees of Fahrenheit's ſcale. Mr. Hunter found the rectum of the common *fowl* to be 103, 103½, and 104 degrees; and in a young *gooſe*, we obſerved the thermometer to ſtand at 103 degrees in the rectum, and when inſerted into the cavity of the body, to riſe and remain at 104 degrees. It is difficult to explain either the cauſe or the neceſſity of the high temperature of birds. It has been accounted for by their reſpiration being more perfect from the air paſſing twice through their lungs; but even ſuppoſing this would alter their degree of animal heat, the occaſion does not ſeem to exiſt, as birds have not that double reſpiration which is ſuppoſed, as has been already ſhewn.

It is to be preſumed, that the warmth of birds may depend, in a degree, upon the ſtructure of their ſkin, and the nature of their coverings, which are not deſigned to admit of much evaporation from the ſurface of their bodies; but it can hardly be ſuppoſed, that this, of itſelf, would be ſufficient to produce a temperature ſo much higher than is found in other animals, and maintain it ſo uniformly and permanently as it exiſts throughout the whole claſs of birds.

No experiments have yet been made to determine the powers which birds poſſeſs of reſiſting the influence of external temperature; but it is to be inferred from analogy, that they can ſuſtain greater extremes of both heat and cold than other animals, without ſuffering an alteration in their proper degree of temperature; but that, at the ſame time, birds would ſooneſt yield to diſſolution upon any material change in their natural ſtandard, it being found that animals generally enjoy independence of temperature, in proportion as it exceeds that to which they are commonly expoſed, and that the higher their natural ſtandard, the more inconvenience ariſes from any alteration of it.

Blood Veſſels.

The organs of circulation in birds have obtained but little of the attention of comparative anatomiſts. The larger branches of the arteries and veins, which lie near ſome of the viſcera, have alone received any deſcription; and that rather from being involved in the account of other parts, than for their own ſake. The diſtribution of the blood veſſels of birds, notwithſtanding this, is not the leaſt intereſting part of their anatomy, as will appear from the enſuing deſcription, which has been taken chiefly from the *ſwan*, *gooſe*, *duck*, *ſtork*, and *common fowl*, in which it was found ſo much alike, that it may be preſumed the ſame arrangement of the blood veſſels prevails with little variety in all birds.

The Arteries

Proceed from a ſingle trunk which ariſes from the left ventricle of the heart. This trunk is ſo ſhort, that it is concealed by the other parts on the baſis of the heart, and is only brought into view after the reflections of the pericardium, and the adjoining veſſels are detached by diſſection. It is from thence, that as the parts are commonly beheld, there appear to be three great arteries iſſuing together from the middle of the heart, which are the primary branches into which the aorta is divided. The firſt branch is to the left ſide, and after it is ſent off, the trunk affects to turn over the auricle, before it gives the branch of the right ſide; theſe two branches paſs in a curved manner from the heart towards the axillæ, in the form of horns, and each is analogous to the *arteria innominata* of the human ſubject, ſo that inſtead of one, there may be reckoned two *arteriæ innominatæ* in birds. After theſe branches are parted with, the arterial trunk is continued over the auricles, and on reaching the back part of the heart, becomes the *deſcending aorta*.

The *arteria innominata* firſt ſends off the common trunk of the carotid and vertebral arteries, which before its diviſion gives off one or two ſmall branches; one of theſe runs down upon the lungs in company with the par vagum, and appears to ſupply branches to the aponeuroſis of the lungs, and the air-cells at the upper part of the thorax; the other branch, after ſupplying the lymphatic gland of the neck with ſeveral ſmall arteries, aſcends upon the ſide of the œſophagus, to which, and the inferior larynx, the diviſions of the trachea, and to the parts and integuments of the ſide of the neck, its branches are diſtributed, anaſtomoſing with the ſuperior œſophageal and tracheal arteries. This branch is often not ſent off until the trunk divides into the vertebral and carotid, in which caſe it comes from the latter artery. Sometimes in the *duck*, the *ſupra-ſcapular* artery, which is uſually derived from the vertebral, is a branch of the common trunk

The *carotid* artery, after parting from the vertebral, proceeds to the middle of the neck, and ſoon diſappears; being covered by the muſcles of the anterior part of the neck, under which it lies hidden, and in cloſe contact with its fellow of the other ſide, to very near the head. If, during its courſe in this ſituation, it gives any branches, they are too inſignificant to be noticed.

The carotid artery emerges from between the muſcles of the neck, at about the third or fourth vertebra from the head; and after giving a branch downwards, amongſt the lateral muſcles of the neck, it runs along the outer edge of the rectus major anticus muſcle, to behind the angle of the jaw, where it divides into its ſeveral branches.

An artery firſt goes off poſteriorly, which paſſes a little forwards under the branch of the os hyoides, and after ſending

ing

ing ſome blood to the muſcles of the neck, makes a turn backwards, enters the foramen in the tranſverſe proceſs of the ſecond vertebra, and terminates by a ſingular anaſtomoſis in the vertebral artery.

The next branch is analogous to the *internal carotid*; it goes forward alſo under the os hyoides, and paſſes behind the muſcles of the jaws cloſe upon the lower part of the ſkull, at which place it ſends a branch upwards, which appears to penetrate the bones on the outſide of the ear, and ſupply the organ of hearing, ſend a branch into the ſkull, and another through the articulation of the jaw, to unite with the ophthalmic, and contribute to the plexus at the back of the orbit. The internal carotid then enters an oſſeous canal, which runs along the baſis of the cranium, between the tables of the bone, and at the lower and back part of the orbit, the artery receives a remarkable anaſtomoſing branch of the internal maxillary, which almoſt equals in ſize the carotid itſelf; and theſe two veſſels produce by their union, one, which paſſes almoſt directly into the cranium at the uſual place for the entrance of the carotid artery. This veſſel forms within the ſkull an anaſtomoſis ſimilar to the circle of Willis; but the branch which occupies the place of the *baſilary artery*, is very ſmall, and appears to be furniſhed entirely from the anaſtomoſis of the carotids, and deſigned only to ſupply the medulla oblongata and ſpinal marrow. The branches of the internal carotid are thickly ſpread in an arboreſcent form upon the ſurfaces of the brain; ſome on the outſide, and others on the internal ſuperficies of the ventricles, and the fiſſure between the two hemiſpheres. The carotid alſo, as uſual, ſends off the *ophthalmic* artery, which, beſides ſupplying the eye and the parts in the orbit, produces ſeveral inoſculations with the branches of the external carotid, which will be noticed hereafter. After the trunk of the carotid has parted with the two branches juſt deſcribed, it paſſes for a little way downwards and forwards behind the angle of the jaw, and divides at once into different branches, correſponding to thoſe of the external carotid in mammalia, the firſt of which might be called the *æſophageal* or *laryngeal* artery. This veſſel ſends a branch to the muſcles upon the horn of the os hyoides, and then turns downwards and divides into two branches, one to the trachea, and the other to the œſophagus, upon the ſide of which parts they deſcend to near the thorax, where they inoſculate with the tracheal and œſophageal branches of the common trunk of the carotid and vertebral arteries.

The *external maxillary artery* dips in between the pterygoid muſcle, and that which is ſituated at the back of the lower jaw for opening the mouth; it then paſſes behind the articular bone, and gives twigs upwards to the muſcles of the jaws, and to the plexus at the back of the orbit: upon emerging from behind the articular bone, it lies under the zygomatic proceſs of the jaw, and ſends an artery upwards, which is diſtributed to the temporal and maſſeter muſcles; and proceeding under the triangular tendon that comes from the inferior margin of the orbit to the lower jaw, it divides into two principal branches: one of theſe paſſes along the ſide of the upper jaw, gives a branch upwards to the fore part of the orbit which unites with the ophthalmic artery, and is loſt at the top of the head. This branch is very large in birds with combs, as in conjunction with the ophthalmic, it furniſhes numerous veſſels to theſe vaſcular parts. The artery then goes on and ſupplies branches to the ſides of the head before the orbits, and to the integuments and ſubſtance of the upper mandible, inoſculating with the palatine branches of the internal maxillary artery. The ſecond portion of the external maxillary proceeds to the lower jaw, to which, and the lower part of the maſſeter muſcle, it is diſtributed. The external maxillary ſupplies the place of the *temporal*, *labial*, *angular*, *naſal*, and *mental* arteries of mammalia.

The *laryngeal*, or *poſterior palatine* artery is a little branch of the external carotid, which is ſent off poſteriorly oppoſite to the external maxillary artery. Its branches are exhauſted upon the back part of the fauces, the muſcles for moving the upper jaw, and poſterior nares.

The *lingual*, or *ſub-maxillary* artery paſſes under the muſcles which connect the os hyoides to the lower jaw, and cloſe upon the back of the membrane of the lower part of the mouth, it ſends a branch to the œſophagus and trachea, ſupplies the muſcles of the os hyoides, the tongue, the lower ſurface of the mouth, and furniſhes the artery which enters the ſubſtance of the lower jaw.

Juſt at the origin of the ſub-maxillary artery, there is another little branch of the carotid, which is loſt upon the muſcles of the os hyoides.

The *internal maxillary* artery is, as uſual, the continuation of the trunk of the external carotid; it runs forwards between the pterygoid muſcle, and the lining of the mouth, upon the ſide of the long muſcle for moving the upper jaw, and divides into two principal branches; one of them proceeds under the tendon of the long muſcle to get upon the palate, where it forms two branches, of which one runs along the external ſide of the palate, between the membrane and the bone of the mandible to the extremity of the bill, where it becomes united to the ſame branch of the oppoſite ſide, as alſo to the middle artery of the palate. The other branch lies alſo ſuperficially under the membrane which lines the mouth. It paſſes onwards to meet its correſponding veſſel of the oppoſite ſide with which it becomes actually incorporated, and by their union a ſingle artery is generated, which runs along the middle line of the palate to the end of the mandible, where it unites with the lateral branches as already mentioned. At the junction of the veſſel of each ſide to form the middle palatine artery, two branches go off, which are loſt upon the lining of the mouth, and the interior of the organ of ſmell.

The other branch of the internal maxillary artery is reflected upwards towards the orbit, below which it divides and unites again forming a triangle, through which the vein paſſes; at this place it produces a remarkable plexus of veſſels, like the rete mirabile of the carotid artery of quadrupeds, which is increaſed by branches from the ophthalmic and the palatine arteries, and from which the back part of the organ of ſmell receives its ſupply of blood.

The internal maxillary artery then runs directly backwards below the orbit, paſſes between the radiated or fan-ſhaped muſcle which moves the upper jaw, and the pterygoid proceſs; and turning inwards round the baſis of the cranium becomes incorporated with the *internal* carotid artery juſt as it enters the boney canal, which conducts it to the brain.

The *vertebral artery*, ſoon after it parts from the carotid, ſends off a branch backwards, which paſſes over the neck of the ſcapula and is loſt among the muſcles on the poſterior part of the ſhoulder, inoſculating with the articular and other arteries about the joint; this branch might be called the *ſupra-ſcapular*. In the *duck* we have obſerved it before it makes the turn over the ſcapula to ſend an artery upwards along the muſcles of the neck.

The trunk of the vertebral artery proceeds obliquely upwards, and having entered the foramen in the tranſverſe proceſs of the ſecond cervical vertebra, gives off a large branch downwards, which is diſtributed between the vertebræ, and to the ſpinal canal in the manner of the intercoſtal arteries, with which it anaſtomoſes upon arriving in the thorax.

The remainder of the vertebral artery is continued upwards in the canal formed in the tranſverſe proceſſes of the cervical vertebræ, diminiſhing gradually in conſequence of branches it ſends off between each vertebra to the ſpinal marrow and the muſcles of the neck. Near the head, the artery is found conſiderably reduced; and within the laſt foramen in the tranſverſe proceſſes, terminates entirely by inoſculation with the reflected branch of the carotid, as before noticed.

The extraordinary anaſtomoſes and the plexuſes which are to be obſerved in the arteries of the head in birds are not eaſily accounted for. It ſeems poſſible that they may be required in conſequence of the great length of the neck in theſe animals; it being well known that frequent communication amongſt the veſſels, although it diminiſhes the impetus of the circulation, inſures a free and uninterrupted motion of the blood.

After the common trunk of the carotid and vertebral is detached from the arteria innominata, this veſſel may aſſume the name of the *ſubclavian*. While paſſing under the clavicle, it ſends off ſome important branches: the firſt might be called a *pectoral artery*, it proceeds upwards upon the internal ſurface of the pectoralis minimus muſcle, which it ſupplies; and then dividing into two branches, one paſſes over the anterior edge of the clavicle, and under the pectoralis medius, between which and the ſternum it runs, detaching its branches to the muſcle; the other ſends firſt along the under ſide of the clavicle a branch which is again ſubdivided and diſtributed to the outſide of the ſhoulder joint and to the deltoid muſcle, in which it inoſculates with the articular artery. The veſſel then paſſes between the clavicle and the fork-ſhaped bone, and on a ligament which connects the head of the clavicle to that of the ſcapula, and diſperſes its branches upon the upper part of the ſhoulder joint forming anaſtomoſes with the neighbouring arteries.

The next branch of the ſubclavian is the *humeral artery*; it ariſes from the upper ſide of the veſſel, and makes a ſlight curve to reach its ſituation on the inſide of the arm, in order to diſpenſe its branches in the manner hereafter deſcribed.

The *internal mammary* artery is given off juſt as the ſubclavian leaves the cheſt. It divides into three branches, one ramifies upon the inner ſurface of the ſternum; another upon the ſternal ribs, and the intercoſtal muſcles; and the third runs along the anterior extremities of the vertebral ribs, ſupplying the intercoſtal muſcles, &c.

The chief peculiarity of the arteries of the ſuperior extremity in birds, conſiſts in the great magnitude of the veſſels which ſupply the pectoral muſcles; theſe, inſtead of being inconſiderable branches of the axillary artery, are the continuations of the trunk of the ſubclavian, of which the humeral is only a branch.

The *great pectoral or thoracic artery* paſſes out of the cheſt over the firſt rib, and cloſe to the ſternum, and immediately divides into two branches. One of them ramifies in the ſuperior part of the pectoralis major, and the other is exhauſted in the lower part of the muſcle, and ſends off a branch analogous to the long thoracic artery of mammalia.

The *humeral artery*, while within the axilla, gives a ſmall branch backwards to the muſcles, under the ſcapula, and upon reaching the inſide of the arm produces an artery, that ſoon divides into the articular and the profunda humeri. The *articular* artery paſſes round the head of the humerus, underneath the extenſors; its branches penetrate the deltoid muſcle, and anaſtomoſe with the other ſmall arteries around the joint.

The *profunda humeri* as uſual turns under the extenſor muſcles, to reach the back of the bone, at which place, in birds, it ſeparates into two branches, of which one deſcends upon the inſide, and the other upon the outſide of the articulation of the humerus with the radius and ulna, and there inoſculate with the recurrent branches of the arteries of the fore arm.

After the humeral artery has ſent off the profunda, it deſcends along the inner edge of the biceps muſcle, detaching ſome branches to the neighbouring parts; upon arriving at the fold of the wing it divides into two branches, one of theſe is analogous to the ulnar artery, and the other from its poſition deſerves to be called rather the interoſſeous than the radial artery.

At the place where the humeral produces the two arteries of the fore arm a ſmall branch is ſent off, which is loſt upon the fore part of the joint, and in anaſtomoſes with the recurrent of the ulnar, and the profunda humeri.

The *ulnar artery* is the principal diviſion of the humeral; it proceeds ſuperficially over the muſcles which are analogous to the pronator, ſends a large recurrent branch under the flexor ulnaris to the back of the joint upon which it ramifies and forms anaſtomoſes with the profunda humeri. The artery then proceeds along the inner edge of the ulnar muſcles, to which it diſtributes branches. It is afterwards ſeen paſſing over the carpal bone of the ulnar ſide, and under the annular ligament, at which place it ſends off ſome branches which ſpread upon the joint and inoſculate with ſimilar ones of the interoſſeous artery. Very ſoon after the ulnar artery gets upon the metacarpus it dips in between the bones and re-appears upon the oppoſite ſide lying under the roots of the quills, to each of which it ſends an artery; it preſerves this ſituation to the end of the metacarpal bones, where it paſſes between the ſtyle analogous to the little finger and the principal or fore finger, and purſues its courſe along the edge of the latter, to the extremity of the wing, ſupplying each of the true quills with an artery and ſending at each joint of the finger, a croſs branch to communicate with the anaſtomoſing branches on the oppoſite ſide.

The *interoſſeous* artery detaches firſt a branch of ſome ſize to the membrane which is ſpread in the fold of the wing, upon which it forms ſeveral ramifications. After this the artery dips down behind the pronator muſcles to get into the ſpace between the ulna and radius. It here gives a branch backwards to communicate with the others about the joint, and proceeds in the interoſſeous ſpace as far as the carpal joint, during which courſe they become much diminiſhed from giving off ſeveral branches which are diſtributed to the integuments and the quills placed upon the outſide of the ulna. The remainder of the interoſſeous artery is expended in ſmall branches upon the back of the carpal joint, the baſtard quills, and along the radial edge of the metacarpus and bones of the fore finger, where it forms communications with the croſs branches of the ulnar artery already mentioned.

From this deſcription it will be perceived, that no artery exiſts in birds ſtrictly analogous to the radial; that there are no palmar arches; and that the ſize of the interoſſeous artery, and the courſe of the ulnar along the outſide of the metacarpus are peculiarities which ariſe from the neceſſity of affording a large ſupply of blood to the quills during their growth.

The *deſcending aorta* makes a curve round the right auricle in order to get upon the poſterior ſurface of the heart, after which its courſe is cloſe along the ſpine, in which ſituation it is bound down by cellular ſubſtance, and the ſtrong membrane or aponeuroſis, which covers the lungs on their anterior part. The firſt branches which this veſſel appears to ſend off are *bronchial arteries*; they ariſe from the fore part of the aorta juſt when it arrives upon the ſpine; and having entered

entered the lungs, their ramifications accompany thofe of the pulmonary arteries. They appear alfo to fend branches to the fpine, and the fpaces between the ribs.

The *intercoſtal arteries* do not take their origin from the aorta in numerous and regular branches as in mammalia, but conſiſt originally of but few veſſels, which are multiplied by anaſtomoſes with each other, and with the arteries which come out of the ſpinal canal. An arterial plexus is thus formed round the heads of the ribs, from which a veſſel is ſent to each of the intercoſtal ſpaces. Many of theſe branches beſides ſupplying the intercoſtal muſcles and ribs, are continued into the muſcles upon the outſide of the body and the integuments. The anaſtomoſis of the intercoſtal arteries round the ribs is very ſimilar to the plexus which is produced by the great ſympathetic nerve in the ſame ſituation.

The aorta produces no branch which deſerves the name of the *phrenic* artery, as birds do not poſſeſs that muſcular ſeptum of the body, to which the artery of this name is diſtributed in other animals.

The *cæliac artery* is a very large ſingle trunk, and ariſes from the fore part of the aorta, even higher than the zone of gaſtric glands. It deſcends obliquely for a ſhort way and then gives off a branch which ſoon divides into two or three others that are ſpread upon the lower part of the œſophagus, and the ſide of the zone of gaſtric glands, uniting with the other arteries of the œſophagus above, and extending downwards upon the poſterior ſide of the ventricle, and anaſtomoſing with the anterior gaſtric artery. The trunk of the cœliac now divides into two very large branches, which from their diſtribution we have choſen to call the poſterior and the anterior gaſtric arteries.

The *poſterior gaſtric artery*, almoſt as ſoon as it is formed, detaches the *ſplenic* artery; and very ſoon after, it furniſhes from the poſterior ſide of the veſſel, the *right hepatic artery*. This branch proceeds to the right lobe of the liver, which it enters on the ſide of the hepatic duct; after having divided into two or three minute arteries on its way to the liver, it ſupplies the hepatic duct with a branch which accompanies the duct to the inteſtine, and is there loſt. The poſterior gaſtric artery then runs down upon the back of the gizzard, and oppoſite to the origin of the firſt inteſtine it ſends off an artery which proceeds directly to one of the cæca, upon which and the ſide of the next inteſtine it is expended, inoſculating at the end of the cæcum, with branches of the meſenteric artery, which are diſtributed to the adjoining portion of the ſmall inteſtine. The poſterior gaſtric then furniſhes a large veſſel which runs upon the gizzard and divides into two chief branches, which penetrate the ſubſtance of the digaſtric muſcle, in which they are loſt.

The next branch of the poſterior gaſtric artery is the *pancreatic*. It runs between the two pancreatic glands, diſpenſing branches to each, and to the duodenum. After this the trunk of the poſterior gaſtric divides into two branches which furniſh twigs to the muſcular parietes of the ventricle, and run along the margins of the upper and lower portions of the digaſtric muſcle, ſupplying them with numerous twigs, and anaſtomoſing with the ramifications of the other gaſtric arteries.

The *anterior gaſtric artery* deſcends to the angle formed by the bulbus glandulofus and the gizzard, and there ſends off a ſmall branch which ſpreads upon the zone of gaſtric glands, and inoſculates with the firſt ramifications of the cœliac, and immediately afterwards it detaches a large artery, which runs round the ſuperior margin of the digaſtric muſcle, which it furniſhe swith many twige, and communicates freely with the correſponding branch of the poſterior gaſtric artery.

Three ſmall *hepatic arteries* take their origin from this branch of the anterior gaſtric, juſt as it paſſes over the higheſt part of the margin of the gizzard; theſe veſſels enter the fiſſure in the left lobe of the liver. The anterior gaſtric artery now proceeds along the fore-part of the gizzard, ſending one or two branches into the muſcular ſubſtance, and near the tendon it terminates in two large veſſels, one of which is diſtributed upon the left ſide of the digaſtric muſcle and the other paſſes a little over the tendon and then divides into two arteries; which produce ſeveral branches that diſappear in the ſubſtance of the gizzard, and between the digaſtric muſcles and the parietes of the ventricle, anaſtomoſing with the veſſels of the poſterior ſide.

The *ſuperior meſenteric artery* takes its origin from the fore part of the aorta a little below the cœliac, and proceeds for ſome way without detaching any branches; after which it experiences the ſame kind of diviſion and ſubdiviſion that takes place in mammalia; and the numerous arteries which are thus ultimately produced are ſpent upon the ſmall inteſtines. One of the firſt and largeſt branches of the ſuperior meſenteric, however, is allotted to ſupply one of the cæca, and and eſtabliſh a communication with the inferior meſenteric, and gaſtric arteries. This branch, ſoon after it leaves the trunk of the ſuperior meſenteric, divides into two. One deſcends upon the rectum, where it meets with the inferior meſenteric artery, with which it produces a very remarkable anaſtomoſis, ſimilar to the meſenteric arch in the human ſubject; this united artery ſupplies the rectum and origin of the cæca. The ſecond portion of this branch of the ſuperior meſenteric, runs in the ſpace between the laſt part of the ſmall inteſtine, and the cæcum of one ſide ſending numerous branches to each, and at the end of the cæcum, communicates in a palpable manner with another branch of the ſuperior meſenteric artery, which runs upon the adjoining part of the ſmall inteſtine.

A branch ariſes from the anterior part of the aorta, juſt below the lungs; it is deſigned for the nutrition of the organs of generation, and except in the ſeaſon for propagation, is ſo ſmall as to be diſcovered with difficulty; but when the teſticles become enlarged, it is conſiderably increaſed in ſize in the male bird, and much more ſo in the female, when the ovary and oviduct are developed for producing eggs. It nearly equals the ſuperior meſenteric artery during the period of laying, in which ſtate we ſhall deſcribe it. It is a ſingle artery like the cæliac and the meſenteric, proceeds at a right angle from the aorta, and ſoon ſends off a branch which goes into the kidney of the left ſide, to which it gives ſome twigs, and afterwards emerging from the kidney, it runs in the membrane of the oviduct, upon which it is diſtributed. After this branch is detached, the artery projects a little farther forwards into the cavity and divides into two branches, one of theſe goes to the ovary, in which it ramifies, and furniſhes an artery of ſome ſize to each of the cyſts containing the ova. The other is diſtributed in numerous branches to the membrane and ſuperior parts of the oviduct, and inoſculates with the other arteries of the oviduct. It deſerves to be remarked, that this and all the other arteries which are furniſhed to the oviduct, have a tortuous or undulating courſe, in the ſame manner as the veſſels of the uterus of the human ſubject.

There are no regular emulgent arteries in birds; the kidnies deriving their blood from various ſources, which will be pointed out as they occur.

The inferior extremity is ſupplied with two arteries, which have a ſeparate origin from the aorta. One correſponds with the *ſemoral* artery, and the other deſerves the name of *iſchiadic* artery.

The *femoral artery* is a ſmall trunk which takes its origin from the ſide of the aorta, oppoſite to the notch in the bones of the pelvis immediately under the laſt rib. This notch is formed into a round hole in the recent ſubject, by a ligament which is extended from it to the rib; and it is through this hole that the femoral artery makes its exit from the pelvis; juſt before it paſſes out upon the thigh, it ſends off a long branch which runs backwards the whole length of the margin of the pelvis diſpenſing arteries to the abdominal muſcles on one ſide, and the obturator internus on the other. This branch alſo appears to ſupply one to the oviduct. The femoral artery, immediately after leaving the pelvis, ſeparates into two branches; one goes upwards and outwards, ramifying amongſt the muſcles in that ſituation; the other turns downwards, and is diſtributed to the flexors of the limb, and round the joint, and ſends an artery to the edge of the vaſtus internus, which can be traced as far as the knee. The kidnies appear to derive ſome irregular inconſiderable branches from the femoral artery while it is within the pelvis.

The *iſchiadic artery* is the principal trunk of the lower extremity, exceeding very much in ſize the femoral. When it is produced by the aorta, it appears to be the continuation of that trunk; the remaining part of the aorta becomes ſo much and ſo ſuddenly diminiſhed, and ſeems as it were to proceed as a branch from the back part of the veſſel.

The iſchiadic artery, while in the pelvis, is concealed by the kidnies, in which ſituation it gives a branch from its lower ſide, which divides into three others that are diſtributed to the ſubſtance of the kidnies; one of theſe on the left ſide is continued out of the kidney to be loſt upon the oviduct. The artery leaves the pelvis by the iſchiadic foramen, in company with the great nerve; while within the foramen, it gives a branch obliquely downwards under the biceps to the muſcles lying on the pelvis; and as it paſſes over the adductor, it ſends off another along the lower edge of that muſcle, which is chiefly loſt in the ſemimembranoſus. It then detaches ſeveral ſmall branches to the muſcles on the outer and fore part of the thigh, ſome of which anaſtomoſe round the joint with the branches of the femoral artery. Juſt as the iſchiadic arrives in the ham, it furniſhes a very large branch downwards, which divides into two; one goes under the gaſtrocnemius, to which and the deep ſeated flexors its branches are diſtributed as far as the heel; the other is analogous to the *peroneal artery*; it goes to the outſide of the leg, ſupplies the peroneal muſcles poſteriorly, and paſſes along the outer edge of the flexors of the toes to the heel, above which, and behind the flexor tendon, it divides, running on each ſide of the heel, and forming ſeveral articular arteries around the joint, and communicating with the other branch, and with the anterior tibial, and the metatarſal branch of the plantar artery.

The *articular* arteries go off next from the artery in the ham; the two principal ones are deep ſeated. One proceeds under the vaſtus internus to the external part of the joint; the other is large, and ſituated upon the inſide. It forms two veſſels, one is the true articular artery, and ſpreads upon the ligaments of the joint, the other is diſtributed in the ſubſtance of the flexor of the heel, which is placed upon the inſide and fore part of the leg, and comes out upon the edge of this muſcle to be loſt in the integuments.

The *poſterior tibial artery* is extremely ſmall; it only ſupplies muſcular branches to the internal head of the gaſtrocnemius, and ſome of the flexors of the toes; it is loſt on the inſide of the heel in anaſtomoſes with the peroneal artery, and other ſmall ſuperficial branches.

The trunk of the artery of the leg now gets upon the poſterior ſurface of the tibia, and ſends off through the deficiency left between the tibia and fibula at the ſuperior part, a branch, which is diſtributed to all the muſcles upon the fore part of the leg. The artery then creeps along the back of the bones for ſome way, and paſſing between them above, where the fibula is anchyloſed with the tibia, it re-appears on the anterior part of the leg in the ſituation of the *anterior tibial artery*; at this place it detaches ſome very ſmall branches, which frequently divide and unite again, to produce a moſt ſingular reticulation or plexus of veſſels, which cloſely adheres to the trunk of the artery, and is continued with it as far as the articulation of the tibia with the metatarſal bone, where it diſappears without ſeeming to anſwer any uſeful deſign. This plexus reſembles in appearance exactly the diviſion of the arteries of the extremities, which has been deſcribed by Mr. Carliſle in the tardigrade quadrupeds, but differs from it in this circumſtance, that the trunk of the artery is preſerved behind it, without ſuffering any material diminution of its ſize.

The anterior tibial artery furniſhes no branch of any importance during the time it is proceeding along the fore part of the leg. It paſſes under the ſtrong ligament which binds down the tendons of the anterior muſcles of the leg, and over the fore part of the joint on the inſide of the tendon of the tibialis anticus; at which place it diſtributes ſome branches which inoſculate with the other arteries round the joint; it then purſues its courſe in the groove along the anterior ſurface of the metatarſal bone, and covered by the tendon of the flexor digitorum. On coming near the foot, it ſends off an artery, which divides, behind the joint of the internal toe, into two branches; one goes between the internal and middle toes, ramifies upon both their joints, and unites with the artery in the ſole of the foot; the other is diſtributed between the internal toe and the pollex or toe which occupies the place of the great toe; the main artery now paſſes to the ſole of the foot through a hole in the metatarſal bone left for the purpoſe, when the original parts of this bone were united by oſſification. In this ſituation the artery might receive the name of the *plantar*. It has ſcarcely paſſed through the bone, when it divides into ſix branches; three of theſe are diſtributed to the tendons and ligaments, &c. on the outſide of the foot and the back of the metatarſus, anaſtomoſing with the deſcending branches of the peroneal artery; the fourth branch ſupplies the pollex, and alſo ſends a branch upon the metatarſus. The remaining branches are deſigned for the three principal toes; one dips in between the internal and middle toe, unites with the anterior branch of the metatarſal artery, and is diſtributed to the ſides of theſe toes as far as their extremity. The other divides, between the external and middle toe, into two branches, which run upon the oppoſite ſide of each of theſe toes to the end.

When the feet are webbed, the digital arteries ſend off numerous branches, which, ramifying in the membrane between the toes, eſtabliſh a communication with each other. The preſent deſcription has been taken from birds which poſſeſs three principal toes, and the back toe, or pollex; but no material difference can be expected in thoſe with a greater number of toes.

After the trunk of the aorta has detached the iſchiadic arteries, it is continued along the ſpine, ſending ſmall branches analogous to the *lumbar* arteries, one of which aſcends upon the rectum, ſupplies the place of the *inferior meſenteric*, and unites with the ſuperior meſenteric, as already mentioned. The aorta ſeparates above the coxygeal vertebræ into three branches; two of theſe proceed late-

laterally, and are diſtributed to the neighbouring parts, and to the kidnies and oviduct; the third branch deſcends to the very point of the tail, upon the muſcles and quills of which its branches are exhauſted.

The arterial ſyſtem of birds differs from that of other animals chiefly in the frequent anaſtomoſes, which exiſt more eſpecially amongſt the arteries of the head and the viſcera. Similar communications occur between the veins, which are even in ſome inſtances more ſingular and unaccountable, as will be perceived by the following deſcription, which has been taken principally from the *gooſe*, *duck*, and *common fowl*.

Veins.

The venous ſyſtem returns the blood to the heart by means of three trunks; two of theſe, for the convenience of deſcription, we ſhall call the ſubclavian veins, although they do not correſpond in every reſpect with the veins of this name in mammalia; the other trunk is analogous to the inferior vena cava.

The *ſubclavian vein* is compoſed of the jugular and vertebral, and the veins which belong to the ſuperior extremity or wing.

The *vertebral vein* is lodged in the ſame canal with the vertebral artery; it anaſtomoſes between the vertebræ with the veins upon the ſheath of the medulla ſpinalis, which are the continuation of the ſinuſes of the brain; in conjunction with theſe, therefore, the vertebral vein may be conſidered as anſwering the purpoſe of the internal jugular of mammalia. It appears alſo to form at the baſis of the cranium a free communication with the jugular vein, and to receive by occaſional branches, blood from the muſcles of the neck.

The *jugular vein* is a ſingle trunk in birds, and does not admit of the diſtinction into external and internal; it proceeds ſuperficially along the ſide of the neck in company with the par vagum nerve. The vein of the right ſide exceeds the other in ſize; it is often twice as large. The jugular vein receives ſeveral lateral branches from the muſcles and integuments of the neck, the œſophagus, &c.; one of theſe near the head is much larger than the reſt; it lies deep amongſt the muſcles, and appears to communicate with the vertebral vein. There is a branch of the jugular which goes amongſt the muſcles of the tongue and of the os hyoides, and another for the muſcles within the jaws and the integuments in the back of the mouth; theſe might be called the *lingual* and *ſubmaxillary* veins.

The two jugular veins form a moſt remarkable communication with each other immediately below the cranium, by means of a croſs branch, generally of an equal ſize with the trunks themſelves. From each ſide of the arch thus formed there iſſues a large veſſel, which is made up of the veins of the external part of the head; one of theſe paſſes round the articular bone, and apparently penetrates the joint of that bone with the lower jaw; it appears in ſeveral branches upon the ſide of the cheek, and ſpreading from the ear, in the manner of the portio dura nerve of the human ſubject, and contributes to form a plexus of veins below the poſterior part of the orbit, ſimilar to the arterial plexus already deſcribed in that ſituation. The principal branch of the veins of the head paſſes obliquely round the inter-articular bone, and below the orbit divides into ſeveral large veſſels; one of which belongs to the back part of the palate; another aſcends in the orbit, and unites with the ophthalmic vein; and a third is diſtributed to the interior of the organ of ſmell, the palate, and the external parts of the upper and lower jaws. Theſe branches produce plexuſes along the baſe of the orbit and the external edge of the palate, which correſpond to thoſe of the arteries before deſcribed.

In all the ſubjects we diſſected for the veins we failed to diſcover any direct communication between the jugular vein and the ſinuſes of the brain; and in every inſtance the external veins of the head appeared to be ſufficiently large of themſelves to produce the trunk of the jugular. It may therefore be preſumed, that if any branch analogous to the internal jugular vein paſſes through the poſterior foramen lacerum, it is very inconſiderable, and incapable of tranſmitting the blood of the brain.

The *ſinuſes of the brain* ſeem to diſcharge their contents principally into ſome veins, which lie in the membrane forming the ſheath of the ſpinal canal, and theſe appear to diſpoſe of their blood gradually, as they deſcend in the neck, by means of lateral communication with the vertebral veins. The ſinuſes, which immediately open into the ſpinal veins, are ſituated upon the back of the cerebellum, and produce by anaſtomoſes with each other, with the ſuperior longitudinal ſinus, and with others along the ſides of the brain, an union of veſſels, of a diamond ſhape.

The ſinuſes of the brain in birds generally are irregular in their form, and conſiſt of flattened canals; and not only the ſinuſes on the back of the cerebellum, but the ſpinal veins appear ſo like extravaſation, that accurate and repeated obſervations are neceſſary to diſcover them to be real veſſels.

The principal ſinuſes, beſides thoſe upon the cerebellum, are the ſuperior longitudinal, and one which runs along the lower edge of each hemiſphere of the cerebrum; there appears to be alſo one upon the ſide of the cerebellum, correſponding to the lateral ſinus. All the ſinuſes communicate with each other on the back of the cerebellum as already mentioned. The ſuperior longitudinal ſinus is continued at its anterior part under the frontal and naſal bones, and anaſtomoſes with the ophthalmic and naſal veins. There are other ſinuſes in the ſeveral duplicatures of the dura mater, which are too ſmall to be eaſily traced, or to deſerve much regard.

The *veins of the wing*, or ſuperior extremity, have a leſs curious diſtribution than thoſe of the head. The branches which are derived from the parts within the cheſt, the muſcles about the ſcapula, and the pectoral muſcles, accompany the arteries of the ſame parts, ſo regularly that their courſe does not require deſcription.

The vein lies conſiderably lower in the axilla than the artery, but ſtill continues to receive correſponding branches. The trunk of the vein deſcends in the courſe of the humeral artery, but more ſuperficially; in this ſituation it may be called the *baſilic*, or more properly the *humeral*, vein. There is no vein in birds which deſerves the name of the *cephalic*; there are branches of the humeral vein, accompanying the articular and profunda arteries, and at the middle of the humerus, a large branch of the vein enters the bone; there are alſo two very ſmall branches which lie in cloſe contact with the humeral artery, which they accompany nearly its whole length.

The principal vein of the wing divides into two, oppoſite to the joint of the humerus with the fore arm. One of theſe branches belongs to the ſides of the radius; it receives blood from the muſcles and ſkin on the upper part of the fore arm, but its chief veſſels lie between the integuments of the fold of the wing. The other branch of the humeral vein croſſes the fore arm, juſt below the articulation, in company with the nerve, and running along the inferior edge of the ulna, receives a branch from between the baſis of each quill, is continued along the ligament which ſuſtains the reſt of

the

the quills to the extremity of the wing, receiving many veins of the joints from the oppofite fide of the fingers. Befides thefe large fuperficial veins of the fore arm, there appears to be one, and fometimes two, fmall accompanying veins to the ulnar and interoffeous arteries.

The *inferior vena cava*, before it enters the auricle, receives as ufual the hepatic veins; thefe are numerous, and open into the cava, as it paffes behind the liver, or more frequently within the fubftance of that vifcus in the back part. We have reckoned in the *cock* two large and two fmall hepatic veins from the right lobe, and one large branch from the left lobe, befides fix minute veins, which came indifferently from both lobes.

The trunk of the vena cava is very fhort in the abdomen; it feparates into two great branches analogous to the *primary iliac veins*, oppofite to the renal capfules; thefe turn to each fide, and experience a very fingular diftribution. On coming near the edge of the pelvis each of thefe two veins forms two branches; one of which collects the blood of the lower extremity, as hereafter defcribed; the other paffes ftraight downwards unbedded in the fubftance of the kidney, and admits the feveral emulgent veins, which are very large, and are feen to pafs for fome way obliquely in the kidney, before their termination. The defcending branch of the iliac alfo receives the ovarian veins, and when arrived at the lower end of the kidney, divides into three branches; one tranfmits the blood of the mufcles of the tail and parts adjacent; another accompanies the ureter to the fide of the rectum, and is diftributed about the anus and parts of generation, anfwering to the *hæmorrhoidal veins*; the third paffes inwards to the middle line between the kidnies, and there unites with the correfponding branch of the oppofite fide. The veffel which is in this manner produced, receives all the blood of the rectum from the anus to the origin of the cœca, anaftomofing below with the branches of the hæmorrhoidal veins; and at the upper part of the rectum, it becomes continuous with the trunk of the veins of the fmall inteftines, forming the moft remarkable anaftomofis in the body, both on account of its conſequences and the fize of the veffels by which it is effected. By means of this communication, the blood of the vifcera, and the external parts of the body, flows almoft indifferently into the vena cava and vena portæ; for the anaftomofing veffels are fufficiently large to admit the ready paffage of a conſiderable column of blood in proportion to the whole mafs which circulates in the body of the bird: for inftance, in the *goofe*, the communicating veins of the pelvis are equal in fize to a goofe quill, and in the *oſtrich* and *caſſowary* they are as thick as a finger. The advantage which appears to refult from this remarkable union of veffels, is the prevention of congeftion, or the overloading either the heart or liver with blood, as the one organ has the power of relieving the other. It would feem from this, as well as feveral other provifions of the fame kind, that the circulation would be more liable to obftruction in birds than other animals. It is difficult to fay, however, to what cauſe ſuch an effect ought to be afcribed. Is it from the compreffion ſuſtained by the heart and other vifcera, by means of the air-cells during refpiration? Or, is the mode of progreſſion by flight capable of impeding the motion of the blood?

The anaftomofis of the pelvic veins, in being the means of conveying common venous blood into the liver, goes to prove, that the blood of the vena portæ does not require any peculiar preparation by circulation in the fpleen or other vifcera, which has been conceived as neceffary by fome phyſiologiſts to fit it for the fecretion of bile.

The *vena portæ* belongs almoft exclufively to the right or principal lobe of the liver. It is formed by three branches. The *ſplenic vein* is the fmalleft, and is added to the vena portæ, juft as it penetrates the liver on the fide of the hepatic duct. The next is made of two branches; of which one returns the blood of the poſterior gaſtric artery, and therefore may be called the *poſterior gaſtric* vein; and the other is furniſhed by the pancreas and duodenum, and therefore is the *pancreatic* vein. The third and largeſt branch of the vena portæ is the *meſenteric vein*, which not only collects the blood from all the fmall inteſtines, but likewiſe receives the *inferior meſenteric*, or vein of the rectum, which forms the communication that has been deſcribed with the pelvic veins.

The *veins of the left lobe of the liver*, are furniſhed in the *goofe* by thoſe which accompany the anterior gaſtric artery, and ſome branches from the head of the duodenum.

The *anterior gaſtric veins* produce two ſmall trunks, which enter at the two extremities of the fiſſure, in the concave ſurface of the left lobe of the liver, as it lies upon the edge of the gizzard; the veins from the head of the duodenum furniſh a ſmall veſſel which paſſes backwards to penetrate the poſterior part of the fiſſure in the left lobe.

In the *cock*, the veins that the left lobe of the liver derives from the anterior gaſtric, are more numerous than in the *goofe*.

The veins of the zone of gaſtric glands, and of the lower portion of the œſophagus, do not contribute to the ſecretory veſſels of the liver, but proceed to the ſuperior part of that viſcus, to terminate in the vena cava; as does alſo the umbilical vein.

The vein which returns the blood of the inferior extremities, is divided in the pelvis into two branches, which correſpond with the femoral and iſchiadic arteries; the one paſſes through the iſchiadic foramen, and the other through the hole upon the anterior margin of the pelvis: but the proportion they bear to each other in magnitude, is the very reverſe of what occurs in the arteries; for the anterior vein is the principal one, whilſt the other is not a very conſiderable veſſel, and receives its ſupply of blood from the muſcles at the poſterior part of the joint.

The *femoral vein*, immediately without the pelvis, gives branches on both ſides, which receive the blood of the extenſor and adductor muſcles at their ſuperior part: the trunk paſſes obliquely under the acceſſory muſcle of the flexor digitorum, and over the os femoris, where it lies ſuperficially; it then winds under the adductor muſcles, and gets into the ham, where it receives many muſcular branches, and comes into company with the artery and nerve. It here divides into the *tibial* and *peroneal* veins. The firſt is joined by ſome branches from the ſurface of the joint anſwering to the articular arteries; it alſo receives the *anterior tibial* vein which accompanies the artery of the ſame name. The tibial vein proceeds down the leg along with the artery on the inſide of the deep-ſeated flexors of the heel: it turns over the fore part of the articulation of the tibia with the metatarſal bone, in order to get upon the inner ſide of the metatarſus; above the origin of the pollex, it receives a communicating branch from the peroneal vein, and immediately after, two branches from the toes: one of them comes from the inſide of the internal toe; the other ariſes from the inſide of the external and middle toes, unites at the root of the toes in the ſole of the foot, and is joined by a branch from the pollex, before its termination in the internal vein of the metatarſus.

The *peroneal vein* derives its principal branches, along with thoſe of the peroneal artery, from the muſcles on the outſide of the leg. The trunk of the vein comes out from the peroneal

peroneal muſcles, and paſſes ſuperficially over the joint at the heel, and along the outſide of the metatarſus: near the pollex, or great toe, it ſends a branch round the back of the leg, to communicate with the tibial vein; after which, it is continued upon the outſide of the external toe to the extremity, receiving anaſtomoſing branches from the tibial vein.

Where the veins run ſuperficially upon the upper and lower extremities, they ſeem to ſupply the place of the branches of the *cephalic*, *baſilic*, and the two *ſaphenæ*; but the analogy is loſt upon the upper arm and thigh: theſe branches forming deep-ſeated trunks: this conſtitutes the greateſt peculiarity in the diſtribution of the veins in the extremities of birds.

Kidnies.

Theſe organs occupy the poſterior part of the common cavity of birds, from the laſt rib to near the coxygeal vertebræ; they fill all the cavities and depreſſions of the bones of the pelvis; the poſterior ſurface, therefore, of the kidnies is extremely irregular; their anterior part is rather flat, and they are notched upon the external edge, which gives uſually the appearance of their being compoſed of three lobes. but the inequalities of the edge, ſeem to ariſe rather from the kidnies being larger at one place than at another, than from an original diviſion into lobes: the prominences correſpond to the moſt depreſſed parts on the pelvis; accordingly, the kidnies are obſerved to form a projection at the upper end, where they lye on the depreſſion of the oſſa ilia, again oppoſite to the hollow on the inſide of the iſchiadic foramen, and laſtly, at the lower part of the kidney, where it fills the concavity of the iſchium.

The kidnies have a covering of thin peritoneum, and under this, they ſeem to poſſeſs another thin membranous tunic, which cloſely inveſts them, as well where they are applied to the bones, as anteriorly; this coat alſo appears to be reflected into the ſubſtance of the kidnies, and to form the cellular connections of the different parts which compoſe theſe organs. According to the academicians, the kidnies of the *cormorant* are ſeparated from the other parts of the lower belly, by a diſtinct membrane, and inſtead of being divided into three lobes, are toothed like a cock's comb on their gibbous part.

The texture of the kidnies is very fragile; readily giving way under the ſlighteſt injury. They yield to the preſſure of the finger a granular feel, as if compoſed of a number of minute bodies, eaſily ſeparable from each other: the ſurface of the kidnies, alſo, preſents the appearance of an aggregation of ſmall glands.

The trunks and larger branches of the blood-veſſels of the kidnies have been already deſcribed. The termination of the minute ramifications of the artery cannot be ſo clearly perceived as in mammalia. When coloured fluids are thrown in by the artery, the whole ſubſtance of the kidney appears to equally admit the injection: the minute branches of the blood-veſſels are too numerous, therefore, to allow of a diſtinct view of the figure aſſumed by the ſecretory extremity of the artery; but it is probable, from the ſtructure of the kidney differing in other circumſtances, that it is not wound into a coil, as in man and quadrupeds.

The kidnies of birds, in general, do not poſſeſs any cavity for collecting the urine, previous to its expulſion by the excretory duct: each of the little maſſes which form the original glands, produces a duct; theſe are joined by the neighbouring ducts, and thus others are generated, which terminate in the *ureter* or common excretory duct of each kidney. The ureter lies upon the anterior ſurface of the kidney, partially embedded in its ſubſtance, ſo that it is viſible along the whole gland, except at the upper part.

The members of the academy deſcribe the kidnies of the *oſtrich* as being evidently compoſed of diſtinct glands, and that the ureter did not lie as in other birds, ſuperficially, but was concealed in the glandular ſubſtance; in which ſituation it ſuffered a degree of dilatation, forming as it were, a *pelvis*, the whole length of the kidney, into which the different excretory ducts diſcharged their contents; not, however, from *papillæ*, as in mammalia, but by open and plain orifices. Mr. Ranby, in his account of the anatomy of the *oſtrich*, ſtates, that he found the ureters occupy their uſual ſituation on the middle line of the anterior ſurface of the kidney; but that the ſuperior branch of the ureter was very conſpicuous, and entered the middle of the kidney, where it formed a very large *pelvis*.

The ſtructure of the ureters appears to be exactly the ſame which theſe ducts poſſeſs in the human ſubject.

The courſe of the ureters, after leaving the kidnies, is behind the rectum, to which they become connected by the peritoneum covering the inteſtine: they proceed, for a very little way, involved in the coats of the back of the rectum, and open uſually upon two little papillæ, which project into the cloaca, or termination of the rectum. The orifices of the ureters in the cloaca, are much leſs than the width of tubes to which they belong; this, therefore, added to the obliquity with which they perforate the cloaca, anſwers all the purpoſes of a valve, and prevents any regurgitation of the urine back upon the kidnies.

The pariſian diſſectors obſerved in the *caſſowary* and *demoiſelle* of *Numidia* (*ardea virgo*), that the ureters became united to the excretory duct of the teſticle, at the lower part of the kidney; the common duct produced by their union terminated, as uſual, in the back of the cloaca. This ſtructure certainly does not exiſt in the generality of birds.

The above deſcription anticipates the obſervation, that birds are unprovided with any diſtinct reſervoir for urine; analogous to the *bladder*: it is the caſe throughout the whole claſs, without an exception, that the fæces and urine are expelled together; but the dilatation of the end of the rectum or cloaca, in ſome ſpecies, ſupplies the want of the urinary bladder in a great degree, and renders the ejections of both the urine and fæces leſs frequent than they would otherwiſe be, by affording a temporary accommodation to a conſiderable quantity of excrement. Theſe dilatations are remarkably large in the *oſtrich*, *parrot*, &c. See that part of the article which treats of the great inteſtine of birds.

It is a matter of common obſervation, that the excrements of birds are of a white colour, and appear as if they contained ſome cretaceous ſubſtances: this effect is univerſally attributed to an admixture with the urine, which is ſuppoſed to be of this colour and conſiſtence; it deſerves to be mentioned, however, that if the urine be expreſſed from the kidnies, or examined before it has paſſed into the rectum, it is neither white, nor of a chalky conſiſtence, but a limpid aqueous fluid, which exhales an urinous ſmell, that is very perceptible in the larger birds, from which ſome quantity of the urine may be obtained, by compreſſing the kidnies. It would ſeem more probable, that the white and chalky appearance of the excrements of birds, depended upon the quantity of calcareous matter contained in the ſolid parts of the fæces, than that it is derived from the urine. In proof of this ſuppoſition, it may be remarked,

that

that upon one occaſion, where we fed a fowl with madder for a different purpoſe, the cretaceous part of the excrement loſt its uſual whiteneſs, and became of the pale pink colour which madder is well known to communicate to calcareous earths.

Renal Capſules.

Theſe bodies hold the ſame ſituation in birds as in mammalia; they alſo uſually poſſeſs an irregularly triangular figure. The proportion which they bear in ſize to the kidney, is perhaps leſs than generally occurs in quadrupeds. In the *gooſe*, they are each about as large as a pea. The colour of the renal capſules is in every inſtance more or leſs yellow. Several of the older anatomiſts have deſcribed a ſingle renal capſule in ſome ſpecies of birds: the miſtake ſeems to have ariſen from their being occaſionally ſo cloſely applied to each other, that they appear as one body.

The renal capſules of birds do not poſſeſs any cavity or dilated part for venous blood, which renders it probable that the enlargement of the capſular vein, which has attracted ſo much attention in the human ſubject, is no way concerned with the function of theſe bodies.

Having diſcuſſed the ſtructure and operations of thoſe organs which are more immediately concerned in ſupporting the life of the individual, we ſhall proceed to conſider thoſe which are ſubſervient to the ſecond order of functions.

ORGANS EMPLOYED IN THE EXERCISE OF THE GENERATIVE FUNCTIONS.

Male parts of Generation.

The *teſticles* of birds are always two in number; they are ſituated on the inſide of the body, high up in the loins, upon the ſuperior edge of the kidnies; from which poſition they never deſcend at any period of life, as in mammalia. Conſequently, birds are not provided with a *ſcrotum*, or any external pouch for the accommodation of thoſe glands. The figure of the teſticles are moſt commonly oval; occaſionally they are of an elongated form, as in the *caſſowary*. See *Plate* VII. in the *Anatomy of Birds*; *fig.* 1. Sometimes the teſticles are nearly round, as in the *curaſſow*, and other inſtances.

The teſticles appear to receive a covering from the peritoneum; but their proper tunic is remarkably ſtrong, denſe, and inelaſtic.

It will always be a matter of great difficulty, to exhibit ſatisfactorily, the intimate ſtructure of the teſtes of birds, as a ſucceſsful injection from the vas deferens is nearly impoſſible. The ſeminiferous tubes are ſo tender, that they do not ſuſtain the leaſt force without being ruptured; and at the period when the teſtes are fully developed, they are loaded with their own ſecretion, a circumſtance highly unfavourable to the expoſition of the ſtructure of theſe organs by the means of injection. The blood-veſſels of the teſticle are eaſily traced; ſome of them paſs in the uſual manner directly from the back part, through the glandular ſubſtance, to the ſurface, where they unite with others which ſpread in an arboreſcent form, under the capſules of the teſtes. The great maſs of theſe glands is evidently made up of tubes, which are convoluted in all directions, and are ſeparated into bundles or packets, by very thin cellular membranes. Their connection with the ſecretory extremities of the hæmatic arteries, and their termination in the excretory duct, are, however, involved in obſcurity, for the reaſons already given.

The teſticles of birds differ very much in ſize at different ſeaſons of the year. When theſe organs are not exerciſed in the act of generation, they become remarkably diminiſhed; but, during the period in which the female lays her eggs, they acquire a bulk even beyond what might be expected, from the ſize of the bird to which they belong. This ſubject has been ſtrikingly illuſtrated by Mr. Hunter, in a ſeries of figures repreſenting the variation of bulk which takes place every ſpring in the teſticles of the *common ſparrow*; by which it is ſhewn, that the teſticles of this bird are ordinarily about the ſize of pin-heads, but, during the ſeaſon of propagation, acquire nearly the bulk of piſtol balls. See *Plate* VII. in the *Anatomy of Birds*; N° 1. exhibits the teſtes as they exiſt in the month of January; N° 2. as they are in the middle of February; N° 3. as they are found in the beginning of March; N° 4. their ſize in the latter end of March; and N° 5. the bulk they aſſume in the middle of April.

The *vas deferens*, or excretory duct, ariſes uſually from the poſterior part of the teſticle, and probably always ſuffers a certain degree of convolution or coiling upon itſelf, correſponding to the *epidydimis*, which generally differs more or leſs in colour from the body of the gland. In the *curaſſow* and *buſtard*, it has been obſerved to be black; in the *caſſowary* yellow; and in the *ardea virgo*, a green colour. The academicians repreſent the epidydimis of the *caſſowary* as being extended for ſome way above the teſticle, and conſiderably enlarged at the top. See *Plate* VII. in the *Anatomy of Birds*. *Fig.* 1. *a a* the two teſtes; *b b* the epidydimis of each ſide; *c c* the vaſa deferentia; *d d* the ureters coming from the kidney to unite with the vaſa deferentia; *e e* the excretory ducts common to both the kidnies and the teſticles.

In the *oſtrich*, the epidydimis turns up on the ſide of the teſticle; and in the *ardea virgo*, it is pendulous from it, and only connected by one end. The vas deferens alſo in this bird, appears to ariſe from the body of the teſtis, inſtead of the epidydimis; and at its lower part, the duct unites with the ureters, in the ſame way as is repreſented in the *caſſowary*. In the *caſſowary*, the epidydimis is ſituated below the teſticle, which it almoſt equals in ſize.

In moſt birds the vaſa deferentia proceed to their termination, without undergoing any remarkable degree of convolution, or experiencing any dilatation analogous to the *veſiculæ ſeminales*; but in the *cock*, theſe ducts are compoſed of convolutions or reflections of a tube from ſide to ſide, which are ſo cloſely applied to each other, that a longitudinal ſection of the duct preſents the appearance of a ſeries of cells, which ſeem to communicate with each other in the middle. Theſe become larger and more numerous towards the lower part of the vas deferens, and are capable of containing a conſiderable quantity of ſemen. It may be preſumed, therefore, that the *cock*, and other ſalacious birds, are provided with theſe receptacles of ſemen to enable them to meet the exigency of frequent copulation; and it is alſo to be obſerved, that thoſe birds which have the vaſa deferentia more ſimply formed, do not perform the act of coition ſo rapidly as the gallinaceous fowl. See *Plate* VII. in the *Anatomy of Birds*. *Fig.* 2. exhibits the genital organs of the *common cock*; *a a* the teſticles of an oval ſhape; *b b* the epidydimis at the poſterior part of each; *c c* the vaſa deferentia, one of which is cut open to expoſe the loculated appearance it preſents internally.

The *penis*, in thoſe birds where it has been obſerved to exiſt, is fixed upon the end of the rectum, immediately within the verge of the anus; it is uſually of a pyramidal figure, and in its ordinary ſtate is twiſted like a ſcrew; its external tunic is derived from the inteſtine, and is formed into a number of little rugæ, or proceſſes, giving the edges of the peni, in its contracted ſtate, a jagged or notched appearance. The body of the penis is compoſed of a white ligamentous

mentous ſubſtance, which ſupplies the place of the *corpora cavernoſa*, but does not ſeem to contain any cells or cavity internally.

There is a groove, correſponding to the *urethra*, along the ſide of the white ligament; it takes the ſpiral courſe of the penis, and in no inſtance could we diſcover that it formed a diſtinct canal, the external coat of the penis appearing always to dip into the groove, ſo that it was viſible externally; and hence it might be ſaid that the *urethra* of birds is ſituated upon the outſide of the penis. See *Plate* VII. in the *Anatomy of Birds*. *Fig.* 3. repreſents theſe parts as they are found in the *gander; a* the penis, ſhaped like a ſcrew, with the edges denticulated or notched by the folding of the external coat; *b b* the urethra commencing upon the left ſide of the penis, and continued upon the ſame ſide around the ſpire or ſcrew; and at the end of the penis the ſulcus gradually diſappears.

The form of the *oſtrich*'s penis is not ſpiral; it is alſo ſmooth upon the ſurface, and in ſhape it has been likened to a calf's tongue. The Pariſian anatomiſts deſcribe it as being compoſed of white thick membranes, and of two ſtrong hard ligamentous ſubſtances. They appeared to conſiſt of very compact tranſverſe fibres; one of the membranes was thicker than the other, and afforded a covering to the penis; the other enveloped immediately each of the two ligaments, which were ſeparated from each other, and united about two fingers from the extremity. One was longer than the other, and meaſured two inches. The origin of the penis was at the cartilaginous ſwelling, which is ſituated at the junction of the bones of the pubis; from thence it was turned downward, and contained in a little pouch, which was placed at the lower part of the cloaca, in which the penis was continued to the anus. This ſmall pouch can be diſtinctly ſeparated from the large bag of the cloaca, by the contraction of the margin of its foramen. The leſſer pouch only permits the excrements to paſs from the other occaſionally, and when it is cloſed, forms a ſort of ſheath for the penis.

The penis of birds receives ſome diſtinct muſcular faſciculi from the rectum, which are inſerted into the root of the ligamentous body; they appear to have the power of retracting it, or rolling it into the ſpiral form, and may perhaps render it more ſteady during coition.

The muſcles of the penis are large in the *oſtrich*. The academicians deſcribe four of them, two on each ſide. The two firſt took their origin from the internal part of the os ſacrum, and deſcended along the pouch of the rectum, for the ſpace of two lines, which they penetrated near the extremity, and paſſing under the ſphincter ani, were inſerted at the baſe of the penis. The two other muſcles went from the internal part of the os ilium towards the bottom of the kidnies, and deſcended by the ſides of the ureters, and after perforating the rectum, were attached to the lateral parts of the penis.

The penis of birds is unfurniſhed with any ſtructure ſimilar to the *glans* or *prepuce*; from which it might be queſtioned whether it is capable of receiving any peculiar ſenſations during the act of copulation. It would ſeem probable, however, that the penis is the chief ſeat of pleaſure in birds as well as mammalia, becauſe it changes its form during coition, and experiences a great degree of relaxation afterwards. The penis of the *drake* is protruded ſome inches out of the anus during the performance of the venereal act; and after the orgaſm is concluded, it is ſo much relaxed, that the animal has not the power of retracting it for ſome minutes; in which condition the penis hangs from the anus, and ſo much reſembles an earthworm, that the ducks miſtake it for one, and attempt to ſwallow it. It is remarkable, however, that the greater number of birds are either unprovided with a penis, or have merely a rudiment of it, which is incapable of conducting the ſemen into the organs of the female.

In thoſe birds which want the penis, it is very eaſy to perceive the manner in which the vaſa deferentia terminate: thus, in the *common cock* they can be readily traced paſſing along the ſides of the ureters to the back of the cloaca, into which they open a little lower than the ureters upon two papillæ, which are elevated upon a ridge formed by the internal coat of the inteſtine, juſt within the verge of the anus. Theſe papillæ are prominent and ſharp pointed; and although the ducts are of ſome ſize immediately behind, the aperture on the point of the papillæ is ſo extremely ſmall, that it is diſcovered with difficulty, and will ſcarcely ſuffer the fineſt briſtle to paſs through it. See *Plate* VII. in the *Anatomy of Birds*, *fig.* 2.; *c c* the two ſharp papillæ, upon the points of which the vaſa deferentia terminate in the *cock*. A briſtle is introduced into one of them, and above them, and nearer the centre of the inteſtine are ſeen the orifices of the ureters deſignated by the letters *d d*.

As theſe birds have no means of conveying the ſemen into the body of the female, a mutual everſion of the extremity of the inteſtine always takes place during the copulation of fowl.

The termination of the excretory ducts of the teſticle are difficult to diſcover in moſt of the birds which are furniſhed with a penis. This ariſes partly from the coats of the ducts becoming extremely thin and delicate near the extremity, and partly from the papillæ upon which they open into the gut being in thoſe caſes ſo ſmall as very eaſily to eſcape obſervation.

The academicians did not ſucceed in tracing the vaſa deferentia to their termination in any of the birds they diſſected. They relate, however, that the penis of the *oſtrich* and *caſſowary* had no communication with the ducts, nor did they contain any tube in the internal part by which they could give paſſage to the ſemen. In all the birds we have examined, we could not perceive the leaſt appearance of a canal in the interior part of the penis, or any means of communication between it and the vaſa deferentia.

In the *gander* we have been able to diſcover the mode in which the ſemen is diſcharged from the excretory ducts. At ſome diſtance behind the root of the penis there are two papillæ, ſurrounded by a number of ſmall follicular glands; they are not ſo far aſunder as thoſe of the *cock*, and ſo little prominent, that unleſs minutely examined, they are not diſtinguiſhable from the glandular parts of the ſurface of the inteſtine which lie next them, and might eaſily be miſtaken for a prominent edge of one of the follicles: from the point of theſe papillæ a duct can be traced, as in the *cock*, to the back of the inteſtine; but furniſhed with coats ſo thin that it is perfectly tranſparent. See *Plate* VII. in the *Anatomy of Birds*, *fig.* 3. *c c* the ſmall papillæ on which the vaſa deferentia terminate in the *gander*. Some ſmall follicular glands are ſeen around them, and farther within the inteſtine the ureters open, as indicated by the letters *d d*; at theſe points alſo there are ſome ſmall mucous glands.

Mr. Home has deſcribed the penis of the *drake* as poſſeſſing a diſtinct canal analogous to the urethra of mammalia, into which the vaſa deferentia enter cloſe to its origin at the verge of the anus. He ſtates the penis to meaſure, when pulled out to its full extent, ſix inches long, but that when left to itſelf it diſappears within the verge of the anus, in conſequence of the contractile power of the urethra. (See Phil. Tranſact. vol. xcii. p. 361.) The repreſentation of the penis of the *drake* is copied in *Plate* VII. of the *Anatomy*

of Birds, fig. 4. *aa* the verge of the fundament furrounded by feathers; *bb* the urethra or feminal canal laid open throughout its whole extent; *cc* the orifices of the vafa deferentia; *d d* the external tunic of the penis laid open, and from its elafticity thrown into ferpentine folds.

It deferves to be mentioned, that Blafius alfo fuppofed the vafa deferentia of the *drake* terminated in the penis, although he fpoke doubtingly, not having actually traced them thither. See Anatome animalium Gerardi Blafii.

In the *gander, fwan, caffowary*, and other birds which we have examined, the channel that runs upon the external part of the penis fupplies the place of the urethra, and appears fully competent to anfwer the purpofe of a conduit to the femen, when it is introduced into the organs of the female.

Befides the mucous follicles furrounding the termination of the ureters and feminal ducts, there are fome others much larger upon the margin of the anus, on each fide of the bafe of the penis. In the *gander* we have noticed twelve of thefe, fix on each fide. They appear like maffes of fat lying under the inner membrane of the inteftine. The three outer glands have wide orifices which lead to a cavity within of fome fize; they furnifh fpecimens of fimple mucous follicles, a greater fize than are almoft ever met with, even amongft the largeft animals. See *Plate* VII. in the *Anatomy of Birds, fig.* 3. *eee* the large follicular glands on the margin of the anus of the *gander*; *fff* the three fmaller glands next the penis. The anal glands are very remarkable in the *caffowary*.

No chemical analyfis of the femen of birds has yet been attempted. The undertaking will be attended with fome difficulty, from the fmall quantity which can be collected for inveftigation.

Female Parts of Generation.

There are no parts of the ftructure of birds which deviate, more from that of mammalia, than the female organs of generation: not only their conftruction, but their functions, differ fo much, that the fame names cannot be applied to each, without extending analogy beyond what is juftifiable. The genital organs of the female bird ftrictly conift but of two parts, an *ovary* and *ovarian tube*; for the different portions of the latter, which have received the names of *uterus* and *vagina*, perform very different functions from the fame parts in other animals.

The *ovary* of birds is always fingle, which is a peculiarity of ftructure hardly ever met with in the other claffes of animals. It is fituated over the defcending aorta, above the kidnies. Inftead of the ova being imbedded in a folid mafs, as in mammalia, they are contained in membranous cyfts, which are prolonged into peduncles, or footftalks, that are attached to the bafis of the ovary, thus prefenting the appearance of a cluiter, or bunch of fruit, from whence the older anatomifts were in the habit of calling the ovary of birds, the *racemus vitellorum*. Before the ovary, however, is developed, the rudiments of the eggs do not project beyond the furface, but lie in clofe contact with each other, and are inclofed by the external membrane of the ovary, fomething in the manner of the ova of fifh, or amphibia. The capfules which inveft the ova of birds in the mature ftate, appear therefore to be formed by the extenfion of the outer membrane of the ovary, juft as the contents of a hernia obtain during their protrufion a covering of peritoneum. The membranous bags, in which the ova are included, adhere to the proper tunic of the egg at the anterior part only; for poftenorly they are quite diftinct, being prolonged into a funnel, or tube, which forms the peduncle to each ovum. The blood-veffels are tranfmitted through this funnel, and ramify in the fpace left between the capfule and the back part of the ovum, diftributing their branches in a fimilar way to the central artery of the eye upon the back of the cryftalline lens in mammalia. The capfules are extremely vafcular at every part, except a certain portion of the anterior furface, which appears like a white ftreak, or broad line. When the eruption of the ovum takes place, this part of the capfule gives way, after which the cyft appears like the cup of an acorn, when the nut has been fhed. The older anatomifts almoft univerfally believed that the capfules of the ova were imperfect at their anterior part, and that the white ftreak was owing to the proper tunic of the ovum being actually expofed at this place; they deferibe the capfule as being extended upon the ova in a manner fimilar to the internal coats of the eye, and, like them, terminating by a defined line at the anterior part. The celebrated Harvey, however, obferved that the membrane compofing the capfules was continued over the anterior part of the ovum, at which place it became very thin. The obfervations we have made on this fubject confirm the aflertion of Harvey; we have always been able to detect a very fine pellucid membrane extended over the white line, which has all the appearance of being the continuation of the capfule. The coat of the capfule confifts of feveral indiftinct layers; and it is one of thefe only which appears to pafs over the white line. The feparation of the tunic of the capfules into layers is probably not an original formation, but is produced by the increafe which takes place in the number and fize of the blood veffels, and therefore the part which lies over the white ftreak might be confidered as more nearly refembling the membrane of the capfule as it firft exifted. There are many inftances of parts, on changing their pofition, either acquiring or lofing vafcularity, and becoming fo much altered in their ftructure and appearance, that feparately they could not be recognized for the fame. The tunica conjunctiva of the eye affords a well known example of this fort.

The portion of the capfule correfponding to the white line, from being bereft of blood-veffels, becomes thin, is eafily ruptured, and is incapable of fupporting any internal actions, in confequence of injury; we accordingly find, that this part fuffers laceration when the ovum is fhed, without the leaft inflammation fucceeding, or any procefs fimilar to that which arifes upon the rupture of the ovary in mammalia. There is no depofition of new fubftance in the cavity of the cyft, or *corpus luteum*, formed. The lacerated portions of the membrane difappear (probably by abforption), and the edges aflume the appearance of being cut, the capfules become contracted and thickened, and remain hollow, prefenting very exactly the refemblance of cups or the calyces of flowers, and thence they have been often called the *calyces*.

The bafe of the ovary, in which all the pedicles of the ova terminate, is of a peculiar texture. It is porous and tough, and feems to be compofed of an intermixture of veffels and ftrong cellular fubftance; it adheres firmly to the parts upon which it is placed.

The *ova*, during the time they remain in the ovary, poffefs only the yolk and the cicatricula; the whites and the fhell being added to them during their paffage through the oviduct. Many of the blood-veffels which are diftributed between the capfule and the ovum, penetrate the membrane of the latter, in order to fupply blood for the nutrition of the egg during its growth. But when the ovum arrives at maturity, thefe branches degenerate, and difappear entirely before the ovum is expelled from its cyft.

For the illuftration of the ftructure of thefe parts, fee

Plate VII. of the *Anatomy of Birds*. *Fig.* 5. exhibits the genital organs of the *hen* during the ſeaſon for laying eggs; at the ſuperior part is ſeen the *ovary*, or *racemus ovorum*, or *vitellarium*. The ova are arranged according to their ſtate of growth. The largeſt are moſt external and pendent from their footſtalks; thoſe leſs advanced are cloſe upon the matrix or baſis of the ovary; many of them are as yet but imperfect rudiments of the ova, and appear but as white ſpecks in the matrix. The capſules of the ova, near maturity, diſplay a very beautiful and luxuriant diſtribution of blood-veſſels upon every part of their ſurface, except where the ova are to come out; *a a* point out the ſtripe on the anterior part of each capſule, which is devoid of blood veſſels; *b* a capſule which has ſhed its ovum, exhibiting the appearance of a cup or calyx.

The *ovarian tube*, or *oviduct*, during the ſeaſon of laying, fills the greater part of the lower belly; it forms a number of curves or convolutions ſimilar to the inteſtines, which, however, are not permitted the ſame latitude of motion amongſt each other, becauſe the prolongation of peritoneum, which includes the oviduct, is remarkably ſtrong, and is not ſo long as the parts it contains, and therefore the convolutions are coiled cloſe together, and even ſome of them are doubled up within the peritoneum. The diſproportion between the oviduct and peritoneum, which inveſts it, ariſes from the additional bulk the ovary acquires when its functions are exerciſed, whilſt the peritoneum muſt preſerve at its back part its original extent, i. e. the length of the left kidney, from the middle of which it is reflected.

There is no decided muſcular coat belonging to the oviduct; there are, however, muſcular fibres between the peritoneal and internal coats of thoſe parts, which have received the names of uterus and vagina; upon the former they are tranſverſe, and upon the vagina the courſe of the fibres appears to be longitudinal.

The internal coat of the oviduct is the moſt remarkable part of its ſtructure; and upon it chiefly depends the diſtinctions which have been made of the tube into *infundibulum*, *Fallopian tube*, *uterus*, and *vagina*.

The *infundibulum* is the extreme part of the tube next the ovary; it is compoſed apparently of a ſingle thin membrane; the peritoneum and the internal tunic becoming both delicately fine, and ſo cloſely united to each other, at this place, that they ſeem to be but one. This membrane is expanded beneath the ovary in a looſe manner, like the folds of a garment, and is faſtened by its ſuperior edge to the baſis or matrix of the ovary; and inferiorly it is connected to the uterus: by which means the folds of the membrane are always kept ſpread out, ready to catch the ova as they are diſcharged from the racemus or vitellarium. The paſſage from the membranous expanſion of the tube into the oviduct is contracted, and thence occurs the ſimilitude of this part to a funnel, and the application of the term *infundibulum*.

The next portion of the oviduct, or *Fallopian tube*, is of conſiderable length, being ſeveral times coiled backwards and forwards upon itſelf. It is very nearly of the ſame width at every part; and the inner membrane is ſingularly ſoft, and forms numerous thick folds, which take an oblique or ſpiral courſe. The internal ſurface of this part of the tube reſembles very much that of the digeſtive ſtomach in ruminating animals.

Where the part termed the *uterus* commences, there is a contraction of the tube, to which ſucceeds a dilatation of an oval or egg ſhape; in this the internal membrane acquires more firmneſs, and inſtead of the ſoft white ſpiral plicæ, produces an immenſe number of ſtrong vaſcular proceſſes or floccuſi, which give the internal part of the uterus the appearance of being fringed or foliated.

The tube again becomes diminiſhed in capacity, and its ſtructure changed, to form the portion conſidered analogous to the *vagina*. At the origin of this part from the oval dilatation there are ſeveral annular contractions; after which, the canal undergoes ſome degree of convolution, which is concealed by the peritoneal coat. The internal membrane produces longitudinal rugæ, or folds, which do not project far into the cavity of the tube.

The oviduct finally opens into the cloaca on the left ſide, not by a ſimple aperture, but the extremity of the vagina is protruded for ſome way into the cavity of the inteſtine, appearing as if a portion of the oviduct were turned inſide out; and to the puckered foramen thus produced, the older anatomiſts, who were always deſirous of comparing the ſtructure of other animals with that of the human ſubject, gave the name of *vulva*. See *Plate* VII. in the *Anatomy of Birds*, *fig.* 5.; *c c c* the membranous expanſion of the oviduct, *d d* its attachments to the ovary and the uterus, *e* the aperture leading from the infundibulum to the interior of the oviduct; *f f f f f* the convoluted part of the oviduct, which is ſuppoſed to be analogous to the Fallopian tube, and a part of it laid open to exhibit the ſpiral folds of the internal membrane; *h h* the oval cavity or uterus cut open, and a portion of it turned backward to expoſe the foliated ſtructure of the internal membrane; *i i* the vagina detached in a degree from its peritoneal covering to bring it more into view; *k* the cavity expoſed, ſhewing the longitudinal folds; *l* the projection of the end of the oviduct into the cloaca, with the corrugated foramen by which it opens into the gut; *m* a portion of the rectum, left to explain the connection theſe parts have to each other; *n n* the ureters, through which a briſtle is introduced.

The uſes which the ſeveral parts of the oviduct of birds ſerve, are very peculiar, and can hardly be compared with the functions of the genital organs of other animals. When the ovum is ſhed from the vitellarium, it is but imperfectly formed; and in paſſing along that portion of the oviduct which has been called the Fallopian tube, it meets with an albuminous fluid, which is ſecreted in abundance from the plicated membrane; a certain quantity of this fluid attaches itſelf to the ovum, and conſtitutes the whites and the chalazes. The egg now aſſumes an oval figure, and while ſtill ſoft, deſcends into the dilated part of the oviduct, in which it is detained for ſome time, and obtains the calcareous covering or ſhell; after which, the lower portion of the duct, or the vagina, ſuffers itſelf to be enlarged, and the egg is expelled from the body of the bird. For the further hiſtory of the formation of the ovum, we refer the reader to the article Egg. In birds, and all animals ſtrictly oviparous, the evolution of the embryo, and the growth of the fœtus, is carried on without the body of the parent, and therefore the functions of the organs of generations in theſe animals are confined to the developement and perfection of the ovum, which, as already obſerved, is partly accompliſhed in birds, while the egg remains in the ovary, and partly while it traverſes the ovarian tube. It therefore ſeems improper to borrow the terms applied to the organs of viviparous animals in the deſcription of thoſe which only miniſter to the formation and ſupport of the ova. The progreſs of the fœtus in birds; its mode of exiſtence while in the egg, and the proviſions for its ſubſiſtence afterwards, will be treated of under the head of Incubation, which ſee.

It is not eaſy to determine how far the male ſemen is conveyed into the organs of birds during copulation. The older anatomiſts aſſerted, that the two papillæ on which the vaſa

deferentia terminate, were introduced into the orifice of the oviduct within the cloaca; and it has been obſerved, that the hen, before coition, everts the inteſtine ſo much, that the orifice of the vagina is viſible on the outſide of the body, which would render the inſertion of the male organ very practicable, eſpecially in thoſe birds which are provided with a penis. The impregnating liquor muſt be tranſmitted as far at leaſt as the part in which the egg is clothed with the ſhell; for afterwards it would be incapable of exerting any influence upon it; and it is probable that it reaches the ovum even before it acquires the whites, otherwiſe the ſtimulus could not be immediately communicated to the *cicatricula*. Many have ſuppoſed, that the ſemen produced a vapour which was propagated to the ovary itſelf; but the exiſtence and operation of the *aura ſeminalis* are now generally diſbelieved.

Upon the margin of the anus of birds there is uſually obſerved a projection which has been conſidered analogous to the *clitoris*. The academicians obſerved, that it poſſeſſed in the *female oſtrich* the ſame muſcles which belonged to the penis. This part, from its ſituation, is little expoſed to agitation or friction in venereal congreſs, and from its covering, which is the common integument of the anus, cannot be endowed with peculiar or delicate ſenſation. It may therefore be looked upon as one of the examples of uniformity of plan which are ſo often diſplayed in the works of nature, without the accompliſhment of any immediate or obvious effect.

The female organs of generation of birds ſuffer even a greater alteration than the male parts, in conſequence of the ceſſation of their functions. Before and after the period of laying has commenced, the ovary and oviduct, which in their developed condition are the largeſt of the viſcera, are ſo diminutive, that they are hardly to be ſeen; the ovary is a very ſmall maſs, which appears to be compoſed of an aggregation of minute pale yellow grains; the oviduct is a mere membranous ſubſtance, with ſcarcely any cavity, like a degenerated blood-veſſel; and the aperture, which at one period permits the egg to paſs through it, is ſo nearly obliterated, that it is perceived with difficulty, and is ſo cloſe that it does not ſuffer the ſmalleſt inſtrument, or even air, to eſcape from it into the inteſtine.

Mr. Hunter, and others, have obſerved, that even the ſexual characters of ſome female birds have entirely changed, after the time they ceaſed to lay. This phenomenon has been remarked moſt frequently in the *pea fowl*. Several hens of this genus have aſſumed the manners and plumage of the cock ſo nearly, that their real ſex could only be decided by anatomical inſpection.

Organs subservient to the Performance of the Animal Functions.

Bones.

The oſſeous fabric of the bodies of birds conſtitutes one of the moſt curious and characteriſtic parts in the anatomy of this claſs of animals; being in many reſpects ſo curiouſly formed, that the analogy between them and the ſame organs of other animals can ſcarcely be traced.

The bones of birds have been obſerved to vary in their colour. The water birds have them of a duller white than the other ſpecies, in conſequence of their abounding with marrow. The bones which contain air, are always of the fineſt colour, much exceeding in whiteneſs the bones of any quadruped: they are alſo of a harder and cloſer texture. Beemann, in the voyage of Dampier, has obſerved that the *black fowl* of the iſles of Cape-Verd, and other birds of theſe iſlands, had black bones, and Daubenton reared ſome hens of this kind. The ſame peculiarity has been noticed in the *pintado*; but ſome preparations which were preſerved by Mr. Hunter to illuſtrate this ſubject, ſhew that it is the perioſteum in which the blackneſs reſides.

The chemical principles of the bones of birds, do not differ from thoſe of mammalia, except in there being a greater proportion of the calcareous phoſphat in the long bones, filled with air. The arrangement of the oſſeous particles appears to be in layers, rather than fibres, ſucceſſively formed, and cloſely applied to each other.

The *bones of the head*, as in the other animals with vertebræ, conſiſt of thoſe of the *cranium*, or brain-caſe; and thoſe which contain the organs of ſenſe, or, as they are commonly termed, bones of the *face*.

The *external form of the cranium* differs according to the ſpecies: a longitudinal and vertical ſection of it uſually exhibits the cavity to be ſomewhat of an ovular ſhape, of which the end next the face is rather pointed. In the *owl*, the cavity of the cranium is an oval, with the axis nearly vertical. The ſame bones enter into the compoſition of the cranium in birds, as in mammalia; but the ſutures are obliterated at ſo early an age in the former, that their cranium commonly appears as a ſingle bone, and therefore, in order to examine the bones of the head ſeparately, a very young ſubject muſt be choſen.

The *os frontis* is originally made of two portions: they form the principal parts of the roof of the orbits, and a portion of the ſeptum which divides one orbit from the other. They ſend down, on each ſide, a pointed proceſs, almoſt to the baſe of the bill. The prominences which are ſeen upon the heads of the *caſſowary*, *hornbill*, *pintado*, and the *curaſſow*, &c. are attached to the os frontis, but were originally formed by diſtinct oſſifications, in the ſame manner as the bones on the tarſus, which ſerve as the mould for the *ſpurs*. The caſque of the *caſſowary's* head is filled with numerous cells: in the *pintado*, the texture is more like that of the other bones.

The *parietal* bones are alſo in two pieces at one period, although the diſtinction is but rarely ſeen. They reſemble two ſemi-ſpheres, hollowed out on the inſide, to receive the brain.

The *temporal* bones compoſe the poſterior parts of the orbits, and exhibit a remarkable depreſſion between two projecting proceſſes, for lodging the muſcles employed in the motions of the lower jaw. The zygoma is not joined to the temporal bone.

The *occipital* bone originally conſiſts of four portions; one placed ſuperiorly, another below, and two laterally. When theſe are united, the bone has an annular figure, incircling the foramen magnum. The ſurface by which it articulates with the firſt cervical vertebræ, is a ſingle ſpherical protuberance, which is placed upon the anterior edge of the great foramen, and is received into a correſponding depreſſion of the atlas. The mobility of the head is much encreaſed by this mode of articulation.

The *ſphenoidal* bone forms the greater part of the baſe of the cranium, its proceſſes are leſs evident in general, than in mammalia, although it furniſhes a remarkable one which proceeds anteriorly like a ſtilet, and receives upon its edge the ends of the inter-articular bones, and the palatine bones and vomer, which are each adapted to fit this proceſs, and to ſlip along it, as the upper jaw is moved. The ſphenoid bone wants the pterygoid proceſſes, theſe belonging to the palatine bones in birds.

The *internal ſurface of the cranium* exhibits a ſharp ridge, which divides the cavity into two principal foſſæ. The one contains the hemiſpheres of the cerebrum, the other, which is ſituated in the poſterior and inferior part of the cranium, accom-

accommodates the two thalami nervorum opticorum, the cerebellum, and medulla oblongata, &c. On the ſurface of the ſuperior foſſa there are two ſlight projections, produced by the back of the orbits, and a ſmall ſpinous ridge along the top of the cranium, which marks the diviſion of the hemiſpheres; the inferior foſſa diſplays a number of depreſſions, correſponding to the ſeveral parts it contains. There are alſo two irregular projections on the ſide, formed by the internal organ of hearing, and anteriorly the eminence called the *ſella turcica*, is to be ſeen, with a deep round cell for lodging the pituitary gland. The depreſſions on the internal part of the cranium are deepeſt in the *parrot* and *accipitrine* birds.

The *foramina of the cranium* vary in many reſpects from what occurs in mammalia.

The foramina through which the olfactory nerves are tranſmitted are only two in number; they proceed from a little depreſſion at the anterior part of the ſkull, and open upon the upper and poſterior ſurface of the orbit, along the ſuperior part of which they are continued, as a deep groove, or rather more than a ſemi-canal, to the upper and back part of the noſe, where there is another foramen or ſlit, formed by the ethmoidal bone.

The *optic foramina* ariſe cloſe together on the inſide of the cranium, being only ſeparated from each other by the thin partition of the orbits; this is frequently found deficient at the poſterior part, and in that caſe the two optic foramina are thrown into one.

The *ſpheno-orbitar* fiſſure does not exiſt in birds. The parts which are tranſmitted through it in mammalia, paſs by diſtinct holes: ſome of theſe are arranged round the optic foramina, and one is found on the baſis of the ſkull.

The *foramen rotundum* and *foramen ovale*, are ſupplied by a ſingle hole. It is ſeen on the line dividing the optic and baſilar foſſæ.

The *canalis carotideus* appears to commence far back, on the outſide of the cranium, and juſt as it turns up to open upon the ſella turcica, there is a ſmall foramen for the tranſmiſſion of the communicating branch of the internal maxillary artery.

The *foramen lacerum anterius* does not exiſt, and the *poſterior foramen lacerum* is ſmall, and placed within and under the external meatus auditorius.

The *meatus auditorius internus*, is a very palpable foramen in birds.

The *bones of the face* in birds, although they differ extremely in form from thoſe of mammalia, ſtill preſerve in general a diſtant analogy, by which they can be diſtinguiſhed and compared.

The *ſeptum* of the orbits, notwithſtanding its ſtructure, is ſo diſſimilar, muſt be conſidered as analogous to the *ethmoid bone*. It is united to the os frontis ſuperiorly, and to the ſphenoidal bone below; it is at beſt but a lamina, or plate of bone, ſo thin that it is nearly tranſparent; and in numerous inſtances is in part membranous. At the back of the organ of ſmell there is occaſionally a proceſs which projects a little from the ſeptum, and then turns down forming a ſlit, through which the olfactory nerve paſſes. This proceſs may be compared to the *os planum*, and the ſeptum itſelf, although it is not continued far into the noſe, may perhaps be thought analogous to the *naſal lamella* of the ethmoid bone.

There is a bone uſually of a triangular ſhape, which is attached to the anterior, and outer angle of the os frontis. This bone Cuvier has called the *lacrymal*, and others the *ſuperciliary*. It is in a certain degree moveable on the os frontis. Its two poſterior angles form the ſuperciliary or anterior edge of the orbits. The ſuperior of them is continued farther backwards in the *diurnal birds of prey* than others, giving a conſiderable prominence to the upper edge of the orbit. In the *oſtrich*, the ſuperciliary arch is made of a number of ſmall bones, which are continued from the lacrymal bone, and are diſtinct from the os frontis. The lower of the poſterior angles of the lacrymal bone is prolonged conſiderably in the *duck*, but much more in the *parrot*, in which it goes ſo far back as to join the projection of the temporal bones, and thus completes the frame of the orbit.

The remaining bones of the face either enter into the compoſition of the mandibles, or are provided for the motion of theſe parts. The ſuperior mandible is made up of the *oſſa naſi*, *oſſa maxillaria*, and *inter maxillaria*, the *vomer*, the *malar*, and *palatine* bones; the extremity of the mandible appears to be formed originally by a diſtinct bone, which is added, as it were, to all the reſt. The ſeparate parts of the mandible are not to be diſtinguiſhed in the adult bird, but in young ſubjects they come eaſily aſunder.

The *palatine* bones are ſo thin at their connection with the poſterior part of the mandible, that they readily bend. At the back part, they ſpread out into two wings or the *pterygoid proceſſes*, leaving a ſlit-ſhaped aperture for the poſterior nares, in which is ſeen the vomer; where the palatine bones are joined above, there is a groove or gutter formed, which receives the inferior edge of the ſeptum of the orbits, and on which the palatine bones have a degree of motion when the upper mandible is raiſed.

The *zygoma* is one of the moſt remarkable parts of the head of birds. It is a very long delicate bone, extended in a ſtraight line from the inferior and back part of the upper mandible to the outſide of the articular bone immediately above the articulation of the lower jaw. It is, as in mammalia, originally compoſed of two pieces, which in large birds are always viſible. The anterior portion has been commonly deſcribed as a proceſs of the palatine bones, but it is really produced from the part of the mandible that correſponds to the *os malæ* or *jugule*, as it ought, in order to be conſiſtent with analogy. The junction of the zygoma to the articular bone, is in a degree moveable; this, added to its general ſlenderneſs and flexibility, allows it to yield to all the motions of the ſuperior mandible.

There are two bones belonging to the head of birds, to which there are none analogous in mammalia. One of theſe has been called by Dumeril the *ſquare bone*, but improperly, as it is in no inſtance exactly ſquare, and when its proceſſes are eminent, it is rather of a triangular form. We have choſen, both from its office and ſituation, to call it the *articular* bone.

This bone is interpoſed between the articulation of the lower jaw, and the os temporis: with both of theſe it produces a true joint. The articular ſurface it preſents to the temporal bone, is like the two condyles of the occiput of mammalia, and between theſe the end of the bone contributes to the formation of the cavity of the tympanum. The articular ſurface next the lower jaw is made of two irregular eminences, placed obliquely acroſs, forming a double pulley. On the outſide of this the temporal extremity of the zygoma is attached, and on the inſide there is articulated another ſlender bone, which, from its ſituation, deſerves to be named the *inter-articular bone*. There is a proceſs from the anterior part of the articular bone, which paſſes up into the orbit, and receives the attachments of muſcles.

The *inter-articular bone* is connected by a moveable joint to the articular. It is a ſmall, ſtraight, three-ſided bone, ſlightly

ſlightly enlarged at the extremities. It is directed forwards and inwards, and at the anterior extremity touches the inter-articular bone of the oppoſite ſide; at this place the ends of both are placed againſt the poſterior extremity of the palatine bone, and are hollowed ſo as to encompaſs the lower edge of the ſeptum of the orbits, along which they have ſome degree of motion, when urged forwards by the articular bones.

The effect of this mechaniſm is, that whenever the inferior end of the articular bone is brought forwards, which is accompliſhed in a degree by the opening of the lower jaw, but ſtill more by particular muſcles, to be hereafter deſcribed, the inter-articular bones preſs againſt the extremity of the palatine bones, and they communicate the impulſe to the whole ſuperior mandible, which being very thin at its junction with the os frontis, ſuffers itſelf to be puſhed up or elevated from the line it commonly holds, and in this manner the mouth of birds is dilated in part by the motion of the upper as well as the lower jaw.

The *parrot* is remarkable for having a great degree of motion in the upper mandible; in this bird the ſuperior mandible is at all times ſeparate from the frontal bone, they being only connected to each other by a very flexible ligament.

The *inferior mandible* appears to be formed originally of four pieces; two of theſe correſpond with the bones of the inferior maxilla, and the others produce the mould on which the lower part of the bill grows. The formation of the inferior jaw, independent of its connection with the bill, differs very much from that of mammalia. There are no *condyles*, nor any proceſs deſerving the name of *coronoid*, and the angle of the jaw is the thickeſt and loweſt part of it. The articulation is made by two depreſſed ſurfaces placed on the ſide of a cavity, into which the poſterior pulley of the articular bone ſlips in the motions of the jaw.

The form of the bones of the mandibles is preciſely the ſame of the horney bill, with which they are covered; except in ſome *water birds*, the bill aſſumes more or leſs of a conic figure; ſometimes compreſſed, ſometimes arched, in ſome caſes elongated, in others ſhort, and varying in the degree of ſharpneſs, ſtrength, and ſolidity. As the diverſity, however, which occurs in the mandibles of birds, is an external appearance, and belongs rather to the ſcience of natural hiſtory, than to comparative anatomy, it would be improper to diſcuſs the ſubject in the preſent article.

The peculiarities of the *foſſæ* and *foramina of the face* in birds, depend chiefly upon the form and proportions of the bones.

The *orbitar* foſſæ are ſo large, that they appear to occupy the greateſt part of the profile of the head of birds. They extend in the ſkeleton from the roof of the ſkull to the palate, and communicate with the poſterior part of the organ of ſmell. Cuvier very aptly compares them to the impreſſion which one would conceive might be left by pinching the ſkull between two fingers, provided it were in a ſoft ſtate.

The *naſal foſſæ* are continuous with the orbitar. They open upwards by the two external nares, or noſtrils, and below by the poſterior nares. The ſeptum naſi proceeds ſo ſhort a way in the noſe, that the naſal foſſæ make but one cavity. The external apertures of the nares are found in the bone, at the baſe of the convex ſurface of the bill.

The *temporal foſſæ* are not croſſed by the zygoma. They vary in depth according to the ſtrength of the muſcles employed in raiſing the lower jaw; they are therefore moſt plain in the rapacious birds, and thoſe with long or heavy bills.

The *ſpheno-maxillary fiſſure* can have no exiſtence in birds from the figure and extent of their orbits; neither have they the *internal orbitar*, and *ſub-orbitar foramina*, or the *ſpheno-palatine* canal.

The *inciſive* foramina are ſmall and numerous in the *heron*, *flamingo*, *eagle*, &c. There is but one of a moderate ſize placed near the baſe of the bill in the *duck*, the *curaſſow*, the *cormorant*, and the *ſpoon-bill*, &c. In the *caſſowary*, the foramen inciſivum is ſmall, and near the end of the mandible, but in the *oſtrich* it is of great ſize. The *ſtork* has a long ſlit, into which open an immenſe number of minute holes.

The *os hyoides* poſſeſſes a ſingular conformation in birds. The body of the bone is in general of a ſhort round figure, ſomewhat enlarged at its poſterior extremity, at which place it is articulated with the two *cornua*. Theſe reſemble horns exactly, both in their ſhape and direction; they are terminated by additional pieces, which form a ſort of joint with the principal part of the horn, and generally conſiſt entirely of cartilage. To the poſterior end of the body or middle bone of the hyoides, there is articulated a ſmall ſtyloid or dagger-ſhaped bone, which proceeds directly backwards, and ſoon terminates in a point. There is alſo a bone articulated with the anterior extremity of the body of the hyoides, which penetrates the ſubſtance of the tongue, and partakes in a certain degree of the form of that organ: it is commonly terminated by a pointed cartilage, which is attached to it by a moveable joint, and is continued to near the tip of the tongue. This bone we ſhould chooſe to call the *lingual*.

The os hyoides and lingual bone are ſingularly formed in thoſe birds which have the power of protruding their tongue to take their food. In the *woodpeckers*, for inſtance, the cartilaginous extremities of the horns of the hyoides are immenſely long, and when the tongue is not projected, are lodged in a groove or furrow, which runs over the whole head, and terminates only at the root of the bill. The lingual bone in theſe birds alſo is not cartilaginous at its extremity, but is covered with a hard or horny ſubſtance, which protrudes beyond the ſoft parts of the tongue for the diſtance of about the quarter of an inch, ending in a point, and furniſhed with a number of ſharp barbs, or ſpiculæ, which are moveable in the poſterior direction only; ſo that, like the teeth of ſome fiſh, they ſuffer the inſects on which the bird preys to be eaſily perforated by the end of this inſtrument, but render it impoſſible for them afterwards to retreat.

The vertebræ of the different regions of the ſpine of birds do not bear the ſame proportion to each other with reſpect to number that is uſual in other animals. The cervical portion in this claſs is generally compoſed of a much greater number of vertebræ than any other diviſion of the ſpine. The length of the neck is in moſt birds determined by the height of the legs. Thoſe *water birds*, however, which procure their ſubſiſtence by fiſhing, are provided with long necks, and at the ſame time ſhort limbs, as in the *cormorant*, *divers*, &c. The dorſal vertebræ are uſually leſs numerous than in quadrupeds. The vertebræ of the loins become anchyloſed with the bones of the pelvis, and with each other at an early period, and conſequently it is difficult to reckon them. The caudal vertebræ are moſt numerous in thoſe birds which make the greateſt uſe of the tail, ſuch as the *ſwallow*, *woodpecker*, *oſtrich*, &c.

The following table, which is extracted from Cuiver's Lectures on Comparative Anatomy, exhibits the variety which exiſts with reſpect to the number of the vertebræ in many ſpecies.

TABLE of the Number of the Vertebræ in Birds.

SPECIES.	Ver. of the neck.	Ver. of the back.	Ver. of the facrum.	Ver. of the coccygis.
Vulture	13	7	11	7
Eagle	13	8	11	8
Bald-Buzzard	14	8	11	7
Sparrow-Hawk	11	8	11	8
Common Buzzard	11	7	10	8
Kite	12	8	11	8
Great Horned Owl	13	7	12	8
Common Owl	11	8	11	8
Fly-Catcher	10	8	10	8
Black-bird	11	8	10	7
Tanager	10	8	9	8
Crow	13	8	13	7
Magpie	13	8	13	8
Jay	12	7	11	8
Starling	10	8	10	9
Grofs-beak	10	7	12	7
Bull-finch	10	6	11	6
Sparrow	9	9	10	
Gold-finch	11	8	11	8
Titmouſe	11	8	11	7
Lark	11	9	10	7
Red-breaſt	10	8	10	8
Swallow	11	8	11	9
Goat-ſucker	11	8	11	8
Humming Bird	12	9	9	8
Hoopoe	12	7	10	7
King's-fiſher	12	7	8	7
Wood-pecker	12	8	10	9
Toucan	12	8	12	more than 7
Parrot	11	9	11	8
Pigeon	13	7	13	7
Peacock	14	7	12	8
Pheaſant	13	7	15	5
Turkey	15	7	10	5
Curaſſow Bird	15	8	10	7
Oſtrich	18	8	20	9
Caſſowary	15	11	19	7
Flamingo	18	7	12	7
Heron	18	7	10	7
Stork	19	7	11	8
Crane	19	9	12	7
Spoonbill	17	7	14	8
Avoſet	14	9	10	8
Plover	15	8	10	7
Lapwing	14	8	10	7
Woodcock	18	7	13	8
Curlew	13	8	10	8
Oyſter-catcher	12	9	15	
Rail	13	8	13	8
Coot	15	9	7	8
Jacana	14	8	12	7
Pelican	16	7	14	7
Cormorant	16	9	14	8
Sea-ſwallow	14	8	10	8
Gull	12	8	11	8
Petrel	14	8	??	8
Swan	23	11	14	8
Goofe	15	10	14	7
Barnacle	18	10	14	9
Duck	14	8	15	8
Sheldrake	16	11	11	9
Scoter, or Black Diver	15	9	14	7
Merganſer	15	8	13	7
Grebe	14	10	13	7

The *cervical vertebræ* are joined to each other by a mode of articulation which admits of very free motion in two directions;—laterally, and backwards or forwards. This depends upon the form of the articular ſurfaces of the bodies of the vertebræ, which conſiſt of two portions of a cylinder applied croſsways with reſpect to each other, and both a little hollowed for their mutual accommodation. The cylinder on the inferior part of the vertebræ, performs by its revolution the motion to either ſide; and when that of the ſuperior part revolves, the neck is bent either backwards or forwards. The cylinders at the top of the neck admit of motion forwards; but thoſe of the middle and inferior part of the cervical ſpine are incapable of performing a free motion forwards, as one contains a ſlight depreſſion on its anterior part, which receives the edge of the other. The neck of birds, therefore, poſſeſſes in the contracted ſtate, or when at reſt, ſomewhat of the figure of an S, which is accompanied with ſeveral advantages to theſe animals. They are enabled by it to throw the weight of the neck and the head more over their centre of gravity, without which ſome ſpecies would be unable to preſerve their equilibrium; and by combining the S like motion with that to each ſide, birds acquire a greater degree of flexibility in the neck than is poſſeſſed by other animals; they can touch every point of their own body with the bill, and thus ſupply the want of the prehenſile faculty of the ſuperior extremity or the tail, of which they are deprived by their peculiar mode of progreſſion.

The ſurfaces of the articular proceſſes lie nearly in the direction of the bodies of the vertebræ, but in ſome parts have a degree of obliquity conformable to the S like ſhape of the neck.

The ſpinous proceſſes are only to be obſerved on the ſuperior and inferior portions of the cervical ſpine, where they exiſt both on the anterior and poſterior parts of the vertebræ. In birds with long necks there is a foſſa on each ſide of the poſterior ſpinous proceſſes, for the attachment of the cervical ligament, or *ligamentum nuchæ*. This ſubſtance is to be obſerved perhaps in all birds, but is very remarkable in the *ſtork*, *ſwan*, *caſſowary*, and *oſtrich*. In the laſt bird it is nearly as ſtrong as it exiſts in the larger quadrupeds: the ſame kind of ligament is alſo interpoſed between the ſpinous proceſſes of the dorſal vertebræ.

The tranſverſe proceſſes of the vertebræ of the middle of the neck ſpread forwards, and ſend down a ſtyloid proceſs of ſome length. Theſe give attachment to muſcles, and form in ſome birds a ſort of canal on the anterior part of the neck, which contains the two carotid arteries. The anterior ſtyloid proceſſes are little obſervable in the *rapacious* and *paſſerine* tribes, the *parrot* &c; but are uſually very marked in the long-necked birds.

The *dorſal vertebræ* of birds have ſcarcely any motion, in order

order that the trunk of the body may not be affected by the motions of the wings in flight.

Their ſpinous proceſſes are commonly anchyloſed with each other, which ſometimes occurs alſo with reſpect to the tranſverſe proceſſes. In the *oſtrich* and *caſſowary*, the proceſſes of the dorſal vertebræ are diſtinct, and poſſeſs a degree of motion from which however theſe birds cannot ſuffer any inconvenience, as they do not fly.

The *caudal vertebræ* have ſpinous proceſſes on both the anterior and poſterior ſurfaces; and the tranſverſe proceſſes are uſually very prominent. The laſt bone of the tail, is, in moſt birds, of a plough-ſhare ſhape for the attachment of the quills. It is ſmall and conic in the *new, holland oſtrich*, and *caſſowary*; and in the *peacock*, it is thin, oval, and ſituated horizontally. It is wanting in a variety of the domeſtic cock found in America.

The *ſternum* forms one of the moſt characteriſtic bones in the ſkeleton of birds. It is a very broad thin bone, covers the anterior part of the common cavity, like a buckler, and produces from its middle line, in every bird which is capable of flying, a thin plate of bone, which reſembles very much the keel of a ſhip; but it is moſt prominent at its anterior part. The upper edge of the ſternum preſents two narrow depreſſions, which receive the ends of the two clavicles; and to the moſt anterior point of the keel the fork-ſhaped bone is commonly attached. The poſterior edge is thin, and in moſt ſpecies, contains a ſpace on each ſide, which is filled with membranes. In the *accipitres*, *parrot*, and moſt *aquatic* birds, this is an oval hole; but in the *gallinæ* it is an oblong vacancy. The keel appears to be added to the ſternum, merely for the attachment of the great pectoral muſcle. Accordingly, we find its projection is proportioned to the neceſſity there is for uſing this muſcle during flight; and in the *oſtrich* and *caſſowary*, which do not employ their wings as organs of locomotion, the keel is abſent, and the ſternum is round and ſmooth on the external ſurface, and is very ſmall in proportion to the magnitude of theſe birds.

The *ribs* of birds have been divided, like thoſe of mammalia, into true and falſe, or as Vic d'azir has termed them, the *ſterno-vertebral* and *vertebral*. The true ribs are made of two pieces, which are each compoſed of bone: the poſterior portion is affixed to the ſpine by means of two branches, of which one is articulated with the body, and the other with the tranſverſe proceſs of the ſame dorſal vertebra. The anterior piece is articulated by one end, with the lateral edge of the ſternum; and by the other, to the end of the vertebral portion. The ſternal extremities of the ribs, being diſtinct bones, deſerve to be called *ſternal ribs*, which term we have employed in other parts of this article. Moſt of the true ribs are furniſhed, about their middle, with a thin oſſeous proceſs, which proceeds obliquely backwards from the poſterior edge of one rib, and over-laps the one next behind it, and ſometimes even goes on to cover two ribs, as in the *colymbus criſtatus*. The ſternal and vertebral portions of the true ribs form, at their junction, an angle which points backwards, and is very acute in the firſt ribs, which proves that the thorax of birds is chiefly dilated by the anterior part of the ſternum, being carried forwards from the dorſal ſpine; at which time, the moveable angles of all the ribs become very obtuſe. Theſe angles are ſcarcely obſervable in the *ſtruthious* birds. Their ribs aſſume very much the figure of thoſe of mammalia.

The number of the ſterno-vertebral ribs is liable to vary. There are, on each ſide, four in the *cuckoo* and the *caſſowary*; five in the *crow*, *african oſtrich*, and *ſtork*; ſix in the *bittern*; ſeven in the *eagle*, the *buzzard*, the *owl*, the *crane*, and the *duck*; eight in the *creſted grebe*, and ſeveral other waterfowl; and nine in the *ſwan*.

The *vertebral*, or *falſe ribs*, are in moſt birds placed at the anterior part of the thorax, which is the reverſe of what is obſerved in mammalia. When there are any of theſe ribs ſituated poſteriorly, they are only one or two pair, and imperfectly formed; there are two pair in the *ſtruthious* birds, which do not project far from the ſpine.

The *bones of the pelvis* become conſolidated together at a very early period. Their original parts are therefore very difficult to diſtinguiſh. The portion correſponding to the *os ilium* bears ſome reſemblance to that bone in mammalia; but the iſchium and pubis cannot be recogniſed by their figure, and are only to be known by their relation to the different foramina. There is a very long, ſlender bone, originally connected to the ilium, on the fore-part of the acetabulum, which ſupplies the place of the *pubis*. This bone runs parallel to the anterior part of the iſchium, with which it is occaſionally joined towards its extremity, but never unites with the bone of the oppoſite ſide, except in the *oſtrich*, in which bird the bones of the pubis are broad at their ſymphiſis, and ſtand a little forwards, producing ſomething of the appearance of the pelvis of mammalia. The pubis unites with the iſchium in the *accipitres* for a conſiderable way, and leaves a diſtinct hole analogous to the *foramen ovale*; and the ſpace between theſe bones poſſeſſes in all birds, at the anterior part, the traces of this foramen.

The *iſchium* is commonly united to the ſacrum and back of the ilium, by the part which correſponds to the iſchiadic *ſpine*; conſequently, the iſchiadic foramen is complete in the ſkeleton of birds. In the *oſtrich* and *caſſowary*, however, the iſchium is ſeparate from the ſacrum, and is a long, ſlender ſtyloid bone, like the pubis. There is no tuberoſity to the iſchium, that part being thin and extended, except in the *oſtrich*, where it becomes ſomewhat enlarged. The iſchium appears to be joined to the pubis in the *new, holland oſtrich*, by the intervention of another ſhort bone.

The *bones of the ſhoulder* are very peculiar in birds; beſides the clavicles and ſcapulæ, there is an additional ſingle bone, called the *fork*: it uſually poſſeſſes the figure of a V; the point is attached to the moſt anterior part of the keel of the ſternum, and the ends of the branches are ſecured by a ligament on the inſide of the dorſal extremities of the clavicles, and alſo to the poſterior proceſs of the ſcapulæ, which is analogous to the acromion. The fork frequently approaches more to the figure of an U than a V. Its angle is alſo often at ſome diſtance from the ſternum, to which it is bound by a ligament. In the *gallinæ*, it terminates in a thin plate, from which a ligament is extended to the keel of the ſternum. As a general obſervation, it may be ſtated, that the fork is ſtrong and elaſtic, and its branches wide, arched, and carried forwards upon the body, in proportion as the bird poſſeſſes ſtrength and rapidity of flight; and accordingly, the *ſtruthious* birds, which are incapable of this mode of progreſſion, have the fork very imperfectly formed. The two branches are very ſhort, and never unite in the *african oſtrich*, but are anchyloſed with the ſcapulæ and clavicle. The *caſſowary* has merely two little proceſſes from the ſide of the clavicle which are the rudiments of the branches of the fork. In the *new holland oſtrich*, there are two very ſmall thin bones, which are attached to the anterior edge of the dorſal end of the clavicles, by ligament; they are directed upwards towards the neck, where they are faſtened to each other

other by means of a ligament, and have no connection whatever with the ſternum.

The *clavicle* is a ſtraight bone in birds; it does not lie in a tranſverſe direction with reſpect to the trunk of the body, but proceeds upwards and forwards towards the lower part of the cervical ſpine; and in proportion to the length and projection of the clavicle, the bird poſſeſſes ſtrength of wing and activity of flight. The clavicle at its articulation with the ſternum is thin and broad; but the reſt of the bone is of a round ſhape: it produces a proceſs from the poſterior part of its dorſal extremity, which is united to the head of the ſcapula, and in conjunction with it, forms a depreſſion analogous to the glenoid cavity, although not of the ſame figure. The inſide of the extreme part of the dorſal end of the bone, is joined by ligament with the branch of the fork, as already mentioned.

The clavicles of the *ſtruthiæ* are remarkably ſhort, and are anchyloſed with the ſcapulæ at leaſt.

The *ſcapulæ* are two long, plain bones, with ſharp edges, reſembling, in a great degree, the blade of a knife; they lie parallel to the dorſal ſpine, and have no proceſſes, except the one which contributes with the clavicle to form the cavity for lodging the head of the humerus; and a little eminence oppoſite to this, which ſeems analogous to the *acromion*, and is joined to the end of the branch of the fork. The ſcapulæ, like all the other bones of the ſhoulder, are very ſhort in the *ſtruthiæ*, not paſſing beyond the firſt two or three ribs; although in many other birds theſe bones reach as far as the pelvis.

The *humerus* is a round, ſmooth bone, more or leſs enlarged, and flattened at the extremities; the ſurface by which it articulates with the foſſa in the ſcapula and clavicle, is at the very end of the bone, and is formed of a portion of a cylinder, inſtead of a ſphere, which is moſt ſuitable to the motions of the humerus in birds, they being almoſt confined to the elevation and depreſſion of the wing. The external tuberoſity of the humerus is very ſmall; but the ſpine which leads from it is greatly elevated in moſt ſpecies of birds. The internal tuberoſity is, on the other hand, remarkably large, and furniſhes a proceſs at its upper part, which correſponds, in ſome reſpects, with the coracoid proceſs of the ſcapula in mammalia. The humerus is long, in proportion to the other bones of the wing in the *African oſtrich*, and takes the curvature of the bird's body. It is extremely ſhort and ſmall, and without proceſſes, in the *New Holland oſtrich*, and *caſſowary*.

The humerus is connected with the bones of the fore arm by an articular ſurface, ſimilar to that of the human ſubject.

The *radius* is uſually a much more ſlender bone than the ulna, with which it is never obſerved to be anchyloſed.

The *ulna* exhibits no remarkable proceſſes; it forms a pully on its lower end. Theſe two bones are flat in the *manchot* (*aptenodytes*), and are joined by an articulation which permits motion in ſeveral directions, with two tubercles, one above, and the other below the anterior edge of the humerus. The wing of this bird, both in its ſtructure and offices, reſembles a fin. The ulna and radius are nearly of an equal ſize in the *ſtruthiæ*; they are both very ſmall, and have but little motion on the humerus.

There are but two *carpal* bones in birds; one is applied to the end of the radius, and prevents the motion of the lower part of the wing beyond the line of the radius; the other moves a little upon the end of the ulna, to which its form is adapted. It has often a little proceſs from its lower edge, which is analogous to the *os piſiforme*. The carpal bones are obliterated in the *ſtruthious* birds.

The *metacarpus* conſiſts of two bones, which are united at their ſuperior part by anchyloſis for ſome way. At this place there are ſome eminences which appear like the remains of the ſecond row of carpal bones ſoldered together. The articulation of the metacarpus with the carpus is the ſegment of more than the half of a pulley, which is grooved in the middle, and revolves within a correſponding ſurface of the lower carpal bone. This motion, for the convenience of deſcription, is called flexion and extenſion; but it is in ſtrictneſs a lateral movement back upon the ulna, and accompanied with a degree of rotation, by which the concave figure of the wing is loſt in the very action of folding it. There is a ſtyloid proceſs on the upper part of the radial ſide of the metacarpus, which gives attachment to a ſmall pointed bone, ſupplying the place of the *thumb*. A ſimilar bone is affixed to the extreme end of the ſmall branch of the metacarpus, and correſponds to the *little finger*. The *principal*, or *fore finger*, which terminates the wing, is articulated with the large or radial branch of the metacarpus. It conſiſts of two phalanges, and the firſt exhibits marks of having been originally two bones. The two pieces of the metacarpus are to be ſeen in the *African oſtrich*, as alſo the three fingers; each of which is furniſhed with a hook, which is covered with a horn, like a claw; but in the *New Holland oſtrich* the metacarpus is a ſingle bone, and there is but one finger, which is alſo terminated with a claw. All the bones of the hand are compreſſed into thin plates in the *manchot*.

The *thigh-bone* of birds has nothing very peculiar in its form; it wants the ſmall trochanter; it is ſingularly ſhort, in proportion to the other parts of the limb, in ſuch birds as have long legs; it is longeſt in the *accipitres*, and ſhorteſt in ſome water-birds. The femur is ſtrong in all the *gallinæ*; and in the *ſtruthiæ* it is of an immenſe thickneſs; it is bent in the *cormorant* and the *little grebe*.

There is a certain portion of the ligament of the extenſor muſcles of the leg converted very early into bone; and this ſeems in general to ſupply the place of the *patella*; it is not uſually preſerved in ſkeletons.

The *tibia* reſembles in its form the ſame bone in mammalia. There are ſeveral prominent edges on the fore part of its head for the attachment of muſcles. The lower end of the tibia forms a pulley with a groove along the middle. The head of the tibia is prolonged in a remarkable manner upon the thigh, in the *grebes* and the *diver*.

The *fibula* is a very ſmall bone, and is ſoon anchyloſed to the ſide of the tibia.

The *tarſus* and *metatarſus* conſiſt, in the adult bird, but of one bone; it exhibits, however, grooves correſponding to the diviſions which exiſted between its ſeveral pieces when it was firſt formed. Theſe are ſtrongly marked in the long-legged birds, and ſhew that the metatarſus contained originally as many bones as there are principal toes. There is uſually alſo a prominence on the poſterior part of the head of the bone which repreſents the *os calcis*. The inferior extremity of the metatarſal bone produces a proceſs ſhaped like a pulley for the articulation with each of the principal toes

There are three bones in the compoſition of the tarſus and metatarſus of the *manchot* ſeparate from each other in the middle; and therefore theſe birds are plantigrade, or walk upon the metatarſus as well as the toes.

The extraordinary length of limb which belongs to ſome kinds, as the *ſtruthious* and *wading birds*, depends upon the extent of the tibia and metatarſal bone.

The *ſtork*, and ſome others of the *grallæ*, which ſleep ſtanding on one foot, poſſeſs a curious mechaniſm for preſerving the leg in a ſtate of extenſion, without any, or at leaſt with little muſcular effort. There ariſes from the fore part of the head of the metatarſal bone a round eminence, which paſſes up between the projections of the pulley on the

anterior part of the end of the tibia. This eminence affords a ſufficient degree of reſiſtance to the flexion of the leg to counteract the effect of the oſcillations of the body, and would prove an inſurmountable obſtruction to the motion of the joint, if there were not a ſocket within the upper part of the pulley of the tibia, to receive it when the leg is in the bent poſition. The lower edge of the ſocket is prominent and ſharp, and preſents a ſort of barrier to the admiſſion of the eminence, that requires a voluntary muſcular exertion of the bird to overcome, which being accompliſhed, it ſlips in with ſome force like the end of a diſlocated bone. Dumeril and Cuvier have deſcribed a ſimilar apparatus to this in the knee of the *ſtork*; but they muſt have confounded, in an unaccountable manner, the one joint with the other; for the articulation of the femur with the bones of the leg in the common *ſtork (ardea alba)*, certainly exhibits nothing peculiar in its ſtructure. See *Plate* VIII. in the *Anatomy of Birds*. *Fig.* 1. repreſents the anterior part of the articulation of the tibia with the metatarſus in the *ſtork*; *a* the tibia, *b* the metatarſal bone, *c c* the prominent edges of the pulley on the end of the tibia, *d* the round eminence of the head of the metatarſus, *e* the ſocket in the tibia, which receives the eminence during the flexion of the joint.

The *bones of the toes* vary in number, increaſing from the inner to the external toes. Birds with four toes have the number of the phalanges in the following order, 2, 3, 4, 5; thoſe with three toes have them, 3, 4, 5, except the *caſſowary* and the *New Holland oſtrich*, which have four joints to each toe. The *African oſtrich* has only two toes, and four phalanges to both. Moſt birds have the three principal toes ſituated before, and the pollex attached to the inner and back part of the metatarſal bone near its extremity. The *buſtard*, *caſſowary*, *New Holland oſtrich*, the *plover*, the *oyſter catcher*, and the *long legged plover*, have but three toes; and the *albatroſs*, *petrell*, and *penguin*, want the pollex. All the *ſcanſores* have their toes oppoſed to each other, two behind and two before.

It would have rendered the deſcription of the bones tedious and confuſed, to have given frequent references to the plates which repreſent them; the reader, therefore, will have occaſion to contemplate the relation the different figures bear to each other; and to facilitate ſuch compariſon, ſimilar letters are employed to indicate ſimilar parts in each of the ſkeletons choſen to illuſtrate the ſubject.

When birds tranſport themſelves from one place to another, it is moſt commonly by the act of flying; which conſiſts in the ſucceſſive elevation and depreſſion of the wings; the latter motion being performed with ſo much force and velocity, as to compreſs a volume of air, the re-action of which is ſufficient to impel forwards the whole body of the bird. The various kinds of flight depend upon the different ways of employing the wings, and the habits and œconomy of the individual, which it is the buſineſs of the naturaliſt to point out. Many birds are capable of uſing other modes of locomotion beſides flying, for which their ſtructure is equally well adapted; for inſtance, ſome tribes almoſt conſtantly inhabit the water, and ſwim with the greateſt eaſe; others walk or run with the greateſt rapidity; and others tranſport themſelves chiefly by the effort of climbing. We have, therefore, ſelected a ſkeleton to exhibit the organs employed in each of theſe ſpecies of locomotion. See *Plate* VIII. in the *Anatomy of Birds*. *Fig.* 2. repreſents a ſkeleton of the *New Holland oſtrich*, which was brought into this country by an ingenious young ſurgeon, Mr. Langſtaff. It ſeems to partake of the ſtructure of both the *caſſowary* and *African oſtrich*, but it bears the greateſt likeneſs to the latter; and therefore we have called the bird an oſtrich, although it has hitherto been conſidered by ſome naturaliſts as a caſſowary. This ſkeleton affords the beſt example of a *running* bird, which is at the ſame time incapable of flight. The ſternum and bones of the wing are ſmall; the centre of gravity is thrown fairly between the legs; and the inferior extremities are long, and of an immenſe diſproportionate ſtrength. *Fig.* 3. of the ſame plate exhibits the ſkeleton of the *lark*, which, as being a bird of high flight, forms a ſtriking contraſt with *fig.* 2.

Plate IX. of the *Anatomy of Birds*, contains the ſkeletons of a *climbing* and a *ſwimming* bird. *Fig.* 1. is the ſkeleton of the *parrot*. The body is round and contracted; the neck ſhort, ſtrong, and flexible in different directions; the ſternum and bones of the ſhoulder rather ſmall; but its chief characters are the long thigh, and very ſhort metatarſus, furniſhed with the climbing toes; by which means the bird can graſp any foreign ſubſtance, and apply the feet to any part of its own body, after the manner of the prehenſile members of other animals.

Fig. 2. of *Plate* IX. ſhews the ſkeleton of the *creſted grebe* (*colymbus criſtatus*). The neck is much bent; the parts of the upper extremity rather ſmall; the ribs ſtrong, and reaching far back; the ſternum long; and the body poſſeſſes very much the form of a boat; the inferior extremity ſituated far behind, and the thigh bone very ſhort, and the toes long and expanded; all which circumſtances are neceſſary to the performance of the actions of ſwimming and diving with facility.

The ſeparate parts of the ſkeletons, in *Plates* VIII. and IX. in the *Anatomy of Birds*, are indicated as follows.

Parts compoſing the head; a the occiput, *b* parietal bone, *c* os frontis, *d* temporal bone, *e* os lacrymale, or ſuperciliary bone, *f* naſal bone, *g* ſuperior maxilla, *h* malar bone, *i* bone of the upper mandible, *k* palatine bone, *l* ſeptum of the orbits, *m* articular bone, *n* interarticular bone, *o* zygoma, *p* inferior maxilla, *q* bone of the lower mandible, *r* external nares, *s* deficiency in the ſeptum of the orbits where the optic foramina open, *t* temporal foſſa, *u* ſpongy bone in the organ of ſmell.

Parts of the ſpine and trunk; a cervical vertebræ, *b* their tranſverſe proceſſes, *c* the ſtyles which deſcend on the forepart, *d* articular proceſſes, *e* poſterior ſpinous proceſſes, *f* ſpines on the anterior part of the bodies of ſome of the vertebræ, *g* dorſal vertebræ, *h* lacral vertebræ, *i* vertebræ of the tail, *k* the laſt, or caudal bone, *l* os ilium, *m* iſchium, *n* pubis, *o* foramen ovale, *p* iſchiadic foramen, *q* vertebral or falſe ribs, *r* the true ribs, *s* the ſternal portions, *t* intercoſtal proceſſes, *u* the part of the ſternum next the body, *v* the keel, or projecting part, *x* deficiency at the lower part of the ſternal bone.

Parts belonging to the wing; a the fork, *b* the clavicle, *c* the ſcapula, *d* the humerus, *e* its inner tuberoſity, *f* the external tuberoſity, *g* the ſpine for the attachment of the deltoid and pectoral muſcles, *h* the ulna, *i* the radius, *k* the carpal bone on the radial ſide, *l* the ulnar carpal bone, *m* the head of the metacarpus, *n* the large branch, *o* the ſmaller one, *p* the ſtyle of the metacarpus, *q* the pollex or thumb, *r* the little finger, *s* the principal or fore finger.

The parts of which the lower extremity conſiſts; a the femur, *b* its ſingle trochanter, *c* the tibia, *d* the elongation of the head of the tibia which occurs in the *grebe*, &c. *e* the fibula, *f* the metatarſus, *g* the prominence at the heel, *h* the pollex, or back toe, *i* the principal or anterior toes.

Muſcles.

When the writing of the preſent article was begun, it was intended to give a full deſcription of the muſcles of birds; but as the ſubject has already extended beyond the length

length that was expected, and if this were done, would exceed the bounds usually allotted to a single article, we shall only point out the most striking peculiarities in the muscular system, and correct some errors into which other writers have fallen in their accounts of this part of the anatomy of birds.

The muscles which move the lower jaw, do not differ essentially from those of mammalia. There is no marked distinction between the *masseter and temporal muscles*; they form one mass which arises from the temporal fossa and inferior part of the orbit, passes under the zygoma, and covers the side of the lower jaw from the joint to the commencement of the bill.

There is a tendon which lies over the muscles on the side of the jaws, usually of a triangular figure; it is attached to the inferior bony portions of the orbit, connects them to each other, and thus completes the margin of the orbit. It is affixed to the protuberance on the outside of the lower jaw, near the joint, and seems to prevent the mouth opening beyond a certain distance.

Birds have none of the *muscles of the face*, as they have no soft parts for them to move.

The lower jaw is depressed by a muscle which arises by two portions, one from the hollow behind the side of the occiput, the other from the surface behind and below the external meatus auditorius; both are inserted upon the back of the lower jaw. This muscle, although so unlike the *digastricus*, supplies its place, and fulfils its office.

There are three muscles for moving the upper jaw, which are quite peculiar to birds. The *first* is of a radiated or fan shape; it arises from the septum of the orbit, and passing obliquely backwards, is inserted by tendon into the external surface of the end of the inter-articular bone, just when it becomes joined to the articular. By pulling the posterior end of the inter-articular bone upwards, the opposite end is pushed forwards, which produces the elevation of the upper jaw in the manner already described.

The *second* is a short thick muscle, arising from below the posterior part of the orbit, and before the external meatus auditorius, and inserted into the inner surface of the body of the articular bone and its anterior process, where it joins the inter-articular bone; it elevates the posterior end of the inter-articular bone, and thus raises the upper jaw.

The *third* muscle is for depressing the superior jaw; it is of a long taper shape, has one attachment to the inside of the lower jaw, and then becomes affixed to the inside of the inter-articular bone, the internal part of the pterygoid process, and sends a small tendon to the integument of the palate, just where the horny covering of the mandible commences. It is difficult to distinguish it from the pterygoid muscle, which appears to aid it in the depression of the superior mandible.

The tongue enjoys much less variety of motion in birds than in mammalia; it is only capable of being protruded, retracted, turned to each side either directly or obliquely, slightly rotated, and depressed at the point. There are a great many muscles, however, employed in the performance of these motions; some of these act upon the os hyoides, and others upon the lingual bone.

The first is analogous to the *stylo-hyoideus*; arises from the upper and back part of the lower jaw, divides into two slips; one goes to the styloid bone of the os hyoides, where it meets its fellow: the other slip passes to the inner part of the middle bone or body of the hyoides; it retracts the tongue.

The second corresponds to the *mylo-hyoideus*; it is a broad thin muscle, proceeds from the inside of the lower jaw, except its posterior edge, which comes from the outer part of the jaw; it is inserted upon the concave side of the cartilaginous extremity of the horn of the os hyoides, around which it forms a muscular sheath; its use is to protrude the tongue.

The third muscle appears to answer to the *genio-hyoideus*; it comes from the superior edge of the lower jaw internally, and becomes attached to its fellow on the other side upon the styloid bone of the hyoides; protrudes the tongue a little from the obliquity of its direction, and seems to commence the actions of deglutition by elevating the parts in the bottom of the mouth. We did not observe this muscle in the *cock*.

The fourth muscle of the tongue is extended from the horn of the os hyoides at its root, to the styloid bone, where it joins the muscle of the opposite side. They approximate the horns of the hyoides, during the protrusion of the tongue.

The fifth is a very small muscle, lying along the internal surface of the horn of the os hyoides; it sends a delicate tendon to the under surface of the lingual bone, depresses the point of the tongue, and if it acts singly, turns the tongue.

The sixth is a little short muscle, which arises from the end of the middle bone of the hyoides, and is affixed to the under part of the lingual bone; depresses the tip of the tongue, and raises the base. This is a single muscle.

The seventh muscle lies along with its fellow upon the anterior surface of the superior larynx; it is attached to the root of the lingual bone. Its uses are to depress the base of the tongue, and thus elevate the point, and to retract the tongue while in the mouth.

The eighth is short; arises from the junction of all the bones of the os hyoides on the lower surface, and is inserted into the upper and outer corner of the base of the lingual bone. It brings the tongue into a straight line, after the other muscles have depressed the tip.

The ninth muscle is the last; it is very minute, and passes from the base of the lingual bone to the very tip of the cartilage; depresses the point of the tongue without elevating its root.

The muscles which protrude and retract the tongue, are remarkably large in the *woodpeckers* and *wrynecks*.

The *muscles which move the head and neck*, are even more complicated in birds than in other animals. Most of them have their attachments so numerous and intermixed, that no description can convey an adequate idea of them.

The *longus colli* begins in the thorax on the anterior spines of the dorsal vertebræ; its fasciculi go from the anterior part of the cervical vertebræ to the styles and transverse processes; and their tendons are longest at the superior and inferior part of the neck.

The *rectus capitis major anticus* is continued from the head as low as the fifth vertebræ of the cervical spine.

On the posterior part of the spine there is a small muscle which seems to represent the superior part of the *trapezius*; it is extended from the transverse processes of the four first cervical vertebræ to the back of the occiput; it brings the head backwards and to one side.

There are a great number of fasciculi interposed between the transverse and articular processes at the back of the neck. These tendons pass over several vertebræ before they are inserted on the middle of the neck, which is the part most bent backwards.

A muscle which has been considered analogous to the *cervicalis descendens*, is the chief extensor of the neck of birds. It arises from the spine of the back, opposite to the se-

cond rib, by tendon, which, on coming upon the neck, receives ſeven ſlips of muſcle, which deſcend from the ſpines of the ſeven inferior cervical vertebræ. The muſcle then proceeds on the neck as a diſtinct ſlip, and at the upper part produces three tendons, which go to the back of the articular proceſſes of the ſecond, third, and fourth cervical vertebræ. Theſe tendons receive muſcular ſlips from the back of the ſpine as low as the ſeventh vertebræ, or where the other ſlip began to deſcend. The aſcending faſciculi furniſh the tendons to the fifth and ſixth vertebræ, and to the atlas. This muſcle is enabled, on account of its deſcending and aſcending faſciculi, to extend the neck even while the head is erected. Cuvier deſcribes the muſcle ſomewhat differently in the *heron* and *buzzard*. The above account is from the *gooſe*.

There is a curious ſhaped muſcle along the inſide of the preceding, which Cuvier compares to the *biventer cervicis*. It commences by a ſlender tendon from the ſpinous proceſs of the firſt dorſal vertebra, becomes fleſhy at the lower part, tendinous along the middle, and again fleſhy near the head, and is inſerted into the occiput. Although it extends the whole length of the neck, it is ſo ſlender that its tendon is not thicker than a piece of twine or thread. It aſſiſts in the extenſion of the neck and elevation of the head.

The *trachelo-maſtoideus* ariſes in birds from the anterior part of the ſecond, third, and fourth cervical vertebræ, and is inſerted upon the ſide of the occiput.

The *complexus* proceeds from but a few of the articular proceſſes of the neck; and the *ſplenius* does not exiſt in birds.

Cuvier deſcribes three *recti capitis poſtici;* but theſe muſcles do not deſerve to be ſo called.

The firſt, which he names the *rectus maximus*, ariſes from the ſpine of the dentata, and is inſerted into the ſide and back of the occiput. It brings the head backwards, and to one ſide, and reſembles in figure and office the *ſplenius capitis*.

The ſecond, or *rectus major poſticus*, proceeds obliquely from the ſpine of the dentata, under the preceding, to the depreſſion on the back of the occiput.

The third, or *rectus minor*, is only a few fibres mixed with the ligament, which connects the head with the ſpine.

The *muſcles of the back* conſiſt of a few fleſhy fibres intermixed with portion of tendon, which are moſtly oſſified in full grown birds; they lie on each ſide of the dorſal ſpine, which they ſtrengthen but cannot move.

The *muſcles of the tail* are diſtinct, and generally large; ſome are calculated to raiſe the tail, ſome to depreſs it, others to move it laterally, and others again to unfold the quills of this part.

The firſt is the *levator coccygis* of Vic d'Azir; it ariſes from the back of the ſacrum and the tranſverſe and ſpinous proceſſes of the firſt caudal vertebræ, and ſends diſtinct tendons to each of the ſpinous proceſſes of the tail and the caudal bone. There is a fleſhy ſlip alſo accompanying the laſt tendon. This muſcle, as its name implies, elevates the tail.

The ſecond, or *depreſſor coccygis* of Vic d'Azir, is ſituated within the pelvis, and ariſes from the end of the ſacrum and the iſchium, where they join; alſo from the tranſverſe proceſſes of the bones of the tail. It is inſerted by tendons into the ſpinous proceſſes of the under ſurface of the caudal vertebræ, and diſtributes a number of muſcular fibres in different directions on the baſis of the lateral quills. This muſcle depreſſes the tail, and appears alſo, from its attachment to the ligament of the quills, to be capable of converging them.

The third ariſes from the poſterior edge of the anterior part of the pubis, and the tendon covering the lower part of the belly, and is inſerted on the baſe of the ligament which ſuſtains the lateral quills. When this muſcle acts ſingly, it brings the tail downwards and to one ſide; if, with its fellow, it depreſſes the tail directly; but at all times it tends to ſpread the quills of the tail.

The fourth is the *motor lateralis coccygis* of Vic d'Azir, who deſcribes its origin different from what we have obſerved it to be. It ariſes from the laſt tranſverſe proceſs of the ſacrum and the firſt of the coccyx, and it turns round to be inſerted in common with the preceding muſcle upon the root of the ligamentous ſubſtance, which connects the lateral quills. It moves, when acting alone, the tail to one ſide; but combined with its fellow and other muſcles, unfolds the quills of the tail in the manner of the ſticks of a fan.

The fifth muſcle is in part covered by the third; it is attached to the whole of the poſterior margin of the pelvis, except the extreme portion of the pelvis, and in the *gooſe* ſpreads even upon the parietes of the belly round the anus; it then proceeds to be inſerted, along with the depreſſor coccygis, on the under part of the caudal or laſt bone of the tail. Its office is, with its fellow and the depreſſor, to lower the tail.

The ſixth is the *cruro-coccygeus* of Vic d'Azir; it ariſes by thin tendon from the inner and back part of the thigh bone, where it is conjoined with one of the muſcles of the thigh. It is inſerted, along with the other muſcles of the tail, into the under part of the caudal bone. This muſcle draws the tail to one ſide; but when its action is combined with its fellow, it is the moſt powerful flexor or depreſſor of the tail.

The *muſcles of the trunk* deviate more from the ſtructure of mammalia than the muſcles of birds do in general, and have been but very imperfectly deſcribed by Cuvier and others.

The *ſcaleni* are merely two ſlips of muſcle, which deſcend from the next tranſverſe proceſs upon the firſt and ſecond ribs.

The *triangularis ſterni* takes its origin from the ſuperior corner of the ſternum and the four ſuperior ribs, where they join this bone, and is inſerted into the moveable angles of the four ſuperior ribs after the firſt. It compreſſes the ſuperior part of the thorax, and thus brings forwards the lower end of the ſternum; it is, therefore, a muſcle of expiration.

The abdominal muſcles conſiſt of three layers.

The firſt repreſents the *obliquus externus*, although its fibres are arranged tranſverſely. It ariſes from the edge of the ilium and pubis by a very thin tendon, and from the lower edges of the ribs, by diſtinct tendinous proceſſes, and is inſerted into the ſide and lower edge of the ſternum, and the middle line of the belly, to unite with the muſcle of the oppoſite ſide. From this muſcle paſſing over the moveable angles of the ribs, its action influences the whole cavity of the body; for at the ſame time that it compreſſes the abdomen, it raiſes the anterior part of the ſternum, by drawing the poſterior part backwards, and thus dilates the thorax, and becomes a muſcle of inſpiration, explaining by this means the effect we have already repreſented inſpiration to produce upon the abdominal air-cells.

The ſecond is the *obliquus aſcendens;* it is made of two portions, the one a little overlapping the other; the anterior is analogous to the *rectus abdominis*, and ariſes from the pubis and middle line of the belly; the other portion ariſes from the edge of the ilium and loweſt rib. The fibres of each portion aſcend in their proper directions to be inſerted on the lower edge of the ſternum, and the tendon filling the

the ſpace between the ribs and the ſternum. This muſcle, like the preceding, diminiſhes the abdomen, and dilates the anterior part of the thorax.

The third layer anſwers to the *tranſverſalis abdominis*. It proceeds from the oſſeous margin of the abdomen to the middle line, where it meets its fellow. They conſiſt of ſeparate faſciculi at the ſuperior part; and the fibres are collected round a point in the centre, where the yolk paſſed into the belly of the chick.

There is a very thin ſlip of muſcle, which croſſes the loweſt part of the belly; it is ſituated ſuperficially, and lies over ſeveral of the muſcles of the tail. In the *gooſe* it ariſes from the iſchium, where that bone joins the pubis; and in the *fowl* it is only attached by cellular membrane to the ſurface of the muſcles of the thigh. It is inſerted, in both caſes, on the ſide of the anus, which it ſeems deſigned to dilate.

We have obſerved in the *fowl* two very ſlender faſciculi of muſcle to deſcend from the ſide of the rectum, one to the ligament ſupporting the quills of the tail, the other to the inſide of the pelvis. They are both probably intended to produce the everſion of the inteſtine during coition.

The *muſcles belonging to the wing* do not differ in their arrangement and ſtructure from thoſe of the anterior extremity of mammalia ſo much as might be ſuppoſed, conſidering how little theſe members reſemble each other in their functions.

The *latiſſimus dorſi* ariſes only from the ſpines of the dorſal vertebræ; it reſembles, however, the muſcle of the ſame name in mammalia.

A muſcle, analogous to the inferior portion of the *trapezius*, is obſerved at the ſhoulder. It comes from the ſpinous proceſſes of the three laſt cervical and all the dorſal vertebræ, and is inſerted into the inner and back part of the fork and poſterior edge of the ſcapula. We have not perceived the diſtinction of this muſcle into two parts on the ſhoulder, as ſtated by Cuvier.

The *ſerratus major anticus* is only inſerted into the point of the ſcapula. This muſcle has been called by Vic d'Azir, the *ſubſcapularis*.

The *coſto-ſcapularis* of Vic d'Azir goes from the firſt ribs to the neck of the ſcapula. It appears to be analogous to the *pectoralis minor* of the human ſubject.

The *rhomboides* is not diviſible into *major* and *minor*. It ariſes, as uſual, from the ſpine, and is inſerted in the poſterior edge of the ſcapula.

A muſcle, analogous to *levator ſcapulæ*, ariſes by three ſlips from the tranſverſe proceſs of the laſt cervical vertebra and the firſt and ſecond ribs. It is inſerted into the middle of the ſcapula, which it elevates and draws backwards. The motions of the ſcapula are neceſſarily very limited from its mode of connexion with the neighbouring bones; and its rotation is reſtrained by a ligament which joins the point of the ſcapula with the dorſal ſpine. It is requiſite the bones of the ſhoulder ſhould be kept very ſteady during flight.

There are three pectoral muſcles.

The *pectoralis maximus* of Vic d'Azir might be called, with more propriety, the *depreſſor alæ magnus*. It ariſes from the whole of the body and heel of the ſternum, except a certain portion of the anterior ſurface occupied by the next muſcle over which it lies, and from the ſide of the fork and the laſt ribs, and is inſerted into the ſpine on the outſide of the humerus, where it is connected by ligament with the deltoid muſcle. The pectoralis maximus has commonly more ſtrength than all the other muſcles of the body united, which is required to accompliſh the depreſſion of the wing in oppoſition to the whole weight of the bird during flight.

The *pectoralis medius* of Vic d'Azir might be called the *levator alæ*. It is affixed to the fore part of the body and keel of the ſternum, the ſide of the clavicle, and the membrane which fills the interſpace between that bone and the fork. It ſends its tendon over the head of the ſcapula through the pully formed by all the bones of the ſhoulder, to be inſerted on the external tuberoſity of the head of the humerus. By means of the pulley it elevates the humerus, and conſequently the wing; and from occupying the lower part of the cheſt, the weight is kept in the ſituation moſt convenient for the bird during flight.

The *pectoralis minimus* of Vic d'Azir, or *depreſſor alæ minor*, ariſes from a portion of the ſternum behind the articulation of the clavicle, and from the inſide of the ſternal extremity of the clavicle. It is inſerted under the head of the humerus; depreſſes the wing, and brings it cloſe to the body.

The *ſubclavius* is extended from the inſide of the ſternal extremity of the clavicle to the adjoining part of the internal ſurface of the ſternum. It is impoſſible to conceive the uſe of this muſcle, unleſs it be to ſtrengthen the joint, as its attachments are incapable of motion towards each other. There are muſcles analogous, as much as the form of the bones will permit, to the *ſubſcapularis*, *teres major* and *minor*, *ſupra ſpinatus*, and *infra ſpinatus*.

Cuvier deſcribes two little muſcles which come from the inſide of the clavicle to the head of the humerus. We have obſerved a muſcle in the *fowl* which appears to correſpond to one of theſe; it ariſes from the inner ſurface of the clavicle, and its joint with the ſternum, paſſes over the firſt rib, and is affixed to the top of the inner tubercle of the head of the humerus. It rotates the wing inwards, when it has been ſpread in flight. The lower edge of this muſcle, and the inſide of the teres major, produce a moſt delicate tendinous cord, or fibre, which deſcends on the back of the upper arm, and is loſt amongſt the ligaments of the quills below the elbow. The effect of this, if any, is to bring the wing nearer the body, and perhaps ſpread the quills.

The *deltoides* is ſmall, and of two portions. One ariſes from the fork at the top of the ſhoulder, and ſends a ſmall tendon to the aponeurotic expanſion of the fold of the wing. This tendon, as it proceeds along the edge of the expanſion, acquires exactly the ſtructure and the elaſticity of the *ligamentum nuchæ*; it then becomes like common tendon, paſſes over the end of the radius, and is inſerted into the ſtyle of the metacarpal bone. It bends the fore arm, extends the hand, and, in conſequence of the elaſticity of the tendon, contracts the ſoft part of the fold of the wing. This portion of the deltoid has eſcaped the obſervation of Cuvier and other writers, although the ſtructure of the tendon is one of the moſt extraordinary circumſtances in the anatomy of birds. The remaining portion of the deltoid is analogous to the ſame muſcle of the human ſubject, and brings the wing upwards and backwards in flight.

The muſcle which repreſents the *biceps flexor cubiti*, takes its origin from the end of the clavicle, where it joins the fork; and from the ſharp tubercle of the humerus, which is analogous to the coracoid proceſs, the chief part of the muſcle proceeds to be inſerted into the inſide of the neck of the radius; but as it deſcends, a ſmall portion goes off, and is expanded in the fold of the wing, and attached to the outer ſide of the arm. This expanſion of tendon correſponds to the aponeuroſis of the biceps muſcle of the human ſubject; but inſtead of lying cloſe to the fore arm, it is ſpread out and covered with the common integuments.

The *brachialis internus* is very ſmall, being only attached

to

to the fore part of the end of the humerus between the condyles.

There is a ſhort muſcle which ariſes from the ligament that conjoins the clavicle and the head of the humerus, and is inſerted upon the flat external ſurface between the two tubercles. It is an *elevator* of the wing. It is peculiar to birds, and has not yet been deſcribed.

The *extenſor cubiti* conſiſts of two portions: the one, called by Vic d'Azir the *extenſor longus*, comes from the junction of the fork and ſcapula; the other ariſes in a forked manner from the poſterior ſurface of the humerus, and is the *extenſor brevis*.

The *anconeus minor* of Cuvier is the external and lower part of the *extenſor brevis*. It is a diſtinct muſcle in the *fowl*, though not in the *goose*.

Although the bones of the fore arm do not admit of *pronation* and *ſupination*, the muſcles which perform theſe motions in other animals, exiſt in birds, and anſwer different purpoſes.

The *ſupinators* reſemble thoſe of the human ſubject. The *longus* terminates on the ſtyle of the metacarpal bone, and ſerves both to bend the arm on the humerus, and extend the metacarpus, or lower part of the wing. The *ſupinator brevis* bends the fore arm. The place of the *pronator teres* is ſupplied by two muſcles very much like it in ſhape; they act as flexors of the fore arm. There is a triangular muſcle which in ſome degree fills the ſituation of the *pronator quadratus*; it ariſes from the end of the ulna, and ſends a broad tendon over the carpus to the higheſt ſcabrous ſurface on the metacarpal bone. It extends the hand, or lower part of the wing, giving it at the ſame time a degree of pronation, which the carpal joint permits, in order to render the wing concave when it is extended.

The *flexors and extenſors*, ſituated on the fore arm of birds, reſemble in ſhape and arrangement generally thoſe of the human ſubject, but commonly have their uſes changed, and often even reverſed, in conſequence of the difference in the figure of the bones and the plan of their articulations.

The muſcle which correſponds in ſituation to the *extenſor carpi ulnaris*, performs the motion which is called flexion of the lower part of the wing.

There is a ſtrong muſcle ariſing from the external condyle of the humerus, and implanted into the ſide of the ulna oppoſite the radius, for almoſt its whole length. It raiſes the fore arm on the radius, and ſeems to be the muſcle called by Vic d'Azir *flexor profundus*.

The muſcle analogous to the *extenſor pollicis longus*, has its tendon inſerted into the ſtyle of the metacarpus, and into the ſhort abductor. It extends the hand on the fore arm.

The *ulnar flexor* bends the parts of the wing.

The *flexor ſublimis* comes from the internal condyle, is attached to the lower carpal bone, and ſends a tendon to the baſe of the firſt joint of the principal finger, bends the hand, but extends the finger.

The *flexor digitorum profundus* ariſes from the inner ſurface of the ulna; its tendon paſſes over a little pulley on the metacarpal bone, and terminates on the end of the laſt joint of the principal finger, which it extends, but bends the wing.

The *extenſor communis digitorum* and *indicator* ariſe from the external condyle and inſide of the radius. They ſend tendons to the firſt and laſt joints of the principal finger, which they extend.

The fingers of birds are furniſhed with many ſhort muſcles; and notwithſtanding they are very palpable, ſeem to have eſcaped the obſervation of Cuvier and other anatomiſts.

The *flexor brevis pollicis* comes from the inſide of the head of the metacarpal bone to the flat ſurface of the bone of the thumb. The *extenſor brevis pollicis* proceeds from the triangular ſurface of the metacarpus, behind the joint, to the baſe of the thumb. The *abductor pollicis* is extended between the ſtyle of the metacarpal bone and the outer edge of the bone of the pollex. The *adductor pollicis* is expanded between the branch of the metacarpus and the bone of the thumb. The *abductor*, or *extenſor brevis indicis*, is extended all along the radial edge of the metacarpal bone, and is ſpread upon the root of the firſt joint of the principal finger. It brings the finger into a line with the metacarpus. The *adductor indicis* comes from the ulnar ſide of the large branch of the metacarpus to the root of the firſt joint of the fore finger. The *abductor minimi digiti* lies along the ulnar edge of the ſmall branch of the metacarpus; and as the little finger is tied to the other by ligament, this muſcle produces the lateral flexion or abduction of both. The laſt is the *interoſſeus*; it fills the ſpace between the branches of the metacarpus, and its tendon paſſes along the back of the principal finger to the extremity; it bends the firſt joint laterally, and extends the reſt of the finger.

The *muſcles of the lower extremity* are very numerous in birds, and poſſeſs ſeveral peculiarities, notwithſtanding the motions of this member are ſo ſimple. The articulation of the femur with the pelvis permits the thigh to move freely forwards and backwards, but does not allow it to be carried under the body, or far outwards. The motions of all the other joints of the inferior extremity are merely flexion and extenſion.

In conſequence of the form of the pelvis, the *iliacus*, the *pſoas magnus* and *parvus*, the *obturator externus* and *quadratus lumborum*, do not exiſt in birds. Cuvier alſo ſtates the *pyriformis* and *gemini* to be wanting; but we have ſeen a little muſcle which paſſes from the projection above the acetabulum to the trochanter, which appears to ſupply the place of the *pyriformis*.

The *obturator internus* is generally a large muſcle, and paſſes over a pulley at the fore part of the foramen ovale, where it receives two little ſlips analogous to the *gemini*: they are inſerted into the outer part of the trochanter.

There are three *gluteal muſcles*, as in quadrupeds. The *gluteus maximus* is attached by a broad thin tendon to the prominence along the dorſum of the ilium, covers the outſide of the thigh, and contributes to form the extenſor tendon on the ſide of the knee. The anterior part of this muſcle correſponds to the *tenſor vaginæ femoris*. The *gluteus medius* occupies its uſual ſituation. The *gluteus minimus* is a maſſy muſcle, ſo much placed on the anterior edge of the ilium, that Vic d'Azir conſidered it (perhaps not improperly) as the *iliacus*. It brings the thigh directly forwards, and rotates the knee inwards.

The muſcle analogous to the *quadratus femoris* is large and of a pyramidal ſhape. It retracts the thigh.

The *extenſor muſcles* of the leg reſemble thoſe of mammalia. The *vaſtus internus* ſends its tendon to be diſtinctly attached to the head of the tibia. The *ſartorius* alſo is an extenſor of the leg on the thigh.

There are *three flexors* of the leg: one, which, although ſingle, is, from its inſertion into the back of the fibula, analogous to the *biceps* of the human ſubject; another, on the inſide, is attached to the tendon of the extenſors of the heel, as well as to the tibia. This muſcle might be called either *gracilis* or *ſemimembranoſus*, for it reſembles both. The third flexor is in the middle. It comes from the iſchium; and as

it deſcends, it receives a broad ſlip of muſcle from the back of the femur. It is inſerted on the back of the tibia, and the tendon covering the extenſors of the heel.

There is a large muſcle on the inſide of the thigh, which ſupplies the place of the *triceps*. It performs adduction, but it is alſo employed in carrying the limb backwards.

A muſcle, which Cuvier appears to reckon as the *ſecond adductor*, ariſes from the back of the iſchium, and is inſerted into the middle of the femur in company with the *cruro-coccygeus* muſcle. It retracts the limb.

The muſcles for extending the heel, and conſequently the lower part of the leg of birds, differ in many reſpects from the *gaſtrocnemii* of mammalia. The tendo achillis is produced by three portions of muſcle; and, after paſſing over a moveable cartilaginous pulley which is placed on the heel, it ſpreads on the ſides of the metatarſal bone. The firſt portion ariſes from the inner and fore part of the joint of the knee, and is connected for ſome way with another muſcle, which lies on the outſide of the joint. The ſecond portion is ſmall, and from the back of the internal condyle of the femur. The third is a very ſtrong muſcle ariſing by tendon from the outſide of the thigh bone, juſt above the condyle. Theſe three heads appear to be the *external gaſtrocnemius*.

The *ſoleus* is repreſented by a muſcle which ariſes from the outer part of the knee joint, from the upper part of the tibia, and from the fore part of the fibula. It is inſerted into the pulley on the heel, and ſends a tendon to join that of the flexor of the firſt phalanx of the toes; and therefore it bends the toes while it acts on the heel.

There is alſo a muſcle which appears to ſupply the place of the *plantaris*. It comes from the back of the head of the tibia, and affixes its delicate tendon to the inſide of the moveable pulley of the heel.

The *tibialis anticus* ariſes by two heads, and is inſerted into the fore part of the upper end of the metatarſal bone. It bends the joint of the heel.

The *tibialis poſticus* is not found in birds.

There is a ſhort *peroneal* muſcle which is inſerted into the outſide of the metatarſal bone. It merely bends the joint.

The other muſcles ſituated along the legs, are for the flexion and extenſion of the toes. The *extenſor longus digitorum* exhibits no peculiarity, except that its tendon goes through a hole in the end of the tibia. There is no *long extenſor* for the back toe.

The *flexors* of the toes are very complicated: they may be divided into the *flexor ſublimis* and *flexor profundus*. The firſt is compoſed of ſeveral portions; two of theſe are *peroneal* muſcles, and ſend their tendons to the firſt joint of the internal toe and the ſecond phalanx of the middle toe; the two other portions of the *flexor ſublimis* ariſe, one from the outſide of the fibula, and the other from the back of the joint and internal condyle of the femur. The one on the fibular ſide is joined by the tendon of the *acceſſorius femoralis flexorum*: a muſcle, which ariſes from the ſpine of the pubis, runs along the thigh, and ſends its tendon through a ſheath that runs over the ligament of the patella, to arrive on the fibular ſide of the leg. The two portions of the flexor, after this, unite, ſeparate, and unite again, and at laſt produce three tendons, of which two go to the firſt phalanges of the internal and middle toes, and the third to all the joints of the outer toe except the laſt. Thoſe tendons which paſs beyond the firſt joint, are *perforating* as well as *perforated*.

The *flexor profundus* ariſes as two diſtinct muſcles; the one from the back of the femur, and the other from the back of the bones of the leg. The two tendons unite on the back of the metatarſal bone, and ſend off tendons to the laſt phalanges of the toes, which perforate thoſe of the flexor ſublimis.

All the flexor tendons are incloſed in a tendinous ſheath, as they paſs along the back of the metatarſus; and ſome of them go through the moveable cartilaginous pulley of the heel, and others run in ſheaths formed in the cartilage which covers the top of the metatarſal bone.

The circumſtance of the flexion of the toes accompanying that of the other joints of the lower extremity of birds, was long ago obſerved by Borelli, and attributed by him to the connexion the flexors of the toes have with the upper parts of the limb, by which they are mechanically ſtretched when the knee is bent. This explanation has been controverted by Vic d'Azir and others, who have referred the effect to the irritability of the muſcles. The opinion of Borelli appears, notwithſtanding, to be well founded; for not only the tendon of the acceſſory flexor paſſing round the knee, but the courſe of the flexor tendons over the heel and along the metatarſus, muſt neceſſarily cauſe the contraction of the toes, when either of theſe joints are bent; and if the phenomenon was not produced on mechanic principles, it would be impoſſible for birds to exhibit it during ſleep, which they do, or to prove the effect on the limb of a dead bird, than which nothing is more eaſy. The utility of this contrivance is great in all birds, but particularly ſo to the rapacious tribe, which by this means graſp their prey in the very act of pouncing on it; and it is ſtill more neceſſary to thoſe birds which perch or rooſt during their ſleep, as they could not otherwiſe preſerve their poſition when all their voluntary powers are ſuſpended.

There are ſix long ſmall muſcles lying on the metatarſal bone; they are largeſt and beſt marked in thoſe birds which walk moſt. Two of theſe are on the poſterior ſurface; one goes to the baſe of the external toe, which it *abducts*; the other is inſerted into the root of the back toe, which it *bends*. On the anterior part of the metatarſus there are four muſcles: the firſt *extends* the back toe; the ſecond goes to the baſe of the firſt toe, and *abducts* it; the third is ſpread on the root of the middle toe, which it *extends*; the fourth lies along the outſide of the metatarſus, perforates the end of the bone, and is implanted into the inſide of the external toe, and *abducts* it.

Brain.

This organ exhibits ſeveral deviations from the ſtructure of the brain of mammalia, which afterwards appear in a more marked manner in the inferior claſſes of animals. Accordingly, in the ſcale of exiſtence, or with reſpect to ſenſitive or mental faculties, the rank of birds is clearly fixed below that of mammalia, and above that of other animals. The rules which have been eſtabliſhed to determine the degree of intelligence poſſeſſed by ſpecies or individuals, according to the proportion the brain bears to the whole body, or other parts of the nervous ſyſtem, do not appear ſo applicable in birds as in mammalia. It is, however, very difficult to appreciate the capacity of birds, as they are ſo much the ſlaves of inſtinct, that it is often impoſſible to diſcover whether their actions ariſe from the impulſe of this principle, or depend upon the recollection and aſſociation of external ſenſations. The largeſt birds generally have the ſmalleſt proportion of brain to the whole body; and ſome of the ſmall birds have the proportion of brain ſo great, that they would, agreeable to the rules laid down, excell in mental endowments man himſelf: for inſtance, the brain of the *canary bird* is equal to the one fourth of the whole body; and in the human ſubject it is only the one-twenty-fifth part. The diameter of the

the brain, in relation to the medulla oblongata, has been aſcertained only in a few ſpecies of birds, in which it has been obſerved as follows:

	Medulla oblongata.	Brain.
Falcon	13	34
Owl	14	35
Duck	10	27
Turkey	12	38
Sparrow	7	18

The brain of birds is inveſted with the ſame coverings which are deſcribed in mammalia.

The *form* of the cerebral maſs is very different from that of the human brain, which chiefly ariſes from the optic thalamic being viſible externally. The *hemiſpheres* are therefore proportionately diminiſhed. They aſſume the ſhape of a heart with the point turned forwards. On the lower part of the ſide of the hemiſphere, there is a depreſſion which correſponds to the *foſſa* of *Sylvius*, and is the only appearance of a diviſion into *lobes*. Underneath the hemiſpheres the *thalami nervorum opticorum* are found, as two diſtinct tubercles, each equalling in magnitude a lobe or diviſion of the brain. They unite before the infundibulum, and ſend off the optic nerves; there are, therefore, ſix parts, or principal eminences, of the brain of birds, viſible externally; the two hemiſpheres, the two thalami, the cerebellum, and the medulla oblongata. There are no *convolutions*, or winding impreſſions, on the ſurface of any of theſe parts, except the cerebellum, which is tranſverſely furrowed, but not divided into two lobes. The *medulla oblongata* is round, and ſmooth on the under ſurface, being unfurniſhed with the eminences called *pons Varolii*, *corpora pyramidalia*, and *corpora olivaria*.

On ſeparating the hemiſpheres a little, it is perceived that they are united at their lower part, or over the third ventricle. The junction is effected by white medullary ſubſtance, which afterwards ſpreads in a radiated manner, on the ſurfaces of the hemiſpheres that are oppoſed or applied to each other, almoſt as high as the top of the cerebrum. In reality, this medullary union of the hemiſpheres correſponds to the *fornix*, and can, like it, be traced to the anterior commiſſure in the third ventricle; but inſtead of being connected to the *ſeptum lucidum* and *corpus calloſum*, as theſe parts do not exiſt in birds, it ſpreads on the inner ſurfaces of the hemiſpheres, and thus contributes to form the internal parietes of the lateral ventricles.

Behind the radiated partition of the hemiſpheres, and without the third ventricle, the *poſterior commiſſure* preſents itſelf, and conſiſts uſually of more than one white line connected together by a white fibre, like a nerve paſſing obliquely acroſs. The vault of the *canalis medius* is alſo viſible, and is compoſed in part of a white medullary band; and behind this, another white cord runs acroſs, which is the fourth pair of nerves at their origin.

The *lateral ventricles* are not prolonged poſteriorly, nor poſſeſs what is called the *reflected horn*; the *great* and *leſſer hippocampus* have therefore no exiſtence.

The *corpus ſtriatum* fills the ventricle almoſt entirely, projecting from the external ſide of it in the ſhape of a kidney. It does not exhibit on a ſection regular or ſtrong marked ſtriæ.

There are no *tubercula quadrigemina*.

The *pineal gland* reſts upon a flat ſurface; it is very ſmall, and inveloped in pia mater, and covered by a large vein. The plexus choroides alſo at this place divides into two tufts, or bunches, which paſs into the lateral ventricles by two foramina in the back of the internal parietes.

The *third ventricle* poſſeſſes its uſual ſituation between the thalami and its ſlit-like ſhape, and communicates with the canalis medius under the poſterior commiſſure, and with the infundibulum behind the anterior commiſſure.

The *infundibulum* and *pituitary gland* are both large in proportion to the other parts.

The *thalami nervorum opticorum* contain each a ventricle, which opens into the canalis medius; therefore, there may be ſix ventricles reckoned in the brain of birds.

The *fourth* ventricle exhibits no peculiarity.

There are no eminences correſponding to the *corpora candicantia*; Cuvier has deſcribed four round eminences between the thalami and corpora ſtriata, which are particularly plain in the *oſtrich*. Theſe are analogous to the tubercles of the brain of fiſhes.

The olfactory nerves ariſe, in birds, from the very points of the hemiſpheres, and often have a degree of enlargement at their origin, which reſembles the olfactory tubercles of fiſhes. There are eight other pair of cerebral nerves, which have nothing very peculiar in their origin.

See *Plate* X. of the *Anatomy of Birds*. *Fig.* 1. preſents a lateral view of the brain of the *gooſe* abſtracted from the head; *a* the hemiſphere, *b* the depreſſion analogous to the fiſſura Sylvii, *c* the optic thalamus, *d* the cerebellum, *e* the medulla oblongata, *f* the beginning of the medulla ſpinalis, *g* the infundibulum, *h* the pituitary gland. The different nerves are indicated by numbers, as they ariſe, from 1 to 9. N° 1. the olfactory nerve, N° 2. the optic, N° 3. the oculo-muſcular nerve, N° 4. the patheticus, N° 5. the trifacial nerves, N° 6. the nervus abducens, N° 7. the ſeventh pair, or auditory, N° 8. the eighth pair, N° 9. the hypogloſſal nerve.

Fig. 2. of the ſame plate, ſhews the internal parts of the brain, as they are expoſed without diſſection, ſimply by puſhing the hemiſpheres to each ſide, and drawing the cerebellum a little back: *aa* the two hemiſpheres, *b* the cerebellum, *c* the medulla oblongata, *ee* the radiated white lines ſeen ariſing from the junction of the hemiſpheres, and forming part of the parietes of the lateral ventricles, *f* the tranſverſe medullary cords correſponding to the poſterior commiſſure, *g* the white band of the roof of the canalis medius, *h* the fourth pair of nerves croſſing behind it, *i* the pineal gland obſcured by the vena galeni and the plexus choroides, *k* the latter paſſing into the ventricle.

The third figure of the tenth plate of the *Anatomy of Birds*, gives a view of the interior of the ventricles of the thalami nervorum opticorum, and the third ventricle: *aa* the hemiſpheres laid down very much to each ſide, by which the white partition is ruptured, and the third ventricle brought into view, they are alſo pulled forwards to expoſe the thalami; *b* the cerebellum; *c* the medulla oblongata; *dd* the two optic thalami, that on the right ſide is cut open to ſhew the ventricle and its communication with the canalis medius; *e* the tract of the third ventricle and canalis medius, along which a briſtle is paſſed into the fourth ventricle; *f* the anterior commiſſure, which ſeems to produce the medullary radii that unite the hemiſpheres.

Nerves.

The *olfactory nerve* has been already mentioned to paſs along a canal, or groove, in the upper and inner part of the orbit, to reach the naſal cavity; in which its diſtribution will be pointed out in deſcribing the organ of ſmell.

The *optic nerves* purſue their ordinary courſe, as in other animals.

The diſtribution of the *third*, *fourth*, and *ſixth* pair of nerves, is almoſt the ſame as in mammalia.

The branches of the *fifth* pair bear great reſemblance to the

the ſame nerves in quadrupeds. They are diſtributed to the bill, and are therefore the nerves of the organ of touch in birds, under which head they will be farther noticed.

The *portio dura* of the ſeventh pair, or the *facial* nerve, is ſo ſmall in birds, that it can hardly be diſcovered. Its offices are not required, in conſequence of the ſtructure of the parts of the face in theſe animals.

The *portio mollis* is remarkably ſoft; when it ariſes from the brain, it is a tender pulp, of a reddiſh colour.

The *par vagum*, or *pneumo-gaſtric* nerve of the eighth pair, ſometimes paſſes out of the cranium in two or three filaments, which afterwards rejoin. On leaving the ſkull, this nerve communicates with the lingual and gloſſo-pharyngeal nerves. The par vagum, after this, paſſes as a diſtinct ſtrong cord along the neck, in company with the jugular vein, and deſcending into the cheſt, forms the *cardiac* and *pulmonary plexuſes*, as in mammalia. The two nerves unite behind the heart, and proceed along the œſophagus, to terminate in anaſtomoſes with the great ſympathetic nerve. We have not obſerved the *recurrent* branch of the eighth pair.

The *gloſſo-pharyngeal* nerve of the eighth pair makes its exit from the cranium through the poſterior foramen lacerum in two filaments, which immediately unite to form a quadrangular ganglion, which ſends off a ſmall nerve to the anterior muſcles of the neck, and another branch to anaſtomoſe with the par vagum; the nerve then deſcends along the œſophagus, and divides into two branches, of which one paſſes upwards to the muſcles of the os hyoides, which include it between them, and the other furniſhes a branch to the lingual nerve, and afterwards is expanded upon the œſophagus.

The *hypogloſſal nerve* is ſmall where it paſſes through the condyloid foramen of the cranium; it croſſes and partly unites with the par vagum, at which place it detaches a filament towards the thorax, which ſeems analogous to the *deſcendens noni*. The trunk of the hypogloſſus goes forwards under the horn of the os hyoides, and divides into two principal branches, which are diſtributed to the tongue.

The *cervical*, *dorſal*, *lumbar*, and *ſacral* nerves, ariſe from the medulla ſpinalis exactly as they do in quadrupeds, and only vary in their number, which is determined by the number of vertebræ belonging to each region of the ſpine.

The *phrenic nerve* is not found in birds, in conſequence of the abſence of the diaphragm.

The *intercoſtal*, or *great ſympathetic nerve*, is deſcribed as entering the cranium by the foramen lacerum poſterius. It unites with the fifth and ſixth pairs, and produces a lenticular ganglion below the ſkull, which communicates with the eighth and ninth pair of nerves. The appearance of the ſympathetic nerve is, however, ſoon loſt on the neck; for the cervical nerves form their anaſtomoſes with each other in the vertebral canal, from which a nerve is ſent out between each vertebra to ſupply the muſcles and integuments of the neck. Theſe nerves are remarkably large. On coming into the thorax the great ſympathetic ſends a branch to the pulmonary plexus of the par vagum; it anaſtomoſes alſo with the brachial plexus; and below the ſecond rib, the ſympathetic commences a ſeries of ganglia, which are very conſpicuous between each of the ſucceeding ribs, but become leſs viſible along the remaining part of the ſpine. Theſe ganglia are central points for the union of a number of nerves. They receive filaments from each other, which paſs over the heads of the ribs; they communicate backwards with the ſpinal nerves; they detach on the outſide the intercoſtal nerves, which are large, and beſides ſupplying the intercoſtal ſpaces, give branches to the muſcles and integuments upon the ſides of the body; they laſtly ſend off filaments anteriorly, which anaſtomoſe with each other on the ſide of the dorſal ſpine, and form cords, which become the ſplanchnic nerves. In this manner there is produced on each ſide of the dorſal ſpine a reticulation of nerves which incloſes in its meſhes the heads of the ribs, and has a ſtriking effect. The firſt dorſal ganglion unites with the brachial plexus and the cardiac plexus of the par vagum.

The *ſplanchnic* nerves, after being formed by the anterior branches of the ſympathetic, paſs to the roots of the principal arteries of the viſcera. Thoſe of the cæliac artery produce a plexus round the trunk of this veſſel, and where the artery is divided, there are one, two, or three enlargements, which are analogous to the *ſemilunar ganglia*; and the nerves which depart from theſe, incloſe the arteries in a reticulated manner, and repreſent the *ſolar plexus*.

There are ſimilar plexuſes on the other chief arteries of the trunk, which correſpond to the *ſuperior* and *inferior meſenteric* and *renal* plexuſes, &c.

The nerves of the ſolar plexus accompany the branches of the cæliac artery to the ſtomach, ſpleen, liver, and pancreas, around which they continue to form numerous anaſtomoſes, that may be compared to the *ſtomachic*, *ſplenic*, *hepatic*, and *pancreatic plexuſes*.

The *nerves of the wing* more nearly reſemble thoſe of the ſuperior extremity in mammalia, than Cuvier has repreſented. The *brachial plexus* is produced by the two laſt cervical and firſt dorſal, and not, as he has ſtated, by the laſt cervical and two firſt dorſal nerves. The union of theſe three branches gives riſe to three others, which are diſtributed in the following manner:—The firſt is a very fine filament, which runs down on the inſide of the arm, and is loſt about the internal part of the elbow. This is analogous to the *internal cutaneous* nerve. The ſecond is a large cord; it gives off a very large branch, which divides into many others, for the ſupply of the pectoral muſcles; it ſends ſeveral ſmaller branches to the muſcles under the clavicle, and about the joint, and then proceeds to the inner edge of the biceps muſcle, along which it deſcends to the fold of the arm, after giving ſome large muſcular branches. Before it reaches the joint, it divides into two branches; one of which is analogous to the *ulnar* nerve, and the other ſoon divides again into nerves which are ſimilar to the *median* and *muſculo-cutaneous*. The *median* dips down amongſt the muſcles on the middle of the fore arm, to which it gives branches, and afterwards runs along the interoſſeous ſpace, paſſes under the annular ligament of the carpus, and is diſtributed to the ſhort muſcles of the digiti. The branch analogous to the *muſculo-cutaneous* nerve, is expanded upon the muſcles on the upper edge of the radius.

The *ulnar* nerve, although it appears to be incorporated with the *median* on the upper arm, can be eaſily ſeparated from it and traced to its proper origin in the brachial plexus. After this nerve leaves the median, it turns over the end of the foramen to get upon the edge of the ulna. It gives filaments to the muſcles in this ſituation; but its chief branch runs down ſuperficially upon the ligaments of the quills in company with the vein, and goes ultimately to be loſt upon the ulnar edge of the hand.

The third cord furniſhed by the brachial plexus, ſupplies the place of the *radial* nerve. It detaches ſeveral filaments to the muſcles on the inſide and back of the ſcapula. It gives off alſo the *articular nerve*, and then winds round the humerus between the extenſor muſcles, to which it furniſhes ſome large filaments. On coming to the outſide of the humerus, it ſends a branch between the integuments of the

fold of the wing. The nerve now turns round the neck of the radius, beneath the muſcles, and forms two branches: of which one paſſes under the muſcles to the outer ſide of the ulna, along which it runs ſuperficially to the hand; the other branch paſſes on the radial ſide, but more deeply amongſt the muſcles, goes under the annular ligament of the carpus, proceeds between the branches of the metacarpus, and is finally loſt on the back of the ligiti.

Although Cuvier has given a more accurate deſcription of the nerves of the lower extremity, than of thoſe of the wing, it nevertheleſs needs correction in ſeveral particulars, which we have ſupplied.

The *obturator* and *femoral* nerves ariſe from the ſame plexus which is formed by the two laſt lumbar nerves, by a communicating branch from the firſt ſacral pair. The obturator nerve paſſes through the upper part of the foramen ovale, and is diſtributed to the muſcles around the hip joint, eſpecially the adductor. The femoral nerve paſſes out of the pelvis in company with the artery, over the upper edge of the ilium. It divides into three branches, which are diſperſed amongſt the muſcles and integuments on the anterior and inner part of the thigh. Some of theſe filaments are long, and deſcend ſuperficially for a conſiderable way upon the limb.

The *iſchiadic* nerve is compoſed of the five ſuperior ſacral nerves; and as ſoon as it departs from the plexus, even within the pelvis, is eaſily ſeparable into its primary branches. Immediately after it paſſes through the iſchiadic foramen, it ſends filaments to the muſcles on the outer part of the thigh; it then proceeds under the biceps muſcle, along the back of the thigh, about the middle of which it becomes divided into the *tibial* and the *peroneal* nerves.

The *tibial* nerve, even before it arrives in the ham, ſeparates into ſeveral branches, which paſs on each ſide of the blood-veſſels, and are chiefly diſtributed to the muſcles on the back of the leg. Two of theſe branches, however, are differently diſpoſed of: the one accompanies the poſterior tibial artery down the leg, paſſes over the internal part of the pulley, and is loſt in ſmall filaments, and anaſtomoſes with a branch of the peroneal nerve, on the inner ſide of the metatarſus; the other branch runs down on the peroneal ſide of the leg, along the deep ſeated flexors of the toes, paſſes in a ſheath formed for it on the outer edge of the moveable pulley of the heel, and proceeds under the flexor tendons along the metatarſal bone, to be diſtributed to the internal part of the two external toes.

The *peroneal nerve* is directed to the outer part of the leg; it dips in above the gaſtrocnemii muſcles, and runs through the ſame ligamentous pulley that tranſmits the tendon of the biceps muſcle; it then detaches ſome large filaments to the muſcles on the anterior part of the leg, under which it divides into two branches, which proceed cloſe together, in company with the anterior tibial artery, to the fore part of the ankle joint, at which place they ſeparate; one paſſes ſuperficially over the outer part of the joint; the other goes firſt under the tranſverſe ligament which binds down the tendon of the tibialis anticus muſcle on the tibia, and then over the inner part of the joint, below which it divides into two branches, the one is diſtributed to the inner ſide of the metatarſus and the tibial ſide of the pollex and to the next toe; the other turns towards the centre of the metatarſal bone, and penetrates the tendon of the tibialis anticus juſt at its inſertion, and then rejoins the branch of the peroneal nerve it accompanied down the leg. They continue their courſe together again in the anterior furrow of the metatarſal bone; and at the root of the toes, ſeparate once more, and proceed to the interſpaces of the three anterior toes, and each divides into two filaments, which run along the ſides of the toes to the nail.

Organs of Touch.

As the ſenſe of touch is beſtowed upon animals to enable them to diſcern the forms and ſtates of aggregation of external matter, it reſides more eſpecially in the extreme parts of their bodies, and when moſt perfect, exiſts in ſome member which is conſtructed for including or taking hold of extraneous ſubſtances. There is no part of the body of birds capable of conveying an accurate impreſſion of touch, but the feet and the bills; their upper extremities and tail being ſimply inſtruments of motion. Different ſpecies enjoy this in different degrees, and poſſeſs it more or leſs in the bill or feet, in proportion as they employ theſe parts in the purſuit or examination of their food; theſe being the only occaſions on which birds exerciſe their functions of touch. The *ſcanſores*, *accipitres*, and *paſſerine* tribe have moſt ſenſation in their feet, while the *grallæ* and *anſeres*, eſpecially thoſe that have long or broad bills for feeling out their food, like the *ſnipe*, or *duck*, poſſeſs a very great ſuſceptibility of impreſſion in their bills.

The organization of the feet of birds, as far as concerns their offices as inſtruments of touch, is ſimilar to that of the digitated mammalia and reptiles. The ſkin on their lower ſurfaces is endowed with more than common vaſcularity, is largely ſupplied with nerves, and is elevated into thoſe little regular eminences called *papillæ*, in which the ſenſe of touch more immediately reſides.

The ſtructure, on which the ſenſibility of the bill depends, is different from the preceding. It conſiſts in the magnitude and diſtribution of the fifth pair of nerves. Theſe are divided, as in mammalia, into three branches, the *ophthalmic*, the *ſuperior maxillary*, and the *inferior maxillary*.

The *ophthalmic* enters the orbit by a hole beſide the optic foramen, paſſes for ſome way in an oſſeous canal before it arrives in the naſal cavity, where it diſtributes ſome branches to the ſeptum and turbinata, and to the external naris, and then goes on as two branches; one runs in the ſubſtance of the upper jaw, which it perforates at the end in many filaments, to terminate under the horny integument of the bill; the other paſſes between the membrane of the palate and the bill, and is loſt in a number of fibrils at the apex of the bill.

The *ſuperior* and *inferior maxillary* nerves come out of the cranium by the ſame hole. The *ſuperior*, after diſpenſing branches to the muſcles in its courſe, is finally diſtributed to the lateral parts of the bill, which, if notched along the edge, as in ſome water birds, each denticulation receives ſeveral filaments. The *inferior maxillary* deſcends to the lower jaw, which it penetrates, after ſending a branch to the integuments of the ſide of the bill; and running in the maxillary canal, ſends filaments to the edge of the bill, and terminates, like the ophthalmic, on the apex of the lower mandible.

Theſe nerves are of great ſize in the *gooſe*, *duck*, &c. in which they render the bill a very delicate organ of touch. See *Plate* X. in the *Anatomy of Birds*. *Fig.* 4. is the ſection of the head of a *duck*, made by dividing the organ of ſmell longitudinally, and by removing the bill and bone of the mandible, in order to bring into view the diſtribution of the fifth pair of nerves: *a a* the ophthalmic nerve coming from the upper part of the orbit, and proceeding along the ſeptum naſi; *b* the branch which paſſes in the ſubſtance of the mandible, to be loſt on the point of the bill, *c* the branch that runs on the membrane of the palate to the end of the bill; *d* the ſuperior maxillary nerve dividing on the membrane of the palate, and ſending its filaments to the denticuli on the ſide of the bill; *e* the inferior maxillary running

ning in the canal of the lower jaw, and ſending filaments to the denticuli on the edge of the mouth, and ending on the point of the bill; *f* the naſal branch of the ophthalmic diſtributed to the ſeptum.

External Parts, or Integuments.

The *feathers* with which the bodies of birds are clothed, render them leſs capable of receiving the more ſimple impreſſions of touch, than moſt other animals. They alſo ſerve to defend them againſt the exceſſes of temperature. The ſtructure and mode of growth of theſe ſubſtances are conſidered in another part of the dictionary. See FEATHERS.

The *cuticle* of birds is remarkably thin, but reſembles in ſtructure the epidermis of mammalia. It is ſhed generally along with the feathers.

The *rete mucoſum* is not obſervable, except in thoſe parts which are uncovered by feathers, and poſſeſs peculiar colours, as the cere and caruncles of the head, the feet, and bills; where it is of courſe found to vary in colour as thoſe parts do.

The *cutis* is in moſt birds extremely thin and delicate in its texture, appearing often like a fine ſingle lamina, inſtead of an intermixture of fibres as in mammalia. It is, however, of ſome ſtrength in the *water birds* and the *accipitres*; it is thinneſt in the *paſſeres*. The external part of the cutis is never *pcpillated*, but when it covers the under ſurfaces of the toes which are deſigned to receive the impreſſions of external bodies.

The *muſcles of the ſkin*, in conſequence of the ſize of the external coverings, are in general very evident, and particularly in thoſe birds which move the feathers of the creſt, neck, or tail, as the *hoopoes*, *cockatoos*, *herons*, &c.

The following cutaneous muſcles are common to all birds. Two fleſhy ſlips, which ariſe from behind each ſide of the head behind the meatus auditorius, and go backwards to be loſt in the integuments. A thin expanſion of muſcle along the anterior and lateral parts of the neck; it takes a longitudinal courſe, but is connected with ſome tranſverſe fibres between the jaws; this muſcle correſponds with the *platyſma myoides*. There is a muſcle, ariſing in a ſerrated manner from two or three of the lower ribs, and extending upwards to the axilla and outſide of the ſhoulder. We have perceived, in the *gooſe*, a very thin ſlip of muſcle proceeding from the poſterior part of the branch of the pubis to the ſkin on the inſide of the knee; and Cuvier conſiders the red granular appearance under the ſkin on the back of the pelvis as muſcular ſubſtance.

The functions of the ſkin of birds, as an organ of abſorption and excretion, appear to be very imperfect. The clothing of feathers alone diſqualifies it in a great degree for the performance of theſe proceſſes. The thinneſs and ſimple organization of the ſkin itſelf renders it probable that its ſecretory powers are but inconſiderable. It does not alſo poſſeſs thoſe various glands which are ſo abundantly beſtowed upon the ſkin of other animals for its preſervation and defence againſt the operation of external ſubſtances. Birds are, however, provided with two peculiar glands for the purpoſe of furniſhing an oily fluid, to keep the feathers in order and defend them againſt the effects of moiſture.

The *oil glands* are two oblong or oval-ſhaped bodies, with one end more pointed than the other, and ſituated under the ſkin on each ſide of the ſpinous proceſſes of the caudal vertebræ. They approach each other, and touch at their points, which are directed backwards, and thus produce very commonly between them the figure of a heart. They are covered by a ſtrong denſe white tunic, and their interior ſtructure conſiſts of a number of ſmall tubes arranged in a radiated manner around a vacancy, or canal, which runs nearly in the middle of the gland, into which they all open and diſcharge their contents, in the ſame way as the tubuli uriniferi do into the pelvis of the kidney. The middle canal leads to a papilla on the ſkin of the rump, and terminates in a ſimple foramen. It deſerves remark, that the tubes towards the circumference of the glands are ſoft and indiſtinct, and their contents are liquid and pale coloured; but before their termination, the tubes acquire more firmneſs, are a little ſeparated into packets, their ſecretion becomes an opake yellow, and of more conſiſtence; thus affording an obvious and intereſting view of the change which may be wrought upon ſecreted fluids after their formation, while they are paſſing through their glands. The fluid produced by the glands on the rump of birds, although of an unctuous nature, is ſtill not pure animal oil. It has more conſiſtence, and is leſs affected by heat; which properties it principally acquires in the ends of the tubes, before they open into the common duct, as already mentioned. It is, however, ſufficiently oleaginous to prevent the adheſion of moiſture to the ſurface of the feathers. When birds make uſe of it, they turn their head round to the rump, and compreſs the glands with the bill, when a quantity of oily matter exſudes, with which they beſmear their feathers, arranging the barbs upon their ſhafts at the ſame time by means of the bill. Theſe glands, as might be preſumed from their uſe, are particularly large in the *ſwimming birds*. See *Plate* X. in the *Anatomy of Birds*. *Fig.* 5. ſhews the oil glands of the *duck* of their natural ſize: *a a* the two glands; *b b* their foramina on the papilla, into each of which a briſtle is introduced; *c c* the integuments reflected on each ſide to bring the glands into view. *Fig.* 6. of the ſame plate is a ſection of one of the oil glands ſomewhat magnified; *a* the canal in the centre into which the radiated tubes open; *bb* the external portion of the tubes; *cc* the interior extremities more diſtinct, and of a deeper colour.

Organ of Smell.

The ſhape and ſituation of the *noſtrils* are uſed by naturaliſts as claſſific characters of birds; and therefore do not require particular conſideration here. They conſiſt of two ſlits, varying in the length and width, commonly placed on each ſide behind the baſe of the bill. There are no muſcles provided for dilating and contracting their aperture, as in mammalia.

The interior of the organ of ſmell is formed by a ſeptum and three turbinated bodies, over which the pituitary membrane is ſpread.

The *ſuperior turbinatum* aſſumes in general the ſhape of a bell; it is formed of cartilage, and is attached to the os frontis and lacrymale; it is hollow within, and divided by a ſlight prominence into two apartments, which are continued for a little way in a tubular form; the external ends by a blind extremity behind the middle turbinatum; the internal opens into the cavity of the noſe. The ſuperior turbinatum is ſmall in the *paſſeres* and *gallinæ*, ſomewhat larger in the *ſcanſores*, increaſes in bulk in the *accipitres*, and ſtill more in the *anſeres*, and in the *grallæ* it is greateſt of all. According to the obſervations of Scarpa, the acuteneſs of ſmell is exactly proportioned to the magnitude of this part of the organ, as it is upon it only and the ſeptum that the olfactory nerve is ſpread.

The *middle turbinatum* has been likened by Scarpa to a cucurbite. It is connected on the external part to the cartilaginous pinna of the nares and the bony proceſs of the upper jaw, and inferiorly it is attached to the cartilaginous ſeptum of the noſe. It is compoſed of a cartilaginous lamina, which in the *gooſe* makes two folds and an half; but in the *grallæ* it is compreſſed, and forms only one turn and an

half. Harwood has ſtated theſe turbinata to be membranous in the *caſſowary* and *albatroſs*; and Cuvier has obſerved them to be compoſed of bone in the *toucan* and *hornbill*.

The *inferior turbinatum* is an oſſeous fold, continued from the pinna of the naris, and united on the other ſide to the ſeptum. See *Plate* X. in the *Anatomy of Birds*. *Fig.* 7. exhibits the interior of the naſal cavity of the *gooſe*, the ſeptum being removed; *a* the canal through which the olfactory nerve paſſes to the noſe; *b* the cavity of the ſuperior turbinatum; *c* its internal tube; *d* the external tube; *e* the middle turbinatum; *f* its deep or firſt winding; *g* the ſecond; *h h* two pins paſſed from the windings into the naſal cavity; *i* the inferior turbinated bone; *k* its junction with the ſeptum; *l* the cartilaginous appendix of the middle turbinatum; *m* a pin introduced through the external naris; *n* the poſterior naris.

The *pituitary* membrane is fine where it inveſts the ſuperior turbinatum, and thicker and more villous over the middle one; it is covered with pores, which diſcharge mucus on its ſurface. The blood veſſels on the interior of the noſe are beautifully reticulated.

The *olfactory nerve*, as already deſcribed, ariſes from the point of the hemiſphere of the cerebrum, and paſſes through an oſſeous canal to the ſuperior part of the naſal cavity. On arriving there it breaks into a great number of filaments, ſome of which are ſpread upon the ſuperior turbinatum, and others run about as far on the ſeptum naſi. See *Plate* X. in the *Anatomy of Birds*, *fig.* 4. *g* the nerve proceeding along the canal above the orbit; *h* the appearance of the nerve on the ſeptum of the *duck*; and *fig.* 8. of the ſame plate exhibits a ſection of the head of the *heron*, a bird with an acute ſenſe of ſmell; *a* the trunk of the olfactory nerve; *b* its diſtribution on the ſuperior turbinatum, which is very large; *c c* the middle turbinatum proportionably reduced in ſize; *d* inferior turbinatum; *e* its connection with the ſeptum; *f* the aperture of the external naris.

Scarpa made a number of experiments with different ſpecies of birds, in order to determine their capacity for diſcerning odours. He mixed various ſtrong ſmelling ſubſtances with their ordinary food, which in ſome were taken with indifference, but in others the repugnance to the ſcented food was ſo great, that the birds periſhed rather than eat it. He was thus enabled to form a ſcale of the different degrees of perfection in which birds enjoy the ſenſe of ſmell, which accorded exactly with the extent of the ſurface allowed for the diſtribution of the olfactory nerves. The ſcale he has laid is as follows: *gallinæ*, *paſſeres*, *picæ*, *anſeres*, *accipitres*, and *grallæ*.

Organ of Taſte.

The ſenſe of taſte is ſo imperfect in moſt birds, that it might be doubted whether it exiſted at all or not. The form and motions of the tongue unfit it for being applied to the ſuperficies of ſubſtances; the glairy tenacious fluid, with which the ſurfaces of their mouths are beſmeared, is not calculated for the ſolution of ſapid bodies; and the ſhape and ſtructure of the papillæ of the tongue ſeem to render them nearly incapable of impreſſion; and further it may be obſerved, that birds commonly ſwallow their food without examination, or a minute diviſion of its parts.

The motions and internal formation of the tongue have been already diſcuſſed; it only remains, therefore, to notice the figure and integuments; but as theſe have been deſcribed by natural hiſtorians in almoſt every genus, it is only neceſſary to ſpeak of them in a very general way at preſent.

The *form* of the tongue may be commonly gueſſed at from the ſhape of the bill, with which it correſponds in a certain degree. In the *gallinæ* and *paſſeres* it is an elongated triangle, the point being turned forwards; in the *grallæ* it is generally of the ſame figure, the triangle being however lengthened in proportion to the bill; the broad-billed birds, as the *ſwan*, *gooſe*, &c. have the tongue broad and round at the end.

The *parrot* has a thick round fleſhy tongue, not unlike that of mammalia.

Several birds have the tongue biſid at the point.

The *African oſtrich* has a broad tongue, but ſo ſhort, that its exiſtence has been often doubted. The *New Holland oſtrich* has a very thin ſmall tongue, and nearly an equilateral triangle.

The *papillæ*, or projecting points of the integument of the tongue are very various in their ſhape and arrangement. In moſt inſtances the tongue is ſmooth, except at its baſe, where it is furniſhed with ſharp reflex papillæ, which are commonly cartilaginous, and often covered with bone. In many birds there are proceſſes along the upper ſurface or the edge of the tongue, which are inveſted with a horny or oſſeous ſubſtance. The *vulture* has cartilaginous ferræ along the edges of the tongue. The *toucans* have fine horny briſtles along the ſides, which give their tongue a reſemblance to a feather.

On the lateral parts of the back of the tongue of the *flamingo*, there are two rows of bony proceſſes, ſhaped like hooks, with their points turned backwards.

The *duck*, *gooſe*, *ſwan*, &c. have, beſides ſharp briſtles and denticulations, ſome rows of little oſſeous plates with their thin edges turned toward the fauces.

Birds have frequently the edges of the poſterior nares, and other prominent parts of the fauces furniſhed with reflected ſpiculæ, ſimilar to thoſe on the tongue; from which it is probable, that both are intended to aſſiſt in the action of ſwallowing the food, rather than to receive the impreſſions of ſapid ſubſtances.

The *parrot* is the only bird which appears to taſte its food, and hence it poſſeſſes ſoft papillæ, of which ſome are really *fungiform*.

It is probable, that the *humming* birds poſſeſs the ſenſation of taſte, as their tongue is flexible and tubulated, through which they ſuck, like inſects, their fluid aliment.

Organ of Hearing.

Birds are unprovided with the *concha*, or that external projection of the ear which is obſerved in man and quadrupeds, for collecting the rays of ſound; but to compenſate for the want of it, ſome of the internal parts of the organ are formed upon a larger ſcale. The feathers are arranged in ſome ſpecies, however, around the meatus auditorius in ſuch a way as to produce, in a degree, the effect of the concha. This is moſt obſervable in the *owls*, in which alſo the membrana tympani lies at the bottom of a cavity, which is lined by a reflection of the common integuments that forms folds ſomething analogous to the projections of the human concha; and in the *white owl*, there is a ſquare membrane, which ſerves as an operculum to the anterior part of the cavity.

The *frame* of the membrana tympani, or the bone which ſurrounds it, is more prominent in ſome birds than in others; but generally it does not project ſufficiently to deſerve the name of a canal. It is imperfect anteriorly, where the articular bone is ſituated, to which the membrana tympani is in part attached. In the *white owl*, however, the oſſeous frame of the meatus is completed by the bones of the head alone.

The *membrana tympani* is always more or leſs of an oval figure. It poſſeſſes the ſame ſtructure as in mammalia, but is very thin; the convex, or conic ſurface, is

external,

external, inſtead of pointing inwards, as in man and quadrupeds.

The *cavity of the tympanum* is irregular on the internal ſurface, and is wideſt at its outer part. Beſides the uſual foramina leading to the labyrinth and Euſtachian tube, it contains three others, which communicate with the cells of the bones of the cranium. Theſe are widened into ſomething like canals, where the holes open into them. The largeſt of the foramina is in the back of the tympanum, and leads to the poſterior cells, and communicates above the foramen magnum with the cellular canal of the other ſide. The ſecond opening is placed at the anterior part of the tympanum, and conducts to the cells on the lower and anterior part of the cranium. The third foramen is continued amongſt the cells which ſurround the labyrinth. Thus the cavities of each tympanum have a communication with the interior of all parts of the cranium, and with each other, from which they might be reckoned as making only one cavity. The end of the articular bone alſo, where it contributes to form the parietes of the tympanum, has a foramen, by which it derives its ſupply of air. The *auditory* cells of the cranium of birds are analogous to the maſtoid of the human ſubject; but from their extent, multiply found much more. They are of the greateſt magnitude in the *nocturnal birds of prey*, and eſpecially in the *white owl*; the *goat ſucker (caprimulgus)* has them alſo very large. They diminiſh in the other birds, in which the poſterior canals have no direct communication with each other. They are little obſervable in the *ſtruthiæ*; and the *parrot* appears to want them altogether, but in their place the cavity of the tympanum is enlarged poſteriorly.

The *Euſtachian tube* is very large in birds; it is an oſſeous canal, and terminates by a ſmall aperture cloſe to the one of the other ſide, within the fiſſure of the poſterior nares.

The foramina, which lead into the labyrinth, are ſituated within a foſſa. They do not merit the diſtinctions of *foramen ovale* and *foramen rotundum*, being both oval, and only ſeparated by a ſmall bony proceſs.

The *officula auditus* are ſupplied by a ſingle bone and ſome cartilaginous proceſſes. The officulum conſiſts of a ſtalk or pedicle, crowned by an oval plate, which is applied to the foramen that leads into the veſtibule of the labyrinth. At the other extremity it becomes extended and united to two or three cartilaginous proceſſes, which form a triangle that is attached to the membrana tympani.

The pediculated bone of the tympanum is moved by *one muſcle*, which comes from the occiput behind the ear, and penetrating the cavity, is affixed to the triangle that is connected to the membrana tympani. This muſcle is a *tenſor*, and draws the membrana tympani outwards. It is counteracted by two ſmall tendinous cords that are extended to the internal parietes of the tympanum.

The *labyrinth* of the ear of birds conſiſts only of the *veſtibule* and *three ſemicircular canals*, and the rudiment of the *cochlea*.

The *veſtibule* is ſmall in proportion to the other parts.

The *canals* have been termed by Scarpa, from their gradation in bulk, *canales major*, *minor*, and *minimus*. The largeſt is moſt ſuperior, and has a vertical poſition. The ſmalleſt is ſituated horizontally. The canalis minor aſcends upon the major, and opens into its ſide. They contain correſponding tubes of vaſcular membrane; and they alſo poſſeſs the *ampullæ*, on which the nerves are diſtributed in the ſame manner as in mammalia.

The place of the *cochlea* is ſupplied by a ſhort oſſeous *tube*, very ſlightly bent, and either blunt or enlarged at the extremity. Its interior is occupied by two ſmall cylinders of fine cartilage, each a little twiſted, and united at their origin and termination. They proceed from the oſſeous bar, which ſeparates the two foramina that correſpond to the foramen ovale and rotundum. The ſulcus, which is left between the cartilages, is dilated near the point, and accommodates the ſame branch of the auditory nerve which is ſent to the cochlea in mammalia. This nerve ſpreads in fine filaments upon the united extremity of the cartilaginous cylinders. The tube is divided by the preſence of the cartilages into two ſcalæ, which communicate with the veſtibule and the foramen rotundum.

The *ſtruthious birds* have the tube correſponding to the cochlea, very ſmall in proportion to the other parts.

The *auditory nerve* is received into a foſſa, and there breaks into five branches; one is the *facial*, or *portio dura*, and the others are ſent to the ſemicircular canals and the tube. The facial nerve receives a filament from the par vagum, which traverſes the ear, and is afterwards diſtributed to the palate.

Comparetti has deſcribed two canals leading from the labyrinth of birds, which correſpond with the *aqueducts* of the ear of mammalia.

For the illuſtration of the organ of hearing, ſee *Plate* X. in the *Anatomy of Birds*. *Fig.* 9. repreſents a diſſection of the poſterior portion of the ſkull of the *white owl* (*ſtrix flammea*), which expoſes both the parts of the tympanum and the labyrinth; *a* the membrana tympani, which is incloſed in a perfect frame of bone in this bird; *b* the cavity of the tympanum laid open on the other ſide of the head; *c* the pediculated bone, or officulum, in ſitu; *d d d* the ſemicircular canals; *e* the tube analogous to the cochlea; *f f* the air-cells expoſed by the diviſion of the cranium. *Fig.* 10. ſhews the officulum and the membrana tympani abſtracted from their ſituation and magnified; *a a* the membrane; *b* the flat head or diſk of the officulum; *c* the pedicle; *d* the extremity which unites with the cartilages, and forms the triangle that is connected to the membrana tympani. *Fig.* 11. exhibits a magnified view of a diſſection of the labyrinth of the *gooſe*, in which the membranous parts and the diſtribution of the nerves are diſplayed; *a* the trunk of the auditory nerve; *b* the portio dura; *c c c* the three branches of the portio mollis going to the ſemicircular canals; *d* the nerve of the cochlea running in the ſulcus, and ramifying on the apex of the cartilages; *e* the oſſeous part of the tube analogous to the cochlea; *f* the inferior cartilaginous cylinder; *g* the ſulcus between it and the ſuperior, which is concealed from view by the nerve; *h h h* the three ampullæ of the membranous ſemicircular canals; *i* the canalis major; *k* the canalis minor; *l* its communication with the major; *m* the canalis minimus; *n* the hole which correſponds to the foramen ovale. *Fig.* 12. is the cartilaginous body removed from the oſſeous tube; *a* the ſuperior cylinder; *b* the inferior; *c* their junction where they commence; *d* the cavity at the apex of the cylinders laid open; *e* the nerve of the cochlea; *f* its expanſion in the cavity of the apex of the cartilaginous body.

Organ of Sight.

The peculiarities in the ſtructure of the eyes of birds are chiefly intended to facilitate the perception of objects through a rare medium, and accommodate viſion to different diſtances.

The *form of the eye* is admirably adapted in moſt ſpecies to promote both theſe effects. The anterior circle of the globe of the eye always projects more than in other animals; and in many ſpecies it is prolonged in a tubular form, and in thoſe caſes the cornea alſo is remarkably gibbous. The *owl* furniſhes the moſt ſtriking example of the diſproportion between the anterior and poſterior ſpheres of the eye. The

axis

axis of the anterior portion being twice as great as that of the other. The obvious conſequence of this figure of the globe of the eye is to allow room for a greater proportion of the aqueous fluid, and for the removal of the chryſtalline lens from the ſeat of the ſenſation, and thus produce a greater convergence of the rays of light, by which the animal is enabled to diſcern the objects placed near it, and to ſee with a weaker light; and hence *owls*, which require this ſort of viſion ſo much, poſſeſs the ſtructure fitted to effect it in ſo remarkable a degree.

The *ſclerotic coat* of the eye in birds is thin and flexible on the poſterior part, but anteriorly its form is maintained by the interpoſition of a number of bony plates between its layers. Theſe vary from thirteen to twenty, and are arranged in a circle immediately behind the cornea, with their edges overlapping each other. They are commonly flat thin ſcales, and nearly of a ſquare figure, but become elongated from before backwards in proportion as the bird poſſeſſes the power of changing the convexity of the cornea. In the *owls* the ſcales compoſe not only all the projection of the eye (the cornea excepted), but contribute to form the poſterior ſphere. The ſcales are capable of a degree of motion upon each other, which is, however, reſtrained within certain limits by the attachments of their anterior and poſterior edges to the ſclerotic coat; and by their being bound together with a tough ligamentous ſubſtance, which ſeems to be the continuation of the ſclerotic between the edges that overlap each other.

The *cornea* poſſeſſes the ſame ſtructure as in mammalia, but differs with reſpect to form. When the poſterior part of the eye is compreſſed by the muſcles, the humours are urged forwards and diſtend the cornea; which, at that time, becomes much more prominent in moſt birds than it is ever obſerved in mammalia; and under ſuch circumſtances, the eye is in a ſtate for perceiving near objects. When the muſcles are quite relaxed, the contents of the eye-ball retire to the poſterior part, and the cornea becomes flat, or even depreſſed: this is the condition in which we always find the eye of a dead bird, but we can have no opportunity of perceiving it during life. It is only practiſed for the purpoſe of rendering objects viſible that are placed at an extreme diſtance. From the well known effects of form upon refracting media, it muſt be preſumed, that the cornea poſſeſſes very little, if any, convexity, when a bird, which is ſoaring in the higher regions of the air, and inviſible to us, diſcerns its prey upon the earth, and deſcends with unerring flight to the ſpot, as is cuſtomary with many of the rapacious tribe.

There are other circumſtances in the anatomy of the eye of birds, which have been ſuppoſed to concur with the extraordinary variation in the figure of the cornea, in producing its capacity for the perception of remote objects: theſe will be mentioned in their proper place.

The *choroid coat* differs in no material point from that of the human ſubject. The *ciliary proceſſes* of the choroides are very ſmall and ſhort; being merely ſerrated ſtriæ. There appears to be no *tapetum*.

The *iris* is ſometimes of brilliant colours, which are employed by naturaliſts as diſtinguiſhing ſpecific characters of birds. *Parrots* have the power of voluntarily producing a great degree of motion in the iris. It does not appear, however, that other birds are capable of commanding the motions of this part.

The *pecten*, or *plicated membrane*, is the moſt ſingular part of the ſtructure of the eye of birds. It appears to grow from the choroides where the optic nerve penetrates that coat; but on cloſer inſpection it is found to have no intimate connexion with it. In ſtructure, however, it is perfectly ſimilar to the choroides. The form of this part varies in different ſpecies; in general, it conſiſts of a membrane folded backwards and forwards on itſelf, like the plaits of a garment, and preſenting, when viewed on the ſide, ſomething of the appearance of the teeth of a comb; on which account, the name of *pecten* has been applied to it. In the *ſtruthious birds*, the folds of the pecten are larger, and collected towards the point, giving it a reſemblance to a purſe. The Pariſian academicians therefore, in taking their deſcription of this part from the *oſtrich*, called it the *marſupium nigrum*, by which name it is ſtill very commonly known. The plicated membrane proceeds into the ſubſtance of the vitreous humour, and uſually becomes attached to the poſterior part of the capſule of the cryſtalline lens a little to one ſide. In ſome inſtances it does not come into immediate contact with the capſule of the lens, but ends a very ſhort way behind it amongſt the cells of the vitreous humour: ſuch is the caſe in the *turkey*, *jackdaw*, and ſeveral other birds. The number of the folds of the pecten vary. There are ſixteen in the *ſtork*, fifteen in the *oſtrich*, and ſeven in the great *horned owl*.

The functions of the plicated membrane have been often diſcuſſed, but ſtill remain involved in ſome degree of doubt. Haller, and others, conſider it as the medium through which the veſſels are conducted to the cryſtalline lens; but there appears no reaſon for ſuch a proviſion to exiſt in birds. Petit was of opinion that it abſorbed the lateral rays of light, in order that objects placed immediately before the eye might be more diſtinctly ſeen; which is highly improbable, as the ſcope of viſion is full as extenſive in birds as in other animals. The beſt ſupported theory on this ſubject is Mr. Home's. The plicated membrane, according to his experiments, poſſeſſes a contractile power, and affords the means of withdrawing the lens from the anterior part of the eye, when the organ is adapted to the perception of remote objects; thus acting in concert with the change of figure in the cornea. Experiments, however, upon the operations of the eye are ſo delicate in their nature, that they are ſeldom to be relied upon, and accordingly in different hands they have afforded very different reſults; but the doctrine of the muſcularity of the plicated membrane is almoſt proved by its ſeeming neceſſity for the explanation of the powers of adaptation of the eyes to different diſtances, which birds poſſeſs in a degree far ſuperior to all other animals; and it ſeems fair to infer that if the accommodation of viſion depends upon the motion of the cornea, and the receſſion of the lens in thoſe animals which are ſo eminently endowed with it, ſimilar means are employed for the ſame purpoſe in the other claſſes which poſſeſs the faculty in a leſs degree. For the more ample diſcuſſion of this ſubject, ſee Mr. Home's lectures on muſcular motion, publiſhed in the Philoſophical Tranſactions for the years 1794, 1795, and 1796; Dr. Olbers' "De oculi mutationibus internis," Gotting. 1780; "The Eſſays of Petit, Mem. de l'Acad." 1735, p. 163. 1736, p. 166; "Obſervations on the Eyes of Birds," by Mr. Pierce Smith, Phil. Tranſ. for 1795;" and "Dr. Young's Lecture on the Mechaniſm of the Eye," Phil. Tranſ. 1801.

The *optic nerve* paſſes through an oblique ſheath in the back of the ſclerotic coat, during which it changes from a round to a flattened ſhape, and, as ſuch, enters the eye, preſenting on the inſide an elongated white line, inſtead of a round diſk, from which the retina is produced. The origin of the plicated membrane covers the entrance of the optic nerve.

The *humours*, as well as the ſhape of the eye and the ſtructure

ture of its coats, indicate the peculiar viſion of birds and the kind of medium they inhabit. The *aqueous humour*, as already obſerved, is extremely abundant. It poſſeſſes conſiderable refractive eſpecially powers in the higher regions of the atmoſphere. The *cryſtalline* is remarkably flat and ſoft, as its offices can be ſo well ſupplied by the aqueous fluid in a rare medium. Both the form and the proportions of the humours in the eyes of all birds derive great illuſtration from being compared with thoſe of *fiſhes*, which, in conſequence of their continual reſidence in ſo denſe a medium as water, have theſe parts formed upon a plan the very reverſe.—Their eye is flat anteriorly; the aqueous fluid ſmall in quantity, and of conſiderable conſiſtence; and the lens ſpherical and hard, more eſpecially in the centre. The *cormorant* has the cryſtalline more ſpherical than other birds, from being obliged to ſeek its food under the water.

The *muſcles* for the motion of the eye-ball are ſix in birds, as in the human ſubject; the four ſtraight and two oblique. The tendons of the recti cannot be traced farther than the circle of imbricated bones. The operation of the ſtraight muſcles, when acting together upon the figure of the eye (which, as already obſerved, is ſo ſtriking in birds), depends upon the bony ſcales of the anterior part of the ſclerotic, and the thinneſs and pliability of that tunic poſteriorly. The ſuperior oblique muſcle does not paſs through a pulley.

The *external eye-lids* are chiefly cloſed in birds by the elevation of the lower one, although there is an orbicular muſcle which ſurrounds both. The inferior eye-lid is larger and thicker than the other, and contains internally an oval cartilaginous plate, under which the fibres of the orbicularis palpebrarum paſs. There is alſo a peculiar muſcle, which comes from the floor of the orbit, and acts as a *depreſſor* of the inferior eye-lid.

The *internal eye-lid*, or *membrana nictitans*, is a thin ſemitranſparent membrane, which lies cloſe to the globe of the eye. It has a vertical poſition, and, when not employed, is folded back by virtue of its own elaſticity, and remains concealed from view in the corner of the eye next the noſe. It is, however, capable of being ſpread over the whole of the anterior part of the organ, by means of the combined action of two curiouſly contrived muſcles. One of them is of a ſquare figure, and thence called *quadratus*; it ariſes from the upper and back part of the eye-ball, and approaching the optic nerve, terminates abruptly in a circular edge, which contains a pulley for the paſſage of the tendon of the *pyramidalis*. This muſcle ariſes from the ſide of the ſclerotic next the noſe a little inferiorly, and produces a fine tendon, which runs through the pulley formed in the free edge of the quadratus, and afterwards returns in a cellular ſheath on the lower ſurface of the ſclerotic, and becomes attached to the margin of the membrana nictitans, along which it is continued for ſome way, and gradually loſt.

The *lacrymal gland* is ſmall in moſt birds. The *glandula harderi* exiſts, and is larger than the lacrymal. Cuvier deſcribes it as being generally ſituated between the adductor and levator muſcles, and as having a ſingle excretory duct, which perforates the membrana nictitans, and diſcharges upon its inner ſurface a yellow tenacious fluid. Many *water birds* have a hard granular body placed at the ſuperior part of the orbit, which ſeems to perform the office of a lacrymal gland; and although its excretory ducts have not been yet ſeen, it probably furniſhes a fluid of a peculiar nature, for the defence of the eye againſt the effects of the water and other accidents to which aquatic birds are expoſed.

The figures, which ſerve to explain the organization of the eye, are found in *Plate* XI. of the *Anatomy of Birds*. *Fig.* 1. ſhews the cornea and imbricated bony ſcales of the *gooſe*, as an example of the figure theſe parts commonly aſſume in birds. *Fig.* 2. repreſents the ſame parts in the *horned owl*, in which the cornea will be ſeen very prominent, and the ſcales greatly elongated, forming the fore part of the eye into a tube. *Fig.* 3. exhibits a lateral view of the cryſtalline lens and the plicated membrane in the *gooſe's* eye; *a* the pecten attached to the poſterior part of the lens a little to one ſide; *b* the edge of the lens marked by the ciliary proceſſes; *c* the anterior part, which is particularly flat in birds. *Fig.* 4. ſhews the pecten and the lens in the relative ſituation they hold in the eye of the *turkey*; *a* the plicated membrane; *b* the lens; *c* the outline of the eye; *d* the optic nerve. *Fig.* 5. is a ſection of the eye of the *emeu*; *a a* the cut edges of the ſclerotic coat; *b b* the edges of the choroides; *c* the retina; *d* the plicated membrane formed like a purſe. *Fig.* 6. preſents the anterior part of the eye of the *caſſowary*, with the membrana nictitans partially drawn over it, which is ſo fine a film that the parts of the eye are ſeen through it. *Fig.* 7. is the poſterior view of the *caſſowary*'s eye, all the muſcles, &c. being removed, but thoſe for moving the membrana nictitans: *a* the muſculus quadratus; *b* the pyramidalis at its origin; *c* its tendon paſſing through the pulley in the edge of the quadratus; *d* the tendon proceeding on the ſclerotic coat.

Organ of Voice.

Until within theſe late years this part of the anatomy of birds has been involved in obſcurity. Although ſeveral of the older anatomiſts deſcribed the ſtructure by which birds produce ſound, they were ignorant of its uſes, from being miſled by analogy, and ſuppoſing that this organ occupied the ſame ſituation in all animals. Even ſome of the deſcriptions of the ableſt of the modern anatomiſts have been erroneous or imperfect. The ſubject has been moſt laboriouſly and ingeniouſly inveſtigated by Cuvier. He diſſected the organs of voice of more than one hundred and ſixty ſpecies of birds, and publiſhed the reſult of his inquiries in two memoirs; the principal one will be found in the Magazin Encyclopedique, tom. 2, to which we would refer the reader for numerous and minute details, that would be burthenſome to introduce into the preſent work.

The true ſeat of the organ of voice in birds is at the bifurcation of the trachea, and not, as general analogy would dictate, at the ſuperior larynx, which is in birds little more than a ſimple rima, or ſlit, formed, however, with ſomewhat differently ſhaped cartilages than belong to the reſt of the trachea, and furniſhed with muſcles for opening and cloſing the aperture. The mechaniſm of the inferior larynx, which fits it for the production of ſound, depends upon the figure of its cartilages, and the expanſion of its membranous parts.

The two branches of the bronchia are compoſed of ſemirings of cartilage; the internal ſurfaces, or thoſe oppoſed to each other, being membranous. The ſemi-rings next the trachea are often large, and always leſs curved than thoſe near the lungs. The conſequence of which is, that the membranous part of the bronchiæ becomes expanded in proportion to its diſtance from the lungs, and towards the bifurcation uſually aſſumes an oval figure, to which Cuvier has given the name of the *tympaniform membrane*.

Where the bronchiæ open into the trachea, there is the appearance internally of the reed of a muſical inſtrument. This is produced by a thin and elaſtic fold of the inner membrane, which projects upwards from each ſide. The aperture is divided into two, ſometimes by an oſſeous bar extended acroſs from before backwards, and ſometimes merely by the angle produced by the union of the two bronchiæ.

When the air is expelled from the lungs and air-cells with force

force through the bronchiæ, a lively vibration is excited in the tympaniform membrane and the reed-ſhaped aperture, or glottis, upon which the production of the voice eſſentially depends.

The magnitude, figure, and proportions of the inferior larynx vary more or leſs in almoſt every ſpecies, which Cuvier has taken great pains to point out.

The trachea is commonly enlarged, at its bifurcation, by the expanſion and union of its laſt cartilaginous rings, which is deſigned to afford ſtrength to the voice.

In the *ſtare* and the *ſinging birds*, the laſt rings of the trachea are united into a ſingle piece, of which the baſe is wide, and furniſhed with two points that are joined by a tranſverſe oſſeous bar in ſuch a way, that the trachea communicates by two openings with each of the bronchiæ.

In the *parrot*, the laſt rings of the trachea are united, and form a tube a little compreſſed on the ſides. The very laſt ring is almoſt ſquare; it is alſo flattened before and behind, and furniſhed poſteriorly with two points. There is no partition within. The ſides of the bronchiæ, oppoſite to each other, are membranous. The firſt ſemi-ring is large, flat, and ſhaped like a creſcent; the ſecond, third, and fourth ſemi-rings unite in one piece; and the fifth, ſixth, and ſeventh are conſolidated into a ſimilar plate. The edges of both, however, preſent the marks of their original parts.

In the *nocturnal birds of prey*, the laſt ring of the trachea is divided by a bone.

In the *ſcolopax ruſticola*. the four laſt cartilaginous rings of the trachea are incomplete poſteriorly, and the tympaniform membrane is continued up between them.

The male birds of the *duck* kind, and the genus *mergus*, have the laſt rings of the trachea united, and forming a cartilaginous or bony ſack, called by authors the *ampulla*, or the *labyrinth*. This part, in the *mallard*, forms two dilatations; the one on the right is ſmall, and reſembles a truncated cone, with a prominence from the baſe behind. The left is a large veſicle irregularly rounded, and produces at the lower part a pyramidal projection. Its right ſurface is a little flattened below, and its inferior border is indented. The cavity is interrupted by projections, or ſepta, in ſuch a manner, that the air cannot paſs from the left bronchia into the trachea, but through the capſule, although on the right ſide it may. The entrance to the bronchiæ is provided with a thick membrane, under which there are ſome glands reſembling the *ſynovial*, that ſecrete a mucous fluid.

The form and internal partitions of the ampullæ of the *drakes* of other ſpecies and the *merganſers*, are different in every inſtance. Their deviations are deſcribed at length by Cuvier. See Memoire ſur le larynx inferieur des oiſeaux, Magazin Encyclopedique, tom. 2d.

Two ſpecies of *vulture* (V. *papa* and V. *aura*) were obſerved by Cuvier to be deprived of the organ of voice, there being neither the tympaniform membrane, nor any contraction, or projecting elaſtic parts at the entrance of the bronchiæ into the trachea.

The voice of birds is modified, and the tones rendered more acute or grave, by means of two deſcriptions of muſcles. The firſt are common to all ſpecies, and have been long known and deſcribed. They were called by Vic d'Azir the *inferior* or *external laryngeal*. They are two fleſhy cords, and ariſe from the triangular proceſſes of the ſternum, to which the ſuperior ribs are joined within the cheſt, and proceed to the ſide of the trachea, above the bifurcation, along which they aſcend for its greateſt length. Their effect is to depreſs the inferior larynx, and contract the bronchia, and thereby relax the tympaniform membrane, and deepen the tone of voice, and in ſome circumſtances they may alſo bring the trachea forwards. Theſe were the only muſcles obſerved by Cuvier in the *gallinæ*, and moſt of the *anſeres*. It is probable, that no others are to be found alſo in the *ſtruthious* birds.

The ſecond kind of muſcles are confined to the inferior larynx; they are ſhort, and ſituated upon each ſide of the bifurcation of the trachea; and, except in the *parrot* tribe, are all conſtrictors, or intended to render the tympaniform membrane tenſe, and thus exalt the tones of voice.

In moſt birds, which do not ſing, there is but a ſingle pair of conſtrictors, one on each ſide, which ariſes from ſome of the laſt rings of the trachea, and is inſerted into ſome of the firſt ſemi-rings of the bronchia. Theſe *muſcles* are longeſt in the *nocturnal birds of prey*, extending from the baſe of the trachea to the ſeventh ſemi-ring. The conſtrictor is attached to the fifth ſemi-ring in the *cuckow*, the *heron*, and *bittern*. The latter birds owe their ſtrength of voice to the elaſticity of the ſemi-rings, and the extent of the tympaniform membrane. The *goat-ſucker*, *king-fiſher*, and *pelican*, have the conſtrictor muſcle affixed to the ſecond ſemi-ring of the bronchia; and the *woodcock*, *phalarope*, *coots*, and the *plovers*, and *recurviroſtra*, and probably all the weak billed *grallæ*, have it inſerted into the firſt ſemi-ring.

The larynx of *ſinging birds*, and ſome others, is provided with five conſtrictors on each ſide, which Cuvier has named, according to their ſituation and direction.

1. The *anterior longitudinal conſtrictor*.
2. The *poſterior longitudinal conſtrictor*.
3. The *ſmall longitudinal conſtrictor*.
4. The *oblique conſtrictor*.
5. The *tranſverſe conſtrictor*.

Theſe almoſt ſurround the bifurcation of the trachea, to which they have all the ſame attachments, as near as may be. The two firſt are inſerted into the third ſemi-ring; the two next into the ſecond ſemi-ring; and the laſt is affixed to the firſt ſemi-ring, and particularly to a little cartilage that is joined to it.

Cuvier has obſerved the five pair of conſtrictors in all the ſinging birds, in the *ſtare*, in all the *paſſeres*, except the *ſwallow* and *goat-ſucker*, and in the *crow*, *raven*, *jay*, and many of the *pie* kind.

The moſt complicated inſtrument of voice, amongſt birds, is that of the *parrot* tribe. It poſſeſſes three pair of muſcles; but one pair is intended to relax the opening of the glottis.

The *principal conſtrictor* ariſes from the laſt ring but one of the trachea, deſcends almoſt perpendicularly upon the laxator, and then goes on to be inſerted into the union of the fifth, ſixth, and ſeventh ſemi-rings of the bronchia. Its attachment being joined to the ſemicircular plate, it urges the upper part of the plate inwards, and thus contracts the glottis.

The *auxiliary conſtrictor* occupies, for a certain diſtance, the anterior part of the trachea, and ſends off a tendon, which is loſt in the preceding muſcle; its operation, therefore, is exactly the ſame.

The *laxator* is placed under the two other muſcles; it ariſes along the ſide of the trachea, and expands upon the inferior concave edge of the laſt ring; in drawing which outwards, the muſcle enlarges the glottis.

See *Plate* XI. in the *Anatomy of Birds*. *Fig.* 8. ſhews the external appearance of the inferior larynx in the *owl*; *a* the lower part of the trachea; *b* the two bronchiæ; *c* the external laryngeal muſcles, which are common to all birds; *d* the conſtrictor. *Fig.* 9. of the ſame plate exhibits the organ of voice in the *thruſh*; *a* the anterior longitudinal conſtrictor; *b* the tranſverſe conſtrictor partially expoſed under

under it; *e* the poſterior longitudinal conſtrictor, detached at one extremity, and turned outwards: and *Fig.* 10. affords another view of the ſame ſubject; the poſterior longitudinal conſtrictor is turned down to expoſe thoſe that lie behind it; *a* the little longitudinal conſtrictor; *b* the oblique conſtrictor. *Fig.* 11. of *Plate* X. repreſents the anterior part of the organ of voice in the *parrot*; *a* the principal conſtrictor; *b* the auxiliary one; *c* the laxator: and *Fig.* 12. gives a lateral view of the ſame parts, which are indicated by correſponding letters.

The *trachea*, in ſeveral birds, is found to aſſume ſingular forms, and to ſuffer enlargements at particular places. Theſe have long attracted the attention of naturaliſts. Some of the beſt obſervations on the ſubject have been made by Dr. Bloch of Berlin, and by Pallas, Silberſchlag, Beckmann, and Otto, who have each publiſhed in the Berlin Tranſactions, ſee Beſch. des Berl. Nat. Fr. i. ii. iii. & iv. But by far the moſt copious account of the peculiarities of the trachea of birds, has been given by Dr. Latham in the Linnæan Tranſactions, vol. iv. p. 90.

The deviations from the common ſtructure of the trachea, have been divided by Dr. Latham into two kinds. In one the windpipe does not alter its capacity, but poſſeſſes an unuſual length, which is diſpoſed of either in convolutions on the outer part of the body underneath the integuments, or in a cavity formed within the ſternum for the purpoſe. The other kind of deviation conſiſts in dilatations occurring either at the biſurcation of the trachea, or both there and in the middle of the tube.

The trachea of the *wood grous*, when arrived at the crop, takes a bend upwards for a little way, and again turns down, and purſues its courſe to the lungs. There has been no peculiarity obſerved in the other birds of this genus which viſit this kingdom.

In the *marail turkey* (*penelope marail*), the trachea makes a round turn on the outſide of the top of the ſternum, and then enters the cheſt.

In the *male parraka pheaſant*, the wind-pipe deſcends under the ſkin more than half the length of the body, before it returns to enter the thorax.

The *guan* (*penelope criſtata*) has the trachea ſtill longer than the preceding. It paſſes to the very bottom of the belly, and then turns up again, before it makes the double. See *Plate* XI. in the *Anatomy of Birds*, *fig.* 13.

The *Indian cock* was obſerved by the academicians to have a degree of convolution in the trachea, which varies ſomewhat in different individuals.

The *cuſhew curaſſow* has the moſt remarkable convolutions of the trachea. It firſt deſcends upon the right pectoral muſcle to the end of the ſternum, where it makes a convolution to the left, ſomething in the ſhape of a ring, after which it returns to the right pectoral muſcle, and goes over the clavicle into the thorax.

The *ſemi-palmated gooſe* of *New Holland* has an extenſive convolution of the trachea under the ſkin. Its note is ſaid to be very muſical.

The *ardea virgo*, *the wild* or *whiſtling ſwan*, and the *crane*, have the winding of the trachea accommodated in the keel of the ſternum. It is ſingular that this ſtructure does not exiſt in the *tame ſwan*, which in other reſpects ſo much reſembles the wild bird. See *Plate* XI. in the *Anatomy of Birds*. *Fig.* 14. ſhews thoſe parts in the *wild ſwan*; *a a a* the ſternum cut open to expoſe the cavity which lodges the trachea; *b b b* the trachea; *c c* the fork; *d d* the clavicles. The above ſtructure belongs to both ſexes.

The dilatations of the trachea are confined to two genera, *anas* and *mergus*; and as already obſerved, are only to be met with in the male birds.

The bony enlargements at the biſurcation into the bronchia, which are called *ampullæ*, or *labyrinths*, exiſt in every ſpecies of duck and merganſer. They conſiſt of two cells, one in general much larger than the other. In ſome inſtances the parietes of the cells are in a great meaſure formed by a membrane ſpread acroſs it, like the head of a drum. There is alſo a bony arch turned acroſs to give ſtrength. This is the caſe in the *ſcaup duck*, the *pochard*, *tufted duck*, the *ſmew*, *&c.* See *Plate* XI. *Fig.* 15 is the end of the wind-pipe of the *pochard* (*anas ferina*).

The trachea of the *golden eye duck* is very curious. The labyrinth is more complicated than uſual; and there is a ſingular enlargement in the middle, which is formed by cartilaginous joints, or plaits, placed obliquely, and folding over each other, ſo that the part admits of being contracted and lengthened, as the motions of the neck may require.

The *velvet duck* is diſtinguiſhed by two very remarkable oſſeous enlargements, one is ſituated immediately below the ſuperior larynx, and another in the middle of the wind-pipe. The lower part does not form the uſual ampulla, but the bronchiæ become for a little way bony canals. See *Plate* XI. in the *Anatomy of Birds*. *Fig.* 16. repreſents the trachea of the *velvet duck*; *a* the *ſuperior*, or laryngeal oſſeous cell; *b* the bony cavity of the middle; *c c* the oſſeous parts of the bronchiæ.

The *red-breaſted merganſer* has the middle of the trachea formed like that of the *golden eye duck*, only the plaits are made of bone, and curiouſly furrowed: indeed all the trachea of the merganſers, as Dr. Latham obſerves, conſiſts of little elſe than bone.

A very little compariſon of the mechaniſm of wind muſical inſtruments with the organs of voice in birds, will ſhew how nearly they are allied to each other; and it may be obſerved, that the ſound produced by ſome of the larger birds is exactly ſimilar to the notes that proceed from a *clarionet* or *hautboy* in the hands of an untutored muſician. The inferior glottis exactly correſponds to the reed, and produces the tone or ſimple ſound. The ſuperior larynx gives it utterance as the holes of the inſtrument; but the ſtrength and body of the note depend upon the extent and capacity of the trachea, and the hardneſs and elaſticity of its parts. The convolution and bony cells of the wind pipe, therefore, may be compared with the turns of a *French horn*, and the diviſions of a *baſſoon*; and they produce the proper effects of theſe parts in the voices of thoſe birds in which they are found.

Bird, in *Aſtronomy*, *Avis Indica*. See Apus.

Bird of *Phœbus*, the *Raven*, one of the ſouthern conſtellations. See Corvus.

Birds, in *Ancient Augury*. Preſcience, or knowledge of futurity, was ſuppoſed, among the ancients, a natural faculty of birds, owing, perhaps, to their nearer intercouſe with heaven, or their breathing a purer and more celeſtial air than other animals. Hence it was, that divination by birds obtained among the ancient Greeks and Romans, being performed by obſerving, and interpreting the flight, chirping and feeding of divers birds. (See Augury.) Birds, with regard to augury and divination, were of divers kinds, viz. *Aves auſpicatæ*, or *felices*, thoſe which naturally portended good: ſuch were the dove, ſwan, &c. *Aves inauſpicatæ*, *diræ*, *ominoſæ*, thoſe which boded ſome evil or miſchief: ſuch were the kite, raven, crow, and owl, every where, except at Athens. *Admiſſiva*, that which excites and encourages the conſulter to execute what he has in view. *Arciva* or *arcula*, that which forbad a thing to be done; otherwiſe

called *clivia*, *clamatoria*, and *prohibitoria*, *inebra*, and *inhibæ*. *Incendiaria*, that which gave omen of a fire, or other calamity; or which is ſeen carrying a firebrand from the funeral pile to a houſe. *Remora*, that which ſtays or delays an action. *Siniſtra*, that on the left hand, denoted a happy or proſperous omen; and was alſo called *fecunda*, *proſpera*. *Alites*, thoſe which gave omens by their wings and flight. *Oſcines*, thoſe by their ſinging or chirping. *Pulli*, by their pecking. *Præpetes*, thoſe which by their flight, or perching, gave happy omens. *Inferæ*, or *inebræ*, thoſe which in like manner gave ill omens.

Bird, William, in *Muſical Biography*. This worthy and admirable ſcholar of the profound Tallis, is ſuppoſed to have been the ſon of Thomas Bird, one of the gentlemen of Edward the ſixth's chapel, in which he was himſelf a finging-boy. By the great number of his eccleſiaſtical compoſitions to Latin words, and the ſeveral portions of the Romiſh ritual which he ſo frequently ſet to muſic, and publiſhed late in life, he ſeems to have been long a zealous adherent to that religion. He muſt, however, have conformed to the church eſtabliſhments of queen Elizabeth's reign; for, in 1563, he was choſen organiſt of Lincoln cathedral, where he continued till 1569, when, upon the accidental death of Robert Parſons, who was drowned at Newark-upon-Trent, he was appointed gentleman of the chapel royal. Notwithſtanding which office, he ſeems to have compoſed the chief part of his Choral Muſic to Latin words, and to have publiſhed it in that language, as late as the middle of the reign of king James I.

In 1575, it appears by the title-page of the "Cantiones Sacræ," and the patent annexed to that work, that he and Tallis were not only gentlemen of the royal chapel, but organiſts to her majeſty queen Elizabeth. Indeed both muſt have been great performers on the organ, to have been able to play ſuch of their pieces for that inſtrument as are ſtill preſerved; in which the paſſages, though awkward to performers who are only accuſtomed to modern muſic, muſt have been ſuggeſted by perſons that were habituated to the complicated, and now, almoſt, invincible difficulties of the ſixteenth century. And though the compoſitions for keyed-inſtruments by theſe great maſters of harmony, are totally unimpaſſioned, and without grace, it is impoſſible not to regard their ingenuity and contrivance in the texture of the parts, with reſpect and wonder!

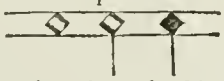
If we conſider the elaborate ſtyle of compoſition which prevailed, particularly in the church, during the time of Bird, and that he, like his maſter Tallis, was not only ambitious of vanquiſhing its uſual difficulties in the conſtruction of fugues and canons, but fought new complications, perplexities, and involutions in the motion and arrangement of the parts, the following liſt of his works will not only manifeſt diligence, but fecundity.

Beſides the great ſhare he had in the "Cantiones Sacræ," publiſhed in conjunction with his maſter Tallis, in 1575, when his name firſt appears as an author; and without enumerating many admirable compoſitions for the church and chamber, ſtill ſubſiſting, but which were never printed, or, at leaſt, not till after his deceaſe, he publiſhed "Pſalms, Sonnets, and Songs of Sadneſs and Pietie," of five parts, 1588; "Liber primus ſacrarum Cantionum, quinque vocum," 1589; "Songs of ſundrie Natures, ſome of Gravitie, and others of Myrth, fit for all Companies and Voyces," 1589; "Gradualia ac Cantiones Sacræ, Lib. primus et ſecundus," 1607 and 1610. The laſt work publiſhed by himſelf, was entitled, "Pſalms, Songs, and Sonnets: ſome ſolemne, others joyful, framed to the Life of the Words, fit for Voyces or Viols, of three, four, five, and ſix partes," 1611. Dr Tudway's collection, in the Britiſh Muſeum, contains a whole ſervice in D minor, by Bird, with reſponſes, and the anthems, "Sing joyful unto God,"—"O Lord, turn thy Wrath,"—(all publiſhed in the ſecond and third volumes of Dr. Boyce's Cathedral Muſic.)—"O Lord, make thy Servant;" "Save me, O God;" "Prevent us, O Lord;" "Civitas ſancti tuo." one of his Sacrarum Cantionum, or Sacred Songs, publiſhed 1589, has been long ſung in our cathedrals to the Engliſh words, "Bow thine ear, O Lord," and is one of the admirable pieces of harmony in the ſecond volume of Boyce's printed collection.

Dr. Aldrich, who was a great admirer and collector of the works of Bird, and who adapted Engliſh words to moſt of his compoſitions which have been uſed in our cathedrals, and that were originally ſet to parts of the Romiſh ſervice, in Latin, has bequeathed to Chriſt Church, Oxon, beautiful and correct copies of moſt of his productions, in a ſet of books, ſmall 4to. In this library near forty of his compoſitions are preſerved; and in another ſet, many more, with thoſe of Tallis, Taverner, Tye, White, Redford, both the Mundys, Shepherd, Bull, and other contemporary Engliſh maſters.

Bird's pieces for the organ and virginals are almoſt innumerable. In a magnificent folio manuſcript, curiouſly bound in red morocco, formerly in Dr. Pepuſch's collection, which is generally known by the name of "Queen Elizabeth's Virginal Book," there are near 70 of his compoſitions.

The firſt piece by Bird, in this book, and the eighth in the collection, is a Fantaſia, which generally implies a Fugue, in which the ſubject is as frequently changed as in ancient Choral Muſic, where new words require new accents and intervals; for as yet, it was not the cuſtom in compoſing fugues to confine a whole movement to one theme: and here Bird introduces five or ſix, wholly different and unconnected with each other.



The ſubject of the ſecond compoſition, by Bird, in the Royal Virginal Book, is the tune of an old ballad, "John come kiſs me now;" of which, with great labour and ingenuity, he has varied the accompaniments ſixteen different ways; for while the treble, baſe, or ſome inward part, is always playing the original air, three other parts are moving in fugue, or running rapid and difficult diviſions. No. 52, is another Fancie; and 56, a Pavan, by Bird; which implied a grave majeſtic dance, in common time, ſimilar to the movement of the peacock. This ſtrain was uſually followed by the Galliard; which, on the contrary, was a gay and lively dance, in triple time, but on the ſame ſubject as the preceding Pavan. No. 58, is entitled, "The Carman's Whiſtle." From No. 58 to 69, the compoſitions are all by Bird; conſiſting chiefly of old tunes, with variations; among which is "Fortune," a plaintive and expreſſive melody, to which the ballad, called "Titus Andronicus's Complaint," inſerted in Reliques of ancient Engliſh Poetry, vol. i. p. 204, was originally written. It has been imagined that the rage for variations, that is, multiplying notes, and diſguiſing the melody of an eaſy, and, generally, well-known air, by every means that a *ſpacca nota*, or note ſplitter, fees poſſible, was the contagion of the laſt century; but it appears from the Virginal Book, that this ſpecies of influenza, or corruption of air, was more exceſſive in the ſixteenth century, than at any other period of muſical hiſtory.

Crowded and elaborate as is the harmony, and uncouth and antiquated the melody, of all the pieces in this collection by various compoſers, there is a manifeſt ſuperiority in thoſe of Bird over all the reſt, both in texture and deſign. In a later age his genius would have expanded in works of invention, taſte, and elegance; but, at the period in which

he flouriſhed, nothing ſeems to have been thought neceſſary for keyed-inſtruments, except variations to old tunes, in which all the harmony was crowded, which the fingers could graſp, and all the rapid diviſions of the times, which they could execute. Even nominal fancies were without fancy, and confined to the repetition of a few dry and unmeaning notes in fugue, or imitation. Invention was ſo young and feeble, as to be unable to go alone; and old chants of the church, or tunes of the ſtreet, were its leading ſtrings and guides.

Though the reformation had baniſhed ſuperſtition from the land, fragments of *canto fermo*, like rags of Popery, ſtill remained in our old ſecular tunes, and continued to have admiſſion in the new. Indeed the melodies of all the reſt of Europe had no other model than the chants of the church, till the cultivation of the muſical drama; whence all the rhythm, accent, and grace of modern muſic, have manifeſtly been derived.

Beſides the great number of Bird's compoſitions for keyed-inſtruments, which are preſerved in the Virginal Book of queen Elizabeth, another manuſcript collection of his pieces ſtill ſubſiſts, under the title of "Lady Nevil's Muſic Book." It is a thick quarto, very ſplendidly bound and gilt, with the family arms beautifully emblazoned and illuminated on the firſt page, and the initials H N at the loweſt left hand corner. The muſic is all written in large, bold characters, with great neatneſs, on four ſtaved paper, of ſix lines, by Jo. Baldwine, a ſinging-man at Windſor, and a celebrated copyiſt of queen Elizabeth's time. The pieces contained in this collection, ſixteen of which are entered in that queen's virginal book, amount to forty-two, with variations to many of them, of the moſt laboured and difficult kind. The notes, both white and black, are of the lozenge form, like thoſe of the printed muſic of the ſame period.

Lady Nevil ſeems to have been the ſcholar of Bird, who profeſſedly compoſed ſeveral of the pieces for her ladyſhip's uſe.

None of Bird's pieces for keyed inſtruments ſeem to have been printed, except eight movements in a thin folio book of leſſons that was engraved on copper, and publiſhed in the reign of king James I. under the following title: "Parthenia, or the Maidenhead of the Muſicke that ever was printed for the Virginalls. Compoſed by three famous maſters: William Bird, Dr. John Bull, and Orlando Gibbons, gentlemen of his majeſtyies moſt illuſtrious chappel." Theſe leſſons, though not equally difficult with ſome of thoſe in the Virginal Books of queen Elizabeth and lady Nevil, are rather more dry and ungraceful.

The canon, *Non nobis Domine*, appears in none of his works publiſhed by himſelf, or collected by others, before the year 1652; when Hilton inſerted, and prefixed the name of Bird to it, in a collection of catches, rounds, and canons. But as no claim was laid to it by, or in favour of, any other compoſer, before or ſince that time, till about the middle of the laſt century, when it was given to Paleſtrina by Carlo Ricciotti, who publiſhed, in Holland, among his concertos, a fugue in eight parts, on the ſame ſubject, there ſeems no doubt remaining of our countryman Bird having been the author of that pleaſing and popular compoſition.

Bird died in 1623, ſurviving his maſter Tallis thirty-eight years; and if we ſuppoſe him to have been twenty in the year 1563, when he was choſen organiſt of Lincoln, he muſt have been eighty at his deceaſe. Peacham, in his Complete Gentleman, ſpeaks of him with great reverence; "For Motets and Muſicke of piety and devotion, as well for the honour of our nation, as the merit of the man, I preferre above all others our Phœnix, Maſter William Byrd, whom in that kind I know not whether any may equall. I am ſure none excell, even by the judgement of France and Italy, who are very ſparing in their commendation of ſtrangers, in regard of that conceipt they hold of themſelves. His Cantiones Sacræ, as alſo his Gradualia, are meere angelicall and divine; and being of himſelfe naturally diſpoſed to gravity and piety, his veine is not ſo much for light madrigals or canzonets; yet his Virginella, and ſome others in his firſt ſet, cannot be mended by the firſt Italian of them all." *Second Impreſſion*, p. 100. His pupil, Morley, in his *Introduction*, every profeſſor and muſical writer of his own and later times, never mention him but with the higheſt reſpect. At this remote period but little, however, can be known of his private life, which was too ſtudious and ſedentary to have furniſhed hiſtory, at any time, with events of general intereſt. With reſpect to what Ant. Wood aſſerts in his Faſti, that "Bird was excellent in mathematics," it is, in his uſual way, ſupported by no proof; and indeed mathematics have ſo little to do with practical muſic, either in compoſition or performance, that thoſe muſicians, who are moſt ignorant of the ratio or philoſophy of ſounds, ſeem conſtantly to have arrived at the higheſt degree of excellence in the ſelection, combination, and refinement of them in practice, by the mere aſſiſtance of experience, and the gift of good ears and powerful nerves. That he was a diligent cultivator of his art appears from his numerous works, which are more the productions of meditation and ſtudy, than of haſte and enthuſiaſm. That he was pious, the words he ſelected, and the ſolemnity and gravity of ſtyle with which he ſet them, ſufficiently evince. Of his moral character and natural diſpoſition, there can, perhaps, be no teſtimonies more favourable, or leſs ſubject to ſuſpicion, than thoſe of rival profeſſors, with whom he appears to have lived during a long life with cordiality and friendſhip. And, of the goodneſs of his heart, it is, to us, no trivial proof, that he loved, and was beloved, by his maſter, Tallis, and ſcholar, Morley; who, from their intimate connexion with him, muſt have ſeen him *en robe de chambre*, and been ſpectators of all the operations of temper, in the oppoſite ſituations of ſubjection and dominion.

Indeed, the beſt memorials of a profeſſional man's exiſtence are his ſurviving works; which, from their having been thought worthy of preſervation by poſterity, entitle him to a niche in the Temple of Fame, among the benefactors of mankind. The phyſician who heals the diſeaſes, and alleviates the anguiſh of the body, certainly merits a more conſpicuous and honourable place there; but the muſician, who eminently ſooths our ſorrows, and innocently diverts the mind from its cares during health, renders his memory dear to the grateful and refined part of mankind, in every civiliſed nation.

Bird *cherry*, in *Botany*. See Prunus *Padus*.

Bird's *eye*. See Adonis.

Bird's *foot*. See Ornithopus.

Bird's *foot trefoil*. See Lotus.

Bird's *neſt*, a name uſed by ſome for the daucus, or carrot; and by others for ophrys.

Bird's *neſt, purple*. See Orchis.

Bird *pepper*. See Capsicum.

Bird's *tongue*. See Senecio.

Birds *canary*. See Canary *birds*.

Bird of the *wiſe*, among *Alchemiſts*, is the philoſophical mercury; and, in general, ſublimations or ſubſtances ſpiritualized by the ſeparation of their terreſtrial part.

Bird, *golden*, the hermetic matter partly matured.

Bird, *green*, the philoſopher's ſtone, at the time when its green colour appears.

Birds, *Cyprian, aves Cypricæ*, or *aviculæ Cypriæ*, is a denomination given to a kind of odorous candle, made of the matter of troches, and burnt for the ſake of their fumes, called alſo, from their figure, *baculi*, or *ſticks*.

Bird *of Hermes, avis*, or *avicula Hermetica*. Alchemiſts ſpeak much of that which flies in the night without wings. Some will have the *avicula Hermetica* to be an univerſal ſalt prepared from dew.—It alſo denotes red-lead.

Birds, *decoy*, are thoſe which are trained up to call and allure others into the fowler's nets, ſnares, lime-twigs, or the like. See Decoy.

Birds, *Humming*. See Humming-*bird*.

Birds, in *Domeſtic Economy*, and in reference to their uſe as aliments. See Fowl.

Bird, in *Falconry*, denotes a hawk, or falcon. See Falcon. *Nidis birds, aves nidulariæ*, denote thoſe taken while in the neſt. *Ramage bird, arborariæ aves*, are thoſe only arrived at ſtrength ſufficient to fly from branch to branch. *Hagard bird*, is that which has lived at liberty, and is thence more wild and untractable. *Bird of the fiſt*, is that which having been reclaimed, returns to, and perches on the hand, without the help of a lure. *Bird of lure*, ſignifies that which comes to the lure, and by that means to the hand. *Baſtard bird*, a hawk, for inſtance, bred of a hawk and a lanier; or a ſaker, bred of a ſaker and a lanier. *Coward birds*, thoſe which only purſue their game for their own belly, and which are not to be reduced to juſt ſport; as ravens, kites, &c.

Bird, in *Geography*, the name of a ſmall iſland in Dunmannus bay, in the county of Cork, Ireland.—Alſo, another ſmall iſland in Strangford lough, and county of Down.—Alſo, one of the Bermudas iſlands.—Alſo, a ſmall iſland in the gulf of St. Lawrence, 21 leagues W. of cape Anguilla on the iſland of Newfoundland. N. lat. 47° 55′. W. long. 60° 45′.—Alſo, an iſland in the ſouthern Pacific Ocean, diſcovered by capt. Cook, in 1769, in his voyage from Cape Horn to Otaheite, covered with verdure, and inhabited. S. lat. 17° 48′. E. long. 216° 24′.—Alſo, an iſland in the ſouthern Pacific Ocean, near the north weſt coaſt of the iſland of New Georgia, diſcovered by capt. Cook, in 1775. S. lat. 54°. W. long. 38° 22′.—Alſo, an iſland of the ſame ocean, diſcovered in 1788, by the commander of the Prince of Wales, and ſo called from its being the reſort of many birds. This ſolitary iſland, or rather ſingle rock, riſing out of the immenſe ocean, was particularly examined by Vancouver, in 1794. Its greateſt extent, in a direction S. 74 W. and N. 74 E. did not exceed one mile; and its northern, eaſtern, and weſtern extremities, againſt which the ſea broke with great violence, preſented a very awful appearance, riſing perpendicularly from the ocean in lofty rugged cliffs, inacceſſible except to its winged inhabitants; on its ſouthern ſide the aſcent is not ſo ſteep and abrupt; and near its weſtern extremity is a ſmall ſandy beach, where in fine weather, and with a ſmooth ſea, a landing might probably be effected. At this place was the appearance of a little verdure, though it was deſtitute of tree or ſhrub; every other part was apparently without ſoil, and conſiſted only of the naked rock. The whole circumference does not exceed a league, and it is ſituated in N. lat. 23° 6′. E. long. 198° 8′. It lies from Onehow, one of the Sandwich iſlands, N. 51 W. at the diſtance of 39 leagues; it is recognized by the natives of thoſe iſlands under the appellation of "Modoo Mannoo," that is, bird iſland; and from its great diſtance from all other iſlands, and its proximity to their iſlands, it ſeems to claim ſome pretenſions to be ranked in the group of the Sandwich iſlands; which ſee.—Alſo, a ſmall iſland near the north-eaſt coaſt of New Holland, lying low and almoſt covered with birds; 4 leagues N. W. from cape Grenville. For other iſlands under this denomination; ſee Aves.

Bird *fort*, an American fort on Monongahela river 40 miles ſouth of Fort Pitt.

Birds-*Key*, or *Round iſland*, a ſmall iſland, or rock, among the Virgin iſlands, in the Weſt Indies; 2 leagues S. of St. John's iſland; and 3 N. E. from St. Croix, or Santa Cruz. N. lat. 17° 55′. W. long. 64° 36′.

Birds, *Meſſage, aves internunciæ*, denote thoſe that are employed to convey letters or other diſpatches, either for the ſake of expedition or ſafety. See Carrier-pigeon and Aleppo.

Bird, *mocking*, the *turdus polyglottus*; which ſee. See alſo Mock *bird*.

Bird-*bolt*, in *Heraldry*, is a ſmall arrow with a blunt head, and often repreſented in armory, with two and ſometimes three heads rounded, but in that caſe the number of heads muſt be noticed.

Bird-*call*, a ſmall ſtick cleft at one end, in which is put a leaf of ſome plant, that ſerves to counterfeit the call of ſeveral birds, and to bring them to the net, ſnare, &c. by which they are taken. A laurel-leaf fitted on the bird-call counterfeits the voice of lapwings, a leek, that of the nightingale, &c. See Call, and Bird-catching.

Bird-*Catching*, in its moſt comprehenſive ſenſe, denotes the art of taking birds or wild-fowl, either for food, or for enjoying the pleaſure of their ſong in cages, or for preventing the deſtruction which ſome ſpecies of them occaſion to the huſbandman. Some recur to it as an amuſing paſtime, and others practiſe it as a profitable employment; and with a view to one or other of theſe objects, various modes of taking birds have been adopted, and the practice is in ſome places reduced to a kind of ſyſtem. One of theſe methods is denominated Bat-Fowling, or, as ſome term it, *Bat-folding*. For this purpoſe, five or ſix perſons commonly provide themſelves with a large net, expanding, when open, to the extent of a man's arms, and about three yards high, and formed of meſhes ſo ſmall as not to allow the eſcape of the ſmalleſt bird. The extremities of the net are attached to two poles, held one in each hand of the perſon who has the management of it. With this, and a large lanthorn affixed to a pole, the party proceeds to corn-fields, out-houſes, yew-hedges, thatched buildings, &c. The cords of the net being ſeparated to their utmoſt extent, it is placed before any ſpot where birds are ſuppoſed to rooſt, and the light being held before the centre of the net, the aſſiſtants in this operation beat the hedges, ricks, eaves, &c. with poles; and the birds, thus alarmed, fly towards the light, upon which the perſon who holds the net claps its poles together, and encloſes the birds. From the latter circumſtance, the net is called a *clap-net*. Sparrows, larks, thruſhes, and the other ſmall birds are thus caught in great numbers in dark nights. Another method of bat-fowling, is performed by means of a long net drawn over the ground, followed by a perſon bearing a light; and this net, in its paſſage, encloſes and confines any birds that happen to be under it. But one of the moſt ingenious and ſyſtematic methods of bird-catching, is practiſed principally in the vicinity of London, by perſons who find a ready market for birds uſed as food, or who deal in ſong-birds, which, at certain ſeaſons of the year, change their ſituation, and are hence denominated birds of flight, in the language of this art. The birds, uſually taken on ſuch occaſions, are wood-larks, titlarks, linnets, aberdavines, gold-finches, and green-finches. They are princi-

pally

pally taken during what is called their flight, or while they congregate for the purpoſe of propagating their ſpecies. The wild birds begin to fly in the month of October, and part of the preceding and following months; and the flight in March is much leſs conſiderable than that of Michaelmas. It is to be noted alſo, that the ſeveral ſpecies of birds of flight do not appear exactly at the ſame time, but follow one another in ſucceſſion. The pippet, which is a ſmall ſpecies of lark, inferior in its ſong to other birds of that genus, begins his flight, every year, about Michaelmas; and then the wood-lark, linnet, gold-finch, chaffinch, green-finch, and other birds of flight ſucceed; all of which are not eaſily to be caught, or in any numbers, at any other time, particularly the pippet and the wood-lark. Theſe birds, during the Michaelmas and March flights, are chiefly on the wing from day-break to noon, though there is afterwards a ſmall flight from two till night; but this is ſo inconſiderable, that the bird-catchers always take up their nets at noon. Another circumſtance worthy of notice is, that, during their flitting, they always fly againſt the wind; hence the bird-catchers eagerly contend for that point; ſo that if it be weſterly, the bird-catcher, who lays his nets moſt to the eaſt, is ſure almoſt of catching every thing, provided that his call-birds are good: a gentle wind to the ſouth-weſt generally produces the beſt ſport. The nets uſed by the bird-catchers are about 12 yards long, and 2½ wide; which are known in moſt parts of England by the name of "day-nets," or "clap-nets," but the beſt are thoſe that are uſed in the neighbourhood of London. Theſe nets are ſpread upon the ground parallel to one another, and at ſuch a diſtance, that when turned over, they ſhall coincide. The remaining apparatus conſiſts of lines ſo faſtened to the nets that the bird-catcher is able, by a ſudden pull, to draw the net over the birds that may have alighted in the ſpace between their parallel ſides. Theſe birds are enticed to alight by others uſually denominated "call-birds," of which there are generally five or ſix linnets, two goldfinches, two greenfinches, one woodlark, one red-poll, a yellow hammer, a titlark, and an aberdavine, and perhaps a bullfinch. Theſe are placed at ſmall diſtances from the nets in little cages. Beſides theſe, the bird catcher has others called "flur-birds," which are placed within the nets, raiſed upon the flur, and gently let down at the time the wild birds approach them. This "flur" is a moveable perch to which the bird is tied, and which the bird-catcher can raiſe or depreſs at pleaſure, by means of a long ſtring faſtened to it. Theſe flur-birds generally conſiſt of the linnet, the goldfinch, and the greenfinch, which are attached to the flur by what is called a "brace," which ſecures the birds without injuring their plumage. This brace is a ſort of bandage, formed of a ſlender ſilken ſtring, that is faſtened round the body of the bird, and under the wings in ſuch a manner as to prevent the bird's being hurt, however it may flutter when it is raiſed. The call-birds are particularly trained for the ſervice to which they are appropriated. Accordingly, the bird-catchers contrive to improve the ſong of theſe birds, by cauſing them to moult before the uſual time. For this purpoſe, they put them, in June or July, into a cloſe box, under two or three folds of blankets, and leave their dung in the cage to increaſe their heat; and in this ſtate they continue, being, perhaps, examined once a week to have freſh water. The air of the cage is ſo putrid, that they want little or no food, as they eat ſcarcely any thing during the whole period of their confinement, which is about a month. The birds frequently die under this operation; and on this account the "ſtopped bird," as it is called, is the more valuable. When the bird hath thus prematurely moulted, he is "in ſong," while the wild birds are "out of ſong;" and his note is louder and more piercing than that of a wild one; and his plumage is by this proceſs equally improved. The black and yellow in the wings of the goldfinch, for example, become deeper and more vivid, and acquire a very beautiful gloſs, which is not to be ſeen in the wild bird. The bill, which in the latter is likewiſe black at the end, becomes in the "ſtopped bird" white and more taper, as are alſo its legs; and, in ſhort, there is as much difference between a wild and a ſtopped bird, as there is between a horſe, which is kept in body cloths, and one at graſs. When the bird-catcher hath laid his nets, he diſpoſes of his "call-birds" at proper intervals; and Pennant obſerves, that a malicious joy appears in the ſe call-birds, to bring the wild ones into the ſame ſtate of captivity; and this is alſo the caſe with regard to the decoy ducks. After they have ſeen or heard the approach of the wild birds, which they obſerve long before it is perceived by the bird-catchers, the intelligence is announced from cage to cage, with the utmoſt ecſtacy and joy. The note, by which they invite them down, is not a continued ſong, like what the bird uſes in a chamber; but "ſhort jerks," as they are called by the bird catchers, which are heard at a great diſtance. So powerful is the aſcendency of this call over the wild birds, that the moment they hear it, they alight on a ſpot, within twenty yards of three or four bird-catchers, which otherwiſe would never have attracted their notice. It alſo frequently happens, that if, by pulling the ſtring, half a flock only ſhould be caught, the others who have eſcaped, will immediately return to the nets, and ſhare the fate of their companions; and if only one bird ſhould eſcape, that bird will ſtill venture into the ſcene of danger, till it be caught; ſuch is the faſcinating power which the call-birds poſſeſs with regard to the others. A bird, acquainted with the nets, is by the bird-catchers termed a "ſharper;" and this bird they endeavour to drive away, as they can have no ſport, while it continues with them. Theſe ſportſmen frequently lay conſiderable wagers, whoſe call-bird can "jerk" the longeſt, as this circumſtance determines their ſuperiority. With this view, they place them oppoſite to each other, near an inch of candle, and the bird that jerks the oftneſt, before the candle is burnt out, wins the wager. Some birds have given 170 jerks in a quarter of an hour, and a linnet has been known, in ſuch a trial, to perſevere in its emulation, till it ſwooned from the perch; thus, as Pliny (l. x. c. 29.) ſays of the nightingale, "victa morte finit ſæpe vitam, ſpiritu prius deficiente quàm cantu."

It is obſervable, that bird-catchers immediately kill the hens of every ſpecies of birds they take, as they are incapable of ſinging, and inferior in plumage. The pippets, likewiſe, are indiſcriminately deſtroyed, as the cock does not ſing well. The dead birds are commonly ſold for three-pence or four-pence a dozen. The fleſh of theſe is regarded as a delicate acquiſition at the tables of the luxurious; and yet the taſte for ſmall birds is far from being ſo prevalent in England as it is in Italy, where they are eaten under the name of "beccaficos." However, the luxury of the modern Italians will appear to be parſimony, when compared with the extravangance of their predeceſſors the Romans. (See *Clodius Æsop.*) The higheſt price given for ſinging birds in London, Mr. Pennant informs us, is about five guineas; this ſum having been paid for a chaffinch, that had a particular and uncommon note, under which it was intended to train others, and five pounds ten ſhillings have been given for a call-bird linnet.

Mr. Pennant informs us, that when the titlarks are caught in the beginning of the ſeaſon, it frequently happens, that 40 are taken without one female; the caſe is the ſame with the wheatear, and probably with reſpect to other birds: and this

this circumſtance confirms the obſervation of Linnæus, that the male chaffinches fly by themſelves, and the flight precedes the females; and the fact extends to other birds. Such birds as breed twice a year have generally in their firſt brood a majority of males, and in their ſecond of females.

As the bullfinch, though it is not properly either a ſinging bird, or a bird of flight, its range being merely from hedge to hedge, fetches a good price on account of its learning to whiſtle tunes, and as it ſometimes flies over the fields where the bird-catchers lay their nets, they have often a call-bird to enſnare it, though moſt of them can imitate the call with their mouths. It is a peculiarity with regard to this bird, that the female anſwers the purpoſe of a call-bird, as well as the male, which is not to be experienced in any other bird taken by the London bird-catcher. The nightingale, though diſtinguiſhed as a ſinging-bird, moves only from hedge to hedge, and does not take the periodical flights of other birds in October and March; and therefore it is not claſſed by the bird-catchers among the birds of flight. The perſons who catch theſe birds, make uſe of ſmall trap-nets, without call-birds, and are conſidered inferior in dignity to other bird-catchers, who will not rank with them. The arrival of the nightingale is expected by the trappers in the neighbourhood of London, the firſt week in April; at firſt, none but cocks are taken, but in a few days the hens make their appearance, generally by themſelves, though ſometimes a few males come along with them. They are caught in a net-trap, the bottom of which is ſurrounded with an iron-ring; and the net itſelf is ſomewhat larger than a cabbage-net. When the trappers hear or ſee them, they ſtrew ſome freſh mould under the place, and bait the trap with a meal-worm from the baker's ſhop. In this way ten or twelve nightingales have been caught in a day. Pennant's Zool. vol. ii. Append.

Birds are caught in traps of various kinds; and frequently by nooſes of hairs. In this way, great numbers of wheat-ears are annually taken on the various downs of England. Small holes are dug by the ſhepherds in the ground, in each of which is placed a nooſe. Whenever a cloud obſcures the ſun, theſe timid birds ſeek for ſhelter under a ſtone, or creep into any holes that preſent themſelves; and they are thus enſnared by the nooſes which faſten around their necks. Woodcocks and ſnipes are taken likewiſe by nooſes of horſe-hair placed along their paths, in marſhes and moiſt grounds. Wild ducks in all their varieties are taken in vaſt numbers every winter on our coaſts by means of decoys. (See Decoy.) Groufe and partridges are taken by means of nets, either at night when reſting on the ground, by obſerving where they alight, and when ſetted, drawing a net over that part of the field; or, in the day, a very ſteady dog is uſed to point at them. The attention of the birds being thus fixed, two perſons, drawing the two extremities of a large net, paſs it over them, and thus ſecure a whole pack of groufe, or covey of partridges at once. Pheaſants are ſometimes taken by night, by holding flaming ſulphur under the trees on which they are obſerved to perch, the ſuffocating effluvia of which make them fall ſenſeleſs. Mons. Pratty informs us, that, during his travels in North America, he took great numbers of the paſſenger-pigeon in a ſimilar manner. For various methods of taking larks; ſee Alauda. For the uſe of bird-lime among bird-catchers; ſee Bird-Lime.

In various parts of the world, peculiar modes are adopted for enſnaring and taking birds, ſome of which, whilſt they are hazardous to thoſe who practiſe them, excite no inconſiderable degree of ſurpriſe, and even of anxiety, in the ſpectators. Thus, in the Orkney iſlands, where the birds that inhabit the rocks, and the eggs which they depoſit among the cliffs, ſupply the principal food of many among the poorer inhabitants, the intrepid and adventurous fowlers climb rocky precipices more than fifty fathoms above the ſea, and paſs from one ſhelf or ledge to another, whoſe breadth is barely ſufficient for reſting places to the birds, which depoſit their eggs upon them. In this hazardous employment, the adventurers are commonly lowered from above by means of a rope, formed often of brittle materials, and held by a ſingle aſſiſtant. Faſtened to this rope, the intrepid peaſant deſcends, and ſearches all the cavities for eggs, ſpringing from one projecting ledge to another, by the help of a pole, whilſt the aſſiſtant, upon receiving the neceſſary ſignals, ſhifts the rope from one part of the rocky precipice to another. If the weight of the fowler and of his booty ſhould, in theſe perilous circumſtances, overpower his aſſociate above, or the craggy rock cut the rope, inevitable deſtruction muſt await the adventurer; for he will either be daſhed againſt the projecting rock, or drowned in the ſubjacent ſea. But the moſt ſingular ſpecies of bird-catching is in the holm of Noſs, which is a huge rock ſevered from the iſle of Noſs by ſome unknown convulſion, and diſtant from it about 16 fathoms. The oppoſite cliffs are ſeparated by the raging ſea. The adventurer, having reached the rock in a boat, and aſcended to the top of it, faſtens ſeveral ſtakes in the ſhallow ſoil that is found on the ſurface of the rock; and ſimilar ſtakes are alſo attached to the edge of the correſponding and oppoſite cliff. A rope is then fixed to the ſtakes on both ſides, upon which a machine, called a cradle, is contrived to ſlide; and by the help of a ſmall parallel cord faſtened in like manner, the daring adventurer wafts himſelf over, and returns with his booty.

In the Feroe iſlands the method of bird-catching is more extraordinary and hazardous than any which has already been recited. The cliffs, to which the fowlers recur, are in many caſes 200 fathoms high; and they are traverſed both from above and below. In the firſt caſe, the fowlers provide themſelves with a rope 80 or 100 fathoms long; and the adventurer faſtens one end about his waiſt and between his legs, and having recommended himſelf to the protection of the Almighty, he is lowered down by ſix aſſociates, who place a piece of wood in the margin of the rock, that the rope may be preſerved from being fretted and broken by its ſharp edge. To his body is faſtened a ſmall line which ſerves for enabling him to give the neceſſary ſignals, when he wiſhes to be raiſed or lowered, or ſhifted from one place to another. In changing his ſituation, he is expoſed to the hazard of injury from looſened and falling ſtones, which, falling on the head, muſt inevitably deſtroy him, if he were not in ſome degree protected by a ſtrong thick cap. The fowlers, by their aſtoniſhing dexterity, contrive to place their feet againſt the front of the precipice, and to dart themſelves ſome fathoms from it, for the purpoſe of ſurveying the rooſting places of the birds, and projecting themſelves into the deep receſſes, where they lodge. There the fowler alights; and diſengaging himſelf from the rope, which he fixes to a ſtone, collects the booty at his leiſure, attaches it to his girdle, and when this is done, reſumes his ſuſpended poſture. He will alſo, when occaſions require it, ſpring from the rock, and in this attitude, by means of a fowling net, fixed to the end of a ſtaff, catch the old birds which are flying to and from their retreats. When this hazardous operation is finiſhed, he gives a ſignal to his companions above, who pull him up, and divide the booty. The feathers are preſerved for exportation; the fleſh is partly eaten freſh, and the greater

greater part is dried for winter's proviſion. In fowling from below, the party have recourſe to a boat, and when they have arrived at the baſe of the precipice, one of the moſt intrepid of them faſtens a rope about his waiſt, and being furniſhed with a long pole, with an iron hook at one end, either climbs, or is thruſt up by his companions, who place a pole under him, to the next footing ſpot within his reach. By means of the rope he hoiſts up one of the boat's crew; and the reſt are drawn up in the ſame manner, each of them being furniſhed with his rope and fowling ſtaff. They then purſue their journey upwards, till they arrive at the region of birds; and they wander about the cliff in ſearch of them. They next act in pairs; one faſtens himſelf to the end of his aſſociate's rope, and, in places where birds have neſtled beneath his footing, he ſuffers himſelf to be lowered down, depending for ſafety on the ſtrength of his companion, by whom he is again hauled up; but it ſometimes happens, that the perſon above is overpowered by the weight, and in this caſe, both inevitably periſh. The fowl is flung into the boat, which attends their operations, for the purpoſe of receiving the booty. The fowlers often paſs ſeven or eight days in this perilous occupation, and lodge in the crannies which they find in various parts of the precipice.

In ſome remote parts of Ruſſia there is practiſed a ſingular invention for taking great quantities of gelinottes or grous. They chooſe the moſt open places in the birch woods; and there they plant long forks in the earth oppoſite the larger trees. On theſe forks is laid a horizontal ſtick, gallows-wiſe, to which are tied ſmall bundles of ears of corn. At a ſmall diſtance from this part of the contrivance, is a kind of large funnel or inverted cone, made with long birch twigs, thin and flexible, the lower extremities of which are ſtuck in the earth, very near to one another; but by ſpreading towards the top, forms there an opening of above a yard in diameter. In this opening is placed a wheel made of two circles that interſect each other, and are ſurrounded with ſtraw and ears of corn. This wheel turns on an axis faſtened to the ſides of the funnel in ſuch a manner, that there is room enough between the ſticks of the cone, and the circles, to admit of the wheel's turning freely about. The birds firſt perch upon the tranſverſe ſtick near the tree; and when they have a mind to fall upon the corn tied to the wheel, they muſt neceſſarily ſtand upon one of the projecting parts of the circles of which it is compoſed. At that inſtant the wheel turns, and the gelinotte falls, head foremoſt, to the bottom of the trap, which is there ſo contracted, that he cannot get out. They ſometimes find the machine half full of gelinottes.

The following method of netting or catching of wild pigeons is eagerly purſued as a diverſion in different parts of Italy, particularly by the inhabitants of Cava, in the Hither Principato, and is thus deſcribed by Mr. Swinburne. The people "aſſemble in parties; and if any ſtranger chances to ſtray to their rendezvous, give him a moſt cordial welcome. I am not in the leaſt ſurpriſed (ſays Mr. Swinburne), at their paſſionate fondneſs for this ſport, as I found it extremely bewitching, keeping the attention conſtantly alive, and the ſprings of the mind pleaſingly agitated by expectation; the ſituations where the toils are ſpread are incomparably beautiful, the air is pure and balſamic, and every thing around breathes health and ſatisfaction. When the periodical flights of ſtock-doves return from the northern and weſtern parts of Europe, to gain warmer regions for their winter abode, the fowler repairs to the mountain, and ſpreads his nets acroſs the intermediate hollows, the paſſes through which the birds direct their courſe, to avoid unneceſſary elevation in their flight. Theſe nets are hung upon a row of large trees planted for the purpoſe. The branches being very thick and cloſe at top, and the bore lofty and bare, a great opening is left below for the toils, which reach to the ground; and, by means of pulleys, fall in a heap with the leaſt effort. Sometimes they are extended upon poles that exceed the height of the trees. At a ſmall diſtance is a lofty circular turret, like a column with a little capital or cap, upon which a man is ſtationed to watch the approach of the game. As he commands a free view over all the country, and practice has made his ſight as acute as that of the lynx, he deſcries the birds at a wonderful diſtance. The doves advance with great velocity; but the alert watchman is prepared for them; and juſt as they approach his poſt, hurls a ſtone above them with a ſling: upon this the whole flock, whoſe fears have birds of prey for their great object, ſuppoſing the ſtone to be an enemy of that kind ready to pounce them, dart down like lightning to avoid the blow by paſſing under the trees; but there they ruſh into the jaws of death, by daſhing againſt the net, which inſtantly drops, and ſo entangles them that not one of them can eſcape the active hands of the fowler. Theſe birds are ſometimes taken by dozens at one fall, and are accounted fine eating. The dexterity with which the ſlingers manage their weapon is very remarkable; they throw the ſtone to a great height without any violent effort, and even without whirling the ſling round before they diſcharge the pellet. In the Pyrenean mountains, where the ſame diverſion is followed, the watchmen uſe a bow and arrow, trimmed with the feathers of a hawk."

The following ſimple but ingenious method of catching aquatic birds is uſed in Mexico by the natives. The lakes of the Mexican vale, as well as others of the kingdom, are frequented by a prodigious multitude of ducks, geeſe, and other water-birds. The Mexicans leave ſome empty gourds to float upon the water, where thoſe birds reſort, that they may be accuſtomed to ſee and approach them without fear. The bird-catcher goes into the water ſo deep as to hide his body, and covers his head with a gourd; the ducks come to peck at it; and then he pulls them by the feet under water, and in this manner ſecures as many as he pleaſes.

Sir George Staunton, in his "Embaſſy to China," (vol. ii. p. 400.) informs us, that water-fowl are taken upon the Wee-Chaung-hoo lake in that country by a ſimilar device. Empty jars or gourds are ſuffered to float about upon the water, that ſuch objects may become familiar to the birds. The fiſherman then wades into the lake with one of thoſe empty veſſels upon his head, and walks gently towards a bird; and lifting up his arm, draws it down below the ſurface of the water, without any diſturbance or giving alarm to the reſt, ſeveral of which he treats in the ſame manner, until he fills the bag which he had brought to hold his prey. This contrivance is not ſo ſingular as it is that the ſame device ſhould have occurred in the New Continent, as Ulloa aſſerts, to the natives of Carthagena, upon the lake Cienega de Teſias.

Birds, *fiſhing with*, is a ſingular mode of fiſhing practiſed in ſome of the lakes of China, and particularly deſcribed in the account of the late embaſſy. Upon a lake near the imperial canal were obſerved thouſands of ſmall boats and rafts, conſtructed for this ſingular kind of fiſhing. On each boat or raft were ten or twelve birds, which, at a ſignal from the owner, plunged into the water; and it was aſtoniſhing to obſerve the enormous ſize of the fiſh with which they returned, graſped within their bills. Theſe birds appeared to be ſo well trained, that it did not require either ring or cord about their throats, to prevent their ſwallowing

any

any portion of their prey, except what the maſter was pleaſed to return to them for encouragement and food. The boat uſed by theſe fiſhermen is of a remarkable light make; and is often carried to the lake, together with the fiſhing birds, by the men who are there to be ſupported by it. The bird trained for this purpoſe is a ſpecies of pelican, deſcribed by Dr. Shaw, from a ſpecimen ſubmitted to his inſpection, as "the brown pelican or corvorant, with white throat, the body whitiſh beneath and ſpotted with brown, the tail rounded, the irides blue, the bill yellow." Staunton's embaſſy to China, vol. ii. p. 388.

Bird-*lime*, a viſcid ſubſtance, prepared various ways, and from various materials, for the catching of birds, mice, and other vermin.

The bird-lime ordinarily uſed among us, is made from holly-bark, boiled ten or twelve hours. When the green coat is ſeparated from the other, it is covered up a fortnight in a moiſt place, then pounded into a rough paſte, ſo that no fibres of the wood be left, and waſhed in a running ſtream till no motes appear, put up to ferment four or five days, ſkimmed as often as any thing ariſes, and laid up for uſe. To uſe it, a third part of nut oil, or any thin greaſe, is incorporated with it over the fire.

The miſletoe affords a juice, even ſuperior to that of the holly; and if a young ſhoot of the common elder be cut through, a ſtringy juice will draw out in threads, and follow the knife like bird-lime, or the juice of holly. It ſeems in this tree to be lodged, not in the bark, but in certain veins juſt within the circle of the wood. The roots of all the hyacinths alſo afford a tough and ſtringy juice of the ſame kind, and ſo do the aſphodel, the narciſſus, and the black bryony root, in a ſurpriſing quantity.

The bird-lime brought from Damaſcus is ſuppoſed to be made of ſebeſtins, their kernels being frequently found in it: but this does not endure either froſt or wet. That brought from Spain is of an ill ſmell: that of the Italians is made of the berries of miſletoe, heated, mixed with oil, as before; to make it bear the water, they add turpentine. It is ſaid, the bark of our *viburnum* or wayfaring ſhrub makes bird-lime as good as the beſt.

Bird-lime is a ſubſtance very apt to be congealed, and rendered unſerviceable by froſts; to prevent which it is proper, at the cold ſeaſons, to incorporate ſome petroleum with it, before it is uſed. The method of uſing it is to make it hot, and dip the ends of a bundle of rods in it; then to turn them about and play them together, till a ſufficient quantity is extended over them all. If ſtrings or cords are to be limed, they are to be dipped into the bird-lime, while very hot. The cords may be put in cold, but the rods ſhould be warmed a little. Straws are to be limed while the matter is very hot: a large bundle of them ſhould be put in at one, and worked about in it, till they are well beſmeared. When thus prepared, they ſhould be preſerved in a leather bag, till they are uſed. When the twigs or cords are to be put in places ſubject to wet, the common bird-lime is apt to have its force ſoon taken away: it is neceſſary, therefore, to have recourſe to a particular ſort, which, from its property of bearing water unhurt, is called *water-bird-lime*; and is prepared thus: Take a pound of ſtrong and good bird-lime, waſh it thoroughly in ſpring-water, till the hardneſs is entirely removed; and then beat it well, that the water may be ſeparated from it; then dry it well, and put it into an earthen pot; add to it as much capon's greaſe as will make it run. Then add two ſpoonfuls of ſtrong vinegar, one ſpoonful of oil, and a ſmall quantity of Venice turpentine. Let the whole boil for ſome minutes over a moderate fire, ſtirring it all the time. Then take it off; and when there is occaſion to uſe it, warm it, and cover the ſticks well with it. This is the beſt ſort of bird-lime for ſnipes, and other birds that love wet places.

In order to uſe the common bird lime, cut down the main branch or bough of any buſhy tree, whoſe twigs are thick, ſtraight, long, and ſmooth, and have neither knots nor prickles. The willow and the birch trees will beſt anſwer the purpoſe. Trim off all the ſuperfluous ſhoots; and when the twigs are made neat and clean, let them be well covered with the bird-lime, within four inches of the bottom, but without touching the main bough from which they proceed. Some art is neceſſary to lay on the bird-lime properly; ſo that it be neither too thick, which would give the birds a diſtaſte, and prevent their approaching it; nor too thin, ſo that it would not hold them when they touch it. Having prepared the buſh, let it be placed in ſome dead hedge, or among growing buſhes, near the outſkirts of a town, a farmer's yard, or ſuch ſituation, if it be in the ſpring, when the birds reſort to ſuch places. If it be uſed in ſummer, let the buſh be fixed in the midſt of a quick ſet hedge, or in groves, buſhes, or white thorn trees, near fields of corn, hemp, flax, and the like; and in the winter, near ſtacks of corn, hovels, barns, and ſuch places. When the lime-buſh is thus planted, the ſportſman muſt ſtand as near it as he can, without being diſcovered, and contrive to make ſuch ſorts of notes as the birds do when they call to one another. Bird-calls may be uſed for this purpoſe; but the moſt expert method is to imitate with the voice the notes of call of the ſeveral birds. When a ſingle bird is thus enticed to the buſh, and faſtened to it, the ſportſman is to wait till, by ſtruggling to releaſe itſelf, it becomes more ſecurely attached, and by its fluttering it has brought other birds to the buſh; ſo that in this way ſeveral may be caught at once. The time of the day for this ſport is from ſun-riſe to 10 o'clock, and from 1 till ſun-ſet. Another mode of bringing the birds together is by a ſtale; ſuch as, a bat faſtened in ſight at a diſtance, or an owl, which is followed by ſeveral ſmall birds, which, alighting on the lime-buſh, will be entangled. The ſkin of an owl ſtuffed, or even the image of an owl carved on wood and painted in its natural colours, has been ſucceſsfully uſed for the ſame purpoſe.

M. Barrera, phyſician at Perpignan, diſcovered an animal bird-lime, prepared of the bolls of a ſort of caterpillars, by putrefying them in the earth, ſteeping them in water, and then pounding and mixing them with olive oil. Fontenel. Hiſt. Acad. Scienc. 1720, p. 12.

Birds, *migration of*, See Migration.

Birds' *neſts*, in *Cookery*, the neſts of a ſmall Indian ſwallow, very delicately taſted, and frequently mixed among ſoups. Mr. Marſden in his account of Sumatra, ſir George Staunton in his embaſſy to China, and many other travellers of more ancient and modern date, have recited ſeveral particulars concerning theſe edible neſts. But we have a more minute and ample deſcription of them, as well as of the birds by which they are formed, in the *third* volume of the "Tranſactions of the Batavian Society in the iſland of Java, for promoting the arts and ſciences." The birds that conſtruct them are of a blackiſh grey colour, ſomewhat inclining to green, but gradually changing on the back to the tail, and on the belly, into a mouſe colour. The length of the bird, from the bill to the tail, is about 4½ inches; and its height, from the bill to the extremity of the middle toe, 3¾ inches. The diſtance from the tip of one wing to that of the other, when extended, is 10¾ inches; the largeſt feathers of the wings are about 4 inches in length. The head is flat; but, on account of the thickneſs of the feathers, appears round, and large in proportion to the ſize of the

reſt of the body. The bill is broad, terminating in a ſharp extremity, and incurvated like an awl. Its width is increaſed by a naked piece of ſkin, reſembling parchment, which, when the bill is ſhut, is folded together; but when open, is conſiderably extended, and enables the bird, while on wing, to catch with greater eaſe the inſects that ſerve it for food. The eyes are black and large; the tongue is ſhaped like an arrow, and not forked; the ears are flat, round, naked ſpots, with ſmall oblong openings, and are wholly concealed under the feathers of the head; the neck is very ſhort, as well as the legs and bones of the wings; the thighs are wholly covered with feathers; and the very tender lower parts of the legs, and the feet, are covered with a ſkin like black parchment. Each foot has four toes; three before, and one turned backwards. The toes are ſeparate to their roots; and the middle one, together with the claw, is as long as the lower part of the leg. Each toe is furniſhed with a black, ſharp, crooked claw, conſiderably long, by which the bird can eaſily attach itſelf to crags of rocks. The tail is as long as the body, together with the neck and head: when extended it has the form of a wedge, and conſiſts of ten large feathers; the four firſt of which on each ſide are long, and, when the tail is cloſed, extend almoſt an inch beyond the reſt. The other feathers decreaſe towards the middle of the tail, and are equal to about the length of the body. The whole bird is very light and tender; ten of them together weighed little more than 2½ ounces. The Javaneſe call it "lawit;" but thoſe who live in the mountains, "berongdagæ," or "waled:" voerong, in the Malay language, ſignifying in general a bird.

There are two places in particular, near Batavia, where theſe birds are found in great numbers. The firſt, Calappa Nongal, lies about 10 miles ſouth of the city; and the other, Sampia, is ſomewhat more diſtant to the ſouth-weſt: but both are in that range of high land extending towards the ſea, and apparently different from the large ridge that extends over the whole iſland. Beſides theſe there are alſo other places in the ſame diſtrict, or at a greater diſtance from the coaſt, which either produce a few, or are carefully concealed by the Javaneſe, to whom they are known. The two bird mountains above-mentioned, called by the Javaneſe (goa) caverns, are inſulated rocks, hollow within, and pierced with numerous openings of different ſizes; but ſome ſo ſmall, that they ſeem to be peculiarly adapted to the ſecurity of theſe little animals. On the outſide, theſe rocks are covered with various kinds of tall trees; and within, they conſiſt of grey calcareous ſtone and white marble. To the ſides of theſe caverns the birds affix their ſmall neſts in horizontal rows, and ſo cloſe as almoſt to adhere together. They are conſtructed at different heights, from 50 to 300 feet; and no cavity that is dry and clean is left unoccupied; but if the ſides of the caverns be in the leaſt wet or moiſt, the birds deſert them. At day-break theſe birds fly abroad from their holes, with a loud fluttering noiſe; and in dry weather riſe inſtantaneouſly to ſuch a height in the atmoſphere, for the purpoſe of ſeeking their food in diſtant parts, that they are ſoon out of ſight. In the rainy ſeaſon they never wander far from their holes, particularly in Java, where ſome rocks are ſituated near the ſhore. About 4 in the afternoon they return, and confine themſelves ſo cloſely to their retired habitations, that none of them are ſeen to fly either out or in, except thoſe that are hatching. They feed upon all ſorts of inſects that hover over the ſtagnated water; and theſe, by the eaſy extenſion of their bills, they readily catch. Their moſt deſtructive enemy is a kind of hawk, which ſeizes many of them as they iſſue from their holes, and which the people frighten away by ſhooting at them. Their neſts are prepared, ſays this writer, from the ſtrongeſt remains of the food which they uſe, and not of the ſcum of the ſea, or of ſea-plants, as ſome have aſſerted. On this ſubject, however, there have been different opinions. Kæmpfer ſays, that the ſubſtance with which they form their neſts is the molluſca or ſea-worm; according to Le Poivre, fiſh-ſpawn; according to Dalrymple, ſea-weeds; and according to Linnæus, the animal ſubſtance often found on the ſea-beach, and called by fiſhermen blubbers or jellies. In proof of his opinion, this author ſuggeſts, that it is known from experience, that thoſe birds, which build their neſts in the two rocks beforementioned, have never been found on the ſea-coaſt, and could not poſſibly fly thither and return again in ſo few hours, on account of the high intervening mountains, and the ſtormy winds that often prevail among them. The great difference in the colour and value of theſe neſts proves, that their goodneſs depends merely on the ſuperabundance and quality of the inſects on which they feed, and perhaps on the greater or leſs ſolitude of the place where they ſeek nouriſhment. Thoſe found in the territory of Calappa Nongal and Goagadja are exceedingly grey, and worth one third leſs than thoſe produced in the territory of Sampia; and theſe latter are not to be compared with an excellent ſort which is every year imported from Ternate and Paſſier, or which is to be found on the ſurrounding iſlands, particularly to the eaſt of Borneo. Theſe birds occupy two months in preparing their neſts: they then lay their eggs (two in number), on which they ſit for 15 or 16 days. As ſoon as the young are fledged, people begin to collect the neſts, which is regularly done every four months; and this forms the harveſt of thoſe who are the proprietors of the rocks. The buſineſs of taking down the neſts is performed by perſons accuſtomed from their youth to climb theſe rocks. For this purpoſe they conſtruct ladders of reeds and bamboos, by which they aſcend to the holes; or, if the caverns are too deep, they employ ſhip-ropes. When they have deſcended to the bottom of the caverns, they place bamboos with notches in them againſt the ſides, if theſe be ſufficient, in order to get up to the neſts; but if they cannot thus reach them, they aſcend the ladders, and pull down the neſts with poles of bamboo made for that purpoſe. There are alſo certain holes to which people can aſcend by means of ſteps made of bamboos; but theſe are very few. This employment is very dangerous: many loſe their lives in purſuing it, and more particularly thoſe who attempt to rob theſe caverns at improper ſeaſons; for guarding againſt whoſe depredations, there are ſmall watch-houſes conſtructed in their vicinity. The mountaineers who engage in this occupation, never undertake their labour till they have ſlaughtered or ſacrificed a buffalo; which cuſtom is continually obſerved by the Javaneſe, at the commencement of any extraordinary enterprize. On ſuch occaſions they mutter over a few prayers, anoint themſelves with aromatic oil, and fumigate the holes with odoriferous ſubſtances. At the chief of theſe caverns, in the iſland of Java, a particular protecting female deity is worſhipped, under the name of "Raton Laut Ridul," or Princeſs of the South Sea. She is provided with a ſmall hut, and a covered ſleeping place, together with various elegant articles of dreſs, which no one but a princeſs muſt approach. On every Friday, when the neſts are taken down, incenſe is continually burnt; and the body and clothes of every one who intends to aſcend the rocks muſt be expoſed to it. In order to have light in the caverns, they uſe torches made of the reſinous gum of a large tree called "caret," and the inner bark of the arek tree.

The gathering of the neſts continues no longer than a month, and may be repeated three times a year. Some ſay it may be done a fourth time; but the moſt experienced ſay, that

that a neſt, as long as it remains entire, is continually enlarged or made thicker, until it is entirely deſerted by the bird, when it has become dry or hairy in the inſide. When the neſts have been collected, they require only to be dried and cleanſed, and then they are packed in baſkets and ſold to the Chineſe. Their price varies, and depends on their whiteneſs and fineneſs. Some of them have a grey, and others a reddiſh appearance: thoſe of the beſt ſort are exceedingly ſcarce. They are ſold at the rate of from 800 to 1400 rix-dollars per 125 pounds. This high price, and the inſatiable avarice of the Chineſe, give riſe to much diſhoneſty and thieving, eſpecially as the Chineſe make no ſcruple of bribing the watchmen with money, opium, and clothes; nor can any vigilance prevent this fraud. Calappa Nongal and Sampia formerly belonged to the Dutch Eaſt-India company; but, in 1778, the government reſolved to ſell them by auction to the higheſt bidder, and received for them almoſt 100,000 rix dollars. Beſides theſe, there are ſeveral other places of a like kind, though leſs important, in the ſame range of mountains; and there are alſo two or three in the high land, in the interior parts of the country, and ſeveral ſmall ones, which are carefully concealed. Three conſiderable bird-mountains, Goa Daher, Gede, and Nangaſari, are ſituated in the government of Samarang, in Java; and theſe are waſhed by the ſea, which forms its way ſo deep into the latter that fiſh may be caught in it. In theſe places the neſts are of an excellent quality; but the ſteepneſs of the rocks, and the violence of the ſurf, render it very dangerous to collect them; and, therefore, a ſuſpended apparatus of bamboos is employed for this purpoſe. The quantity of theſe neſts, collected annually in the iſland of Java, amounts to 2500 pounds in weight. There are alſo bird caverns in Bantam, and the iſland of Sumatra, in the Andaman and Nicobar iſlands, in the iſland of Borneo, and alſo in Cochin-China. The young birds are eaten both by the Javaneſe and the Europeans in India; but it is difficult to procure them. They are conſidered as very heating: but the neſts, on the other hand, when they have been boiled to a ſlimy kind of ſoup, expoſed in the night-time to the dew, and mixed with ſugar, are very cooling. The Javaneſe, therefore, uſe them in violent fevers; and they are ſaid to be preſcribed with good ſucceſs for ſore throats and hoarſeneſs. This latter uſe of them has probably been derived from the Chineſe, who carry on a great trade by theſe neſts, and eat many of them in the winter, becauſe ſore throats are then very common in the northern part of the kingdom, in conſequence of the people accuſtoming themſelves to ſit very much over the fire. But the author of the paper, from which theſe particulars are extracted, was not able to diſcover this nouriſhing and ſtrengthening quality that has been ſo much extolled, though he uſed a conſiderable number of theſe neſts, prepared in various ways, in order to convince himſelf of the fact. He cauſed them to be examined by able chemiſts; but nothing more could be obſerved than that the ſolution preſented a weak gum, with a diſagreeable taſte, which perhaps might be of ſome uſe in ſlight indiſpoſitions of the breaſt.

Theſe neſts are, therefore, a mere article of luxury to adorn the tables of the rich. The Chineſe are remarkably fond of them. After being ſoaked and well cleanſed, they put them, along with a fat capon or a duck, into an earthen pot cloſely covered, and ſuffer them to boil for 24 hours over a ſlow fire, which they call "timmen;" and, on account of this addition, the whole diſh acquires a more luſcious taſte. The trade in theſe neſts has of late much increaſed. The high and advancing price of them in China makes Batavia the principal mart of this commodity, which is employed, ſince the company have ſurrendered it, very advantageouſly by the inhabitants, to leſſen the prejudicial exportation of ſpecie.

The ſpecies of ſwallow that forms theſe neſts is not to be found in China. Linnæus gives, as a diſtinguiſhing mark of the *hirundo eſculenta*, that it has white ſpots only on the feathers of the tail. But the ſmall birds in Java that conſtruct the neſts, have ſpots neither on the tail nor on any other place. The tail feathers are entirely of one colour, blackiſh grey above, and a little brighter below. Rumphius ſays of his *capodes marinæ*, that the feathers of the tail were ſpotted, and that the breaſt alſo was ſpeckled black and white. Valentin, in his deſcription of the ſmall ſwallow which conſtructs edible neſts, mentions neither ſpots nor ſpeckles; and only ſays, that the belly was undulated black and white. If theſe are to be conſidered as eſſential differences, it will follow that there are two kinds of theſe ſwallows: one with a ſpeckled breaſt, and white ſpots on the tail feathers; and the other, without ſpots or ſpeckles. A third kind of theſe ſwallows would be thoſe called "momos," or "boerungitams." Theſe alſo prepare their neſts of eatable ſubſtances; but on account of the number of ſmall feathers, and other impurities mixed with them, they are not fit to be uſed; and people, therefore, endeavour, as much as poſſible, to exterminate them, as they ſpoil the habitations of the better kinds. They are diſtinguiſhed from the others merely by being larger, and having their legs down to the feet covered with ſmall feathers.

Birds, *pictures of, prepared by means of their own feathers*. For this purpoſe, procure a thin board of deal or wainſcot, well ſeaſoned, that it may not warp. On this paſte white paper, and let it dry: then get any bird which you would wiſh to repreſent, and draw its outline on the paper, in the deſired attitude, and in its natural ſize, with the addition of any landſcape or back-ground, &c. which you may think beſt. This outline ſo drawn is afterwards to be filled up with the feathers from the bird, placing each feather in that part of the drawing correſponding to the part of the bird from which it was taken. To do this, cover the outline repreſentation with ſeveral coats of ſtrong gum-water, allowing it to dry between each coat, till it is of about the thickneſs of a ſhilling. When the ground is thus prepared, take the feathers off from the bird, beginning at the tail or points of the wiugs, and work upwards towards the head. Theſe feathers muſt be prepared by clipping off all the downy part; and the large feathers muſt have the inſides of their ſhafts pared off, ſo that they may lie flat. In laying them on, hold them by a pair of ſmall pliers, and, moiſtening the gummed ground with water, place each feather in its natural and proper ſituation. Keep each feather down, by placing upon it a ſmall leaden weight, till you have another ready to be laid on. Care muſt be taken not to let the gum paſs through the feathers, ſo as to ſmear them or to adhere to the bottom of the weight, and thus pull off or diſorder the poſition of the feathers. When all the feathers are put on, cut a piece of round paper, and colour it to reſemble the eye of the bird, and then ſtick it in its proper place; but the beſt ſubſtitutions for this purpoſe are ſmall eyes made of glaſs. The bill, legs, and feet, muſt be drawn and coloured from nature. When it is finiſhed and adjuſted to your mind, lay a ſheet of paper upon it, and upon that a heavy weight to preſs it down; and after it has remained in that poſition till it is quite dry, it may be preſerved in a glaſs-frame.

Birds, *preſervation of*. Many methods have been uſed by naturaliſts for preſerving dead birds from corruption, in their natural form and colour. Some have taken off the ſkin, with all the feathers upon it, from the body and thighs, leaving the tail, legs and wings, with the whole neck and the bill, and filled it with ſome ſoft ſtuff, ſuch as hay, wool,

wool, or flax. Mr. Kuckahn (ubi infra), and Dr. Lettſom (Naturaliſt's Companion, p. 12, &c.), who approve of this method as one of the moſt compleat and leaſt troubleſome, direct, that after opening the bird by a longitudinal inciſion from the breaſt to the vent, ſeparating the fleſhy parts from the bones, and removing the entrails, eyes, brain, and tongue, the cavities and the inſide of the ſkin ſhould be ſprinkled with the powders (as below); the eyes to be inſerted, for which purpoſe wax may be uſed, or glaſs-eyes of any ſize or colour may be cheaply procured; and the head to be ſtuffed with cotton or tow. When this is done, a wire ſhould be made to paſs down the throat, through one of the noſtrils, and fixed into the breaſt-bone. Wires ſhould alſo be introduced through the feet up the legs and thighs, and inſerted into the ſame bone; and then the body ſhould be filled with cotton to its natural ſize, and the ſkin ſewed over it. The attitude ſhould alſo be regarded; for, in whatever poſition the ſubject is placed to dry, the ſame poſition will be afterwards retained. The powder which he recommends is compoſed of ½ lb. of corroſive ſublimate, ½ lb. of prepared or burnt ſaltpetre, ¼ lb. of burnt alum, ½ lb. of flowers of ſulphur, ¼ lb. of camphor or muſk, 1 lb. of black pepper, and 1 lb. of tobacco ground coarſe. The whole ſhould be mixed together, and kept in a glaſs veſſel ſtopped cloſe.

This method is particularly deſcribed by Mr. Kuckahn, Phil. Tranſ. vol. lx. p. 311, &c. When the above-mentioned proceſs is finiſhed in the manner which he has minutely detailed, he adviſes to bake the birds intended for preſervation in an oven of a due degree of heat; and he obſerves, that baking is not only uſeful in ſuch preſervations, but will alſo be of very great ſervice to old ones, as it deſtroys the eggs of inſects. And it ſhould be, he ſays, a conſtant practice once in two or three years to bake them over again, and to freſh waſh the caſes with a liquid made by diſſolving one pound of camphor in half a gallon of ſpirit of turpentine.

Others have put them into veſſels full of ſpirit of wine, or ſtrong brandy; againſt which it has been objected that ſpirituous liquors change the colours of the feathers; but M. Reaumur concludes from many experiments, that this objection is groundleſs; and he has given ſeveral minute directions for preſerving and conveying them in this way. Others again, eſpecially in countries where ſpices are cheap, have embalmed dead birds. Reaumur obſerves, that powdered alum or lime will ſerve the ſame purpoſe. Another method which has been ſometimes practiſed, is that of drying birds for preſervation in a heated oven. It is of importance, however, that dried birds ſhould be ſecured in boxes or barrels ſufficiently cloſed, that inſects may not ſlip in during the voyage or journey; and all the empty ſpaces left in the barrel ſhould be filled up with hemp, flax, cotton, &c. The ſame ingenious naturaliſt informs us, that quadrupeds, fiſhes, reptiles, and inſects, may be preſerved in the ſame manner with birds. For Reaumur's directions to this purpoſe, ſee Phil. Tranſ. Abr. vol. xi. page 891, &c.

Mr. Chaptal recommends the following method of preparing all kinds of animals for cabinets, as exceedingly ſimple, and ſo certain in its effect that he never found it to fail in a ſingle inſtance. The matter contained in the bowels of the animal muſt be evacuated, either by gradually preſſing the body towards the rectum, or by injecting ſome liquid which may remove every thing that ſtands in its way. After this operation, the end of the rectum ſhould be tied with a thread, and ether ſhould be injected with a proper inſtrument into the body, through the mouth or bill; and when the bowels have been filled with it, the animal is to be hung up by the head. One of the eyes muſt then be ſcooped out, and the brain extracted; after which the head is alſo filled with ether, which muſt be prevented from eſcaping by plugging up the eye hole. On the ſecond or third day the injection of ether is to be repeated; and this proceſs is to be continued till the animal is completely dried. While it is gradually drying, care muſt be taken to give the body its proper poſition; and as ſoon as it is completely deſiccated, it may be put up without further care or any other preparation. Ether is preferable to ſpirits of wine, becauſe, by its evaporation, it carries with it not only its own aqueous particles, but thoſe alſo which it abſorbs from the body. Beſides, this method neither deſtroys the form of the animal, nor tarniſhes the ſplendour of the feathers or hair, and is very cheap; one ounce of ether being in general ſufficient for a ſmall bird. The proceſs of drying, ſays Mr. Chaptal, might perhaps be a little ſhortened by the application of artificial heat. The theory of this proceſs, as this ingenious chemiſt thinks, is, that the ether, while it evaporates, volatiliſes the moiſture in the animal body, and by theſe means effects a gradual deſiccation, and thus removes the only cauſe of corruption.

The method of preſerving birds in Guiana, deſcribed by Bancroft (p. 184.), is as follows: The birds intended for preſervation, and for being conveyed to the cabinets of Europe, are depoſited in a proper veſſel, and covered with high wines, or the firſt running of the diſtillation of rum. In this ſpirit they remain for 24 or 48 hours, or longer, according to their ſize, till it has penetrated every part of their bodies. When this is done, the birds are taken out, and the feathers, which are not at all changed by this immerſion, are placed ſmooth and regular. They are then put into a machine, made for the purpoſe; and the head, feet, wings, tail, &c. are placed exactly agreeable to life. In this poſition they are put into an oven, very moderately heated, where they are ſlowly dried; and they will ever after retain their natural poſition, without danger of putrefaction.

Birds, *ſinging*, are the nightingale, blackbird, ſtarling, thruſh, linnet, lark, throſtle, canary bird, bullfinch, goldfinch, &c. See Song *of birds*.

BIRDAMA, in *Ancient Geography*, a town of India, on this ſide the Ganges, which, according to Ptolemy, was the capital of a people called Porvari.

BIREMIS, from *bis*, *double*, and *remus*, *oar*, in *Antiquity*, a veſſel with one or more rows of oars, ranged, as ſome think, in two ſtages over each other; or a veſſel having two ranks or rows of oars placed over, and aſide of each other. But the particular fabric of theſe veſſels ſeems far from being a ſettled point among the learned. The Roman *biremis* is the ſame with what the Greeks call δικρότα, and ſtands contradiſtinguiſhed from *triremis*, *quadriremis*, &c.

BIRINGOCCIO, or Biringucci, Vannuccio, in *Biography*, a mathematician of Sienna, was deſcended of a noble family, and flouriſhed about the 16th century. After having been employed by the dukes of Parma and Ferrara, he entered into the ſervice of the Venetians. He is ſaid to have been the firſt Italian author who wrote on the art of fuſing and caſting metals; particularly for the purpoſe of making cannon. His work, entitled, "Pirotechnia, &c." was printed at Venice in 1540, 4to; at Bologna, in 1678, 8vo; and at the ſame place in 1550, 1558, and 1559, 4to. A Latin tranſlation of it appeared at Paris in 1572, 4to; and at Cologne, 1658, 4to. A French tranſlation, by Jacob Vincent, was publiſhed at Paris in 1556, and 1559, 4to; and at Rouen in 1627. As a metallurgic writer, who detailed his own obſervations and experiments, and gave a clear and connected account of the chief proceſſes in metallurgy, Biringoccio is highly commended by profeſſor Beckman. Gen. Biog.

BIRKAN, in *Geography*, a town of Arabia, 24 miles ſouth of Saade.

BIRKENFELD, a town of Germany, in the circle of the Upper Rhine, and county of Sponheim, the ſeat of a bailiwic, including 32 villages and two iron founderies. It was taken by the French in 1794; and in their new arrangement, it is the principal place of a diſtrict of the ſame name, in the department of Sarre. The town contains 1061, and the canton 5892 perſons. This diſtrict comprehends 38 communes, and its whole territorial extent includes 1615 kilometres. It is ſituated 30 miles E.N.E. of Treves, and 30 N.N.W. of Deux Ponts.

BIRKENHEAD, or BERKENHEAD, SIR JOHN, in *Biography*, a political writer of ſome celebrity, was meanly deſcended, and born at Northwich, in the county of Cheſter, about the year 1615. In 1632 he was entered as a ſervitor in Oriel college, Oxford, and afterwards became amanuenſis to archbiſhop Laud, who recommended him in 1640 to be choſen probationer-fellow of All-Souls' College. When Oxford became the head-quarters of king Charles I. in the time of the civil war, Birkenhead was ſelected as a proper perſon to write a kind of journal in ſupport of the royal cauſe; which office he diſcharged to the ſatisfaction of his employers, and with reputation and advantage to himſelf. The king appointed him reader in moral philoſophy; and this poſt, more honourable than lucrative, he retained till the year 1648, when he was expelled by the parliament viſitors. From hence he removed to London, where he wrote ſeveral poetical pieces, chiefly of a ſatirical kind, levelled againſt the republicans in power; and, on account of his ſteady attachment to the royal cauſe, he was called the "loyal poet," and ſuffered ſeveral impriſonments. Upon the reſtoration of Charles II. he was rewarded for his loyalty. In 1661, he was created doctor of the civil law, by the univerſity of Oxford; and about the ſame time, was returned to ſerve in parliament for the borough of Wilton. He was knighted in 1662, and ſucceeded ſir Richard Fanſhaw as maſter of requeſts. The favours which he received from the court expoſed him to many ſevere attacks from thoſe who oppoſed it; but he was eſteemed by the learned perſons of his time, and elected a fellow of the Royal Society; and his memory has been tranſmitted with honour to poſterity by Dryden, Langbaine, and Winſtanley, notwithſtanding the reproaches of Anthony Wood. He died in Weſtminſter, in 1679. Biog. Brit.

BIRKESTORFF, in *Geography*, a town of Germany, in the circle of Weſtphalia and duchy of Juliers, one mile north of Dueren.

BIRKET EL HADJIS, or *Lake of Pilgrims*, a lake of Egypt, communicating with the Nile, and ſituate 10 miles E.N.E. of Cairo, near which the companies which form the caravan to Mecca aſſemble.

BIRKET EL KERUN, or CAROUN, a lake of Egypt, 30 miles long and 6 broad in the middle, but of an irregular form, and narrowing towards each end; 40 miles S.W. of Cairo. See MŒRIS.

BIRKHEHER, BLAUER RAKER, in *Ornithology*, the name of the garrulous roller, *coracias garrula* in Friſch. Av.

BIRKIN, in *Geography*, a river of England, which runs into the Bollin, one mile ſouth of Altringham in the county of Cheſter.

BIRKOZOWKA, a town of Poland, in the palatinate of Kiov, 40 miles S.E. of Bialacerkiew.

BIRLAB, a town of Egypt, in the route from Catieh to El Ariſh, 17 miles E.N.E. of Catieh, and at a ſmall diſtance eaſt of the lake of Sebaket Bardoil, or king Baldwin's lake.

BIRLAT, a town of European Turkey, ſeated on a river of the ſame name, in the province of Moldavia, 60 miles N.W. of Galate, and 116 S.W. of Bender.—Alſo, a river which runs into the Siret at Dubravitza, in Moldavia.

BIRMAN, or BURMAN *Empire*, comprizes the kingdoms of Ava and Pegu, and derives its name from the Birmahs or Burmahs, who have been long known as a warlike nation, in the country formerly called "India beyond the Ganges;" its capital being Ava or Aungwa. The boundaries of this empire are not eaſily aſcertained. Burmah, conſidered as diſtinct from Pegu, and ſometimes erroneouſly denominated Ava from its capital, borders on Pegu to the north, and occupies both banks of the river Ava, as far as the frontiers of China. On the north-weſt is Meckley, and on the Weſt Aracan and Roſhaan. On the eaſt it has the kingdom or country of Upper Siam, which begins at a ſmall diſtance eaſtward from the city of Ava; a ridge of mountains ſeparating it from Burmah and Pegu. But the king of Burmah is now ſaid to poſſeſs not only the country of Meckley, in addition to thoſe of Pegu and Burmah, but alſo the whole tract which lies on the north of it, between China, Thibet, and Aſam. According to colonel Symes, to whom we are much indebted for our knowledge of the Birman empire, it appears to include the ſpace between the 9th and 26th degrees of north latitude, and between the 92d and 107th degrees of eaſt longitude, about 1050 geographical miles in length, and 600 in breadth. Such are the aſcertainable limits from the Birman accounts; but it is probable that their dominions ſtretch ſtill farther to the north. The breadth, however, often varies, and is in many places very inconſiderable, on what is called the eaſtern peninſula. To the north this empire is ſeparated by mountains from Aſam, and further to the eaſt it borders on Thibet and China. On the weſt it is divided from the Britiſh dominions in Bengal by a range of mountains, and the little river Naaf; and the limit is continued by the ſea. But the ſouthern and eaſtern boundaries are ſomewhat obſcure. If it be extended to the ninth degree of latitude, it muſt include a conſiderable portion of the Malayan peninſula, or the province of Tenaſſerem, and city of Mergui, formerly regarded as part of Siam; and if, on the eaſt, it be extended to the 107th degree of longitude, it might be ſaid to comprehend almoſt the whole of the country called India beyond the Ganges, as far as the mouths of the Japaneſe river in Cambodia. But it does not appear that Siam is regarded as a portion of the Birman empire, and even in this caſe it would only extend to 103 degrees. In this ſtate of uncertainty, however, we muſt ſatisfy ourſelves with obſerving, that this empire conſtitutes the fifth grand native power in India, ſince Hindoſtan and Perſia have been divided, and may probably extend its authority over Laos and Cambodia, while it remains ſeparated by deſerts and ranges of lofty mountains from the united kingdoms of Cochinchina and Tonquin.

Of the ancient ſtate of the countries which now conſtitute this empire, our knowledge is very imperfect. (See CHERSONESUS.) With regard to their modern hiſtory, Col. Symes obſerves, that we are indebted for our firſt information principally to the Portugueſe, who made themſelves maſters of Malacca early in the 16th century. Accordingly the Portugueſe hiſtorians inform us, that in the middle of this century four powerful ſtates divided among them the regions that lie between the ſouth-eaſt province of Britiſh India, Yunan in China, and the eaſtern ſea; and that their territories, beſides ſome intervening lands belonging to petty independent princes, extended from Caſſay and Aſam on the N.W. as far to the S.E. as the iſland of Junkſeylon. Theſe

nations

nations were known to Europeans by the names of Aracan, Ava, Pegu, and Siam; which ſee reſpectively. The empire of Ava, as it was called, is ſituated eaſtward of Aracan, and ſeparated from it by a ridge of lofty mountains. (See ARACAN.). On the N.W. it is divided from the kingdom of Caſſay by the river Keen-duem; on the north it is bounded by mountains, and petty independent principalities, that lie contiguous to Aſam; on the north eaſt and eaſt it touches on China and North Siam; and on the ſouth its limits have been ſo variable, that it is not eaſy to define them. The city of Prome, or Pee, ſeems to be the original and natural boundary of the Birman empire, though by conqueſts it has been extended much farther to the ſouth. Pegu is the country ſouthward of Ava, which occupies the ſea-coaſt as far as Martaban. (See PEGU.) The kingdom of Siam extended to the ſouth as far as Junkſeylon, eaſt to Cambodia and Laos, and north to Ozemee, probably the Chiamee of Louhere, and Yunan in China. (See SIAM.) Theſe boundaries, however, may be conſidered more as the claim than the actual poſſeſſion of each ſtate; whilſt alternate victory and defeat have occaſionally extended and contracted their dominions. From the Portugueſe we learn, that the Birmans, though formerly ſubject to the king of Pegu, became afterwards maſters of Ava, and cauſed a revolution in Pegu about the middle of the 16th century; extending their kingdom from Maravi, probably Mergui, near Tenaſſerem, to the province of Yunan in China, about 800 miles from north to ſouth, and 250 from eaſt to weſt. The influence of the Portugueſe, which was for ſome time very conſiderable in the Birman and Pegu countries, was ſupplanted by the Dutch; and it appears that, in the beginning of the 17th century, both the Engliſh and Dutch had obtained ſettlements in various parts of the Birman dominions, which were forfeited by the miſconduct of the latter; ſo that Europeans of all nations were baniſhed from Ava. The Engliſh, however, ſeveral years after this expulſion, were reinſtated in their factories at Syriam and Ava, where they traded more as private merchants than on the part of the India company, in whoſe ſervice they were not regularly enrolled. The ſupremacy of the Birmans over the Peguers continued till about the year 1740, when the latter, inhabiting the provinces of Dalla, Martaban, Tongo, and Prome, revolted, and a civil war enſued. In 1744, the Britiſh factory at Syriam was deſtroyed by the contending parties. At length the Peguers, by the aſſiſtance of ſome Europeans, who traded to their ports, gained ſeveral victories over the Birmans, particularly in the years 1750 and 1751; and in 1752 the capital of Ava was inveſted, and the Birmans, after a ſhort ſiege, compelled to ſurrender at diſcretion. The laſt of a long line of Birman kings was taken priſoner; but two of his ſons were fortunate enough to make their eſcape to the Siameſe, where they were kindly received, and aſſured of ſecurity and ſuccour. Upon this conqueſt the principal inhabitants of the country about Ava acknowledged themſelves vaſſals to the victorious king of Pegu, and accepted the preſcribed oath. After ſome time, Alompra, a Birman of low extraction, who had been continued by the conqueror in the poſſeſſion of a ſmall village called Monchaboo, determined to emancipate himſelf from the yoke of oppreſſion. Accordingly, having aſſembled 100 followers, on whoſe fidelity and courage he could rely, he attacked a band of 50 Pegu ſoldiers, who had been ſtationed in Monchaboo, and put every one of them to the ſword; and after ſeveral previous encounters with the Pegu force diſpatched againſt him, he gained poſſeſſion of Ava in 1753. The conteſt was obſtinate and bloody; but Alompra, purſuing his conqueſts, founded the town of Rangoon, or Dzangoon, ſignifying "victory atchieved;" and ſoon after chaſtiſed the people of Caſſay, who had revolted from the Birman authority. In 1756 he blockaded the town of Syriam, which yielded to his arms; and having deprived the capital of any foreign aid by water, he advanced againſt the city of Pegu, inveſted it in January 1757, and in about three months took poſſeſſion of it. He then proceeded to ſubdue the countries to the eaſt of the city, as far as the Three Pagodas, which were the ancient boundary between Pegu and Siam. Tavoy, which was once an independent principality, and recognized as ſuch by the Engliſh in 1753, has been ſince added to the Birman poſſeſſions in this quarter. Alompra, triumphing in his ſucceſs, determined to chaſtiſe the Siameſe, who had afforded an aſylum to his rebellious ſubjects; and for this purpoſe he ordered a fleet to ſail to Mergui, a ſea-port belonging to the Siameſe, which ſoon ſurrendered; and the capture of Mergui was followed by the conqueſt of Tenaſſerem, The next object of Alompra was the reduction of the capital of Siam: but whilſt he was proſecuting the ſiege, he was ſeized with a diſorder which proved fatal, and ſaved the Siameſe from deſtruction. Alompra, appriſed of his approaching end, gave orders for a retreat; when he had arrived within two days' march of Martaban, on the 15th of May 1760, he expired, very much to the regret and ſorrow of his ſubjects, who regarded him as their deliverer, and as a wiſe, powerful, and victorious ſovereign. By the prudence of his councils he ſecured what his valour had acquired; he was not more eager for conqueſt than attentive to the improvement of his territories, and the proſperity of his people; he iſſued a ſevere edict againſt gambling, and prohibited the uſe of ſpirituous liquors throughout his dominions; he reformed the courts of juſtice; he abridged the power of magiſtrates and forbade them to decide at their private houſes on criminal cauſes, or on property where the amount exceeded a ſpecified ſum; every proceſs of importance was decided in public, and every decree regiſtered. His reign was ſhort but vigorous; and if his life had been prolonged, it is probable that his country would at this day have been farther advanced in national refinement and the liberal arts. He did not live to complete his 50th year; his perſon, ſtrong and well proportioned, exceeded the middle ſize; and though his features were coarſe, his complexion dark, and his countenance ſaturnine, there was a dignity in his deportment that became his high ſtation. Alompra, the founder of the Birman empire, was ſucceeded by his ſon Namdogee Praw, who, after ſuppreſſing ſeveral inſurrections, died in 1764, and left an infant ſon, Momien; whoſe uncle Shembuan, ſecond ſon of Alompra, aſſumed firſt the regency, and afterwards the diadem. Shembuan, having uſurped the royal power, diverted the national attention from his conduct, by declaring war againſt Siam; and two armies entered the country from the north and ſouth, which, being united, defeated the Siameſe about ſeven or eight days' journey from their capital. The conſequence of this defeat was the immediate inveſtiture of Siam by the Birmans; and after a ſiege of two months, the capitulation of the city. The king having withdrawn during the progreſs of the ſiege, a Siameſe governor was appointed, who took an oath of allegiance to the Birman monarchy, and engaged to pay an annual tribute. The Chineſe, having planned the ſubjugation of the Birman empire, and concerted meaſures for adding the dominion of the Jerawaddy and the fertile plains of Ava to their empire, advanced in the beginning of the year 1767, from the weſtern frontiers of Yunan, with an army of 50,000 men, to accompliſh their object; but they were met by the Birmans, and after a conflict which laſted three days, totally routed with very dreadful carnage. The lives of the captives were ſpared for the benefit of the country; various employments were aſſigned them; and they were encouraged to marry Birman wives, and to conſider themſelves

felves as natives of the country. The Siamefe, however, though vanquifhed, remained unfubdued; and the inherent enmity that fubfifts between thefe two nations will probably prevent either fervitude or alliance on the part of the one to the other, unlefs they are broken by fuch repeated defeats as muft nearly amount to extirpation. As foon as it was known that the Birmans had withdrawn into their own territories, a Siamefe prince aflumed the monarchy, and in 1771 defeated the Birmans. The king, who had pufillanimoufly abandoned his throne and people, is faid to have perifhed in the woods, probably by the dagger of the ufurper. Shembuan, the Birman fovereign, who had rebuilt ancient Ava, the metropolis of the empire, which had fallen to ruin during the late commotions, purfued his favourite fcheme of extending his conquefts towards the weft, and having advanced within two days' march of Cofpore, the capital of Cachar, forced the raja of the province to fubmit to his power, by the moft unequivocal proofs of vaffalage, according to the cuftom of the country. Shembuan died at Ava in 1776, and was fucceeded by his fon Chenguza, whofe tyrannical conduct occafioned a confpiracy, at the head of which was Shembuan Minderagee Praw, the younger brother of the deceafed Shembuan, and the prefent monarch. Chenguza was flain in 1781, and fell unlamented, as he had lived defpifed. Among other acts of favage cruelty, with which he is charged, one is his conduct towards his fecond wife, the daughter of one of the Attawoons, or privy-counfellors, of his court, a young woman endowed with virtue, beauty, and various accomplifhments. Under the impulfe of fudden rage, he accufed her of infidelity, and without allowing time for cool judgment, pronounced fentence of immediate death. Accordingly the trembling and innocent victim was dragged from the palace, and inclofed in a fack of fcarlet cloth, richly ornamented; thus confined, fhe was put on board a boat, when the fack being fufpended between the narrow necks of two earthen jars, the whole was funk in the deepeft part of the river Jerawaddy. Her afflicted father, overwhelmed with anguifh and deprived of all his offices, retired in defpair to the city of Chagaing; and waited the opportunity that foon after occurred, of being avenged. When Chenguza was forcing his way towards the royal palace, the Attawoon fnatched a fabre from an attendant officer, and at one ftroke cut him through the bowels, and laid him breathlefs at his feet; nor did any perfon offer to prevent or avenge the cruel tyrant's death. Shembuan Minderagee withdrew the feat of government from Ava, and founded a new city called Ummerapoora; which fee. The Birman conquefts having already been extended as far as Mergui to the fouth, and feveral of the northern provinces which formerly belonged to Siam, having been reduced to fubjection and tribute, Shembuan Minderagee, obferving the fupinenefs of the rajah of Arracan, and the unwarlike difpofition of his fubjects, and allured by the fertility of its foil, and its aptitude for commerce, determined to invade the country, and to annex it as an appendage to the Birman crown. Accordingly, in 1783, this conqueft was effected. (See ARRACAN.) The Birman arms were next directed towards Siam. Although the Birmans could not retain poffeffion of its inland parts, they maintained their dominion over the fea-coaft; fo that all the ports on the weftern fhore of the peninfula, as far as Mergui, in N. lat. 12° 20′, continued fubject to them. But they ftill wifhed to obtain the ifland of Junkfeylon, which would give them the entire dominion of the weftern coaft as far as the territories of the Malay prince of Queedah, and not only enable them to monopolize the commerce of the peninfula, but prevent the Siamefe from a communication with India by any other channel than that of the gulf of Siam. A fleet was fitted out in 1785 for fubduing this ifland; but the enterprife failed. The Birman monarch, mortified by the difappointment of his views, refolved as fpeedily as poffible to repair the difgrace; and for this purpofe he marched in the fpring of 1786, from his capital at the head of 30,000 men, with a train of 20 field-pieces, which army was fupported by a fleet of 16 fhips, that blocked up the harbour of Junkfeylon. The fovereign, fanguine in his expectations, had fcarcely entered the Siamefe territories, before he was oppofed by the king of Siam, and, after a furious engagement, completely routed. In the commencement of the enfuing year, the Siamefe invaded the viceroyalty of Martaban, which comprehends within its jurifdiction Tavoy, Mergui, and all the Birman poffeffions towards the fouth; but having laid unfuccefsful fiege to Tavoy, they were obliged to retreat and abandon the enterprife. In 1793 overtures for peace were made on the part of the Siamefe; and they were followed by a negociation, which fpeedily terminated in the ratification of a treaty highly favourable to the Birman intereffs. By this compact, the Siamefe ceded to the Birmans the weftern maritime towns as far as Mergui; thus yielding to them entire poffeffion of the coaft of Tenafferem, and the two important ports of Mergui and Tavoy; which were acquifitions of great moment, confidered either in a political or commercial light. From this ftatement it appears that the Birman empire can fcarcely be computed to extend beyond the 102d degree of longitude, and that only in the part to the north of Siam. The Birmans are indifputably pre-eminent among the nations which inhabit the vaft peninfula that feparates the gulf of Bengal from the Chinefe fea; they poffefs a territory equal in extent to the German empire; and they are bleffed with a falubrious climate, and a foil capable of producing almoft every article of luxury, convenience, and commerce, which the eaft can fupply. After their treaty with the Siamefe, they enjoyed the pleafing profpect of a long exemption from the miferies of war; but their pride and refentment embroiled them in frefh troubles before they had time to profit by the advantages of peace, and threatened to excite againft them a foe more formidable than the Chinefe, Arracaners, Peguers, Siamefe, and Caffayers. The Birman monarch, conceiving that the piratical banditti who infeft the Broken iflands, and commit various depredations to the injury of trade, were protected by the Britifh flag, and that they fought refuge in the Britifh diftricts, ordered a body of 5000 men to enter the territories of the company, in order to feize the delinquent fugitives, and he ftationed an army of 20,000 men at Arracan for the purpofe of fupporting this detachment. As the Birmans had made no previous application for redrefs in a pacific way, a ftrong detachment was formed at the prefidency, and entrufted to the conduct of major-general Erfkine, for refifting this aggreffion. On the approach of the Britifh general, the Birman chief propofed terms of accommodation, ftipulating for the furrender of the fugitives as the bafis of the agreement. The general declined all treaty whilft the Birmans continued on Engliſh ground; but after a repreſentation of the caſe made in perſon by the Birman chief, he gave hopes, that if the Birmans peaceably retired, the governor-general would inſtitute a regular inquiry into the grievance which was the ſubject of complaint. The Birman chief, profeſſing his reliance on the declaration of general Erſkine, agreed to withdraw his troops, and conducted his retreat in the moſt orderly manner. The matter was afterwards inveſtigated, and the guilt of the delinquents being ſatisfactorily proved, they were delivered over to their own laws, by whoſe ſentence two out of the three that had been accuſed underwent capital puniſhment. The amicable termination of this difference afforded favourable opportunity for acquiring a more accurate knowledge than had hitherto been obtained, of a people, whoſe ſituation, extent of territory,

tory, and commercial connexions with Britiſh India, rendered a liberal intercourſe with them highly deſirable. The trade between Calcutta, Madras, and Rangoon, the principal Birman port, had of late years ſo rapidly increaſed, as to become an object of national importance; more particularly on account of the teak timber, the produce of Ava and Pegu, whence Calcutta and Madras draw all their ſupplies of wood for ſhip building and for various other purpoſes. A commerce in one article ſo eſſential, and on a general ſcale ſo extenſive as to require an annual return of Indian commodities to the amount of 200,000l., was an object well worth cultivating. With this view ſir John Shore (now lord Teignmouth) thought proper, in 1795, to ſend a formal deputation to the Birman court. The particulars of this embaſſy are deſcribed by Col. Symes, with whom the conduct of it was entruſted. "The Birmans," ſays this writer "under their preſent monarch, are certainly riſing faſt in the ſcale of oriental nations; and it is to be hoped, that a long reſpite from foreign wars will give them leiſure to improve their natural advantages. Knowledge increaſes with commerce; and as they are not ſhackled by any prejudices of caſts, reſtricted to hereditary occupations, or forbidden from participating with ſtrangers in every ſocial bond, their advancement will, in all probability, be rapid. At preſent, ſo far from being in a ſtate of intellectual darkneſs, although they have not explored the depths of ſcience, nor reached to excellence in the finer arts, they yet have an undeniable claim to the character of a civiliſed and well inſtructed people. Their laws are wiſe, and pregnant with ſound morality; their police is better regulated than in moſt European countries; their natural diſpoſition is friendly and hoſpitable to ſtrangers; and their manners rather expreſſive of manly candour, than courteous diſſimulation: the gradations of rank, and the reſpect due to ſtation, are maintained with a ſcrupulosity which never relaxes. A knowledge of letters is ſo widely diffuſed that there are no mechanics, few of the peaſantry, or even the common watermen (uſually the moſt illiterate claſs), who cannot read and write in the vulgar tongue. Few, however, are verſed in the more erudite volumes of ſcience, which, containing many Shanſcrit terms, and often written in the Pali text, are (like the Hindoo Shaſters) above the comprehenſion of the multitude; but the feudal ſyſtem, which cheriſhes ignorance, and renders man the property of man, ſtill operates as a check to civilization and improvement. This is a bar which gradually weakens, as their acquaintance with the cuſtoms and manners of other nations extends: and unleſs the rage of civil diſcord be again excited, or ſome foreign power impoſe an alien yoke, the Birmans bid fair to be a proſperous, wealthy, and enlightened people."

The preſent capital of the Birman empire is Ummerapoora, and one of its chief ports is Rangoon; which ſee reſpectively. Its other principal towns will occur in the courſe of this work. See Arracan, Ava, Chagaing, Martaban, Merghi, Monchaboo, Munnipoora, Pagahm, Pegu, Perſaim, Prome, Syriam, Tenaſſerem, Tavoy, &c. The chief rivers of this country are Irrawaddy, or the river of Ava (ſee Ava), whoſe numerous mouths and ſtreams very amply provide the means of inland navigation, Keenduem, Maygue, Pitang, and Thaluan. Its lakes are numerous; among which one of the principal is Tounzamahn. The higheſt range of mountains is probably that which lies on the frontiers of Thibet. The other ranges paſs north and ſouth, except a ſmall range running eaſt and weſt, which ſupplies the ſources of the river of Pegu; but their names are not known, except that of Anoupee, between Ava and Arracan. The foreſts are large and numerous: and ſupply almoſt every deſcription of timber that is known in Hindoſtan; and about four days' journey to the north of the capital firs grow in abundance; but the principal tree of theſe foreſts is the teak, which flouriſhes in many parts of the empire, to the north as well as to the ſouth of the capital. The foreſts, as well as the mountains, of the interior, and, in general, of the whole northern frontier, remain unexplored; and the tigers that infeſt them, prevent their being particularly examined.

The preſent ſovereign of the Birman empire aſſumes the title of "Boa," or emperor; and though the form of government be deſpotic, yet he is accuſtomed to conſult a council of ancient nobles. There is no country of the eaſt in which the royal eſtabliſhment is arranged with more minute attention than in the Birman court; it is ſplendid without being waſteful, and numerous without confuſion. The queen and princes have the title of "Praw," which is both a ſovereign and a facerdotal appellation; and is frequently uſed by an inferior when addreſſing his ſuperior. In the application of this term, it has been ſuggeſted, that there is an obvious analogy between the Birmans and the ancient Egyptians. "Phra," it is ſaid, was the proper name under which the Egyptians firſt adored the ſun, before it received the allegorical appellation of Oſiris, and they conferred this title on their kings and on their prieſts. It has been further conjectured, that the title of "Pharaoh," given to ſucceſſive kings of Egypt, is a corruption of the word "Phraw," or "Praw," in its original ſenſe ſignifying the ſun, and applied to the ſovereign and prieſthood, as the repreſentatives on earth of that ſplendid luminary. However this be, "Praw" is a princely title in the Birman empire. The elder ſon of the king is denominated "Engy Teekien," or "Engy Praw," or prince royal; and as the crown deſcends to the male heirs in a direct line, the ſon takes precedence of his uncles. Next in rank to the princes of the blood royal are the "Woongees," i. e. bearers of the great burthen, who are the chief miniſters of ſtate. Their eſtabliſhed number is four, and they conſtitute the great council of the nation. They ſit in the "Lotoo," or imperial hall of conſultation, every day, except the Birman ſabbath; they iſſue mandates to the "Maywoons," or viceroys of the different provinces; they control every department of the ſtate, and govern the empire in ſubordination to the king, whoſe will is abſolute, and whoſe power is undefined. With theſe are aſſociated, for the purpoſes of deliberation, and of the execution of public buſineſs, four other officers, called "Woondocks," whoſe authority is very inferior and limited. The views and wiſhes of the Woongees are frequently counteracted by the interference of the four "Attawoons," or miniſters of the interior, who are ſelected by the king to be his privy-counſellors, from an opinion of their talents and integrity, and who have acceſs to him at all times, which is a privilege which even the principal Woongee does not enjoy. There are ſeveral other ſubordinate officers, by whom the affairs of government, in its various departments, are tranſacted. There are alſo Woons of the queen's houſehold, and of that of the prince-royal; and each of the junior princes has a diſtinct eſtabliſhment. The Birman government has no hereditary dignities or employments; for on the demiſe of the poſſeſſor, all honours and offices revert to the crown. The order of nobility has different degrees, diſtinguiſhed by the number of ſtrings, or ſmall chains, that compoſe the "tſaloe," or chain, which is the badge of the order. No ſubject is ever honoured with a higher degree than 12; and the king alone wears 24. Rank among the Birmans is indicated by every article of uſe and of ornament; the ſhape of the bectle-box, which is carried by an attendant after a perſon of diſtinction wherever he goes, his ear-rings, cap of ceremony, horſe-furniture, and even the metal of which his ſpit-

ting

ting-pot and drinking cup are made, ſpecify and diſtinguiſh the ſeveral gradations of ſociety; and a perſon who aſſumes the inſignia of a degree, which is not his legitimate right, is ſubject to certain penalties. The court dreſs of the Birman nobility conſiſts of a long robe, of flowered ſatin or velvet, reaching to the ancles, with an open collar and looſe ſleeves; over this hangs from the ſhoulders a ſcarf, or flowing mantle; and on the head is worn a high cap of velvet, either plain, or of ſilk embroidered with flowers of gold, according to the rank of the wearer. Ear-rings are alſo a part of male dreſs; perſons of condition uſe tubes of gold about three inches long, and of the thickneſs of a large quill, expanding at the end like the mouth of a ſpeaking-trumpet; others wear a heavy maſs of gold, beaten into a plate, and rolled up, which forms a large orifice in the lobe of the ear, and by its weight drags it down to the extent ſometimes of two inches. The rank of the females is alſo diſtinguiſhed by their dreſs. The hair, which is tied in a bunch at the top of the head, and bound round with a fillet, has its peculiar and diſcriminating embroidery and ornaments. Over a ſhort ſhift, which reaches to the pit of the ſtomach, and is drawn tight by ſtrings, ſo as to ſupport the breaſts, is a looſe jacket with cloſe ſleeves; and round the waiſt is rolled a long piece of ſilk or cloth, reaching to the feet, and ſometimes trailing to the ground. When women of condition go abroad, they put on a ſilk ſaſh, reſembling a long ſhawl, which croſſes their boſom, and is thrown over the ſhoulders, gracefully flowing on each ſide. Women in full dreſs, ſtain the palms of their hands and their nails of a red colour, for which they uſe a vegetable juice, and ſtrew on their boſoms powder of ſandal wood, or of a bark called ſunneka, with which ſome rub their faces. Both men and women tinge the edges of their eyelids and their teeth with black. Men of rank wear, in common dreſs, a tight coat with long ſleeves, made of muſlin or of very fine nankeen, which is manufactured in the country; alſo a ſilk wrapper that encircles the waiſt; but the working claſs are naked to the middle, except that in the cold ſeaſon they uſe a mantle or veſt of European broad cloth, which is highly prized.

With regard to *religion*, the Birmans are Hindoos, not as votaries of Brahma, but ſectaries of Boodh; which ſee. The latter contend with the former for the honour of antiquity, and are undoubtedly far more numerous. The Cingleze in Ceylon are Boodhiſts of the purer claſs; and the Birmans acknowledge that they originally received their religion from that iſland, which they call "Zehoo." It was brought, ſay the Rhahaans, firſt from Zehoo to Arracan about 600 years ago, and thence was introduced into Ava, and probably into China; for the Birmans confidently aſſert, that the Chineſe are Boodhiſts. However this be, it is allowed, that the bonzes of China, like the Rhahaans of Ava, wear yellow as the ſacerdotal colour, and that in many of their cuſtoms and ceremonies we may trace a very ſtriking ſimilitude. Whatever may be the antiquity of the worſhip of Boodh, the wide extent of its reception is unqueſtionable. The Birmans believe in the metempſychoſis, and that, after having undergone a certain number of tranſmigrations, their ſouls will at laſt be received into their paradiſe on the mountain of Meru, which is the celeſtial north pole of the Hindoos, round which they place the garden of Indra, and which they deſcribe as the ſeat of delights. The Birmans regard mercy as the chief attribute of the deity; and they worſhip God by extending mercy to all his creatures. Of the religious buildings appropriate to the Birman worſhip, the temple of Shoedagon, or Dagoung, near Rangoon, that of Shocmadoo at Pegu, and that of Syriam, are the moſt conſiderable. (See Rangoon, Pegu, and Syriam.) Their prieſts are denominated Rhahaans; and they have numerous kioums or convents which differ in their ſtructure from common houſes, and much reſemble the architecture of the Chineſe. They are made entirely of wood; the roof is compoſed of different ſtages, ſupported by ſtrong pillars; the inſide comprehends one large hall; the whole houſe is open at the ſides; ſome of them are curiouſly carved with various ſymbolic repreſentations of the divinity. They have no apartments for the private recreation of the Rhahaans; publicity being the prevailing ſyſtem of the conduct of the Birmans, who admit of no ſecrets either in church or ſtate. The convents in the neighbourhood of Rangoon are very numerous; and hence it appears that the number of Rhahaans, and of Phonghis, prieſts of an inferior order, vulgarly called Tallapoins, muſt be very conſiderable, amounting to 1500. Like the Carmelites, they go barefooted, and have their heads ſhaven, on which they never wear any covering. The only colour of the garments worn by the prieſthood is yellow; the greateſt part of their bodies is covered with a long looſe cloke, that is wrapped round them; they profeſs celibacy, and abſtinence from every ſenſual gratification. The preſcribed puniſhment for a Rhahaan detected in an act of incontinence, is expulſion and public diſgrace. The delinquent is ſeated on an aſs, and his face is daubed with black paint interſperſed with ſpots of white; and he is thus led through the ſtreets, with a drum beating before him, and afterwards turned out of the city. But ſuch inſtances of degradation rarely occur. The juniors are reſtricted from wandering about licentiouſly, either by day or night; nor can any go abroad without permiſſion from the prior of the convent. The Rhahaans never perform any of the common functions of life, which would tend to divert them from the abſtract contemplation of the divine eſſence. They perambulate the town at the dawn of the morn in order to collect ſupplies for the day; and theſe uſually conſiſt of boiled rice mixed with oil, dried and pickled fiſh, ſweetmeats, fruit, &c. In their walks they never raiſe their eyes from the ground, nor do they even ſtop to ſolicit donations, and ſeldom even look at their benefactors, who are more deſirous to beſtow than they are to receive. The Rhahaans eat only once a day, at the hour of noon; and their ſuperfluous proviſions they diſtribute among the indigent ſtrangers, or the poor ſcholars, who daily attend them to be inſtructed in letters, and taught their religious and moral duties. The Rhahaans are never known to take any public and active part in politics or in war; and as the Birmans and Peguers profeſs the ſame religion, the conquerors, whoever they were, equally reſpected the miniſters of their faith. The head of the Rhahaans at Rangoon, or the "Seredaw," lives in a handſome monaſtery about half a mile from the town; and values himſelf very much on the ſacerdotal titles, conferred on him by the preſent and late king, and which he oſtentatiouſly diſplays engraven on iron plates. There were formerly nunneries of virgin prieſteſſes, who, like the Rhahaans, wore yellow garments, cut off their hair, and devoted themſelves to chaſtity and religion; but theſe ſocieties have been long ſince aboliſhed, as being injurious to the population of the ſtate.

The *laws* of the Birmans are inſeparable from their religion; and, like the latter, of Hindoo extraction. They profeſs to have derived them from Menu, the grandſon of Bramah, the firſt of created kings, who received the ſacred principles on which they are founded by divine revelation, and who promulgated the code. Numerous commentaries on Menu were compoſed by the Munis, or old philoſophers, whoſe treatiſes conſtitute the "Dherma Saſtra," or body of law. The code of Gentoo laws, tranſlated by Mr. Halhed, is ſaid to be a compilation from the different commentaries on Menu. Theſe laws, as well as the religion of the Birmans, found their way into the Ava country from Arracan, and

and came originally from Ceylon about 600 years ago. The Birman ſyſtem of juriſprudence is replete with ſound morality; and is diſtinguiſhed above any other Hindoo commentary for perſpicuity and good ſenſe. It provides ſpecifically for almoſt every kind of crime that can be committed, and adds an ample chapter of precedents and deciſions to guide the inexperienced in caſes of doubt and difficulty. The trial by ordeal, however, is diſgraceful to this code; but it prevails in all countries where the Hindoo religion is profeſſed, and is as ancient as their records. An inſtance of the exerciſe of this mode of trial is mentioned by Col. Symes. Two women having litigated a ſmall property in a court of juſtice; and the judges finding it difficult to decide the queſtion of right, it was agreed to refer the matter to the iſſue of an ordeal. The parties, attended by the officers of the court, the Rhahaans, and a multitude of people, repaired to a tank, or pond. After certain prayers and ceremonials of a purifying nature, the two litigants entered the pond and waded in it, till the water reached as high as their breaſts; they were accompanied by two or three men, one of whom placed them cloſe to each other, and put a board on their heads, which he preſſed down till they were both immerſed at the ſame inſtant. After continuing out of ſight for about one minute and a half, one of them, being nearly ſuffocated, raiſed her head, whilſt the other continued to ſit upon her hams at the bottom, but was immediately lifted up by the man; after which an officer of the court pronounced judgment in her favour, and of the equity of the deciſion none of the bye-ſtanders ſeemed to entertain the ſmalleſt doubt. This practice, however, and that of imprecation, are now loſing ground, and have of late years been diſcountenanced by the judicial courts both of India and Ava. Laws dictated by religion are in general conſcientiouſly adminiſtered. The criminal juriſprudence of the Birmans is lenient in particular caſes, but rigorous in others. Whoever is found guilty of an undue aſſumption of power, or of any crime that indicates a treaſonable intent, is puniſhed by the ſevereſt tortures. The firſt commiſſion of theft does not incur the penalty of death, unleſs the amount ſtolen be above 800 kiat, or tackal, i. e. about 100 l., or attended with circumſtances of atrocity, ſuch as murder or mutilation. In the former caſe, the culprit has a round mark imprinted on each cheek by gunpowder and punctuation, and on his breaſt the word thief, with the article ſtolen; for the ſecond offence he is deprived of an arm; but the third inevitably produces capital puniſhment. Decapitation is the mode by which criminals ſuffer, and in the performance of it the Birman executioners are exceedingly ſkilful. The official hall of juſtice, where the members of provincial governments, and all municipal officers, are accuſtomed to aſſemble for the tranſaction of public buſineſs, in various parts of the Birman empire, is denominated Rhoom. Every man of high rank in the empire is a magiſtrate, and has a place of this deſcription and name contiguous to his dwelling; but it is always on the outſide of the incloſure of his court-yard, and not ſurrounded by any fence or railing, in order to manifeſt publicity, and ſhew that it is the ſeat of majeſty and juſtice, to which all mankind may have free acceſs.

The *population* of the Birman dominions is not eaſily aſcertained with accuracy; but Col. Symes was informed, by a perſon on whoſe teſtimony he could rely, that the number of cities, towns, and villages in the empire amounts to 8000, without including the recent addition of Arracan. Suppoſing, therefore, each town, on an average, to contain 300 houſes, and each houſe 6 perſons, the reſult will give a population of 14,400,000. Few of the inhabitants, he ſays, live in ſolitary habitations, but moſtly form themſelves into ſmall ſocieties; ſo that their dwellings thus collected compoſe their Ruas, or villages; and, therefore, he concludes that if their number, including Arracan, be reckoned at 17 millions, it will not exceed the truth.

With regard to the *military* and *naval* force of the Birmans, we may obſerve, that though every man in the kingdom is liable to military ſervice, and war is deemed the moſt honourable occupation, the regular military eſtabliſhment is very inconſiderable. When an army is to be raiſed, a mandate iſſues from the golden palace to all viceroys of provinces, and miougees of diſtricts, requiring a certain number of men at an appointed day; and the levy is proportioned to the population of the province or diſtrict, eſtimated by the number of its regiſtered houſes. Every two, three, or four houſes are required to furniſh one recruit, or to pay 300 tackal, or about 40l. or 45l., in money. This recruit is ſupplied by government with arms and ammunition, but has no pay. The families of theſe conſcripts are retained in the diſtrict which they inhabit, as hoſtages for the good conduct of the ſoldier; and in caſe of deſertion, or treachery, his wife, children, or parents are dragged forth to execution; nay, cowardice ſubjects the family of the delinquent to capital puniſhment. The infantry and cavalry compoſe the regular guards of the king; the former are armed with muſkets and ſabres, and the latter with a ſpear about ſeven or eight feet long, which they manage on horſeback with great dexterity. The royal magazines are ſaid to contain 20,000 firelocks, which are of a very indifferent kind. The moſt reſpectable part of the Birman military force is their eſtabliſhment of war-boats. The king can command, at a very ſhort notice, 500 of theſe veſſels, which are formed out of the ſolid trunk of the teak tree, excavated partly by fire, and partly by cutting; the largeſt of them are from 80 to 100 feet long, and 8 feet broad, and they carry from 50 to 60 rowers. The prow is ſolid, and has a flat ſurface, on which is mounted a piece of ordnance. Each rower is provided with a ſword and a lance; and, beſides the boatmen, there are uſually 30 ſoldiers, who are armed with muſkets. The attack of theſe gun-boats is very impetuous; and thoſe who conduct them advance to action with a war-ſong, by which they regulate the ſtrokes of their oars, encourage one another, and daunt their adverſaries; and when they grapple, the action becomes very ſevere, as theſe people poſſeſs ſingular courage, ſtrength, and activity. As the veſſels lie low in the water, their principal danger is that of being run down by a larger boat ſtriking on their broadſide. The largeſt of theſe war-boats, which are managed with ſurpriſing dexterity, both in advancing and retreating, as well as in the time of action, do not draw more than three feet of water. The proper weapons of the country are the ſpear, the javelin which is thrown from the hand, the croſs-bow, and the ſabre; the latter of which is uſed by the Birmans, not only as an implement of war, but for various purpoſes of manual labour.

The *revenue* of the Birman empire ariſes from one-fourth of all produce, and of all foreign goods imported into the country. However, as grants to princes of the blood, great officers of ſtate, and provincial governors, are made in provinces, cities, villages, and farms, the rent of which they collect for their own benefit, and money is ſeldom diſburſed from the royal coffers, the Birman ſovereign poſſeſſes immenſe treaſures.

The *climate* of every part of the Birman empire appears to be diſtinguiſhed by its ſalubrity; and the natives are healthy and vigorous. In this reſpect they poſſeſs a decided pre-eminence over the enervated natives of the Eaſt; nor are the inhabitants of any country capable of greater bodily exer-

tions than the Birmans. The ſeaſons are regular, and the extremes of heat and cold are ſeldom experienced; at leaſt, the duration of that intenſe heat, which immediately precedes the commencement of the rainy ſeaſon, is ſo ſhort, that the inconvenience of it is very little felt. The foreſts, however, like ſome other woody and uncultivated parts of India, are extremely peſtiferous; and an inhabitant of the champaign country conſiders a journey thither as inevitable deſtruction. The wood-cutters, who are a particular claſs of men, born and bred in the hills, are ſaid to be unhealthy, and ſeldom attain longevity.

The *ſoil* of the ſouthern provinces of the Birman empire is remarkably fertile, and produces as luxuriant crops of rice as are to be found in the fineſt parts of Bengal. Towards the north the face of the country is irregular and mountainous; but the plains and vallies, particularly near the river, are exceedingly fruitful; they yield good wheat and the various kinds of ſmall grain which grow in Hindoſtan, together with moſt of the eſculent legumes and vegetables of India. Sugar-canes, tobacco of a ſuperior quality, indigo, cotton, and the different tropical fruits, in perfection, are all indigenous products of this country. Beſides the teak-tree, which grows in many parts of the Birman empire, as well to the north of Ummerapoora, as in the ſouthern country, there is almoſt every deſcription of timber that is known in India. The kingdom of Ava abounds in minerals; ſix days journey from Bamoo, which is a province near the frontiers of China, there are mines of gold and ſilver, called "Badouem;" there are alſo mines of gold, ſilver, rubies, and ſapphires, at preſent open on a mountain near the Keenduem, called "Wooboolootaun;" but the moſt valuable, and thoſe which produce the fineſt jewels, are in the vicinity of the capital, nearly oppoſite to Keoum-meoum. Precious ſtones are found in ſeveral other parts of the empire. The inferior minerals, ſuch as contain iron, tin, lead, antimony, arſenic, ſulphur, &c. occur in great abundance: amber, of a conſiſtence unuſually pure and pellucid, is dug up in large quantities near the river: gold likewiſe is diſcovered in the ſandy beds of ſtreams which deſcend from the mountains. Between the Keenduem and the Irrawaddy, to the northward, there is a ſmall river called "Shoe Lien Kioup," or the ſtream of golden ſand. Although the Ava empire produces no diamonds and emeralds, it affords amethyſts, garnets, very beautiful chryſolites, jaſper, loadſtone, and marble: the quarries of the latter lie a few miles from Ummerapoora; and it is equal in quality to the fineſt marble of Italy, and admits of a poliſh that renders it almoſt tranſparent. The ſale of marble is prohibited; but great quantities are conſumed in the manufacture of the images of Gaudma, which are fabricated in the city and diſtrict of Chagain; however, the exportation of theſe marble divinities out of the kingdom is ſtrictly forbidden.

The *commerce* of the Birman empire is very conſiderable. An extenſive trade is carried on between the capital and Yunan in China. The principal article of export from Ava is cotton, of which, it is ſaid, there are two kinds, one of a brown colour, of which nankeens are made, the other white, like the cotton of India. This commodity is tranſported up the Irrawaddy in large boats as far as Bamoo, where it is bartered at the common "jee," or mart, with Chineſe merchants, and conveyed by the latter, partly by land, and partly by water, into the Chineſe dominions. Amber, ivory, precious ſtones, beetle nut, and the edible neſts brought from the eaſtern archipelago, are alſo articles of commerce; in return for which the Birmans procure raw and wrought ſilks, velvets, gold leaf, preſerves, paper, and ſome utenſils of hardware. The commerce between the capital and the ſouthern parts of the empire is facilitated by the noble river that waters the country. Several thouſand boats are annually employed in tranſporting rice from the lower provinces to Ummerapoora and the northern diſtricts. Salt, and gnapee, a kind of fiſh-ſauce uſed with rice, are alſo articles of internal commerce. Articles of foreign importation are moſtly conveyed up the Irrawaddy; and ſome few are introduced by way of Arracan. See ARRACAN. Among the articles of foreign trade, which have found their way into the Birman country, nothing is held in higher eſtimation than the European glaſs-ware imported into Rangoon from the Britiſh ſettlements in India. The Birmans are ſo ſenſible of the advantages of commerce, and ſo deſirous of improving it, and of thus increaſing population, which they conſider as much more eſſential to the ſtrength of a ſtate than the extent of its territory, that they have of late years tolerated all ſects, Pagans and Jews, Muſſulmen and Chriſtians, the diſciples of Confucius, and the worſhippers of fire, and invited ſtrangers of every nation to reſort to their ports; and being themſelves free from thoſe prejudices of caſt, which ſhackle their Indian neighbours, they have permitted foreigners to intermarry and ſettle among them. The children of ſtrangers, whatever be the ſect to which they belong, born of a Birman woman, equally become ſubjects of the ſtate, and are entitled to the ſame protection and privileges, as if they had ſprung from a line of Birman anceſtry. To Britiſh India commercial intercourſe with that part of the Birman empire called Pegu is of great importance. This intereſt involves three diſtinct objects; that of ſecuring from this quarter regular ſupplies of timber for ſhip-building; that of introducing into the country as many of our manufactures as its conſumption may require, and of endeavouring to explore a mart in the ſouth-weſt dominions of China, by means of the great river Ava; and that of guarding with vigilance againſt every incroachment or advance, which may be made by foreign nations to divert the trade into other channels, and to obtain a permanent ſettlement in a country ſo contiguous to the capital of our poſſeſſions. The teak timber for the conſtruction of our ſhips in that part of the world is an article peculiarly intereſting in a political and commercial point of view. Some of the fineſt merchant ſhips at Calcutta have been lately built of this timber. Madras is alſo ſupplied from Rangoon with timber for all the common purpoſes of domeſtic uſe; and even Bombay, although the coaſt of Bombay is its principal ſtorehouſe, finds it worth while annually to import a large quantity of planks from Pegu. It is alſo of importance, not only to promote the exportation of timber from the maritime towns of Pegu, but to diſcourage the building of ſhips in the Rangoon river, in which the Birmans are making rapid progreſs. National ſecurity and commercial advantage demand peculiar attention to both theſe circumſtances. The imports into Rangoon from the Britiſh ſettlements, in the year 1794-5, amounted, it is ſaid, to more than 12 lacks of rupees, or about 135,000l.; and theſe conſiſted chiefly of coarſe piece goods, glaſs, hardware, and broad cloth; and the returns were made almoſt wholly in timber. The maritime parts of this great empire are commodious for ſhipping, and better ſituated for Indian commerce than thoſe of any other power. Great Britain poſſeſſes the weſtern ſide of the bay of Bengal; the government of Ava, the eaſtern. From the mouth of the Ganges to cape Comorin, the whole range of our continental territory, there is not a ſingle harbour capable of affording ſhelter to a veſſel of 500 tons burthen; but Ava comprehends, within her extent of coaſt, three excellent ports; Negrais, the moſt ſecure harbour in the bay; Rangoon, and Mergui, each of which is equally convenient and

much more acceſſible than the river of Bengal, which is the only port in our poſſeſſion within the bay. The entrance into this is an intricate and dangerous channel; but from the harbour of Negrais a ſhip launches at once into the open bay, and may work to the ſouthward without any impediment beſides that which is occaſioned by the monſoon. The Birman empire poſſeſſes ſuch a variety of advantages reſulting from ſituation, extent, produce, and climate, that it may be reckoned, among eaſtern nations, ſecond in importance to China alone; whilſt, from its contiguity to Britiſh India, it is to us of much greater conſequence. To preſerve a good correſpondence and a good underſtanding with the court of Ava is therefore eſſential to our proſperity. It is our intereſt to maintain the independence of the Birmans, and to guard it from foreign encroachment; and then the Birman government will be united to ours in bonds of reciprocal amity and confidence. The reſult of the embaſſy of Col. Symes, ſent by our governor-general of India to the kingdom of Ava in 1795, has been the eſtabliſhment of this kind of amity and friendſhip. To the memorial preſented on this occaſion, the Birman monarch replied: "I, the king immortal, whoſe philanthropy is univerſal, whoſe anxiety for the benefit and welfare of all mankind never ceaſes, direct, that all merchant ſhips of the Engliſh nation, who reſort to Birman ports, ſhall pay cuſtoms, charges, warehouſe hire, ſearchers, &c. agreeably to former eſtabliſhed uſage. Engliſh merchants are to be permitted to go to whatever part of the Birman dominions they think proper, either to buy or to ſell, and they are on no account to be ſtopped, moleſted, or oppreſſed; and they ſhall have liberty to go to whatever part of the Birman dominions they chooſe, for the purpoſe of buying, ſelling, or bartering, &c." by themſelves or their agents; and it is further commanded, that they ſhall be at liberty to fix a reſident at Rangoon, &c. and that Engliſh ſhips driven into Birman ports by ſtreſs of weather ſhall be ſupplied with all neceſſaries, &c. at the current rates of the country; and that the enemies of England, European as well as Indian, ſhall not be allowed to purchaſe warlike weapons, lead, and powder, which reſtriction is extended to all nations."

The *manufactures* of the Birmans conſiſt of cotton and ſilk, ſaltpetre and gunpowder, various kinds of pottery, and marble ſtatues; they alſo excel in gilding, to which purpoſe the greateſt part of their gold is applied, and ſeveral other ornamental manufactures. Their edifices and barges are conſtructed with ſingular oriental taſte and elegance; the moſt remarkable edifice is the Shomadoo at Pegu. Their kioums and temples, which are numerous, exhibit a very rich and fantaſtic kind of architecture; and their grand hall of audience, or Lotoo, at Ummerapoora, is as ſplendid an edifice as can be well executed in wood. Many of their houſes are very ſimple in their ſtructure, and are erected in a day, or even in a few hours. The requiſite materials are bamboos, graſs for thatching, and the ground rattan. The whole edifice is conſtructed without a ſingle nail; a row of ſtrong bamboos, from eight to ten feet high, are fixed firm in the ground, which form the outline, and are the ſupporters of the building; ſmaller bamboos are then tied horizontally, by ſtrips of the ground rattan, to theſe upright poſts; the walls, compoſed of bamboo mats, are faſtened to the ſides, with ſimilar ligatures; bamboo rafters are quickly raiſed, and a roof formed, over which thatch is ſpread in regular layers, and bound to the wood by filaments of rattan; a floor of bamboo is next laid in the inſide, elevated two or three feet above the ground; this grating is ſupported on bamboos, and covered with mats and carpets. A houſe of this kind, ſimple and expeditious in its ſtructure, is nevertheleſs a ſecurity againſt very inclement weather; and if it ſhould chance to be blown down by a tempeſt, the inhabitants might eſcape without injury. They have other buildings, however, of a ſuperior kind; and they were formerly conſtructed of various figures, pyramidal, triangular, or four-ſided, ſurrounded with walls, and adorned with flowers and figures carved in wood, and built with arches. But the art of conſtructing arches has been loſt among the Birmans. From many buildings that now remain, it appears, that they could formerly conſtruct excellent brick arches, both circular and gothic; but now no one in the empire can be found ſufficiently ſkilful to arch over the opening of a window. Maſonry has fallen into neglect; the jealouſy of the late princes having prohibited to private individuals the uſe of brick or ſtone houſes. The Birmans have of late years made rapid progreſs in the art of building boats and ſhips; and theſe may be conſtructed in the Rangoon river for one third leſs than in the Ganges, and for nearly one half what they would coſt at Bombay. It is ſaid, however, that the ſhips of Pegu are not ſo firmly conſtructed as thoſe in our ports. The Birmans, like the Chineſe, have no coin; ſilver in bullion, and lead, are the current money of the country. What foreigners call a tackal, properly kiat, is the moſt general piece of ſilver in circulation; it weighs ten pennyweights ten grains and three fourths; its ſubdiviſions are the tubbee, two of which make one moo; two moo one math; four math one tackal; and 100 tackal amount to one viſs. Rice is ſold by a meaſure called Tayndaung, or baſket, weighing 16 viſs, or about 56 pounds; and of meaſurement there are ſeveral ſubdiviſions. The average price of rice at the capital is one tackal, rather more than half a crown, for a baſket and a half. At Rangoon and Martaban, one tackal will purchaſe four or five baſkets. The Birman meaſures of length are a paul-gaut, or inch, 18 of which compoſe the taim, or cubit. The ſaundaung, or royal cubit (varying according to the will of the monarch), is equal to 22 inches; the dha, or bamboo, conſiſts of ſeven royal cubits; 1000 dha make one Birman league, or dain, nearly equal to two Britiſh miles and two furlongs; the league is alſo ſubdivided into tenths. The Birmans divide their time as follows. The interval in which the finger can be raiſed or depreſſed, is called charazi; 10 charazi make one piaan; 6 piaan one bizana, or about a minute. The day of 24 hours, commencing at noon, is divided into 8 portions, or yettee, of 3 hours each. Theſe diviſions of time are aſcertained by a machine reſembling the hour-glaſs, and ſometimes by a perforated pan placed in a tub of water. They are announced by a ſtroke on an oblong drum, which is always kept near the dwelling of the chief magiſtrate of the city, town, or village; it is commonly raiſed on an high bamboo ſtage, under a roof of mats to protect it from the weather. The Birmans, whatever way they acquired it, have the knowledge of a ſolar year, conſiſting of 365 days, and commencing on the 18th day of April. But the common Birman year is lunar, and of courſe 11 days ſhorter than the ſolar year; it is divided into 12 months; but the Birman lunations conſiſt alternately of 29 and 30 days, occaſioning a difference between the Newtonian and Birman lunar account of 8 hours and 48 minutes. In order to complete a ſolar revolution, they intercalate in every third year a month of 30 days; in this third year the firſt and third months have each 30 days inſtead of 29; they likewiſe ſuppreſs or paſs over a day, and by theſe the number of days in three ſolar years amounts to 1095. But every fourth year will occaſion the difference of a day on account of our leap-year. This, and ſome other defects in their mode of computation, are ſources of confuſion; in order to remedy which, their ſtyle, or mode of calculation,

has frequently been altered by arbitrary authority. The manner in which the Birman month is ſubdivided is peculiar to their nation. Inſtead of reckoning the days progreſſively from the commencement to the cloſe of the month, they advance no farther than the full moon, from which they recede by retrograde enumeration until the month is finiſhed. The Birman month is divided into 4 weeks of 7 days each. The 8th day of the increaſing moon, the 15th or full moon, the 8th of the decreaſing moon, and the laſt day of the full moon, are religiouſly obſerved by the Birmans as ſacred feſtivals. On theſe hebdominal holidays no public buſineſs is tranſacted in the Rhoom; mercantile dealings are ſuſpended; handicraft is forbidden; and the ſtrictly pious take no ſuſtenance between the riſing and the ſetting of the ſun. The Birman æra is ſaid to commence in our year 638, and it is that which is uſed by the philoſophers at Siam; and from them, as a more poliſhed nation, it has paſſed to the Birmans.

The Birmans are very fond of poetry and muſic; the former they call yeddoo; when repeated by a ſcholar, it flows ſoft and meaſured to the ear; ſometimes in ſucceſſive, and often in alternate rhymes. They have epic as well as religious poems of high celebrity, and they are fond of writing in heroic numbers the exploits of their kings and generals.

Muſic is a ſcience which is held in conſiderable eſtimation throughout the Birman empire; and the royal library of Ummerapoora is ſaid to contain many valuable treatiſes on the art. Some of the profeſſional muſicians diſplay conſiderable ſkill and execution, and the ſofter airs are pleaſing even to an ear unaccuſtomed to ſuch melody. The principal inſtruments are a ſoum, or harp, made of light wood, hollowed and varniſhed, reſembling a canoe with a deck; at the extremity a piece of hard wood is neatly faſtened, which tapers to the end, and riſes in a kind of curvature over the body of the harp; from this curvature, the ſtrings, uſually made of wire, are extended to a bridge on the belly of the inſtrument; it has two ſounding holes, one on each ſide of the bridge. The ſize of the ſoum varies from two to five feet in length. The turr reſembles our violin; it has only three ſtrings, and is played on with a bow. It is ſaid to be an original inſtrument of the country. The pullaway is a common flageolet. The kyzzoup is a collection of cymbals, ſuſpended in a bamboo frame. The patola, or guitar, is a curious inſtrument, of the form of a crocodile in miniature; the body is hollow, with ſounding holes on the back; three ſtrings of wire extend from the ſhoulder to the tail, and are ſupported on bridges at each extremity; the ſtrings are tuned by means of pegs in the tail, to which they are faſtened; it is played on by the finger, and is generally uſed to accompany the voice. The boundaw is a collection of drums, of oblong form and different ſize, which are ſuſpended perpendicularly in a wooden frame by leathern thongs. The whole machine is about five feet in diameter, and four feet high. The performer ſtands in the centre, and beats on the drums with a ſmall ſtick. This inſtrument is always introduced in a full band, and much uſed in proceſſions. The heem is the pipe of Pan, formed of ſeveral reeds neatly joined and ſounded by a common mouth-piece, and producing, when ſkilfully played on, a very plaintive melody. The Birmans are fond of ſinging and dancing; and the three laſt days of the ſolar year are commonly devoted to mirth and feſtivity. At Pegu they have a theatre, which is an open court, ſplendidly illuminated by lamps and torches, and in which dramatic performances are exhibited. Indeed, at all feſtivals they have dramatic entertainments, conſiſting of muſic, dancing, and action, with a dialogue in recitative. The ſubject is generally taken from the legends of their heroes, eſpecially of Rama. The beſt actors are ſaid to be natives of Siam; and in one of theſe we are told that the dialogue was ſpirited without cant, and the action animated without being extravagant; the dreſſes of the principal performers were alſo ſhowy and becoming. By way of interlude between the acts, a clowniſh buffoon entertained the audience with a recital of different paſſages, and by grimace and frequent alterations of tone and countenance, extorted loud peals of laughter from the ſpectators. The Birmans delight in mimicking, and are very expert in the practice, poſſeſſing uncommon verſatility of countenance. By pantomimic looks and geſtures, they exhibit a maſterly diſplay of the paſſions, making ſudden tranſitions from pain to pleaſure, from joy to deſpair, from rage to mildneſs, from laughter to tears, and of varying the expreſſion of terror and of idiotiſm, with ſurpriſing effect. On the laſt day of the Birman year, the 17th of April, there is a kind of ſport that is univerſally practiſed throughout the Birman dominions, to waſh away the impurities of the paſt year, and to commence the new year free from ſtain. Women on this day are accuſtomed to throw water on every man they meet, which the men have the privilege of returning. This paſtime is conducted with great decorum; and a woman who declines taking a part in it, is conſidered as avowing her pregnancy, and paſſes without moleſtation. At the cloſe of Lent, or during the whole ſeventh month, called Sadeen-guit, there are illuminations; every houſe has erected by it a kind of maſt, from which are ſuſpended one or more lamps. In the royal palace, a pyramid of lamps, at leaſt 150 feet high, is ſupported by a bamboo ſcaffolding. At this time the nobles from all parts of the empire reſort to court to pay their homage to the king. During the principal days and nights of theſe feſtivals, there is almoſt a conſtant ſucceſſion of wreſtling, dancing, muſic, proceſſions, fire-works, and theatrical entertainments.

The Birman alphabet conſiſts of 33 characters, having as many diſtinct ſounds, excluſive of various marks and contractions, that ſupply the place of long and ſhort vowels, diphthongs, &c. like the other alphabets of the Hindoo claſs. It has no repreſentation of the vowel correſponding with our ſhort *a*; this is nevertheleſs to be pronounced after every ſimple ſound or conſonant not ſupplied with another vowel, unleſs it be forbidden by a mark of eliſion placed over the letter, or excluded by the junction of two or more conſonants. The Birmans write from left to right; and though they have no diſtinguiſhing interval between their words, they mark the pauſes of a ſentence and the full ſtops. Their letters are diſtinct, and their MSS. are in general very beautiful. It has been the opinion of ſome of the moſt enlightened writers on the languages of the eaſt, that the "Pali," or ſacred language of the prieſts of Boodh, is nearly allied to the Shanſcrit of the Bramins. The character in common uſe throughout Ava and Pegu is a round Nagari, derived from the ſquare Pali, or religious text; it is formed of circles and ſegments of circles, variouſly diſpoſed and combined, whilſt the Pali, which is ſolely applied to purpoſes of religion, is a ſquare letter, chiefly conſiſting of right angles. Their common books, like thoſe of the Hindoos in the ſouthern parts of India, are compoſed of the palmyra leaf, on which the letters are engraved with a ſtylus. In their more elegant books, the Birmans write on ſheets of ivory, or on very fine white palmyra leaves. The ivory is ſtained black, and the margins are ornamented with gilding, while the characters are enamelled or gilded. On the palmyra leaves the characters are in general of black enamel; and the ends of the leaves, and the margins, are painted

painted with flowers in various bright colours. A hole through both ends of each leaf, ſerves to connect the whole into a volume, by means of two ſtrings, which alſo paſs through the two wooden boards that ſerve for binding. In the finer binding of books of this kind, the boards are lacquered, the edges of the leaves cut ſmooth and gilded, and the title written on the upper board; the two ends are by a knot or jewel ſecured at a little diſtance from the boards, ſo as to prevent the book from falling to pieces, but ſufficiently diſtant to admit of the upper leaves being turned back, while the lower ones are read. The more elegant books are in general wrapped up in ſilk cloth, and bound round by a garter, on which the Birmans have the art to weave the title of the book. In every Kioum, or monaſtery, there is a library or repoſitory of books, uſually kept in lacquered cheſts. In the royal library the number of theſe cheſts was not leſs than 100. The books were regularly claſſed, and the contents of each cheſt were written in gold letters on the lid. Some of theſe books exhibited very beautiful writing on thin leaves of ivory, the margins of which were ornamented with flowers of gold, neatly executed. The library contained books upon various ſubjects; more on divinity than any other; but hiſtory, muſic, medicine, painting, and romance, had their ſeparate treatiſes. Col. Symes thinks it not improbable, from the cheſts which he inſpected, that his Birman majeſty may poſſeſs a more numerous library than any potentate from the banks of the Danube to the borders of China. Books in the Pali text are ſometimes compoſed of thin ſtripes of bamboo, delicately plaited, and varniſhed over in ſuch a manner as to form a ſmooth and hard ſurface upon a leaf of any dimenſions: this ſurface is afterwards gilded, and the ſacred letters are traced upon it in black and ſhining japan. The margin is illumined by wreaths and figures of gold, on a red, green, or black ground. As moſt of the Birmans are taught to read and write, they carry with them a ſheet of thick and ſtrong blackened paper, called a parawaik, or paruvek, in which they enter their accounts, copy ſongs, till they can repeat them from memory, and take memorandums of any things that are curious. On theſe parawaiks the zares, or writers, in all courts and public offices, take down the proceedings and orders of the ſuperior officers. It is about 8 feet long, and 18 inches wide, and folds up like a fan; each fold being about ſix inches, and in length the whole breadth of the ſheet. They write on this with a pencil of ſteatites; and the characters are effaced by rubbing them over with charcoal, and the leaves of a ſpecies of dolichos.

In the recitation of poetry, the language is exceedingly melodious; even the proſe of common converſation appears to be meaſured, and the concluding word of each ſentence is lengthened by a muſical cadence, that marks the period to the ear of a perſon wholly unacquainted with the meaning.

Of the *coſmography* and *aſtronomy* of the Birmans, deduced from their moſt ancient writings, the following particulars will be ſufficient. They conceive that the univerſe, called logha, which ſignifies ſucceſſive deſtruction and reproduction, after it had been deſtroyed by fire, water, or wind, is again, of itſelf, reſtored to its ancient form. The earth, they ſuppoſe to be a plane ſomewhat elevated in the centre, and ſurrounded by a chain of very lofty mountains. Its diameter is 1,203,400 juzana, each juzana being 44,800 cubits or nearly 12 miles; its circumference is three times its diameter; and its thickneſs 240,000 juzana, of which one half is duſt, and the other half a ſolid rock, and the whole ſupported by a double thickneſs of water, reſting on twice its thickneſs of air, below which is a vacuum. Beſides our earth, there are 10,100,000 others, mutually touching in three points, and forming a ſimilar number of equilateral ſpaces, which, not being penetrated by the ſun's rays, are filled with water intenſely cold. In the middle of the moſt elevated part of our earth, the Birmah writings place Mienmo, the largeſt of all mountains, elevated above the ſurface of the ſea 84,000 juzana, and deſcending as far below it, ſupported by three feet of carbuncles, having its eaſtern face ſilver, the weſtern glaſs, the northern gold, and the ſouthern pale-coloured carbuncle, and ſurrounded by ſeven chains of hills. In the middle of the ocean, oppoſite to the four cardinal points of this mountain, are placed four large iſlands, the habitations of men and other animals; and beſides theſe the Birman writers allow 2000 of a ſmaller ſize, 500 belonging to each of the larger ones. The ocean is in various parts of very different depths. All living beings are diſtributed into three claſſes; generating beings; thoſe which are material, but do not generate; and immaterial beings, or ſpirits, each of which is ſubdivided into ſeveral diſtinct ſpecies. The Birman writings admit of tranſmigration, alleging, that in death, whether of man, beaſt, or any living being, the ſoul periſhes with the body, and after this diſſolution, out of the ſame materials another being ariſes, which, according to the good or bad actions of the former, becomes either a man, or an animal, &c. and they teach, that all beings are revolving in theſe changes, till they become entitled by their actions to Nieban, the moſt perfect of all ſtates, in which they are free from change, miſery, death, ſickneſs, or old age. The Birman writings alſo announce the opinion of an infinite number of worlds in conſtant ſucceſſion, without beginning and without end. Theſe writings mention eight planets, viz. the Sun, Moon, Mercury, Venus, Mars, Jupiter, Saturn, and another named Rahu, which is inviſible. The ſun is 50 juzana in diameter, the moon 49, Mars 12, Mercury 15, Jupiter 17, Venus 19, and Saturn 13; and their circumferences are triple their reſpective diameters. They ſuppoſe that the ſun, moon, and ſtars revolve round the great mountain Mienmo in a circle, the plane of which is parallel to the earth. The ſtars, according to them, purſue a conſtant courſe, without declining to the north or ſouth; but the ſun, moon, and other planets have a declination; and the ſun, in proceeding from the north to the ſouth, and from the ſouth to the north, always touches the twelve conſtellations, which we call the twelve ſigns of the zodiac, and in the ſpace of one year returns to the ſame place in the heavens from which he ſet out. This ſame revolution is performed by the moon in a month. The ſun's motion, they ſay, is quicker than that of the moon; and by his diurnal revolution, when he is in the ſouthern iſland it is mid-day, in the northern it is midnight, in the eaſtern iſland the ſun ſets, in the weſtern it riſes. Although the ſun, moon, and ſtars appear to us round, we are not to ſuppoſe them to be ſpheres, but this is a fallacy of viſion. The inviſible planet Rahu ſerves the purpoſe of explaining eclipſes; for being a huge monſter, he takes the ſun and moon either into his mouth or under his chin, and thus cauſes either total or partial eclipſes. As to the heat and cold which are experienced at different ſeaſons of the year, the Birmans ſay, that from the vernal equinox to autumn, the ſun is always tending to the north, and the moon inclining to the ſouth; the ſeaſon is then hot, becauſe the ſun's rays, which are naturally hot, then prevail; but from the autumnal equinox to the vernal, the ſun inclines to the ſouth, and the moon to the north, and the moon's rays, which are by nature cold, predominate, and produce cold. They aſſign ſeven cauſes of rain, of which ſome are phyſical, and ſome moral. Theſe aſtronomical and phyſical ideas of the Birman writings were probably brought from Hindoſtan, together with their religion and laws; but

for

for a more particular account of them, we ſhall refer to the Aſiatic Reſearches (ubi infra).

Among the Birmans there are ſeveral hiſtories, containing an account of the lives and actions performed by the different families of their princes; which hiſtories are very fabulous, and abound with the recital of omens and prodigies. Indeed, the Birmans are much attached to divination. No perſon will commence the building of a houſe, a journey, or the moſt trivial undertaking, without conſulting ſome perſon of ſkill, in order to find a fortunate day or hour. Friday is a moſt unlucky day, on which no buſineſs ought to be commenced. On medicine the Birmans have ſeveral books, containing the deſcription of 96 genera of diſeaſes, with various recipes for their cure. Mummy is with them a favourite medicine, and they are not unacquainted with the uſe of mercury in the cure of lues venerea; but their mode of adminiſtering it is neither certain nor ſafe. Moſt of their remedies, however, are taken from the vegetable kingdom; and they are chiefly of the aromatic kind, nutmegs being one of their moſt favourite medicines. Although they are well acquainted with the plants of their country, the practice of their phyſicians is almoſt altogether empirical, and they poſſeſs certain recipes and noſtrums, the efficacy of which they extol, and which have been tranſmitted from their anceſtors for ſeveral generations. They combine with their medical practice great faith in amulets and charms. In ſurgery, they proceed no further than dreſſing wounds and ſetting bones. Of late the inoculation for the ſmall-pox has been introduced into Arracan.

The ſtate of *agriculture* in the Birman empire is not particularly illuſtrated by Col. Symes. It ſeems, however, to be purſued with conſiderable avidity; and the ſoil in many parts is capable of cultivation, and its productions, which are naturally numerous, admit of further improvement. The cattle uſed in ſome parts of the country for tillage and draft are remarkably good; they put only a pair of them to the plough, which is little different from the plough of India, and turns up the ſoil very ſuperficially. In their large carts they yoke four ſtout oxen, which proceed with the ſpeed of a hand-gallop, and are driven by a country-girl ſtanding up in her vehicle, who manages the reins and a long whip with eaſe and dexterity. Many of the riſing grounds are planted with indigo; but the natives ſuffer the hills for the moſt part to remain uncultivated, and only plough the rich levels. They every where burn the rank graſs once a year to improve the paſture. The Birmans will not take much pains; they leave half the work to nature, which has been very bountiful to them. In the neighbourhood of Loonghee, many fields are planted with cotton, which thrives well; ſeſamum is alſo cultivated in this ſoil, and is found to anſwer better than rice, which is moſt productive in low and moiſt grounds. In the ſuburbs of Pagahm, there are at leaſt 200 mills employed in expreſſing oil from the ſeſamum ſeed. In this operation the grain is put into a deep wooden trough, and preſſed by an upright timber fixed in a frame: the force is increaſed by a long lever, on the extremity of which a man ſits and guides a bullock that moves in a circle; thus turning and preſſing the ſeed at the ſame time. The machine is ſimple, and yet effectually anſwers the purpoſe. Waggons form a caravan for travelling from the ſouthern country towards the capital. Of theſe there are ſometimes as many as 18, each of which is drawn by ſix bullocks, and is covered with a tilted roof of bamboo, overlaid with painted cloth, for throwing off the rain. They contain not only merchandize, but alſo whole families, the wives, children, monkies, cats, parroquets, and all the worldly ſubſtance of the waggoners. Each bullock has a bell under his throat. They travel ſlowly, from 10 to 15 miles a day. At night they are diſpoſed in a circle, and form a barrier, within which the carriers feed their cattle, light fires, and dreſs their victuals, ſecure from the attacks of tigers, which much infeſt the leſs populous parts of the empire.

We ſhall cloſe this article with a brief account of the *perſons*, *diſpoſition*, and *manners* of the inhabitants of the Birman empire, and of ſome of their ſingular *cuſtoms*. The Birmans, in their features, bear a nearer reſemblance to the Chineſe than to the natives of Hindoſtan. The women, particularly in the northern part of the country, are fairer than the Hindoo females, but leſs delicately formed; they are, however, well made, and in general inclined to corpulence; their hair is black, coarſe, and long. The men are not tall in ſtature, but active and athletic; their appearance is youthful from the prevalent cuſtom of plucking their beards inſtead of uſing the razor; they tattoo their thighs and arms into various fantaſtic ſhapes and figures, which in their opinion operate as a charm againſt the weapons of their enemies. Neither the men nor women are ſo cleanly in their perſons as the Hindoos of India, among whom diurnal ablution is a religious as well as a moral duty. Girls are taught, at an early age, to turn their arms in a manner which makes them appear diſtorted: when the arm is extended, the elbow is inverted, the inſide of the joint being protruded, and the external part bending inwards. The general diſpoſition of the Birmans is ſtrikingly contraſted with that of the natives of India, from whom they are ſeparated by a narrow range of mountains, which in many places admit of an eaſy intercourſe. Nevertheleſs, the phyſical difference between the nations could ſcarcely be greater, if they had been ſituated at the oppoſite extremities of the globe. The Birmans are a lively, inquiſitive race, active, iraſcible, and impatient. As the paſſion of jealouſy ſeems to have no influence among them, their wives and daughters are not concealed from the ſight of men; and they are allowed as free intercourſe with each other as the rules of European ſociety admit; but in other reſpects women have juſt reaſon to complain of their treatment. They are conſidered as very inferior and ſubordinate; and even the law ſtamps a degrading diſtinction between the ſexes; the evidence of a woman not being received as of equal weight with that of a man, and a woman not being ſuffered to aſcend the ſteps of a court of juſtice, but being obliged to deliver her teſtimony on the outſide of the roof. The cuſtom of ſelling their daughters, and even their wives, to ſtrangers, though confined to the loweſt claſſes of ſociety, and frequently the conſequence of pecuniary embarraſſment, is not regarded as ſhameful, nor is the female diſhonoured by it; and hence it is that women ſurrender themſelves the victims of this barbarous cuſtom with apparent reſignation. But no man, who leaves the country, is permitted to carry his temporary wife along with him. Every attempt of this kind is watched and guarded; and a ſhip, in which any females are conveyed away, can never return to a Birman port but under penalty of confiſcation of the property, and the infliction of a heavy fine and impriſonment on the maſter. Men are allowed to emigrate; but the exportation of women, would, in the opinion of the Birmans, impoveriſh the ſtate, by diminiſhing the ſources of its population. The females, who are reduced to the neceſſity of purſuing a courſe of proſtitution, are not at their own diſpoſal, nor are they allowed to receive the earnings of their unhappy profeſſion. They are ſlaves ſold by creditors to a licenſed pander, for debts more frequently contracted by others than themſelves. According to the laws of Pegu, he, who

who incurs a debt which he cannot pay, becomes the property of the creditor, who may claim him as a ſlave, and oblige him to perform menial ſervice until he liquidates the debt. His immediate relations are alſo liable to be attached; and innocent women are often dragged from domeſtic comfort, and are ſold to the licenſed ſuperintendant of the tackally, who, if they poſſeſs attractions, pays a high price for them, and reimburſes himſelf by the wages of their proſtitution. On the banks of a ſmall creek, between the town of Maindu and Baſſien, is a village called Mima-Shun-Rua, or the village of proſtitutes, which is inhabited altogether by women of this deſcription. Birman wives are ſaid to be in general chaſte and faithful; their ſedulous employment affording no leiſure for the corruption of their minds. A woman of the higheſt rank ſeldom fits in idleneſs at home; her female ſervants, under her direction and ſuperintendance, like thoſe of the Grecian dames of antiquity, ply the various labours of the loom. Weaving is chiefly a female occupation; and moſt Birman families manufacture all the cotton and ſilk that are required for their domeſtic conſumption. The women in this country manage alſo the moſt important mercantile concerns of their huſbands, and attend to their intereſts in all out-door manufactures; they are to the greateſt degree induſtrious, and are ſaid to be good mothers; and they therefore merit a higher rank than that which is aſſigned them, and better treatment than they experience. The Birmans, in ſome reſpects, particularly towards their enemies and invaders, diſplay the ſeverity of barbarians, but in others, all the humanity and tenderneſs of poliſhed life. At home they manifeſt an amiable benevolence, adminiſtering aid to the infirm, the aged, and the ſick; filial piety is inculcated as a ſacred precept, and its duties are religiouſly obſerved. A common beggar is no where to be ſeen; every individual is certain of receiving aſſiſtance, which, if he is unable to procure it by his own labour, is provided for him by others.

Among the Birmans, marriages are not contracted till the parties attain the age of puberty; the contract is purely civil; and the eccleſiaſtical juriſdiction has no concern with it. The law prohibits polygamy, and recognizes only one wife; however, concubinage is admitted to an unlimited extent. Concubines, who live in the ſame houſe with the legitimate wife, are obliged by law to perform menial ſervices for her; and when the huſband dies, they become the property of the ſurviving widow, unleſs he ſhall have emancipated them by a ſpecific act previous to his deceaſe. When a young man is deſirous of eſpouſing a girl, his mother, or neareſt female relation, firſt makes the propoſal in private; if the ſuit be well received, a party of his friends proceed to the houſe of the parents of the young woman, with whom they adjuſt the dotal portion. On the morning of the bridal day, the bridegroom ſends to the maiden three loongues, or lower garments; three tubbeeks, or ſaſhes; and three pieces of white muſlin; ſuch jewels alſo, ear-rings, and bracelets, as his circumſtances will admit: a feaſt is prepared by the parents of the bride, and formal writings are executed: the new-married couple eat out of the ſame diſh: the bridegroom preſents the bride with ſome læpack, or pickled tea, which ſhe accepts, and returns the compliment; and thus the ceremony ends.

When a man dies inteſtate, three-fourths of his property go to his children born in wedlock; and one fourth to the widow, who is the guardian both of the property and the children, until the latter attain the age of maturity. A Birman funeral is ſolemnized with much religious parade and external demonſtration of grief; beſides the mourning relations, the attendants, who follow the corpſe, which is carried on a bier, are women hired for the occaſion, who precede the body, and chant a dirge-like-air. The Birmans burn their dead; but as the ceremony of burning is expenſive, the bodies of paupers are either buried or caſt into the river. The mode of burning is as follows: the bier is placed on a funeral pile ſix or eight feet high, made of billets of dried wood laid over one another, with intervals for admitting a free circulation of air, ſo as to increaſe the flame. The Rhahaans walk round the pile, reciting prayers to Gaudma, until the fire reaches the body, when the whole is quickly reduced to aſhes, which are gathered and depoſited in a grave. Perſons of high diſtinction are embalmed, and their bodies are preſerved in ſome kioum, or religious building, ſix or eight weeks before they are committed to the funeral pile. Honey is ſaid to be the principal ingredient uſed for preſerving the body from putrefaction.

As to their food, the Birmans, compared with the Indians, are groſs and uncleanly. Although their religion forbids the ſlaughter of animals in general, yet they apply the interdiction only to thoſe that are domeſticated. All game is eagerly ſought after, and in many places publicly ſold; reptiles alſo, ſuch as lizards, guanas, and ſnakes, conſtitute a part of the ſubſiſtence of the lower claſſes. They are alſo extremely fond of vegetables.

Among the vegetable productions of this country we may enumerate the white ſandal-tree, and the aloexylum verum, much valued for the grateful odour of their ſmoke; the teak-tree (tectonatheca) already mentioned; the ebenoxylum verum, producing the true jet black ebony wood; the ſycamore fig, Indian fig, and banyan tree; the bignonia indica, nauclea orientalis, corypha ſeribus, one of the loftieſt of the palm-trees, and excoecaria Cochinchinenſis, remarkable for the crimſon under-ſurface of its leaves. To the claſs of plants uſed in medicine and the arts, we may refer the ginger and cardamum, found wild on the ſides of rivers, and cultivated in great abundance; the turmeric, uſed by the natives of the coaſt to tinge and flavour their rice and other food; the betel pepper, fagaria piperita, and 3 or 4 kinds of capſicum; the juſticia tinctoria, yielding a beautiful green tinge; morinda umbellata, gamboge, and carthamus, furniſhing yellow dyes; the red wood of the lawſonia ſpinoſa, and Ciſalpina ſapan, and the indigo. The bark of the nerium antidyſentericum, called codagapala, and that of the laurus cuiilavan, the fruit of the ſtrychnos nux vomica, the caſſia fiſtula, the tamarind, and the croton tiglium, the inſpiſſated juice of the aloe, the reſin of the camphor-tree, and the oil of the ricinus, are occaſionally imported from this country for the European diſpenſaries. The cinnamon laurel, ſometimes accompanied by the nutmeg, the ſugar-cane, bamboo, and ſpikenard, are found throughout the whole country; the laſt on dry hills; and the bamboo and ſugar cane in rich ſwamps. The ſweet potatoe, ipomæa tuberoſa, mad-apple and love-apple (ſolanum melongena and lycoperſicon), nymphæa nelumbo, gourds, melons, water-melons and various other eſculent plants, enrich, by cultivation, this country; and the plantain, cocoa-nut, and ſago palm, are produced more ſpontaneouſly. The vine grows wild in the foreſts, but its fruit is much inferior for want of cultivation, and through exceſs of heat, to that of the ſouth of Europe; but this country is amply ſupplied with the mango, pine-apple, ſapindus edulis, mangoſteen plum, averrhoa carambola, cuſtard-apple, papaw-fig, orange, lemon, and lime, and many other exquiſite fruits. The animals of the Birman empire correſpond with thoſe of Hindoſtan. The wild elephants of Pegu are very numerous; and allured by the early crops of rice, commit great devaſtation among the plantations that are expoſed to their ravages. The king

is the proprietor of these animals; and one of his Birman majesty's titles is "Lord of the white elephant, and of all the elephants in the world." The forests abound with tigers. Their horses are small, but handsome and spirited, hardy and active; and are frequently exported in timber-ships bound for Madras and other parts of the coast, where they are disposed of to considerable advantage. Their cows are diminutive, resembling the breed on the coast of Coromandel; but their buffaloes are noble animals, much superior to those of India, and are used for draft and agriculture; some of them are of a light cream colour, and are almost as fierce as tigers, who dare not molest them. The ichneumon, or rat of Pharaoh, called by the natives Ounbaii, is found in this country; but there is no such animal as the jackal in the Ava dominions, though they are very numerous in the adjoining country. Among the birds, which are the same with those of other parts of India, is one called the Henza, the symbol of the Birman nation, as the eagle was of the Roman empire; it is a species of wild fowl called in India the Brahminy goose; but the natives of Ava do not deify this bird.

The Birmans seem to be in possession of several small islands in the gulf of Martaban, the Magnus Sinus of antiquity, and of others to the south and west. Symes's Embassy to the Kingdom of Ava, 3 vols. 8vo. passim. Asiatic Researches, vol. vi. p. 163—308. See Arracan, Ava, and Pegu.

BIRMINGHAM, is justly esteemed the greatest manufacturing town in England, and we may safely assert, that in the quantity, variety, elegance, and utility of its manufactured articles, it surpasses any town in Europe. To enable the stranger and foreigner to appreciate the general character of this place, with its various subordinate features, we will endeavour to depict them to the fancy, in a concise and perspicuous narrative. Its distinguishing characteristic is appropriately displayed in the following lines by Mr. Jago, in his poem of "Edge-hill,"

"'Tis noise, and hurry all,—the throng'd street,
The close-pil'd warehouse, and the busy shop.
With nimble stroke the tinkling hammers move;
While slow and weighty the vast sledge descends,
In solemn base responsive, or apart,
Or socially conjoin'd in tuneful peal.—
How the coarse metal brightens into fame,
Shap'd by their plastic hands! what ornament!
What various use!—Nor this alone thy praise,
Thine too of graceful form, the letter'd type!
The friend of learning, and the poet's pride."

The etymology of the name of this town is not readily attained, as it has been written Brumwycheham, Bromwycham, and various other ways; indeed, in common conversation, it is frequently pronounced Bromidgham. The town lies near the centre of the island, in the north-western extremity of the county of Warwick. It is in the diocese of Lichfield and Coventry, in the deanery of Arden, and in the hundred of Hemlingford. The superficial contents of the parish are 2864 acres. In 1800 here were 16,403 houses, 1875 of which were uninhabited. The whole population was 73,670, of whom 34,716 were males, and 38,954 were females.

In the scale of national importance, Birmingham bears an exalted situation; without recurring to its ancient history, the modern inhabitants have, by laudable industry, raised it perhaps to the acme of manufacturing and commercial fame. The sagacious and elegant Burke emphatically pronounces Birmingham the "Toy Shop of Europe." This designation must not, however, be taken in its literal sense, as the articles of utility made in this town far exceed those intended only for shew and ornament. Many of our cities are attractive for their venerable ruins and grand cathedrals, but of those Birmingham is destitute. The traveller who delights in seeing the human race profitably employed to their own, and their country's advantage, will disregard the smoke which sometimes envelopes the town, and discern through the veil the bright beams of industry enlightning vast piles of riches: justice, however, will compel him to acknowledge, that profligacy has contrived to insinuate itself within too many dwellings of the labouring classes, producing idleness, discontent, drunkenness, and riots, of which several instances might be cited, exclusive of that grand convulsion which attended the commencement of that revolution in France, which in its consequences has so severely oppressed this, and almost every other nation. The Ikenild-street, one of the great Roman military roads, comes within a mile of Birmingham, and in Sutton park and Coldfield, four miles from the town, it remains nearly as perfect as if just completed; one of the principal evidences of the antiquity of Birmingham is, that it is contiguous to two Roman roads, the Ikenild, and Shirley streets

The family of Birmingham were lords of this manor till 1537, at which period it is said to have been obtained by the duke of Northumberland, through the success of a deep-planned scheme. Having endeavoured in vain to purchase it, he contrived to make Edward Birmingham appear as an accomplice in a highway robbery, and offered him his interest to save a forfeited life, on condition of selling him the manor. The manor-house, which is now called the mote, still remains, though the site has been converted into a manufactory, and an apartment is shewn where the ancient lords held their court-leets.

The parish of Birmingham is smaller than any in its neighbourhood. Mr. Hutton observes, that when Alfred found a town, he allotted a much smaller space of land to it, than when he portioned a village, obviously intending the former for trade and commerce, and the latter for agriculture; this circumstance seems to prove that Alfred *found* Birmingham a *town*. "The buildings occupy the south-east part of the parish, which, with their appendages, are about 800 acres. This part being insufficient for the extraordinary increase of the inhabitants, she has of late extended her buildings along the Bromsgrove road, near the boundaries of Edgbaston, and on the other side planted some of her streets in the parish of Aston."

"The situation is elevated, and the soil one solid mass of dry, reddish sand, through which the water descends freely, thus making even the cellars comfortable habitations;" the same author adds facetiously, that though metals of various sorts are found in great plenty above the surface, we know of nothing below except sand, gravel, stone, and water. All the riches of the place, like those of an empiric in laced clothes, appear on the outside. "There is not any natural river in the parish, but in the lower parts of the town are two excellent springs of soft water, suitable for most purposes, one at the top of Digbeth, the other Lady well; and at the latter place are seven of the most complete baths in the kingdom. They cost 2000l. in erecting, and are ever ready for the accommodation of hot or cold bathing, for immersion or amusement, with conveniency for sweating. That appropriated to swimming is 18 yards by 36, situate in the centre of a garden, in which are 24 private undressing houses, and the whole surrounded by a wall ten feet high."

Mr. Hutton mentions several instances of longevity, which seem to demonstrate either that the air is too pure to be rendered unwholesome by the smoke of the town, or that

ſmoke and ſteam are not ſo prejudicial to health as have been imagined: his inſtances are one perſon aged 100, a ſecond 103, a third 104, and a fourth 107, four upwards of 90, and 13 upwards of 80.

Birmingham is not a place a gentleman would chuſe to make a reſidence. Its continual noiſe and ſmoke prevent it from being deſirable in that reſpect.

Many ancient families who once flouriſhed at and near Birmingham, are mentioned by Mr. Hutton to have fallen into irretrievable decay; one inſtance is worth tranſcribing. "We have among us a family of the name of Middlemore, of great antiquity, deducible from the conqueſt; who held the chief poſſeſſions, and the chief offices in the county, and who matched into the firſt families in the kingdom, but fell with the intereſt of Charles I., and are now in that low ebb of fortune, that I have frequently, with a gloomy pleaſure, relieved them at the common charity board of the town."

It appears upon record, that in 1251, William de Birmingham, lord of the manor, procured an additional charter from Edward III. reviving ſome decayed privileges, and granting others; among the laſt was that of the Whitſuntide fair, to begin on the eve of Holy Thurſday, and to continue for four days. At the alteration of the ſtyle in 1752, it was prudently changed to the Thurſday in Whitſun week, that leſs time might be loſt to the injury of the manufacturers and their workmen. The ſame perſon alſo procured another fair, to begin on the eve of St. Michael, (which is commonly called the Onion fair, on account of the great quantity of onions ſold at the time) both of which are at this day in great repute. The horſe fair, which formerly was kept in Edgbaſton-ſtreet, was, in 1777, removed to Brick-kiln-lane; and that for beaſts, which uſed to be in the High-ſtreet, into Dale-end, in 1769.

Near Birmingham, on the London road, is Camp-hill, where the army of prince Rupert were encamped, during the ſiege in 1643. The inhabitants are accuſed of diſloyalty by lord Clarendon, for ſeizing the carriages which contained the royal plate and furniture. The prince, with 2000 men, had been commanded by the king to open a communication between Oxford and York, but the hardy and imprudent inhabitants of this town dared to oppoſe this force, with only a company of foot, and a troop of horſe. Though they had thrown up ſome ſlight works, and blockaded the ſtreets, yet the king's army forced through theſe trifling obſtructions, and entered the town ſword in hand. The earl of Denbigh, a royaliſt, was killed in this affair, as was a clergyman who acted as governor for the parliament, and who refuſed quarter. Birmingham had a narrow eſcape from deſtruction, for the exaſperated commander ordered the place to be burnt, but ſome favourable circumſtance confined the conflagration to a few houſes in Bull-ſtreet.

The plague of 1665, was imported into the town in a box of cloaths brought to the White Hart inn. Hence the fatal poiſon inſinuated itſelf through the ſtreets and houſes, deſtroying great numbers of the inhabitants, whoſe bodies ſoon filled the church-yard, and alſo an acre of land at Ladywood green, which was afterwards called the Peſt-ground.

Although ſome degree of eminence attached to Birmingham previouſly to the reign of Charles II., yet it is from that period that its rapid increaſe muſt be dated. Building leaſes then became common, and numbers of houſes aroſe to accommodate the increaſing population which aſſembled, in conſequence of the cultivation of the mechanical arts.

About the year 1700, the number of ſtreets in Birmingham was only 30, but now there are nearly 250; beſides, ſeveral of the oldeſt are conſiderably improved and augmented. This will, in ſome meaſure, aſſiſt the imagination in comprehending the amazing increaſe of the town in ſize, wealth, and manufactures, during that time; and it is no preſumption to ſuppoſe, that it has not yet arrived at its zenith; one inſtance of increaſe will be ſufficient to point out the general improvement. Between the roads to Wolverhampton and Dudley, there were only three houſes March 14, 1779. By that day twelve months they increaſed to 53, and March 14, 1781, there were 144. The ſame day in 1791, there was an addition of 833.

Thomas Sherlock, biſhop of London, purchaſed of the ladies of the manor in 1730, land worth 400l. per annum; in 1758, the income was doubled. He always refuſed to let it on building leaſes, alledging, that his ſucceſſor would be compelled to remove the rubbiſh at the expiration of the terms; ſir Thomas Gooch, who held the land after the above prelate, procured an act about 1766, for ſetting aſide the prohibitory clauſes of the biſhop's will; immediately let the ground, and improved the rents to 2400l. per annum; it appears from the books of the poor-rates, that leſs than 5000 houſes pay the parochial dues, and more than 8000 houſes are exempt; this fact denotes the prevailing deſcription of population.

Manufactures, &c. The extraordinary increaſe in the ſize, population, and proſperity of Birmingham, ariſes principally from its proximity to the coal mines, from the nature of the ſoil, from its canals, from the ſucceſsful exertions of a few individuals in ſome manufacturing ſpeculations, and from its being exempt from borough, and corporate laws and reſtrictions. To inveſtigate and detail the whole of theſe cauſes, with their effects, would occupy more ſpace than we can conſiſtently appropriate. The moſt prominent characteriſtics, however, ſhall be narrated. To the late John Taylor, eſq. a man of great induſtry and ingenuity, the public are indebted for the gilt button, the japanned and gilt ſnuff-box, with the numerous claſs of enamels; alſo the painted ſnuff-box, at which employ, one ſervant earned 3l. 10s. per week, by painting them at a farthing each. In his ſhops were weekly manufactured buttons to the amount of 800l. excluſive of other valuable productions, and eighty guineas have been given him for a ſingle toy made at his ſhop. He died in 1775, at the age of 64, after acquiring a fortune of 200,000l. His ſon is now partner in one of the largeſt provincial banking houſes in England.

The greateſt and moſt noted manufactory of this place, and perhaps in Europe, is that at Soho, about two miles from Birmingham. This is the property of Meſſrs. Boulton and Watt, who have advanced certain pieces of mechaniſm and productions of art to a ſtate of excellence, that have excited the aſtoniſhment and admiration of nations. The large warehouſes, work-ſhops, and the elegant manſion of the former gentleman, cover the declivities of a hill, which a few years back was a barren heath, tenanted only by rabbits, and a warrener's hut; now this once deſolate ſcene is converted into an emporium of arts and beauties. Such are the wonderful powers of human ingenuity and induſtry. In 1757, this ſpot, with ſome contiguous land, was leaſed for 99 years, to Meſſrs Ruſton and Evans, who erected a houſe and a mill for rolling metal, &c. At Lady day 1762, Mr. Boulton bought the whole, and removing to it ſoon afterwards from Birmingham, commenced the preſent extenſive premiſes, which were nearly completed in 1765, at an expence of 9000l. He now admitted a partner, Mr. Fothergill, into the concern, and

eſtabliſhed an extenſive correſpondence throughout Europe. To obtain and ſupport a reputation, every encouragement was afforded to men of genius in drawing, modelling, and other branches of the arts. An imitation of or molu in vaſes, tripods, and candelabras, was adopted, accompanied by ſo much ſkill and elegance, that univerſal approbation followed; this led to the manufacture of wrought ſilver, and an application was made to parliament in 1773, for an aſſay office, to be eſtabliſhed at Birmingham. The polygraphic art had its origin at Soho. This method of copying pictures in oil, by a mechanical proceſs, was conducted by F. Eginton, who has ſince executed a great number of fine ſpecimens of painting, or ſtaining of glaſs. The encauſtic mode of ſtaining glaſs, or fixing the vivid and fine graduating colours upon that tranſparent material, was ſuppoſed to be loſt, but it has been revived and brought to great perfection by this gentleman. Since 1784, he has executed ſeveral large windows for various cathedrals, churches, and gentlemen's manſions. (See GLASS-PAINTING.) Among the various machines, &c. invented and conſtructed at Soho, there is one entitled to diſtinguiſhed notice for its great national utility and importance. This is the *ſteam engine*, which has acquired extraordinary force and improvements by Mr. James Watt, one of the proprietors of the Soho firm. To him the ſcientific world is much indebted for various other inventions and improvements in mechanics. With a vigorous comprehenſiveneſs of mind, he embraces every mathematical and mechanical ſubject from the ſimpleſt to the moſt complex and profound. He procured a patent for the ſteam engine in 1768, and ſeven years afterwards, entering into partnerſhip with Mr. Boulton, began to conſtruct thoſe machines at Soho. Since that period, they have been generally adopted in the mines and manufactories all over the kingdom. (See STEAM-ENGINE.) The following liſt of curious and uſeful articles are manufactured at theſe works, which, when fully employed, give ſupport to upwards of 600 labourers. Buttons of all kinds; poliſhed ſteel, and jettina ſteel-toys; poliſhed ſteel watch-chains; patent cork-ſcrews, &c. Buckles and lachets of all ſorts; plated and ſilver goods for the dining and tea-table, ſide-board, &c.; medals and coins of various ſizes and metals. The late beautiful new coinage of copper, and alſo the re-ſtamped dollars; all come from the Soho mint. The coining mill or engine firſt erected here in 1783, has been much improved ſince that period, and is now adapted to work eight machines at once, each of which will ſtrike from 70 to 84 pieces per minute, the ſize of a guinea; or between 4,000 and 5,000 per hour. Thus the eight machines will work between 30,000 and 40,000 coins in one hour. Theſe machines are operated on by the ſteam-engine, and perform the following proceſſes: 1ſt. rolling the maſſes of copper into ſheets; 2nd, fine rolling of the ſame cold, through cylindrical ſteel rollers; 3rd, clipping the blank pieces of copper for the die; 4th, ſhaking the coin in bags; 5th, ſtriking both ſides of the coin, and milling it, at the ſame time diſplacing it, and placing another for the ſame operation. To its other properties, this ingenious machine adds the almoſt magical one of preventing fraud, by keeping an accurate account of every coin which paſſes through it. Dr. Darwin has deſcribed this ſingular apparatus in the following appoſite poetical lines:

——"Now his hard hands on Mona's reſted creſt,
Boſom'd in rocks, her azure ores arreſt;
With iron lips his rapid rollers ſeize
The lengthened bars in their expanſive ſqueeze;
Deſcending ſcrews with pond'rous fly-wheels wound
The tawny plates, the new medalion's round;
Hard dies of ſteel, the cupreous circles cramp,
And with quick fall, his maſſy hammers ſtamp.
The harp, the lily, and the lion join,
And George and Britain guard the ſplendid coin."

Rolled metals of all kind of mixtures, are prepared here; beſides pneumatical apparatus, large and portable; alſo copying machines, and in ſhort, almoſt every ſort of article for uſe or ornament.

Beſides the manufactories already named, Birmingham contains ſeveral others, which are entitled to our conſideration; and although we cannot allow ſpace for particulars, yet we muſt not paſs them altogether unnoticed.

Meſſrs. Richards's in High-ſtreet, is ſtyled the toy-ſhop of Birmingham; the elegance and variety of the articles are not to be equalled, with the exception of the ſhow-room at Soho. Mr. Clay's japan manufactory is not leſs celebrated, particularly when it is conſidered that the japan is fixed on common brown paper. To thoſe may be added Clarke and Aſhmore's manufactory of whips. Gill's gun, bayonet, and ſword manufactory, ſuppoſed to be one of the beſt in the world; and Galton's for ſporting guns. Previous to the reign of William III. guns were moſtly imported from Holland; but that monarch having once expreſſed ſome regret at this circumſtance, and deplored the neceſſity of ſending abroad for the article, Sir Richard Newdigate, M. P. for Warwickſhire, being preſent, aſſured the king that his conſtituents would undertake to ſupply the demands of government. An order was given, and being readily and correctly executed, Birmingham has continued from that period to be the great and principal place of manufacture for this deſtructive weapon. See GUN.

Leather appears to have been manufactured here in great quantities in the early periods of the hiſtory of Birmingham; but in 1795, there was but one tanner in the place.

Within the laſt century, the manufacture of ſteel into almoſt every kind of toy and ornament took its riſe; a large ſtreet bears the name of Steel-houſe-lane, from the extenſive works carried on there. Here are alſo very large braſs works erected on the banks of the canal, on the road to the five-ways, near which ſtand the ruins of the manſion built by the late John Baſkerville, who made great improvements in the art of printing. See BASKERVILLE.

Places of Amuſement and Curioſity. In New-ſtreet is a muſeum, or repoſitory of natural and artificial curioſities, the property of J. Biſſet, a gentleman who has publiſhed ſome ingenious poems and uſeful books. His "Magnificent Directory," is a novel, handſome, and uſeful work, in which are contained elegantly engraved emblematical cards of addreſs of a great number of the merchants, manufacturers, tradeſmen, &c. throughout England.

The firſt *Theatre*, eſtabliſhed at Birmingham, was ſituated in Moor-ſtreet, about 1740; that in King-ſtreet was erected 1765, and enlarged 1774; in the ſame year, it was tranſferred to a religious ſociety, and another built in New-ſtreet, at an expence of 5660l. and managed with great ſucceſs by Mr. Yates. In 1791, it was burnt by ſome incendiaries, who have never been diſcovered; ſince that period, the proprietors have re-built it in a very ſplendid manner for 14,000l. with an aſſembly room and a tavern annexed to it. Mr. Macready of Covent Garden theatre is the preſent manager, who generally preſents his audiences with the beſt London performers during the ſummer months. Concerts and muſical parties are held weekly during winter; and the ſummer produces a variety of public gardens, the principal of which are Vauxhall and Spring-gardens.

Govern-

Government. Birmingham is governed by three acting magiſtrates; the officers choſen annually are the high-bailiff, who inſpects weights and dry meaſures, and the markets; the low-bailiff, who ſummons juries, and chuſes all the other officers; two conſtables and one headborough; two high taſters, who examine the quality of beer and its meaſure; two low taſters or meat conners, who inſpect the meat expoſed to ſale, and cauſe that to be deſtroyed which is unfit for uſe; two affeirers, and two leather-ſellers, whoſe offices are now only nominal.

Deritend, a hamlet of Birmingham, ſends its inhabitants to the court leet of that town, where all the above officers are choſen and ſworn, in the name of the lord of the manor.

An act of parliament paſſed in 1752, which eſtabliſhed a *Court of Requeſt*, conſiſting of 72 commiſſioners, three of whom are a quorum; they ſit every Friday morning in a room of the Red Lion inn; the clerks attend to give judicial aſſiſtance, who are always profeſſors of the common law, and choſen by the lord of the manor and the commiſſioners for life: ten of the commiſſioners are ballotted out every other year, and ten others elected from among the inhabitants. The beneficial effects of a humane ſociety for the recovery of ſuſpended animation were firſt extended to Birmingham in 1790. About the ſame period a committee of reſpectable inhabitants was eſtabliſhed to watch over the common intereſts, under the title of the "Commercial Committee."

In 1791, W. Villars, eſq. then high bailiff, opened a market for haw, ſtraw, &c.

A public library was founded in 1779, which has flouriſhed greatly, and contains nearly 10,000 volumes, ſupported by upwards of 500 ſubſcribers. An elegant pile of building was erected in Withering-ſtreet for the purpoſes of the inſtitution in 1797. A rival made its appearance in 1796, with every proſpect of ſucceſs; beſides thoſe, there are medical and law libraries, and many reading ſocieties. Birmingham contains two churches, and four chapels; beſides ſeveral meeting houſes.

Churches. St. Martin's church, denominated the Old church, was raiſed previouſly to the year 1300. It is of ſtone, and occupies the ſite of, or is the firſt ſacred building belonging to the place. In 1690, it was thought neceſſary to caſe the church and tower with brick. The walls ſupport the arms and monuments of ſeveral titled and ancient families. Under the ſouth window are two of white marble, one of which is ſuppoſed to have been erected for William de Birmingham, who was captured by the French at the ſiege of Bellegard in 1297. He wears a ſhort mantle, &c. and bears a ſhield with the bend lozenge. This church was repaired and altered in 1786, at an expence of 4000l. The patronage belonged to the family of Birmingham till 1537, ſince which period it has been poſſeſſed by the Dudleys, the crown, the Marrows, the Smiths, and finally the Tenants. The rectory was valued in the king's books 1291, at 5l. per annum, and in 1536, at 19l. 3s. 6d. The income is now upwards of 1000l. and expected to be 2000l. after the expiration of certain leaſes.

St. Philip's, or the *New* church, is a handſome pile of building, but how Mr. Hutton or any other perſon could fancy and ſay that the ſteeple is erected after "the model of St. Paul's in London, but without its weight," is to us inconceivable, as there is not a line of it that reminds the ſpectator either of the dome or turrets of the metropolitan edifice. It muſt be allowed that the tower of St. Philip's finiſhes with an attic and a diminutive cupola, but there ends the reſemblance. This church is advantageouſly ſituated on an eminence, and the ſite was given by Robert Philips, eſq. It was begun by act of parliament in 1711, under a commiſſion conſiſting of 20 of the neighbouring gentry appointed by the biſhop of the dioceſe under his epiſcopal ſeal. In 1715, it was conſecrated, and finiſhed in 1719, at the real coſt of only 5012l. though the eſtimated value was nearly 20,000l. This circumſtance aroſe from the gift of materials, &c. The church-yard conſiſts of four acres, and is interſected by handſome walks, ſhaded by trees in double and treble rows, and is ſurrounded by elegant buildings. Two thouſand perſons may be conveniently accommodated in St. Philip's church, which has contained nearly 3000. William Higgs, firſt rector, founded a theological library for the uſe of the neighbouring clergy, and bequeathed 200l. to augment it. The Rev. Spencer Madan erected a room in 1792, adjoining the parſonage, and termed it the parochial library. The rectory is worth about 300l. per annum.

St. Bartholomew's Chapel, capable of containing 800 perſons, was erected in 1749, on a ſite given by John Jennens, eſq. an opulent land-holder of Birmingham. Mrs. Jennens, through the good offices of Mrs. Weaman, added 1000l. and the remaining ſum was received in contributions from pious inhabitants. The chapel and tower are handſome, and the former preſents a line north and ſouth. The altar-piece is the gift of Baſil, earl of Denbigh, and the communion plate that of Mary Carleſs.

St. Mary's Chapel was erected in 1774; on a ſpot of ground given by Mary Weaman, whoſe family has the patronage. The incumbency is valued at 200l. per annum.

St. Paul's Chapel is a ſtone building erected in 1779, by virtue of the ſame act which founded St. Mary's. Charles Colmore, eſq. gave the ground; a ſteeple is intended, and the eaſt window was decorated in 1791, with painted glaſs, repreſenting the converſion of St. Paul, by Francis Eginton, who received 400 guineas for the ſame.

The houſe of a celebrated phyſician of Birmingham, Dr. Aſh, was purchaſed in 1789 by an attorney, who converted it into an elegant chapel, at the expence of his own ruin, where he cauſed the ſervice of the church to be chanted by a numerous choir, accompanied by an organ. Dr. Croft, and ſome other clergymen, afterwards purchaſed it, and engaged to officiate there regularly. The congregation chiefly conſiſts of ſoldiers from the neighbouring barracks.

Diſſenting Meeting Houſes. Old Meeting-ſtreet received its name from the old meeting erected in the reign of William III. which was deſtroyed in 1791 by the mob. The truſtees recovered 1390l. 7s. 5d. damages, and rebuilt the preſent building, at an expence of 5000l.

The *New Meeting* built 1730, ſhared the fate of its parent in 1791, and has never been rebuilt. The celebrated Dr. Prieſtley preſided over the ſpiritual concerns of this place of worſhip at the period of its deſtruction, and narrowly eſcaped perſonal injury, or perhaps death, from the furious populace. He fled, and finally retired into exile, within the ſtate of Pennſylvania, where he died 1804, with the fame of an excellent philoſopher and experimentaliſt. (See PRIESTLEY.) The truſtees having loſt their licence, could not recover damages, but the king granted his warrant upon the treaſury for 2000l.

The *Union Meeting* in Livery-ſtreet, originally an amphitheatre for the exhibition of equeſtrian exerciſes, being unoccupied at the period of the riots, the congregations of the two meetings hired, and converted it into a place of worſhip. After the re-erection of the old meeting, they ſeparated, reſigning the Union meeting to the new

meeting aſſembly, who occupy it till their place of worſhip is re-built.

Carrs-Lane Meeting, a kind of chapel to the old meeting, was erected in 1748. This ſociety has 800l. bequeathed by John England in 1771, and 40l. 18s. per annum, termed Scot's truſt.

A *Baptiſt Meeting* in Canon-ſtreet, was founded in 1738, and has continued proſperouſly to the preſent period.

The *Quakers* have a meeting in Bull-ſtreet, frequented by a large, peaceable, and rich congregation; behind it is a ſpacious burial-ground. The methodiſts are now very numerous; previous to 1782, there was but one congregation, whoſe place of worſhip had been a theatre; whence they removed to a ſplendid meeting in Cherry-ſtreet, erected at an expence of 1200l. John Weſtley, their chief prieſt, preached in it for the firſt time July 7, in the above year; three others have ſince been erected and purchaſed in Colehill-ſtreet, Deritend, and Newhall-ſtreet. The laſt was erected as a new Jeruſalem temple, for the Swedenborgians, but in too magnificent a ſtyle for their revenues. The methodiſts bought it, and the original poſſeſſors built a ſmaller temple.

A ſmall *Roman Catholic Chapel* is ſituated at Eaſy-hill, in the place of one deſtroyed during the deſtructive riots. A Jewiſh ſynagogue, a baptiſt's meeting, and an independent meeting, lady Huntingdon's meeting, and ſome other places of worſhip, are found in this town, which, like moſt manufacturing places, is diſtinguiſhed for its number of diſſenters of different ſects.

Charities. Some of the ſtreets of Birmingham are kept in repair by emoluments ariſing from ſmall eſtates. William Leech, who lived in the reign of Henry VIII. bequeathed certain eſtates to the town, in truſt to ſixteen inhabitants, for repairing the ſtreets. This perſon founded the almshouſes in Steel-houſe lane for poor widows. Fentham's truſt is 100l. per annum, and applied to teaching poor children reading, and for cloathing ten poor widows. The date of the donation is 1712. Mr. Crowley gave in 1733, ſix houſes for the ſupport of a ſchool for ten girls.

The *Free School* was erected on the ſite of the guild of the holy croſs, which had an endowment or lands for the maintenance of two prieſts, worth twenty marks per annum, given by Thomas de Sheldon, John Coleſhill, John Goldſmith, and William Attſlowe. In 1393, the bailiff and inhabitants obtained a patent for augmenting the foundation, and adding a brotherhood, which flouriſhed till the general diſſolution, and was then valued at 31l. 2s. 10d. per annum. Edward VI. granted the lands belonging to the guild in 1552, at the ſuit of the inhabitants to nineteen perſons, as bailiff and governors of the free grammar ſchool of king Edward VI., to hold in common ſoccage at a rent of 20s. per annum. Their ſucceſſors erected the preſent building in 1707, which is large and handſome, has a neat tower in the centre, and a ſtatue of Edward VI. in front. The chief maſter's ſalary is 120l. the ſecond 60l. two uſhers 40l. each for writing and drawing, and a librarian 10l. There are ſeven exhibitions of 25l. per annum each for the univerſity of Oxford, and the poſſeſſions are valued at 1200l. per annum.

The *Blue Coat School* was erected 1724, but enlarged and improved in 1794, at an expence of 2500l. The revenues are 1327l. and 150 boys and 40 girls receive the benefits of the inſt tution.

The *Diſſenters Charity School* was held at the old meeting, but after that was deſtroyed, a building was purchaſed in Park-ſtreet, and has been much improved. The children received are 40 boys and 20 girls.

The *Work-houſe* erected 1733, coſt 1173l. a wing was added for an infirmary 1766, and another in 1779, at an expence of 1100l. The inhabitants pay a rate of 6d. in the pound, which raiſes 17,000l. per annum, and relief is afforded to 7000 perſons. There are twelve overſeers.

The *General Hoſpital* was erected 1766, and two wings were added 1791. It is ſupported by voluntary contributions, and many large bequeſts; the phyſicians generally give their aſſiſtance gratis.

The *Priſons* in Peck-lane and Deritend are diſagreeable and unwholeſome, and both are licenſed as public houſes.

The *Canal* between this place and Wedneſbury, was made in conſequence of an act obtained in 1767. It is twenty-two miles in length, uniting with the Staffordſhire canal; the ſhares were 140l. each, and the expence 70,000l.; they ſold in 1782 for 370l. each, and in 1792 for 1170l. Sir Thomas Gooch leaſed the proprietors ſix acres of land at 47l. per annum, which they converted into a wharf, and erected a handſome office on it. The boats are drawn by one horſe, and are about twenty-five tons burthen. Coals are little more than half the price they were before this canal was made. Several other canals, equally beneficial, have ſince been completed, opening a communication between this town, and almoſt every principal town in the kingdom.

The *Barracks* ſtand on five acres of land, held by government at one penny per yard. They were erected in 1793 for 13,000l. and will accommodate 162 men.

There are three extenſive Breweries near Birmingham, Richards's in Deritend for ale, Giles and Forreſts Worſtone-lane, for ale and porter, and the Britannia, Walmer-lane, belonging to Clay and co.

The Riots already alluded to, conſtitute an unpleaſant feature in the hiſtory of this town, and whilſt they ſerve to characterize the folly and infatuation of the lower claſſes of ſociety, will, we truſt, operate as a warning example to the riſing generation. A few perſons aſſembled at the hotel Birmingham, July 14, 1791, to celebrate the anniverſary of the French revolution. A mob collected round the houſe, broke the windows, and immediately proceeded to Dr. Prieſtley's new meeting. This, and the old meeting, were ſoon burnt to aſhes, and the doctor's houſe and furniture, with his valuable library, apparatus, and MSS. ſhared the ſame devaſtating fate. On July 15, the manſions of John Ryland, eſq. at Eaſy-hill, and Bordeſley hall, the ſeat of John Taylor, eſq. together with the houſe, ſtock in trade, books, furniture, &c. of Mr. Hutton, author of the "Hiſtory of Birmingham," were deſtroyed. Saturday the 16th witneſſed the deſtruction of Mr. Hutton's houſe at Saltley, the reſidences of George Humphreys, William Ruſſel, and John Taylor, eſqs. The latter, Bordeſley-hall, was occupied by lady Carhampton, mother to the duchefs of Cumberland, but neither her blindneſs through age, nor connection with the king, could prevent the mandate of removing her furniture from the mob, who frantiely offered to aſſiſt: "She was therefore, like Lot, haſtened away before the flames aroſe, but not by Angels." The reverend Mr. Hobſon's and Mr. Harwood's houſes were next burnt; thoſe of the Rev. Mr. Coates, Mr. Hawkes, and Thomas Ruſſell, eſqs. were plundered. On Sunday the 17th, Kingſwood meeting periſhed in flames, the parſonage houſe, and that of Mr. Cox, licenced for public worſhip. The mob this day plundered Edgbaſton-hall, Dr. Withering's, and attacked Mr. Males houſe, but hearing in the evening that a troop of horſe approached, they gradually diſperſed, after deſtroying property to the amount of 60,000l. To reimburſe the ſufferers, an act was obtained in 1793. The war ſucceeding, greatly injured Birmingham, and this cannot be more clearly

clearly proved than by referring to the 1875 uninhabited houſes in the year 1800. There are two morning papers publiſhed at Birmingham; Aris's Birmingham Gazette, and Swinney's Birmingham Chronicle, &c. Mr. Swinney alſo carries on a conſiderable type foundery, which is the only provincial one in the kingdom. "This neighbourhood," ſays Mr. Hutton, "may juſtly be deemed the ſeat of the arts, but not the ſeat of the gentry. None of the nobility are near us, except William Legge earl of Dartmouth, at Sandwell, four miles from Birmingham. The principal houſes in our environs are thoſe of the late ſir Charles Holte at Alſton; ſir Henry Gough Calthorpe at Edgbaſton; George Birch, eſq. at Handſworth; John Gough, eſq. at Perry; and John Taylor, eſq. at Bordeſley and at Moſely, all joining to the manor of Birmingham; excluſive of theſe, there are many retreats of our firſt inhabitants, acquired by commercial ſucceſs." Hockley Abbey, near Soho, is the reſidence of Mr. Richard Ford, an ingenious ſmith, who had the honour of preſenting his majeſty with an iron carriage made by himſelf. It is a modern curious building, with the upper part repreſenting a ruin, and is ſurrounded by beautiful grounds and walks, interſperſed with fanciful curioſities. The moſt *conſiderable* ſeats in the vicinity of Birmingham, are Hagley, 12 miles diſtant; Enville, 18 miles diſtant; and the Leaſowes, 6 miles diſtant. The latter will long be preſerved in the memory of every reader of Shenſtone, whoſe creation it was, and whoſe taſte it diſplayed in an eminent degree. It now belongs to Charles Hamilton eſq. who has judiciouſly reſtored the neglected beauties of the place. Hagley, the ſeat of lord Littleton, has been particularly celebrated in the writings of Pope, Thomſon, Hammond, and other poets. Enville, the ſeat of the earl of Stamford, is a ſcene of great natural beauty. For further particulars relating to Birmingham, its manufactories, and neighbourhood, ſee Hutton's "Hiſtory of Birmingham," 8vo. Shaw's "Hiſtory of Staffordſhire," fol. "A companion to the Leaſowes, Hagley, and Enville," 12mo. Biſſet's "Poetic Survey round Birmingham," 8vo. Phillip's "Hiſtory of Inland Navigation," 4to. &c.

BIRON, Armand, de Gontault, baron of, in *Biography*, was born about the year 1524, and roſe gradually from the condition of a page to Margaret queen of Navarre, to the rank of marſhal of France, which he obtained from Henry III. in 1577. After the death of this king, he was one of the firſt to acknowledge Henry IV. as lawful poſſeſſor of the crown, and ſerved him with advantage at the battles of Argues and Ivri. At the cloſe of the action, to the victorious iſſue of which he contributed, by his command of the reſerve, though he was not engaged, he ſaid to Henry, who had much expoſed himſelf, "You, Sire, have acted the part of Biron to-day, and he has acted yours." Under Henry III. he occupied the poſt of lieutenant-general of Guienne, in which he gained great advantages over the Calviniſts; and he alſo reduced part of Normandy to the obedience of Henry IV. To his ſon, who ſolicited a ſmall force for the purpoſe, and with the promiſe of ruining the army of the dukes of Parma and Mayenne, he replied; "I believe you may; but then we ſhall have nothing farther to do but to plant cabbages at Biron." Soon after, in 1592, he loſt his life by a cannon ball, at the ſiege of Epernai. In his military character, he was a rigid diſciplinarian, and required prompt obedience. When an officer, whom he had commanded to burn a houſe, deſired an order to this effect, under his own hand, Biron inſtantly diſcharged him, alledging "he would have nothing to do with people who were afraid of juſtice; and that every ſoldier who dreaded a pen, muſt tremble at a ſword." He was a polite ſcholar, but of a mercenary and intemperate diſpoſition. He wrote "Commentaries" of his tranſactions, which were loſt. Gen Dict. Nouv. Dict. Hiſt. Mod. Un. Hiſt. vol. xxi. p. 54. &c.

Biron, Charles de Gontault, duke of, the eldeſt ſon of the preceding, was born in 1562; and having ſerved under his father, he diſtinguiſhed himſelf in ſeveral battles and ſieges. Henry IV. diſtinguiſhed him by tokens of forbearance and favour, on account of his faithful and active ſervices. He created him admiral of France in 1592, marſhal and governor of Burgundy in 1594, and honoured him with erecting the barony of Biron into a dukedom and peerage. He alſo employed him in ſeveral important diplomatic embaſſies; but his pride and ambition rendered him incapable of gratitude. Allured by flattering proſpects, he engaged with Spain and Savoy in a conſpiracy againſt his maſter; and at length his haughty conduct cauſed him to be arreſted for his treaſons, tried, and condemned to loſe his head; and the ſentence was executed in the court of the baſtile, July 31, 1602. He ſubmitted with reluctance, and betrayed cowardice at the time of his death. He was vain, arrogant, and malicious; he changed his religion twice before he attained the age of 16 years, and manifeſted a total want of principle and integrity. His paſſion for gaming, reduced him, notwithſtanding his rapacity, to various difficulties; and he was only eſtimable when he was actively employed. Although the king incurred ſome blame for ſacrificing the life of a ſervant who had been eminently uſeful, and honoured with his peculiar friendſhip, Biron deſerved to ſuffer as a traitor. Gen. Dict. Nouv. Dict. Hiſt. Mod. Un. Hiſt. vol. xxi. p. 99, &c.

Biron, in *Geography*, a town of France, in the department of the Dordogne, 3½ leagues ſouth of Belvez.—Alſo, an iſland in the gulf of St. Lawrence, 26 leagues weſt of cape Anguilla. N. lat. 47° 50'. W. long 61° 5'.

BIROSTRIS, in *Conchology*, a ſpecies of Bulla, that inhabits Java. The ſhell has two beaks, which are elongated and ſmooth; margin thickened outwardly. Gmelin, Liſter. This ſpecies is not unlike *Bulla volva*, but is ſmaller, being only about the ſize of a horſebean; and it is alſo narrower; ſmooth, whitiſh, fleſh-coloured; beaks unequal, obliquely truncated, and one of them a little aſcending; aperture nearly equal, but wideſt at one end.

BIROTA, *Birotum*, from *bis* and *rota*, *wheel*, a kind of vehicle denominated from the two wheels whereon it moved. The birota, by the conſtitution of Conſtantine, was drawn by three mules, and carried 200 pounds weight; by which it was diſtinguiſhed from the *rheda*, which carried 1000 pounds, and was drawn by eight, and in winter by ten mules.

BIRR, in *Geography*, or, as it is called by act of parliament, *Parſons Town*, the largeſt poſt and market town in the King's county, Ireland, ſituated on the river called the *Little Breſna*, which divides the King's county from the county of Tipperary, on the ſouth-weſt. This town has breweries, diſtilleries, malt-houſes, cloth and ſerge manufactories, a bank, an excellent market, and a barrack for two companies of foot. The caſtle at the weſtern extremity of the town, belonging to the family of Parſons, was beſieged by Sarſfield, lord Lucan, general of the Iriſh, in the war of the revolution of 1688, and relieved by general Kirk. There is a ſtatue of William, duke of Cumberland, ſtanding on a ſtone pillar of the Doric order, erected in 1747, in honour of the victory at Culloden. Birr is 65 miles weſt by ſouth from Dublin, 6 ſouth from Banagher on the Shannon, and near 12 from Portumna. N. lat.

N. lat. 53° 4'. W. long. 7° 52'. Beaufort.—Coote's Survey of King's County.

BIRRETUM, or Birretum, in *Writers of the Middle and Lower Ages*, a thin black cap or cover for the head, made of linen, fitted close to the head, and pointed by a pyramid, anciently worn by priests, soldiers, doctors, &c. Du Cange. The word *birretum*, sometimes written *birrettum* and *biretum*, is also applied to a cap or coif of a judge, or serjeant at law. The birretum also denotes the cap worn by the novices in the Jesuits order, formerly of a square, now a round figure. The birret was the ordinary cover of the head in France 500 years ago. It took its denomination from *birrus* or *birrum*, the coat anciently used by ecclesiastics; with which the cap was then of a piece, and made part of it; so that the whole covered, not only the head, but the shoulders. Afterwards, when they began to retrench the lower part, still retaining the upper, it was no longer called *birrus*, or *birrum*, but diminutively *birret*, or *birretum*.

BIRRUS, an ancient habit worn by the Christians in Africa. The word is also written *byrrus*, supposed to be formed from πυῤῥος, on account of its red colour. Some will have the birrus an episcopal habit. Others extend it to all the clergy. Others, on juster grounds, make it the common coat of all the Christians in that quarter.

BIRS, or Birsh, in *Geography*, a river of Switzerland, which runs into the Rhine near Basle. Near this river, and not far from the town of Basle, are the hospital and burying ground of St. James, famous in the history of Switzerland for a desperate combat in 1444, between the Swiss and the dauphin of France, afterwards Lewis XI., in which Swiss valour and intrepidity were very signally displayed. Upon this occasion 1500 Swiss charged 8000 of the enemy's cavalry with such determined and well conducted valour, as to drive them back; and when the enemy received reinforcement, the Swiss renewed the assault, and forced them to repass the river Birs, and join the main body of the army. The Swiss, encouraged by this success, and also exasperated with the most spirited indignation against the invaders of their country, rashly attempted, against the remonstrances of their officers, to force their passage over a bridge guarded by a large body of the enemy; but this gallant effort not succeeding, they threw themselves into the river, and gained the opposite shore, in the face of a battery of cannon, that was playing against them. But they were now opposed to an army of 30,000 men advantageously posted in an open plain. In these desperate circumstances they had no alternative, but to throw down their arms, or gloriously expire. They bravely preferred death; 500 took possession of a small island near the bridge, and after resolutely defending themselves to the last extremity, were cut to pieces. A like number forced their way through the ranks of the enemy, and marched towards Basle; when they were opposed by a large party of horse posted to prevent the inhabitants of the town from sallying forth to the relief of their countrymen. Being now surrounded on all sides, they threw themselves into the hospital of St. James; and, lining the walls of the burying-ground, resisted for some time the united assaults of the French army. At length the hospital being set on fire, and the cannon having battered down the walls of the burying-ground, they no longer fought in hopes of victory; but still resolving to sell their lives as dearly as possible, they continued to defend themselves to the last gasp.

Æneas Sylvius (afterwards pope Pius II.) relates, among other actions of singular valour excited by this heroic troop, the following instance, that deserves to be recorded. Four French soldiers assaulted a single Swiss, and having killed and stripped him, proceeded to insult the corpse; one of his companions, incensed at this brutal action, seized a battle-axe, rushed upon the four, slew two of them, and drove the others to flight; then flinging the dead body of his friend upon his shoulders, carried it to a place of security; and returning to the attack, fell by the hand of the enemy. Of the whole number, only 16 escaped from the field of battle; and these, agreeably to the old Spartan discipline, were branded with infamy, for not having sacrificed their lives in defence of their country. Among those who were desperately wounded and left upon the field, only 32 were found alive. The names of many of these glorious combatants were registered, and still remain upon records. The loss of the enemy was great; and they were effectually prevented from prosecuting their designs upon Switzerland, and compelled to retire in a shattered state into Alsace. Lewis himself declared, that such another victory would ruin his army. This combat may be considered as forming a remarkable æra in the history of the Swiss; for it gave rise to their treaty with Charles VII.; being the first alliance which they contracted with France. The Swiss still talk of this famous action with the warmest enthusiasm; and the inhabitants of Basle form parties every year, and go to an inn situated near the hospital and burying-ground, in order to commemorate, in a red wine produced from some vineyards planted on the field of battle, the heroic deeds of their countrymen, who so gloriously sacrificed their lives. This wine is highly prized by the Basileans, and called "the blood of the Swiss."

By the side of the Birs there is a fertile plain, on which are several pleasant villages; and the extremity of the plain is closed by a rock, through which opens the celebrated pass called "Pierre Pertuis," which see. At the bottom of this rock, the Birs bursts from the ground in several copious springs, and turns two mills within a few paces of its principal source.

BIRSK. See Borsk.

BIRSKA, a river of Siberia, which runs into the Lena, 28 miles south-west of Olekminsk.

BIRSTEIN, a town of Germany, in the circle of the Upper Rhine, and county of Isenburg, 26 miles E.N.E. of Frankfort on the Mayne.

BIRTERBURY, or Bitterbui *Bay*, a considerable bay on the west coast of Ireland, in the county of Galway, open to the Atlantic. It is capacious and well sheltered, has good ground, and will admit the largest ships, which may ride here from four to eight fathoms water; yet it is probably never visited, except by fishermen and smugglers. N. lat. 53° 20'. W. long. 9° 53' 30" from Greenwich. M'Kenzie.

BIRTH, in a general sense. The word is of Saxon origin, and is used to denote both the act of coming into life, which is called child-birth, and the offspring or thing born, and in these senses we meet with it in our best writers.

But thou art fair, and at thy birth, coming into the world.
Shakespear's King John.

Others hatch their eggs, and tend the birth, (young ones) until they are able to shift for themselves. Addison, Cicero says, "Feræ diligunt partus suos," beasts love their offspring.

Birth, in *Midwifery*, is used as synonimous to labour, or the power by which the fœtus is excluded from the uterus, and in this sense we say, the birth (labour) was easy, expeditious, tedious, difficult, &c. It is also, though not very properly, used by midwives, to signify the external orifice of the vagina; thus, when in labour, the head of the child begins to

to dilate the external orifice, or to emerge, it is ſaid to be in the birth.

Birth, *Natural*, when the head of the fœtus preſenting to the uterine orifice, the labour is completely effected by the pains, without the interference of art. See Labour, Natural.

Birth, *Premature*, when by any accident or derangement of the health of the woman, or of the fœtus, pains are excited, and the fœtus is expelled before it has attained its maturity. See Abortion, and alſo Labour, Premature.

Birth, *Preternatural*, or acroſs, when, in labour, the arm, ſhoulder, ſide, breech, or any other part than the head of the fœtus preſent to the uterine orifice. See Labour, *Preternatural*, and Cross-*birth*.

Birth, *Laborious*, when in labour the head of the fœtus preſenting, yet on account of the ſtraitneſs of the pelvis, the pains are inſufficient for its expulſion, whence recourſe is neceſſarily had to the aſſiſtance of the laver, forceps, crochet, &c. See Laborious *Birth*, or Labour.

Birth, *Monſtrous*, when the fœtus is deformed or miſhaped, and has more or fewer organs than is natural. See Monster.

Births, *Seven Months*, partus ſeptimeſtris, children born at the end of the ſeventh month, or 210 days from the time of conception, being now complete in all their members, and having acquired a certain degree of ſtrength and firmneſs of conſtitution, are not unfrequently reared or brought up.

Births, *Eight Months*, partus octimeſtris, that is children born at the end of the eighth month, or after completing 240 or 242 days in the womb. Theſe were ſuppoſed by the ancients, but erroneouſly, to be leſs vivacious, and conſequently leſs likely to be preſerved alive, and to grow up to manhood, than ſeven months children. This opinion, founded on a miſtaken idea of the upright poſition of the fœtus in utero during the former months of pregnancy, and of the neceſſity of its making an evolution, about the end of the ſeventh month, to prepare it for the birth, is conſidered under the article *Poſition of the fœtus in Utero*, which ſee.

For the number of births, ſee Marriage; under which the proportion of *births* to marriages, of *births* to burials, and of male *births* to females is computed. See alſo Mortality.

Birth, *After*. See Placenta.

Birth is alſo uſed for a perſon's deſcent; and it is either high or low according to the circumſtances of his anceſtry.

Birth, Berth, or Birthing, among *Seamen*, denotes the due diſtance obſerved between ſhips lying at an anchor, or under ſail. A convenient place a-board for a meſs to put their cheſts, ſleep, &c. is alſo called a *birth*.—There is uſually one of theſe in ſhips of war between every two guns. And a proper place to moor a ſhip in is called by the ſame name, as is alſo the ſtation in which a ſhip rides at anchor. To *take a good birth*, is to remove to ſome diſtance off any point, rock, or other thing which the ſeamen would avoid or go clear of.

Birth, *Expoſition of*, among the *Ancients*, was where a new-born infant was expoſed or caſt away, and left to the mercy of the firſt-comer, who might either take and bring it up, or ſuffer it to periſh. See Exposing of *Children*.

Birth, *Suppoſition of*, *partus ſuppoſitio*, in the *Civil Law*, is a crime for which accuſation may be intented by thoſe who have intereſt therein, and is puniſhed with death, like the *crimen falſi*, or forgery.

Birth, *Suppreſſion of*, *partus ſuppoſitio*. See Abortion.

Birth-*Day*, the anniverſary return of the day on which a perſon was born. This anſwers to what the ancients called γενέθλιον, *genethlion*, *natalitius dies*, *natalitia*, and, in the middle age, *genetalius*. The ancients made much of their religion to conſiſt in the celebration of birth-days, and took omens from thence of the felicity of the coming year. We meet with birth-days of the gods, emperors, great men, poets, and even private perſons; and beſides, the birth-days of cities, as Rome and Conſtantinople, were celebrated with great pomp by the inhabitants. Virgil's birth day was held very ſtrictly by the wits and poets who ſucceeded him. Pliny (Epiſt. lib. iii. ep. 7.) aſſures us, that Silius kept it, with more ſolemnity than he did his own.

The manner of celebrating birth-days was by a ſplendid dreſs; wearing a ſort of rings peculiar to that day; offering ſacrifices, the men to their genius, of wine, frankincenſe; the women to Juno; giving ſuppers, and treating their friends and clients; who, in return, made them preſents, wrote and ſung their panegyrics, and offered vows and good wiſhes for the frequent happy returns of the ſame day. The birth-days of emperors were alſo celebrated with public ſports, feaſts, vows, and medals ſtruck on the occaſion. But the ancients, it is to be obſerved, had other ſorts of birth-days beſides the days on which they were born. The day of their adoption was always reputed as a birth-day, and celebrated accordingly.

The emperor Adrian, we are told, obſerved three birth-days; viz. the day of his nativity, of his adoption, and of his inauguration. (Fab. Bib. Græc. tom. xii. lib. vi. cap. 6.) In whoſe times it was held, that men were not born only on thoſe days when they firſt came into the world, but on thoſe alſo when they arrived at their chief honours and command in the commonwealth, e. gr. the conſulate. Hence that of Cicero in his oration Ad Quirites, after his return from exile: "A parentibus id quod neceſſe erat, parvus ſum procreatus, a vobis natus ſum conſularis." Beſides, thoſe who returned from baniſhment, were alſo conſidered as being born again, *renati*, and ever after called the day of their return their birth-day. Thus Cicero to Atticus: "Diemque natalem reditus mei cura ü in tuis ædibus amæniſſimis agam tecum, & cum meis." Cenſorinus has a treatiſe De Die *Natali*, addreſſed to Q. Cerellius; as a compliment on his birth-day.

Birth-*Days of the Saints and Martyrs*, *natales ſanctorum*, denote the days of their deaths.

In reality, *natalis* among the ancients, was not reſtrained to birth-days, but extended to all feaſt-days.

Hence it is we meet with *natalis ſolis*, *natalis calicis*, *natalis eccleſiæ*, *natalis reliquiarum*, &c.

Birth-*Sin*, in *Theology*, the ſame with *original ſin*, which ſee.

Birth-*Wort*, in *Botany*. See Aristolochia.

BIRTHA, in *Ancient Geography*, *Tekrit*, a town of Aſia, in Meſopotamia, on the Tigris, ſouth of the confluence of the Zabus Minor with this river.—Alſo, a town of Arabia Deſerta, ſeated on the Euphrates, according to Ptolemy.

BIRTHAMA, or Bithaba, a town of Aſia, in Aſſyria, according to Ptolemy.

BIRTHIN, in *Geography*, a river of Monmouthſhire, which runs into the Uſk, near the town of Uſk.

BIRU, a town of South America, in the empire of Peru, diſtant 10 leagues from Truxillo, and inhabited by about 70 families of Spaniards, Indians, Mulattoes, and Meſtizos. About half a league to the north of it is a rivulet, from which are cut ſeveral trenches for watering the grounds, which of courſe are equally fertile with thoſe in the vicinity of Truxillo. S. lat 8° 24′ 59″. W. long. 69° 17′.

BIRUCKPOUR, a fortreſs of Hindoſtan, in Malva

country, and circar of Chanderee; 55 miles eaſt of Chanderee.

BIRVIESCA, Birbusca, or Bribiesca, a mean and wretched town of Spain, in Old Caſtile, 15 miles N. E. of Burgos.

BIRUISA, a river of Siberia, which runs into the Tchinna. N. lat. 57° 35'. E. long. 95° 14'.

BIRUTCH, or Biruitsch, a town and diſtrict of Ruſſia, in the government of Voronetz, ſeated on the river Sofna, which falls into the Don; 50 miles ſouth of Voronetz.

BIRZA, or Birz, a town of Poland, in the palatinate of Troki. N. lat. 56°. E. long. 24° 40'.

BIS, in *Botany*, a name given by ſome old writers to the napellus, or monk's-hood, and by others to the cicuta or hemlock.

BIS, Lat. *twice*. In *Muſic*, when a paſſage which ought to be repeated, has, through miſtake, or to ſave room, been omitted, the word *bis* placed over ſuch paſſage, with dots at the beginning and end, implies that the whole is to be repeated.

Example.

Bis-*annual*, a name given by *Botaniſts* to thoſe plants which ordinarily do not flower till the ſecond year.

BISA, or Biza, a coin in Pegu, current there for half a ducat. The denomination is alſo given to a kind of weight uſed in the ſame country, equivalent to two Venetian pounds five ounces, or to three pounds nine ounces of the ſmaller weight of that city.

BISACCIO, in *Geography*, a town of Italy in the kingdom of Naples, 12 miles N.N.E. of Conza. N. lat. 41° 3'. E. long. 15° 35'.

BISACUTA, in *Middle Age Writers*, an ax with two edges, or which cuts either way; or a miſſive weapon pointed at both ends. Walſingham repreſents the *ſecuris bifacuta* as peculiar to the Scotiſh nation. See Battle-*Axe*.

BISALTÆ, in *Ancient Geography*, the name of a people who inhabited a ſmall country bordering on the Sinus Strymonicus, in the northern part of Macedonia. Their chief cities were Euporia, Oſſa, and Calitera.

BISALTIDE, in *Entomology*, a ſpecies of Papilio (*Dan. Feſt.*) that inhabits Surinam. The wings are ſlightly tailed, fulvous, black at the tips; beneath, two ocellar dots on the anterior pair, and three on the poſterior ones. Fabricius, &c.

BISAMRAZE, in *Zoology*, *Sorex moſchatus*, Gmelin, and *long-noſed beaver* of S. G. Gmelin, i't. &c.

BISAMTHIER, *Moſchus moſchiferus*, or *Thibet muſk* in Gefn. Quadr.

BISANTHE, or Rædistus, in *Ancient Geography*, a town of Thrace on the confines of the Propontis, at the bottom of a kind of gulf, and at a ſmall diſtance S.W. from Perinthe.

BISANT. See Besant.

BISBÆA, a feaſt celebrated by the Meſſapii, after the pruning of their vines, to obtain of the gods that they might grow again the better. The word is formed from βις, uſed by ſome for a *vine*.

BISCAINO, Bartolomeo, in *Biography*, an eminent artiſt, was born at Genoa in 1632, and inſtructed in the firſt principles of painting and deſign by his father Giovanni Biſcaino, a landſcape painter of reputation. He afterwards perfected himſelf, particularly in the art of colouring, under Valerio Caſtelli. By his early death, at the age of 25 years, the expectations of thoſe who admired his talents and performances were diſappointed. Some of his etchings are executed in a bold ſtyle, reſembling thoſe of Caſtiglione, but all more finiſhed. His figures are elegant, firmly compoſed, and drawn in a very maſterly manner; he has given beauty and character to the heads; and the other extremities are peculiarly correct, and marked with great ſpirit. Some of the principal are the following: "Moſes in the ark of bulruſhes;" A Nativity, with angels;" "The wiſe-men's offering;" "The Circumciſion of Chriſt;" and a "Bacchanalian." Strutt.

BISCARA, or Bescara, in *Geography*, a decayed city of Africa, in the kingdom of Algiers, the capital of the diſtrict of Zaab or Zeb, belonging to the province of Conſtantine. It is the reſidence of a Turkiſh garriſon, and has a ſmall caſtle, built by Haſſan, the bey of Conſtantine, and chiefly defended by ſix ſmall pieces of ordnance, and a few unwieldy muſkets, mounted on carriages. It is a place of great antiquity, built by the Romans, and deſtroyed by the Arabs, who afterwards rebuilt it. It is at preſent as indifferently peopled as it is weakly defended; the houſes being infeſted by ſwarms of ſcorpions, vipers, and poiſonous reptiles, and the inhabitants being obliged to deſert the city and retire into the country in the ſummer, when theſe noxious animals are intolerable. The inhabitants of this place, and its adjacent diſtrict, called "Biſcaris," lead a kind of wandering life, and live in tents. Few of them can be employed in agriculture and paſturage from the nature of the country; but thoſe of the ſuperior claſs carry on ſome commerce, notwithſtanding their poverty and indigence, in negroes and oſtrich feathers. The pooreſt of them migrate every year to the city of Algiers, and other towns of the kingdom, and are employed in the meaneſt and moſt ſubordinate offices, ſuch as cleanſing of ſtreets, emptying vaults, ſweeping chimnies, and carrying burdens. Having in the courſe of two or three years accumulated a capital of from ſix to ten zechins, they return home, and on account of the ſcarcity of coin among them, are reckoned among the wealthy of the land. In the capital, they conſtitute a kind of corporation, and have even a common treaſury for the purpoſe of mutually relieving one another. They are the only claſs of free ſervants, and are highly eſteemed for their fidelity. In winter, as well as in ſummer, they ſleep wrapped up in rags, on a kind of benches before the ſhops, and others place themſelves at the gates of the different roads, for the convenience of opening them to paſſengers. They are not only deſerving of the confidence that is repoſed in them, but their diſpoſition is placid and obliging, and their perſeverance in labour is indefatigable. Thoſe among them who are guilty of any breach of truſt, are puniſhed by their chiefs. They are employed by the Europeans as ſervants, and as they can ſpeak, beſides the language of the country, the "lingua Francia," are found ſingularly uſeful. The villages which they inhabit in their own country are ſmall, and remarkable only for their meanneſs and poverty. N. lat. 34° 30'. E. long. 5° 15'.

BISCARGIS, or Bissangis, in *Ancient Geography*, a town of Spain on the right ſide of the Iberus, N.W. of Dertoſa.

BISCAY, in *Geography*, a province of Spain, called "the lordſhip of Biſcay," is, in its moſt appropriate and reſtricted ſenſe, bounded on the north by the bay of Biſcay, on the ſouth

ſouth by a chain of the Pyrenées, which ſeparates it from Old Caſtile and Alava, on the weſt by Aſturias, and on the eaſt by Guipuſcoa; and in extent its length is about 116 miles, and breadth much leſs, the greateſt breadth being 80 miles, but very unequal. In its more general and comprehenſive ſenſe, Biſcay is divided into three parts; viz. Biſcay, properly ſo called, Guipuſcoa, and Alava; and, accordingly, it is bounded on the weſt by that narrow tract of Old Caſtile which reaches to the ſea and Aſturias; parted from Old Caſtile on the ſouth-eaſt by the ridge of the Aſturian mountains branching from the Pyrenées, and by the ſame mountains from Navarre, and by the river Cidarſo from France, on the eaſt; and waſhed on the north ſide by the Cantabrian ſea, now commonly called the bay of Biſcay. The country is for the moſt part mountainous and barren; but its vallies produce corn ſufficient for the ſupply of the inhabitants, and a ſmall quantity of flax. Apples are very plentiful, of which is made cyder, the common beverage of the people. They have alſo a weak wine, called "Chacolino," which is pleaſant, though it will not keep long, and is uſed inſtead of ſmall beer. They have alſo citrons and oranges in great abundance. The adjacent ſea ſupplies excellent fiſh, and the foreſts yield great quantities of timber for ſhipping. But the moſt valuable treaſure of this country conſiſts of its inexhauſtible mines of excellent iron, which is tranſported from hence into all parts of the world. The country has been long famous for its iron-works, and eſpecially for its manufacture of ſwords and knives. Some have computed the amount of its annual manufacture of iron and ſteel into arms, nails, iron tools, bars, &c. at 300,000 quintals. The air of this province is mild, pure, and more temperate than that of the other provinces of Spain; and the inhabitants have been diſtinguiſhed by their attachment to liberty, and reſiſtance to oppreſſion. Their anceſtors, the Cantabri, were but imperfectly ſubdued by Auguſtus, and their mountains have, in every ſucceeding age, afforded them a retreat from the encroachments of arbitrary power. The Biſcayners are ſaid to be of Celtic or Gothic extract; and have preſerved more of their ancient genius, laws, government, and language, than perhaps any other people in Europe, except the Welſh, Scots Highlanders, and wild Iriſh, who are probably of the ſame origin, and whoſe language much reſembles the Biſcayan. They have always maintained a diſtinguiſhed reputation for valour; and the beſt ſoldiers and ſailors of Spain have been the natives of this country. They eſſentially differ from the other Spaniards in the openneſs of their temper, and animation of their manner; and though they are choleric even to a proverb, and not deſtitute of pride and vanity, they are obliging, polite, and friendly. Their females are beautiful, lively, and cheerful. Their dreſs is neat and paſtoral; their hair falling down their backs in long plaits, with a handkerchief twiſted round it. The moſt ſingular part of the dreſs of the men is the covering of their legs, round which they wrap a piece of coarſe grey or woollen cloth, faſtening it with many folds of tape. The three provinces of Biſcay, Alava, and Guipuſcoa, have been the aſylum of liberty and induſtry, and to theſe cauſes their proſperity may be aſcribed. When the king, who is ſtyled merely "lord of Biſcay," wants a ſupply either of men or money, he announces his will to the province; which furniſhes its contingency of both; the latter being levied upon the different cities and communities, according to a certain regiſter, ſo that in effect Biſcay may be ſaid to tax itſelf. In this province are no biſhops. Its privileges, which are extenſive, it has watched over with a jealous eye. The language of Biſcay is accounted aboriginal; it is ſaid to be the Cantabrian, or ancient language of Spain, which was a branch of the Celtic, and firſt gave way to the Romaniſh; which ſee. It is ſo totally different from the Caſtilian, that the peaſants ſcarcely underſtand a ſingle word of Spaniſh. The capital of Biſcay is Bilbao, which ſee. Its other chief towns are Orduna, Durango, Fontarabia, St. Sebaſtian, Toloſa, and Vittoria.

Biscay, *Bay of*, that part of the Atlantic which lies north of the province of Biſcay, between the projecting coaſts of France and Spain, and extends from cape Ortegal to Breſt. It advances fartheſt to the land between Bayonne and St. Sebaſtian; and it likewiſe advances conſiderably at Rochelle and Rochefort.—Alſo, a large bay on the coaſt of Newfoundland, between cape Race and cape Pine. It lies in the N.E. corner of Trepaſſey bay, on the S.E. part of the iſland. N. lat. 46° 50′. W. long. 53° 6′.

Biscay, *New*, a province of Mexico in North America, in the audience of Guadalajara, bounded on the north by New Mexico, on the eaſt by New Leon and the river Bravo, on the ſouth by Cinaloa and Culiacan, and on the weſt by Navarre, Sonora, and Haqui, on the borders of the gulf of California. It is computed to be about 300 miles from eaſt to weſt, and 360 from north to ſouth. The country is mountainous, but well watered, fruitful, and moderately temperate, rich in corn, cattle, and other productions; and alſo in mines of ſilver and lead. The original inhabitants have four large towns in the moraſſes, which are difficult of acceſs, and by means of which they avoid total ſubjection; and therefore the Spaniards have built three ſmall fortified and well inhabited towns for the defence of their ſilver mines. The capital is Durango. This province lies between the latitudes of 27° and 33° N. and between 105° and 108° W. long.

BISCEGLIA, a town of Naples, in the province of Bari, having the ſee of a biſhop, ſuffragan of Trani; it is pleaſantly ſituated on an eminence in the midſt of orchards and villas. The walls are of ſtone and very lofty; and it has hundreds of ſubterraneous refervoirs and ciſterns, cut in the ſolid rock, and arched over with ſtones and ſtucco, in order to collect and preſerve the rain-water, which is the only ſort with which they are ſupplied in a diſtrict, ſo totally deſtitute of ſprings. Biſceglia is 4 miles diſtant from Trani.

BISCHBURG, or Bischofsburg, a town of Pruſſia, in the county of Ermeland, 54 miles ſouth of Konigſberg.

BISCHEIM, a town of Germany, in the circle of the Upper Rhine, and county of Lichtenberg, on a ſmall river which runs into the Rhine, 8 miles N. E. of Straſburg.

BISCHOFFLACK, or Schotia Koloka, a town of Germany, in the duchy of Carniola, 27 miles N.N.E. of Trieſte.

BISCHOFFSHEIM, a town of Germany, ſeated on the Tauber, in the circle of Franconia, but belonging to the electorate of Mentz; 64 miles S.E. of Mentz.

BISCHOFFSTORF, a town of Germany, in the duchy of Stiria, 13 miles E.N.E. of Gratz.

BISCHOFSHEIM, a town of Germany, in the circle of Franconia, and biſhopric of Wurzburg, ſeated on the Rhom, 32 miles north of Wurzburg.—Alſo, a town of Germany, in the circle of the Upper Rhine, and county of Hanau-Munzenburg, 3 miles W.N.W. of Hanau.

BISCHOFSTEIN, or Bistein, a town of Pruſſia, in the county of Ermeland, 42 miles ſouth of Konigſberg.

BISCHOFSWERDA, a town of Germany, in the circle of Upper Saxony, and margraviate of Meiſſen, ſeated on

an iſland in the river Weſenitz, the principal commerce of which is in white thread; it has two churches; 20 miles eaſt of Dreſden.

BISCHOFSWERDER, a town of Pruſſia, in the province of Oberland, 80 miles S.S.W. of Konigſberg.

BISCHOFZELL, a town of Swiſſerland, in the Thurgaw, ſeated at the confluence of the rivers Sitter and Thur, 11 miles ſouth of Conſtance. This town has a caſtle, in which reſides the bailiff of the biſhop of Conſtance, who exerciſes juriſdiction over the Catholics, and receives a moiety of the fines. N. lat. 47° 25′. E. long. 9° 13′.

BISCHOP, or Biskop, John de, in *Biography*, an excellent artiſt, was born at the Hague in 1646, and is much commended as a painter; and his drawings, in which he imitated with great exactneſs the ſtyle of the beſt maſters, are much eſteemed and ſought after by the curious. But he is moſt generally known as an engraver. His works are chiefly etchings, harmonized with the graver; and though ſlight, yet free, ſpirited, and pleaſing. He gives a richneſs to the colour, and a roundneſs to the figures, far beyond what is uſually done with the point, ſo little aſſiſted by the graver. His figures are generally well drawn, more in a manner than a correct ſtyle; but his extremities are not always well marked, nor his heads equally expreſſive and beautiful. His excellence was owing chiefly to his own genius, as he never ſtudied under any maſter. He worked chiefly at Amſterdam, and died in 1686. The following prints are worthy of notice: viz. "Chriſt and the Samaritan woman," from Annibale Caracci; "Joſeph diſtributing corn to the Egyptians," from B. Breenberge; "The Martyrdom of St. Laurence," from the ſame. Strutt.

Bischop, or Biskop, Cornelius, a painter of portrait and hiſtory, was born at Antwerp, ſay ſome, or, according to others, at Dort, in 1630, and was the diſciple of Ferdinand Bol, whoſe pencil, tint of colouring, ſtyle, and manner, he reſembled, and to whom he has been thought by ſome competent judges not to be inferior. He died in 1674. A painting by this maſter, conſiſting of a few figures by candle-light, was ſo much admired by Louis XIV., that he purchaſed it at a high price, and placed it in the royal collection. The king of Denmark alſo admitted his works among thoſe of the beſt maſters. It is obſerved, however, that they are not worthy of that high commendation which is beſtowed upon them by the Flemiſh writers. Pilkington.

BISCHWILER, in *Geography*, a town of France, in the department of the Lower Rhine, and chief place of a canton in the diſtrict of Straſburg, ſeated on the Motte near the Rhine, and defended by a caſtle, flanked with towers, and guarded by ditches; 10 miles north of Straſburg. The town contains 3449 inhabitants, and the canton 13,968. Its territorial extent comprehends 265 kiliometres, and 21 communes.

BISCIA, in *Ichthyology*, one of the ſynonymous names among old writers for the pipe-fiſh, tobacco-pipe-fiſh, needle-fiſh, or trumpet-fiſh; and *ſyngnathus acus* of Linnæus and Gmelin.

BISCOPSVAARE, in *Geography*, a town of Norway, 48 miles eaſt of Bergen.

BISCROMA, Ital. for a demiſemiquaver, in *Muſic*. If ſingle, it has three hooks ; if two or more, they have three ties . See Time-table.

BISCUIT. See Bisket.

Biscuit, in *Pottery*, a name given to porcelain, when baked and not glazed; and this is more or leſs beautiful, according to the nature of its compoſition. See Porcelain, and Pottery.

BISCUTA, in *Entomology*, a ſpecies of Formica, with a bidentated thorax; and a double petiole ſcale. Inhabits Cayenne. Fabricius Spec. Inſ.

BISCUTELLA, formed of *bis*, and the diminutive of *ſcutum*, the fruit reſembling a double ſhield, in *Botany*, *Buckler muſtard*, or *baſtard Mithridate muſtard*. Lin. gen. 808. Reich. 872. Schreb. 1084. Juſſ. 239. Gærtn. t. 141. Thlaſpidium. Tournef. 101. Claſs and Order, *tetradynamia ſiliculoſa*. Nat. Ord. *ſiliquoſæ*, *cruciformes*, or *cruciferæ*. Gen. Char. *Cal.* perianth four leaved; leaflets ovate, acuminate, gibbous at the baſe, coloured, deciduous. *Cor.* four-petalled, cruciform; petals oblong, obtuſe, ſpreading. *Stam.* filaments ſix, the length of the tube of the corolla; two oppoſite ſhorter; anthers ſimple. *Piſt.* germ compreſſed, orbiculate, emarginate; ſtyle ſimple, permanent; ſtigma obtuſe. *Per.* ſilicle erect, compreſſed, flat, ſemibifid, with roundiſh lobes, two-celled; partition lanceolate, ending in a rigid ſtyle; cells two valved, affixed to the partition, on its ſtraight margin. *Seeds.* ſolitary, roundiſh, compreſſed, in the middle of the cell. *Obſ.* The two outer leaflets of the calyx in ſome ſpecies have a tubular-concave melliferous prominent baſe.

Eſſ. Char. *Silicle* compreſſed, flat, rounded above, and below two-lobed. *Cal.* leaflets gibbous at the baſe.

Species, 1. B. *auriculata*, ear-podded buckler-muſtard. Thlaſpi. Bauh. pin. 107. n. 3. prodr. 49. n. 8. Raii hiſt. 837. n. 4. Leucoium montanum ſ. pedato. Col. ecphr. 2. 59. t. 61. Jondraba Barr. ic. 230. "Calyxes gibbous on each ſide with the nectary, filicles running into the ſtyle." In a wild ſtate this plant riſes about a foot in height, but in gardens nearly two feet, dividing into ſeveral branches; the flowers are produced at the ends of the branches in looſe panicles, and are of a pale yellow colour. The nectarious gland is very large, and the calyx bagged out very much at the bottom. A native of the ſouth of France and Italy. Cultivated in Kew garden by Mr. J. Sutherland in 1683, and flowering in June and July. 2. B. *apula*, ſpear-leaved buckler-muſtard. B. didyma. Lin. ſpec. 911. Hort. Cliff. 329. 2. Upſ. 185. Thlaſpi. Raii hiſt. 837. n. 3. Clypeatum. Cluſ hiſt. 2 133. Jondraba. Col. ecphr. 1. 283. t. 285. f. 1. "Silicles ſcabrous; leaves lanceolate, ſeſſile, ſerrate." A native of Italy. Cultivated in 1759, by Mr. Miller. Flowering in June and July. 3. B. *lyrata*. Thlaſpi biſcutatum, &c. Bocc. ſic. 45. t. 23. Raii hiſt. 837. n. 6. "Silicles ſcabrous; leaves lyrate." A native of Spain and Sicily. 4. B. *coronopifolia*. "Silicles ſmooth; leaves toothed, rough with hairs." Allioni thinks this a variety of the ſecond, proceeding from a dryneſs of ſoil; for it is found in very dry barren places in Spain, Italy, and Germany. Gouan is of opinion that this and the ſecond, third, and fourth are one ſpecies. 5. B. *lævigata*. ſmooth buckler-muſtard. B. didyma. Scop. Carn. n. 804. Clypeola didyma. Crantz. Auſtr. 20. Leucoium. Col. ecphr. 1. 283. t. 285. f. 2. Raii hiſt. 836. n. 2. "Silicles ſmooth; leaves lanceolate, ſerrate." The whole plant is acrid; the root perennial, according to Jacqui, but, according to others, annual. A native of Italy and Auſtria. Found at very different heights in the mountains, with variation of ſtature, from half a foot to a foot and a half. Flowering in lower ſituations in April and May; in higher ones in July and Auguſt; in our gardens in June and July. Introduced here in 1777 by M. Thouin. 6. B. *ſempervirens*, ſhrubby buckler-muſtard.

muſtard. Thlaſpi biſcutellatum, &c. Barr. ic. t. 841. Bocc. muſ. 197. t. 122. "Silicles ſomewhat ſcabrous; leaves lanceolate tomentoſe." A native of Spain. Introduced into Kew garden in 1784 by Meſſrs. Lee and Kennedy.

Propagation and Culture. Theſe are all annual plants, except the laſt, and periſh ſoon after they have perfected their ſeeds. They ſhould be ſown in ſpring or autumn, upon a border of light earth, in an open ſituation, where they are to remain. Thoſe ſown in autumn will come up in about three weeks, live through the winter, and flower early in the following ſummer, and thus good ſeeds may be always obtained; but thoſe that are ſown in the ſpring decay in bad ſeaſons before the ſeeds are ripe. The autumnal plants flower in June, and the ſpring plants in July, and their ſeeds ripen in about ſix weeks, and if they are permitted to ſcatter, young plants will be produced without any care. They require only to be kept free from weeds, and to be thinned where they are too cloſe, leaving them eight or nine inches aſunder. They have no great beauty to recommend them. Martyn's Miller.

BISDORF, in *Geography*, a town of Germany, in the circle of Upper Saxony, and principality of Anhalt-Cothen, 3 miles north of Cothen.

BISECTION. See Bissection.

BISELLIARII, or Biselliari, in *Antiquity*, thoſe who enjoyed the honour or privilege of the biſellium.

The word occurs in ancient inſcriptions. Cn. Plaetorio Viviro Augustali Biselliario. Gruter. Inſcr. p. 1099.

The *honor biſellii* appears to have been much the ſame with what in France is called *droit de fauteuil;* and the biſelliarii thoſe who in public aſſemblies enjoy this diſtinction of the *fauteuil*, while other perſons are obliged to ſtand, or ſit on benches, ſtools, or ordinary chairs. Scaliger, in his index to Gruter, miſtook the biſelliarii for artificers who made theſe ſeats.

BISELLIUM, from *bis* and *ſella*, *a chair*, a kind of ſeat or chair, larger and richer than ordinary, big enough to hold two perſons, wherein to ſit in courts, theatres, and other public aſſemblies.

BISEPTEMGUTTATA, in *Entomology*, a ſpecies of Coccinella, of a pale yellow colour, with fourteen white ſpots. Schaller. Country unknown.

BIS-ERGOT, in *Ornithology*, a name given by Buffon to the Gmelinian *tetra bicalcaratus*.

BISERRULA, ſo named from the fruit "biſerrato fructu," in *Botany*. Lin. Gen. 893. Reich. 966. Schreb. 1209. Juſſ. 358. Gærtn. t. 154. Pelecinus, Tourneſ. 234. Claſs and order, *diadelphia decandria*. Nat. Ord. *Papilionaceæ* or *leguminoſæ*. Gen. Char. *Cal.* perianth, one-leaved, tubular, erect, ſemiquinquefid; teeth ſubulate, equal, the two upper ones more remote. *Cor.* papilionaceous; banner larger, reflected on the ſides, aſcending, roundiſh; wings ovate-oblong, free, ſhorter than the banner; keel the length of the wings, obtuſe, aſcending. *Stam.* filaments diadelphous (ſimple and nine-cleft), aſcending at their tips, incloſed within the keel; anthers ſmall. *Piſt.* germ oblong, compreſſed; ſtyle tubulate, aſcending; ſtigma ſimple. *Per.* legume large, linear, flat, two-celled; partition contrary to the valves. *Seeds* very many, kidney-form, compreſſed.

Eſſ. Char. legume two-celled, flat; partition contrary.

Species. 1. B. *Pelecinus*, baſtard hatchet-vetch. Aſtragalus. Mor. hiſt. 2. 107. ſ. 2. t. 9, f. 6. Securidaca. Bauh. Pin. 349. 3. Cluſ. hiſt. 2. 238. Ger. emac. 1234. f. 6. Park. Theatr. 1089. f. 5. Raii hiſt. 939, n. 16. Lunaria radiata Robini. Bauh. hiſt. 2. 348. f. 2. An annual plant, growing naturally in Italy, Sicily, Spain, and the ſouth of France. Cultivated in Kew garden in 1640.

Propagation and Culture. It is propagated by ſeeds, ſown in this country in autumn, on a bed of light earth, where the plants will come up in about three weeks, and live well in the open air. They ſhould either be ſown where they are to remain, or tranſplanted when very young. After the plants are come up, they will only require to be kept free from weeds, and to be thinned to the diſtance of a foot from one another. They flower in June, and the ſeeds ripen in September. They may be alſo ſown in ſpring, and treated in the ſame manner. Two or three of theſe plants may be cultivated for the ſake of variety, but they have not much beauty. Martyn's Miller.

BISERT, in *Geography*, a town of Ruſſia, ſeated on a ſmall river which runs into the Upha, in the government of Perm, 80 miles S.S.E. of Perm.

BISERTA, or Bizerta, a ſea-port town of Africa, in the kingdom of Tunis, pleaſantly ſituated upon a canal betwixt an extenſive lake and the ſea, at the bottom of a large gulf, about 8 miles to the ſouthward of Cape Blanco. N. lat. 37° 5′. E. long. 10° 15′. It is about a mile in circuit, defended by ſeveral caſtles and batteries, the principal of which are towards the ſea. Bizerta is a corruption of the "Hippo-Diarrhytus" or "Zaritus" of the ancients; though the preſent inhabitants derive its name from their own language, and ſuppoſe it to be the ſame with "Benſhertd," i. e. the offſpring of a canal or rivulet. The lake upon which Bizerta is ſeated has an open communication with the ſea; and, according to an obſervation of the younger Pliny (Ep. xxxiii. l. 9.), is either continually receiving a freſh ſtream from the ſea, or elſe diſcharging one into it; ſo that the water loſt by the lake by exhalations is ſoon ſupplied by the ſea, which in hot ſeaſons runs into it with a very briſk current, in order to maintain the equilibrium, in the ſame manner as is obſerved between the Atlantic ocean and the Mediterranean. The millets of this lake are reckoned the beſt in Barbary. Great quantities of their roes are dried and made into "Botargo," and ſent from hence to the Levant, where they are eſteemed a great dainty. The channel of communication betwixt the lake and the ſea is the port of "Hippo-Diarrhytus," which ſtill receives ſmall veſſels; though it muſt have been formerly the ſafeſt as well as the moſt beautiful haven of this part of Africa. There are ſtill remaining the traces of a large pier, that was carried out into the ſea, to break off the N.E. winds; the want of which, together with the diſinclination of the Turks to repair it, will in a ſhort time make the haven uſeleſs, which, in any other country, would be ineſtimable. Scylax calls it only "Hippo," and Diodorus Siculus gives it the name of "Hippoacra." By the direction of Scipio's marches it ſeems to have been the rich anonymous town mentioned by Livy (l. xxix. 28.). If the Turks encouraged trade and induſtry it would deſerve this appellation, becauſe, beſides fiſh and fruit of all kinds, it abounds with corn, pulſe, oil, cotton, and a variety of other valuable productions. The gulph of Bizerta, the "Sinus Hipponenſis" of the ancients, is a beautiful ſandy inlet, nearly four leagues in breadth. As its bottom is low, it affords a delightful proſpect, through a variety of groves and plantations of olive trees, to a great diſtance into the country; but to the caſtward, the view is bounded by a high rocky ſhore, extending as far as cape Zibeeb. Bizerta was formerly a large town, and is ſaid to have contained 6000 houſes; whereas now the town, and its dependent villages, ſcarcely contain the ſame number of inhabitants. It has, nevertheleſs, two capacious priſons for ſlaves, a large

magazine for merchandiſe, and two towers, with ſome other out-works to defend the entrance of the haven. It is well ſupplied with freſh water from the ſurrounding ſprings, and with great variety of fiſh from the adjacent lake. Moſt of the inhabitants are employed in the fiſhing trade, which begins about the end of October, and ends in the beginning of May. The people are poor, and reckoned proud, ill-natured, and treacherous; inſomuch that Muley Haſun Bey, one of their ſovereigns, uſed to ſay of them, that neither fear nor love could keep them faithful. Bizerta has eight villages under its government, a large plain called "Mater," and the territory of Choros, the "Clypea" or "Corobis" of the ancients, which is extenſive, and inhabited by a number of perſons who are poor, meanly clad, and coarſely fed. Their dreſs conſiſts merely of a piece of coarſe cloth wrapped round their bodies, and another, in the form of a turban, round their heads; and moſt of them are without covering either to their feet or legs. Thoſe of the poorer claſs ſleep on ſkins laid on the floor; and the rich lie in narrow couches fixed againſt the wall, about 5 or 6 feet high, to which they aſcend by a ladder. Their choiceſt dainty is their "couſcou," made of flour, eggs, and ſalt, which they dry and keep through the year. They are expert horſemen, and ride without either ſaddle or bridle; nor do they ever ſhoe their horſes. They are much expoſed to the depredations and oppreſſions of the neighbouring Arabs. The Biſertines, both of the city and country, are very ſuperſtitious, and hang about their own necks, and thoſe of their horſes, a number of amulets, which are ſcraps of paper or parchment, on which ſtrange characters are inſcribed, and ſewn up in a piece of leather, ſilk, &c. and thought, when worn about their perſons, to be a preſervative againſt all accidents.

BISET, Charles Emanuel, in *Biography*, a painter of hiſtory and converſations, was born at Mechlin, in 1633; and in his early productions manifeſted a lively and ready invention. He was diſtinguiſhed by the multitude of figures which he introduced into his deſigns, and by his variety of drapery, peculiar to every nation. At a diſtance, his pictures, which conſiſted chiefly of balls, concerts, and gay aſſemblies, correctly deſigned and well-coloured, had a ſtrong effect; but more nearly inſpected, they ſhewed a neatneſs of pencil, a ſpirited touch, and a good expreſſion. Pilkington.

Biset, in *Ornithology*, *Columba livia*, or ſtock dove, in Buffon's Hiſt. Birds.

BISHOP, in *Eccleſiaſtical Hiſtory*, a prelate, or perſon conſecrated for the ſpiritual government and direction of a dioceſe. The word comes from the Saxon *biſchop*, and that from the Greek επισκοπος, an *overſeer* or *inſpector*; which was a title the Athenians gave to thoſe whom they ſent into the provinces ſubject to them, to ſee whether every thing was kept in order; and the Romans gave the ſame title to thoſe who were inſpectors and viſitors of the bread and proviſion. It appears from a letter of Cicero, that he himſelf had a biſhopric; being "epiſcopus Oræ et Campaniæ."

A biſhop differs from an archbiſhop in this, that an archbiſhop with biſhops conſecrates a biſhop, as a biſhop with prieſts ordains a prieſt; that the archbiſhop viſits a province, as the biſhop a dioceſe; that the archbiſhop convocates a provincial ſynod, as the biſhop a dioceſan one; and that the archbiſhop has canonical authority over all the biſhops of his province, as the biſhop over the prieſts in his dioceſe. It is a long time ſince biſhops have been diſtinguiſhed from mere prieſts or preſbyters; but whether that diſtinction be of divine or human right, whether it was ſettled in the apoſtolical age, or introduced afterwards, is much controverted. Thoſe who are advocates for the divine right of epiſcopacy, and who trace its inſtitution to the times of the apoſtles, maintain that, in the earlieſt age of the Chriſtian church, there were three different orders of miniſters appointed by the apoſtles for the diſcharge of the public offices of religion; viz. biſhops, prieſts, or preſbyters, and deacons. In proof of this point they refer us to the teſtimony of ancient eccleſiaſtical writers, whence they deduce, as they conceive, the moſt ſatisfactory evidence, that biſhops were inſtituted by the apoſtles, and that they continued afterwards as a diſtinct order from that of prieſts. To this purpoſe they allege, that Irenæus, a father of the ſecond century, ſays (l. iii. c. 3.), "We are able to enumerate thoſe who by the apoſtles were made biſhops in the ſeveral churches, and their ſucceſſors, to this time." He adds, "Polycarp was not only inſtructed by the apoſtles, and acquainted with many of thoſe who ſaw our Lord, but was alſo by the apoſtles made biſhop of the church of Smyrna in Aſia." Tertullian alſo, a writer of the ſame century (De Præſcr. adv. Hæret. p. 78.), challenges certain heretics to "exhibit the order of their biſhops, ſo ſucceeding each other from the beginning, that the firſt biſhop had for his author and predeceſſor ſome one of the apoſtles, or of thoſe apoſtolical men who perſevered with the apoſtles; for in this manner apoſtolical churches aſſert their rights: thus, the church of Smyrna has Polycarp, who was placed there by John; the church of Rome has Clement, who was ordained by Peter; and other churches ſhew other perſons, who, by being placed in the biſhoprics by the apoſtles, tranſmitted the apoſtolical ſeed." Cyprian alſo ſays (Ep. 69. ad Flor.), "that the biſhop, who is one and preſides over the church, through the proud preſumption of certain perſons, is deſpiſed; and thus the man, who is honoured by the ſanction of God, is judged unworthy by men." In an epiſtle aſcribed to Ignatius (Ad Antioch. c. 7), but probably ſpurious, though very ancient, it is aſſerted, that Evodius was conſecrated a biſhop by the apoſtles. And Chryſoſtom ſays (Hom. 42. in Ignat.), "that Ignatius converſed familiarly with the apoſtles, and was perfectly acquainted with their doctrine, and had the hands of apoſtles laid upon him." In a fragment of an epiſtle of Dionyſius, biſhop of Corinth in the ſecond century, preſerved by Euſebius (H. E. l. 4. c. 23.), it is ſaid, that Dionyſius the Areopagite, who was converted by St. Paul, was appointed the firſt biſhop of Athens. Euſebius and Socrates have given us the catalogues of the biſhops of many cities, from the times of the apoſtles; and Epiphanius (lib. 2. Hær. 66.) has left us a catalogue of the biſhops of Jeruſalem, from St. James the apoſtle to Hilarion, who was biſhop in his time. It is further alleged, that biſhops, prieſts, and deacons, are mentioned together as three ſeparate orders. Ignatius, in his Epiſtle to the Magneſians (§ 2.), mentions Damas as biſhop of Magneſia, Baſſus and Apollonius as preſbyters, and Sotian as deacon, in the ſame church; and in his epiſtle to the Philadelphians (§ 7.), he ſays, "Attend to the biſhop, to the preſbytery, and to the deacons;" and in his epiſtle to the Trallians (§ 2.), he ſays, "Be ye ſubject to the biſhop, as to Jeſus Chriſt; to the preſbyters, as the apoſtles of Jeſus Chriſt; and to the deacons, as to miniſters of the myſteries of Jeſus Chriſt;" he then adds, (§ 3.), "without theſe there is no elect church, no congregation of holy men." The authority of Ignatius, who lived in the beginning of the ſecond century, is conſidered as deciſive. Clement of Alexandria, in the ſubſequent part of the ſame century, ſpeaks of the three progreſſive orders of deacons, prieſts, and biſhops (Strom. l. 6.); and there are ſeveral early inſtances of biſhops, who had been preſbyters and deacons in the ſame church. Irenæus was firſt preſbyter, then biſhop

biſhop of Lyons; Dionyſius firſt preſbyter, then biſhop of Rome; and Eleutherius, firſt deacon, then biſhop of Rome; and all theſe three lived in the ſecond century. "When your captains," ſays Tertullian (De Fugâ in Perſ.), "that is to ſay, the deacons, preſbyters, and biſhops fly, who ſhall teach the laity that they muſt be conſtant? And upon another occaſion, ſpeaking of baptiſm, he ſays (De Baptiſm. c. 17.), "the high-prieſt, who is the biſhop, has the chief right of adminiſtering it, then the preſbyters and deacons, but not without the authority of the biſhop." Origen, in many places, ſpeaks of biſhops as ſuperior to preſbyters and deacons; and many authors compare the biſhops, called by the Greeks ἀρχιερεῖς, and by the Latin fathers "ſummi ſacerdotes" and "principes ſacerdotum," preſbyters and deacons of the Chriſtian church, to the high-prieſt, prieſts, and Levites under the Jewiſh diſpenſation; and hence preſbyters afterwards obtained the name of prieſts. Clement, a diſciple of the apoſtle, ſays (Ep. ad Cor. § 40), "To the high-prieſt are given his proper duties; to the prieſts their proper place is aſſigned; and to the Levites their proper ſervices are appointed:" in which paſſage this ancient father is ſpeaking of the biſhop, preſbyters, and deacons of the Chriſtian church; and Tertullian, in the paſſage juſt cited, called the biſhop the high-prieſt. Jerome, though he is ſometimes repreſented as unfavourable to the cauſe of epiſcopacy, is ſtill more expreſs, and denominates (Epiſt. ad Evag.) the order of biſhops, prieſts, and deacons, an apoſtolical tradition. "To what purpoſe," ſays Optatus (lib. i.), "ſhould I mention deacons, who are in the third, and preſbyters, who are in the ſecond degree of prieſthood, when the very heads and princes of all, even certain of the biſhops themſelves, were content to redeem life with the loſs of heaven?" In the tenth canon of the council of Sardis, held A. D. 347, it is enjoined that a perſon ſhould not be raſhly and lightly appointed a biſhop, a prieſt, or a deacon. It is further pleaded, that epiſcopal power was not called in queſtion in the three firſt centuries; but towards the end of the fourth century, Aerius, an Arian, wrote againſt it, and maintained that there ought to be no order in the church ſuperior to that of preſbyters. Nevertheleſs, it is alleged, that no advocate is found for his opinion in the centuries immediately following; and that even Aerius allowed there had been biſhops in the Chriſtian church from the earlieſt period. From theſe ſeveral teſtimonies it is inferred, that biſhops were appointed by the apoſtles; that there were three diſtinct orders of miniſters, viz. biſhops, prieſts, and deacons, in the primitive church; and that there has been a regular ſucceſſion of biſhops from the apoſtolic age to the preſent time; and the enemies of epiſcopacy are challenged to produce evidence of the exiſtence of a ſingle ancient independent church fairly eſtabliſhed, which was not governed by a biſhop. While the apoſtles lived, the churches, it is ſaid, were ſubject to their authority and government; and to this circumſtance it is owing, that little is ſaid concerning the diſtinction and power of miniſters, in the Acts and Epiſtles; but when the goſpel was ſpread into diſtant parts, and the apoſtles were under a neceſſity of diſcontinuing their viſits, or rendering them leſs frequent, they found it expedient for the better government of the Chriſtians, and in order to put a ſtop to their ſchiſms and contentions, which began to make their appearance both among the preſbyters and their congregations, to place the ſupreme authority in one perſon, who, from the ſuperintending care which he was to exerciſe, was called Επισκοπος, a biſhop; and this word, which was perhaps at firſt applied indiſcriminately to all who had any ſpiritual office in the church, was now conferred on him who was its chief governor.

The biſhops were at firſt appointed by the apoſtles, and afterwards choſen by the preſbyters and the congregations at large; and in both caſes they were generally taken from the preſbyters of the reſpective churches, except in thoſe inſtances in which they were the immediate companions of the apoſtles. Accordingly Jerome, (De Eccleſ. Script.) where he is ſpeaking, as it is ſuppoſed, of the apoſtolical times, in which James was made biſhop of Jeruſalem by the apoſtles; Timothy biſhop of Epheſus, and Titus biſhop of Crete, by St. Paul; and Polycarp biſhop of Smyrna, by St. John; obſerves, that "churches were governed by the common advice of preſbyters; but when every one began to reckon thoſe whom himſelf had baptized, his own, and not Chriſt's, it was decreed in the whole world, that one, choſen out of the preſbyters, ſhould be placed over the reſt, to whom all care of the church ſhould belong, and ſo the ſeeds of ſchiſm ſhould be removed." When St. Paul was at Miletus, A.D 58, and convened the elders of the church at Epheſus, no mention is made of the biſhop; and in his addreſs to them he calls them "biſhops or overſeers of the flock;" hence it is inferred, that the word biſhop was not then the appropriate name of the perſon who held the firſt office in the church, or rather, that there was as yet no ſuch perſon in the church at Epheſus. But in the year 64, St. Paul found it neceſſary to place Timothy in that ſituation, with power to prevent the preaching of any unſound doctrine, and to ordain and exerciſe authority over preſbyters, that is, with epiſcopal power; and in his epiſtle, written to him in that year, he ſpeaks expreſsly of the "office of a biſhop," and gives a detailed account of the qualifications of a biſhop. See 1 Tim. i. 3. v. 1, 19, 22. 1 Tim. iii. 1. We have alſo a ſimilar account in the epiſtle to Titus, written in the ſame year; and he was inveſted with the further power of rejecting heretics from the churches over which he preſided. See Titus iii. 10. Hence it is concluded, that in the year 64 there was ſuch an office as that of biſhop. St. Paul, addreſſing his epiſtle to the Philippians, uſed the word biſhops in the plural number, and does not mention preſbyters; whence it is thought by Chryſoſtom, Theodoret, Jerome, and indeed by almoſt all commentators, that by biſhops we are here to underſtand preſbyters; and it is therefore preſumed, that there was then no biſhop, in the ſtrict ſenſe of the appellation, at Philippi, A. D. 62. From a compariſon of theſe different paſſages it has been conjectured, that Paul began to eſtabliſh epiſcopacy immediately after his releaſe from his firſt confinement at Rome. However, it is acknowledged, that at this early period there was not a biſhop in every church. Nevertheleſs, it is inferred from St. Paul's epiſtles, that he gave the miniſters of the churches which he founded, a certain power over their reſpective congregations, and as St. Paul and the twelve apoſtles acted equally under the influence of the Holy Ghoſt, it is preſumed, that they inveſted all, whom they appointed to preach the goſpel, with a ſimilar degree of power; and thus church authority is derived from the apoſtles themſelves. This power, thus originally given, was not limited to the primitive ages; it is ſuppoſed to have been tranſmitted to thoſe "faithful men who ſhall be able to teach others alſo" (2 Tim. ii. 2.), and to remain in the church under different modifications, as eſſentially neceſſary for the purpoſes ſpecified by the apoſtle, Epheſ. iv. 13, 14.

At firſt the juriſdiction of a biſhop was confined to the walls of his own city; but afterwards, when the goſpel made its way into towns and villages, the concerns of the Chriſtians that inhabited them, would naturally fall under the cognizance and direction of the biſhops of the neighbouring cities; and thus dioceſes would be gradually formed. See Diocese. In proceſs of time, it is ſuppoſed, the affairs of the church would require the conſultation and co-ope-

co-operation of different biſhops; and therefore, as before, one of the preſbyters of a city was raiſed to be a biſhop, and to have authority over other preſbyters, ſo one of the biſhops of a province was ſelected and inveſted with certain authority over other biſhops, and he was called an archbiſhop; and in the appointment of archbiſhops, the civil importance of the city ſeems to have been regarded, for we find the metropolitan biſhops were generally archbiſhops, and hence archbiſhops were called metropolitans. Archbiſhops, it has been ſaid, were firſt appointed in the ſecond century; and they had power to aſſemble the biſhops within their reſpective provinces, to regulate the election of biſhops, to conſecrate them, to hear appeals from their deciſions, and to take cognizance of their general conduct. See ARCHBISHOP and PATRIARCH.

It is ſometimes urged, that biſhops, prieſts, and deacons, are now, in their office and authority, very different from what they formerly were; but this, ſay the advocates of epiſcopacy, is no more than a neceſſary conſequence of a change of times and circumſtances. They do not contend, that the biſhops, prieſts, and deacons of England are at preſent preciſely the ſame that biſhops, preſbyters, and deacons were in Aſia Minor, 1700 years ago. They maintain, however, that there have been always biſhops, prieſts, and deacons in the Chriſtian church, ſince the days of the apoſtles, with different powers and functions in different countries and at different periods; but the general principles and duties, which have reſpectively characterized theſe clerical orders, have been eſſentially the ſame at all times and in all places; and the variations which they have undergone, have only been ſuch as have ever belonged to all perſons in public ſituations, whether civil or eccleſiaſtical, and which are, indeed, inſeparable from every thing in which mankind are concerned in this tranſitory and fluctuating world. A learned prelate, who flatters himſelf that, by the teſtimonies and arguments, of which we have above given a general account, he has proved epiſcopacy to be an apoſtolical inſtitution, readily acknowledges, however, that there is no precept in the New Teſtament, which commands that every church ſhould be governed by biſhops. As it has not pleaſed the Almighty to preſcribe any particular form of civil government for the ſecurity of temporal comforts to his rational creatures; ſo neither has he preſcribed any particular form of eccleſiaſtical policy as abſolutely neceſſary to the attainment of eternal happineſs. And though the Scriptures contain no directions concerning the eſtabliſhment of a power by which miniſters are to be admitted to their ſacred office, yet he conceives, that from the apoſtles, epiſcopal ordination has been regularly conveyed to us; and the legiſlature of this kingdom has recognized and confirmed this power to biſhops. See ORDINATION. Elements of Chriſtian Theology, by lord biſhop of Lincoln, vol. ii. p. 376—401.

Perſons, on the other hand, who do not admit of epiſcopacy to be of apoſtolic and divine inſtitution, contend, that the terms επισκοπος and πρεσβυτερος, that is, biſhop and preſbyter, are uſed promiſcuouſly in the New Teſtament, to which they think it neceſſary to appeal, as to the ſole authoritative rule of faith and practice, and that they denote the ſame, and not a diſtinct order or office in the Chriſtian church. To this purpoſe they allege the paſſage already cited, Acts xx. 17. 28. in which the ſame perſons are denominated preſbyters and biſhops. Thus alſo the name, office, and work of a biſhop and preſbyter appear to be the ſame, in Titus i. 5. 7.; and unleſs the apoſtle be charged with arguing very incoherently, he muſt mean the ſame thing by elder, v. 5., and biſhop, v. 7. In like manner, preſbyters are exhorted (1 Pet. v. 1, 2.) to diſcharge the office of biſhops. The word επισκοπος, it is ſaid, was properly the name of office, and πρεσβυτερος was a title of reſpect, borrowed from the Jewiſh cuſtom, which was analogous to that of other nations, of calling not only the members of the Sanhedrim πρεσβυτερους, elders or ſenators, but alſo the members of the city council. It has been moreover affirmed, that not a ſingle paſſage from the apoſtolical writings has yet been produced, in which it appears from the context, that the two terms πρεσβυτερος and επισκοπος mean different offices; and that there is the ſtrongeſt poſitive evidence, which the nature of the thing can admit, that in theſe writings the two terms uniformly mean the ſame office. The apoſtle Paul, in the directions he gave to Timothy, about the proper ſupply of churches with ſuitable miniſters, takes particular notice, merely, of two orders, one called biſhops, and the other deacons; and hence, it is argued, that if by biſhops be meant, what in modern ſtyle is ſo denominated, thoſe who have the charge of many preſbyters, it is aſtoniſhing that he ſhould not think it of importance to give any directions about the qualifications of preſbyters, whilſt he is particular in ſpecifying the qualifications of deacons, who were to occupy an order allowed to be much inferior to the other; and if he here means by biſhops only preſbyters, as ſome friends of epiſcopacy have ſuppoſed, it is ſtrange that an office ſo important as that of biſhops, if it was a different and ſuperior office, ſhould have been entirely overlooked. From St. Paul's addreſs to the Philippians, ch. i. 1. it is inferred, that there were but two orders then eſtabliſhed, viz. biſhops, i. e. ordinary paſtors or preſbyters, and deacons. If there was a biſhop in the modern ſenſe at Philippi, when the apoſtle wrote that letter, it ſeems ſtrange that the chief perſon in the ſociety ſhould be the only perſon diſregarded by the apoſtle. Moreover, in the epiſtle written by Polycarp to the ſame ſociety, about 60 years after this time, we find mention of only theſe two orders, the preſbyters and the deacons; nor is it of any conſequence whether we call their paſtors biſhops with the apoſtle, or preſbyters with Polycarp, as both ſpeak of two orders only among them. In the whole book of Acts, the ſtated paſtors of the churches are denominated preſbyters; the collection for the poor Chriſtians is ſent to the preſbyters; nor do we find a ſingle hint of any different claſſes of preſbyters. The appellation επισκοποι, biſhops, occurs but once, and in the paſſage where it is applied to thoſe that are denominated preſbyters. It is urged further, that the impoſition of hands, which has been conſidered by many as a neceſſary attendant on ordination, is attributed in 1 Tim. iv. 14. to the preſbytery: Paul and Barnabas were ordained by certain prophets and teachers in the church of Antioch, and not by any biſhop, of whom there is not a word in that whole ſolemnity, preſiding in that city, Acts xiii. 1, 2, 3; and it is alleged, as an acknowledged and inconteſtible fact, that preſbyters, in the church of Alexandria, ordained even their own biſhops for more than 200 years in the earlieſt ages of Chriſtianity. It appears alſo, from the firſt epiſtle of Clemens Romanus to the Corinthians, chap. xlii. that there were two diſtinct orders, viz. biſhops and deacons, eſtabliſhed by the apoſtles in the church; and by biſhops he means the ſame with thoſe who, in the book of Acts, are called πρεσβυτεροι, preſbyters, or ordinary teachers. Since it muſt therefore be admitted, that in the New Teſtament, and alſo in this work of Clement, the words επισκοπος and πρεσβυτερος are, not occaſionally, but uniformly, uſed ſynonymouſly, the diſcovery that there was not any diſtinctive appellation for ſuch an office as that now called biſhop, is adduced as affording a ſtrong preſumption, that it did not exiſt. Another teſtimony alleged to the ſame purpoſe is

that of Polycarp, who takes notice only of two orders of miniſters in the church; for in ch. v. of his epiſtle to the Philippians, he enjoins the people to be ſubject to their preſbyters and deacons, as to God and Chriſt; hence it is inferred, that if this ancient father had known of any higher order in the church, ſuch as was that of a biſhop in leſs than 150 years after his time, he would have been the principal, if not the only perſon, to whom their ſubjection would have been enjoined by a Chriſtian writer. It is obſerved further, that though he ſpecifies the duties and qualifications of deacons in ch. v., and thoſe of preſbyters in ch. vi., and through the whole of the epiſtle, thoſe of the people, he no where mentions what is proper in the character and conduct of a biſhop. Upon the whole, it ſeems evident that Polycarp knew of no Chriſtian miniſter ſuperior to the preſbyters.

It has been alleged by the advocates of epiſcopacy, that the biſhops are the proper ſucceſſors of the apoſtles, not in the general character of teachers, but in their ſpecial function as apoſtles (ſee Stillingfleet's Works, vol. i. p. 371.); whilſt the preſbyters and deacons were merely the ſucceſſors of thoſe who were, in the beginning, ordained by the apoſtles. But that the apoſtles could not have any proper ſucceſſors has been evinced by the following conſiderations. The indiſpenſible requiſite in the character of an apoſtle, which was that of having ſeen Jeſus Chriſt after his reſurrection, demonſtrates that their office could be but temporary. Beſides, they were diſtinguiſhed by prerogatives, which did not deſcend to any after them; of this kind were their having received their miſſion immediately from Chriſt, and not by any human ordination or appointment; the power of conferring miraculous gifts by impoſition of hands; and the knowledge which they had by inſpiration of the whole doctrine of Chriſt. Moreover, the object of their miſſion was altogether of a different kind from that of any ordinary paſtor; and this was to propagate the goſpel throughout the world both among Jews and Pagans, and not to take charge of any particular flock. Further, as a full proof that the matter was thus univerſally underſtood, both in their own age, and in the times immediately ſucceeding, no one, on the death of an apoſtle, was ever ſubſtituted in his room; inſomuch that when that ſacred college was extinct, the title became extinct with it. It is alike true alſo of the evangeliſts, that their office was temporary, and that their charge extended to the whole church; and their title, like that of an apoſtle, ſunk with thoſe who firſt enjoyed it. Such were Philip, Timothy, Titus, and probably Mark, and Luke. As to the dates or poſtſcripts ſubjoined to the epiſtles in the common bibles, and diſtinguiſhing Timothy and Titus by the appellation of biſhops, it is now univerſally agreed among the learned, that they are of no authority. They are not found in ſome of our beſt and moſt ancient MSS.; and they are generally allowed to be the ſpurious additions of ſome eaſtern biſhop or monk, at leaſt 500 years after Chriſt. It is certain, however, that in the three firſt centuries, neither Timothy nor Titus is ſtyled biſhop by any writer. In the iſland of Crete, of which Titus is ſaid to have been ordained the firſt biſhop, there were no fewer, according to the earlieſt accounts and catalogues extant, than 11 biſhops. Indeed, ſo little can the inſtructions given by Paul to Timothy and Titus be made to quadrate with any ordinary miniſtry that ever obtained in the church, that the learned Dr. Whitby (ſee his Preface to the epiſtle to Titus) concludes, that their's was extraordinary as well as temporary, and that they were not ſucceeded in it by any that came after them. Hence it is inferred, that all the arguments alleged in favour of the diſtinction between biſhops and preſbyters in the early age of the church, by Epiphanius and others, from ſome paſſages in the epiſtles to Timothy and Titus, proceed upon the miſtaken notion, that they were properly biſhops in the modern acceptation of the term; a notion utterly unknown to that Chriſtian antiquity, which deſerves the name of primitive, and alſo incompatible with the authentic accounts we have concerning theſe extraordinary miniſters, who were not made biſhops till about 500 years after their death.

Some have deduced an argument in favour of the apoſtolical antiquity of epiſcopacy, from the epiſtles to the ſeven churches of Aſia mentioned in the Apocalypſe, which are addreſſed to the angels of theſe ſeparately in the ſingular number. From the firſt chapter of that book it appears, that each epiſtle is intended for the whole church or congregation mentioned in the direction or ſuperſcription; and yet one perſon, called the angel of that church, is addreſſed in the name of the whole. Hence ſome have inferred, that the perſon denominated angel, was an order differing from that of other miniſters, and ſuperior to it; whilſt others have conſidered the appellation as deſcriptive of the whole collective body. An intermediate opinion, advanced by ſome critics, is more probable. This ſuppoſes the neceſſity, for the ſake of order, that in their conſiſtories or congregations one ſhould preſide, both in the offices of religion, and in their conſultations for the common good; and that this preſident, or chairman, is here addreſſed under the name of angel. This interpretation affords us alſo the moſt plauſible account of the origin of the more conſiderable diſtinction, which afterwards obtained between biſhop and preſbyter. It was the diſtinction of one paſtor in every church, marked by the apoſtle John, though not made by any who had written before him, which led Tertullian, whoſe publication firſt appeared about a century after the apoſtles, to conſider him as the inſtitutor of epiſcopacy. By thoſe who deny the ſuperiority of biſhops to preſbyters in the firſt age of the church, it is alleged, that the firſt reformers and founders of the church of England, as well as many of its moſt learned and eminent doctors, have not pretended this diſtinction to be of divine, but merely of human inſtitution; not grounded upon ſcripture, but only upon the cuſtom or ordinances of this realm. To this purpoſe, the declaration made of the functions, &c. of biſhops and prieſts, and ſigned by more than 37 civilians and divines, among whom were 13 biſhops, Cranmer and others, affirms, that in the New Teſtament there is no mention made of any degrees or diſtinctions in orders, but only of deacons or miniſters, and of prieſts or biſhops. (See Bp. Burnet's Hiſt. Ref. vol. i. Append. p. 321.) Beſides, the book, entitled "The Inſtitution of a Chriſtian Man," ſubſcribed by the clergy in convocation, and confirmed by parliament, owns biſhops and preſbyters to be the ſame. Moreover, that the main ground of ſettling epiſcopal government in this nation, was not any pretence of divine right, but the convenience of that form of church government to the ſtate and condition of the church at the time of the reformation, the learned Stillingfleet affirms (Irenic. c. 8. Works, vol. ii. p. 396, &c.), and proves it to be the ſentiment of archbiſhop Cranmer and of other reformers, in the reigns of Edward VI. and of queen Elizabeth, ſuch as archbiſhop Whitgift, biſhop Bridges, Loe, Hooker, Sutcliffe, Hales, Chillingworth, &c. It was alſo the opinion of archbiſhop Uſher, that biſhop and preſbyter differed only in degree and not in order; and that in places where biſhops could not be procured, the ordination of preſbyters was valid. See Ordination. "As for the notion of diſtinct offices of biſhop and preſbyter," ſays biſhop Burnet, in his "Vindication of the Church of Scotland," p. 336. "I confeſs it is not ſo

clear

clear to me, and therefore ſince I look upon the ſacramental actions as the higheſt of ſacred performances, I cannot but acknowledge thoſe who are empowered for them muſt be of the higheſt office in the church."

Although, in the apoſtolic times, biſhops and preſbyters were ſynonymous, and co-ordinate with reſpect to their miniſterial powers, and they were ordained to their office by prayer, accompanied with impoſition of hands; yet a certain priority, or preſidentſhip, for the ſake of order, or in deference either to ſeniority or to diſtinguiſhed talents, was allowed to one of their number. But he ſeems to have been only a kind of moderator in their aſſemblies, and to have had no more power than that of giving a ſingle vote in common with the reſt of his brethren. By thoſe who adopt this reaſoning, and who trace the original of the diſtinct order of biſhops, which was introduced in the ſecond and third centuries, to this practice, it is allowed that paſtors were from the beginning veſted with a ſuperintendency over the congregation or church merely in ſpiritual matters; and it is alleged, that ſome of the titles that are thus given them in Scripture, ſuch as ἡγεμονοι, προιστάμενοι, guides and governors, imply this kind of ſuperintendence. But at this time ſeveral things relating to the church were conducted in common by the paſtors, the deacons, and the whole congregation. To this claſs we may refer all matters of ſcandal and offence, and alſo the election of their paſtors and their deacons. Accordingly, Clement, in the fore-cited epiſtle, ch. xliv. ſpeaking of the paſtors, uſes this expreſſion: "Thoſe who were conſtituted by the apoſtles, and afterwards by other eminent men, with the conſent of the whole congregation." It appears alſo, by the epiſtles of Cyprian, written about the middle of the third century, that for the firſt three ages of the church, no final reſolution was taken in any affair of moment, without communicating it to the people, and obtaining their approbation. In the ſecond century a ſettled diſtinction obtained, in ſeveral reſpects, between the preſident, choſen by a plurality of votes, and diſtinguiſhed by the appropriate title of biſhop, which had before been common to all the preſbyters, and the other preſbyters. Many other titles, beſides that of biſhop, which they had all enjoyed in common, were reſtricted to him who was regarded as their head, ſuch as ἡγεμονος, προεστως, πρωτοκαθεδρος, προισταμενος, ποιμην, and ſome others. Theſe titles, independently of the talents, virtues and ſervices that attended them, claimed reſpect and deference. The concurrence of the preſident thus honoured, was conſidered as a neceſſary ſanction to all eccleſiaſtical reſolutions and meaſures; and by degrees every act became valid which bore the ſtamp of his authority. Thoſe who preſided over churches, which were eſtabliſhed in ſome of the principal cities, were honoured with peculiar pre-eminence, and to this advancement analogy to the civil government did not a little contribute. It is not improbable, that the church of Jeruſalem, when it became numerous, and was deprived of the miniſtry of the apoſtles, who were gone to inſtruct the other nations, was the firſt which choſe a preſident or biſhop; nor is it leſs probable, that the other churches followed by degrees this example.

The firſt ancient author who mentions biſhop, preſbyter, and deacon, as three diſtinct orders in the church, is, as we have already obſerved, Ignatius, who is ſuppoſed to have written about the 16th year of the ſecond century. But as ſeveral of the epiſtles aſcribed to him, are ſpurious, no great ſtreſs can be laid upon his authority. However, he ſeems, with peculiar earneſtneſs, to inculcate obedience and ſubjection to the biſhop, as well as to the preſbyters and deacons. Mr. Dodwell accounts for his zeal in eſtabliſhing the biſhop's authority, by ſuppoſing that it was at that time a new thing, totally unknown in the church; and, according to this opinion, he ſays, that it is in vain to look for any trace of epiſcopal authority in the New Teſtament. Irenæus, who is ſuppoſed to have written about the middle of the ſecond century, ſometimes uſes the names biſhop and preſbyter indiſcriminately, and at other times with ſome kind of diſtinction; but it is not eaſy to determine, whether by theſe two appellations he means the ſame order, or two different orders. Dr. Pearſon admits that theſe names are often interchanged by this father, and others of his time, even to the end of the century; but he affirms at the ſame time, that in regard to their own contemporaries, the offices of individuals are never thus confounded, inſomuch that a perſon, who was in their time a biſhop, is not called a preſbyter, nor is a preſbyter called a biſhop. It is allowed, that the diſtinction of theſe orders began about this time generally to prevail, though the difference was not nearly ſo conſiderable as it became afterwards. Another author, by whom the three orders ſeem to be diſcriminated, and whoſe teſtimony is commonly adduced in ſupport of their apoſtolical inſtitution, is Pius, biſhop of Rome, who is ſuppoſed to have written before the middle of the ſecond century, but after Ignatius and Polycarp: he uſes an expreſſion, however, which does not indicate any high opinion of the ſuperiority of the biſhop in his time; "Let the preſbyters and deacons reverence thee (the biſhop), not as their ſuperior, but as Chriſt's miniſter." Clement of Alexandria, at the cloſe of the ſecond century (ſee his Strom. l. 1.), ſtrongly marks the diſtinction between preſbyter and deacon; but he ſeems to intimate, that the diſtinction between biſhop and preſbyter was, even in his days, comparatively not worthy of his notice. At this time, however, every church had its own paſtor, or biſhop, and only one under this appellation, and every biſhop had only one congregation or church. Sir Peter, afterwards lord, King (ubi infra) has proved theſe aſſertions by a variety of citations from ancient writers; he has alſo ſhewn, that a biſhop's dioceſe did not exceed the bounds of a modern pariſh. See Diocese. The preſbyters, according to this writer, were the curates and aſſiſtants of the biſhop, and though inferior to them in degree, yet they had the ſame inherent right with the biſhops, and were equal to them in order. "A biſhop," ſays this author, "preached, baptized, and confirmed, ſo did a preſbyter; a biſhop excommunicated, abſolved, and ordained, ſo did a preſbyter; whatever a biſhop did, the ſame did a preſbyter; the particular acts of their office were the ſame." In the age of Cyprian, about the middle of the third century, it appears that the preſbyters were conſidered as veſted with the power of conferring orders. (Cyp. Epiſt. 5. and 75.) In the age of Hilary, about the middle of the fourth century, it appears, that the whole diſtinction of the epiſcopate is aſcribed by him to ſeniority in the miniſtry, without either election or ſpecial ordination. When the biſhop died, the ſenior colleague ſucceeded of courſe. As to ordination, it was the ſame in both; and biſhop meant no more than firſt among the preſbyters, or ſenior preſbyter. Jerome, who wrote about the end of the fourth and beginning of the fifth century, ſays (In Titum. l. 5. Op. vol. x. p. 1700.) that, among the ancients, prieſts and biſhops were the ſame; but that by degrees the care of a church was aſſigned to one perſon, in order to prevent diſſenſion. In another place (Op. vol. vi. p. 198.) he ſays, "Let the biſhops know, that they are above prieſts more by cuſtom than by the appointment of Chriſt." He alſo obſerves (Anecdotes, p. 24, 54.), that at the beginning, churches were governed by the common council of preſbyters, like an ariſtocracy; but afterwards the ſuperintendency was given to one of the

preſbyters, who was then called the biſhop, and who governed the church, but ſtill with the council of the preſbyters. Dr. Hammond (Annot. Acts xi. 30.) has advanced a ſingular opinion, viz. that the apoſtles inſtituted only the offices of biſhop and deacon, and that the intermediate office of preſbyter was ſoon afterwards introduced. But that ſuch a middle order ſhould be erected at once, immediately after the times of the apoſtles, is much more unlikely, than that it aroſe gradually out of an inconſiderable diſtinction, which had obtained from the beginning.

At the cloſe of the third century, the eccleſiaſtical government, which very generally prevailed, was of that kind which might juſtly be denominated a parochial epiſcopacy. The biſhop, who was properly the paſtor, had the charge of a ſingle pariſh; and the pariſhioners aſſembled for the purpoſes of public worſhip, and for the celebration of religious inſtitutions, in one place, at which the biſhop commonly preſided; the biſhop was aſſiſted by preſbyters, who formed his council in judicial and deliberative matters, and who performed religious functions both public and private. To theſe were added deacons. See DEACON. The next ſtep was the extenſion of the overſight of one biſhop to many congregations, which branched out of the original church by an acceſſion of converts; and in this ſtage of the progreſs of epiſcopacy, the ſeveral preſbyters had their ſeparate pariſhes, and continued in ſubordination to the biſhop, who was acknowledged as their common head. At this period, an order of biſhops, called *chorepiſcopi*, or rural biſhops (ſee CHOREPISCOPUS), held the middle rank between biſhops and preſbyters, being inferior to the former, and ſuperior to the latter. This ſtate of the church may be denominated dioceſan epiſcopacy.

Though biſhops, in the opinion of thoſe whoſe ſentiments we are now repreſenting, were originally no other than preſbyters; the manner of their ordination being the ſame, and the preſbyters diſcharging every part of the office of a biſhop; no ſooner was the diſtinction between them eſtabliſhed, than the biſhops began to appropriate certain functions to themſelves. It appears, by the act of the third council of Carthage, A.D. 397, that, whereas, before, prieſts had the power of aſſigning the time of public penance, and of giving abſolution, as alſo of conſecrating virgins, and of making the chriſm, without the advice of the biſhop, all theſe things were forbidden by theſe canons, and appropriated to the biſhops. But the principal circumſtance by which the biſhops were afterwards diſtinguiſhed, was the power of confirming the baptized, when that chriſm was applied. See CONFIRMATION. After the reign of Adrian, when Jeruſalem was utterly deſtroyed, and the Jews diſperſed, an opinion began to prevail among Chriſtians, that their miniſters ſucceeded to the characters, rights, and privileges of the Jewiſh prieſthood; and this was another ſource of honour and profit to the clergy. Another circumſtance, which contributed in no ſmall degree to the progreſs of epiſcopal authority, was the conſtitution of provincial councils, which inſenſibly ſuperſeded the importance of particular churches, and enabled the biſhops by an alliance with them to obtain a much larger ſhare of executive and arbitrary power. As ſoon as they became connected by a ſenſe of their common intereſt, they were empowered to attack, with united vigour, the original rights of their clergy and people. "The prelates of the third century," ſays Gibbon (Hiſt. vol. ii. p. 335, &c.), "imperceptibly changed the language of exhortation into that of command, ſcattered the ſeeds of future uſurpations, and ſupplied, by ſcripture allegories and declamatory rhetoric, their deficiency of force and reaſon. They exalted the unity and power of the church, as it was repreſented in the epiſcopal office, of which every biſhop enjoyed an equal and undivided portion. Princes and magiſtrates, it was often repeated, might boaſt an earthly claim to a tranſitory dominion; it was the epiſcopal authority alone, which was derived from the deity, and extended itſelf over this and another world. The biſhops were the vicegerents of Chriſt, the ſucceſſors of the apoſtles, and the myſtic ſubſtitutes of the high prieſt of the Moſaic law. Their excluſive privilege of conferring the ſacerdotal character, invaded the freedom of clerical and popular elections; and if, in the adminiſtration of the church, they ſtill conſulted the judgment of the preſbyters, or the inclination of the people, they moſt carefully inculcated the merit of ſuch a voluntary condeſcenſion. The biſhops acknowledged the ſupreme authority which reſided in the aſſembly of their brethren; but in the government of his peculiar dioceſe, each of them exacted from his *flock*, the ſame implicit obedience as if that favourite metaphor had been literally juſt, and as if the ſhepherd had been of a more exalted nature than that of his ſheep." The ſame cauſes, which at firſt had deſtroyed the equality of the preſbyters, introduced among the biſhops a pre-eminence of rank, and from thence a ſuperiority of juriſdiction. In ſpring and autumn, when they met in provincial ſynod, the multitude was governed by the wiſdom and eloquence of a few; and, beſides, the office of perpetual preſidents in the councils of each province, was conferred on the biſhops of the principal city; and theſe aſpiring prelates, who ſoon acquired the lofty titles of metropolitans and primates, ſecretly prepared themſelves to uſurp over their epiſcopal brethren the ſame authority which the biſhops had ſo lately aſſumed above the college of preſbyters. Hence gradually aroſe the pre-eminence which the ambition of the Roman pontiff gained over the other provinces and churches. King's Conſtitution, &c. of the Primitive Church, ch. i.—v. Campbell's Eccl. Hiſt. vol. ii. Moſh. Eccl. Hiſt. vol. i. p. 104, &c. Neal's Hiſt. Purit. vol. i. p. 670, &c. 4to. Pierce's Vindication.

It is the opinion of many approved writers on this ſubject, among whom may be reckoned many epiſcopalians and diſſenters in our own country, and many learned foreigners, that no particular form of church government was authoritatively preſcribed either by our Lord or his apoſtles; but that Chriſtians were left at liberty to chooſe ſuch as might be beſt adapted to their circumſtances and to the ſtate of ſociety, and moſt conducive to the edification and tranquillity of the church, and of individuals in future ages. See CHURCH.

When new occaſions required new meaſures, in a little time the functions of the prieſthood were divided, and the prieſts diſtinguiſhed into degrees; the political part of religion being aſſigned principally to biſhops, and the evangelical to the prieſts, &c. or rather, as ſome will have it, the functions of teaching and preaching were reſerved to the biſhop, and that of ordination ſuperadded; which was their principal diſtinction, and the mark of their ſovereignty in their dioceſe.

By the ancient diſcipline, biſhops were to be married once, and not to put away their wives on pretence of religion; but a ſecond marriage was a diſqualification for this order. If they lived chaſte, they were ranked as confeſſors.

Some biſhops in the middle age, on account of their *regalia*, or temporalities, were obliged to a military ſervice called *hoſtis*, by which they were to lead their vaſſals into the field, and attend the king in his military expeditions. This Charlemagne excuſed, and even forbade; but the prohibition was little regarded, ſince we find the thing often practiſed afterwards. Du-Cange.

The election of biſhops was anciently placed in the clergy

and the people of the parish, province, or diocese, or of the clergy and laity, as they were afterwards called; nor did any church apply to the neighbouring bishops to assist at the ordination. Irenæus was ordained by priests only; and such was the general custom of the church of Alexandria, till the beginning of the fourth century. Cyprian also says, that it belonged to the people chiefly to choose worthy pastors, and to refuse the unworthy. Thus Alexander was chosen bishop of Jerusalem, Fabianus and Cornelius of Rome, and Cyprian of Carthage. When the people had thus elected a bishop, they presented him to the neighbouring bishops for their approbation and consent; because, without their concurrent assent, no bishop could be legally instituted, or confirmed. This was the case with regard to Alexander, already mentioned, and Sabinus, bishop of Emerita in Spain. After election and confirmation, the next act was the ordination or installment of the bishop, which was done in his own church by the neighbouring bishops, who were invited to attend on the occasion. The attendance of the neighbouring bishops, which seems to have been at first voluntary on both sides, became customary, and at length necessary; and it was an established rule, that the concurrence of these was indispensible, one of whom laid his hand on the head of the new bishop, when he was recommended by prayer to the blessing of God. In the third century, this was always done by the metropolitan bishop; or at least it was never done without his consent or order. The second council of Nice ordered that bishops should be chosen by other bishops; but in the west, the people preserved the right of choosing their bishops, till after the reign of Charlemagne and his sons; and it was not taken from them till the council of Avignon, in 1050. Basnage Hist. Eglises Reformées, vol. iii. p. 24.

Under the plea of the tumult that attended popular elections, the emperors, and other sovereigns of Europe, took the appointment in some degree into their own hands; reserving to themselves the right of confirming these elections, and of granting investiture of the temporalities, without which confirmation and investiture, the elected bishop could neither be consecrated, nor receive any secular profits. This right was acknowledged in the emperor Charlemagne, A. D. 773, by pope Adrian I. and the council of Lateran, and universally exercised by other Christian princes; but the policy of the court of Rome contrived to exclude the laity from any share in these elections, and to confine them wholly to the clergy; but the mere form of election appeared to the people to be of little consequence, while the crown was in possession of an absolute negative, which was almost equivalent to a direct right of nomination. Indeed, princes and magistrates, patriarchs and popes, have usurped the power of electing bishops. The election was to be within three months after the vacancy of the see; and the person to be chosen out of the clergy of that church. Formerly the bishop claimed a share in the election of an archbishop; but this was set aside by the popes.

In England, during the Saxon times, the right of appointing to bishopries is said to have been in the crown, because the rights of confirmation and investiture were, in effect, though not in form, a right of complete donation. But when, by length of time, the custom of making elections by the clergy was fully established, the popes began to except to the usual method of granting these investitures, which was "per annulum et baculum," by the prince's delivering to the prelate a ring, and pastoral staff, or crosier; pretending that this was an encroachment on the church's authority, and an attempt by these symbols to confer a spiritual jurisdiction: and pope Gregory VII. about the close of the 11th century, published a bull of excommunication against all princes who should dare to confer investitures, and all prelates who should venture to receive them. At length, however, when the emperor Henry V. agreed to remove all suspicion of encroachment on the spiritual character by conferring investitures for the future "per sceptrum" and not "per annulum et baculum;" and when the kings of England and France consented also to alter the form in their kingdoms, and receive only homage from the bishops for their temporalities, instead of investing them by the ring and crosier; the court of Rome found it prudent to suspend for a while its other pretensions. This concession was obtained from king Henry I. in England, by means of that obstinate and arrogant prelate archbishop Anselm; but king John, about a century afterwards, in order to obtain the protection of the pope against his discontented barons, was also prevailed upon to give up by a charter, to all the monasteries and cathedrals in the kingdom, the free right of electing their prelates, whether abbots or bishops; reserving only to the crown the custody of the temporalities during the vacancy; the form of granting a licence to elect, which is the original of our congé d'elire," on refusal whereof the electors might proceed without it; and the right of approbation afterwards, which was not to be denied without a reasonable and lawful cause. This grant was expressly recognized and confirmed in king John's Magna Charta, and was again established by stat. 25 Edw. III. st. 6. § 3. But by stat. 25 Hen. VIII. cap. 20. the ancient right of nomination was, in effect, restored to the crown. The English succession of protestant bishops stands on this last ground. The king being certified of the death of a bishop by the dean and chapter, and his leave requested to elect another, the *congé d'elire*, or usual licence, is sent to them, with a letter missive, nominating the person whom he would have chosen. The election is to be within twelve days after the receipt of it, otherwise the king by letters patent appoints whom he pleases; and the chapter, in case of refusing the person named by the king, incurs a *præmunire*. The election, or nomination, if it be of a bishop, must be signified by the king's letters patent to the archbishop of the province; if it be of an archbishop, to the other archbishop and two bishops, or to four bishops; requiring them to confirm, invest, and consecrate the person so elected; which they are bound to perform immediately, without any application to the see of Rome. If such archbishop, or bishops, refuse to confirm, invest, and consecrate such bishop elect, they shall incur all the penalties of a *præmunire*. After election, and its being accepted of by the bishop, the king grants a mandate under the great seal for confirmation, which the archbishop consigns to his vicar-general, consisting mostly in a solemn citation of such as have any objections to the bishop elect, a declaration of their contumacy in not appearing, and an administration of the oaths of allegiance and supremacy, of simony, and canonical obedience. Sentence being read by the vicar-general, the bishop is installed in the province of Canterbury by the archdeacon: the fact is recorded by a public notary; and the bishop is invested with full powers to exercise all spiritual jurisdictions, though he cannot sue for his temporalities till after consecration. Then follows the consecration by the archbishop, or some other bishop appointed by lawful commissions, and two assistant bishops: the ceremony of which is much the same as in the Romish church, save that, having put on the episcopal robe, the archbishop and bishops lay their hands on the new prelate's head, and consecrate him with a certain form of words. The fees of the whole process are said to amount to about 600l.

The process of the translation of a bishop to another bishopric

ſhopric only differs in this, that there is no conſecration. The age of a biſhop is to be at leaſt thirty years; and, by the ancient diſcipline, none were to be choſen but thoſe who had paſſed through all the inferior orders; but, in ſome caſes of neceſſity, this was diſpenſed with, and deacons, nay laymen, were raiſed *per ſaltum* to the epiſcopal dignity.

The form of conſecrating a biſhop is different in different churches. Ordinarily, at leaſt three biſhops are required in the ceremony of conſecrating a biſhop: but, in ſome caſes a ſingle one might ſuffice. In the Greek church, the candidate for the epiſcopate, who is always an *archimandrite* or *hieromachus*, i. e. an abbot or chief monk in ſome monaſtery, being named to the vacant ſee, and the election being confirmed, repairs, at the time appointed, to the church where the conſecration is to be performed. Being arrived, he is introduced by the proto-pope and proto-deacon to the archbiſhop and biſhops, who are arranged in proper order on a temporary theatre or platform erected in the church for the occaſion. He there gives an account of his faith; declares ſolemnly that he has neither given nor promiſed money, or any bribe-worthy ſervice, for his dignity; and promiſes to adhere ſteadily to the traditions and canons of the eaſtern church, to viſit his dioceſe regularly, and to oppoſe ſtrenuouſly all innovations and hereſies, particularly the errors of the Latin church. This being done, the archbiſhop ſays, "The grace of the Holy Spirit, through my humility, exalts thee N. archimandrite or hieromachus, beloved of God, to be biſhop of the cities N. N. which God preſerve." With much ceremony the biſhop elect is then conducted from the theatre, within the rails of the holy altar, where he kneels down with the other biſhops, who hold open over his head the holy goſpel with the letters inverted, the archbiſhop ſaying aloud, "The divine grace, which always healeth our infirmities, and ſupplieth our defects, by my hand conducteth thee N. archimandrite or hieromachus, beloved of God, biſhop elect of the cities of N. N. which God preſerveth—Let us pray therefore for him, that the grace of the moſt Holy Spirit may come upon him." Then the prieſts ſay thrice, "Lord have mercy upon us;" and while the biſhops continue to hold the goſpel, the archbiſhop ſigns the newly conſecrated biſhop thrice with the ſign of the croſs, ſaying, "In the name of the Father, and of the Son, and of the Holy Ghoſt, now and for ever, even unto ages of ages. Amen." Then all the biſhops putting their right hands on his head, the archbiſhop prays that he may be confirmed in the office of which they have judged him worthy, that his prieſthood may be rendered irreproachable, and that he himſelf may be made holy and worthy to be heard of God. After this, one of the aſſiſting biſhops reads a ſhort litany in a low voice, to be heard only by thoſe within the altar, and the other biſhops make the reſponſes. At the end of the litany, the archbiſhop, laying his hand again upon the head of the newly conſecrated biſhop, prays in very decent and devout terms, that Chriſt will render him an imitator of himſelf, the true ſhepherd; that he will make him a leader of the blind, a light to thoſe who walk in darkneſs, and a teacher of infants; that he may ſhine in the world, and receive at laſt the great reward prepared for thoſe who contend boldly for the preaching of the goſpel. After this the paſtoral ſtaff is delivered to the new biſhop, with a very proper and ſolemn exhortation from the archbiſhop, to feed the flock of Chriſt committed to his care. King's Rites and Ceremonies of the Greek Church.

In the Romiſh church, the biſhop elect being preſented by the elder aſſiſtant to the conſecration, takes the oath: he is then examined as to his faith; and after ſeveral prayers, the New Teſtament is drawn over his head, and he receives the chriſm or unction on his head. The paſtoral ſtaff, ring, and Goſpel, are then given him; and after communion, the mitre is put on his head: each ceremony being accompanied with proper prayers, &c. the conſecration ends with Te Deum.

Theſe laſt mentioned ceremonies are laid aſide in the conſecration of Engliſh biſhops. Nevertheleſs, the book of conſecration, compoſed by the biſhops, and approved by Edward VI. in the third year of his reign, and, two years afterwards, confirmed by act of parliament, in which ſome of them are enjoined, is declared to be the ſtandard for this purpoſe by the thirty-ſixth article. In queen Mary's reign this act was repealed, and the book of common prayer, and the book of ordination, were by name condemned. When Elizabeth came to the throne, queen Mary's act was repealed, and king Edward's prayer-book was again authorized; but the book of ordination was not expreſsly named, becauſe it had been a part of the common prayer book; and therefore it was not thought neceſſary to ſpecify the office of ordination any more than any other office of the common prayer book. But biſhop Bonner contended, that as the book of ordination had been by name condemned in queen Mary's reign, and had not been ſince revived by name, it was ſtill condemned in law; and, conſequently, that all ordinations conferred according to that form, were illegal and invalid. To obviate this objection, it was declared in a ſubſequent ſeſſion of parliament, that the office of ordination was conſidered as part of the common prayer book; and it was farther declared, that all ordinations which had been performed according to that office, were valid; and upon the ſame principle a ſimilar clauſe was inſerted in the 36th article.

The function of a biſhop in England may be conſidered as two-fold; viz. what belongs to his *order*, and what belongs to his *juriſdiction*. To the *epiſcopal order* belong the ceremonies of dedication, confirmation, and ordination; to the *epiſcopal juriſdiction*, by the ſtatute law, belong the licenſing of phyſicians, ſurgeons, and ſchoolmaſters, the uniting ſmall pariſhes (though this laſt privilege is now peculiar to the biſhop of Norwich), aſſiſting the civil magiſtrate in the execution of ſtatutes relating to eccleſiaſtical matters, and compelling the payment of tenths and ſubſidies due from the clergy.

By the common law, the biſhop is to certify the judges, touching legitimate and illegitimate births and marriages; and by that and the eccleſiaſtical law, he is to take care of the probate of wills, and granting adminiſtrations; to collate to benefices, grant inſtitution on the preſentation of other patrons, command induction, order the collecting and preſerving the profits of vacant benefices for the uſe of the ſucceſſors, defend the liberties of the church, and viſit his dioceſe once in three years. To the biſhop alſo belong ſuſpenſion, deprivation, depoſition, degradation, and excommunication.

The biſhops of England are all barons: barons in a threefold manner; viz. *feudal*, in regard of lands and baronies annexed to their biſhoprics; by *writ*, as being ſummoned by writ to parliament; and alſo by *patent* and *creation*. When William the conqueror thought proper to change the ſpiritual tenure of frank-almoign, or free alms, under which the biſhops held their lands during the Saxon government, into the feudal or Norman tenure by barony; their eſtates were ſubjected to all civil charges and aſſeſſments, from which they were before exempt; and, in right of ſucceſſion to thoſe baronies, which were unalienable from their reſ-

pective dignities, the biſhops and abbots were allowed their ſeats in the houſe of lords. But though theſe lords ſpiritual are, in the eye of the law, a diſtinct eſtate from the lords temporal, and are ſo diſtinguiſhed in moſt of our acts of parliament, yet in practice they are uſually blended together under one name of "the lords;" they intermix in their votes; and the majority of ſuch intermixture joins both eſtates. And from this want of a ſeparate aſſembly, and ſeparate negative of the prelates, ſome writers have argued very cogently, that the lords ſpiritual and temporal are now in reality only one eſtate; which is unqueſtionably true in every effectual ſenſe, though the ancient diſtinction between them ſtill nominally continues. For if a bill ſhould paſs their houſe, there is no doubt of its validity, though every lord ſpiritual ſhould vote againſt it, of which Selden and ſir Edward Coke give many inſtances; as, on the other hand, judge Blackſtone preſumes it would be equally good, if the lords temporal preſent were inferior to the biſhops in number, and every one of thoſe temporal lords gave his vote to reject the bill; though ſir Edward Coke ſeems to doubt, whether this would not be an "ordinance," rather than an "act," of parliament. Bl. Com. vol. i. 156. Biſhops have the precedence of all other barons, and ſit in the upper houſe as barons. They are twenty-four in number, excluſive of the biſhop of Sodor and Man, who has no ſeat in the houſe of peers, beſides two archbiſhops. Archbiſhops are diſtinguiſhed by the titles of "Grace," and "Moſt reverend father in God by divine Providence;" and biſhops, by thoſe of "Lord," and "Right reverend father in God by divine permiſſion." The former are ſaid to be "inthroned," and the latter "inſtalled." See ARCHBISHOP.

With reſpect to the order of precedency among one another, the archbiſhop of Canterbury takes the lead, then the archbiſhop of York, next to him the biſhops of London, of Durham, and of Wincheſter. The other biſhops follow according to the ſeniority of their conſecration; excepting only, that a biſhop being a privy counſellor, takes place after the biſhop of Durham.

Biſhops have two ſpecial privileges next to regal: the firſt, that in their courts they ſit, and paſs ſentence, of themſelves, and by their own authority; the biſhops' courts being not like other courts, but writs are ſent out in their own name, *teſte* the biſhop, not in the king's name, as is done in the king's courts: the ſecond, that, like the king, they can depute their authority to another, as their ſuffragan, chancellor, commiſſary, &c.

They have this advantage alſo over lay-lords, that, in whatever Chriſtian country they are, their epiſcopal degree and dignity are acknowledged; and they may, *quatenus* biſhops, ordain, &c.

They have ſeveral immunities, as from arreſts, outlawries, diſtreſs, &c. liberty to hunt in the king's foreſts, &c. to have *certain tuns of wine duty free*, &c. Their perſons may not be ſeized, as lay-peers may, upon contempt, but their temporalities alone. They may qualify as many chaplains as a duke, viz. ſix. But, as they have no right to be tried themſelves in the court of the lord high ſteward, as peers, they ought not to be judges there. For, though they are lords of parliament, and ſit there by virtue of the baronies, which they hold "jure eccleſiæ," yet they are not ennobled in blood, and conſequently not peers with the nobility, but merely lords of parliament. 3 Laſt. 30, 31. Staunf. P. C. 153. In caſes of capital offence, the biſhops uſually withdraw voluntarily, but enter a proteſt, declaring their right to ſtay. It is obſervable, that in the 11th chapter of the conſtitutions of Clarendon, made in parliament 11 Henry II. they are expreſsly excuſed, rather than excluded, from ſitting or voting in trials, when they come to concern life or limb. The determination of the houſe of lords in the earl of Danby's caſe, (Lords' Journ. 15 May, 1679), which hath ever ſince been adhered to, is conſonant to theſe conſtitutions, "that the lords ſpiritual have a right to ſtay and ſit in court in capital caſes, till the court proceeds to the vote of guilty, or not." This reſolution, however, extends only to trials in full parliament; for to the court of the lord high ſteward, in which no vote can be given, but merely that of guilty, or not guilty, no biſhop, as ſuch, ever was or could be ſummoned: and though the ſtatute of king William regulates the proceedings in that court, as well as in the court of parliament, yet it never intended to new-model or alter its conſtitution, and conſequently does not give the lords ſpiritual any right in caſes of blood which they had not before; and their excluſion is more reaſonable, becauſe having no right to be tried in this court, as we have already ſaid, they ought not to be judges there.

By law, the crime of *epiſcopicide*, which a clergyman commits by killing his biſhop, is petty treaſon.

In Canada there is a biſhop, reſident at Quebec; and there are two biſhops in America. In Denmark they have no archbiſhop, but there are ſix ſuperintendents, or biſhops; four in Norway, and two in Iceland. The chief ſee is that of Zealand, which yields about 1000l. a year; the others are thoſe of Funen, valued at 760l., Aarhuus at 600l., Aalborg at 400l., Ripan at 400l.; in Norway, Chriſtiana or Aggerhuus at 400l., Chriſtianſand at 600l., Berghen at 400l., and Drontheim at 400l. The biſhoprics of Skalholt and Holun, in Iceland, are only valued each at 150l.; but though far inferior in nominal value to the others, they may be conſidered, on account of the cheapneſs of living in Iceland, equal in real profit to the largeſt of the others. The biſhop of Zealand, who is firſt in rank, and the biſhop of Aggerhuus, are metropolitans. They have no temporalities; keep no eccleſiaſtical courts; have no cathedrals or prebends, &c. but are only *primi inter pares*, having the rank above the inferior clergy of the province, and inſpection over their doctrine and manners. They are allowed two or three pariſhes each. Their habit is common with that of the other miniſters. In Sweden are fourteen dioceſes; the archbiſhopric of Upſala, and the biſhoprics of Lindkoeping, Skara, Strængnæs, Wœſteras, Wexio, Abo, Lund, Borgo, Gotheborg, Calmar, Carliſtadt, Hermoſand, and Wiſby, or Gothland. The revenues of Upſala and Wœſteras amount to about 1000l. a year; and thoſe of the loweſt biſhopric to 300l. There are alſo three ſuperintendents, who rank as biſhops, but do not ſit in the houſe; theſe are the firſt chaplain to the king, the rector of St. Nicholas at Stockholm, and the firſt chaplain of the navy. The biſhops are bound to reſidence, except during the meeting of the diet. A conſiſtory of the clergy of the dioceſe elects the archbiſhop and biſhops, by preſenting them to the king for his nomination. They have alſo eccleſiaſtical courts, &c.

BISHOP-*abbot*, *epiſcopus abbas*, was an abbot inveſted with the epiſcopal order; of which we meet with ſeveral in the richer and more conſiderable monaſteries.

BISHOP, *acephalous*, he who is immediately ſubject to the papal ſee, without any metropolitan over him.

BISHOP, *boy*. It was an ancient cuſtom in ſuch churches as had cathedral ſervice, for the little choriſters, on St. Nicholas' day, December the 6th, to elect one of their number to be the *epiſcopus puerorum*, the bearn, i. e. infant, or choriſter biſhop; who continued to preſide over the reſt, with an imitation of all the epiſcopal functions, till Innocent's Day, Dec. 28, and then, after ſolemn proceſſions and great pageantry, he laid down his office. He was

chofen on St. Nicholas day, becauſe St. Nicholas was the patron ſaint of children; he having, when an infant, ſhewn ſuch ſingular piety, as the legend ſays, that when he was at his mother's breaſt, he would not ſuck on Wednefdays and Fridays, that he might obſerve the faſts of the church.

The ceremonies attending the inveſtiture of the *epiſcopus puerorum*, are preſcribed by the ſtatutes of the church of Sarum, which contain a title *de epiſcopo choriſtarum;* and alſo by the proceſſional. From theſe it appears, that he was to bear the name and ſtate of a biſhop, habited, with a croſier or paſtoral ſtaff in his hand, and a mitre on his head. His fellows, the reſt of the children of the choir, were to take upon them the ſtyle and office of prebendaries, and yield to the biſhop canonical obedience; and farther, the ſame ſervice as the very biſhop himſelf, with his dean and prebendaries, had they been to officiate, were to have performed, the very ſame, maſs excepted, was done by the choriſters and his canons upon the eve and the holiday. The uſe of Sarum required alſo, that upon the eve of Innocent's day, the choriſter biſhop, with his fellows, ſhould go in ſolemn proceſſion to the altar of the Holy Trinity, in copes, and with burning tapers in their hands; and that during the proceſſion, three of the boys ſhould ſing certain hymns mentioned in the rubric. The proceſſion was made through the great door at the weſt end of the church, in ſuch order, that the dean and canons went foremoſt, the chaplain next, and the biſhop, with his little prebendaries, laſt; agreeably to that rule in the ordering of all proceſſions, which aſſigns the rearward ſtation to the moſt honourable. In the choir was a ſeat or throne for the biſhop; and as to the reſt of the children, they were diſpoſed on each ſide of the choir, upon the uttermoſt afcent. And ſo careful was the church to prevent any diſorder which the rude curioſity of the multitude might occaſion in the celebration of this ſingular ceremony, that their ſtatutes forbid all perſons whatſoever, under pain of the greater excommunication, to interrupt or preſs upon the children, either in the proceſſion or during any part of the ſervice directed by the rubric; or any way to hinder or interrupt them in the execution or performance of what it concerned them to do. Farther it appears, that this infant-biſhop did, to a certain limit, receive to his own uſe, rents, capons, and other emoluments of the church. In caſe the little biſhop died within the month, his exequies were ſolemnized with great pomp; and he was interred, like other biſhops, with all his ornaments. The memory of this cuſtom is preſerved, not only in the ritual books of the cathedral church of Saliſbury, but by a monument in the ſame church, with the ſepulchral effigies of a choriſter biſhop, ſuppoſed to have died in the exerciſe of his pontifical office, and to have been interred with the ſolemnities above noted.

From what period we are to date the progreſs of this ridiculous ceremony, it is not eaſy to diſcover, but it ſeems more than probable that it originated with the ancient MYSTERIES. In the wardrobe accompt of Edward I. publiſhed by the ſociety of antiquaries, we find a boy-biſhop, Dec. 7, 1290, ſaying veſpers before the king, in his chapel at Heton near Newcaſtle upon Tyne, for which he, and the boys who ſung with him, received 40s.

This eſtabliſhment, but with a far greater degree of buffoonery, was common in the collegiate churches of France. (See Dom. Marlot. Hiſtoire de la Metropole de Rheims, tom. ii. p. 769.) A part of the ceremony in the church of Noyon was, that the children of the choir ſhould celebrate the whole ſervice on St. Innocent's day. (Brillon. Dictionaire des Arrets, artic. Noyon. ed. 1727.) In a curious book, called Voyages Liturgiques de France (Par. 8vo. 1718, p. 33.) is this account of the ſame practice in the church of Vienne in Dauphiny. "Le jour de Nöel après Vêpres, le jour de S. Etienne, et le jour de St. Jean l'Evangeliſte, on faiſoit des proceſſions ſolennelles pour les diacres, les pretres, et les enfans de Chœur, comme autrefois à Rouen. Il y avoit auſſi le lendemain à la meſſe ſolennitè pour eux. Les enfans de Chœur y avoient leur PETIT EVEQUE, qui faiſoit tout l'office, excepté à la meſſe. And in the ſtatutes of the archiepiſcopal cathedral of Tulles, given in the year 1497, it is ſaid, that during the celebration of the feſtival of the boy-biſhop, "*Moralities* were preſented, and ſhews of *miracles*, with farces and other ſports, but compatible with decorum. After dinner they exhibited, without their maſks, but in proper dreſſes, ſuch farces as they were maſters of, in different parts of the city." In England too it appears, that the boy-biſhop, with his companions, went about to different parts of the town; at leaſt viſited the other religious houſes. (See the Computus Rolls of Wincheſter College, A. 1461.). And Strype records (Eccleſ. Memorials, iii. 310. ch. xxxix. and p. 387. ch. i.), that when this, among other ancient ceremonies, was reſtored by queen Mary, in 1556, "on St. Nicolas's even, ſaint Nicolas, that is, a boy habited like a biſhop in *pontificalibus*, went abroad in moſt parts of London, ſinging after the old faſhion, and was received with many ignorant but well diſpoſed people into their houſes, and had as much good cheer as ever was wont to be had before."

In the ſtatutes of Eton college, given in 1441, the *epiſcopus puerorum* is ordered to perform divine ſervice on St. Nicholas's day; and in thoſe of Wincheſter college, 1380, *pueri*, that is, the boy-biſhop, and his fellows, are permitted on Innocent's day to execute all the ſacred offices in the chapel, according to the uſe of the church of Sarum. A ſimilar clauſe to that at Eton occurs in the ſtatutes of King's college, Cambridge; and Mr. Warton obſerves, in his hiſtory of Poetry, that the anniverſary cuſtom at Eton of going *ad montem* originated from the ancient and popular practice here deſcribed.

In a ſmall college, for only one provoſt, five fellows, and ſix choriſters, founded by archbiſhop Rotheram in 1481, in the obſcure village of Rotheram, in Yorkſhire, this piece of mummery was not omitted. The founder leaves by will, among other bequeſts to the college, "a myter for the barne-biſhop of cloth of gold, with two knopps of ſilver, gilt and enamelled." Hearne's Liber Niger Scacc. Append. 674. 686.

From the paſſage already quoted from the Voyages Liturgiques de France, it appears that, at leaſt in one church, the *maſs* was not allowed to be celebrated by the boy-biſhop; and it is alſo expreſsly prohibited in the uſe of Sarum: but other and more frequent inſtances occur where the buffoonery was carried even to this height. In a fragment of the cellarers *Computus* of Hyde abbey near Wincheſter, A. D. 1397, we have a charge "pro epulis *pueri* CELEBRANTIS in feſto Sancti Nicolai;" and ſo late even as the reign of Henry VIII. we find the ſame ceremony at St. Paul's.

It is ſurpriſing that Dean Colet, a friend to the purity of religion, and who had the good ſenſe and reſolution to cenſure the ſuperſtitions and fopperies of popery in his public ſermons, ſhould countenance this idle farce of the boy-biſhop in the ſtatutes of his ſchool at St. Paul's, which he founded with a view of eſtabliſhing the education of youth on a more rational and liberal plan than had yet been known, in the year 1512. He expreſsly orders, that his ſcholars "ſhall every Childermaſs (that is Innocent's) day, come to Pauli's churche, and hear the *childe-biſhop's* (of St. Paul's cathedral) ſermon,

ſermon. And after be at the hygh maſſe; and each of them offer a penny to the ch[illegible] biſhop, and with them the maiſtris and iurv yors of the [illegible]."

This ſing[illegible]dac[illegible]ſolom [illegible], however, prohibited in the coun[illegible]l of [illegible]s A.D. 1435; and, not ſo much for its ſuperſtition as its [illegible]d abſurdity, was abrogated in this country by king Henry VIII. in 1542, the words of whoſe proclamation may be ſeen in Mr. Warton's Hiſtory of Engliſh Poetry, vol. iii. p. 322. But queen Mary, who with the cat[illegible]lic [illegible]r reſtored all the pageantries of popery to their ancient ſplendour, revived the mummery before us; and [illegible] Nov. 13, 1554, an edict was iſſued by the biſhop of London t[illegible]ll the clergy of his dioceſe, to have a *boy-biſhop* in proſ[illegible].

We are hardly apt, that on the acceſſion of Elizabeth, this filly mockery was ſet aſide; but Mr. Warton was inclined to think, that the practice of our plays being acted by the children of St. Paul's church and the chapel royal, which continued till Cromwell's uſurpation, might be deduced from the *myſteries* and *moralities* which attended the ridiculous feſtival of St. Nicolas. See the Northumberland Houſhold Book, p. 440. Drake's Eboracum, p. 481. Warton's Hiſt. of Eng. Poetry, i. 248. ii. 375. 389. iii. 302. 303. 32[illegible]. Proceſſionale Eccl. Sarum, edit. Rothom. 1555. Dugdale's Hiſt. of St. Paul's, 205, 206. Anſtis Ord. Gart. ii. 309. Knight's Life of Dean Colet, p. 362. Hawkin's Hiſt. of Muſic, ii. 5. Strype's Eccleſ. Mem. iii. 202. ch. xxv. 205, 206. ch. xxvi. Dugd. Monaſt. iii. 169, 170. 279.

Bishop, *cardinal*, a biſhop in chief, or *in capite*. St. Gregory ſometimes uſes the term for a proper biſhop. Anciently there were alſo biſhops, who by a peculiar privilege from the holy ſee, were ranked, and had a ſeat among the cardinals.

Bishops, *cathedral*, was alſo a title given to the proper biſhop, by way of diſtinction from the *chorepiſcopi*.

Bishops, *commendatory*, or biſhops "in commendam," are cardinals not of the order of biſhops, or other prelates, who yet hold biſhopries "in commendam." The appellation had its origin during the reſidence of the papal ſee at Avignon, whence ſcarce any cardinal, prieſt, or deacon, was created, who held not one, two, three, or more biſhopries in commendam. Du-Cange.

Bishop *deſigned*, *epiſcopus deſignatus*, denoted a coadjutor of a biſhop, who, in virtue of his office, is to ſucceed at the incumbent's death.

Bishop-*elect*, is he who has the king's nomination, with the ſanction of the chapter; but without conſecration.

Bishops, *exempt*, thoſe freed from the juriſdiction of the metropolitan, and immediately ſubject to the ſee of Rome alone.

Bishop *of the palace*, *epiſcopus palatii*, was probably the ſame with biſhop of the king's chapel, a title in the court of Bohemia. Du Cange. It was alſo a title given thoſe biſhops, who, by licence of the pope dwelt in palaces of kings, to be in readineſs for ſpiritual ſervice and council in church matters.

Bishop *of the prime ſee*, denoted a "primate," otherwiſe denominated a "ſenior biſhop." See Primate.

Bishop *in partibus infidelium*, he who is dignified with the title of a biſhopric, whoſe diſtrict or dioceſe is in the poſſeſſion of infidels or hereties. By the canon law, a biſhop *in partibus* is qualified hereby to be a coadjutor of another biſhop. The denomination took its riſe from the expulſion of the biſhops and clergy out of the Holy Land by the Saracens; when flying into Italy for ſhelter, coadjutories were given them for their ſubſiſtence.

Bishops, *regionary*. See Regionary.

Bishops, *rural*. See Chorepiscopus.

Bishops, *ſuffragan*, are coadjutors or aſſiſtants of dioceſan biſhops, authorized by commiſſion from them.

Bishops, *vague*, thoſe without any dioceſe, ſometimes attendant in camps, or in foreign countries, for the converſion of infidels. The like vague biſhops were ſometimes alſo granted by popes to monaſteries, exempt from the juriſdiction of the dioceſan, where they performed all the epiſcopal functions. Du-Cange.

Bishop, *univerſal*, or *catholic*, is a title given to the patriarch of Armenia.

Bishop *of the catholic or univerſal church*, a title ſometimes aſſumed by the popes.

Bishop *of biſhops*, was a title anciently given to the prelates of ſome of the greater and more honourable ſees, as Jeruſalem and Rome. The firſt who had the title was James, biſhop of Jeruſalem. Some will have the appellation to have been common to all biſhops.

Bishops, in the *Lutheran Church*, are thoſe more uſually called *ſuperintendants*, which ſee.

The Calviniſts allow of no other biſhops beſides preſbyters; but the Lutherans make ſome diſtinction, and give a ſuperiority or pre-eminence over the reſt of their "biſhops," "ſuperintendents," or "overſeers."

Bishop is alſo a quality ſometimes attributed to ſecular princes, in reſpect of their ſupremacy or juriſdiction in matters belonging to religion. See Supremacy. In this ſenſe it is that the emperor Conſtantine, in a letter to the biſhops in his dominions, calls himſelf "common biſhop," as being in ſome reſpects general biſhop of the whole Roman world.

Bishop *of the Jews*, the head of that people in England, choſen by themſelves, to whom they ſubmitted to be judged and governed according to their law. Prideaux's Connect. part ii. lib. v. p. 478. This officer, which ſubſiſted under our Norman kings, and was licenſed by them, anſwered to the Echmalotarchs in Babylon, and the Alabarchs in Egypt.

Bishops *at cheſs*, a kind of pieces, the third in rank, below queens, but above knights, diſtinguiſhed by their cloven heads. In Latin writers of the middle age, the biſhop is called *alphinus*; and by the French *le fou*, the *fool* or *madman*. See Chess.

Bishop's *Court*. See Court.

Bishop's *ſee*, or *ſeat*, originally denoted the throne or chair in the church where the biſhop ſat. It was alſo denominated Apsis.

Bishop's *ſee* alſo denotes the city or place where the reſidence of the biſhop is fixed.

Every biſhop's ſee was anciently called "ſedes apoſtolica;" though the appellation has ſince been reſtrained to the ſee of Rome.

Anciently biſhops ſeem to have had a right in England to ſit as judges in the hundred and county-courts. In aftertimes, they were forbid to ſit in ſecular courts, and had ſeparate courts erected for them; which proved an occaſion of much diſpute between the two juriſdictions. No church tenant might be ſued in any court but the biſhop's. There are alſo traces of a ſeparate court of the biſhops much earlier, among our Saxon anceſtors in the eighth century. The regard borne to the character of biſhops, made them the common arbitrators even of ſecular cauſes: they had the cognizance of all cauſes concerning lands in "frank-almoign;" and for eccleſiaſtics, were judges even in capital cauſes.

Bishop's *weed*, in *Botany*. See Ammi.

Bishop, *Bird*, in *Ornithology*. See Tanagra Episcopus.

Bishop *and his Clerks*, in *Geography*, a cluſter of dangerous rocks, near the weſt coaſt of South Wales, at the entrance of St. George's channel, 4 miles weſt of St. David's. N. lat. 51° 54'. W. long. 5° 20'.

Bishop's *Auckland*. See Auckland.

Bishop's *Caſtle*, a market and borough town of Shropſhire, in England, ſpreads its ſcattered houſes over the ſide of a conſiderable eminence, at the baſe of which runs the ſmall river Clun. This town is an old corporation, and made its firſt return to parliament in the 27th of Elizabeth. Previous to that period, it belonged to the ſee of Hereford, and derived its name from being one of the ſeats, or caſtellated manſions, of the biſhops. The corporation conſiſts of a bailiff, recorder, and fifteen aldermen, who, with about thirty other inhabitants called burgeſſes, elect two members for the town. Here is a large weekly market on Fridays, which is much frequented by the Welſh, as are its ſix annual fairs. At ſome of the latter a great quantity of ſheep and pigs are ſold. This town was formerly under the protection of a caſtle, which is entirely deſtroyed. Biſhop's caſtle is 156 miles N.W. from London. It contains 241 houſes, and 1076 inhabitants.

At *Snede*, about two miles and a half N.W. from Biſhop's caſtle, a priory of black canons was founded in the time of Henry III., but was ſoon afterwards removed to *Cherbury*. This place, ſeated near the Severn, is ſuppoſed to have been built by Ethelfleda, and was afterwards poſſeſſed by the family of the Herberts, one of whom was created lord Herbert of Cherbury. This gentleman wrote an account of his own life, which has been publiſhed by Horace Walpole at his private preſs at Strawberry hill. Not far from this town, on the borders of Montgomeryſhire, is an ancient encampment called *Biſhop's Moat;* and at Clun are the remains of an ancient caſtle, near which is a camp called *Bury-ditches*. About three miles hence is *Walcot*, the ſeat of lord Clive, who is patron of this borough. In the vicinity of Biſhop's caſtle, are three lofty ſingular hills, reſpectively named Corndon-hill, Church-Stoke-hill, and Squilfar hill. At *Moor Park* is a reſpectable ancient manſion; the grounds are finely diverſified, and abound with fine woods.

Bishop's *Iſland*, a ſmall rocky iſland in Mal-bay, on the weſt coaſt of the county of Clare, in Ireland. N. lat. 52° 38'. W. long. 9° 35'. Beaufort.

Bishop's *Stortford*, a market town of Hertfordſhire, in England, is placed on the ſide of a hill, near the weſtern borders of Eſſex. Seated in the midſt of a corn country, it is remarkable for its number of malt houſes, and for the quantity of malt annually made here; this is diſtinguiſhed by the name of brown malt, and is diſpoſed of principally to the London brewers. It is conveyed to the metropolis in barges, by a navigable canal, which was cut in 1779, and which joins the river Lee, at about 14 miles diſtance from this town. Before this navigation was opened, the malt, which is now lodged here, was carried to Ware and Stanſted, as the neareſt places for water-carriage; but ſince the above period, Stortford has become the depot for the malt made in this town and the neighbouring villages.

This place was evidently of ſome note previous to the conqueſt, as it appears from the Domeſday Survey, that the conqueror gave the town and caſtle to Maurice, biſhop of London. From this evidence it appears, that the caſtle here, which bore the name of Waytemore, was ſtanding prior to the Norman invaſion, though ſome writers aſſert that it was erected by William. It was probably repaired and ſtrengthened by him, but Mr. Salmon ſeems juſtified in the opinion, that it was conſtructed by the Eaſt Saxons to defend their borders. The lands paying caſtle-guard, lie between this place and the Ermine-ſtreet, one of the great Anglo-Roman roads. The hill, or keep, on which the caſtle ſtood, is artificial, being evidently raiſed with earth brought from ſome diſtance. On the top was a well, and a breaſtwork of ſtone and mortar. A bank of earth runs from the ſummit acroſs the moory ground to the north-eaſt. "This caſtle," ſays Salmon, "muſt have been of ſome conſequence in the time of king Stephen, becauſe of the great deſire Geoffrey de Magnaville had, either to be maſter of it, or to have it pulled down; and Maud the empreſs engaged him to do one or t'other." The ſecurity derived from this fortification gave origin to the town, which had increaſed to ſome conſequence in the time of king John, who created it a borough, and inveſted the inhabitants with certain corporate privileges. This monarch ſeized the caſtle and town from W. de St. Maria, the biſhop of London, who was one of the three biſhops deputed to execute the pope's interdict upon England. This period was diſtinguiſhed by the alarming jealouſies and animoſities between the king and the pope with his prelates; and as Salmon expreſſes it, "the caſtle, at Stortford, ſtands yet a monument of king John's power and revenge, and the Biſhop's lands remain a monument of the pope's entire victory over him." In the time of Edward III. the town and caſtle, &c. again reverted to the biſhop of London, in whoſe ſee it ſtill continues, and who appoints a bailiff for this liberty, which includes the town and thirteen contiguous pariſhes. The Biſhop's priſon was ſtanding in biſhop Bonner's time, but that and all the other old buildings have been ſince demoliſhed.

The ſtreets of the town are diſpoſed in the form of a croſs, with two long ſtreets interſecting each other at right angles. Though no particular manufacture is carried on here, yet the town is reſpectable and populous; it contains 456 houſes, and 2305 inhabitants. Here are a very conſiderable weekly market for grain, &c. on Thurſdays, and three annual fairs, which are moſtly appropriated to the ſale of horſes and cattle.

The church, dedicated to St. Michael, is a large lofty ſtructure, and, like moſt buildings dedicated to that ſaint, ſtands on the higheſt ground in the neighbourhood. There were anciently three guilds and a chantry endowed here; and in the choir are nine ſtalls on each ſide. The interior of this building is decorated with a number of monuments, ſome of which are ancient. The great tythes of the pariſh are in the hands of laymen. In the town are ſome meeting-houſes for diſſenters, methodiſts and quakers, alſo ſome almshouſes, and a ſchool-houſe. The latter was built from a ſubſcription among the gentlemen of Hertfordſhire and Eſſex, who were inſtigated to this act by Dr. Thomas Tooke. This gentleman was zealouſly indefatigable in promoting and eſtabliſhing the foundation which has proved beneficial to the town, and highly honourable to its founder and patrons. The building ſtands on arches, beneath which is a ſpace for market and ſhops. Dr. Tooke revived an annual ſchool-feaſt here, and charged his own eſtate with an annual preſent to the preacher. He alſo gave a chalice of 20l. value to the church, and was a great benefactor to the ſchool-library, which is a very good one, and was firſt eſtabliſhed by the Rev. Thomas Leigh, who was vicar of the church in 1680, &c. Beſides other donations to this library, it is cuſtomary for every gentleman to preſent a book at the time of leaving the ſchool. Biſhop's Stortford derives its compound name from being the property of the biſhop of London at an early period, and from its ſituation on the banks of the river Stort, which ſeparates it on the eaſt from the hamlet

hamlet of Heckerill. At a ſhort diſtance north of this town is Hadham parva, which is noted from being the burial place of the Capels, earls of Eſſex. Biſhop's Stortford is 30 miles north of London. Salmon's Hiſtory of Hertfordſhire.

Biſhop's *Waltham*, a ſmall town of Hampſhire, in England, derives a part of its name from having been a ſeat of the biſhops of Wincheſter. Some of their palace ſtill remains at a ſmall diſtance weſt of the town, and the ſcite now belongs to the ſee. Leland deſcribes it as "a right ample and goodly maner place, moted aboute, and a praty brooke running hard by it. It hath been of many biſhops' buildinge." The celebrated William of Wykeham, biſhop of Wincheſter, reſided here during the laſt three years of his life, and died in this manſion, A. D. 1404, in the 80th year of his age. The houſe was partly demoliſhed in the civil wars of Charles I. when biſhop Kyrl was in poſſeſſion. Biſhop's Waltham is noted for its ſchools, both for gentlemen and ladies. It contains 191 houſes, and 1773 inhabitants, and has three annual fairs.

About five miles ſouth of the town is *Wickham*, a village rendered memorable from being the birth-place of the above-named biſhop. See Wykeham.

BISHOPING, in *Horſemanſhip*, is a term probably derived from *Biſhop*, the name of a horſe-dealer, and denoting a trick of the dealers in horſes for making them appear younger than they are, with a view of impoſing upon the purchaſer.

This is done by excavating the corner tooth of the inciſors with a ſteel graver or file, and afterwards blackening the cavity with a hot iron. This mark, or excavation, is deemed by many the criterion of age, and that the horſe is young while this is preſerved.

To avoid being impoſed upon, the purchaſer ſhould conſider the general figure, not only of the corner tooth, but of all the inciſor teeth of the upper and lower jaw, for they all undergo a perpetual change of figure by age and wear.

An inciſor tooth of the horſe, at its firſt emerging from the jaw, has the viſible part of it flat and covered every where with enamel; the outſide ſharp and projecting higher than the inſide, with a conical cavity in the middle, of various depth in different horſes, which renders it of not much value in deciding upon the age; in ſome it is ſo ſhort as to be obliterated by the ſixth year; in others it is ſo long as to be found till nine or ten, or later; it is, therefore, not a certain criterion of age: the general figure of the tooth is more to be depended upon in our eſtimation. The lateral width of the recent tooth, and its flatneſs, are very remarkable, and can never be imitated; as this wears away, the tooth daily increaſes in its tranſverſe width, that is from front to back, and diminiſhes in its lateral width, forming, as the wear advances, nearly a triangle; theſe angles at length by age gradually diſappear, and the tooth preſents a rounder ſurface on its upper part, and at length the tooth becomes flattened on the ſides, and actually wider from front to back than from ſide to ſide. For it ſhould be recollected, that the tooth is formed in its whole extent previous to its appearance externally, and that the jaw is abſorbed, to allow of its wear: the enamel, like a ſhell, deſcribing the figure and boundary of the tooth, which hollow ſhell is afterwards filled up with bone. A tranſverſe ſection, therefore, of the tooth, or a ſeries of them at different diſtances from its point, afford the exact figures of the ſurfaces of the teeth at the various periods of their wear, and allowing for contingencies which occaſion the teeth to be worn with more or leſs rapidity, as in crib biters, &c. will afford the trueſt criterions of age, and render impoſition in this way impracticable.

The teeth alſo they pretend, in ſome inſtances, to excavate on the inſide, and to ſharpen with a file: theſe bungling attempts, however, in no way reſemble the natural markings or ſurface of the tooth, nor could impoſe upon any one the leaſt experienced in obſerving the teeth. For what we conſider the beſt indications of the age of horſes, however, we refer the reader to the article Teeth *of Horſes*.

BISHOPRIC, the juriſdiction of a biſhop, or the diſtrict within which it is compriſed, called alſo "dioceſe," which ſee.

There are twenty-four biſhopries, and two archbiſhopries, in England and Wales. To the old ones ſubſiſting before the times of the Reformation, Henry VIII. by letters patent added ſix more biſhopries; viz. thoſe of Weſtminſter, Cheſter, Gloceſter, Peterborough, Briſtol, and Oxford, ſtat. 34 & 35 Hen. VIII. cap. 17. Theſe ſees were all founded in the courſe of the years 1540, 1541, and 1542.

The ſee of Weſtminſter, having never had but one biſhop, was united to that of London, and its biſhop tranſlated to Norwich, by Edward VI. in 1550. The remaining biſhopries are comprehended under two provinces, thoſe of Canterbury and York. The province of Canterbury includes the following biſhopries, viz. 1. The biſhopric of London, containing Eſſex, Middleſex, and part of Hertford, and extending its juriſdiction to the Weſt India iſlands. 2. Wincheſter, comprehending Surry, Hampſhire, and the iſles of Wight, Jerſey, Guernſey, and Alderney. 3. Litchfield and Coventry, to which belong Stafford, Derby, and part of Warwick and Shropſhire. 4. Lincoln, comprehending Lincoln, Leiceſter, Huntingdon, Bedford, Buckingham, and part of Hertford. 5. Ely, containing Cambridgeſhire. 6. Saliſbury, to which belong Wilts and Berkſhire. 7. Exeter, including Cornwall and Devon. 8. Bath and Wells, comprehending Somerſetſhire. 9. Chicheſter, to which belongs Suſſex. 10. Norwich, containing Norfolk, Suffolk, and a ſmall part of Cambridge. 11. Worceſter, comprehending Worceſter and part of Warwick. 12. Hereford, including Hereford and part of Shropſhire. 13. Rocheſter, to which belongs part of Kent. 14. Oxford, including Oxfordſhire. 15. Peterborough, containing Northampton and Rutland. 16. Gloucester, comprehending Glouceſterſhire. 17. Briſtol, to which belongs the city of Briſtol, part of Glouceſterſhire, and the county of Dorſet. 18. Landaff, comprehending Glamorgan, Monmouth, Brecknock, and Radnor. 19. St. David's, including Pembroke, Cardigan, and Caermarthen. 20. St. Aſaph, containing the greateſt part of Flint, Denbigh, and Montgomery, and ſome part of Shropſhire. 21. Bangor, to which belong the counties of Angleſey, Caernarvon, Merioneth, and part of Denbigh and Montgomery. The province of York comprehends,— 22. Durham, containing Durham and Northumberland. 23. Carliſle, including great part of Cumberland and Weſtmoreland. 24. Cheſter, to which belong Cheſhire, Lancaſhire, Richmondſhire, which is part of York, together with part of Cumberland and Weſtmoreland. 25. Iſle of Man. The value of theſe ſees is not eaſily aſcertained, as it is very different from that which is ſtated in the king's books. It is a certain fact, whatever may be the primary occaſion of it, that the revenues of the biſhopries are very unequal in value, and that there is alſo a great inequality in the patronage appertaining to the different ſees. Adverting to this circumſtance, Dr. Watſon, the preſent biſhop of Landaff, addreſſed a "Letter to his Grace the Archbiſhop of Canterbury," printed in 1783, propoſing a ſcheme for rendering the biſhopries more equal to each other, with reſpect to both income and patronage, by annexing part of the eſtates, and part of the preferments, of the

the richer biſhoprics, as they became vacant, to the poorer. The advantages, reſulting from the accompliſhment of this object, and recited by the learned prelate, are ſuch as follow: The poorer biſhops would thus be freed from the neceſſity of holding eccleſiaſtical preferments "in commendam" with their biſhoprics; a practice, which bears hard upon the rights and expectations of the reſt of the clergy; which is diſagreeable to the biſhops themſelves; which expoſes them to much, perhaps undeſerved, obloquy; but which certainly had better not ſubſiſt in the church. The biſhops would alſo thus acquire a greater independence in the houſe of lords; and the meaſure would contribute to reduce the influence of the crown in that houſe. This plan would likewiſe enſure a longer reſidence of the biſhops in their reſpective dioceſes, as temptations to tranſlations would be thus removed, and prelates would of courſe become more attached to their particular ſituations, gain a more intimate acquaintance with their clergy, and ſerve, by their doctrine and example, to produce the beſt effect in the conduct both of clergy and laity. See AUGMENTATION.

In Ireland there are 18 biſhoprics, and 4 archbiſhoprics. Under the archbiſhop of Armagh, the primate, are the biſhops of Meath, Kilmore and Ardagh, Dromore, Clogher, Raphoe, Down and Connor, and Derry. Under the archbiſhop of Dublin are Kildare, Ferns and Laughlin, and Oſſory. Under the archbiſhop of Caſhel are Waterford and Liſmore, Limerick, Killaloe, Cork and Roſs, and Cloyne. Under the archbiſhop of Tuam are Elphin, Cloyne, and Killala and Achonry. The primacy is eſtimated at 8000l. a year, Derry at 7000l., and the other biſhoprics from 4000l. to 2000l. The catholics have a hierarchy nearly ſimilar; but the metropolitans and biſhops are conſidered by the proteſtants as merely titular.

The ancient eccleſiaſtical eſtabliſhment of Scotland compriſed two archbiſhoprics, thoſe of St. Andrews and Glaſgow, and eleven biſhoprics (that of Edinburgh having been only eſtabliſhed by Charles I.), which, in the order of antiquity, may be thus enumerated; Galloway (St. Andrews), Dunkeld, Moray; five founded by David I., Brechin, Dumblane, Aberdeen, Roſs (Glaſgow); that of Argyle, or Liſmore, was founded about the year 1200, becauſe the biſhops of Dunkeld did not ſpeak the Iriſh tongue; the biſhops of Orkney and of the weſtern iſlands date from an earlier period, while their ſees were not ſubject to the Scottiſh crown. But ſince the revolution in 1688, the eccleſiaſtical government of Scotland is of the Preſbyterian form; and of courſe they have no biſhoprics.

Biſhoprics, as well as archbiſhoprics, may become void by death, deprivation, and reſignation; but a biſhop muſt reſign to his metropolitan. See ARCHBISHOPRIC.

BISI, BONAVENTURA, in *Biography*, an eminent painter and engraver, and a monk, as ſome ſay, of the order of St. Francis, was born at Bologna, and became a diſciple of Lucio Maſſari. His chief excellence conſiſted in copying in miniature the pictures of Corregio, Guido, Titian, and other maſters, which he finiſhed with ſurpriſing beauty and elegance. Many of his works, which are highly valued, are in the duke's gallery at Modena. He alſo amuſed himſelf by etching ſome few plates from Parmegiano, Guido, &c. One, probably from his own deſign, was a "Holy Family," with Elizabeth and St. John, dated 1631. He died in 1662; but his age is not known. Strutt and Pilkington.

BISIGNANO, in *Geography*, an inconſiderable town of Naples, in the province of Calabria citra, ſeated on a hill near the river Crati, ſurrounded by lofty mountains, and defended by a ſtrong fortreſs. It gives the title of prince to the laſt remaining branch of the ancient houſe of San Severino, and is a biſhop's ſee, ſuffragan of Roſſano; diſtant 16 miles W. S. W. from Roſſano, and about 18 miles N. from Coſenza. N. lat. 39° 38'. W. long. 16° 22'.

BISK, or BISQUE, in *Cookery*, a rich ſort of broth or ſoup, made of pigeons, chickens, force-meat, mutton-gravy, and other ingredients. The word is French, formed, as ſome think, from *biſcocta*; becauſe the *biſque*, conſiſting of a diverſity of ingredients, needs ſeveral repeated coctions to bring it to perfection. There is alſo a *demi-biſque*, made at a low expence, in which only half the ingredients are uſed; and a *biſque* of fiſh, made of carps, minced with their roes and lobſters.

BISKET, BISQUET, or BISCUIT, uſually denotes a delicate kind of bread prepared by the confectioners, of fine flour, eggs, ſugar, and roſe or orange water; or of flour, eggs, and ſugar, with aniſe-ſeeds and citron-peel; baked in the oven in tin or paper moulds. The word comes from the Latin *bis*, *twice*, and the French *cuit*, *coctus*, q. d. *baked*. We find divers ſorts of ſuch biſkets, as ſeed-biſket, fruit-biſket, long-biſket, round-biſket, Naples-biſket, ſponge-biſket, &c.

BISKET, *ſea*, is a ſort of bread much dried, to make it keep for the ſervice of the ſea. It was formerly baked twice or oftener, and prepared ſix months before the embarkation. It will hold good a whole year. To preſerve ſea-biſkets from inſects, Dr. Hales adviſes to make the fumes of burning brimſtone paſs through the caſks full of bread. Biſket may be likewiſe preſerved a long time, by keeping it in caſks well calked, and lined with tin.

The ſhip-biſcuit is too hard for ſome teeth; and in this caſe, it may be ſoftened by toaſting. But ruſk is better; for being made of good fermented bread, ſliced, and baked a ſecond time, the pieces imbibe the water eaſily, ſoften immediately, and digeſt more kindly, and are therefore more wholeſome than the unfermented biſcuit. Ruſk, ſays Dr. Franklin, is the true original biſcuit, ſo prepared to keep for ſea, being twice baked, as its name imports. See Franklin's Maritime Obſervations, in Amer. Tranſ. vol. ii. p. 322.

The ancients had their biſket prepared after the like manner, and for the like uſe as the moderns. The Greeks called it ἄρτος δίπυρος, q. d. "bread put twice to the fire." The Romans gave it the name of "panis nauticus," or "capta." Pliny denominates it "vetus aut nauticus panis tuſus atque iterum coctus." By which it appears, that after the firſt baking, they ground or pounded it down again for a ſecond. In ſome middle-age writers, it is called "paximas," "paximus," and "panis paximatus."

Among the Romans, we alſo meet with a kind of land-biſket for the camp-ſervice, called "buccellatum," ſometimes "expeditionalis annona," which was baked much, both to make it lighter for carriage, and leſs liable to corrupt, the coction being continued till the bread was reduced one fourth of its former weight.

The proceſs of biſket baking for the Britiſh navy is as follows; and it is equally ſimple and ingenious. The meal, and every other article, being ſupplied with much certainty and ſimplicity, large lumps of dough, conſiſting merely of flour and water, are mixed up together: and as the quantity is ſo immenſe, as to preclude by any common proceſs a poſſibility of kneading it, a man manages, or, as it is termed, rides a machine which is called a horſe. This machine is a long roller, apparently about four or five inches in diameter, and about ſeven or eight feet in length. It has a play to a certain extention, by means of a ſtaple in the wall, to which is inſerted a kind of eye, making its action like the machine by which they cut chaff for horſes. The lump of dough being placed exactly in the centre of a raiſed platform, the

man fits upon the end of the machine, and literally rides up and down throughout its whole circular direction, till the dough is equally indented; and this is repeated till it is ſufficiently kneaded; at which times, by the different poſitions of the lines, large or ſmall circles are deſcribed, according as they are near to or diſtant from the wall, till you have fairly the idea of an immenſe pentagraph. The dough in this ſtate is handed over to a ſecond workman, who ſlices it with a prodigious knife; and it is then in a proper ſtate for the uſe of thoſe bakers who attend the oven. Theſe are five in number; and their different departments are as well calculated for expedition and correctneſs, as the making of pins, or the working or printing of types. On each ſide of a large table, where the dough is laid, ſtands a workman; at a ſmall table near the oven ſtands another; a fourth ſtands by the ſide of the oven, to receive the bread; and a fifth, to ſupply the peel. By this arrangement the oven is as regularly filled, and the whole exerciſe performed in as exact time as a military evolution. The man on the further ſide of the large table moulds the dough, having previouſly formed it into ſmall pieces, till it has the appearance of muffins, although rather thinner, and which he does two together, with each hand; and as faſt as he accompliſhes this work, he delivers his work over to the man on the other ſide of the table, who ſtamps them with a docker on both ſides with a mark, on which are cut the broad  , the letters PLY, and the number of the oven in which the biſcuits are to be baked. As he rids himſelf of this work, he throws the biſkets on the ſmaller table next the oven, where ſtands the third workman, whoſe buſineſs is merely to ſeparate the different pieces into two, and place them immediately under the hand of him who ſupplies the oven, whoſe work of throwing, or rather chucking, the bread upon the peel, muſt be ſo exact, that if he looked round for a ſingle moment, it is impoſſible he ſhould perform it correctly. The fifth receives the biſket on the peel, and arranges it in the oven; in which duty he is ſo very expert, that though the different pieces are thrown at the rate of ſeventy in a minute, the peel is always diſengaged in time to receive them ſeparately. As the oven ſtands open during the whole time of filling it, the biſkets firſt thrown in would be firſt baked, were there not ſome counteraction to ſuch an inconvenience. The remedy lies in the ingenuity of the man who forms the pieces of dough, and who, by imperceptible degrees, proportionably diminiſhes their ſize, till the loſs of that time, which is taken up during the filling of the oven, has no more effect to the diſadvantage of one of the biſcuits than to another.

So much critical exactneſs and neat activity occur in the exerciſe of this labour, that it is difficult to decide whether the palm of excellence is due to the moulder, the marker, the ſplitter, the chucker, or the depoſiter; all of them, like the wheels of a machine, ſeeming to be actuated by the ſame principle. The buſineſs is to depoſit in the oven ſeventy biſkets in a minute; and this is accompliſhed with the regularity of a clock; the clack of the peel, during its motion in the oven, operating like the pendulum.

The biſcuits thus baked are kept in repoſitories, which receive warmth from being placed in drying lofts over the ovens, till they are ſufficiently dry to be packed into bags, without danger of getting mouldy; and when in ſuch a ſtate, they are then packed into bags of a hundred weight each, and removed into ſtorehouſes for immediate uſe.

The number of bake-houſes, belonging to the Victualling Office at Plymouth, are two; each of which contains four ovens, which are heated twenty times a day; and in the courſe of that time bake a ſufficient quantity of bread for 16,000 men. The granaries are large, and well conſtructed; when the wheat is ground, the flour is conveyed into the upper ſtories of the bake-houſes, whence it deſcends through a trunk in each immediately into the hands of the workmen.

The bake-houſe, belonging to the Victualling Office at Deptford, conſiſts of two diviſions, and has twelve ovens; each of which bakes twenty ſhoots daily (Sundays excepted); the quantity of flour uſed for each ſhoot is two buſhels, or 112 pounds, which baked produce 102 pounds of biſket. Ten pounds are regularly allowed on each ſhoot for ſhrinkage, &c.

The allowance of biſket in the navy is one pound for each man per day, ſo that one of the ovens at Deptford furniſhes bread daily for 2040 men.

BISLAN, in *Geography*, a town of Egypt on the Nile, 3 miles ſouth of Damietta.

BISLEY, anciently called *Biſſlege*, is a ſmall market town, and a very extenſive and populous pariſh of Glouceſterſhire, in England. The pariſh includes an area of 6000 acres, the ſurface of which is diverſified with ſteep hills and narrow valleys. On the ſides of the former are ſome incloſed arable lands, interſperſed with copſes; and the latter are moſtly kept for meadow paſturage. Biſley, Chalford, and ſome neighbouring hamlets, are chiefly inhabited by perſons engaged in the woollen manufactures; and many fulling and dreſſing mills are erected on the river which runs through this pariſh. A ſmall weekly market is held here on Thurſdays, and here are two conſiderable fairs yearly. The church is a large handſome building, and, being ſeated on a high hill, is conſpicuous for many miles. Here is a ſmall free ſchool, and an endowment for clothing ſix widows yearly. The *canal*, which unites the Thames and Severn, paſſes through this pariſh; and near the verge of it, at Sapperton, enters a ſubterraneous *tunnel*, which is cut through the earth to an extent of two miles and five furlongs. This tunnel is lined with maſonry, and arched over at top, with an inverted arch at the bottom, except at thoſe places where the ſolid rock rendered it unneceſſary. The expence of cutting it was about eight guineas per cubic yard; but the plan of uniting the waters of the two great Britiſh rivers induced the proprietors to encounter extraordinary expence and trouble. The connection of the rivers Thames and Severn, by means of this canal, and alſo with the internal parts of the kingdom, by the Oxford and Coventry canals, which lead to Birmingham, and alſo to the counties of Staffordſhire, York, Cheſter, and even to Weſtmoreland, forms a line of communication with the capital of the greateſt importance, and which has proved of great utility to the manufacturing towns through which it paſſes. On the 29th of April 1789, the acting engineer, Mr. Clowes, paſſed through the tunnel for the firſt time, in a veſſel of thirty tons burthen; and the junction was completed, and a veſſel paſſed from the Severn into the Thames, for the firſt time, on the 19th of November in the ſame year, in the preſence of a large concourſe of people, who came to witneſs and rejoice at the ſight. In 1788, their majeſties went from Cheltenham, on purpoſe to view this tunnel, which excited their ſurpriſe and admiration, more particularly when they learnt it had been conducted and completed by a private gentleman. The canal is 30 miles and 7 chains in length; in which courſe the water is raiſed 241 feet 3 inches, and made to fall 130 feet 6 inches. In the pariſh are 922 houſes, and 4227 inhabitants. Rudge's Hiſtory of the County of Glouceſter. Phillips' Hiſtory of Inland Navigation.

BISLINGUA, *double-tongue*, in *Botany*, a name uſed by many authors for the narrow-leaved *ruſcus*, or *butcher's broom*;

broom; called by many others the Alexandrian bay, or *laurus Alexandrie*.

BISMARCK, in *Geography*, a town of Germany, in the circle of Upper Saxony, and Old Mark of Brandenburgh; 12 miles weſt of Stendal.

BISMEO, or Bismea, a town of Africa, in the kingdom of Algiers, 25 miles weſt from Algiers.

BISMILLAH, in the *Mahometan Cuſtoms*, a ſolemn form, viz. *in the name of the moſt merciful God*, conſtantly placed at the beginning of their books and writings in general, as a peculiar mark or diſtinguiſhing characteriſtic of their religion; it being counted an impiety to omit it.

The Jews, for the ſame purpoſe, make uſe of the form, "in the name of the Lord, or, "in the name of the great God." Sale.

Bismillah is alſo uſed among the Arabs, as a word of invitation to eat. An Arab prince will frequently ſit down to eat in the ſtreet before his own door, and call all that paſs, even beggars, by this word, who do not fail to come and ſit down to eat with him; for the Arabs are great levellers, and ſet every body on a footing with themſelves. Pocock's Egypt, &c. p. 483.

BISMUTH, *Wiſmutum*, Wallerius; *Wiſmuth*, or *Biſmuth*, Germ.; *Biſmuth*, Fr.; *Plumbum cinereum*, *Antimonium ſemininum*, *tin-glaſs*, of the older chemiſts.

Biſmuth is a brittle metal, of a reddiſh white colour, and foliated fracture, is fuſible at nearly the ſame temperature with lead, ſoluble with eaſe in nitric acid, and precipitable from it in the form of a white oxyd by the addition of pure water.

§ 1. *Ores of Biſmuth.*

Sp. 1. *Native Biſmuth. Gediegen Wiſmuth.*

The colour of this mineral is ſilver-white, with a ſlight tinge of red, frequently exhibiting an irideſcent appearance on its ſurface. It occurs very rarely in maſs, being generally diſſeminated, or inveſting; it is alſo met with feather-ſhaped, or reticular, or in lamellæ of a rectangular or triangular ſhape, either ſolitary, or heaped upon each other. It exhibits a metallic luſtre of conſiderable brilliancy. Its fracture is perfectly foliated, or broad ſtriated. It is ſemiductile, and breaks with ſome difficulty into irregular, ſomewhat blunt-edged fragments. Sp. grav. according to Kirwan, = 9.57.

Native Biſmuth is fuſible at a very moderate temperature, often by the heat of a common candle; when expoſed to the action of the blowpipe on charcoal, it volatilizes in the form of a white vapour, not unfrequently accompanied with an arſenical ſmell. It diſſolves very eaſily, and with effervеſcence, in cold nitric acid; and is precipitable in the form of a white powder, on the addition of pure water.

The only two ſubſtances, with which native biſmuth is liable to be confounded, are the ſulphuret of biſmuth and dendritical ſilver; the former of theſe, however, is not ſoluble with effervеſcence in cold nitric acid; and the latter may be diſtinguiſhed by its colour and ductility.

Biſmuth is one of the moſt partially diffuſed metals hitherto known; and it is chiefly found native, accompanied with kupfernickel, white and grey cobalt, black blende, native ſilver, and rarely galena. Its gangue is quartz, calcareous ſpar, or baroſelenite; and it has hitherto been found only in veins in primitive mountains.

It is found at Joachimſthal, in Bohemia; at Freyberg, Annaberg, &c. in Saxony; in Sweden, Tranſylvania, and Britany.

Sp. 2. *Sulphuretted Biſmuth. Wiſmuth glanz*, Emmerling. *Biſmuth ſulphuré*, Hauy.

The colour of this ſubſtance is between lead-grey and tin-white; but on the ſurface it is uſually yellowiſh or irideſcent. It is found either lamellar and in maſs, or diſſeminated, or in ſmall acicular cryſtals. Its primitive figure, according to Hauy, is that of a quadrangular priſm. Its internal luſtre is metallic and very brilliant; its fracture is broad or narrow ſtriated, or foliated like galena. Sp. gr. according to Kirwan, = 6.131. It ſtains the fingers in a ſlight degree; and when reduced to powder, is of a gliſtering black.

When expoſed to the blowpipe, it melts eaſily, giving out a ſulphureous odour and a blue flame, and is almoſt entirely volatilized before it can be brought to the metallic ſtate. There has been no very accurate analyſis made of this ore; but from the experiments of Sage and La Peyrouſe it appears to contain about 60 per cent. of biſmuth, 36 of ſulphur, and a little iron. There is ſome external reſemblance between the lamellar variety of this mineral and galena; but the ſuperior fuſibility of the former is an eaſy and infallible characteriſtic.

Sulphuret of biſmuth is very rare; and, where it occurs, is always accompanying native biſmuth. It is found at Joachimſthal, in Bohemia; Altenberg and Johann-Georgenſtadt, in Saxony; and at Baſtnas, near Riddarhytta, in Sweden.

Sp. 3. *Oxyd of Biſmuth. Biſmuth ochre*, Kirw. *Wiſmuth-ocker*, Emmerling. *Biſmuth oxydé*, Hauy.

This mineral is of a greeniſh yellow colour, paſſing into aſh-grey, or ſtraw colour. It is ſometimes found in maſs, but more commonly diſſeminated or inveſting. It is opaque, and poſſeſſes a ſlight degree of internal luſtre. Its fracture is fine-grained, uneven, or earthy. Sp. grav. conſiderable, but has not yet been accurately aſcertained. It is either friable, or of the conſiſtence of chalk, but occaſionally gives fire with ſteel, on account of the particles of quartz with which it is mixed.

When expoſed to the action of the blowpipe on charcoal, it is very eaſily reducible to the metallic ſtate. It is ſoluble in nitric acid without effervеſcence, and precipitable for the moſt part by the addition of water.

Oxyd of biſmuth is an extremely rare mineral. It has hitherto only been found at Schneeberg, in Saxony, accompanying native biſmuth; in the Black Foreſt mines, in Swabia; and at Joachimſthal, in Bohemia. It is often confounded with the green earthy iron ore; but may be at once diſtinguiſhed by its eaſy reduction before the blowpipe. Emmerling, vol. ii. p. 434, &c. Wiedenmann, p. 887. Brochant, v. 2. p. 343. Hauy, v. 4. p. 184. Kirwan, vol. ii. p. 263.

§ 2. *Aſſay and Analyſis of Biſmuth Ores.*

Sulphur and iron are the only ſubſtances that have been as yet detected in combination with this metal, as far as can be inferred from very imperfect analyſes of the preceding ores. But Klaproth, in his examination of the biſmuthic ſilver ore from Shapbach (Analyt. Eſſ. vol. i. p. 556.), found it to be a combination of lead, ſilver, iron, copper, and ſulphur, with biſmuth; and from the experiments of this able chemiſt is deduced the following general method of analyſing the ores of biſmuth.

Having reduced the ore to a tolerably fine powder, pour upon it, in a capacious flaſk, five times its weight of nitric acid previouſly diluted with one third of water. The acid will begin to act immediately, without the aſſiſtance of heat; nitrous gas will be diſengaged in great quantity; and the ſolution will aſſume a greeniſh yellow colour. When the acid has taken up as much it can, or nearly ſo, pour it off, and digeſt the undiſſolved reſidue in a moderate heat, with equal parts of nitric acid and water, renewing the

menſtruum from time to time, till all the ſoluble parts of the ore are taken up. Add together the ſolutions, and reduce them by gentle evaporation to about half their bulk (if any cryſtals are depoſited, add a little pure warm water juſt ſufficient to take them up again); then pour the whole into a large quantity of rain water, at leaſt twenty times the bulk of the ſolution. The liquor will immediately aſſume a milky appearance, and, by ſtanding a ſhort time, will depoſit a white heavy precipitate (*a*), which, when carefully lixiviated, is *pure oxyd of biſmuth*. Add all the liquors together, and concentrate them by evaporation to one half of their bulk; then drop in a ſtrong ſolution of muriated ammonia, as long as any precipitate takes place; decant the ſupernatant fluid as accurately as poſſible, and, without waſhing the precipitate, digeſt it for ſome time with moderately ſtrong nitric acid; the undiſſolved part of the precipitate being ſeparated, waſhed, and dried, is *pure muriat of ſilver* (*b*). The nitrous ſolution is now to be diluted with a large quantity of cold water, and a precipitate of oxyd of biſmuth (*c*) will be thrown down. The diluted nitrous ſolution being mixed with the other liquor, the whole muſt be evaporated, till a conſiderable number of cryſtals are depoſited; at this time, the addition of ſulphuric acid will occaſion a white depoſit of *ſulphat of lead* (*d*). The remainder of the ſolution is now to be ſuperſaturated with cauſtic liquid ammonia, by which the *iron* will be depoſited in the ſtate of brown oxyd (*e*), and the copper will form with the ammonia a blue ſolution; this being ſaturated ſlightly to exceſs with ſulphuric acid, will depoſit the *copper* (*f*) upon a piece of clean iron. The reſidue of the ore that was undiſſolved by nitric acid, being weighed, and expoſed to a low red heat, will give out its *ſulphur* (*g*), the quantity of which may be eſtimated with conſiderable accuracy by the loſs of weight. It is now finally to be digeſted with ten times its weight of boiling muriatic acid, by which ſome oxyd of lead will be taken up; and this, by evaporation and the addition of ſulphuric acid, may be procured in the ſtate of ſulphated lead (*h*). The reſidue being waſhed and dried is the ſtony gangue of the ore (*i*).

Hence the ore will be decompoſed into

Oxyd of biſmuth (*a*) and (*e*),
Muriated ſilver (*b*),
Sulphated lead (*d*) and (*h*),
Oxyd of iron (*e*),
Metallic copper (*f*),
Sulphur (*g*),
Stony matrix (*i*)

§ 3. *Reduction of Biſmuth ores.*

The ſeparation of this metal from the ſubſtances with which it is found united in the mine, and the reduction of it to a marketable ſtate, is perhaps the eaſieſt of all the metallurgical proceſſes, on account of the ready fuſibility of biſmuth, and its being found for the moſt part in the metallic ſtate. The following were the methods practiſed in the time of Agricola (De Re Metallica, p. 349.) A round pit, two or three feet wide, was lined with well rammed clay and charcoal, and covered with billet wood, upon which were laid alternate ſtrata of ore and wood. When the pile was thus built to a ſufficient height, fire was applied to the top, and the biſmuth, as the heat penetrated through the maſs, became melted, and trickled down into the hole beneath, where it collected in an irregular maſs; being then withdrawn, and broken into pieces, it was remelted in iron or earthen pots, ſeparated from the impurities that floated on its ſurface, and finally caſt into flat cakes, or loaves, for ſale. Another method was to divide a large pine tree longitudinally, and cut out the central part of the wood, thus forming it into a gutter; this being placed ſomewhat inclined, the ore was laid in the upper end, on a bed of chips and ſmall wood, ſufficient, when ſet on fire, to liquify the biſmuth, which, flowing down, was collected in a hole or veſſel placed at the end of the trough.

The ſcarcity of wood has, however, put an end to theſe rude and extravagant methods; and the ores of biſmuth are now reduced in a common reverberatory furnace, the bed of which is lined with charcoal, whence the melted metal is removed in iron ladles, and caſt into maſſes weighing twenty or thirty pounds, in which ſtate it is brought to market.

§ 4. *External Characters and Phyſical Properties.*

Biſmuth is a white metal with a reddiſh yellow tinge; is conſiderably hard, but brittle, exhibiting a broad foliated fracture; has a bright, almoſt ſpecular metallic luſtre; and is ſomewhat ſonorous, when ſtruck. Though brittle, it may be compreſſed very conſiderably by judicious hammering, and therefore varies greatly in its ſpecific gravity. According to Muſchenbrocck, its ſp. gr. when freſh melted, is $= 8.716$; but when laminated, is $= 9.638$. Bergman fixes its gravity at 9.67; and other authors make it as high as 9.8, or even 10. The laminæ, of which this metal is compoſed, have but little adheſion to each other; hence the primitive form of its cryſtals, which is that of a regular octahedron, may very eaſily be aſcertained by diſſection. It is fuſible at 460° Fahr., and may be poured into a paper cone without burning it. If, after it has begun to ſolidify, the fluid part is poured off, a groupe of cryſtals is obtained in cubes, or rectangular volutes. When expoſed in cloſe veſſels to a violent heat, it ſublimes and attaches itſelf to the cooler part of the apparatus in the form of brilliant plates.

§ 5. *Oxyds of Biſmuth.*

The combined action of air and moiſture upon biſmuth, at the uſual temperature, is very ſlight; it becomes covered with a reddiſh grey ſuperficial tarniſh, and afterwards appears to undergo no further change. At a melting heat, it ſhortly becomes covered with an irideſcent film, and by expoſing freſh ſubſtances to the air, is wholly converted into a yellowiſh brown oxyd, weighing about $\frac{1}{12}$ more than the original metal. This oxyd melts into a yellow glaſs at a moderate red heat, and ſoon penetrates through the moſt compact earthen crucibles, though not quite ſo eaſily as glaſs of lead does. When biſmuth is expoſed to a ſtrong heat, with free acceſs of air, it burns with a faint blue flame, and throws up at the ſame time a copious white oxyd, which was formerly called *flowers of biſmuth*; towards the end of the proceſs the oxyd acquires ſomewhat of a yellowiſh tinge, probably on account of a ſmall portion of ſulphur, or other impurities. The glaſs, or vitreous oxyd of biſmuth, is a very active flux for earths and the more difficultly fuſible oxyds; on account, however, of the ſuperior cheapneſs and efficacy of lead, it is ſeldom uſed for this purpoſe.

§ 6. *Action of Acids on Biſmuth.*

1. Concentrated ſulphuric acid has no action on biſmuth, except when boiling hot; in this ſtate, it is rapidly decompoſed, giving out ſulphureous acid gas, and reducing the metal to a white pulverulent oxyd; by a low red heat the decompoſition is ſo complete, that a quantity of actual ſulphur is volatilized. The white maſs being waſhed with a little warm water, parts with nearly the whole of its acid, holding a ſmall portion of biſmuth in ſolution: this fluid, by careful evaporation, depoſits minute ſoft cryſtalline needles of ſulphat of biſmuth, from which, by the mere affuſion of water, the metal may be ſeparated in the form of white oxyd. The ſulphated oxyd, produced in the firſt

part

part of the proceſs, is remarkably more difficult of reduction than any of the pure oxyds of § 5.

2. Sulphureous acid is incapable of attacking metallic biſmuth, but readily combines with its oxyd, forming a white inſoluble ſulphite of a ſulphureous flavour, reducible into metallic globules before the blowpipe, decompoſable with effervescence by ſulphuric acid, and when diſtilled, giving out its acid, a maſs of pure white oxyd remaining behind.

3. Nitric acid acts upon biſmuth in a remarkably violent manner. If the metal is in powder, and the acid ſomewhat concentrated, at the inſtant of their mixture, even without the aſſiſtance of heat, a rapid decompoſition of the acid takes place, accompanied with the production of nitrous gas, azot, and ſometimes of ammonia; and the biſmuth is converted into a white oxyd. If the acid is previouſly diluted with an equal weight of water, and the biſmuth is added gradually in ſmall pieces, the decompoſition goes on more quietly, the metal is diſſolved in proportion as it oxydates, and the acid may be made to take up nearly half its weight of biſmuth. By cautiouſly adding to this ſolution an equal bulk of diſtilled water (each portion being well mixed with the whole maſs by ſtirring, before the addition of a ſucceeding portion), a black pulverulent precipitate takes place, which has not yet been analyſed, but has been taken for ſulphur or charcoal. If the acid made uſe of is ſtill more dilute, conſiſting, for example, of four parts of water, and one of nitric acid, the black matter is not diſſolved. Nitrat of biſmuth, when thus purified, is clear and colourleſs, and by gentle evaporation cryſtallizes in the form of flattened rhomboids, or compreſſed tetrahedral priſms terminated by three ſided pyramids. This ſalt, when expoſed to a dry air, is conſiderably efflorescent; but in a humid air, becomes covered with a white, ſomewhat moiſt coating of oxyd. When thrown on hot coals, it detonates feebly, giving out faint red ſparks, and leaves behind a greeniſh yellow oxyd of difficult reduction. If a cryſtal of nitrated biſmuth is thrown into ſome pure water, it immediately becomes covered with a white opaque oxyd; but the decompoſition of this ſalt is more ſtriking, if a ſolution of it is made uſe of. For this purpoſe, let a jar be nearly filled with clear rain water, and drop into it nitrat of biſmuth as long as any precipitation takes place, then mix the whole by agitation, and let it ſtand for an hour to ſettle. The bottom of the veſſel will now be covered with a fine heavy powder of a dazzling white, which, when repeatedly waſhed and dried, is pure oxyd of biſmuth, formerly called *magiſtery of biſmuth*, and well known as a coſmetic under the name of *blanc de fard*. This preparation, if made with pure nitric acid, and well waſhed, is of a dead white; but if a little muriatic acid is mixed with the nitric, and the precipitate is waſhed with a *ſmall* portion of *cold* water, it will be in the form of minute glittering ſcales with a beautiful pearly luſtre, and is then called by the French *blanc de perles*. In both ſtates it is extenſively employed, particularly by the French ladies for whitening the ſkin, but is ſubject to turn grey, brown, and even black, by any hydrogenous and ſulphureous vapours. This oxyd of biſmuth does not appear to retain any nitric acid; and its component parts are fixed by Bergman at 77 of metal, and 23 of oxygen; but, by the more accurate experiments of Klaproth, its contents are aſcertained to be 81 of metal to 19 of oxygen. Nitrated biſmuth is not, however, totally decompoſable by water; for the clear fluid, that is ſeparated by filtration from the oxyd, may ſtill be made to yield a precipitate by a carbonated alkali, muriatic acid, or muriated ammonia. Klaproth found (Analyt. Eſſ. vol. i. p. 557.), that 100 grains of biſmuth, diſſolved in nitric acid, yielded with water 88 grains of oxyd, and 35 more were obtained from the diluted ſolution, by the action of muriatic acid added in drops as long as any precipitate enſued. This oxyd is very eaſily reduced by fuſion in a covered crucible, with a little nitre and tartar.

4. Biſmuth in the metallic ſtate is acted upon with difficulty by muriatic acid, even when it is concentrated and aſſiſted by heat. During the digeſtion, a ſmall quantity of fetid hydrogen gas is given out; and, by ſlow evaporation, ſmall deliqueſcent needle-ſhaped cryſtals are depoſited of muriat of biſmuth. This ſalt, however, may be obtained in much greater quantity, and more eaſily, by ſubſtituting the oxyd of biſmuth for the pure metal. If the ſaline maſs, which remains behind after evaporation to dryneſs, is diſtilled in a glaſs retort, nearly the whole of it comes over at a moderate heat, and concretes into a ſoft white maſs, called formerly *butter of biſmuth*. Butter of biſmuth, like butter of antimony, is intenſely cauſtic to the taſte, deliquiates in a moiſt air, and when dropped into water, is decompoſed, a fine white oxyd being precipitated.

5. Liquid oxy-muriatic acid acts upon metallic biſmuth with conſiderably more energy than muriatic acid does: the metal is oxydated without the diſengagement of hydrogen, and the reſult is muriat of biſmuth. It is probable, that by ſubſtituting the oxyd of biſmuth for the pure metal, oxymuriat of biſmuth might be produced: this, however, is not as yet confirmed by experiment. If biſmuth, previouſly reduced to fine powder, is poured into oxymuriatic acid gas, the metal is inſtantly ignited and oxydated, and falls in a ſhower of fire to the bottom of the veſſel.

6. Tincture of galls, or gallic acid, precipitates biſmuth of a greeniſh colour from its ſolution, as pruſſiated potaſh does of a yellowiſh colour.

7. There is ſcarcely any thing known concerning the other biſmuthic ſalts. They are formed by digeſting the yellow oxyd in the various acids that have not been already mentioned, and are for the moſt part but little ſoluble in water. The proportions of their ingredients have not been aſcertained with any accuracy, nor are they applied to any uſe.

§ 7. *Action of the Alkalies and Earths on Biſmuth.*

The fixed alkalies have no effect on metallic biſmuth, but unite both in the humid and dry way with its oxyd. Ammonia is ſaid to acquire a greeniſh yellow colour by digeſtion with the metal when pulverized, and certainly diſſolves its oxyd in conſiderable proportion. The action of the earths upon biſmuth is unknown, except that ſilex and oxyd of biſmuth combine by fuſion into a clear greeniſh yellow glaſs.

§ 8. *Action of the Neutral Salts on Biſmuth.*

None of the neutral ſalts in ſolution appear to exert any affinity on biſmuth or its oxyds; but, in a dry heat, many of them are decompoſed by it.

Nitre, being mixed with pulverized biſmuth, and projected into a red hot crucible, is decompoſed with a ſlight detonation; the biſmuth becomes oxydated, and then unites in part with the alkaline baſe of the nitre.

Muriat of ſoda, according to Pott, is in ſome degree decompoſable by metallic biſmuth. This fact, however, is not confirmed by later chemiſts; and it is probable, that the ſalt, which Pott made uſe of, was not free from muriated magneſia, and that the biſmuth was partly oxydated.

Muriated ammonia is totally decompoſable by oxyd of biſmuth. On the firſt impreſſion of the fire, very pure ammoniacal gas is diſengaged; and by a low red heat, the muriated biſmuth riſes in the form of a thick white vapour, which concretes, in the receiver and neck of the retort, into *butter of biſmuth*; if the oxyd of biſmuth is in very ſmall proportion

proportion to the muriat of ammonia, the greater part of this falt rifes entire, but mixed with a little muriat of bifmuth, forming the *bifmuthic flowers of fal-ammoniac* of the old chemifts. When thefe flowers are thrown into water, the bifmuth is depofited in the form of a white oxyd.

Oxymuriat of potafh mingled with powdered bifmuth, and projected into a hot crucible, is decompofed with great violence, and the metal is completely oxydated. A mixture of three parts of this falt, and one of bifmuth, produces a flafh and a loud detonation, if laid on an anvil and ftruck fmartly with a hammer.

§ 9. *Bifmuth with combuftible Bodies.*

If one part of fulphur, and four of bifmuth, are triturated together, and afterwards expofed to a full red heat in a covered crucible, a brilliant ftriated metallic mafs of fulphuret of bifmuth is obtained, fimilar in its properties to the native fulphuret mentioned in § 1. It may be made to cryftallize, by allowing it to cool very gradually, and pouring off the fluid part as foon as the furface is crufted over. The cavity thus formed will be found to be lined with long tetrahedral prifms croffing each other, and occafionally of a deep irideficent blue and red colour, forming groupes of exquifite beauty. The fulphuret of bifmuth is much lefs fufible than the pure metal; it parts with nearly the whole of its fulphur by long roafting, and is decompofable by nitric acid, which diffolves the bifmuth without touching the fulphur.

Sulphuretted hydrogen converts the white oxyd of bifmuth into a black mafs, of which neither the properties nor proportions have been afcertained.

Phofphorus has very little affinity for this metal. Pelletier tried in vain by feveral methods to prepare phofphuret of bifmuth. In fome of his experiments, the metallic globule, when red hot, gave out a faint lambent flame, but exhibited no other proof of combination with phofphorus. Fat oils, by the affiftance of heat, diffolve the oxyd of bifmuth, and form with it a thick tenacious plaifter.

§ 10. *Alloys of Bifmuth.*

Bifmuth appears to increafe remarkably the fufibility of all the metallic compounds into which it enters; but it is to be lamented, that we are greatly in want of accurate experiments on this intereffing branch of enquiry.

1. *Bifmuth and gold.* See GOLD.
2. *Bifmuth and filver.* See SILVER.
3. *Bifmuth and iron.* See IRON.
4. *Bifmuth and copper.* See COPPER.
5. *Bifmuth and lead.* Equal parts of thefe two metals unite eafily by fimple fufion, forming an alloy of a brilliant white colour, confiderably harder than lead, and, though not ductile, more malleable than pure bifmuth. By diminifhing the proportion of bifmuth, the malleability of the mafs is increafed, without fenfibly impairing its fufibility, hardnefs, and luftre.

6. *Bifmuth and tin.* A fmall quantity of bifmuth increafes the hardnefs and brilliancy of tin, without rendering it lefs ductile; hence the beft foils for glafs mirrors are made of this alloy, as alfo are fome kinds of pewter.

Bifmuth with lead and tin. Fufible metal. Plumbers' folder. The fufibility of the alloys of bifmuth is in no inftance fo remarkable as in that difcovered by Newton, and thence commonly called Newton's fufible metal. It is made by melting together eight parts of bifmuth, five of lead, and three of tin. The mafs is very brittle, and when broken exhibits a porcellanous appearance, with little or no luftre; it is fo fufible as to become liquid when held on a piece of ftiff paper over a candle, without fcorching the paper; and becomes as fluid as quickfilver in boiling water. If the bifmuth is reduced to one part, the proportions of lead and tin remaining the fame, the alloy is plumbers' folder; and it differs from the preceding in being fomewhat lefs fufible and confiderably malleable.

7. *Bifmuth and mercury.* See MERCURY.
8. *Bifmuth and iron.* See IRON.

§ 11. *Medical Ufe of Bifmuth.*

The magiftery, or white oxyd, is the only form of bifmuth which is employed medicinally. It is prefcribed with fuccefs in fpafmodic affections of the ftomach. Gren. Syftem. Handbuch, v. iii. p. 292. Leonhardi's Macquer. art. Wifmuth. Fourcroy Syft. des Connaiff. Chimiques, vol. v. Beaumé Chem. experimentale, vol. ii.

BISNAGUR, in *Geography*, an ancient kingdom of Hindoftan, called Narfinga, from the name of one of its rajahs, or fovereigns, was formerly the moft extenfive, powerful, and rich monarchy in the Indies, and comprehended almoft all the countries in the peninfula fouth of the 16th parallel, or the whole of the Carnatic and fome other kingdoms. Some have diftinguifhed between the kingdoms of Bifnagur and Narfinga, but it is not eafy to determine, whether they were two fucceffive, or two co-exifting kingdoms. It appears, probable, however, that in the 16th century Bifnagur included the greateft part of the peninfula. The inhabitants of this ancient empire, which is faid to have continued 800 years, were Pagans, and denominated Badagus; and fpoke the Tamul, or Damul language, which is the fame with the Malabaric; but the Canadagun was ufed at court. According to the Portugueſe writers, the kingdom of Charnataka had no fovereign prince till the year 1200, and the firft was Boka, a fhepherd, who ftyled himfelf rau or rajah, that is emperor; which title has defcended to his fucceffors. Boka, it is faid, in memory of a victory which he obtained over the king of Delhi, built the famous city of Vifianagur, corruptly called Bifnagur. The crown continued in his line till it was ufurped by Narfinga, from whom this kingdom took its name, as it did that of Bifnagur from the city. The king of Bifnagur was a powerful prince about the year 1520; and about the year 1565 the capital was reforted to by merchants from all parts, as being the greateft, if not the only mart for diamonds in the eaft; and its riches were equal to its extent. At this time it was invaded by the king of Vifapour, and other northern princes of the Deccan; and in 1567 the rajah, or king, retired, with his court, firft to Penuconda, and at a fubfequent period, or about 1597, its exifting fovereign removed to Kandegheri, or Chandegheri, an inland city, ftrong by nature and fortified by art, fo as to be deemed impregnable. About the middle of the 17th century, this large monarchy was again invaded and utterly deftroyed, by Adel Shah, king of Vifiapour, who formed a league with the king of Golconda for this purpofe. The unfortunate rajah fled into the mountains, where he remained in 1667. About 20 years after, the kingdom of Bifnagur fell under the power of the Moguls, by the conqueft which Aurungzebe made of the kingdoms of Vifiapour and Golconda.

BISNAGUR, rather BIJINAGUR, fometimes written BEEJANUGGUR, the capital of the above kingdom, is fituated on the fouth bank of the Toombuddra river, and according to M. Buffy's map, diftant about 30 miles S. E. or S. S. E. from Bancapour. Ferifhta fays, that it was founded by Belaldeo, king of the Carnatic, in 1344, and was thus placed in order to guard the northern frontier of his empire. See the preceding article. This city was vifited by Cæfar Frederick in 1565, and was then a very large city; its circuit, as he fays, being 24 miles, and containing within it a number of hills and pagodas. He reckons it 8 days' journey,

journey, or about 140 geographical miles, from Goa. Its ruins are extenſive, ſeveral rugged hills and rocks being covered with temples that ſtill appear beautiful; the circumference ſeems to be about 8 miles. N. lat. 15° 15'. E. long. 76° 34'. Beejanuggur lies directly oppoſite to Annagroondy, ſeated about 2 miles from the north bank of the river Toombuddra, which is at preſent the principal town of a ſmall diſtrict of the ſame name; one being the Jaghire, or eſtate, the other the place of reſidence of the deſcendant of the ancient kings of Beejanuggur, who, about $2\frac{1}{2}$ centuries ago, ruled the greateſt part, if not the whole, of the peninſula, under the title of the empire, or kingdom of Canhara. Lieutenant Emmit, an Engliſh officer, who examined the ruins of Beejanuggur, traced between immenſe piles of rocks, crowned with pagodas, ſeveral ſtreets from 30 to 45 yards wide, ſome of which now produce fine rice. One ſtreet extends about N. E. and S. W. half a mile, and is about 35 yards broad, having colonnades of ſtone on each ſide, and a very large pagoda at the S. W. end, in perfect repair. On the weſt ſide of this ſtreet is a large mango grove, which is bounded by the Toombuddra. Many ſtreams flow through theſe veins, which have been formerly employed to fill a great number of canals. Comlapour fort is diſtant about half a mile, and ſurrounded with hills through which the road winds in aſcents and deſcents, paved with large ſtones.

BISNEE, a town of Aſia, in the country of Bootan, 116 miles S. E. of Taſſaſudon, and 188 N. E. of Moorſhedabad.

BISNOW, or Bischnou, a ſect among the Indian banians, or caſt of merchants. The banian ſect conſiſts of two leſſer ones; that of *biſnow*, and that of *ſamarath*. The followers of the former hold one God, whom they call *ram-ram*, and allow of no lieutenants, or deputy-gods, as is done by thoſe of the ſect *ſamarath*; but they allow their god a wife, and have idols, which they dreſs up with gold chains, and collars of pearl and precious ſtones, and pay them worſhip, by ſinging hymns in their temples, and dancing before them to the ſound of flageolets and kettle-drums.

In this ſect, the wives do not burn themſelves after their huſbands' death, as is practiſed by thoſe of the *ſamarath* ſect; but content themſelves with a perpetual widowhood.

BISOMUM, Disomum, compounded of *bis*, *twice*, and the Greek σωμα, *body*, or *aſhes of a body*, in *Antiquity*, a tomb for two bodies, or the aſhes of two. The ancients frequently buried two, three, or four bodies in the ſame ſepulchre, diſpoſed a-ſide of each other; for it was held an impiety to lay one a-top of another. Hence the ſepulchres of the primitive Chriſtians had the words *biſomi*, *triſomi*, *quadriſomi*, &c. inſcribed on them, to indicate the number of bodies depoſited in them. Du-Cange.

BISON, in *Entomology*, a ſpecies of Scarabæus, with the anterior part of the thorax pointed; and two lunated horns on the head. Inhabits Spain, and the ſouthern parts of France. Colour black. The female has on the anterior margin of the thorax an elevated or carinated edge.

Bison, in *Zoology*. See Bos Ferus, or *Wild-Ox*.

BISPINOSA, in *Entomology*, a ſpecies of Mantis, with a roundiſh thorax, bidentated in front; wing caſes very ſhort, and bordered with yellow. Fabricius.

Bispinosa, a ſpecies of Cicada (*Mannifera*, *Tettigonia*). It is of a large ſize, and inhabits the iſland of Sumatra. The colour is brown, with a ſingle ſpine on each ſide of the thorax; wings duſky, with a ſtreak of black ſpots. Fabricius Mantiſ.

BISPINOSUS, a ſpecies of Cerambyx (*Stenocorus*) that inhabits South America. Thorax unarmed, and ſlightly tuberculated; wing-caſes bidentated; joints of the antennæ armed with two ſpines; and the body teſtaceous. Fabricius.

Bispinosus, a ſpecies of Carabus that inhabits Europe. This is of a black colour; poſterior part of the thorax truncated; anterior ſhanks with two ſpines. Linn. Leſk. Muſ.

Bispinosus, a ſpecies of Tabanus, found about Goettingen, and deſcribed by Fabricius. The colour is brown; abdomen ferruginous, and black at the baſe, with two ſpines on the ſcutel.

BISQUET. See Bisket.

BISSA, in *Geography*, a town of Servia on the Danube, 16 miles S. S. E. of Orſova.

BISSACRAMENTALES, in *Eccleſiaſtical Hiſtory*, a denomination given by ſome Romiſh writers to proteſtants, on account of their only holding two ſacraments, viz. baptiſm and the ſupper.

BISSAG, in *Geography*, a town of Croatia, 16 miles N. E. of Agram.

BISSAGOS, the name of a cluſter of iſlands and ſhoals, lying off the weſt coaſt of Africa, between the mouths of the rivers Rio Grande and Cacheo, and between about 10° 30' and 11° 30' N. lat. and 15° 10' and 17° W. long. The principal of theſe iſlands, and that which lies neareſt the coaſt is Boolam, or Bulam, which ſee. Each of the inhabited iſlands is governed by a chief, who aſſumes the title and power of a king. All theſe petty monarchs are independent, and frequently at war with each other, which they carry on by means of canoes, capable of containing from 25 to 40 men, with their proviſions, and alſo their arms, which are ſabres, and bows and arrows. The negroes of theſe iſlands are tall, ſtrong, and healthy, though they live only on fiſh, nuts, and palm-oil; chuſing rather to ſell the rice, millet, and other produce of the earth to the Europeans, than to reſtrain their paſſion for trinkets and ornaments. They are idolaters, and are ſaid to be ſavage in their diſpoſition, not only to ſtrangers, but to one another, when they happen to quarrel, which is frequently the caſe; and if they are diſappointed in gratifying their revenge, they will drown, or ferociouſly ſtab themſelves.

BISSAO, an iſland on the weſt coaſt of Africa, ſeparated from the continent by a channel, which connects two bays of the ſea, within the Biſſagos iſlands, between 11° 15' and 11° 29' N. lat. and 15° 11' and 16° 30' W. long. Both the Portugueſe and French began to trade at an early period with this iſland; the former have a fort upon it, and the latter a factory. The Dutch have in vain attempted to obtain a ſettlement. The iſland is 35 or 40 miles in circumference, and riſes from the ſea, of which it has an agreeable proſpect, by an eaſy aſcent to an eminence in the centre of the iſland. Its ſurface is hilly, and the hills are ſeparated by beautiful and fertile vales, which are watered by ſmall rivulets. The whole, a few groves of palm-trees excepted, is in a ſtate of cultivation, and produces, beſides oranges, mangoes, and bananas, and other fruits afforded by the warm climates, wheat and maize, which grow luxuriantly, and reſemble, by the ſize to which the ſtems riſe, reeds or bamboos. Their cattle are likewiſe of an extraordinary ſize; and they are amply ſupplied with both milk and wine. The importation of wine is prohibited, and the ſoil does not ſuit the rearing of horſes. The inhabitants, who are in a ſtate of almoſt perpetual conteſt with thoſe of the neighbouring iſlands and continent, live in cottages diſperſed over the iſland, which bears no trace of a town, except where the

French and Portugueſe have eſtabliſhed themſelves. The dreſs of the married women conſiſts of a cotton girdle, and bracelets of glaſs, coral, and copper; but the virgins are altogether naked; and thoſe of high quality mark their bodies with hideous figures of ſnakes and other reptiles. The princeſs of the iſland is only diſtinguiſhed from other females by the elegance of theſe paintings, and the richneſs of her bracelets. The dreſs of the men of all ranks is merely a ſkin fixed before and behind to their girdle. One ſingular ornament is a large iron ring, upon which they ring changes with a piece of iron, ſo as to converſe as freely with their caſtanets as if they uſed the moſt poliſhed language. This artificial language is uſed only by perſons of rank and faſhion. All the Biſſaons are idolaters, but their ſyſtem of religion is very confuſed and unintelligible. Beſides their chief idol, called "China," every one creates a divinity according to his own fancy; trees are held ſacred by them, and, if they do not adore them as gods, they worſhip them as the reſidence of ſome divinity. Their government is deſpotic, the will of the emperor being the law to his people; at his death all his women and ſlaves are ſacrificed and buried near their maſter, in order to attend him in the other world. Although they are at almoſt perpetual war with ſome of their neighbours, they have among themſelves no civil diſcord. Before the emperor reſolves to invade any adjacent territories, he orders the "bonbalon" to be ſounded, which is the general ſignal to arms, on which all perſons in the pay of government aſſemble at a fixed place, and embark on board their canoes, each of which carries about 30 men, and the whole fleet conſiſts of about 30 canoes. Before the fleet ſails, they offer ſacrifices in great number to their gods, which are made of wood, and the favourable anſwer of the prieſts, when they conſult theſe deities, enſures their ſucceſs. When they attack any towns or villages, they carry off the inhabitants, and every article of value, and divide the booty between the emperor and thoſe that have been engaged. The ſlaves are ſold to the Europeans, except ſuch as are of quality or fortune, who are reſtored to their friends on condition of their ſending a number of ſlaves in their room. The emperor is ſaid to allow free commercial intercourſe with all ſtrangers. The Portugueſe demoliſhed their fort on the iſland in 1703. See Balontes, Bissagos, and Bulam.

BISSECTION, in *Geometry*, the diviſion of any quantity into two equal parts, otherwiſe called *bipartition*, which ſee. See alſo Division, &c.

BISSENDORF, in *Geography*, a town of Germany, in the circle of Weſtphalia, and biſhopric of Oſnabruck, 5 miles S. E. of Oſnabruck.

BISSENPOUR, a ſmall diſtrict of Bengal in the Eaſt Indies, which is governed by a Bramin family of the tribe of Rajpoots, and which has uniformly preſerved its independence. In this diſtrict, it is ſaid, the purity and equity of the political ſyſtem of the Indians are found unadulterated. By the ſingular ſituation of this country, its inhabitants have been enabled to maintain their primitive happineſs, and the gentleneſs of their character; and they have been ſecured from the danger of being conquered, or of imbruing their hands in the blood of their fellow-creatures. Nature has ſurrounded them with water, and they only need to open the ſluices of their rivers in order to inundate the whole country. The armies that have been ſent to ſubdue them have been ſo frequently drowned, that the plan of enſlaving them has been laid aſide; and the projectors have thought proper to content themſelves with an appearance of ſubmiſſion. In Biſſenpour, liberty and property are ſacred; robbery is unknown; and every ſtranger, who enters this territory, is under the protection of the laws, which provide for his ſecurity. The guides, to whoſe conduct he is committed, become reſponſible for his perſon and effects; whilſt he remains, he is maintained and conveyed with his merchandiſe at the expence of the ſtate, unleſs he expreſſes his deſire to ſtay longer than three days in the ſame place; and ſhould this be the caſe, he is obliged to live at his own charge. In this ſtate, it is ſaid, probity and honeſty are ſo prevalent, that if any one find a purſe, or any other article of value, he hangs it upon the firſt tree he finds, and informs the neareſt guard, who gives notice of it to the public by beat of drum. Out of about 330,000l. annually received at an average by the government, without injury to agriculture or trade, what is not wanted to defray the unavoidable expences of the ſtate, is laid out in improvements. The rajah is enabled to engage in theſe liberal employments, as he pays the Moguls only ſuch tribute, and at ſuch times, as he thinks proper. Raynal's Hiſt. Settl. Eaſt and Weſt Ind. vol. i. p. 415.

BISSENPRAAG, a town of Aſia in the country of Sirinagur, ſituated near the baſe of a mountain, on which ſtands the famous temple of Buddreenaat. It is a place of ſome importance, as being the reſidence of the pundits and principal Hindoos of Buddreenaat. Here they hold their durbars, exerciſe their laws, and the duties of their religion, in the greateſt ſtate of ſecurity from foreign intruders, and can at any time ſeclude themſelves from the reſt of the world, by a removal of the "joalahs," or rope bridges, which form the communication acroſs the Aluknundra. This river receives at Biſſenpraag another river, proceeding from the eaſtward as large as itſelf, called "Dood Ganga," or the Milk river, and alſo "Dhoulee." Near its junction with the Aluknundra, it runs between two villages, called "Gurra" and "Nitty." The town conſiſts of about 800 houſes, and is a place of ſome trade; the inhabitants are all Hindoos. Aſiat. Reſ. vol. vi. p. 346.

BISSET, Charles, in *Biography*, ſtudied medicine ſeveral years at Edinburgh, as he informs us in his Eſſay on the medical conſtitution of Great Britain, publiſhed in 1762, and was then promoted to be ſecond ſurgeon to the hoſpital in Jamaica, where he continued from 1740 to 1745, when he returned to England, and purchaſing a commiſſion in the army, he ſerved as lieutenant and engineer in Flanders until the peace in 1748. He now reſumed the practice of ſurgery, and ſettled at Skelton in Cleveland, Yorkſhire, and ſoon after publiſhed "A Treatiſe on the ſcurvy," 1755, 8vo. He had before, viz. in 1751, publiſhed "An Eſſay on the theory and conſtruction of fortifications." In 1765 he obtained a diploma from the univerſity of St. Andrews, conſtituting him doctor in medicine. He died at Knayton near Thirſk, in May 1791, in the 75th year of his age. New Gen. Biog. Dict.

BISSEXTIALIS, or Bissextialis *olla*, an ancient meaſure or veſſel, containing twelve ounces, or two Sextaries.

BISSEXTILE, or Leap-year, in *Chronology*, a year conſiſting of 366 days, happening once each four years, by reaſon of the addition of a day in the month of February, to recover the ſix hours which the ſun ſpends in his courſe each year, beyond the 365 days ordinarily allowed for it.

The day thus added, is alſo called biſſextile; Cæſar having appointed it to be introduced by reckoning the 24th of February twice; and as this day, in the old account, was the ſame as the ſixth of the calends of March, which had been long celebrated among the Romans on account of the expulſion of Tarquin, it was called "bis ſextas calendas Martii;"

Martii;" and from hence we have derived the name biſſextile.

By the ſtatute *de anno biſſextile*, 21 Hen. III. to prevent miſunderſtandings, the intercalary day, and that next before it, are to be accounted as one day.

The aſtronomers concerned in reforming the calendar, by order of pope Gregory XIII. in 1582, obſerving, that the biſſextile in four years added 44 minutes more than the ſun ſpent in returning to the ſame point of the zodiac; and computing that theſe ſupernumerary minutes in 133 years would form a day; to prevent any changes being thus inſenſibly introduced into the ſeaſons, directed, that, in the courſe of 400 years, there ſhould be three biſſextiles retrenched: ſo that every centeſſimal year, which, according to the Julian account, is biſſextile, or leap-year, is a common year in the Gregorian account, unleſs the number of centuries can be divided by 4, without a remainder. Thus 1600 and 2000 are biſſextile; but 1700, 1800, and 1900 are common.

The Gregorian computation was received in moſt foreign countries ever ſince the reforming of the calendar; and by act of parliament, paſſed anno 1751, it commenced in all the dominions under the crown of Great Britain, in the year following, ordering that the natural day following the ſecond of September, ſhould be accounted the fourteenth; omitting the intermediate eleven days of the common calendar. See CALENDAR.

BISSINGEN, in *Geography*, a town of Germany, in the circle of Swabia, and county of Pattingen Wallerſtin, 4 miles S. S. W. of Haarburg.

BISSOOLY, a principal fort of Hindoſtan, lying at or near the entrance of the hills, 42 coſſes S. E. from Jummoo. Major Rennell places it in his map on the north bank of the Rauvee, 6 or 7 coſſes above Kullanore, or 41½ above Lahore, or, in other words, about 59 geographical miles E. 30° N. from Lahore. N. lat. 32° 30'. E. long. 75°.

BISSOWIE, a town of Hindoſtan, in the country of Oude, and circar of Rohilcund, 25 miles weſt of Bereilly, and 85 E. S. E. of Delhi.

BISTAM, a ſmall city of Perſia, in the province of Comis, on the north of the Great Salt Deſert, rarely viſited by travellers. N. lat. 35° 30'. E. long. 54° 30'.

BISTER, a town of Swiſſerland, in the Upper Vallais, near the ſouth bank of the Rhone. N. lat. 46° 19'. E. long. 7° 52'.

BISTI, a ſpecies of Perſian money, valued at ſixteen or eighteen French *deniers*. Some repreſent the biſti as an ancient ſilver coin; others, as Chardin, make it only a money of account, and call it dinar biſti.

BISTONES, in *Ancient Geography*, the name of a people who inhabited that part of Thrace, which was bounded on the north by mount Rhodope, on the eaſt by the Hebrus, on the weſt by the Neſſus, and on the ſouth by the Ægean ſea. Its capital was Tinda. Theſe people were ſubdued firſt by the Macedonians, and at length by the Romans. Xerxes, according to Herodotus, traverſed their country in marching againſt Greece. Hence "Biſtonius tyrannus" is uſed by Lucan to denote Diomedes, king of Thrace, who fed his horſes with human fleſh; and "Biſtonius turbo," expreſſing a wind blowing from Thrace.

BISTONIS, a lake on the ſouthern coaſt of Thrace, N. E. of Abdera.

BISTORT, or SNAKEWEED, in *Botany*. See POLYGONUM.

BISTORY, or BISTOURY, in *Surgery*, is a cutting inſtrument, formed like a ſmall knife. It may be either ſtraight or curved, double-edged or with a ſingle edge, ſharp pointed, round pointed, or with a probe point, &c. Sometimes it is made to ſhut within a handle; at other times the blade is fixed and immoveable. For particular purpoſes, the blade is concealed, ſo as to project only at the moment when the inſtrument is uſed by the ſurgeon; on which account it is called by the French *biſtouri caché*. On ſome occaſions, it is found convenient to employ a director, or a canula, at the ſame time we introduce the biſtory: for example, when it is intended to paſs the cutting inſtrument along a narrow ſinus, or under the prepuce, up to a certain ſpot before we make any inciſion, (ſee the articles PHYMOSIS, and SINUS); but wherever there is room for the introduction of a fore-finger, that mode is preferred by modern ſurgeons as a guide to the biſtory, being much more convenient and ſecure than any artificial director. The preciſe form of a biſtory muſt be regulated according to the nature of the operation required, and the end to be obtained. See the article SCALPEL, and conſult the engravings of chirurgical inſtruments attached to this Cyclopædia.

BISTRA, in *Geography*, a town of Bohemia, in the circle of Chrudim. 6 miles S. S. E. of Politzka.

BISTRAIA, a town of Ruſſian Tartary, on the weſt ſide of the Donetz, 70 miles N. N. E. of Azof.—Alſo, a river of Ruſſian Tartary, which runs into the Donetz, 64 miles N. E. of Azof.

BISTRE, among *Painters*, a compoſition made of the moſt gloſſy and higheſt burnt ſoot, pulverized, and paſſed through a fine ſieve, then baked in a little gum-water, and made into cakes: or it is the burnt oil, extracted from the ſoot of wood. It is a brown tranſparent colour, and has much the ſame effect in water-painting, where alone it is uſed, as brown pink in oil.

The beſt is prepared from the ſoot of dry beech wood, by grinding it with urine or water, into a ſmooth paſte, and then diluting it with more water; after the groſſer ſubſtance has ſubſided, the liquor is poured off into another veſſel, and left to ſettle three or four days; the fine matter that remains is biſtre.

That the biſtre of our colour ſhops has been prepared by a proceſs of this kind, and not, as ſome have ſuſpected, by evaporating the infuſion of ſoot to an extract, may be preſumed, ſays Dr. Lewis (Com. Epiſt. Phil. Techn. p. 340.), both from its appearance and its qualities. He obſerves, that different parcels of biſtre differ conſiderably in their colour, on account, probably, of the different qualities of the ſoots from which they were made.

In the Handmaid to the Arts, vol. i. p. 126. we have the following recipe for preparing it. Put the ſoot of dry wood (of beech when it can be procured) into water, in the proportion of 2 pounds to a gallon, and boil them half an hour. Then, after the fluid has ſtood ſome time to ſettle, but while yet hot, pour off the clearer part from the earthy ſediment at the bottom; and if on ſtanding longer it form another earthy ſediment, repeat the ſame method; but this ſhould be done only while the fluid remains hot. Evaporate the fluid to dryneſs; and what remains will be good biſtre, if the ſoot was of the proper kind. That which is good is tranſparent, when moiſtened with water, and of a warm, deep brown colour.

Inſtead of this, ſome uſe the hatches of a pea, with a little Indian ink, others red chalk, others black lead, &c. See WASHING.

BISTRIANKA, in *Geography*, a town of Ruſſian Tartary, on the ſouth ſide of the Don, 100 miles E. N. E. of Azof.

BISTRIATA, in *Entomology*, a ſpecies of CICADA (*Deſſexa*)

fiava) that inhabits France. This is yellow, with two tranſverſe bands of brown. Geoffroy.

BISTRICZ, or BISTRITZ, in *Geography*, a town of Tranſylvania, and capital of a county, to which it gives name, ſituate on the river Biſtricz, which runs into the Samos, 4 miles S. W. of Kezovar. The town is 42 miles N. N. E. of Clauſenburg, and 256 E. of Vienna. N. lat. 47° 33'. E. long. 25° 3'.

BISTRIGALIS, in *Entomology*, a ſpecies of PHALÆNA (*Pyralis*), with cinereous wings, with two ferruginous ſtreaks, and a black dot. Inhabits Europe. Linnæus.

BISTRIGARIA, a ſpecies of PHALÆNA (*Geometra*), with cinereous wings, undulated, with two linear ſtreaks. A native of Europe. Linn. &c.

BISTRIGATA, a ſpecies of PHALÆNA (*Geometra*). It is griſeous, with two whitiſh ſtreaks. Inhabits Europe.

BISTRITZA, in *Geography*, a town of European Turkey, in Moldavia, on a river of the ſame name, which runs into the Siret, 6 miles S. E. of Bakeu. The town is 20 miles S. W. of Jaſſy.—Alſo, a town of Walachia, 16 miles W. S. W. of Kimnik.

BISTRIZ, a town of Moravia, in the circle of Brunn, 6 miles W. S. W. of Els.

BISTROFF, a town of France, in the department of the Moſelle, and chief place of a canton in the diſtrict of Morhange, 4 miles N. N. E. of Morhange.

BISTRY, a town of Bohemia, in the circle of Konigingratz, 10 miles from Gitſchin.

BISUGA, a river of Ruſſian Tartary, which runs into the ſea of Azof, 48 miles S. W. of Eiſkoi.

BISULCATUS, in *Entomology*, a ſpecies of CURCULIO that inhabits Italy. This is black, with a cinereous border all round, and two furrows on the beak. Fabricius.

BISULCUS, a ſpecies of ICHNEUMON, of a black colour, with two impreſſed lines before; legs rufous; ſting ſhort. Linn. Muſ. Leſk.

BITS, or BITTS *for Horſes*, in the *Manege*, are pieces of iron of various figure and conſtruction, which, being placed in the horſe's mouth, ſerve, by the aſſiſtance of the reins, to reſtrain or guide his motions.

The term *bitts*, or *bits*, is conſidered by ſome as originating from the horſe's biting or champing them between the teeth when placed in his mouth; in the French language is uſed a term alſo of ſimilar ſignification, *les mords*, which would ſeem to corroborate the above etymology of it:—another however, equally natural, preſents itſelf in the common word *bit*, or *bitts*, that is *pieces* of iron; this apparatus being always made of one or more pieces of this metal.

The art of bitting horſes may be ſaid to conſiſt in furniſhing the mouth with the moſt proper mouth-pieces, &c. for obtaining from them an obedience to the will of the rider, and exacting a due performance of all the movements and reſtraints which may be deſired, or at leaſt which are dependent upon the operation of the reins. Rightly underſtood, and well adminiſtered, this art affords the power of communicating to the horſe ſupport and confidence, with greater eaſe and ſecurity to the rider. The miſapplication of its rules, on the contrary, or an inattention to them, where the mouth is not totally inſenſible, will produce painful ſenſations to the horſe, with diſguſt and rebellion, and to the rider uneaſineſs and perhaps danger.

It is to be lamented that the preſumptuous opinions of the uninformed have been too much the guide of the public in their eſtimation and choice of the proper bits for horſes, as alſo in too many other things reſpecting theſe uſeful animals, tending often to accumulate unneceſſary ſuffering and miſery upon them. The writers on this ſubject are few and unſatisfactory; we ſhall, however, except Mr. Berenger, whoſe work is a noble effort to emancipate this branch of ſcience from barbarity and ignorance; and from him we ſhall take occaſion to make ſome extracts in the ſequel of this article. Here it will be proper to obſerve, that this author, by the term *bit*, has deſignated the curbed bit only; but we have ventured, for the ſake of purſuing a more connected view of the ſubject, to include in this term any piece or pieces of metal placed in the horſe's mouth, for the purpoſes of guidance or reſtraint.

In our account of the different kinds of bits, and their effects, we ſhall begin, for the ſake of order, with the deſcription of a bit of the moſt eaſy and ſimple conſtruction poſſible, and then proceed to the moſt complicated.

A ſhort iron rod, made rather wider than the mouth of the horſe, and provided with a hook or ring at each extremity for faſtening the reins to, affords us an inſtance perhaps of the greateſt poſſible ſimplicity in the conſtruction of a bit; and ſuch a one only ſlightly curved forwards, to allow more liberty for the tongue, is at preſent in general uſe for the heavier kind of draft horſes, the bearing rein being uſually attached to it, paſſing over the hames of the collar.

A ſimilar rod to the former, broken in two pieces, and connected by a joint in the middle, is the next in point of ſimplicity, and is in common uſe for horſes of light draft, as in thoſe employed for the curricle, coach, &c. and is attached by the bearing rein to the hook of the ſaddle, and this kind of bit is moſtly termed with us a *bridon*.

The next in point of farther complication of parts, and which ſcarcely can be ſaid to differ from the former, is the *common ſnaffle*. This is provided with two croſs pieces, which reſt againſt the lips or ſides of the mouth; for as the ſnaffle is intended for the ſaddle horſe, and the reins go to the hands, ſo the croſs pieces are uſeful in preventing the bits from being drawn through the mouth, which precaution is not ſo neceſſary where the bits are affixed to the bearing rein. The bridon, we may obſerve, is alſo made in general ſmaller than the ſnaffle, as well as without croſs pieces.

The diſtinction, however, between a bridon and ſnaffle is inſignificant and of little conſequence; for on all occaſions croſs pieces are the moſt convenient; and it will be eaſily ſeen that the bridon is merely an imperfect ſnaffle, poſſeſſing no peculiar characters which can form a real diſtinction.

The term, alſo, when confined to this object is miſapplied; for the French, from whom we have borrowed it, by *le bridon* underſtand the ſnaffle and its rein, in oppoſition to *le bride*, by which they denote the *curbed bit* and reins.

In war, and on other occaſions, the *bridon* was uſed as a leſſer bridle, or bridle of reſerve, in caſe of the failure of the former from any accident; and hence the origin of its name.

The number of parts of which the mouth-piece of the ſnaffle is compoſed, may be increaſed to any extent, as it may be made with one, two, or ſeveral joints; but as it is evident theſe additions will not eſſentially alter its properties or effects, it would be uſeleſs to purſue a diſtinct conſideration of them.

But the condition of the ſnaffle admits of being ſo altered and changed by the variation of its figure, its ſubſtance, and its ſurface, as to acquire new properties and effects which will require particular attention; its gentleneſs or rigour will depend almoſt wholly on theſe conditions. A mouth-piece made of two entirely ſtraight pieces will be more ſevere than when theſe are ſomewhat curved, as the curved bit is more apt to embrace and include the lips between it and the bars than the

the ſtraight one. A thin and ſlender bit or ſnaffle, it will be eaſily perceived, will reſt with more ſeverity and ſharpneſs upon the bars than a thick and obtuſe one; the former, therefore, or the ſharp bit, is employed more particularly for reſtraining ſuch horſes as are hard mouthed, and too eager, while the latter is uſed for ſuch as have a proper feeling of the bars, and eſpecially for breaking in young colts.

The ſurface may be varied as to roughneſs or ſmoothneſs, producing alſo different effects. To give the greateſt eaſe poſſible, a large and highly poliſhed bit is neceſſary. This is ſometimes provided with moveable rollers on the axis of the bit, which, turning with every movement of the reins, diminiſh the friction of the bits, and render them leſs irritating. Theſe rollers, however, in reality can have but little effect in the ſnaffle, though of pleaſant effect in the mouth piece of the curb; for this reaſon, that the ſnaffle being jointed in the middle, is drawn by the reins to a ſharp angle in the mouth, ſo that theſe rollers are preſented to the bars in an oblique direction, under which poſition it will be obvious they can have very little or no motion, but, on the contrary, they will tend to render the bits more ſevere by their irregularity; ſo that a well poliſhed ſnaffle is in fact preferable to one of theſe with rollers of the ordinary conſtruction.

On the other hand, to give the greateſt degree of ſeverity to the mouth piece of the ſnaffle, it is twiſted while hot into a ſpiral form, and is made to preſent by this means a ſharp, rough, and unequal ſurface to the jaw, being capable, according to the degree of ſharpneſs to which the edges are wrought, of puniſhing the bars and lips with greater or leſs ſeverity. The different degrees of puniſhment which this kind of bit is capable of inflicting, will perhaps be found ſufficient for all the purpoſes of correction, where recourſe may properly be had to actual force and puniſhment. For it ſhould be always kept in view, that gentle means will produce a good mouth; while harſhneſs and too great ſeverity will tend to deſtroy it altogether.

Thus far the ancients of the moſt remote ages of the world, almoſt as far back as any hiſtory extends, were well acquainted with the uſe of bits. Xenophon, more than 400 years before Chriſt, had deſcribed ſimilar bits as being in common uſe in his time among the Grecian ſtates. He ſpeaks of a ſmooth and a ſharp kind of bit, the latter, if more ſeverity was requiſite, to be armed with points or teeth. In its uſe, however, he enjoins the greateſt tenderneſs, and obſerves, "that when you would wiſh to ſlacken the pace of an eager horſe, which hurries on too faſt, and to pacify his fury, ſo as to make him go more temperately, or even oblige him to ſtop, you ſhould not attempt to do it at once, and with violence, but artfully, and by degrees, gently pulling him in, then yielding the bridle, and playing with his mouth, in ſuch a manner as if you intended rather to win his conſent than force his obedience." Chap. 9, 10.

Beyond the changes above deſcribed, the ſnaffle itſelf does not appear to admit of any alterations worthy of notice. It may, however, be juſt obſerved, that ſome horſemen add a chain to it, extending from cheek to cheek, which reſting looſely on the tongue produces irritation and ſlavering, and, as they imagine, freſhens the mouth. Such a bit is known by the name of the *Rockingham ſnaffle*.

The reins, however, it muſt be remarked, admit of ſome alterations in their diſpoſition, which will influence the effects of the bit on the mouth; as whether they are carried higher or lower. At this preſent time there is a practice more eſpecially in horſes of light draft, as in thoſe for carriages, curricles, and chairs, &c. to diſtort and alter the bearing reins from their natural direction, and to diſpoſe them more perpendicularly and in a line with the head; ſo that inſtead of paſſing ſtraight from the mouth to the horſe's back, they are directed up the ſides of the face, as high nearly as the parotid gland, or baſe of the ear, where they are paſſed through a ring hanging from the head ſtall, and from thence to the hook of the ſaddle. The appearance is ornamental and elegant, and the reins ſo diſpoſed are conſidered as more forcibly elevating the head than if they proceeded to the back in the uſual direction.

As the diſpoſition of the reins, ſo the figure of the bits themſelves, and the ornamental appendages attached to them, admit of almoſt endleſs variety. The manufacturers of theſe articles, availing themſelves of this licence, render their buſineſs more lucrative by as frequent changes as poſſible. Theſe are ſucceſſively introduced as faſhionable novelties, till again for novelty they return to the ſimpleſt practice; and this takes place without any alteration in the principal circumſtances of their conſtruction, properties, or uſe.

The next kind of bits in uſe for horſes is the curbed bit; which, as it is an inſtrument of much greater complication of parts than the ſnaffle, ſo it appears to have been of comparatively recent date.

In ſome of the ſculptured equeſtrian figures of the ancients ſomething like the branches of the curb may be found; but in no inſtance does there appear any thing reſembling the chain, which is abſolutely neceſſary to its effect. Their writings alſo appear to be ſilent on this ſubject. It was probably the invention of Italy or France, which for ſome centuries paſt have taken the lead of the other nations of Europe in teaching the arts of the manege. It was firſt introduced into the Engliſh army by a proclamation made in the third year of king Charles I. ſince which time it has got into univerſal uſe for the army, the field, and the road, ſo that no horſeman deems himſelf perfectly equipped without it. Moſt of thoſe writers who have treated of it in the laſt, and in the century preceding that, and who wrote probably ſoon after the commencement of its uſe, have been very profuſe in their various propoſals for the ſtructure of it, eſpecially in rendering it more complicated, ſevere, and cruel; though it is probable their clumſy figures and repreſentations were never imitated in actual practice. They appear to have been much ſatisfied with their new invention, imagining it a ſure means of reducing horſes to immediate obedience, in ſpite of every obſtacle; and true it is, it can puniſh with extreme ſeverity: but is ſuch a meaſure moſt likely to create vice, or to overcome it? Indeed, according to the opinion of one of the ableſt writers that has ever conſidered this ſubject, and whoſe opinion we ſhall take an opportunity of quoting more fully hereafter, little or nothing has been really gained by its adoption; on the contrary, the ſnaffle poſſeſſes more ſimplicity, power, and perfection.

Stripped of all unneceſſary trappings, this inſtrument conſiſts of the following eſſential parts: a mouth-piece with two ſide branches, or inflexible rods of iron, firmly fixed to the former, and a chain paſſing from ſide to ſide, behind the chin, including the jaw; two eyes or rings at the upper extremity of theſe branches, ſerve to faſten it to the head-ſtall, and to ſtay it in the mouth; two other rings at the lower extremity of the above branches receive the reins, paſſing to the hand, or ſometimes in draft horſes to the hook of the ſaddle, as a bearing rein. Theſe are all the parts really neceſſary to conſtitute the curb.

The bits thus formed being placed in the mouth, and the chain paſſed round the lower jaw, the branches, it will be

readily ſeen, become powerful levers when drawn backwards, acting upon the mouth-piece as a centre, and ſqueezing, by means of the chain, whatever interpoſes between it and the mouth-piece, with a force equal to the length of lever afforded by the lower branch.

This force, it will be perceived, is influenced and regulated not only by the length of the lever below the mouth-piece, but alſo by the greater or leſſer diſtance at which the chain is placed from it. The chain is uſually fixed to the eye of the cheek-piece, where the head-ſtall is faſtened; if, therefore, this part is very long, it is evident it muſt moderate or counteract the power and effect of the lower end of the branch, and render it leſs ſevere by bringing the centre of motion nearer to the middle of the lever.

It appears manifeſt, from the conſtruction of this inſtrument, that its whole force is exerted upon the jaw itſelf, and that it has power to pinch the bars with cruel violence, even to the fracture of the bone, and this with very powerful branches has ſometimes happened. It can alſo cruſh and bruiſe, and totally deſtroy the tender covering of the inſide of the mouth, and the ſkin beneath the jaw.

From conſidering its mode of operating, it might reaſonably be doubted whether it does in reality ſtop the horſe by its power and oppoſed force, as is generally conceived at preſent, or rather by the ſeverity of the pain it inflicts; as ſhould the horſe arm himſelf againſt this, it is totally inſufficient to arreſt his courſe; of which inſtances occur in runaway horſes every day. And we ſhall venture to ſuggeſt, though contrary to the general opinion, that the ſnaffle, even in this reſpect, if the mouth has not been previouſly hardened and ſpoiled by the uſe of the curb, is the moſt powerful inſtrument of the two.

The *mouth-piece* of the curb is uſually provided with an upſet or arch in the middle of it, as it would, if perfectly ſtraight, reſt on the tongue, and occaſion an unpleaſant reſtraint. This paſſage for the tongue is often made ſo narrow and ſmall by the bit makers, that one ſhould apprehend they ſcarcely had a right idea of its uſe. From the circumſtance of its allowing a paſſage for the tongue, it has been called by ſome, the *liberty*; and, for the ſame reaſon, by others, the *porte*: hence we have the porte-mouth bit, vulgarly called among the bit makers and grooms the *Portſmouth* bit: and by a ſuppoſed counter expreſſion to this term, we probably get the *Weymouth*-bit.

In draft horſes, eſpecially for the coach, it is a frequent cuſtom to have affixed to the upper part of the upſet ſmall chains or poliſhed drops of iron, which hanging looſe in the mouth, and falling on the tongue, occaſion the horſe to champ the bits, and create a copious flow of ſaliva, ſo as to flaver the lips with its white froth; and when this happens, it is conſidered by ſome a good ſign of health and gaiety, and that the horſe is well bitted; for, if the bits are diſagreeable to him, he never plays with them, or exhibits any froth, ſay they. Theſe ſmall appendages are termed by the French *les chainettes*, and by the Engliſh *flyers*.

It is further to be obſerved, reſpecting the mouth-piece of the curb, that the ſtraight part which reſts upon the bars of the jaw, is termed by the French *le canon*, and by the old Engliſh writers the *jeive*; and though a highly convenient and uſeful word, it is to be regretted, it is at preſent out of uſe; the French term, which is not ſo expreſſive, having ſuperſeded it. This part ſhould be well poliſhed, and may be made of any proper figure, as that of a cylinder, cone, oval, globular, pear-ſhaped, &c.

It is obvious that the effect of the curb, as far as it reſpects the bars, will be correſpondent to the thickneſs or thinneſs, ſmoothneſs or roughneſs, of this part; the larger and broader it is, the more ſurface it covers; and thus the preſſure, by being diſtributed over more points, becomes leſs felt. This enlargement, however, of the canon or jeive ſhould not be carried to an exceſs, by making it too heavy, or filling the horſe's mouth with more iron than it can conveniently receive, and thus create pain, inſtead of greater eaſe.

To render theſe irons leſs irritating to the mouth, and to avoid their friction upon the bars, the jeives are provided with looſe, moveable rollers of well poliſhed iron, which readily turning on the axis of the bits, very conſiderably diminiſh their ſeverity. Theſe moveable pieces are alſo particularly uſeful in preventing the horſe from catching and holding the bit in his teeth; as the curb, under theſe circumſtances, can ſtill move and act with the ſame freedom as before.

The jeives are ſometimes compoſed of three or four flattiſh knobs, united by a joint to each other, and with a joint to the upſet, which is intended to render it very ſevere; it is obvious, however, that ſuch an alteration muſt bring it nearer to the condition of the ſnaffle; the knobs, however, if they can be drawn tranſverſely acroſs the bars, might produce conſiderable irritation, but not ſo much as they would do if not jointed. This bit is not unfrequently uſed, and is called with us the *Heſſian*-bit.

To the curb is often fixed a ring oppoſite the mouth-piece, which, as it is directly in a line with the axis of the bit, has no other effect when the reins are affixed to it, than a ſnaffle would have, provided with a ſimilar mouth piece. This is termed putting "the reins to the cheek," and for horſes of light draft, whoſe mouths are not ruined, it is by much the beſt, as the mouth is leſs annoyed, and the horſe obeys with more alacrity the guidance of the hand from this point, than from the extremity of the branches, which are particularly ill calculated for this purpoſe: this kind of conſtruction is generally diſtinguiſhed by the name of the *Pelham*-bit.

In the older Engliſh writers, as well as thoſe on the Continent, on the ſubject of bits, we find an appendage deſcribed, which is not at all, at preſent, in uſe; and as it enters the mouth with the mouth-piece, it may, with propriety, be deſcribed along with it. It conſiſted of a chain extending from branch to branch of the banquet, or cheek-piece, being placed rather above the mouth-piece, and parallel to it, and was ſtretched acroſs perfectly ſtraight and tight. This part was called the *water-chain*, and by the French *Trenche-file*: its uſe is not very evident. Mr. Berenger takes notice of it, and obſerves "that it might be uſeful to horſes that are apt to drink or ſwallow the bits, as the expreſſion is, or bury it ſo deep in their mouths, as to hinder it from having a due and juſt effect:" from its being laid aſide ſo generally, we preſume it has at leaſt been thought uſeleſs.

It is a common belief with the grooms, that a great power reſides in the upſet of the mouth-piece, and that the bits are more powerful as this is longer or ſhorter; nothing, however, can be more fallacious than this reaſoning. In the works of Laurence Reeſe, alſo a French writer, we find, in conſonance with this idea, a curb, with an upſet of unuſual length, being deſtined to correct the vices "d'un Rouſſin qui à la bouche d'une diable;" it will be obvious, however, on a moment's reflection, that this part, from being made very lofty, and coming forcibly againſt the palate, would compel the horſe to open his mouth, when it would ceaſe farther to act in any way; with more reaſon, the ſame writer propoſes, on the other hand, "pour donner grand

grand plaiſir," to have a bit conſtructed with a low upſet, and ſufficiently wide, with large, conical, ſmooth jeives for the bars.

Of the chain. The chain is the part moſt eſſentially neceſſary to give effect to all the other parts of the curb, and may be placed, as we have already noticed, at any given diſtance above the mouth-piece; its operation being more powerful, as this diſtance is exceeded by the length of the branches. This poſition, though true as a general principle of reaſoning, appears to be ſubject to the operation of other cauſes in actual practice, which it will be neceſſary to conſider; for, in direct contradiction to this is the aſſertion of Mr. Berenger, who appears to be almoſt the only writer who has truly inveſtigated the merits of this particular object. He obſerves, in regard to this, that the nearer the chain, and the longer the branches, the ſofter and more indulgent its operation. This, on a firſt view, would appear to be in direct variance with the rules above laid down, and irreconcileable to the well known laws of the operation of the lever, and even at variance with his own preceding aſſertions; when, however, we remember the experience and practical knowledge of him who aſſerts it, it deſerves a more particular conſideration; let us firſt admit the truth of the poſition, as it ſeems founded on the ſure teſt of actual experience, and then we ſhould venture the following as the moſt natural explanation of it.

In proportion as the branches are longer, the more extenſive is the circuit their extremities perform in their operation; and therefore, the hand that guides them muſt paſs through a greater ſpace to produce the ſame effect: and now, if the chain be placed very near to, or upon the outſide of the mouth-piece, and be applied not very tight about the chin, yet, in reality, though there would be an apparent increaſe of power by the length of the branches, they would have little or no effect, as they would arrive at the utmoſt extent to which they can be drawn, before the chain would begin to pinch. On this account, the moſt lively effects would be produced by the chain having more ſweep and extent of action, and by the branches being not quite ſo long, as great length alſo adds ſomething to their flexibility, though not to a degree to be worth taking into the account. Still, however, the branches muſt ever obey the common laws of the lever, acting with force proportioned to their length; while ſhorter branches act with greater quickneſs, and are more lively in their impreſſion.

The chain is faſtened on one ſide to the eye of the banquet, where the head-ſtall is faſtened; on the other, to a hook hanging from the ſame part. This chain, as it is at preſent uſed, is compoſed of iron links or rings, ſo beat or indented, as to form, when put together, one uniform nearly flat ſurface; and theſe links, by twiſting or untwiſting, may be made to preſent a ſurface with any degree of roughneſs to the chin.

When great tenderneſs is required, this chain may be covered with leather or cloth; or where a ſtill greater delicacy is deſirable, the curb may be made wholly of leather, without any chain.

The larger and thicker the rings are, provided they are ſmooth and well poliſhed, the eaſier the effect of the chain. In old Engliſh, this chain was called the *kirble;* and hence, by contraction, *kirb;* and finally, by an eaſy tranſition of the *ki* into *cu*, we apprehend that the modern appellation of this inſtrument is obtained.

Of the branches. The proportion which the cheek part bears to the lower extremity of the branches, or rather the poſition of the eye, to which the chain is fixed, determines the degree of power of the bit upon the principle before advanced; that is, if the chain is fixed to the upper extremity of it, as it uſually is to the tranſverſe opening or eye of the head-ſtall.

For the elementary view we are taking of the conſtruction of the bits, it has been only conſidered as a ſtraight, plain lever of indeterminate length; it is, however, in practice, often varied, as in the army, it is uſed of enormous length, and frequently curved like the letter S, by which it is conceived to be rendered more powerful, as well as ornamental; at other times the branch of the bit, with a view of increaſing its force, is carried forward with a ſharp elbow, giving nearly the figure of the letter Z; while by others, with more reaſon, to prevent the horſe from catching the bit in his mouth, it is made with an arch, or ſemicircle, in the middle of the branch, like the letter C, turned backwards for the ſame purpoſe; ſtill, however, in fact, whether bent into that or any other ſhape, it is the length of the lever, and its ſtrength, which alone give the power; it is true, however, that a long curved branch, though more powerful, will render the effect ſomewhat ſofter, as coming from a greater diſtance, eſpecially if the branch is at all flexible and yielding, than it would by the quick and rigid effect of a ſhorter lever, made perfectly ſtraight and inflexible: theſe branches may alſo be turned or bent, not only backward or forward, but alſo outwards and inwards. At their extremities, thoſe turned outwards, are ſaid to be ſtrongeſt of any in their operation.

As to the cheek-piece, or banquet, as it is called by the French, for an appropriate name is wanting to this part in the Engliſh language; the eye of the banquet, ſay the horſemen, commands and gives efficiency to the reſt of the bit; or, in other words, decides the diſtance of the chain from the mouth-piece, or centre of motion; as, however, in ſpeaking of the other parts, we have had occaſion to introduce a ſufficient account of this, it will not be neceſſary farther to give it a ſeparate conſideration; nor will it be uſeful to deſcribe the numerous mongrel herd of bits engendered of the ſnaffle and curb, which are reducible to the properties of one or the other, or partaking of both.

The moſt uſeful bit of the curbed kind, appears to be the *Weymouth*-bit, which is at preſent in common uſe for draft horſes of light work, as for carriages, coaches, &c. It conſiſts of a ſtrong, plain mouth-piece, of uniform thickneſs throughout, without any upſet or jeives, but is ſimply curved forwards, to give liberty to the tongue: this kind of conſtruction is the ſimpleſt perhaps that the curb admits of.

In concluding, it remains for us to notice the proper application and adjuſtment of theſe bits to the horſe's mouth, and to treat of their real effects.

By the management of the head-ſtall, the ſnaffle bits ſhould be ſo adjuſted as to fall in the middle ſpace between the tuſhes and grinders, reſting upon the bars: the mouth-piece of the curb ſhould alſo occupy the ſame ſituation; when, however, it is uſed along with the ſnaffle, the bits of the ſnaffle ſhould be placed higheſt in the mouth.

If the bits are placed too high in the mouth, the horſe carries his head aloft; if too low, he ſtoops the head, and tries to catch them in his teeth.

The thicker and more fleſhy, and the wider or broader the bars of the horſe, the rougher may be the mouth-piece for the leaner and more delicate; conſequently, the bits ſhould be leſs ſevere. Care ſhould alſo be taken that the mouth-piece be well ſuited to the ſize and width of the mouth, and be not too narrow, as this would give pain, by ſqueezing the bars together: if, on the contrary, it is very wide, it reſts with more force on the bars, without the interpoſition

of

of the lips, as is moſt uſually the caſe. Where the tongue is large and prominent, the upſet ſhould alſo be in proportion, otherwiſe the bits could not reſt upon the bars, but would preſs upon the tongue.

In regard to bitting the horſe, and the conſideration of its effects, we cannot deſire to ſee any thing more conſonant to truth and reaſon, than what has been given us by Mr. Berenger, and with ſome uſeful extracts from his valuable performance, we ſhall conclude this article.

Of bitting horſes with the curb. "In the beginning of an undertaking, whoſe aim is to ſubdue and reclaim nature, and that at a time when ſhe is wild, ignorant, and even aſtoniſhed at the attempts which are made upon her, it is evident that ſhe muſt not be treated but with lenity, inſtructed with patience, and by ſmall degrees, and that nothing ſhould be offered that may hurt, ſurprize, or occaſion any diſguſt.

The horſeman, therefore, ſhould not act the part of a tyrant, but of a lover; not endeavour to force her to ſubmiſſion, but ſtrive to gain her conſent and good will by aſſiduity, perſeverance, and the gentleſt attentions; for what proſpect of ſucceſs would rougher manners afford? To what purpoſe would it be to compel a colt to go forward, or turn from fear of the whip or ſpur, and to trot and gallop ſo freely as to ſupple his limbs, and form his paces; if the novelty of the bit, and the unaccuſtomed reſtraint to which it ſubjects him, ſhould vex and confound him, ſo as to make him not know what to do, or how to behave in theſe extremes? It cannot be expected, that he will be guided, and go with eaſe to himſelf, or pleaſure to the rider, if the inſtrument, by which he is to be conducted, offends or gives him pain: all habits and acquirements ſhould be attained gradually, and almoſt imperceptibly: rigour and precipitation would ruin all; and, inſtead of forming the horſe to the execution of what is required, may plunge him into vice and rebellion, ſo as to occaſion much trouble and loſs of time before he can be reduced.

He ſhould not therefore, at firſt, be conſidered as if he was deſigned to be formed to all the delicacy and exactneſs of the bit; and the horſeman ſhould be content, if he will endure it in his mouth, ſo as to grow, by little and little, accuſtomed to it, till the reſtraint becomes by habit ſo familiar and eaſy, that he not only is not offended, but begins even to delight in it; for this purpoſe, great care ſhould be taken that the bit be eaſy and gentle in all its parts; that the mouth-piece be larger than it need be for an horſe already bitted; that it in no wiſe incommodes the bars, ſqueezes the lips, or galls the tongue.

The mouth-piece, called a cannon, with a joint in the middle, will be the moſt ſuitable; the ends of it ſhould be as large and full as the ſize of the mouth will permit, for the thicker and more blunted they are, the eaſier they will be for the horſe, and the *appui* leſs ſtrict and ſevere.

The links of the curb ſhould be big, ſmooth, and well poliſhed: the curb ſomewhat long. The branches ſhould be exactly even with the line of the banquet, to make the appui moderate and equal; they ſhould likewiſe be long; nor does it ſignify of what ſhape they are, for with moſt horſes they ought to be ſo weak, as ſcarcely to have any effect; ſo requiſite it is to guard againſt every thing that may annoy or diſturb the horſe in theſe firſt trials. In order to reconcile him to this new conſtraint, the reins ſhould be held in both hands; and the horſe, for ſome time, ſhould only walk under the rider. Above all, upon this, and all other occaſions, a firm, a light, and diligent hand, is neceſſary.

Such are the outlines and general principles upon which the art of bitting horſes is eſtabliſhed; which art, as far as it reaches, is ſure and conſtant; but which, in ſpite of all the merits and praiſe of which it has ſo long been in poſſeſſion, will, upon a ſerious and ſtrict trial, never, I doubt, be found adequate to the views of a ſound and intelligent horſeman, nor capable of bringing a horſe to that degree of ſuppleneſs and exactneſs of carriage, which the truth and perfection of the art require, theſe attainments ſeeming to have been reſerved for a more ſimple but powerful machine, called the *ſnaffle.*"

"To perform his buſineſs juſtly and gracefully, the animal muſt firſt be made ſupple in his fore parts, and his head and neck ſo managed, that one may be raiſed, and the other arched or bent, more or leſs to the hand to which he is to turn. The bridle, called the bit, is ſo impotent in its endeavours to raiſe the head, that it even produces the oppoſite effect; nor from the confinement in which it keeps the horſe, and the ſmall compaſs it affords for the action of the rein, does it allow the rider ſufficient room to bend him, without pulling down his head, and putting him upon his ſhoulders, both of which are incompatible with the true and ſound principles of the art. The frequent uſe of caveſons and bridons, fully evinces the want of power in the bit to ſupple the horſe, or raiſe the fore part.

The figures and repreſentations of horſes working upon different leſſons, may be appealed to for the confirmation of this aſſertion: the books of paſt times abound with them, eſpecially that boaſted work of that king of horſemen, the duke of Newcaſtle, whoſe horſes are all drawn with their heads between their knees; and yet are exhibited to the equeſtrian world as ſtandards of truth, and models of perfection. The ſucceſſors of this duke, and of other great maſters, as imitators, are generally a blind and ſervile herd, ran headlong into the errors, and adopted the faults of their predeceſſors; and always made uſe of bits, without reflecting upon their effects, or perceiving that they could operate to make the horſe carry low, or to put him upon his ſhoulders, while they thought that he was all the time upon his haunches."

"If ever there was a panacea, or univerſal medicine, the ſnaffle is one, for the mouths of horſes: it ſuits all, and accommodates itſelf to all; and either finds them good, or very ſpeedily makes them ſo; and the mouth once made, will be always faithful to the hand, let it act with what agent it will. This bridle can at once ſubject the horſe to great reſtraint, or indulge it in eaſe and freedom: it can place the head exactly as the horſeman likes to have it, and work and bend the neck and ſhoulders to what degree he pleaſes. He can raiſe the head, by holding up his hand; by lowering it, it can be brought down; and if he chuſes to fix and confine it to a certain degree, he muſt uſe for this, as well as for the purpoſe of *bending*, *double reins;* that is, two on each ſide, the ends of which muſt be faſtened in a ſtaple near the pommel of the ſaddle, or to the girths, higher or lower, as the mouth, proportions of the horſe, and his manner of going require; and if properly meaſured and adjuſted, they will form and command the horſe ſo effectually, as, in a great degree, to palliate many imperfections of the mouth, and many faults in the mould and figure."

"The reins thus faſtened, or even one only, for the ſake of working one jaw and one ſide, will operate more or leſs, as the branches of a bit; and the ſnaffle will almoſt be a bit, a bridon, a caveſon, and martingal, in one. When the horſeman would bend the horſe, he muſt pull the rein on that ſide to which he is going, and lengthen that of the oppoſite, that they may not counteract each other. Nothing

thing will awaken a dull mouth, and bring it to life and feeling, ſo ſoon as this bridle. If the mouth be hard and callous, the iron ſhould be ſo twiſted as to have a ſort of edge, which will ſearch the lips, and when they will permit, the bars alſo; and if gently moved, or drawn from ſide to ſide, keep the mouth freſh and cool. If the twiſted, or rough ſnaffle, be thought too harſh, and the hand not ſkilful enough to moderate its effects, a ſmooth ſnaffle may be uſed; or if a bit of linen be wrapt round the twiſted ſnaffle, it will make it eaſy and ſmooth; and the mouth, once made fine and delicate, will be true to its feelings, will obey the ſnaffle, and follow the hand with as much exactneſs and preciſion as the bit knows to demand, but with more freedom and boldneſs that it ever can allow."

Such are the properties and merits of the ſnaffle, which long obſervation, and not a little experience, have taught the writer of this article to think preferable (generally ſpeaking) to thoſe of the bit; and which he has been therefore induced to point out and recommend with due deference to others, but with a greater deference to truth and juſtice:

"—Detrahere auſus,
Hærentem capiti multa cum laude coronam."

Berenger's Hiſt. and Art of Horſemanſhip, vol.ii. p. 221, &c.

Bit is alſo uſed for a little tool, fitted to a ſtock or handle, for the purpoſe of boring. In this ſenſe, we ſay, the bit of a piercer, an augre, or the like; meaning that iron part of thoſe tools wherewith the holes are bored.

The bit uſed by the block-makers, reſembles the ſhank of a gimblet, from ſix to twelve inches long, and from half an inch to an inch in diameter, and has at its end either a ſcrew, a ſharp point, or edge, for the purpoſe of cutting or boring holes. The *centre-bit* is a bit, having in the middle of its end, a ſmall ſteel point, with a ſharp edge on one ſide to cut horizontally, and a ſharp tooth on the oppoſite ſide to cut vertically. Holes bored with this inſtrument, are not liable to ſplit. The *counterſunk-bit* is a bit having two cutting edges at the end, reverſed to each other, which form an angle from the point. *Gouge-bit* is a bit ſmaller than a centre-bit, with a hollow edge at its end, like a gouge. *Noſe-bit* is a bit ſimilar to a gouge-bit, having a cutting edge on one ſide of the end.

Bit *of a Key*, is that part fitted at right angles to the ſhank of the key, wherein the wards are made. See Lock, &c.

Bit is alſo uſed in *Commerce*, for a piece of coin current in Jamaica, and valued at 7½d.

Bits, or *Bitts*, in a ſhip, denote a frame compoſed of two upright pieces of timber, called the pins, and a croſs-piece faſtened horizontally on the top of them; uſed for belaying cables and ropes to. *Bowline and brace bitts* are ſituated near the maſts; the *fore jeer*, and *top-ſail-ſheet bitts* are ſituated in the fore-caſtle, and round the fore-maſt; the *main jeer*, and *top-ſail-ſheet bitts* tenon into the fore-maſt beam of the quarter-deck; the *riding bitts* are the largeſt bitts in the ſhip, and are thoſe to which the cable is bitted, when the veſſel rides at anchor. The *cable is bitted*, or confined to the bitts by one turn under the croſs-piece, and another turn round the bitt-head. In this poſition, it may be either kept fixed, or it may be veered away.

Bit-*Stoppers*, are thoſe ſtoppers that are uſed to check the cable. See Stopper.

BITAZA, in *Ancient Geography*, a town of Aſia, in Aria, acording to Ptolemy.

BITBOURG, in *Geography*, a town of the Netherlands, in the duchy of Luxemburg before the revolution, but now a principal place of the canton of the ſame name, in the department of Forêts, containing 1638 inhabitants; the population of the canton conſiſting of 7160 perſons. Its territorial extent includes 225 kiliometres, and 12 communes. N. lat. 50° 0′. E. long. 6° 43′.

BITCH, in *Zoology*, is the female of the canine ſpecies, in contradiſtinction to dog. (See Canis.) It is ſometimes uſed in a ſimilar ſenſe with reſpect to foxes, the female being termed a "bitch-fox;" though the more common appellation among ſportſmen is a "vixen." Bitches are ſometimes ſpayed, to prevent their farther propagation; the beſt time for which operation is about after the heat is gone off.

BITCHE, in *Geography*, a town of France, and principal place of a diſtrict, in the department of the Moſelle, containing 2310 inhabitants; the number of thoſe in the canton being 10,441. Its territorial extent is 312½ kiliometres, and it includes 23 communes. It is ſeated on a river at the foot of the Voſges mountains, on the frontiers of Deux Ponts. It was taken by Lewis XIV. and fortified by Vauban; afterwards diſmantled and reſtored to the duchy of Loraine. In 1740, it was again fortified. Before the revolution, it was the capital of a country, including 50 villages. N. lat. 49° 5′. E. long. 7° 44′.

BITCHU, or Bitsiu, a province of Nipon, in the iſlands of Japan, between about 34° 30′ and 35° N. lat. and about 134° 30′. E. long.

BITCHYS, a tribe of Tartars, viſited by La Perouſe in 1787, and deſcribed by him. See Orotchys.

BITE is defined to be a ſolution of the continuity of a ſoft part, cauſed by the impreſſion of an animal's teeth.

Bite of *Mad-dog*. See Hydrophobia.

Bite of *Serpents*. See Poison.

Bite of *Rattle-ſnake*. See Poison.

Bite of the *Tarantula*. See Tarantism.

Bite is alſo applied, in a leſs proper ſenſe, to the impreſſion of other ſharp or pungent bodies. Thus a file is ſaid to bite the metal; aqua fortis bites, or eats into copper. An anchor is alſo ſaid to bite, when it holds faſt in the ground.

BITERLAGH, or Bitherlage, the ancient Daniſh military or camp law.

The word is compounded from *bithe*, *mulct*, and *lagh*, *law*; q. d. the law of *mulcts*, or *vites*.

Among the laws of the Danes, there are two peculiarly eminent; viz. the *bird ſtraa*, or *court law*; and the *bitherlage ractt*, made by Canute the Great, about the year 1035; of which an edition has been given by Reſenius.

BITETO, in *Geography*. See Bidetto.

BITHABA, in *Ancient Geography*, called alſo *Birthama*, a town of Aſia, in Aſſyria, according to Ptolemy.

BITHER, a city of Judæa, called by St. Jerom, Bethoron, which was the place of retreat of the impoſtor Barchochebas, fortified by him, and made the capital of his new kingdom. It was beſieged by the Romans under Julius Severus, A. D. 134, and after an obſtinate reſiſtance, compelled to ſurrender. See Barchochebas, and Bethoron.

BITHEREMAN, a town of Phœnicia, according to Sozomen, ſituate at the extremity of the territory of Eleutheropolis.

BITHIA, a town of Aſia, placed by Ptolemy in Media.

BITHIAS, a town of Aſia, in Meſopotamia, according to Ptolemy.—Alſo, a river of Thrace, according to Appian.

BITHIGA, a town of Aſia, in Meſopotamia. Ptolemy.

BITHYÆ, a people of Thrace, who, according to Steph.

Steph. Byz. derived their name from *Bithys*, a ſon of Mars; but more probably from the river Bithus, or Bithias, mentioned by Appian, and denominated Bathynias by Ptolemy.

BITHYLA, a town of Greece, in the interior parts of Laconia. Ptolemy.

BITHYNIA, a province of that part of Aſia, which was commonly called Aſia Minor. It was anciently known by the names of Myſia, Mygdonia, Bebrycia, and Mariandynia, as well as Bithynia; and extended from Myſia on the weſt, to Paphlagonia on the eaſt. It was bounded on the weſt by the Boſporus Thracius and part of the Propontis, on the ſouth by the river Rhyndacus and mount Olympus, on the north by the Euxine ſea, and on the eaſt by the river Parthenius. Ptolemy enlarged the extent of Bithynia, ſo as to make it comprehend ſome provinces belonging, according to other geographers, to Galatia and Paphlagonia. The chief cities of Bithynia on the coaſt were Myrlea, Daſcylos, Cius, and Nicomedia the metropolis. On the Boſporus ſtood the famous city of Chalcedon. In the Euxine ſea were ſituated the city and ancient republic of Heraclea. The principal inland cities of Bithynia were Pruſa, Libyſſa, and Nicæa or Nice. Its chief rivers were the Pſillis, Colpas, Sangarius or Sagaris, Hipias, Rhebas, and Lycus; all diſcharging themſelves into the Euxine ſea between Chalcedon and Heraclea. As Bithynia lies between 41° and 43° of north latitude, and is watered by many rivers, it once abounded with all the neceſſaries of life. The ancients compare ſome of the inland provinces to the fruitful and delicious vales of Tempe; but at preſent it lies in a great degree neglected and unmanured. Bithynia was anciently inhabited by various nations, differing in their manners, cuſtoms, and language; namely, the Bebryces, the Mariandyni, the Caucones, the Dolliones, and the Cimerii. Theſe different nations were anciently governed by their own kings; Bithynia being, in the earlieſt times, divided into as many kingdoms as nations or tribes. However, in proceſs of time, theſe petty princes were reduced by the more powerful kings of Bithynia. According to Diodorus Siculus, the Bithynians had kings from the time of Ninus; and, according to Appian, they had 49 ſovereigns before the Romans obtained poſſeſſions in Aſia. But this high antiquity is rendered doubtful by the ſilence of Homer reſpecting the Bithynians. Strabo (l. xii.) ſpeaks of one Pruſias, who reigned in Bithynia in the time of Cræſus, the laſt king of Lydia, by whom he was conquered. From this period, the Bithynians continued ſubject firſt to the Lydians, and afterwards to the Perſians, till the reign of Alexander the Great; for we find them mentioned by Herodotus among the many nations that attended Xerxes in his expedition into Greece. While they were ſubject to the Perſians, they ſeemed to have been ſtill governed by their own princes. Under Nicomedes I. the Gauls, whom he called to his aſſiſtance, firſt paſſed into Aſia, and obtained a ſettlement in that part of Aſia Minor, which was called from them Gallo-Græcia and Galatia. The laſt king of Bithynia was Nicomedes IV., who, at his death, in the year before Chriſt 75, bequeathed his kingdom to the Romans, by whom it was reduced to the form of a province.

BITHYNIA, in *Modern Geography*, forms one of the diſtricts of Anatolia, and is the neareſt province to Turkey in Europe, being parted from it only by the ſmall ſtrait called the Thracian Boſphorus. Its principal cities are Pruſa, Nice, and Nicomedia.

BYTHINIARCHIA, a ſort of ſuperior prieſthood in the province of Bithynia, to which belonged the ſuperintendency of the ſacred games, and which gave an exemption to him poſſeſſed of it, called bithyniarcha, from the care of tutorage.

BITHYNIUM, in *Ancient Geography*, the ancient name of a city of Bithynia, afterwards called Claudiopolis.

BITIS, in *Zoology*, a ſpecies of Coluber that inhabits Braſil. Above, this creature is cinereous, yellow, varied with white and red, and tranſverſe brown bands; beneath, yellowiſh, with a middle row of very minute ſcales. Gmel. &c. *Vipera bitis* of Laurent. Amph.

BITON, in *Conchology*, the name of the Linnæan *cypræa pediculus* in Adanſon's Senegal, &c.

Biton, in *Entomology*, a ſpecies of Papilio, ſo named by Eſper. It is *papilio dæmon* of Gmelin.

BITONTO, in *Geography*, a town of Naples, in the country of Bari, about 8 miles from the Adriatic, the ſee of a biſhop, ſuffragan of Bari. This is a fine town, containing 16,000 inhabitants, of more eaſy fortunes, and more poliſhed manners, than thoſe who dwell in the cities along the coaſt; its markets are well ſupplied, and it has an air of affluence. The country between it and Bari, at the diſtance of 9 miles, is very much incloſed; and though ſtony, fertile in corn, almonds, olives, wine, and fruit of all kinds. Near this city an obeliſk was erected by the king of Spain, with ſome fulſome inſcriptions in praiſe of himſelf, his father Philip, his ſoldiers, and the count of Mortemar, who was honoured with the title of duke of Bitonto, for having defeated the Auſtrians on this ſpot in 1734. The monument, however, which records a trivial victory, is crumbling to ruin.

BITTACLE, or Binacle, a ſquare box, or frame of timber, placed in the ſteerage of a ſhip, wherein the compaſs is placed. The word is formed, by contraction, from the French *habitacle, a ſmall habitation*, which ſignifies the ſame.

Large veſſels have two bittacles, a leſſer placed before the pilot, and a greater before the ſteerſman.

In the ſmaller veſſels, the bittacle is divided into three ſpaces or apartments; in large veſſels into five. One for the hour-glaſs; another for the lamp or light; another for the compaſs, &c.

Great care is to be taken in the diſpoſition, framing, &c. of the bittacle, that it ſtand true, and that it be not faſtened together with iron nails, but with wooden pins, becauſe the former would affect the compaſs. See Compass.

BITTENDORF, in *Geography*, a town of Sileſia, in the principality of Neyſze, 2 miles N. of Otmuchar.

BITTER, in *Sea Language*, denotes the turn of the cable round the bitts.

Bitter *almonds*. See Almond.

Bitter *apple*. See Colocynthis.

Bitter *end* of a cable, that end which remains on board round the bitts, when the ſhip is at anchor; the other part of the cable being veered.

Bitter *gourd*. See Colocynthis.

Bitter *place*, *locus amarus*, a poor barren ſoil, by Pliny called *terra amara, ſive macra*.

Bitter *purging ſalt*, *ſal catharticum amarum*. See Epsom *Salt*.

Bitter *ſweet*, in *Botany*. See Solanum.

Bitter *vetch*. See Orobus.

Bitter *waters*. See Water.

Bitter *wine*. See Wine.

Bitter *wood* and *aſh*. See Quassia.

Bitter *wort*. See Gentiana.

BITTERFELD, in *Geography*, a town of Germany, in the circle of Upper Saxony, and electorate of Saxony, ſeated

ſeated on the Moldau, 16 miles S. of Deſſau, and 18 S.S.W. of Wittenberg.

BITTERN, Bittour, in *Ornithology*, the Linnæan *ardea ſtellaris;* which ſee.

Bittern, is alſo a name given to the brine ſwimming upon the firſt concreted ſalt in the ſalt-works; this liquor is laded off, that the ſalt may be taken out of the veſſel, and is afterwards put in again, and affords more ſalt, which is to be ſeparated like the reſt, by lading off the liquor a ſecond time, and ſo on. The bittern, according to Mr. Boyle, is a very ſaline, bitter, ſharp, pungent liquor, which drains off in the making of ſalt from ſea-water; or which remains in the pans, after the coagulation and granulation of the purer and more ſaline part by boiling. A bittern alſo runs, or oozes, from the heaps of foſſile ſalt at Lymington, and Portſea in Hampſhire. Phil. Tranſ. N° 377. p. 348.

Bittern makes the baſis of *ſal catharticum amarum*, or Epsom-salt.

Bittern is the mother-water which remains after the cryſtallization of common or marine ſalt in ſea-water, or the water of ſalt ſprings. It abounds with Epſom ſalt, or the combination of vitriolic acid with magneſia, to which its bitterneſs is owing. It is employed in this country for making a purging bitter ſalt, which proves ſimilar in quality to the ſalt obtained from the Epſom waters, and is commonly ſold under its name. The ley is boiled down to a certain pitch, then filtered and inſpiſſated; the dry matter is calcined, re-diſſolved, and cryſtallized. If the mother-ley be inſpiſſated and diſtilled with vitriolic additions, a ſpirit of ſalt is obtained. Neumann, p. 212.

BITTERS, in the *Materia Medica*. The quality of bitterneſs (a ſimple perception familiar to every one, and which cannot be defined) is much more frequently met with in vegetable matter, than in any other order of natural ſubſtances; and in this, it moſtly reſides in a certain ſoluble matter, with tolerably uniform chemical properties, which has by ſome been denominated *bitter extract*. This diſtinction, though not perfectly accurate, is of conſiderable uſe in pharmacy; for whenever a bitter taſte is perceived in any part of a vegetable, we may conclude, with much probability, that it reſides in this ſpecific part of the vegetable, and eſpecially that it gives certain medicinal properties, which experience has ſhewn to be in the higheſt degree important.

The bitter principle is found in combination with a variety of other active ſubſtances, which modify, alter, correct, or impair its medicinal powers.

A pure, ſimple bitter vegetable (of which gentian, or quaſſia are good examples), is entirely void of ſmell, has neither acerbneſs nor aſtringency to the taſte, nor does it excite nauſea, unleſs in exceſſive quantity. The bitterneſs is readily extracted by almoſt every menſtruum, aqueous, as well as ſpirituous; and in the ſimple bitters, little, if any, difference, is perceived in the ſenſible properties of what is extracted, whatever be the medium. The bitter extract is not volatile by heat: hence, in the diſtillation of bitter plants that yield an eſſential oil (worm-wood, for example), the diſtilled oil has none of this taſte, the whole remaining in the reſidue. A watery, or ſpirituous infuſion of a bitter plant, inſpiſſated nearly to dryneſs, becomes intenſely bitter, often with an empyreumatic, or a ſomewhat altered taſte. This, when further dried, becomes ſolid and pulverulent. The extract is a convenient form for theſe ſubſtances, but the flavour is not ſo acceptable to the palate as the ſimple infuſions.

The bitter extract is conſiderably antiſeptic. Experiments have proved that the putridity of animal matters is much retarded by immerſion in bitter infuſions, even the watery; and ſubſtances already putrid, in ſome degree, loſe their fœtor by this addition. The watery infuſions of bitter vegetables mould by long keeping, and become ſour. This change takes place in ſummer, in five or ſix days, when the infuſion is not very ſtrong. The newly acquired acid taſte in ſome degree maſks the bitterneſs; but this latter quality remains extremely long, and is hardly ever loſt by ſpontaneous decompoſition.

The effect of the ſimple bitter on the human body, is generally conſidered as purely Tonic. It does not raiſe the pulſe; nor does it directly, or conſtantly produce any change in the ſecretions or excretions of the body. Its chief and moſt obvious operation is to increaſe the appetite, and promote the digeſtive powers; and hence it is with reaſon ſuppoſed, that its virtues depend on ſtimulating the fibres of the ſtomach. From this ſingle effect may be derived the well known uſe of bitters, in giving general tone and vigour to the ſyſtem, in a vaſt variety of caſes of debility, unconnected with organic diſeaſe, in checking aceſcency of the ſtomach, heartburn, flatulence, and other ſymptoms indicating a deficiency of the digeſtive powers, and in extending its ſalutary operation through the whole of the alimentary canal, reſtoring the regular and natural action of the bowels impaired by the original defect of the digeſtive organ.

Bitters have been ſuppoſed by ſome to increaſe the intoxicating powers of ſpirituous liquors. This, however, appears to apply only to the *narcotic* bitters, and to be attributable to the narcotic, and not the bitter principle. On the contrary, the ſalutary action of bitters on the digeſtive powers, is well calculated to correct the extreme and peculiar debility of the ſtomach, induced by habitual drinking.

An anthelmintic virtue (or power of expelling worms from the human body) has been attributed very generally to all bitters indiſcriminately. There does not, however, appear to be much foundation for this opinion, unleſs the bitterneſs be combined with a purgative property, as in aloes, or poſſibly a narcotic. The contents of the inteſtines being always intenſely bitter by the natural admixture of bile, it does not appear probable that animals, which live and grow in ſuch a medium, can be much moleſted by a ſmall addition of this principle, though from a vegetable matter.

An exceſſive habit of taking bitters, may finally prove detrimental to the ſtomach, by over-excitement, or by inducing a kind of artificial demand for food in greater quantity than is ſalutary to the general health. A remarkable example of the danger of theſe medicines, long perſiſted in by perſons of gouty habits, is afforded by the operation of the *Portland powder* in this diſeaſe.

The chief combinations of the bitter principle uſed in medicine are *Narcotic bitters*, ſuch as opium, faba Sancti Ignatii, bitter almonds, and the kernels of many fruits: *Aromatic bitters*, as orange-peel, caſcarilla, and wormwood: *Aſtringent bitters*, a very large claſs, and generally combined both with tannin and the gallic acid, of which cinchona, and many other barks are ſtriking examples: *Acid and purgative bitters*; the ſquill, colocynth, aloe, and ſome other combinations of leſs frequency.

For medicinal uſe, the aromatic is always an uſeful addition to the bitter, and is generally employed.

The moſt important of the animal bitters is the bile, the properties of which have been mentioned under that article. In tonic power, it cloſely reſembles the vegetable bitters. Late experiments make it probable, that the *Pruſſic acid*, a very peculiar animal bitter, poſſeſſes properties ſimilar to the vegetable narcotic bitters.

A few of the mineral, or common ſaline combinations, are diſtinguiſhed by bitterneſs of taſte; but it is doubtful how far

far this principle modifies their medicinal powers. The nitrated filver is of this kind, a falt eſteemed to be a very powerful tonic, taken internally in ſmall doſes. Some of the ſaline combinations of magneſia have the ſame taſte, and it is poſſibly on this account, that the ſulphat of magneſia will often be retained by very irritable ſtomachs, when other ſaline medicines are rejected. For the pharmaceutical preparations of the ſeveral bitters, ſee the reſpective articles; as *Gentian, Quaſſia, Columbo, &c.* and that of *Bitter Extract.*

BITTOUR, in *Ornithology*. See Bittern.

BITUBERCULATA, in *Entomology*, a ſpecies of Cassida, of a brown colour, with a white margin; wing-caſes ſpotted with black, and a ſingle tubercle at the baſe of each. A native of Cayenne. Fabricius.

BITUBERCULATUS, a ſpecies of Curculio, that inhabits New Zealand. This is of a ferruginous colour; thorax length of the wing-caſes, and dotted, with two tubercles on the back. Fabricius.

Bituberculatus, a ſpecies of Cryptocephalus (*Crioceris*), that inhabits Africa. It is fulvous; wing-caſes pale, entirely bordered with fulvous. Fabricius.

BITUMEN, *Bitumé*, Fr. The bitumens, properly ſo called, form a ſpecies of compound mineral inflammables, of which the following are the characters. 1. By expoſure to the air, and the application of heat, they burn with a flame more or leſs vivid, and leave ſcarcely any reſidue. 2. By deſtructive diſtillation, they yield a liquid acid, but no ammonia, a variable but ſmall proportion of charcoal being left behind in the retort. 3. They are either liquid, or capable of being rendered ſo by a moderate degree of heat.

Bitumens may be divided into two families, the non-elaſtic and elaſtic. To the former belong naphtha, petroleum, mineral tar, mineral pitch, and aſphaltum; to the latter belong mineral caoutchou, and ſuberiform mineral caoutchou.

§ 1. *Non-Elaſtic Bitumens.*

Naphtha, *Bergnaphtha, Naphte, Bitume liquide blanchâtre*, is a ſubſtance of a light brown, or wine yellow colour, perfectly fluid and tranſparent. It is the lighteſt of all liquids, its ſpecific gravity being =0.708 to 0.732; it has a ſtrong penetrating bituminous ſmell; it takes fire with great readineſs, and burns with a bluiſh yellow flame and copious black ſmoke, leaving no reſidue. It may be rectified by diſtillation with water, in the ſame manner as the eſſential oils, and then becomes colourleſs, and weaker in its odour. It does not combine in any conſiderable degree with either water or alcohol, but unites eaſily with ether, with turpentine, with caoutchou, and the eſſential oils. When rubbed with the cauſtic fixed alkalies, it forms a kind of Starkey's ſoap. The concentrated ſulphuric and nitric acids are decompoſed with vehemence upon it, converting it into a ſolid reſinous ſubſtance ſoluble in alcohol. Even the pureſt naphtha, when expoſed to the air, becomes firſt of a yellow, and then of a browniſh colour, acquires a ſomewhat viſcid conſiſtence, and thus paſſes into petroleum. Naphtha is procured for the moſt part from very copious ſprings of this ſubſtance at Baku on the ſhore of the Caſpian ſea, where it is burnt in lamps inſtead of oil, and is uſed medicinally both externally and internally in rheumatic and other complaints. It is alſo met with in Calabria and ſome parts of Italy.

Petroleum, or *Rock-oil. Erdohl, Stein-ohl. Petrole.* The colour of petroleum is a blackiſh or reddiſh brown; it is fluid, though ſomewhat viſcid; it is almoſt opaque, is unctuous to the touch, and exhales a ſtrong bituminous odour; its taſte is pungent and acid. Sp. gr. 0.847, 0.854. Petroleum may be rectified by diſtillation with water, in which proceſs, the carbon, which thickens and colours it, is left behind in the retort, and a colourleſs fluid comes over, poſſeſſed of all the properties of naphtha. When petroleum is diſtilled *per ſe*, there firſt ariſes ſome naphtha, then a watery empyreumatic acid, and laſtly a thick dark coloured oil, a ſpungy coal remaining in the retort. In its combinations with, and chemical actions on other ſubſtances, it perfectly reſembles the preceding ſpecies. It is found wherever naphtha is, and in many other places among ſtratified mountains, in the vicinity of coal. In England, Coalbrook dale, and Pitchford in Shropſhire, are the principal places where petroleum is found; at the latter place extenſive ſtrata of ſandſtone are ſaturated with petroleum, and the naphtha, procured by diſtillation of the ſtone, is ſold under the name of Betton's Britiſh oil, and is eſteemed an active remedy in ſtrains and rheumatiſm.

Mineral Tar, Barbadoes Tar, *Bergthier, Goudron-mineral.* This ſubſtance differs from the preceding only in degree; it is more viſcid, more opaque, of a darker colour, and, when diſtilled, leaves a larger carbonaceous reſidue. It is found native together with petroleum, and may alſo be procured by the diſtillation of coal.

Mineral Pitch, *Maltha.* The external characters of maltha are extremely ſimilar to thoſe of common pitch; when heated, it emits a ſtrong unpleaſant odour. In cold weather it may be broken, and exhibits a vitreous luſtre; but when warm, it is ſoft and tenacious.

Asphaltum, *Schlachiges Erdpech, Aſphalte.* The colour of this ſubſtance is black or browniſh black; it is light and brittle; when broken, it diſplays a conchoidal fracture and vitreous luſtre; it has little or no odour, unleſs it is rubbed or heated. It is conſiderably inflammable, melts eaſily, and burns away without leaving any reſidue. It is principally found on the ſhores of the Dead Sea, in Syria, and in the iſle of Trinidad in the Weſt Indies.

The principal uſe of aſphaltum is as an ingredient in certain varniſhes, eſpecially that uſed by the copper-plate engravers.

§ 2. *Elaſtic Bitumens.*

Mineral Caoutchou, *Elaſtiches Erdpech, Poix minerale elaſtique.* The colour of this ſubſtance varies from yellowiſh brown to olive brown and blackiſh or reddiſh brown. The light coloured is often in a ſemifluid ſtate, and adheres to the fingers; the olive brown is ſolid and elaſtic; the blackiſh and reddiſh brown are hard and little elaſtic. It occurs ſtalactitical, or inveſting, or in maſſes. Its ſp. grav. in the ſoft varieties is about = 0.9, and in the hardeſt and leaſt elaſtic is = 1.2. It paſſes into aſphaltum.

It is partly ſoluble in ſulphuric ether; but the reſidue of the ſolution, after evaporation of the ether, is not elaſtic; thus forming an eſſential difference between the vegetable and mineral caoutchou.

This ſingular mineral has been hitherto only found in the cavities of a lead mine, near Caſtleton, in Derbyſhire, called the Odin mine, accompanied by aſphaltum.

Suberiform Mineral Caoutchou. This ſubſtance, when recently cut, exactly reſembles fine cloſe cork in its colour and texture; but by expoſure for a few days to the air, it becomes of a pale reddiſh brown colour. It is alſo ſometimes found friable, and paſſing by decompoſition into an ochraceous powder. It has only been found in a rivulet near the Odin mine, whence the preceding is obtained, and appears to differ from it, merely by being penetrated with water. It occurs in nodules of various ſizes, ſome weighing upwards of 13 pounds, the nucleus of which is very commonly the brown perfectly elaſtic mineral caoutchou. Fourcroy Syſt. vol. viii. Brochant. Mineralog. vol. ii. p. 58. Dict. d' Hiſt. Nat. art. *Bitumes.* Gren. Syſt. Handbuch. vol. iii. p. 1. Hatchett on Bitumens in Linnæan Tranſ.

BITURIGES,

BITURIGES Cubi, in *Ancient Geography*, the name of a people who occupied a conſiderable part of Aquitania Prima, and who had been much more powerful before Cæſar's conqueſt of Gaul, than they were afterwards. Livy ſays, that, in the time of Tarquin, they commanded the whole portion of Gaul called Celtic. Their capital was denominated *Avaricum*, which ſee. In the time of Cæſar, theſe people loſt their power, and became ſubject to the Ædui, or at leaſt were reduced to the neceſſity of putting themſelves under their protection.

Bituriges *Viviſci*, a people who inhabited the ſouthern part of Aquitania Secunda, and are ſuppoſed to have derived their origin from the Bituriges Cubi. Their capital was *Burdigala*; which ſee.

BITURIS, a town of Hiſpania Tarragonenſis, in the country of the Vaſcones. Ptolemy.

BITYLA, a town of the Peloponneſus, not far from the Meſſenian gulf, S.W. of Sparta.

BITZLEER, Liwa, in *Biography*, a celebrated Jewiſh rabbi, who flouriſhed in Bohemia about the cloſe of the ſixteenth century. He converſed with the emperor Rodolphus, and he was ſo famous, that the Jews ſaid of him, that all Iſrael drank of his waters, and walked by his light. He founded the academy, called Klauſe, in 1592, which acquired ſuch reputation in his time, that it drew a vaſt concourſe of diſciples to him. He was choſen at laſt ſuperintendant of all the ſynagogues in Poland.

BIVALVE, *two-valved*, in *Conchology*, bivalviæ conchæ, one of the three principal ſections, into which all teſtaceous animals are divided. The Linnæan genera of bivalve ſhells are mya, ſolen, tellina, cardium, mactra, donax, venus, ſpondylus, chama, arca, oſtrea, anomia, mytilus, and pinna. The arrangement of bivalves by Cuivier, Lamarck, and other late naturaliſts, differs materially from that of Linnæus and Gmelin. See Conchology.

Bivalve is alſo applied, in *Botany*, to the *ſiliquæ*, or ſeed-pods, of ſuch plants as open their whole length to diſcharge their ſeeds. Such are peas, beans, &c. which the botaniſts ſay, have bivalve or bivalvular ſiliquæ.

BIVAT, in *Conchology*, the name given by Adanſon to the ſhell called by Linnæus (Syſt. Nat. edit. 10.) *murex ſcabriuſculus*; and *voluta cancellata*. Gmelin.

BIVENTER, from *bis* and *venter*, in *Anatomy*, a name given to muſcles that have two fleſhy portions, which were called bellies, and one tendon. Such muſcles are alſo called *digaſtric*. The term biventer has been applied to a muſcle of the lower jaw and os hyoides, which is deſcribed under its more common title of *digaſtricus*. Albinus alſo denominates a portion of the muſculus complexus of the neck, biventer cervicis. See Complexus.

BIVERI, in *Geography*, a lake of Sicily, near Lentini, which, in ſummer and autumn, renders the ſituation of this town very unwholeſome. The waters of this lake, and of the neighbouring marſhes and ponds, abound with eels and tench, of the roes of which the fiſhermen make a large quantity of botarga, a ſpecies of caviar; it is very ſalt, and has the taſte of tar, but is much reliſhed by the Sicilians.

BIVINCO, the principal place of a canton, in the department of Golo, and iſland of Corſica, the population of which conſiſts of 1573 perſons.

BIVIO. See Bevio.

BIVITTATUS, in *Entomology*, a ſpecies of Scarabæus (*Melolontha*), that inhabits Braſil. It is yellow and very gloſſy; on the head and thorax two common ſtripes, and many abbreviated green ſtriæ on the wing-caſes. Swederus, Nov. Act. Stockh.

Bivittatus, a ſpecies of Curculio, found in St. Thomas's iſland. It is black; wing-caſes ſtriated with dots; marginal and dorſal interrupted ſtripe of yellow. Fabricius.

BIUMBRES, from *bis*, *double*, and *umbra*, *ſhadow*, in *Geography*, an appellation given to the inhabitants of the torrid zone, becauſe at two different ſeaſons of the year, their ſhadows are projected two different ways.

The biumbres are the ſame with thoſe otherwiſe denominated *amphiſcii*.

BIUMI, Paul Jerom, in *Biography*, born at Milan in 1663, ſtudied medicine at Padua, where he was admitted to the degree of doctor in 1685. Returning thence to Milan, he ſoon acquired ſo much fame for his learning and ſkill in his profeſſion, that in 1699 he was made profeſſor of anatomy there, in which ſituation he continued to the time of his death, in 1731. He was author of ſeveral works, of which the following are moſt known: "Encomiaſticon lucis, ſeu lucis encomia in phyſiologicis medicinæ novæ fundamentis e veterum tenebris erutis, atque cultro anatomico, autopſiæque caractere confirmatis," Mediol. 1701, 4to. "Scrutinio di Notomia e di Cirurgia," Milan, 1712, 8vo. Haller. Bib. Anat. et Med. Eloy. Dict. Hiſt.

BIVONA, in *Geography*, a town in the kingdom of Naples, and province of Calabria Ultra, 10 miles N.E. of Nicotera.

BIXA, in *Botany*. Lin. gen. 654. Reich. 710. Schreb. 887. Juſſ. 293. Gærtn. t. 61. Claſs and order, *polyandria monogynia*. Nat. Ord. *columniferæ; tiliaceæ*, Juſſ. Gen. Char. *Cal.* perianth five-toothed, very ſmall, obtuſe, flat, permanent. *Cor.* double; outer with petals five, oblong, equal, large, more rude; inner with five petals like the outer, but thinner. *Stam.* filaments numerous, ſetaceous, ſhorter by half than the corolla; anthers erect. *Piſt.* germ ovate; ſtyle ſiliform, the length of the ſtamens; ſtigma parallely bifid, compreſſed. *Per.* capſule ovate-cordate, compreſſed, fenced with briſtles, bivalve, gaping at the angles, one-celled, with an inner bivalve membrane. *Seeds* numerous, turbinate, with a truncated navel, berried. *Rec.* linear, longitudinal, faſtened to the middle of the valves.

Eſſ. Char. *Cor.* ten-petalled. *Cal.* five-toothed. *Capſ.* hiſpid, bivalve.

Species, 1. B. *Orellana*, arnotto, or anotta. Lin. Spec. 730. Reich. 2. 580. Hort. Cliff. 211. Mat. Med. 135. Gærtn. fruct. 1. 292. Brown. jam. 254. B. Oviedi, l. 8. c. 6. Bauh. Hiſt. 1. 440. Cluſ. exot. 74. Orleana ſ. Orellana. Pluk. phyt. t. 209. f. 4. Comm. Hort. 1. 65. t. 33. Rocu. Merian. ſurin. t. 44. Urucu. Piſo 133. Sloan. jam. 2. 52. t. 181. f. 1. Pigmentaria. Rumph. Amb. 2. 79. t. 19. Arbor Mexiocana, fructu caſtaneæ, coccifera. Bauh. pin. 419. Raii hiſt. 1771. Achiotl. Hernandez. Mexic. 74. This ſhrub riſes with an upright ſtem to the height of eight or ten feet, ſending out many branches at top, which form a regular head. Theſe are garniſhed with heart-ſhaped leaves, ending in a point, which have long footſtalks, and come out without any order. The flowers are produced in looſe panicles at the end of the branches, of a pale peach colour, having large petals. A native both of the Eaſt and Weſt Indies. Introduced here in 1690 by Mr. Bentick.

Linnæus has adopted the South American vernacular name of bixa from Oviedo; and it is known by the ſame name in Holland, Denmark, and other northern countries. In Holland it is likewiſe called Orleane; in German, Anotta, &c. In England this name is adopted, but its orthography is various, as Arnotto, Arnotta, Anotta, Anato, Anoto, and Annoto. The French have adopted the Braſilian name, Uruhu, or Urucu, ſpelling it Roucouyer, Roucou, or Rocurier des Indes. The Portugueſe have alſo the ſame

appellation Urucu, or Urucueira. In Spaniſh it is Anato, or Atolle. In the Mexican language, Achiotl. Scaliger calls it arbor ſinium regundorum, becauſe the Mexicans made plans, and marked the boundaries of their lands on tablets, with the colour prepared from the berries. Tournefort named it Mitella, from the reſemblance of the capſule, when open, to a mitre. For the preparation of the drug, and its uſes, ſee Annotto. The bark of the bixa makes good ropes for common uſe in the Weſt Indies; and pieces of the wood are uſed by the Indians to procure fire by friction.

Propagation and Culture. This plant is propagated by ſeeds, may be eaſily cultivated, and is planted in many parts of Jamaica, Barbadoes, Cayenne, &c. in rich ſoils, and ſhady ſituations, ſhooting luxuriantly near rivulets. It is alſo propagated with us by ſeeds, which are annually brought in great plenty from the Weſt Indies. Theſe ſhould be ſown in a ſmall pot filled with light rich earth, and plunged into a hot-bed of tanner's bark, where, with proper temperature, the plants will appear in about a month; when they are about an inch high, they ſhould be taken out and ſeparated without injuring their roots, and each planted in a pot of light rich earth, and plunged into a freſh hot-bed of tanner's bark, ſhading them every day till they have taken root; afterwards they ſhould be treated like other plants of the ſame country, by admitting freſh air to them in proportion to the warmth of the ſeaſon; and when the heat of the tan declines, it ſhould be turned up to the bottom, and, if neceſſary, freſh tan be added to renew the heat. The plants muſt be refreſhed with water three times a week in ſummer, but not in great quantities, as with much wet their roots would rot. Plants that are raiſed early in ſpring, and properly managed, will be a foot and a half high in autumn, when they ſhould be removed into the bark ſtove, and plunged into the tan-bed. During the winter, they muſt have but little water, and while the plants are young, they ſhould be kept warm; otherwiſe they will caſt their leaves, loſe their tops, and appear unſightly. They muſt be kept conſtantly in the bark ſtove; ſome of them riſe ſeven or eight feet high, with ſtrong ſtems and large heads; but ſeldom produce flowers in Europe. Martyn's Miller.

BIXÆ, in *Entomology*, a ſpecies of Papilio (*Pleb. Urb.*), with roundiſh, brown wings, greeniſh at the baſe, and a milky band on the under ſide of the poſterior wings. Linn. Fabr. &c. Inhabits America.

BIZACIUM, in *Ancient Geography*. See Byzacium.

BIZAM, Chat-Bizam, in *Zoology*, the French name of the Linnæan *viverra tigrina*, which ſee.

BIZAMO, in *Geography*, a kingdom of Abyſſinia, ſituate between the branches of the Nile, called the White and the Blue rivers, about N. lat. 10° 15′. and between 35° and 36° E. long.

BIZANTIA, a town of European Turkey, in the province of Moldavia, 40 miles ſouth-weſt of Birlah.

BIZARRE, Fr. denoting *capricious*, &c. a term uſed among *Floriſts* for a particular kind of carnation, which has its flowers ſtriped or variegated with three or four colours.

BIZE, in *Geography*, a town of France, in the department of the Aude, and diſtrict of Narbonne, 10 miles N. W. of Narbonne.

BIZERTA. See Biserta.

BIZES, in *Ancient Geography*, a river of Bithynia, between Phillis and Rhebas. Amnian. Marcell.

BIZOCHI, or Bisochi, in *Eccleſiaſtical Hiſtory*, a ſect or branch of religious minorites, condemned by ſeveral popes.

The Bizochi were alſo called *fratricelli*, or *fratres de paupere vita*; ſometimes *Bichini* or *Bicchini*, and *Beguins*. The name is formed from *biſaccus*, on account of a double budget, or wallet, wherewith they begged their living. See Beghardi, and Tertiaries.

BIZONE, in *Ancient Geography*, a city of Lower Mœſia, 80 ſtadia north of Dionyſopolis, mentioned by Pliny (l. iv. c. 12.) as having been deſtroyed by an earthquake.

BIZONNES, in *Geography*, a town of France, in the department of the Iſere, and chief place of a canton, in the diſtrict of La Tour du Pin, 12 miles northweſt of Moirans.

BIZU, a town of Africa, in the kingdom of Morocco, ſeated on a mountain in a fertile country, 25 leagues north of Morocco.

BIZYA, in *Ancient Geography*, a town of Thrace, and capital of the country called Aſtica, at ſome diſtance from the ſea, N.W. of Salmydeſſus.

Bizya, in *Geography*, a town of European Turkey, in Romania, 50 miles eaſt of Adrianople.

BLACK, ſomething opake and porous, that imbibes the greateſt part of the light that falls on it, reflects little or none, and therefore exhibits no colour. See Blackness.

Bodies of a black colour are found more inflammable, becauſe the rays of light falling on them are not reflected outwards, but enter the body, and are often reflected and refracted within it, till they be ſtifled and loſt. They are alſo found lighter, *cæteris paribus*, than white bodies, being more porous. It may be added, that clothes dyed of this colour wear out faſter than thoſe of any other, becauſe their ſubſtance is more penetrated and corroded by the vitriol neceſſary to ſtrike their dye, than other bodies are by the galls and alum which ſuffice for them.

The inflammability of black bodies, and their diſpoſition to acquire heat, beyond thoſe of other colours, are eaſily evinced. Some appeal to the experiment of a white and black glove worn in the ſame ſun; the conſequence will be, a very ſenſibly greater degree of heat in the one hand than the other. Others allege the phænomena of burning-glaſſes, by which black bodies are always found to kindle ſooneſt: thus, a burning-glaſs, too weak to have any viſible effect at all upon white paper, will readily kindle the ſame paper rubbed over with ink. Mr. Boyle gives other proofs ſtill more obvious: he took a large tile, and having whited over one half of its ſuperficies, and blacked the other, expoſed it to the ſun; where having let it lie a convenient time, he found, that whilſt the whited part remained ſtill cool, the black part was grown very hot. For farther ſatisfaction, the ſame author has ſometimes left on the ſurface of the tile a part retaining its native red, and expoſing all to the ſun, has found the latter to have contracted a heat in compariſon of the white part, but inferior to that of the black. So alſo on his expoſing two pieces of ſilk, one white, the other black, in the ſame window to the ſun, he often found the latter conſiderably heated, when the former has remained cool. It is obſervable likewiſe, that rooms hung with black are not only darker, but warmer than others. Boyle's Works abridg. tom. i. p. 144. and tom. ii. p. 36. To all which may be added, that a virtuoſo of unſuſpected credit aſſured Mr. Boyle, that, in a hot climate, he had, by carefully blackening the ſhells of eggs, and expoſing them to the ſun, ſeen them thereby well roaſted in a ſhort time.

Dr. Watſon, the preſent biſhop of Landaff, covered the bulb of a thermometer with a black coating of Indian ink, in conſequence of which the mercury roſe ten degrees. Phil. Tranſ. vol. lxiii. part i. p. 40.

Black clothes heat more, and dry ſooner in the ſun, than white clothes. Black is therefore a bad colour for clothes in hot climates; but a fit colour for the linings of

of ladies' ſummer hats. Dr. Franklin's Experiments, Obſervations, &c. 5th edit. p. 483, & ſeq. He obſerves alſo, ibid. p. 382, that a chimney painted black, when expoſed to the ſun, will draw more ſtrongly. We may add, that black mould is a hotter ſoil for vegetables; and garden-walls, painted black, anſwer better for the ripening of wall-fruit, than thoſe of lighter colours.

Black, in matters of dreſs, is the diſtinguiſhing habit of churchmen and mourners. Some will have it, that the common people among the Romans were clothed in black; whence the denomination given them of *turba pullata*.

Black, Joseph, in *Biography*, a celebrated teacher of chemiſtry, was born at Bourdeaux, in France, in the year 1728. His father, who was a native of Belfaſt, in Ireland, but of a Scotch family, carried on the wine trade at Bourdeaux, and lived in intimacy with the famed baron Monteſquieu, who expreſſed his regret in ſtrong terms on Mr. Black's quitting Bourdeaux, when he retired from buſineſs, as appears by ſeveral of his letters which are preſerved by the family. By his mother, Dr. Black was nearly related to the wives of Dr. Adam Ferguſon, and Mr. James Ruſſel, profeſſor in natural philoſophy at the univerſity of Edinburgh, and owed probably much of his knowledge to the inſtruction or information he obtained from them. In the year 1740, his father ſent him to Belfaſt, that he might have the education of a Britiſh ſubject; and from his letters, he appears to have been ſatisfied with the progreſs he made there. In 1746, he went to Glaſgow, where he applied to the ſtudy of medicine, but particularly to chemiſtry, into the knowledge of which he was initiated by Dr. Cullen, who then gave lectures there on that branch of ſcience. Under his direction he made ſuch progreſs, that, in 1756, when Dr. Cullen removed to Edinburgh, Black, who had previouſly taken his degree of doctor, ſucceeded him as profeſſor in medicine, and lecturer in chemiſtry. That he was qualified to fill this office, he had ſhewn by an ingenious eſſay, containing experiments to inveſtigate the nature of magneſia, quicklime, and ſome other alkaline ſubſtances, recommended as ſolvents of the ſtone in the bladder. In the courſe of theſe experiments he demonſtrated the exiſtence of an aërial fluid, which he called fixed air, the preſence of which gave mildneſs, and its abſence cauſticity, to alkalies and calcareous earth; a diſcovery which laid the foundation of the improvements ſince made in our knowledge of gaſes, or aërial bodies, by Prieſtley, Cavendiſh, Lavoiſier, and other chemiſts. The eſſay, containing the account of theſe experiments, was publiſhed in the ſecond volume of "Eſſays phyſical and literary," in 1756. The following year he further enriched his favourite ſcience with his experiments on latent heat, which is found to exiſt in all bodies; explaining in a ſatisfactory manner the connection of heat and fluidity, by which he ſo eſtabliſhed his reputation, that on Dr. Cullen's being promoted from the chemical to the medical chair at Edinburgh, in 1765, he was unanimouſly choſen to ſucceed him as profeſſor in chemiſtry there. His time was now dedicated, and with increaſed ardour, to imparting the knowledge he had acquired to his numerous pupils; and as he was perfectly maſter of the ſubjects on which he lectured, his doctrines were ſo clearly explained, as to be eaſily underſtood by his auditors, many of whom took complete copies of his lectures. By this means the knowledge of the diſcoveries he had made, became widely diffuſed, and his claim to them ſecured to him, which might otherwiſe have been aſſigned to thoſe who improved and extended them. Having thus laid the ground-work for the improvement of the art, he ſeems to have been contented, without attempting to puſh his diſcoveries further. Satisfied with the attention paid him by his pupils, and the gradual extenſion of his fame, of which he received daily proofs, he took little notice of what Prieſtley, Lavoiſier, and other philoſophical chemiſts, were doing, or only noticed them when they had neglected making thoſe acknowledgments to him he knew to be his due. Dr. Robiſon, who had been his pupil, and has lately publiſhed his lectures, with an account of his life, attributes this apparent apathy to the ill ſtate of his health, which, for ſeveral years before his death, did not permit that degree of application and ſtudy, which the farther extenſion of his diſcoveries would have required. "The ſlighteſt cold," he ſays (Preface to the Lectures, p. lx.), "the moſt trifling approach to repletion, immediately affected his breaſt, occaſioned feveriſhneſs, and, if continued two or three days, brought on a ſpitting of blood. In this ſituation nothing reſtored him but relaxation from thought, and gentle exerciſe. The ſedentary life, to which ſtudy confined him, was manifeſtly hurtful; and he never allowed himſelf to indulge in any intenſe thinking, or puzzling reſearch, without finding theſe complaints ſenſibly increaſed." Hence, though he had the honour of being elected one of the foreign aſſociates of the royal academy of ſciences at Paris, and member of the imperial academy at Peterſburgh, he ſent no communications to either of thoſe learned ſocieties. As he ranked high among the teachers of chemiſtry, and his name and character were extended over Europe, his pupils were numerous, and continued increaſing for the whole time he lectured, more than thirty years. In the year 1774, he ſent to the royal ſociety in London, his obſervations on the effect of boiling upon water, in diſpoſing it to freeze; and, in 1791, the Royal Society at Edinburgh publiſhed his analyſis of the waters of ſome hot ſprings in Iceland, in the third volume of their Tranſactions. In this paper, which is drawn up with great accuracy, he treats of the formation of the ſilicious ſtone, which is depoſited by theſe ſprings. His conſtitution becoming more and more feeble, from the frequent returns of his complaint, he was firſt obliged to make uſe of an aſſiſtant in his lectures, and at length, to give them up altogether; the ſmalleſt exertion bringing on a fit of hæmoptoe. "But he ſeemed," Dr. Robiſon ſays (Preface, p. 73.), "to have his complaint almoſt under command, ſo that he never allowed it to proceed far, or to occaſion any diſtreſſing illneſs, and ſo ſpun his thread of life to the laſt fibre, guarding againſt illneſs by reſtricting himſelf to a moderate diet, and meeting his increaſing infirmities with a proportional increaſe of attention and care." On the 26th of November 1799, and in the 71ſt year of his age, he died ſuddenly, without any previous warning. Being at table, with his uſual fare before him, ſome bread, a few prunes, with milk and water for his drink, having the cup in his hand, reſting on his knees, he expired ſuddenly in that poſture, the cup remaining in his hand, and his countenance ſo compoſed and placid, that his ſervant at firſt imagined he was fallen aſleep. He was of a chearful and ſociable diſpoſition, and, as his mind was well ſtored with knowledge, an entertaining companion. His company was therefore much courted; and, as his circumſtances were affluent, he dedicated as much of his time to the pleaſures of ſociety, as was conſiſtent with his avocations. He was never married; he therefore left the principal part of his fortune, which is ſaid to have been conſiderable, among the children of his brothers and ſiſters. Gen. Biog. Dict. Lectures of the Elements of Chemiſtry.

Black, in *Heraldic Engravings*, is expreſſed by croſs lines, and in emblazoning, is termed for commoners *ſable*, for peers *diamond*, and for ſovereigns and princes *ſaturn*.

Black, in the *Manege*. A horſe of a deep, ſhining, and

and lively black is called a *black-more*, or *coal-black*. Horſes black all over are commonly reckoned dull and melancholy; but a white foot, or ſtar in the forehead, gives them a degree of ſprightlineſs. The Spaniſh gravity is ſaid to be beſt pleaſed with thoſe entirely black.

Black, *blue*, in the *Manufactures and Arts*, is the coal of ſome kind of wood, or other vegetable matter, burnt in a cloſe heat, where the air can have no acceſs: the beſt ſort is ſaid to be made of vine-ſtalks and tendrils. The goodneſs of blue black conſiſts in the cleanneſs and blue caſt of its black colour, and the perfect degree of its levigation.

That this preparation, which is ſold in the colour ſhops, is no other than a vegetable coal, appeared from the following experiment of Dr. Lewis. (Comm. Phil. Techn. p. 358.) Laid on a red-hot iron, it burned and glowed like powdered charcoal, and turned into white aſhes; which aſhes, thrown into oil of vitriol diluted with water, very readily diſſolved into a bitteriſh liquor, the characteriſtic by which the vegetable earth is diſtinguiſhed. From what particular vegetable matter this blue-black is procured, experiments, he ſays, cannot diſcover: but it appears from thoſe which he recites, that it may be obtained from many, and that the choice of the vegetable ſubject affects rather the ſoftneſs or hardneſs, than the colour of the coal. Blue-black, perfectly good, may be prepared in the manner directed for *ivory* Black, from the vine ſtalks, or tendrils, or any other twigs of wood, of an acid taſte and tough texture; but the ſoaking in the oil, preſcribed for the ivory, muſt be omitted.

The painters have *blue-blacks*, *brown-blacks*, &c. which may be made by mixing pigments of the reſpective colours, with ſimple black ones, in greater or leſs quantity, according to the ſhade required. The dyers alſo have different blacks, and often darken other colours by ſlightly paſſing them through the black dying liquor; but the term brown-black is in this buſineſs unknown, brown and black being here looked upon as oppoſite to one another. In effect, the colour called brown-black is no other than that which all dyed black clothes change to in wearing; and therefore it is no wonder that it ſhould be excluded from the catalogue of the dyers' colours. The true or ſimple blacks, mixed with white, form different ſhades of grey, lighter or darker, according as the white or black ingredient prevails in the mixt. The black pigments, ſpread thin upon a white ground, have a like effect. Hence the painter, with one true black pigment, can produce on white paper, or on other white bodies, all the ſhades of grey and black, from the ſlighteſt diſcolouration of the paper up to a full black; and the dyer produces the ſame effect on white wool, ſilk, or cloth, by continuing the ſubjects for a ſhorter or longer time in the black bath, or making the bath itſelf weaker or ſtronger.

M. le Blon, in his "Harmony of Colours," forms black by mixing together the three primitive colours, blue, red, and yellow; and Mr. Caſtel, in his "Optique des couleurs," publiſhed in 1740, ſays, that this compound black has an advantage in painting above the ſimple ones, of anſwering better for the darkening of other colours. Thus if blue, by the addition of black, is to be darkened into a *blue-black*, the ſimple blacks, if uſed in ſufficient quantity to produce the requiſite deepneſs, conceal the blue, while the compound blacks leave it diſtinguiſhable. Le Blon has not mentioned the proportions of the three primitive colours neceſſary for producing black. Caſtel directs 15 parts of blue, 5 of red, and three of yellow; and he obſerves, that the colours ſhould be the deepeſt and darkeſt of their reſpective kinds, and that a combination ſhould be made of ſeveral pigments for each colour; for the greater the contraſt of heterogeneous and diſcordant drugs, the more true and beautiful will be the black, and the more capable of uniting with all other colours, without ſuppreſſing them, and even without making them tawney. Dr. Lewis, in his experiments, has not ſo far ſucceeded as to obtain a perfect black by mixing different blue, red, and yellow powders; but he procured very dark colours, ſuch as brown-blacks and grey-blacks.

Black, *bone*, is made of the bones of bullocks, cows, &c. well burnt and ground. To be good, it muſt be ſoft and friable, of a gloſſy caſt. It is in conſiderable uſe, though inferior in goodneſs to ivory-black.

The invention of bone, or ivory black, is attributed to Apelles. Plin. Hiſt. Nat. lib. xxxv. cap. 5.

Black *chalk*. See Chalk, and Killow.

Black, *charcoal*. See Charcoal, and Crayons.

Black, *curriers*, ſignifies a teint or dye laid on tanned leather. Tanned leather is ſo much impregnated with the aſtringent parts of oak bark, or with that matter which ſtrikes a black colour with green vitriol, that rubbing it over three or four times with a ſolution of the vitriol, or with a ſolution of iron made in vegetable acids, is ſufficient for ſtaining it black. Of this we may be convinced by dropping a little of the ſolution on the unblacked ſide of common ſhoe-leather. This operation is performed by the currier, who, after the colouring, gives a gloſs to the leather with a ſolution of gum-arabic and ſize made in vinegar. Where the previous aſtringent impregnation is inſufficient to give a due colour, and for thoſe ſorts of leather which have not been tanned, ſome galls or other aſtringents are added to the ſolution of iron; and in many caſes, particularly for the finer ſorts of leather, and for renewing the blackneſs, ivory or lamp-black is uſed. A mixture of either of theſe with linſeed oil, makes the common oil-blacking. See Currying.

Black, *dyers*, is one of the five ſimple and mother colours uſed in dying: and given differently, according to the different quality and value of the ſtuffs to be dyed. See Dying.

Green vitriol ſtrikes a black colour with vegetable aſtringents, and hence it is the baſis of the black dye for cloth, leather, hats, &c. And as ſolutions of iron with galls, &c. produce the ſame colour, a method is derived from hence of diſtinguiſhing the minuteſt portions of iron in mineral waters, &c. Neumann.

The ſubſtances chiefly employed for producing black colour with vitriol are galls. When a decoction or infuſion of the galls is dropped into a ſolution of the vitriol largely diluted with water, the firſt drops produce bluiſh or purpliſh red clouds, which mingling with the liquor tinge it uniformly of their own bluiſh or reddiſh colour. This difference of the colour, ſays Dr. Lewis (Com. Ph. Tech. p. 346.), ſeems to depend on the quality of the water. With diſtilled water, or the common ſpring waters, the mixture is always blue. A minute quantity of alkaline ſalt previouſly diſſolved in the water, or a ſmall degree of putridity in it, will render the colour of the mixture purple or reddiſh. Rain-water received from the clouds, in clean glaſs veſſels, gives a blue, but if it be collected from the tops of houſes, gives purple with the vitriol and galls. Both the blue and purple liquors, when more of the aſtringent infuſion is added, deepen to a black, more or leſs intenſe, according to the degree of dilution; and if the mixture be a deep opake black, it again becomes bluiſh or purpliſh when further diluted. If it be ſuffered to ſtand in this dilute ſtate for two or three days, the colouring matter ſettles to the bottom in form of a fine black mud, which, by ſlightly

ſhaking the veſſel, is diffuſed again through the liquor, and tinges it of its former colour. When the mixture is of a full blackneſs, this ſeparation does not happen, or in a far leſs degree; for though a part of the black matter precipitates in ſtanding, yet ſo much remains diſſolved, that the liquor continues black. This ſuſpenſion of the colouring ſubſtance in the black liquid may be attributed in part to the gummy matter of the aſtringent infuſion increaſing the conſiſtence of the watery fluid, for the ſeparation is retarded in the diluted mixture by a ſmall addition of gum arabic. If the mixture, either in its black or diluted ſtate, be poured into a filter, the liquor paſſes through coloured, only a part of the black matter remaining on the paper. The filtered liquor, on ſtanding for ſome time, becomes turbid, and full of fine black flakes; but being freed from theſe by a ſecond filtration, it again contracts the ſame appearance, and thus repeatedly, till all the colouring parts are ſeparated, and the liquor has become colourleſs. The colouring matter, thus ſeparated from the liquor, being drained on a filter and dried, appeared of a deep black, which did not ſeem to have ſuffered any change on being expoſed to the air for upwards of four months. When it was made red hot, it glowed and burnt, though without flaming, and became a ruſty brown powder, which was readily attracted by a magnetic bar; though in its black ſtate, the magnet had no action upon it. The vitriolic acid, diluted with water, and digeſted on the black powder, diſſolved the greateſt part of it, leaving only a very little quantity of whitiſh matter. Solution of pure fixt alkaline ſalt diſſolved very little of it; the liquor received a reddiſh brown colour, and the powder became blackiſh brown. This reſiduum was attracted by the magnet after being made red-hot, though not before; the alkaline tincture, paſſed through a filter, and mixed with ſolution of gum vitriol, ſtruck a deep browniſh-black colour, nearly the ſame with that which reſults from mixing with the vitriolic ſolution an alkaline tincture of galls. For an account of the reſult of theſe experiments, ſee Lewis, *ubi ſupra*. See alſo IRON.

For broad-cloths, fine ratines, and druggets, &c. the dyers uſe woad and indigo; the goodneſs of the colour conſiſts in there not being above ſix pounds of indigo to a ball of woad, when the latter begins to caſt its blue flower; and, in its not being heated for uſe above twice. Thus blued, the ſtuff is boiled with alum, or tartar, then maddered; and, laſtly, the black given with galls, copperas, and ſumac. To bind it, and prevent its ſmearing in uſe, the ſtuffs are to be well ſcoured in the fulling mill, when white, and well waſhed afterwards.

For ſtuffs of leſs value, it is ſufficient they be well blued with woad, and blacked with galls and copperas: but no ſtuff can be regularly dyed from white into black, without paſſing through the intermediate blue.

Yet there is a colour called *coal black*, or *Jeſuit's black*, prepared of the ſame ingredients as the former, and ſufficient of itſelf without the blue dye. Here the drugs are diſſolved in water that had boiled four hours, and ſtood to cool till the hand would bear it; then the ſtuff is dipped in it, and again taken out ſix or eight times. Some even prefer this black to the other. This method of dying black is ſaid to have been invented by the Jeſuits, and to have been practiſed in their houſes, where they retained numbers of dyers.

By 23 El. c. 9. nothing of the nature of cloth ſhall be maddered for a black, except it be firſt grounded with woad only, or with woad and anele [blue ind.], unleſs the madder be put in with ſumac or galls; on pain of forfeiting the value of the thing dyed: provided it ſhall be lawful to dye any manner of gall-black, and ſumac-black [*plain black*], wherein no madder ſhall be uſed.

Logwood ſtrikes a black with chalybeate ſolutions and is employed with thoſe liquors for ſtaining wood black, as picture frames, &c. With the addition of galls, it is uſed for dying cloth and hats black. (Neumann's Works, p. 385.) This black colour is not permanent, though beautiful, any more than the natural violet dye of the *logwood*.

Black may be alſo obtained by a ſolution of ſilver in aqua fortis, when the previous matter ſtained with this liquor is expoſed for ſome time to the ſun and air; and alſo from ſolutions of lead in acids, when the ſubjects to which they are applied are expoſed to ſulphureous vapours, or waſhed over with alkaline ſolutions of ſulphur. Calces of lead, melted with ſulphur, form a bluiſh or blackiſh maſs, uſeful in taking caſts from medals. (See CASTS.) Beſides, when a ſolution of ſilver in aqua fortis is added to a ſolution of ſulphur made in alkaline ley, the ſilver and ſulphur unite and precipitate together in the form of a black powder. See DYING, and STAINING.

BLACK, *earth*, is a kind of coal found in the ground, which, well pounded, is uſed by painters in freſco. See *Pit*-COAL, and FRESCO.

There is alſo a kind of black made of ſilver and lead, uſed to fill up the ſtrokes and cavities of things engraved.

BLACK, *German*, or *Frankfort*, is made of the lees of wine burnt, then waſhed in water, and ground in mills for that purpoſe, together with ivory or peach ſtones burnt. Some ſuppoſe, that it is the coal of vine-twigs; but this, ſays Dr. Lewis (Com. Phil. Techn. p. 377.), does not appear to differ, in any great degree, from that of the ſmall branches of other kinds of trees; but the kernels of fruits yield a coal conſiderably more ſoft and mellow, eaſily crumbling between the fingers into a fine meal. That the Frankfort black is no other than a vegetable coal, appeared, from its burning on a red-hot iron, like charcoal powder, into white aſhes, and from the aſhes, like common vegetable aſhes, being plentifully diſſoluble by the vitriolic acid into a bitteriſh liquor, while the aſhes of animal ſubſtances are very ſparingly affected by that acid, and form with it a compound of a different kind of taſte.

This black makes the principal ingredient in the rolling-preſs printers' ink, which ſee. It is ordinarily brought from Frankfort, Mentz, or Straſbourg, either in lumps or powder. That made in France is more valued than that of Germany.

BLACK *glaſs*. See GLASS.

BLACK, *harts*, that which remains in the retort after extracting the ſpirit, ſalt, and oil of hartſhorn. This reſidue being ground up with water, makes a black not much inferior to that of ivory.

BLACK, *Indian*. See *Indian* INK.

BLACK, *ivory*, is made of ivory burnt or charred, ordinarily between two crucibles well luted; which, being thus rendered perfectly black, and in ſcales, is ground in water, and made into troches, or little cakes, uſed by the painters; as alſo by the jewellers to blacken the bottom or ground of the collets, wherein they ſet diamonds to give them their teint or foil. Some recommend ſoaking the chips or ſhavings of ivory in hot linſeed oil, before it is charred.

There are particular machines and contrivances for burning the ivory for theſe purpoſes, by which the colour is rendered more beautiful than that of the coal which remains in the diſtillation. Neumann.

The goodneſs of ivory black, which is the fineſt of all the charcoal blacks, may be perceived by its fulneſs, without a blue caſt; and by the fineneſs of the powder.

In

In the manufacture of this black much impoſition is practiſed, ſo that what is generally ſold under this name is no other than the coal of common bones. Being applied to coarſe purpoſes, and ſold at a low price, it is very groſsly levigated by the hand or horſe-mills which are employed in grinding the bones, and ſo much adulterated with charcoal duſt, which gives it a blue caſt, that it is wholly exploded from delicate uſes, and lamp-black, though inferior with regard to the purity and clearneſs of the black colour, ſubſtituted for it.

The following recipe is given in the Handmaid to the Arts (vol. i. p. 140.) for preparing it in perfection. Take plates, chips, or ſhavings of ivory, and ſoak them in hot linſeed oil; or, if filings are more eaſily procured, they may be uſed moiſtened with the hot oil. Put them into a veſſel, which will bear the fire, covering them with a ſort of lid made of clay and ſand; which ſhould be dried, and the cracks repaired before the veſſel be put into the fire. Let this veſſel be placed in a tobacco-pipe maker's or potter's furnace, or any other ſuch fire; and let it remain there during one of their heats. When it is taken out, the ivory will be properly burnt; and muſt be afterwards thoroughly well levigated on the ſtone with water, or to have it perfectly good, be alſo waſhed over. The ivory may be conveniently burnt in a calcining or ſubliming furnace.

An opake deep black for water colours is made by grinding ivory-black with gum-water, or with the liquor which ſettles from the whites of eggs after they have been ſuffered to ſtand a little. Some uſe gum water and the whites of eggs together, and they ſay, that a ſmall addition of the latter makes the mixture flow more freely from the pencil, and improves its gloſſineſs. It may be obſerved, however, that though ivory-black makes the deepeſt colour in water, as well as in oil-painting, yet it is not on this account always to be preferred to other black pigments. A deep jet-black colour is ſeldom wanted in painting; and in the lighter ſhades, whether obtained by diluting the black with white bodies, or by applying it thin on a white ground, the particular beauty of the ivory-black is in a great meaſure loſt.

Black, *lamp*, or *lam* Black, originally perhaps the ſoot collected from lamps, is generally prepared by melting and purifying reſin or pitch in iron veſſels; then ſetting fire to it under a chimney, or other place made for the purpoſe, lined a-top with ſheep-ſkins, or thick linen cloth, to receive the vapour or ſmoke, which is the black: in which manner they prepare vaſt quantities of it at Paris. In England conſiderable quantities are prepared, particularly at the turpentine-houſes, from the dregs and refuſe parts of the reſinous matters which are there manufactured; but the greateſt part is brought from Germany, Sweden, and Norway. Its preparation is deſcribed in the Swediſh Tranſactions for 1754, as a proceſs dependent on the manufacture of common reſin. The impure reſinous juice, collected from inciſions made in pines and fir-trees, is boiled down, with a little water, and ſtrained, whilſt hot, through a bag: the dregs and pieces of bark, left in the ſtrainer, are burnt in a low oven, from which the ſmoke is conveyed, through a long paſſage, into a ſquare chamber, having an opening in the top, in which is faſtened a large ſack, made of ſleaty or thin-woven woolly ſtuff; the ſoot, or lamp-black, concretes partly in the chamber, from which it is ſwept out once in two or three days, and partly in the ſack, which is now and then gently ſtruck upon, both for ſhaking down the ſoot, and for clearing the interſtices between the threads, ſo as to procure a ſufficient draught of air through it. The more curious artiſts prepare lamp-black for the nicer purpoſes, by hanging a large copper pan over the flame of a lamp with a long wick, ſupplied with more oil than can be perfectly conſumed, ſo as to receive its ſmoke. Soot collected in like manner from fir and other woods, by burning ſmall pieces of them ſlowly under a copper pan, is of a deeper black colour than ſuch as is obtained from the ſame kinds of wood in a common chimney, and little inferior to that of oils. The ſoot of mineral bitumens, in this cloſe way of burning, appears to be of the ſame qualities with thoſe of woods, oils, and reſins. In ſome parts of Germany, it is ſaid, great quantities of good lamp-black are prepared from a ſort of pit-coal.

The goodneſs of lamp-black lies in the fulneſs of the colour, and in its being free from duſt or other impurities. The lightneſs of the ſubſtance furniſhes the means of diſcovering any adulteration, if to a great degree; as the bodies with which lamp-black is ſubject to be ſophiſticated, are all heavier in a conſiderable proportion.

This ſubſtance is uſed on various occaſions, particularly in the printers' ink; for which it is mixed with oils of turpentine and linſeed, all boiled together.

It muſt be obſerved, that this black takes fire very readily, and when on fire is very difficultly extinguiſhed: the beſt method of putting it out is with wet linen, hay, or ſtraw; for water alone will not do it.

A glaſs tube cloſely filled with lamp-black has been found to conduct a conſiderable charge of electricity inſtantaneouſly, and with ſcarce any exploſion. But a coating of this ſubſtance, mixed with tar or oil, is a perfect non-conductor, and has proved a preſervative from lightning, by repelling the electric matter from thoſe parts of the maſts of ſhips which have been covered with it.

Ruſſian lamp-black is prepared from the ſoot of fir, and is collected at Ochta near St. Peterſburg, Moſcow, Archangel, and other places, in little wooden huts, from reſinous fir wood, and the unctuous bark of birch, by means of an apparatus uncommonly ſimple, conſiſting of pots without bottoms, ſet one upon another, and is ſold very cheap. It is three or four times more heavy, thick, and unctuous, than that kind of painter's black which the Germans call "kienrahm," and which is called in Ruſſia "Holland's black." For an account of the ſpontaneous accenſion of Ruſſian fir-black, impregnated with hemp-oil, ſee *Spontaneous* Inflammation.

A *mineral lamp-black* may be procured from pit-coal, or any kind of mineral or foſſil coal, by preſerving the blackeſt particles of the ſmoke ariſing from it in ignition. Mr. Wm. Row of Newcaſtle-upon-Tyne obtained a patent in 1798 for his method of manufacturing this kind of lamp-black. See the ſpecification in the Repertory of the Arts, &c. vol. x. p. 81.

Black *paint*. See Paint.

Black *ſand*. See Sand.

Black *ſealing wax*. See Wax.

Black, *ſoot*, or *chimney*, is a poor colour; but ready for painting black draperies in oil. The ſoot blacks are in general much ſofter and of a more yielding texture than thoſe of the charcoal kind, and require much leſs grinding, for uniting them with oily, watery, or ſpirituous liquors, into a ſmooth maſs; of ſome of them a part is diſſolved by water, or ſpirits of wine, while none of the charcoal blacks have been found to contain any thing diſſoluble. This ſoluble matter of ſoots, however, is not black like the indiſſoluble parts; and in this particular, as well as in the colour of the entire maſs, different ſorts of ſoot differ from one another. Thus the ſoot of pit-coal collected in common chimneys, of itſelf rather greyiſh black than of a full black,

being

being infuſed ſeparately in rectified ſpirit of wine and in water, tinged the former of a tranſparent reddiſh colour, and the latter of a paler reddiſh; while the deeper black ſoot of wood gave, both to ſpirit and to water, an opake dark brown. See Soot.

Black, *Spaniſh*, ſo called becauſe firſt invented by the Spaniards, and moſt of it bought from them, is no other than burnt cork uſed in various works, particularly among painters.

Black *ſtains*. See Staining.

Black *varniſh*. See Varnish.

Black *vegetable juice*. See Anacardium.

Black *Act*, *Waltham*, in *Law*, a name commonly diſtinguiſhing the ſtatute of 9 Geo. I. c. 22. becauſe it was occaſioned by the devaſtations committed near Waltham in Eſſex, by perſons in diſguiſe, or with their faces *blacked*. By this ſtatute it is enacted, that perſons hunting, armed and diſguiſed, and killing or ſtealing deer, or robbing warrens, or ſtealing fiſh out of any river, &c. or any perſons unlawfully hunting in his majeſty's foreſts, &c. or breaking down the head of any fiſh-pond, or killing, &c. of cattle, or cutting down trees, or ſetting fire to houſe, barn, or wood, or ſhooting at any perſon, or ſending letters, either anonymous, or ſigned with a fictitious name, demanding money, &c. or reſcuing ſuch offenders, are guilty of felony, without benefit of clergy. This act is made perpetual by 31 Geo. II. c. 42. See farther 6 Geo. II. c. 37. and 27 Geo. II. c. 15. Blackſtone's Comm. vol. iv. p. 144. 208. 232. 244. The milder puniſhment inflicted by ſtat. 16 Geo. III. c. 30. againſt deer-ſtealers, has been thought a virtual repeal of the puniſhment of the black act above-recited. Leach's Hawk. P. C. i. c. 49. § 7.

Black *bay*, in *Geography*, a bay on the ſouth-eaſt coaſt of Labrador. N. lat. 51° 30′. W. long. 56° 20′.

Black *bear*, in *Zoology*. See Ursus Arctos.

Black-*bellied darter*, and Black-*bellied anhinga* of Latham, in *Ornithology*, the Indian Zoology, &c. This is *Plotus melanogaſter* of Gmelin.

Black-*bellied groſbeak* of Brown's Illuſtrations, is *Loxia afra* of Gmelin.

Black-*bellied green humming-bird* of Edwards; Black-*bellied American humming-bird* of Bancroft; and Black-*bellied humming-bird* of Latham, are all the ſame bird; namely, *Trochilus holoſericeus* of Linn. and Gmel.

Black-*berry*, in *Botany*. See Rubus.

Black-*billed auk* of moſt Engliſh writers, in *Ornithology*, is *Alca pica* of Linn. Syſt. Nat. and Fabricius.

Black-*billed tropic bird*, ſo named in Latham's ſynopſis, is *Phaëton melanorhynchos* of Gmelin.

Black-*billed whiſtling duck* of Sloane, and Brown's Jamaica, is called *Anas arborea* by Gmelin.

Black-*bird*. The proper acceptation of this word among the Engliſh writers of the preſent time, is very clearly underſtood; the *Turdus merula* of Linnæus and other naturaliſts being alone implied. The earlier ornithologiſts of this country are much leſs preciſe in the application of this word: with them, birds of the ſame natural order were ſometimes called black-birds, becauſe they bear a remote reſemblance to the common ſpecies moſt familiarly known by that name, as we find, for inſtance, in the two kinds of turdus, torquatus and roſeus, both of which are called, in a general manner, black-birds, white-ringed black-birds, roſe-coloured black-birds, and the like. Thus far indeed there exiſted a ſtriking natural affinity between the ſpecies, becauſe they all belong to the ſame natural order, and were, in reality, of the family they called merula, which ſeems to have been conſidered in certain inſtances ſynonymous with black-bird. But all the early writers did not confine themſelves to ſuch minute diſtinctions as the generic character afforded: the *black-bird* (razor-billed) of Cateſby, being, for example, of a very diſſimilar genus to that of our common black-bird; namely, the *crotophaga* of modern writers. Again, the *black-bird* (red-breaſted Indian) of Willughby, is one of the *oriolus*; the *black bird* (red-breaſted) of Edwards, belongs to the *tanagra*; and the *black-bird*, or *Chineſe ſtarling* of the ſame author, is a *gracula*. Birds of the ſparrow, titmouſe, and other kinds, altogether remote from the former, were alſo called occaſionally black-birds. We may, therefore, eaſily perceive that the word black-bird was an indefinite term, applied, for the moſt part, to thoſe birds whoſe plumage is of a black colour, without regard to the natural order to which they ought to have been referred, although ſometimes employed to expreſs only that which we ſtill diſtinguiſh by the name of black-bird. See Turdus Merula.

Black-*book* of the *Exchequer*, *Eagle*, *Hellebore*, *Money*, *Order*, *Star*. See the ſeveral articles.

Black-*books*, a name given to thoſe which treat of necromancy, or, as ſome call it, nigromancy.

The black-book of the Engliſh monaſteries, was a detail of the ſcandalous enormities practiſed in religious houſes, compiled by order of the viſitors under king Henry VIII. to blacken them, and thus haſten their diſſolution.

Black-*breaſted grebe* of Latham, in *Ornithology*, is *Colymbus thomenſis* of Gmelin.

Black-*breaſted groſbeak* of Latham, is *Loxia Americana* of Gmelin.

Black-*breaſted humming-bird* of Latham, is ſpoken of by Buffon under the name of *Hauſſe col vert*; Gmelin calls it *Trochilus gramineus*.

Black-*breaſted Indian plover* of Edwards, is a variety of Charadrius Spinosus of Gmelin. The female of this bird is called by Edwards the *ſpur-winged plover*, a name retained by Latham for both ſexes. In Ruſſel's Aleppo it is called the *lapwing*.

Black-*breaſted thruſh*. Latham deſcribes *Turdus cinnamomeus* of Gmelin, under this name in the ſynopſis of birds.

Black-*breaſted titmouſe* of Latham, is *Parus aſer* of Gmelin.

Black-*breaſted wood-pecker* of Latham, is *Picus multicolor* of Gmelin.

Black-*bulfinch* of Albin, like *Pyrrhula nigra* of Briſſon, and *Bouvreuil noir* of Buffon, is nothing more than an accidental variety of the common bulfinch, or *Loxia pyrrhula* of Latin writers. The bulfinch occurs ſometimes of a white colour, as well as black or duſky.

Black-*bulfinch*, (*Little*) of Cateſby and Albin, and Black *groſbeak* of Latham, is *Loxia nigra* of Gmelin.

Black-*canker*, in *Agriculture*, a diſeaſe in turnip and other crops, produced by a ſpecies of caterpillar deſtroying their leaves.

It is obſerved by Mr. Young, in the ſecond volume of the Annals of Agriculture, that "theſe inſects were effectually deſtroyed by Mr. Coke, at Holkham, in Norfolk, by turning a number of ducks among the turnips when injured by inſects. On the 16th of July, ſays he, they were turned into thirty-three acres, having water at one corner of the field, and, in five days, they cleared the whole moſt completely, marching at laſt through the field on the hunt, eyeing the leaves on both ſides with great care to devour

every one they could ſee, and filling their crops ſeveral times in the day. The ducks, after having ſaved about ſixty pounds' worth of turnips, were ſent to the poultry yard." With this view, it has been ſuggeſted by Mr. Middleton in his "Survey of the County of Middleſex," that this ſort of poultry may often be kept with advantage by the farmer.

Black-*canons*, in *Eccleſiaſtical Hiſtory*, a name given to the regular canons of St. Auguſtine, who wore a black mantle over their ſurplice, by way of diſtinction from the *Præmonſtratenſes*.

Black-*cap* of the Engliſh, in *Ornithology*, the *Motacilla atricapilla* of Linnæus. The ſame name is given likewiſe to the *marſh titmouſe*, *Parus paluſtris* of Linn. and the *black-headed gull*, *Larus atricilla* of Gmelin.

Black-*cap* of Ceylon, or *Ceylon black-cap*, the name of *Motacilla zeylonica* of Gmelin, in Brown's Illuſtration of Nat. Hiſt.

Black-*capped humming-bird* of Latham, and *Long-tailed black-cap humming-bird* of Edwards and Bancroft, are *Trochilus polytmus* of Gmelin.

Black-*capped kings-fiſher* of Latham, is *Alcedo atracapilla* of Linn.

Black-*capped lory*, the Engliſh name given by Latham to the *Gmelinian pſittacus lory*. This is the firſt black-cap lory of Edwards.

Black-*capped manakin* of Edwards and Latham, is *Pipra manacus* of Gmelin.

Black-*cape*, in *Geography*, lies on the eaſt coaſt of Newfoundland, S. E. from cape St. Francis.

Black-*cattle*, in *Agriculture*, a ſmall, hardy breed of cattle, moſtly of a black colour, occupying the high or more mountainous diſtricts in the northern parts of the iſland. They are covered with a long cloſe coat of hair, of much the ſame kind as the polled and long-horned breeds. They feed readily in the rich paſtures in the ſouthern parts of the kingdom, where large quantities of them are annually driven and fed for ſale in the London and other markets. Their beef is generally of a fine grain, well marbled, and of a good flavour; but ſometimes not ſo fine and bright in its external appearance as that of other ſorts of cattle, being occaſionally, except when made very fat, ſpotted with black, even upon the choiceſt parts. From their property of becoming quickly fat, and not being of great weight, they ſeem well adapted to the low, rich, grazing diſtricts in the ſouthern counties, where the lands are liable to be poached and injured by the heavier breeds of cattle. They ſeldom weigh more than from twenty to thirty ſtone each, though ſome particular ones have become conſiderably heavier. See Cattle and Live-Stock.

Black-*cheeked eagle*, of Latham's Synopſis, in *Ornithology*, is *Falco Americanus* of Gmelin.

Black-*cheeked thruſh* of Latham, is *Turdus nigerrimus* of Gmelin.

Black-*chin grebe* of Pennant, &c. *Colymbus lebridicus* of Gmelin.

Black-*cock*, of Pennant, Latham, Donovan, &c. is *Tetrao tetrix* of Linnæus. The ſame bird is alſo well known by the name of *black-game*, or *black-grous*.

Black-*cockatoo* of Latham, and *Great black cockatoo* of Edwards, is called by Buffon *Kakatoës noir*, and by Gmelin *Pſittacus aterrimus*.

Black-*collared finch* of Latham, is *Fringilla Abyſſinica* of Gmelin.

Black-*crowned bunting* of Latham, is *Emberiza atricapilla* of Gmelin.

Black-*crowned manakin* of Latham, is *Pipra atricapilla* of Gmelin.

Black-*crowned oriole*, the Engliſh name of *Oriolus Mexicanus* of Linn. in Latham's "Synopſis of Birds."

Black-*crowned plover* of Arct. Zool. is *Charadrius atricapillus* of Gmelin.

Black-*crowned ſhrike* of South America, is *Lanius Americanus* of Gmelin.

Black-*crowned tanager* of Latham, is *Tanagra melanictera* of Gmelin.

Black-*Indian cuckow* of Edwards, is *Cuculus niger* of Linn.

Black-*diver*, or *ſcoter*, of Engliſh ornithologiſts, is *Anas nigra* of Linn. Fn. Suec.

Black *dolphin*, in *Agriculture*, a ſmall inſect which is frequently very deſtructive to bean, turnip, and ſome other crops. Where beans are attacked with theſe inſects, the beſt remedy probably is, as ſoon as they are firſt perceived, to cut off the tops by means of a ſcythe, as they are found to make their firſt lodgments principally in thoſe parts of the plants. See Fly and Turnips.

Black-*duck* of Latham and other writers, in *Ornithology*, is called by Edwards the *great black duck* from Hudſon's bay. This is a very diſtinct ſpecies from the *black duck* of Ray and Willughby, and *velvet duck* of modern naturaliſts. Gmelin calls it *Anas perſpicillata*.

Black-*duck*, or *Great black duck* of Ray and Willughby, is the *velvet duck* of later Engliſh authors, and *Anas fuſca* of the Linnæan Fauna Suecica.

Black-*eagle*, in *Heraldry*, an order of knighthood, inſtituted in Pruſſia, by Frederic I. 14th Jan. 1701. The enſign of the order is a gold croſs of eight points, enamelled blue; in the centre whereof are the letters F. R. in cypher, and in the four angles the eagle of Pruſſia, enamelled black. On collar days, it is worn pendant to a rich collar of gold, compoſed of round pieces of gold, each enamelled with four cyphers of the letters F. R.; in the centre of the piece is ſet a large diamond, and over each cypher a regal crown, all richly chaſed, intermixed with eagles diſplayed, enamelled black alternately, and holding in their claws thunderbolts of gold.

The croſs of the order is worn, on ordinary days, pendant to a broad, orange-coloured ribbon, acroſs the left ſhoulder. The knights have embroidered on the left breaſt of their coats a ſtar of ſilver, like that of the enſign of the order, in the centre of which is an eagle diſplayed black, holding in his dexter claw, a chaplet of laurel, and in the other a thunderbolt, with the motto *Suum cuique* round it. See Plate of *Heraldry*.

Black-*eagle* of Willughby, in *Ornithology*, is *l'Aigle commune* of Buffon, and *Falco melanaëtos* of Gmelin.

Black-*ears*, or *Black-eared lynx*, in *Zoology*, called alſo the *Perſian lynx*, and *Black-eared cat*, is the *Sigah guſh* or *Siyah guſh* of Charleton, and *Caracal* of Buffon. Gmelin mentions this animal under the name of *Felis caracal*. See Caracal, and Sigah Gush.

Black-*earth*, in *Agriculture*, that kind of earth or mould which contains a large portion of carbonaceous or vegetable matter in its compoſition. Soils of this ſort are capable of producing moſt ſorts of grain and other vegetable crops in abundance. See Soil, &c.

Black-*eunuchs*, in the *Cuſtom of Eaſtern Nations*, are Ethiopians caſtrated, to whom their princes commonly commit the care of their women. See Eunuch.

Black-*eye*, in *Botany*, a name given to the germ in beans, which the Romans called hilum. See Germ.

Black-*eye*, *hypoſphagma*, in *Medicine*, a ſuffuſion of blood on the *tunica adnata*, turning livid, occaſioned by a blow. See Ecchymosis.

Black-*faced bunting* of Latham, in *Ornithology*, is *Emberiza quelea* of Gmelin.

Black-*faced finch* of the Arctic Zoology, is *Fringilla criſtata* of Gmelin.

Black-*faced ibis* of Latham, is *Tantalus melanopis* of Gmelin.

Black-*fiſh*, in *Ichthyology*, the name under which *Silurus anguillaris* is deſcribed in Ruſſel's "Hiſt. of Aleppo." This fiſh has a ſingle dorſal fin containing ſeventy rays, and eight beards at the mouth, namely, two on the upper lip, four on the lower one, and two on each ſide of the mouth. There is likewiſe a kind of perch mentioned by Borlaſe as being found in the rivers of Cornwall, which he calls the black fiſh. Pennant ſpeaks of it on the authority of that writer; and Gmelin, after him, gives it as a ſpecies with ſome doubt. This ſpecies meant by Borlaſe is certainly ambiguous. See Perca Nigra.

Black-*fly*, in *Agriculture*, an inſect of the beetle tribe, that often commits great devaſtation among turnip and other crops, deſtroying the young plants, by feeding upon their ſeed-leaves the moment they are protruded and appear above ground. Different remedies have been propoſed for the prevention of the deſtructive ravages of this inſect on turnips, but few of them have been attended with much ſucceſs. The beſt method is probably that of ſowing the ſeed at ſuch a ſeaſon, and under ſuch circumſtances, as that its early vegetation may be quick and uninterrupted, and thereby allow little time for the inſects to feed upon the plants, before they become in broad leaf, and capable of reſiſting its injurious attacks. See Fly and Turnips.

Black-*fly-catcher* of Latham, in *Ornithology*, is *Muſcicapa luzonienſis* of Gmelin.

Black-*foreſt*, *mountains of*, in *Geography*, called in German Schwartzwald, extend from near Neuenburg, in the territories of Wurtemburg, ſouth to the four foreſt towns on the Rhine. The ſouthern part is called the high, and the northern the lower foreſt; the length being about 80 Britiſh miles. To the eaſt the Necker may be conſidered as a boundary, and the breadth may be computed at about 20 Britiſh miles. The eaſtern part preſents a gradual elevation, while the weſtern exhibits precipitous ſummits to the inhabitants of Baden and Alſace. The appellation ſeems to be derived from the thick dark foreſts with which the aſcents are clothed. Beſides paſturage, the inhabitants, partly ſubject to Auſtria, and partly to Wurtemburg, derive advantage from the reſin of the pines, and the timber, of which they make all kinds of utenſils. Some parts are cultivated by ſpreading branches of pine, covered with ſod, which, being burnt, affords an excellent manure, that prepares the ground for four abundant harveſts. A branch of the black mountains ſpreads eaſt from near Sulz, on the Necker, towards the county of Octingen, being more than 60 miles in length. This chain is called the Alb, and ſometimes the Suabian Alps. Buſching traces this ridge from the north-eaſt, the ſource of the Brenz, to the weſt of the Nereſheim, by Wiſenſteig, where the mountains are higheſt. Thence they turn north-weſt to Guttenberg, and weſt to Neiſſen, whence they paſs by Hohenzollern to the Necker, then bend ſouth and weſt between that river and the Danube. Buſching adds, that as this chain riſes inſenſibly at Konigſbrown north-eaſt, ſo it gradually terminates at Ebingen ſouth-weſt. The principal ſummits are in the north and weſt of the ridge; and the foreſts are chiefly beech; while the open ſpaces ſupply paſturage for numerous flocks of ſheep. Of theſe two extenſive ridges of mountains, the Black foreſt, and the Alb, a conſiderable portion pervades the duchy of Wurtemburg; and near Stutgard, the capital, are the mountains of Boyferſteig, Weinſteig, and Haſenſteig. The conſtituent parts of theſe extenſive ridges have been little detailed; but a great part is calcareous, as they ſupply excellent marbles. Near Frudenſtadt, in the black mountains, are mines of ſilver and copper.

Black-*footed pinguin*, or *penguin*, *leſſer pinguin*, *cape pinguin*, *&c.* in *Ornithology*, are different Engliſh names of an individual ſpecies of Aptenodyta in the works of Edwards, Latham, &c. Gmelin names this bird ſpecifically *demerſa*.

Black-*fox*, in *Zoology*. See Canis Lycaon.

Black-*fronted fly-catcher* of Latham, in *Ornithology*, is *Muſcicapa nigrifrons* of Gmelin.

Black-*fryers*, in *Eccleſiaſtical Hiſtory*, a name given to the Dominican order, called alſo *Predicants* and *Preaching fryers*; in France, *Jacobins*.

Black-*game*, in *Ornithology*. See Black-*Cock*.

Black-*graſs*, in *Agriculture*, a ſpecies of American graſs, growing in meadows which border on tide-rivers, well ſupplied alſo with freſh water; for a mixture both of freſh and ſalt water ſeems to be neceſſary for its prolific vegetation. Its ſeeds are ſmall, like thoſe of tobacco; its colour a deep green; and it affords from three to four tons of hay by the acre. This kind of graſs thrives beſt on a clay or ſtrong loam; nor is the vicinity of ſalt water abſolutely neceſſary. The ſeeds have been lately brought over into England, and diſtributed for trial in proper ſoils.

Black-*groſbeak* of Edwards, in *Ornithology*, and the *Angola groſbeak* of Latham are the ſame; *Loxia angolenſis* of Gmelin.—*Obſ.* The *black groſbeak* of Latham is another bird; *Loxia nigra* of Gmelin.

Black-*guillemot* of Pennant and other Engliſh writers of the preſent times, is the *Greenland dove* or *ſea-turtle* of Albin, Ray, Willughby, and *Colymbus grylle* of Linnæus.

Black-*headed bunting* of Latham, is *Emberiza melanocephala* of Scopoli.

Black-*headed creeper* of Latham, and the *Green black-cap fly-catcher* of Bancroft, are of the ſame ſpecies, the latter being only a variety of the firſt. Linnæus calls this kind *Motacilla ſpiza*.

Black-*headed duck* of Shaw's travels, has been ſince named the *Damiatta duck* by Latham, and *Anas Damiatica* by Gmelin in the Linn. Syſt. Nat.—The variety of *Anas boſchas*, or *wild duck*, called *nigra*, from having the head and collar black, might be alſo called the *black-headed duck*.

Black-*headed finch* of Latham, is *Fringilla melanocephala* of Gmelin.

Black-*headed fly-catcher*, of Arctic Zoology; and *black-cap fly-catcher* of Cateſby, is the *muſcicapa fuſca* of Gmelin.

Black-*headed groſbeak* of Latham, is *loxia erythromelas* of Gmelin.

Black-*headed gull*, the Engliſh name of *larus rubicundus*. The ſame bird is alſo called the *pewit black-cap*, or *ſea crow*, by Ray and Willughby.

Black-*headed Indian icterus* of Albin and Edwards, is *ſturnus luteolus* of the tenth edition of the Linn. Syſt. Nat. and *oriolus melanocephalus* of Gmelin.

Black-*headed nut-hatch*, a variety of the common nut-hatch found in Carolina and Jamaica. Buffon and Arct. Zool. *Sitta Europæa* of Gmelin.

Black-*headed plover* of Latham, is *charadrius melanocephalus* of Gmelin.

Black-*headed ſhrike*, a ſpecies of *lanius*, ſo called by Latham: it is the *lanius melanocephalus* of Gmelin.

Black and *ſpotted heath-cock* of Edwards, and *ſpotted grous* of Pennant and Latham, are *tetrao canadenſis* of Gmelin.—*Obſ.* There is another black and ſpotted heath-cock figured alſo by Edwards pl. 71. which, in the 12th edition of the Linnæan Syſt. Nat. is called *tetrao canace*.

Black *heron* of Latham, is the *ardea atra* of Gmelin.

Black-*hooded wheat-ear* of Latham, is *motacilla pileata* of Gmelin.

Black-*humming-bird*, the Linnæan; *trochilus niger* is ſo named in the Synopſis of Latham.

Black *jacana*; the *jacana armata nigra* of Briſſon, and *parra nigra* of Gmelin, bears this name in Latham's Synopſis.

Black *jack*, or *Blend*, is a mineral, called alſo falſe galena and blinde, &c.

Black-*jawed warbler* of Latham, in *Ornithology*, is *motacilla nigriroſtris* of Gmelin.

Black *iſland*, in *Geography*, an iſland near the coaſt of America, belonging to the ſtate of Rhode iſland. N. lat. 41° 7′. W. long. 71° 35′.

Black *iſlands*, iſlands near the caſt coaſt of Labrador. N. lat. 41° 8′. W. long. 56° 30′.

Black *kite*, or *black-gled* of Sibbald, is *falco ater* of Gmelin, and *milvus niger* of Briſſon.—*Obſ.* Gmelin mentions a black variety of falco communis under the ſpecific name of *ater*; it was previouſly deſcribed by Edwards under the name of *black hawk* or *falcon*.

Black *land*, in *Agriculture*, a name given to a ſort of ſoil which has a greyiſh black caſt. This ſort of ſoil, though pale when dry, always blackens by means of rain; and when ploughed up at ſuch times, it ſticks to the plough ſhare; and the more it is wrought, the muddier and darker-coloured it appears. Theſe ſorts of land, when ſomewhat rich, yet porous, light but ſufficiently tenacious, are good both for corn and graſs; but as they are moſtly ſituated in bottoms, the wetneſs often ſpoils them for corn; but when they are dry, they are extraordinarily fruitful, eſpecially for barley; they alſo bear good wheat crops. When they are very rich, they may, if a deep mould, be planted with liquorice, or ſown with hemp, woad, cole, or rape, madder, and other ſimilar plants, that beſt ſuit ſuch lands; and afterwards with corn, when ſome of their fertility is expended. They are capable of bearing excellent clover crops. The beſt manure for theſe ſoils is chalk or lime, where it can be procured.

Black *lark*, in *Ornithology*. Albin deſcribes an accidental variety of the common lark, *alauda arvenſis*, under this name, in the third volume of his Hiſtory of Birds.

Black *lead*, in *Mineralogy*, &c. See Lead and Plumbago.

Black *leather*, in the *Manufactures*, is that which has paſſed the curriers' hands, where from the ruſſet as it was left by the tanners, it is become black, by having been ſcowered and rubbed three times on the grain-ſide with copperas-water.

Black *legs*, a name given in Leiceſterſhire to a diſeaſe frequent among calves and ſheep. It is a kind of jelly, which ſettles in their legs, and often in the neck, between the ſkin and fleſh.

Black *legs*, an appellation given to thoſe gamblers and ſharpers who prey upon the ignorance and credulity of inexperienced and unſuſpecting perſons of property, with whom they contrive to aſſociate, and who ſubſiſt in diſſipation and luxury on the ſpoils acquired by deception and fraud, in a variety of games and ſports which they frequent for this purpoſe. They are juſtly denominated the peſt of civilized ſociety, and ſhould be ſhunned by thoſe who have any concern for their property or reputation, as the moſt dangerous and deſtructive enemies.

Black *lick*, in *Geography*, lies in Weſtmorland county, Pennſylvania, about 36 miles eaſt of Pittſburg.

Black *lory*, of Latham, in *Ornithology*, is *pſittacus novæ Guineæ* of Gmelin.

Black *mail*, in *Engliſh Antiquity*, a certain rate of money, corn, cattle, or other matter, anciently paid by the inhabitants of towns in Weſtmorland, Cumberland, Northumberland, and Durham, to divers perſons inhabiting on or near the borders, being men of name, and allied with others in theſe parts, known to be great robbers and ſpoil-takers; in order to be by them freed and protected from any pillage. Prohibited as felony by 43 El. c. 13.

The origin of this word is much conteſted, yet there is ground to hold the word *black* to be here a corruption of *blank* or white, and conſequently to ſignify a rent paid in a ſmall copper coin called *blanks*. This may receive ſome light from a phraſe ſtill uſed in Picardy, where, ſpeaking of a perſon who has not a ſingle halfpenny, they ſay, *il n' a pas une blanque maille*. The term is alſo uſed for rents reſerved in work, grain, or baſer money, which were called "reditus nigra," in contradiſtinction to the blanch farms, "reditus albi."

Black *martin*, or *ſwift* of the Engliſh, in *Ornithology*, is the *hirundo apus* of Latin writers.

Black *monks*, in *Eccleſiaſtical Hiſtory*, a denomination given to the Benedictins, called in Latin *nigri monachi*, or *nigromonachi*; ſometimes *ordo nigrorum*, the order of *blacks*.

Black *mountains*, in *Geography*. See Black-*Foreſt*. This is alſo a denomination given to an extenſive ridge of mountains in South-Wales, ſeparating the boundaries of the counties of Glamorgan and Brecknock; covered in ſummer with black cattle and ſheep.

Black *necked quail* of Latham, in *Ornithology*, is *tetrao nigricollis* of Gmelin.

Black-*necked ſwan* of Pernett and Latham, ſtands under the name of *anas nigricollis* in the Gmelinian edition of Syſt. Nat.

Black-*necked thruſh* of Latham, is *turdus nigricollis* of Gmelin.

Black *neſs*, in *Geography*, a foul point on the coaſt of France, and in the Engliſh channel, four leagues W. from Calais.

Black *oats*, in *Agriculture*, a ſpecies of oats, much cultivated in the northern parts of England, and eſteemed a very hearty food for horſes. See Oats.

Black *oriole*, of the Arctic Zoology, and Latham's Synopſis, in *Ornithology*, is the *icterus niger* of Briſſon, and *oriolus niger* of Linn. and Gmel.

Black *oriole* (*Leſſer*), the Engliſh name of *oriolus minor*, in Latham's Synopſis.

Black *oſtrich* of Brown's Illuſtrations, &c. is *ſtruthio camelus* of Scopoli, Gmelin, &c.

Black *parrot* of Latham, and *black parrot* of Madagaſcar, and of Edwards, are the ſame; the *pſittacus niger* of Gmelin.

Black *petrel* of Latham, and *great black petrel* of Edwards, ſtands under the name of *procellaria æquinoctialis* in Gmelin's edition of the Linn. Syſt. Nat.

Black *poll warbler* of Latham, is *motacilla ſtriata* of Gmelin.

Black *point*, and *blue point*, in *Geography*, capes of America, within thoſe of Elizabeth and Porpoiſe, in the diſtrict of Maine.

Black *point*, is alſo a point on the weſt coaſt of Africa, between cape Cavallos, and cape Palmas.—Alſo, a point

S. E. from cape Chidley, the north point of the Labrador coaſt. N. lat. about 59° 20′.—Alſo, a point on the coaſt of Spitſbergen, or Eaſt Greenland. N. lat. 78° 30′. E. long. 11° 10′. Variation 10° 42′ W.

Black *pool* lies on the coaſt of Lancaſhire, about 25 miles S. from Lancaſter. The beach is a beautiful level ſand, with an extended ſea before it. This place is frequented for ſummer bathing.

Black *proceſſion*, in *Eccleſiaſtical Writers*, that which is made in black habits, and with black enſigns and ornaments. See Procession.

Anciently at Malta, there was a *black proceſſion* every Friday, where the whole clergy walked with their faces covered with a black veil.

Black *rail* of Latham, in *Ornithology*, is the *rallus niger* of Gmelin.

Black *rat*, in *Zoology*. See Mus-Rattus, or *Common rat*.

Black *red-tail* of Latham, in *Ornithology*, is the *motacilla atrata* of Gmelin.

Black *rents*. See Black *mail*.

Black *River*, in *Geography*, an appellation applied to two ſmall rivers, in Vermont, America; one falling into Connecticut river, at Springfield, and the other running north into lake Memphremagog.—Alſo, a river in New York, which interlocks with Canada creek, and runs north-weſt into Iroquois river, navigable with boats 60 miles.—Alſo, a long river, which riſes in Virginia, and paſſes ſouth-eaſterly into Nottaway river, in North Carolina.

Black *River*, a Britiſh ſettlement at the mouth of the Tinto river, 20 leagues to the eaſt of cape Honduras, the only harbour on the coaſt of Terra Firma, from the iſland of Rattan to cape Gracias a Dios; and for more than ſixty years it was the refuge of the logwood cutters, when the Spaniards drove them from the foreſts of Eaſt Yucatan. This occaſioned adventurers of different deſcriptions to ſettle here, where the coaſt is ſandy, low, and ſwampy; but higher up, near the rivers and lagoons, which are full of fiſh, the ſoil is more fertile, and produces plantanes, cocoa-trees, maize, yams, potatoes, and a variety of vegetables; and the paſſion for drinking induced them to plant ſugar-canes. The foreſts are full of deer, ſwine, and game. The ſhores abound with turtle, and the woods with mahogany, zebra-wood, ſarſaparilla, &c.; and the whole ſettlement flouriſhes ſpontaneouſly without cultivation.

Black *River*, a river of Jamaica, which paſſes through a level country, and is the deepeſt and largeſt in the iſland, ſo as to admit flat-bottomed boats and canoes for about thirty miles.

Black *Rock*, a rock in the mouth of Sligo harbour, in Ireland, which is covered about high water only, and has a conſpicuous tower built on it that ſerves as a beacon.

Black *Rock*, a rock in the bay of Galway, in Ireland, about three miles weſtward of Galway, which dries with ſpring-tide only, and requires attention in navigating that bay. M'Kenzie.

Black *Rocks*, rocks in the Atlantic ocean, near the weſt coaſt of Ireland, about ſix miles N.W. from Saddlehead, in Achil iſle, and ſeven miles W. by S. from Blackſod point.—There are rocks called by the ſame name in Killibeg's bay and Mulroy haven, but they are leſs objects of attention to the navigator. M'Kenzie.

Black *Rock*, a rock near the ſouth coaſt of Wexford, in Ireland, about four miles W. by S. of Carnſore point, which is always above water, and may be ſailed round without danger. M'Kenzie. Boate.

Black *Rock*, a populous village, ſituate on the river Tawe, about a mile above Swanſea, in Glamorganſhire, South Wales, where are conſiderable ſmelting-houſes, and whence are exported coals, &c.

Black *Rock* lies alſo near the extreme north point of the iſland of Antigua, between Humphrey's bay and Boon point. N. lat. 17° 5′. W. long. 61° 58′.

Black-*rod*. See Gentleman-Usher *of*.

Black-*row grains*, in *Mineralogy*, a ſpecies of iron-ſtone, or ore, found in the mines about Dudley, in Staffordſhire.

Black *Sea*, in *Geography*. See Euxine *Sea*.

Black *ſheep*, in *Oriental Hiſtory*, the enſign or ſtandard of a race of Turkmans ſettled in Armenia and Meſopotamia; hence called the *dynaſty of the black ſheep*.

Black *ſhrike* of Latham, in *Ornithology*, is *lanius niger* of Gmelin.

Black *Mexican ſiſkin* of Latham, is *ſringilla catotol* of Gmelin.

Black *ſkimmer* of Latham, *cut-water* of Arct. Zool., *ſea crow* of Edwards, are all names of the ſame bird; the *Rynchops nigra* of Gmelin.

Black *ſquirrel* of Cateſby, is the *ſciurus niger* of Erxleben and Gmelin.

Black *ſtones* and *gems*, according to Dr. Woodward, owe their colour to a mixture of tin in their compoſition.

Black *ſtrakes*, a range of planks immediately above the wales in a ſhip's ſide: they are always covered with a mixture of tar and lamp-black.

Black *ſwallow* of Latham, in *Ornithology*, is the *hirundo apus dominicenſis* of Briſſon, and *hirundo nigra* of Gmelin.

Black *ſwan*. A bird of this deſcription inhabits Botany Bay. Its form reſembles that of the common white ſwan; but the prevailing colour of the plumage is black, inſtead of white; the wings are edged with white; and the bill is red. This ſpecies is deſcribed by Dr. Shaw (Nat. Miſcell.) under the name of *anas atrata*. It is the *black ſwan* of ſeveral writers who have lately treated on the hiſtory of Botany Bay.

Black *tail*, a beacon about 3 leagues diſtant from the Nore in the river Thames.

Black *Tanager* of Latham, in *Ornithology*, is the *emberiza atra* of the 10th edition of the Linn. Syſt. Nat., and *tanagra atrata* of Gmelin.

Black *tern* of modern writers, is the *ſcarecrow* of the old Engliſh ornithologiſts, and *clouen-footed gull* of Willughby. *Sterna fiſſipes* of Brünnich and Gmelin.

Black-*thorn*, in *Botany*, a ſpecies of the *prunus*, which ſee.

Black-*thorn*, in *Agriculture*, a ſpecies of thorn well known, and frequently uſed in making fences, eſpecially in expoſed ſituations. It is not, however, reckoned ſo good for fences as the white-thorn, becauſe it is apt to run more into the ground, and is not ſo certain of growing; but when cut, the buſhes are much the beſt, and moſt laſting of any, for dead hedges, or to mend gaps with. Cattle are not ſo apt to crop fences of this kind as thoſe of the white-thorn ſort. See Hedges.

Black-*throated barbet* of Latham, in *Ornithology*, is *bucco niger* of Gmelin.

Black-*throated bunting* of the Arct. Zool. is *emberiza Americana* of Gmelin.

Black-*throated diver* of Pennant and others, is the ſame bird as Edwards calls the *ſpeckled loon*, and Willughby *Wormius's northern ducker*: *Colymbus arcticus* of Linnæus.

Black-*throated green fly-catcher*, of Edwards's Gleanings, and *green warbler* of Latham; the *motacilla virens* of Gmelin.

Black-

Black-*throated tanager*, of Latham, the *tanagra nigricollis* of Gmelin.

Black-*throated manakin* of Latham, the *pipra nigricollis* of Gmelin.

Black-*throated thruſh* of Latham, is *turdus ater* of Gmelin.

Black-*throated warbler*, of the Arctic Zoology, is *motacilla Canadenſis*, of Gmelin.

Black *tiger*, in *Zoology*. See Felis Discolor.

Black-*tin*, in *Mineralogy*, a denomination given to the tinore when dreſſed, ſtamped, and waſhed ready for the blowing-houſe, or to be melted into metal. Phil. Tranſ. N° 69. p. 2110.

It is prepared into this ſtate by means of beating and waſhing; and when it has paſſed through ſeveral buddles or waſhing troughs, it is taken up in form of a black powder, like fine ſand, called *black-tin*.

Black-*toed gull* of Pennant, Latham, Walcot, &c., in *Ornithology*, is the *larus crepidatus* of Hawefworth and Gmelin.

Black-*toed petrell*. The Gmelinian *procellaria melanopus* is deſcribed under this name in Latham's Synopſis of Birds.

Black *town*, in *Geography*, a ſettlement of 1200 free negroes, erected in 1783, about a mile from the town of Shelburne, in Nova Scotia.

Black *twitch*, in *Agriculture*, a noxious weed, probably the *polygonum convolvulus*, which flouriſhes even in extremely dry ſeaſons, and is very injurious to many crops.

Black *vomit*, in *Medicine*, a diſeaſe to which the inhabitants of Spaniſh North America are ſubject, ſaid to be allied to the yellow fever of the United States, and which, at intervals, ravages the country like a peſtilence. See Fever.

Black *vulture* of Willughby and Latham, in *Ornithology*, is *vultur niger* of Ray, Briſſon, and Gmelin.

Black *vulture (creſted)* of Edwards, the *vultur monachus* of Gmelin.

Black *woodpecker (greateſt)*, Albin. Donovan. &c., the *picus martius* of Linn. Fn. Suec.

Black *wadd*. See Wadd.

Black-*winged parrakeet* of Brown's Illuſtrations, in *Ornithology*, is called by Gmelin *pſittacus melanopterus*.

Black-*winged thruſh* of Latham, is *turdus bambla* of Gmelin.

Black *and white butcher-bird*. Under this title the Linnæan *lanius collaris* is deſcribed and figured by Edwards in his Hiſtory of Birds. Latham calls it the *pied ſhrike*.

Black *and blue creeper* of Edward's Gleanings, the *certhia cyanea* of Gmelin.

Black *and violet creeper* of Latham, is *certhia Braſiliana* of Gmelin.

Black *and white creeper* of Edwards, and *ſmall black and white bird* of Ray and Sloane, are *motacilla varia* of Gmelin.

Black *and white king's fiſher* of Edwards and Latham, is the *alcedo rudis* of Gmelin.

Black *and white wagtail* of Ray, is the *pied wagtail* of Latham, *motacilla maderaſpatana* of Briſſon, and *motacilla madraſpatenſis* of Gmelin.

Black, *white, and red Indian creeper* of Edwards, is the *certhia cruentata* of Linn. and Gmel.

Black *and yellow creeper*. *Certhia flaveola* of Gmelin is deſcribed under this name both by Edwards and Latham.

Black *and yellow daw* of Braſil. Edwards under this title deſcribes a variety of *oriolus Perſicus*, Linn.

Black *and white diver (ſmall)* of Willughby and Edwards, is *alca alce* of Linnæus. This bird is likewiſe called the *Greenland dove*, or *ſea turtle*, by Albin; and is known among later writers by the name of the *little auk*. Pennant. Donov. Brit. Birds, &c.

Black *and white dobchick* of Edwards, is the *duſky grebe* of later writers: *Colymbus obſcurus* of Gmelin.

Black *and white duck (little)* of Edwards, and *ſpirit* of Arct. Zool., are *anas albeola* of Gmelin.

Black *and white Indian falcon*, the Engliſh name of *falco melanoleucus* (Gmel.) in Pennant's Indian Zoology, and Latham's Birds.

Black *and orange finch* of Latham, and *ſmall black and orange bird* of Sloane and Ray, is *fringilla melanictera* of Gmelin.

Black *and white fly-catcher* of Edwards's Gleanings, is *muſcicapa bicolor* of Gmelin.

Black *and white gull* of Ray, Willughby, and Albin, is the *black-backed gull* of modern ornithologiſts. Linnæus calls it *larus marinus*.

Black *and blue humming-bird* of Bancroft, is called by Gmelin *trochilus cyanomelas*.

Black *and yellow manakin* of Edwards, is the variety β of the Gmelinian *pipra aureola*.

Black *and orange-coloured bird (ſmall)* of Ray and Sloane, is *motacilla ruticilla* of Linnæus, and *muſcicapa ruticilla* of Gmelin. This is likewiſe the *black-headed warbler* of Latham, *ſmall American redſtart* of Edwards, and *yellow-tailed fly-catcher* of Edwards's Gleanings.

Black *and white Chineſe pheaſant* of Edwards. This is *phaſianus nycthemerus* of Scopoli and Gmelin. It is likewiſe called the *pencilled pheaſant* by Latham and other late writers.

Black *and yellow friezzled ſparrow* of Edwards's Gleanings, is the *friezzled finch* of Latham, and *fringilla criſpa* of Gmelin.

Black *and white ſtarling* of Willughby, is *ſturnus leucomelas* of Briſſon, which Gmelin gives as a variety of the common ſtare, or ſtarling, *ſturnus vulgaris* of Linnæus.

Black *and white Indian ſtarling* of Edwards. This is *ſturnus contra* of Gmelin.

Black *and blue tanager* of Latham, is the *black and blue titmouſe* of Edwards, and *tanagra Mexicana* of Gmelin.

Black *whytlof*, in our *Old Writers*, bread of a middle fineneſs betwixt white and brown, called in ſome parts *ravel-bread*.

In religious houſes, it was the bread made for ordinary gueſts, and diſtinguiſhed from their houſhold loaf, or *panis conventualis*, which was pure manchet, or white bread.

Black-*work*, iron wrought by the blackſmith; thus called by way of oppoſition to that wrought by white-ſmiths.

BLACKALL, Offspring, in *Biography*, an Engliſh prelate, was born at London, in 1654, and educated at Catherine hall, in the univerſity of Cambridge. Beſides ſeveral promotions in London, he was appointed one of the chaplains in ordinary to king William, though his principles were adverſe to the revolution government, and he refuſed for two years to take the requiſite oaths to king William and queen Mary. On the 30th of January 1699, he preached a ſermon before the houſe of commons, in which he animadverted on a paſſage in Mr. Toland's life of Milton, who, after ſtating the proofs that Dr. Gauden, afterwards biſhop of Exeter, was the true author of the book entitled "Icon Baſilike," and aſcribed to Charles I., obſerves, that many ſuppoſititious pieces, under the name of Chriſt, his apoſtles, and other great perſons, were publiſhed and approved in the primitive times. But as Mr. Toland, in his Amyntor, publiſhed in the ſame year, avowed his belief of the

the genuineneſs of the books of the New Teſtament, Mr. Blackall cloſed the diſpute by the publication of a ſmall pamphlet in 12mo. entitled "Reaſons for not replying to a book lately publiſhed, entitled Amyntor." In 1700, he preached a courſe of ſermons at Boyle's Lecture, publiſhed in the firſt volume of the collection of thoſe ſermons. In 1707, he was promoted to the ſee of Exeter; and in 1709, he was engaged in a controverſy with Hoadly, concerning the inſtitution of civil government, and the meaſures of ſubmiſſion. With reſpect to this controverſy it is ſufficient to obſerve, that the biſhop defends the high-church, tory principles, as they are uſually called, of the divine inſtitution of magiſtracy, and unlimited paſſive obedience and non-reſiſtance, which Hoadly oppoſes. This prelate, whoſe private character, and ſtyle of preaching, are highly extolled by ſir William Dawes, archbiſhop of York, in the preface to his Sermons, died at Exeter, Nov. 29th 1716. His ſermons were collected and publiſhed in 2 vols. folio, Lond. 1723. Gen. Dict. Biog. Brit.

BLACKAMOOR'S Head, in *Chemiſtry*, conſiſts of a conical veſſel, ſurrounded with another of a cylindrical form, filled with cold water, and having a cock to draw it off, when it is become too warm. Both veſſels are made of copper. In the figure, one half is left open to ſhew the cone; the inclination of the ſides of which, according to Chaptal, is moſt proper, when forming an angle of 75 degrees with the baſe. See *Plate* of *Chemiſtry*.

BLACKBALL Head, in *Geography*, a cape on the S.W. coaſt of Ireland, at the north ſide of the entrance into Bantry bay, in the county of Cork. N. lat. 51° 32′. W. long. 9° 55′. M'Kenzie and Beaufort.

BLACKBURN, William, in *Biography*, an eminent ſurveyor and architect, was born in Southwark Dec. 20 1750, and having acquired ſome knowledge of his profeſſion in the ordinary courſe of education, he was admitted a ſtudent at the Royal academy. By this academy he was preſented, in 1773, with the medal for the beſt drawing of the inſide of St. Stephen's church in Walbrook; and the delivery of it by the preſident ſir Joſhua Reynolds was accompanied by a diſtinguiſhed tribute of reſpect to his abilities. About this time he entered into buſineſs in the place of his nativity; but a circumſtance occurred in a few years, which ſerved to eſtabliſh his reputation, and to introduce him into very general notice. In 1779 an act of parliament was paſſed for the erection of places of confinement, under the denomination of "penitentiary houſes." Two edifices of this kind were propoſed to be conſtructed; one for the confinement and employment of 600 males, and the other for the accommodation of 300 females. The three ſuperviſors firſt authoriſed by his majeſty for carrying into effect the proviſions of this act, were John Howard eſq., George Whatley eſq., and Dr. John Fothergill. The death of Dr. Fothergill, and the reſignation of Mr. Howard, diſſolved this commiſſion; and the charge was devolved, in 1781, on ſir Gilbert Elliot, ſir Charles Bunbury, and Thomas Bowdler eſq. The principal object of the plan propoſed was to combine, in the buildings to be erected, ſolitary confinement, with uſeful labour and moral reformation. Accordingly premiums were announced to thoſe who ſhould produce the beſt plans. The higheſt premium of 100 guineas was unanimouſly aſſigned, in 1782, to Mr. Blackburn. In conſequence of this diſtinction, he was appointed by the ſuperviſors to the office of architect and ſurveyor of the projected buildings. The deſigns of government, after ſeveral preparatory ſteps had been taken, were never accompliſhed. However ſchemes of a ſimilar kind were projected in various parts of the country, and the execution of them was entruſted to Mr. Blackburn. Whilſt he was buſily employed in the completion of various deſigns of this kind, and whilſt he was proſecuting a journey to Scotland, for the purpoſe of erecting a new gaol at Glaſgow, he died ſuddenly, Oct. 28th 1790, at Preſton in Lancaſhire; and his remains were removed to London, and interred in the burying-ground of Bunhill-fields.

Mr. Blackburn's ſkill as a draughtſman and an architect, was not confined to priſons and penitentiary houſes; but he was occupied, as far as his time would allow, in preparing various deſigns for churches, houſes, villas, &c.; and in his drawings and deſigns he always manifeſted a correct taſte, and a thorough knowledge of the ſcience to which he was practically devoted. His friends, and the public in general, very juſtly lamented, that by the corpulence to which he was inclined from his early youth, and the increaſe of which no abſtinence, nor any mode of regimen, would reſtrain, he was removed from a ſcene of uſefulneſs and reputation, at ſo early a period as the 40th year of his age. As to his religious profeſſion, he was a proteſtant diſſenter of the preſbyterian denomination; but he combined, with an undiſguiſed and laudable avowal of his own ſentiments, the moſt liberal and candid opinion and conduct with reſpect to all who differed from him. In his natural temper he was chearful and lively; in his converſation agreeable, animated, and inſtructive; in his private character amiable and reſpectable; and in all the relations and intercourſes of domeſtic and ſocial life, eſteemed and honoured. In 1783 he married the daughter of Mr. Joſhua Hobſon, an eminent builder, of the denomination of quakers, by whom he left four children.

Blackburn, in *Geography*, a town of Lancaſhire, England, is ſeated in a valley ſurrounded with hills. It conſiſts of ſeveral ſtreets, irregularly laid out, but intermixed with good houſes. Beſides the pariſh church, here are a newly erected chapel of the eſtabliſhment, and five places of worſhip for as many different ſects of diſſenters. A free-ſchool was founded by queen Elizabeth, and the neceſſitous poor of the town are comfortably provided with a poor-houſe, which has land attached to it for the paſturage of cattle.

The market, on Mondays, is chiefly ſupplied with proviſions from Preſton. Beſides this, here are a fortnight market for cattle, &c. and an annual fair. The town is approached by four ſtone bridges croſſing the river Derwent, whoſe water, being of rather a blackiſh hue, is ſaid, by ſome writers, to have given name to the town. Blackburn has been noted for its manufactures, particularly for an article called *Blackburn-greys*, which were plains of linen-warp ſhot with cotton. The proſperity of Mancheſter, and the great influx of manufacturers to that town and its neighbourhood, have deprived Blackburn of its uſual trade; yet ſome cottons, callicoes, and muſlins are ſtill made here, and the fields around the town are frequently covered with materials to bleach.

The church of Blackburn, previous to the reformation, was attached to the abbey of Whalley. It is now a rectory, poſſeſſed by the archbiſhop of Canterbury, who alſo owns half of the town, which he lets on leaſes of 21 years. The pariſh of Blackburn includes 24 townſhips, and embraces about half the hundred of the ſame name. The land round the town is moſtly a ſandy ſoil, and conſequently unpropitious to agriculture. Coal is found in the ſouthern part of the pariſh, and in great plenty at Darwen, about 4 miles ſouth of the town. An alum mine was found, and much worked here, in the time of Fuller, but from the depth of the ſtrata, and conſequent expence, it was afterwards neglected. Sir Geo. Colebrook, wiſhing to monopoliſe all the alum

alum of the country, purchaſed this, with other mines; but failing in his unjuſt ſpeculations, was obliged to relinquiſh the works at Blackburn. (See ALUM.) Blackburn contains 2352 houſes, 11,980 inhabitants, and is 211 miles N.W. from London. Aikin's deſcription of the country round Mancheſter, 4to. 1795.

BLACKBURN, the name of a river in Scotland, celebrated for its romantic caſcades, for the bold and pictureſque ſcenery adorning its banks, and for a ſingular natural bridge which ſtretches acroſs the ſtream, in the pariſh of Caſtletown. The latter is deemed one of the greateſt curioſities in Scotland. "It is 55 feet long, 10 feet wide, and the thickneſs of the arch is 2 feet four inches of ſolid ſtone. It is not compoſed of one entire rock, but has the appearance of many ſtones of about one foot and a half ſquare, ſet neatly together. The bridge ſlopes a little downwards, and the water ruſhes under the arch, through an opening of 31 feet. Among the caſcades, which ornament and enliven this ſtream, is one of above 37 feet in height, and 20 feet in width; another 31 feet high, and 36 feet broad; and a third 27 feet in height. Theſe waterfalls, combining with the romantic character of the rocks, and the conſtant roar of the daſhing ſtream, preſent a great number of highly pictureſque and intereſting ſcenes. In this wild and romantic vale, nature appears in various forms, now beautiful, then awful, ſometimes ſublime, and frequently terrible." Sir John Sinclair's ſtatiſtical account of Scotland, vol. xvi. communicated by the Rev. Mr. Arkle.

BLACKBURNE, FRANCIS, in *Biography*, a clergyman of the church of England, diſtinguiſhed by his firm attachment to the cauſe of civil and religious liberty, and by his zealous exertions in the promotion of it, was born of reſpectable parents at Richmond, in Yorkſhire, on the 9th of June 1705. Having purſued a courſe of claſſical education, firſt at Kendal in Weſtmorland, and afterwards at the free ſchools of Hawkſhead in Lancaſhire, and of Sedbergh in Yorkſhire, he was admitted, in May 1722, penſioner of Catherine hall, in the univerſity of Cambridge; where he took the degree of batchelor of arts, and was choſen conduct or chaplain-fellow of the ſociety; and on this title he was ordained deacon in March 1728. At this time he flattered himſelf with the expectation of a foundation-fellowſhip; but his avowal of ſentiments with regard to eccleſiaſtical and civil liberty, which he had acquired by the peruſal of the writings of Locke, Hoadly, &c. rendered him obnoxious to a majority of the fellows, who, being high royaliſts on the principle of hereditary right, ſet aſide his juſt claims as the only qualified candidate, and precluded his election, by indulging Mr. Addenbroke with an extraordinary year of grace, and thus keeping the fellowſhip full. This diſappointment induced him to reſign his conductſhip, to quit the univerſity, and to live in retirement with his uncle, Thomas Comber, eſq. of Eaſt Newton, near Helmſley, in Yorkſhire, till ſome church preferment might occur. His views, indeed, were particularly directed to the living of Richmond, the place of his nativity; to which he was inducted upon the death of the incumbent in 1739, having previouſly qualified himſelf for it by taking prieſt's orders. During the interval of his retirement at Eaſt Newton, he caſually found ſome old books that had formerly belonged to his great grandfather, an Oliverian juſtice; and by the peruſal of theſe he was led to entertain favourable ſentiments of the manners and principles of many excellent old puritans, to admire their unaffected and diſintereſted piety, and their zeal for the ſpiritual good of mankind, and to cheriſh that moderation and liberality of temper, and that ardent concern for liberty, which diſtinguiſhed his future conduct. As ſoon as he was inveſted with a parochial cure, he devoted himſelf with exemplary diligence to the ſtudies and duties appropriate to his paſtoral office, which he diſcharged, during a reſidence among his pariſhioners of 48 years, no leſs to their ſatisfaction and improvement, than to his own honour. His firſt appearance as an author was in the year 1742, when he publiſhed an "Aſſize Sermon," preached at York. About the ſame time he wrote two pamphlets concerning the illegal removal of the conſiſtory court and its records from Richmond to Lancaſter, which, in conſequence of a petition from the mayor and corporation to the biſhop of Cheſter, were reſtored. In 1748, he employed a young perſon, who was his curate, to tranſlate Eraſmus's preface to his paraphraſe on the goſpel of St. Matthew; and having written "A Preliminary Diſcourſe addreſſed to the Roman Catholic gentry and laity of Great Britain," he circulated a cheap edition of it, recommending it to the public, partly as an antidote againſt popery, but chiefly as an encouragement to the common people to be diligent in reading the ſcriptures, for the information and improvement of themſelves and families in Chriſtian knowledge and Chriſtian piety. It was not, however, till the year 1750, that Mr. Blackburne began to diſtinguiſh himſelf as a writer in defence of Chriſtian liberty. A work had been publiſhed in the preceding year, intitled "Free and Candid Diſquiſitions relating to the Church of England." This work contained many pertinent obſervations on exiſting defects and improprieties in the eſtabliſhed forms of the church, and propoſals for reviſing the liturgy, and amending ſuch paſſages as were liable to reaſonable objections. Mr. Blackburne was ſuſpected by many, who were acquainted with his ſentiments on the ſubject of an eccleſiaſtical reform, to have had a concern in this publication. But though he had correſponded with the compiler and editor of it, and had ſeen the greateſt part of the work in manuſcript, he had neither written nor ſuggeſted a ſingle line or word. Indeed, he diſapproved the ſtyle and ſpirit of it; and thought them by no means adapted to the occaſion, nor likely to produce effect. "He was rather, perhaps too much (ſays his biographer), inclined to look upon thoſe who had in their hands the means and the power of reforming the errors, defects, and abuſes in the government, forms of worſhip, faith and diſcipline of the eſtabliſhed church, as guilty of a criminal negligence, from which they ſhould have been roufed by ſharp and ſpirited expoſtulations." Nevertheleſs, he thought it his duty to repel the attacks of the adverſaries of this work; and accordingly, he publiſhed, without the knowledge of its editor, or any of his more confidential aſſociates, an "Apology for the Authors of the Free and Candid Diſquiſitions," 1750. But though he engaged in this controverſy, his attention was not diverted from parochial duties; for his next publication was "A ſhort Diſcourſe on the Nature, Obligation, and Benefits of Family Religion," which he publiſhed at his own expence, and diſtributed among his pariſhioners. In this ſame year 1750, notwithſtanding the publication of his "Apology," he was collated to the archdeaconry of Cleveland, and alſo to the prebend of Bilton, by Dr. Matthew Hutton, then archbiſhop of York, to whom he had been for ſome years titular chaplain. Towards the cloſe of the year 1752, he had an opportunity of peruſing the charge delivered by Dr. Butler, biſhop of Durham, to the clergy of his dioceſe at his primary viſitation in 1751; and he found in it ſome doctrines which were, in his opinion, ſo diametrically oppoſite to the principles on which the proteſtant reformation was founded and ſupported, as to deſerve being expoſed and cenſured, in order to prevent the miſchief which they might do under the ſanction of his name. Accordingly, he wrote ſtrictures upon them; and, in oppoſition

to

to the remonſtrances of a friend, who diſſuaded him from publiſhing them, leſt they might be the means of preventing his further preferment. he committed them to the preſs under the title of "A ſerious Enquiry into the Uſe and Importance of external Religion, &c." This piece, which was afterwards printed by Mr. Baron, in the 4th volume of a collection of tracts, entitled, "The Pillars of Prieſtcraft, and Orthodoxy ſhaken," and aſcribed to him as its author, gave great offence, particularly to archbiſhop Secker, and precluded all hopes of preferment in the church, if indeed he had indulged any ſuch hopes, under epiſcopal patronage. The next ſubject of importance, which engaged his attention, was the doctrine of an intermediate ſtate. To this he was led by an "Appendix" to Dr. Law's "Conſiderations on the Theory of Religion," which appeared in 1755, and which inculcated the tenet of the ſleep of the ſoul. This opinion was attacked from ſeveral quarters, and particularly by Dr. Goddard, maſter of Clare-hall, in a ſermon preached at St. Edmund's Bury. Mr. Blackburne defended his friend Dr. Law, in a publication entitled "No Proof in the Scriptures of an intermediate ſtate of happineſs or miſery, between death and the reſurrection." He alſo publiſhed ſeveral other pieces on the ſame topic; ſuch as "Remarks on Dr. Warburton's account of the ſentiments of the early Jews concerning the ſoul;" and "A Review of ſome paſſages in the laſt edition of the Divine Legation of Moſes demonſtrated," which appeared in 1759, and may be conſidered as a ſequel to the "Remarks." He alſo prepared a reply to Dr. Morton, Mr. John Steffe, and Dr. Caleb Fleming, who had publiſhed ſtrictures on Dr. Law's Appendix; and he purſued the diſcuſſion of the ſubject more at large in a work, firſt publiſhed in 1765, and afterwards with conſiderable additions in 1772, and entitled "A ſhort hiſtorical View of the Controverſy concerning the intermediate ſtate between death and the reſurrection, with a prefatory diſcourſe on the uſe and importance of theological controverſy." In 1756, our author publiſhed "Some Sentiments of a country-divine concerning the Ordinance of Baptiſm, &c." occaſioned by letters which paſſed between biſhop Clayton and Mr. Penn on that inſtitution. In the correſpondence between theſe writers, a difficulty occurs in the interpretation of the charge given by our Lord to his apoſtles. Matt. xxviii. 19. Our Lord, it is ſaid, preſcribes *one* preciſe form of words to be uſed in baptiſm; the apoſtles appear, from the Acts and Epiſtles, to have uſed *another;* and the evangeliſts Mark, Luke, and John, do not mention *any preciſe* form whatever. Various hypotheſes have been propoſed by Grotius, Limborch, Lightfoot, Whitby, Clayton, &c. for reconciling the practice of the apoſtles with the precept of Chriſt. Mr. Blackburne, diſſatisfied with all theſe, ſuggeſts that the words in queſtion contain no baptiſmal form at all; and that we ſhould rather follow the apoſtolical form in Acts, as being derived to us by the authority and example of men, who muſt be perfectly ſatisfied that the foundation they built upon was found and good. Accordingly, he propoſes that we ſhould read the paſſage in St. Matthew thus; Πορευθεντες ουν μαθητευσατε παντα τα εθνη (βαπτιζοντες αυτους) εις το ονομα του πατρος, και του υιου, και του πνευματος αγιου; "Go ye therefore, and diſciple all nations (baptizing them) into the name of the Father, and of the Son, and of the Holy Ghoſt." By conſtruction and parentheſis, the command to baptize refers to no particular form at all, and leaves us to ſuppoſe, what was certainly the truth of the matter, that the apoſtles being already well acquainted with the form uſed in the baptiſm of Jeſus, it was quite ſuperfluous to enjoin it here.

In 1758, Mr. Blackburne avowed the ſentiments which he had for ſome time entertained concerning ſubſcription to the liturgy and articles of the church of England, in "Remarks on the Rev. Dr. Powell's ſermon in defence of ſubſcriptions, &c." preached in the preceding year before the univerſity of Cambridge; to which is prefixed "An Addreſs to the younger ſtudents in both our univerſities." The ſubject of ſubſcription had indeed for ſome time engaged his attention; and it was not without ſcruples that he had qualified himſelf to hold the archdeaconry and prebend in 1750; but when he had reaſon to expect further advancement in the church, he reſumed the conſideration of the ſubject, and the reſult was a determination never to renew his ſubſcription. About this time he began to make collections for his famous work entitled "The Confeſſional, or a full and free Enquiry into the right, utility, and ſucceſs of eſtabliſhing Confeſſions of faith and doctrine in Proteſtant churches." This work, in the execution of which he was much encouraged by Dr. Edmund Law, afterwards biſhop of Carliſle, lay by him in manuſcript for ſeveral years, and was at length publiſhed in 1766, 8vo. without his name. It excited, as we may naturally imagine, very general attention both among the partizans of reform and the advocates for exiſting eſtabliſhments. A ſecond edition appeared in 1767; and the controverſy, which it occaſioned, laſted for ſome years, and produced a great number of publications. The third edition, corrected and much enlarged, was publiſhed in 1770; and to this edition has been added from the author's manuſcript, in the late collection of his works, an appendix, containing a ſhort hiſtory of the confeſſions eſtabliſhed in the church of Scotland at different periods. For a further account of the ſubject of this work, and of the arguments for and againſt ſubſcription, ſee SUBSCRIPTION. Soon after the publication of the third edition of the "Confeſſional," the author was induced by ſeveral of his friends to draw up and publiſh "Propoſals for an application to parliament for relief in the matter of ſubſcription to the liturgy and thirty-nine articles of the eſtabliſhed church of England, humbly ſubmitted to the conſideration of the learned and conſcientious clergy of the ſaid church." An aſſociation was formed for this purpoſe, for the reſult of which, ſee ASSOCIATION.

It was natural to imagine, that the author of ſuch a work as the "Confeſſional," written with a view of examining and refuting the ſeveral pleas that had been urged in favour of ſubſcription, and which had convinced many perſons of the inſufficiency of theſe pleas, would have wiſhed to withdraw himſelf from the eſtabliſhed church, which impoſed a ſubſcription that appeared to him to be unjuſtifiable; and accordingly, as the death of Dr. Chandler, in 1766, occaſioned a vacancy in the reſpectable congregation of diſſenters at the Old Jewry, in London, ſome individuals of that ſociety applied to Mr. Blackburne for information, whether ſuch a ſituation would be agreeable to his views, if it were offered to him. But, with the proſpect of a very conſiderable acceſſion to his income, he declined accepting the propoſal, for reaſons that were very ſatisfactory to thoſe who made it. The clear amount of all that he poſſeſſed, as a beneficed clergyman, never much exceeded the ſum of 150l. a-year; whereas, if the removal that had been ſuggeſted to him had taken place, his income would have been nearly trebled. Some other circumſtances alſo afterwards occurred, which had a tendency to detach him from the eſtabliſhed church. Two very reſpectable clergymen, immediately connected with his own family, viz. the learned Mr. Theophilus Lindſey, whoſe excellent character thoſe who are moſt adverſe to his theological opinions concur in applauding, and his ſon-in-law, Dr. Diſney, no leſs eſteemed by all who know him, ſurrendered their preferments, becauſe they diſapproved the doctrines and forms of the eſtabliſhed church.

Mr. Blackburne, however, though he agreed with his valued relatives in many of their objections to the liturgy and articles of the church, differed from them with regard to feveral doctrinal points of importance; and without feeming to advert to his paft fubfcription, in confequence of which he ftill held his church preferments, he fatisfied himfelf with refufing any further preferment, which was actually offered to him, becaufe he was determined not to renew his fubfcription. His continuance in the church cannot be juftly afcribed to any felfifh and interefted motives, becaufe he might have left it with advantage, and he remained in it with a fixed purpofe of accepting no preferment; and he refufed very conliderable offers of this kind. But, in order to vindicate his conliftency, he thought it right to avow his motives for continuing miniiter in the church, while he difapproved many things in her doctrine and difcipline; and with this view he drew up a fhort paper containing "An Anfwer to the queftion, Why are you not a Socinian?" and alfo his reafons for officiating in a church, whofe forms of faith, worfhip, and difcipline, he thought to be in many things highly exceptionable. Thofe who wifh for fatisfaction on thefe points, are referred to the Appendix annexed to the Memoirs of his Life, p. 120. We fhall content ourfelves with obferving, that Mr. Blackburne was a firm believer of the pre-exiftence of Chrift, and that he alfo maintained his divinity, with limitations according to his own ideas, which he believed to be founded on the Scriptures; and with regard to the general fentiments of his creed, he is faid to have more than once declared himfelf a moderate Calvinift. Whatever may be the inconfiftency which fome perfons have charged upon his conduct, he manifefted his eftcem for the church, not only by continuing his own connection with it, but by educating a fon for the clerical office, though the condition of performing any duties, or enjoying any emoluments in that church, was fubfcription, the impofition of which he had ftrongly reprobated and condemned. On this fubject, the further difcuffion of which would lead us beyond our province as biographers, we fhall only fay, "Let every man be fully perfuaded in his own mind; to his own mafter he ftandeth or falleth." See SUBSCRIPTION.

Having been accuftomed from early life to regard the Roman Catholics as dangerous foes to the government and religion of his country, Mr. Blackburne, notwithftanding the enlarged and liberal fentiments avowed by him on all other occafions, wrote againft them with a feverity which the friends of freedom have generally condemned. But an alarm with regard to the fpread of popery, and the evils to be apprehended from it, prevailed very much at the time; and this induced him, in 1768, to publifh a caution againft it, under the title of "Conliderations on the prefent ftate of the controverfy between the Proteftants and Papifts of Great Britain and Ireland, particularly on the queftion, how far the latter are entitled to toleration upon Proteftant principles."

During the intervals of his other profeffional and literary engagements, he employed himfelf in collecting materials for the life of Martin Luther, which he propofed to write according to the pattern of Dr. Jortin's life of Erafmus; but he was diverted from accomplifhing his defign, firft by the death of his friend Thomas Hollis efq. of whom he publifhed "Memoirs," in 2 volumes 4to. in 1780, and afterwards by the lofs of his fecond fon Thomas, in 1782, a phyfician of rifing eminence in the city of Durham, which fo affected him as to render him incapable of finifhing feveral things which he had undertaken. Soon after his eye-fight failed him, and he was under the neceffity of employing an amanuenfis. His mind, however, was ftill enterprifing and active; nor was he prevented by the increafing infirmities of age from profecuting the object of ecclefiaftical reformation, which feems to have occupied his thoughts to the lateft period of his life, and from performing his profeffional duties. Having in the laft year of his life prepared a charge for his 38th annual vifitation in Cleveland, he caufed it to be delivered by his eldeft fon, who ftood by him, and then took leave of his clerical brethren with an addrefs equally pious and affectionate, that muft have deeply impreffed the minds of all who heard it. At the clofe of his vifitation circuit, he was taken ill at the houfe of a friend, and apprehenfive of approaching diffolution, haftened to his rectory at Richmond with all the expedition which the ftate of his health allowed. Within a few weeks after his return, on the morning of Auguft 7th 1787, in his 83d year, he finifhed the protracted courfe of a ftudious and exemplary life, with the fentiment of the amiable Erafmus, and the benevolent Jortin, "I have had enough of every thing in this world," and expired, as he fat in his chair, without a groan. He left a widow, who died Auguft 20th 1799. and four children; viz. Jane, married to the Rev. Dr. Difney, now miniiter of the Unitarian fociety in Eflex-ftreet, London; the Rev. Francis Blackburne, vicar of Brignal, near Greta-bridge, Yorkfhire; Sarah, married to the Rev. John Hall, vicar of Chew Magna, and rector of Dundry in Somerfetfhire; and William Blackburne, M.D. of Cavendifh-fquare, London.

Few perfons have ever been more regular and aflduous in the performance of profeffional duties, whether we conlider him as a parifh prieft, or as an archdeacon, than Mr. Blackburne. Poffeffing naturally a ftrong conftitution of body, and great firmnefs of mind, which he preferved by temperance to a very advanced period, he was capable of intenfe and continued application. He was likewife animated in the difcharge of his clerical functions by a conviction of their importance, and by an ardent defire of promoting the beft intereits of thofe with whom he was connected. In compofing for many years new difcourfes, whenever he officiated, and alfo charges for his archidiaconal vifitations, and in preparing for the prefs a variety of publications, a great part of his time muft have been fpent in ftudy and retirement; and hence he is faid to have acquired the appearance of auiterity; nevertheleis with his intimate friends and affociates he was cheerful and unreferved. As a writer he was nervous and animated; and his public difcourfes were delivered with an unaffected earneftnefs, which proceeded from conviction of the importance of religious truth and duty, and which intereited and impreffed thofe who heard him. In his controverfial writings, it muft be acknowledged, and he himfelf lamented it towards the clofe of his life, that he was occafionally betrayed into precipitance of judgment and afperity of language; but it fhould be recollected, that he contended with a hoft of adverfaries, whofe mode of attack fometimes provoked and juftified his refentment; and that his vehemence and ardour were always accompanied with a high fenfe of integrity and honour, and a laudable folicitude for ferving what he conceived to be the caufe of truth and liberty. The topics of his numerous publications, the principal of which we have above recited, were chiefly theological or controverfial; nevertheleis he was an occafional writer on political liberty, and he largely contributed to a collection of letters and eflays on this fubject, publifhed in 3 vols. 8vo. 1774. A collection of his "Works, theological and miicellaneous, including fome pieces not before printed, with fome account of the life and writings of the author, by himfelf, completed by his fon Francis Blackburne, L. L. B. and illuftrated by an appendix of original papers," has this year (1804) been publifhed in 7 vols. 8vo. The following re-

ſpectful and juſt tribute to his memory cloſes his ſon's account of his life and writings: "Such was Francis Blackburne; a believer of Chriſtianity, from the deepeſt conviction of its truth; a Proteſtant on the genuine principles of the reformation from popery; a ſtrenuous adverſary of ſuperſtition and intolerance, and of every corruption of the ſimplicity or the ſpirit of the goſpel; a zealous promoter of civil liberty; a cloſe and perſpicacious reaſoner; a keen and energetic writer; an attentive, benevolent, and venerable archdeacon; an eloquent and perſuaſive preacher; a faithful paſtor and exemplary guide; of unblemiſhed purity of life, of ſimple dignity of manners; a ſincere and cordial friend; an affectionate huſband, and an indulgent father; in ſhort, a juſt, humane, pious, temperate, and independent man."

BLACKBURNIA, ſo named by Forſter, in honour of John Blackburne eſq. and his daughter Anne, of Orford in Lancaſhire, in *Botany*. Lin. gen. Schreb. n. 199. Forſter gen. 6. Claſs and order, *tetrandria monogynia*. Gen. Char. *Cal.* perianth very ſhort, four-toothed, inferior; teeth ſhort, acute, horizontal. *Cor.* petals four, elliptic. *Stam.* filaments four, ſubulate, rather ſhorter than the petals; anthers heart-ſhaped, erect. *Piſt.* germ conic; ſtyle ſiliform, erect, length of the ſtamens; ſtigma ſimple. *Per.* berry. *Seed*, ſingle.

Eſſ. Char. *Cal.* four-toothed; *pet.* four, elliptic; *anth.* heart-ſhaped; *germ* conic; *ſtigma* ſimple. *Per.* berry, with a ſingle ſeed.

Species 1. B. *pinnata*. Forſt. gen. 6. t. 6. ſ. Auſtr. n. 53. Ptelea pinnata. Linn. ſuppl. 126. A native of Norfolk iſland; found there in 1774. Martyn.

BLACKBURNIÆ, in *Ornithology*, a ſpecies of MOTACILLA, deſcribed in the Arctic Zoology under the name of the blackburnian warbler. The crown is black, with a yellow line in the middle; band through or acroſs the eye black, as are alſo the leſſer wing-coverts; greater wing-coverts, vent, and lateral tail feathers white, the middle ones being duſky black; ſides of the neck, chin, and middle of the belly yellow. A native of New York.

BLACKHEAD, in *Geography*, a cape on the eaſt coaſt of Ireland, at the north entrance into Belfaſt Lough. N. lat. 54° 45′. W. long. 5° 35′.

BLACKHEAD, a cape on the weſtern coaſt of Ireland, in the county of Clare, on the ſouth ſide of the entrance into Galway bay. N. lat. 53° 7′. W. long. 9° 11′.

BLACKHEAD, a cape on the ſouth coaſt of Ireland, within the old head of Kinſale, and on the weſt ſide of Kinſale harbour. N. lat. 51° 38′. W. long. 8° 30′.

BLACKHEAD, a cape on the weſt coaſt of Scotland, in the county of Wigton; 6 miles W.S.W. of Stranraer.

BLACKHEAD, a point of land between Falmouth haven and the Lizard point.—Alſo, one of the peaks between Fermowe's harbour on the eaſt coaſt of Newfoundland, and Agua fort; bald head being the other.—Alſo, a point on the ſouth coaſt of Newfoundland, weſt of cape Race, and half a league further weſt from cape Pine.—Alſo, a point on the eaſt coaſt of the northern iſland of New Zealand, N.N.E. of cape Turnagain, in about 40° 18′ S. Lat.

BLACKING, in the *Arts*, &c. is ſometimes uſed for a factitious black, as lamp-black, ſhoe-black, &c. A mixture of ivory or lamp-black with linſeed oil, makes the common oil-blacking. For a ſhining blacking, ſmall-beer or water is uſed inſtead of oil, in the proportion of about a pint to an ounce of the ivory-black, with the addition of half an ounce of brown ſugar, and as much gum Arabic. The white of an egg, ſubſtituted for the gum, makes the black more ſhining; but is ſuppoſed to hurt the leather, and make it apt to crack.

In 1771 a patent was granted to Mr. William Bayley for preparing a compoſition in cakes, rolls, or balls, which, with the addition of water only, makes an excellent ſhining liquid blacking for ſhoes, boots, &c. The recipe for this purpoſe is as follows: take one part of the gummy juice that iſſues, in the months of June, July, and Auguſt, from the ſhrub called the goat's thorn, four parts of river water, two parts of neat's foot, or ſome other ſoftening lubricating oil, two parts of ſuperfine ivory-black, two parts of deep blue, prepared from iron and copper, and four parts of brown ſugar-candy. Evaporate the water; and, when the compoſition is of a proper conſiſtence, let it be formed into cakes of ſuch a ſize, that each cake may make a pint of liquid blacking.

BLACKLOCK, THOMAS, in *Biography*, was born in 1721, at Annan in Scotland, of parents, who were natives of Cumberland, and who occupied a humble ſtation. At the age of 6 months he was deprived of his ſight by the ſmall-pox; and thus becoming incapable of any mechanical employment, he was in the probable courſe of nature deſtined to be a perpetual charge to his parents. His diſpoſition, however, as he advanced towards maturity, engaged the moſt affectionate attention; and the kindneſs of his father was ſuch as to impreſs his youthful mind, and to engage expreſſions of ardent gratitude. The powers of his mind were no leſs diſtinguiſhed than the amiableneſs of his temper; and he improved the caſual opportunities of cultivating them, which were afforded him by the attention of his father and friends, who read to him ſeveral paſſages out of Engliſh authors, and particularly from the works of our moſt approved and popular poets. Theſe he heard with avidity and delight; and at the early period of his 12th year, he began to imitate what he admired. His performances, as he advanced towards maturity, became the ſubjects of general converſation; and having the misfortune to loſe his father in his 19th year, he was invited, at the age of 20, by Dr. Stephenſon, phyſician at Edinburgh, to remove thither and to purſue his ſtudies at the univerſity. Notwithſtanding the perſonal diſadvantages under which he laboured, he made very conſiderable progreſs in the Latin, Greek, and French languages; but upon the breaking out of the rebellion in 1745, his ſtudies were interrupted, and he retired into the country. On this occaſion he was ſolicited by his friends to publiſh a ſmall collection of his poems at Glaſgow. When the tumult of the rebellion ſubſided, he returned to Edinburgh, and to the proſecution of his ſtudies for 6 years more, during which period he not only perfected himſelf in the languages, but made conſiderable progreſs in all the ſciences, and particularly in polite literature. In 1754 he publiſhed a ſecond edition of his poems, much improved and enlarged; and thus gained the patronage of Mr. Spence, who, by an account of his life, character, and poems, brought him into general notice. By means of a ſubſcription to a 4to edition of his poems, his circumſtances were rendered eaſy and comfortable; and applying himſelf to the ſtudy of theology, he paſſed the uſual trials, and was licenſed in 1759 to be a preacher by the preſbytery of Dumfries. From the diſcharge of the duties of his office he derived great ſatisfaction and reputation. On the alarm of a French invaſion in 1761, he publiſhed a diſcourſe "On the right improvement of time;" and in the ſame year he contributed ſome poems to the firſt volume of Donaldſon's collection of original poems. In 1762 he formed a matrimonial connection, which he regarded as the chief ſource of the felicity of his future life. About this time he was ordained miniſter of Kircudbright, on the preſentation of the earl of Selkirk; but in conſequence of ſome litigations that enſued, he

thought it moſt expedient, within two years, to reſign this preferment, and to retire upon a moderate annuity. With this ſlender proviſion he removed in 1764 to Edinburgh, and opened his houſe for the accommodation of young perſons as boarders and ſtudents. In 1766 the mariſchal college of Aberdeen conferred upon him the degree of doctor in divinity. From this time he continued to maintain his literary character by ſeveral publications, which it will be ſufficient to enumerate. Theſe were "Paracleſis, or Conſolations deduced from natural and revealed religion," in two diſſertations, 8vo. 1767; "Two Diſcourſes on the evidences and ſpirit of Chriſtianity, tranſlated from the French of Mr. James Armand," 8vo. 1768; "A Panegyric on Great Britain," a ſatirical piece, 8vo. 1773; "The Graham, an heroic ballad, in four cantos," 4to. 1774; "Remarks on the nature and extent of liberty, &c. and on the juſtice and policy of the American war, occaſioned by peruſing the obſervations of Dr. Price on theſe ſubjects," 8vo. 1776; and a valuable article, communicated to the editors of the Encyclopædia Britannica, "On the education of the blind," 1783. A 4to edition of Dr. Blacklock's poems was printed in 1793. This edition contains an eſſay on the education of the blind, being a tranſlation of M. Hauy's celebrated eſſay on this ſubject; and prefixed to it we have a new account of the life and writings of the author by Mr. Mackenzie, author of the Man of Feeling, &c. Dr. Blacklock died at the age of 70, in July 1791. With reſpect to his talents, Mr. Hume obſerves, "that he may be regarded as a prodigy;" and to his moral character he bears this honourable teſtimony, that "his modeſty was equal to the goodneſs of his diſpoſition, and the beauty of his genius." In the depreſſed circumſtances of his early life he was ſingularly contented and acquieſcing; but his loſs of ſight deeply affected his ſenſibility, and he deplores it in plaintive accents in one of his poems, written on occaſion of his eſcape from falling into a deep well. At the ſame time he was diſtreſſed by apprehenſions of ſinking into extreme indigence; however he expreſſes his truſt in Providence, and his hope that the clouds which were gathering over him would be diſſipated. Next to his religious principles, were letters, converſation, and muſic, from which he derived his principal ſolace. His poetry is eaſy, elegant, and harmonious; and abounds with images, deduced from viſible objects, and aptly applied. He is ſaid to have compoſed with rapidity, and hence it is owing that his vivacity and animation are often indulged at the expence of correctneſs and regularity. In ſentiment he diſplays much benevolence and tenderneſs of diſpoſition, as well as true piety and philoſophy. Spence, *ubi ſupra*. Gen. Biog.

BLACKMORE, Sir Richard, M.D. an indefatigable writer, poet, and phyſician, was born at Corſham in Wiltſhire, about the year 1650. After ſome years ſpent at a grammar ſchool in the country, he was ſent to Weſtminſter ſchool, and in 1668 to Edmund-hall, Oxford. In 1676 he took his degree of maſter of arts, and continued to reſide at college three years after, but apparently without receiving much benefit from his long reſidence in this ſeat of the muſes, ſcarcely knowing the names or ſituations of places, which an intimacy with claſſical authors muſt have made familiar to him. At ſome time in his life, probably immediately on quitting college, he kept a ſchool, but does not ſeem to have remained long in that ſtation, as he ſoon after went to Paris, and to other places on the continent, with a view, it is probable, of acquiring or improving his knowledge in medicine, in which faculty he took his degree of doctor at Padua. Returning to England, after a ramble of eighteen months, he came to London, and ſettled at firſt in Cheapſide, where he acquired ſo much reputation, that in 1687, he was admitted a fellow of the college of phyſicians. In 1697, he received the honour of knighthood from king William, accompanied with a preſent of a gold chain and medal, which, he intimates, were given him as a reward for ſome ſervices performed at the revolution. The ſame year he was made phyſician in ordinary to the king; an office he held afterwards under his ſucceſſor, queen Anne. He was now in the zenith of his reputation, and having as yet but little expoſed himſelf to the ſcrutiny of the critics by writing, his merit was probably rated much beyond its real ſtandard. To his popularity as a phyſician, and his excellent and unimpeached moral character, it was probably owing, that his firſt production, "Prince Arthur," an epic poem, in ten books, publiſhed a little before this time, acquired ſo much celebrity as to paſs through three editions in the ſpace of two years. Encouraged by this ſucceſs, in 1699 he publiſhed his "King Arthur" in twelve books, with paraphraſes on the book of Job, and on other parts of ſcripture; and in 1700, his "Satire on Wit," in which he took occaſion to retort the ſarcaſms which had been heaped with no ſparing hand on his laſt poems by Dennis, Dryden, Pope, and moſt of the wits of the time. Not deterred by their cenſures, in 1705 he publiſhed "Eliza," another heroic poem, in ten books. "This excited," Johnſon ſays, "neither praiſe nor blame, but ſeems to have dropped dead born from the preſs." In 1712, appeared "Creation," a philoſophical poem, certainly the beſt of his productions. It had the honour of being praiſed by Addiſon, in the Spectator, and Dr. Johnſon has ſince inſerted it in his collection of Engliſh poets, with commendation much beyond its merit. This for a time revived its credit, and gave it a degree of celebrity, which ſeems again to be declining apace. Pleaſed with the reputation procured by this poem, he ſoon after produced his fourth and laſt epic poem in twelve books, intended to commemorate the actions of king Alfred, whoſe name it bore, but like Eliza, it excited little notice; benevolence being aſhamed any longer to patronize, and malevolence weary of inſulting, ſuch frigid abortions. But as if it was to be the fate of this author to try every ſpecies of writing, and to fail in all, on the Spectator ceaſing, he produced, in conjunction with Mr. Hughes, the "Lay Monaſtery;" one paper of which was publiſhed three times in the week. This was only continued to the 40th number. Soon after he gave the world two volumes of eſſays. As theſe were intended to promote the cauſe of virtue and religion, they met with ſome favour. Beſides theſe works, Dr. Blackmore wrote ſeveral tracts on different branches of medicine; on the ſpleen, the gout, the rheumatiſm, the king's evil, the dropſy, the jaundice, the diabetes, the plague; and as inoculation for the ſmall-pox was making ſome progreſs in his time, he thought it incumbent on him to give his decided diſapprobation of the practice. But as by this time he began to be eſteemed ſcarce a better phyſician than a poet, his opinion had fortunately very little weight with the public. The medical tracts are publiſhed together in an 8vo volume, but are little known or noticed. He died on the 8th of October 1729. Gen. Biog. Johnſon's Lives of the Poets.

BLACKNESS, the quality of a black body; or a colour ariſing from a texture and ſituation of the ſuperficial parts of the body, which, as it were, ſtifle, or rather abſorb, the light falling on it, without reflecting any, or very little of it, to the eye. In which ſenſe, blackneſs ſtands directly oppoſed to whiteneſs; which conſiſts in ſuch a texture of parts, as indifferently reflects all the rays thrown upon it, of whatſoever colour they be.

Deſcartes, ſays Dr. Prieſtley (Hiſt. of Viſion, p. 127 and 143, &c.), though miſtaken with reſpect to the nature of light and colours, yet diſtinguiſhes juſtly between black and white, obſerving, that black ſuffocates and extinguiſhes the

rays

rays that fall upon it; but that white reflects them. This, adds the hiſtorian of philoſophy, is the firſt diſtinct account I have met with of this ſenſible hypotheſis. Mr. Boyle alſo made ſeveral obſervations and experiments, which demonſtrate his theory in a very ſatisfactory manner. See BLACK.

Sir Iſaac Newton, in his Optics, ſhews, that for the production of black colours, the corpuſcles muſt be leſs than thoſe which exhibit any other colours; becauſe, where the ſizes of the component particles are greater, there is too much light reflected to conſtitute this colour: but, if they be a little leſs than is requiſite to reflect the white and very faint blue of the firſt order, they will reflect ſo little light, as to appear intenſely black; and yet may, perhaps, reflect it variouſly to and fro within them ſo long, till it happen to be ſtifled and loſt; by which means they will appear black in all poſitions of the eye, without any tranſparency.

And hence it appears, why fire, and putrefaction, by dividing the particles of ſubſtances, turn them black: why ſmall quantities of black ſubſtances impart their colours very freely, and intenſely, to other ſubſtances, to which they are applied; the minute particles of theſe, by reaſon of their very great number, eaſily overſpreading the groſs particles of others. Hence alſo appears, why glaſs, ground very elaborately with ſand, on a copper plate, till it be well poliſhed, makes the ſand, together with what by rubbing is worn off from the glaſs and copper, become very black; and why black ſubſtances do, ſooneſt of all others, become hot in the ſun's light, and burn (which effect may proceed partly from the multitude of refractions in a little room, and partly from the eaſy commotion of ſuch very ſmall particles): alſo, why blacks are uſually a little inclined towards a bluiſh colour; for that they are ſo, may be ſeen by illuminating white paper with light reflected from black ſubſtances, where the paper will uſually appear of a bluiſh white; and the reaſon is, that black borders on the obſcure blue of the firſt order of colours; and therefore reflects more rays of that colour than any other.

BLACKRIE, ALEXANDER, in *Biography*, apothecary, a native of Scotland, publiſhed in 1766 a diſquiſition on medicines that diſſolve the ſtone, in which Dr. Chittick's ſecret is laid open, 12mo. It was reprinted in 1771, with additions. He found the ſolvent to be the lixivium ſaponarium, which may be given, he ſays, advantageouſly, mixed with lime-water, even when blood is voided with the urine. When the bladder becomes ulcerated, wounded by the aſperities of the ſtone, he recommends the parcira brava and uva urſi. When pain in the loins or pubes is violent, he gives opium; and he has known, he ſays, perſons void ſtones in their ſleep, while taking that drug. Perſons who void red ſand or gravel with their urine, are never affected, he ſays, with the ſtone. Haller. Bib. Chirurg.

BLACKS, *Negroes*: a people, ſo called from the colour of their ſkin. For the reaſon of their colour, and the commerce of them, ſee NEGRO.

BLACKS, is alſo a name given to an aſſociation of diſorderly and ill-deſigning perſons, formerly herding chiefly about Waltham in Eſſex, who deſtroyed deer, robbed fiſh-ponds, ruined timber, &c. See BLACK *act*.

BLACKSOD BAY, in ſome old maps erroneouſly called *Black harbour*, in *Geography*, a large bay lying between the peninſula of the Mullet, and the main land of the county of Mayo, Ireland, to the ſouth of the iſthmus. It is well ſheltered, the ground in moſt parts clean, and ſufficiently deep for large ſhips; but the ground being a hard ſand, it is not thought that it will hold well in hard gales from the weſt and ſouth-weſt, eſpecially in the winter time. It is 2½ miles wide at its entrance, and runs about 9 miles inland, with ſeveral creeks communicating with it, of which thoſe within Barnach iſle, and the point of Claggan, are the moſt remarkable. The ſouth-weſt point of this bay is in N. lat. 54° 6′. W. long. 9° 52′ M'Kenzie, &c.

BLACKSOD *Point*, the ſouthern point of the Mullet, a peninſula in the weſtern part of the county of Mayo, Ireland, which forms the weſtern extremity of Blackſod bay. N. lat. 54° 6′. W. long. 9° 52′.

BLACKSTONE, J. in *Biography*, apothecary, of whom nothing is known, but that he publiſhed in 1737, "Faſciculus Plantarum, circa Harefield, ſponté naſcentium, cum Appendice ad loci naturam ſpectante," 8vo. London. Among many common, ſome very rare plants were diſcovered by the author, and are deſcribed in this volume. He alſo publiſhed in 1746, "Specimen botanicum, quo plantarum plurium Angliæ indigenarum, loci naturales illuſtrantur," 8vo. London, an intereſting and uſeful work. Haller. Bib. Botan.

BLACKSTONE, WILLIAM, SIR, knight and L.L.D. a celebrated Engliſh lawyer, was born in London, July 10th 1723, and received the firſt rudiments of learning at the Charter-houſe, where he was admitted upon the foundation in 1735, and whence he was removed, in 1738, to Pembroke college, Oxford. At ſchool and in the univerſity he was diſtinguiſhed by his application and proficiency; and the range of his ſtudies, even at an early period, was ſo extenſive, that he is ſaid to have compoſed a treatiſe on the "Elements of Architecture," for his own uſe at the age of 20. This treatiſe was never publiſhed. As he made choice of the profeſſion of the law, he was entered of the Middle Temple, and quitted Oxford in 1744 to purſue ſtudies, very different from thoſe to which his taſte inclined him at the univerſity. This change of his purſuits is feelingly commemorated in the "Lawyer's Farewel to the Muſe," compoſed about this time, and publiſhed in the fourth volume of Dodſley's Miſcellanies. From this period he aſſiduouſly applied to his profeſſional ſtudies, reſiding occaſionally in chambers in the Temple, for the convenience of attending the courts, and at other times in the univerſity, to which he was much attached. In 1743 he was elected a fellow of All-Souls college, and on the 24th of November 1746 he was called to the bar, and commenced the practice of the law. Deſtitute of a ready elocution, and of other talents requiſite for a popular advocate, his progreſs was ſlow; and he had leiſure to diſcharge the duties of burſar, or ſteward, of All-Souls, which he did with ſuch ſkill and diligence, as to improve the revenues of the college, and to aid in completing the magnificent ſtructure of the Codrington library. A treatiſe which he compoſed on this occaſion is ſtill uſeful in conducting the pecuniary concerns of this ſociety. In 1749, he was appointed recorder of Wallingford in Berkſhire; and deſirous of more conſtant reſidence at Oxford, he took in the following year the degree of doctor of laws. About this time he publiſhed an "Eſſay on collateral conſanguinity;" particularly referring to the claim made by the kindred of the founder of All-Souls to a preference in being elected fellows of that ſociety. It was written in defence of the college, which had lately rejected ſome of theſe claims; but the reaſoning, though ſupported by great learning and ingenuity, is deemed by ſome competent judges inconcluſive. In 1753, Mr. Blackſtone, perceiving, after a trial of ſeven years, that he had no proſpect of ſucceſs in the courts at Weſtminſter, determined to quit London, and to retire to his fellowſhip at Oxford. This reſolution was eventually very favourable both to himſelf and the public. As no public proviſion had been made either by the founders of the Engliſh univerſities, or at any ſubſequent period,

period, for teaching ſtudents the laws and conſtitution of their own country, Mr. Blackſtone undertook to ſupply this defect, and opened a courſe of public lectures upon this intereſting ſubject. With ſuch reputation and ſucceſs did he proſecute his plan, from Michaelmas term 1753, when his firſt courſe of lectures commenced, during a ſeries of ſucceſſive years, as probably to ſuggeſt the idea to Mr. Viner of founding by his will a very liberal eſtabliſhment in the univerſity of Oxford for the ſtudy of the common law. As ſoon as the plan of Mr. Viner's inſtitution could be arranged, Mr. Blackſtone was very properly elected, in October, 175 , the firſt Vinerian profeſſor; and he introduced the duties of his new office by a well-written lecture, adapted both to the ſubject and the audience, which was ſoon afterwards publiſhed, and which has been ſince prefixed to the firſt volume of his Commentaries.

With his engagements as a lecturer, Mr. Blackſtone combined the occaſional exerciſe of his profeſſion as a provincial barriſter; and, in 1754, he was employed as counſel in the great conteſted election for the county of Oxford. The ſubſtance of his pleadings on this occaſion was publiſhed in a pamphlet entitled "Conſiderations on Copyholders;" with a view to the legiſlative deciſion of the point controverted at this election. The argument of this treatiſe is founded on feudal principles, and excludes copyholders from the right of voting; this right being, by his reaſoning, reſtricted to thoſe who have a freehold or permanent intereſt in land, which does not belong to copyholders, whom the feudal ſyſtem conſiders as mere vaſſals, and dependent on the will of the lord. But it has been more liberally argued by others, that a ſeries of legal deciſions has given to this tenure all the permanence of freehold property, and that as the reaſon of the diſtinction between the two ſpecies of tenure has ceaſed, the diſtinction itſelf ought no longer to exiſt. However, in the parliamentary diſcuſſion of this queſtion, the technical arguments prevailed; and a declaratory act was ſoon afterwards paſſed, in conformity to the principles advanced by the profeſſor's treatiſe, excluding copyholders from the right of ſuffrage. In 1759, Blackſtone publiſhed, beſides two tracts of a local and temporary nature, a new edition of the "Great Charter, and Charter of the Foreſt," introduced by an hiſtorical preface, which evinced a conſiderable knowledge of antiquities. In the ſame year, the reputation gained by his lectures encouraged him to return to the temple, and to reſume his attendance at Weſtminſter; where he ſoon acquired profeſſional eminence, and where he was employed for a conſiderable time in almoſt all caſes that required great learning and deep reſearch. In 1761, he was elected member of parliament for Hindon, and had a patent of precedence to rank as king's counſel, having before declined the office of chief juſtice of Ireland. In 1762, he collected and re-publiſhed ſeveral of his pieces under the title of "Law Tracts," in 2 vols. 8vo. In 1763, he was appointed ſolicitor-general to the queen, in the eſtabliſhment of her majeſty's houſehold, and barriſter of the Middle Temple. Having vacated his fellowſhip by his marriage, in 1761, he was immediately afterwards appointed principal of New Inn-hall, by lord Weſtmoreland, then chancellor of the univerſity. But in 1766, he reſigned both this office and his Vinerian profeſſorſhip.

The firſt volume of his lectures was publiſhed in 1765, under the title of "Commentaries on the Laws of England;" a work which ſir William Jones has characterized as "the moſt correct and beautiful outline that was ever exhibited of any human ſcience." In the execution of this undertaking, the author combines the humbler duty of an expoſitor with the higher character of a philoſophical writer on juriſprudence. Under the former character he is entitled to the higheſt praiſe. The ſtyle is correct, perſpicuous, and elegant; and the author has admirably contrived to connect amuſement with inſtruction, and to render the ſtudy of the law as agreeable as it is important and intereſting. Notwithſtanding the immenſe maſs of materials of which this comprehenſive work conſiſts, few errors have been detected in it, and it has been cited as a book of authority.

It has been objected, however, to theſe Commentaries, excellent as they are in a variety of reſpects, that in thoſe parts of them where the author examines the reaſons and principles of law, he does not inveſtigate them with a truly philoſophical ſpirit, and that he does not riſe above the ordinary level of thoſe writers who, in every country and age, have extolled their own municipal inſtitution as "the wiſdom of ages," and "the perfection of reaſon." In diſcuſſing the propriety of particular laws, it is ſaid that "his ingenuity is always occupied by the *forms* of juriſprudence; and inſtead of referring to public convenience and general utility, the ſole ſtandard of all rational legiſlation, he perpetually appeals to thoſe technical arguments which are dignified with the title of "legal reaſons." He is, in all caſes, the advocate and the apologiſt of exiſting inſtitutions; and it is the conſtant tendency of his work to juſtify whatever has been eſtabliſhed by antiquity, to diſcredit the improvements of modern times, and to expoſe to contempt or indignation all propoſals for further change. In his political principles he has been charged with being too much the advocate of prerogative; and his eccleſiaſtical opinions have been thought to incline towards intolerance. Notwithſtanding the undue deference to authority, with which this writer has been charged, there are many paſſages in his admirable work, in which he expreſſes a marked diſapprobation of ſtanding armies and military barracks, and in which he delineates the progreſs of the influence of the crown, and the probable effects of a further increaſe of the national debt. Theſe paſſages, however, have been attributed, by ſome of thoſe who have animadverted on his Commentaries, more to the ſpirit of the times, than to that of the writer. Several obnoxious paſſages in the eccleſiaſtical part of this work were pointed out by Dr. Furneaux and Dr. Prieſtley; but though the author had not magnanimity enough explicitly to acknowledge his errors, theſe paſſages were retrenched in ſubſequent editions. The political principles of the Commentaries were ſome years afterwards, viz. in 1776, more ſeverely noticed in a treatiſe entitled "A Fragment on Government," by Jeremy Bentham, eſq. To the honour of Mr. Blackſtone it ſhould be mentioned, that, notwithſtanding the ſeverity of this author's criticiſm, he afterwards became acquainted with him, and lived with him upon terms of regard and friendſhip.

Having given his opinion in parliament, on occaſion of the debates about the Middleſex election, that an expelled member was not eligible to the ſame parliament, and this opinion appearing to contradict the language of his Commentaries, he was violently attacked for this inconſiſtency by the celebrated Junius and others; but, though he defended himſelf with ingenuity, he inſerted the caſe of expulſion in the next edition of his work, of which he had before taken no notice, as one of the diſqualifications for a ſeat in parliament.

His diſtinguiſhed talents and meritorious ſervices entitled him, without doubt, to the notice and recompence of government. Accordingly, when he declined the offer of being ſolicitor-general, on the reſignation of Mr. Dunning, in 1770, he was appointed immediately afterwards one of the juſtices of the common pleas, which office he held, except for a ſhort interval, during which he accommodated Mr. Juſtice Yates by ſitting as one of the juſtices of the king's

king's bench, till his death. Towards the end of the year 1779, a dropſical diſeaſe, occaſioned chiefly by early application, and by neglect of exerciſe, made rapid advances, and terminated in his death, Feb. 14th 1780, in his 56th year. In private life, judge Blackſtone was diſtinguiſhed for mildneſs and benevolence, and for every domeſtic and ſocial virtue. In ſtudies and avocations that contributed to eſtabliſh his own reputation, and to benefit both his contemporaries and poſterity, he was eminently aſſiduous; and the intervals of leiſure which he enjoyed in the later period of his life were devoted to ſchemes of local improvement in the neighbourhood where he reſided, or to great public undertakings. The two volumes of Reports, which he left in MS. have been publiſhed ſince his death, in 2 vols. folio, with a preface containing memoirs of his life; but their merit is ſaid not to correſpond with the fame of the author. He alſo left in MS. ſeveral ſmall poetical pieces; and his notes on Shakeſpear inſerted in Mr. Malone's Supplement, ſhew how well he underſtood, and how capable he was of appreciating, the excellence of that author. Life prefixed to Blackſtone's Reports. Gen. Biog.

Blackstone, in *Geography*, a ſmall river of America, which has its ſource in Rainſhorn pond, in Sutton, Maſſachuſetts; and, paſſing through Providence, diſcharges itſelf into Narraganſet bay, at Briſtol, receiving in its courſe ſeveral tributary ſtreams.

BLACKSTONIA, in *Botany*. See Chlora.

BLACKWALL, Anthony, in *Biography*, a native of Derbyſhire, was admitted a ſizar of Emanuel college, in the univerſity of Cambridge, in 1690. Having taken the degree of M. A. in 1698, he became head-maſter of the free-ſchool at Derby, and lecturer of the pariſh of All-hallows in that town. In 1706, he excited notice by an edition of the "Moral Sentences of Theognis," with a new Latin verſion, together with notes and emendations. He alſo publiſhed, in 1718, "An Introduction to the Claſſics," 12mo. in which he diſplays their excellence, gives directions for ſtudying them with advantage, and illuſtrates thoſe rhetorical figures by which language is elevated and adorned. In 1722, he was appointed head-maſter of the free ſchool at Market Boſworth, in Leiceſterſhire; and in this ſituation he prepared for the preſs his principal work, entitled "The Sacred Claſſics defended and illuſtrated; an eſſay humbly offered towards proving the purity, propriety, and eloquence of the writers of the N. T. in 2 parts, 4to." This was publiſhed in 1725; and a ſecond edition in 8vo appeared in 1727. After his death, a ſecond volume was publiſhed under the title of "The Sacred Claſſics defended and illuſtrated, the ſecond and laſt volume, in 3 parts," 8vo. 1731. The deſign of the author, in this elaborate and learned work, was to vindicate the writers of the New Teſtament from the charge of barbariſm in their language, and to ſhew that the words and phraſes which they have uſed are to be found in the moſt approved claſſical writers. Many of the obſcurities and ſeeming faults he attributes to tranſpoſitions and miſtranſlations, and he urges the neceſſity of a new verſion. See Bible. This book has been highly valued by biblical ſcholars; and a Latin tranſlation of it was publiſhed at Leipſic, in 1736, by Chriſtopher Wolfius. Nevertheleſs it has been thought by ſeveral very competent judges to be written with more zeal than ſolidity; and Dr. George Campbell, in his Preliminary Diſſertation to his Verſion of the four Goſpels, has attacked the fundamental principle of the work, and made ſeveral particular ſtrictures upon it. Mr. Blackwall was eminently diſtinguiſhed as a ſchoolmaſter, and formed many good ſcholars, among whom was Richard Dawes, author of the Miſcellanea Critica. In his ſchool he uſed a Latin grammar compoſed by himſelf, and publiſhed in 1728 without his name. Sir Henry Atkins, bart., who had been one of his ſcholars, preſented him in 1726, with the valuable rectory of Clapham, in Surry; but he reſigned it in 1729, and returned to Market Boſworth, where he died in 1730.

BLACKWATER, in *Geography*, the name of four rivers in England and Scotland. That of England riſes near the middle of the county of Eſſex, and falls into the mouth of the Thames, where it forms a ſpacious bay called Blackwater bay. Thoſe of Scotland are, 1ſt. in Bamfſhire, 2d. in Berwickſhire, and 3d. in Perthſhire.

Blackwater, the name of ſeveral rivers in Ireland, one of which is very conſiderable. This riſes in the mountains which ſeparate the counties of Limerick and Kerry; and, taking a ſouthern direction, divides the latter county from the county of Cork for about 12 miles. After paſſing at the foot of *Slieve-logher* mountain, from which it receives a large ſupply of water, it runs weſternly acroſs the northern part of the county of Cork, which is about 45 Engliſh miles. In this courſe it paſſes the flouriſhing towns of Mallow and Fermoy, to the former of which it was navigable in lord Orrery's time, and receives the rivers Allo, Awbeg, and Funcheon, beſides many ſmaller ſtreams. A few miles below Fermoy, it enters the county of Waterford, and continues in the ſame direction for 12 miles, when, having paſſed the ancient city of Liſmore, it bends nearly at a right angle to the ſouth at Cappoquin. At this town it becomes navigable, and in its courſe receiving the river Bride, and opening into two or three ſpacious loughs, it flows into the ſea a little below the town of Youghal, which is ſituated on its weſtern bank. This river paſſes for almoſt the whole of its courſe, which, without making any allowance for its great windings, is about 90 Engliſh miles, through a rich and well-wooded country, "equally remarkable," ſays Mr. Young, "for beauty of proſpect and fertility of ſoil." The banks are crowded with a number of fine ſeats, ſome of which, as Dromana and Liſmore caſtle, may vie with thoſe in any country, and have furniſhed artiſts with beautiful landſcapes. The cyder made in its neighbourhood is held in great eſtimation, being preferred to the beſt imported from England, and of courſe brings a very high price. The Iriſh name of this river was Auniduff, or *Awin-dubh*, the black river, and alſo *Awin-more*, the great river, to diſtinguiſh it from the *Awbeg*, or *Awin-beg*, which runs into it. The latter is the Mulla of the immortal Spenſer, who had an eſtate on its banks, where he reſided for a long time. In his marriage of the Thames, he has mentioned the Blackwater and ſeveral of its tributary ſtreams, though not with geographical accuracy, as the Allo does not riſe near Slievelogher, but has the Blackwater between it and that mountain.

> "Swift Auniduff, which of the Engliſhman
> Is called Blackwater, and the Liffar deep,
> Sad Trowis that once his people overran,
> Strong Allo tumbling from Slievelogher ſteep,
> And Mulla mine, whoſe waves I whilom taught to weep."
> Spenſer's Fairy queen, b. iv. c. 11.

—2. Another river, called Blackwater, riſes in the county of Tyrone, and, for the greater part of its courſe, divides that county from thoſe of Monaghan and Armagh. The linen manufacture is extenſively carried on in its neighbourhood, ſo that there are many bleach-greens. The flouriſhing little towns of Aughnacloy, Caledon, Blackwater town, Moy, &c. are on its banks; and its navigation to Lough Neagh, into the ſouth-weſtern angle of which it pours its waters, has been improved at a conſiderable national expence, on account of the collieries at Drumglaſs, in the county of Tyrone.—3. A river Blackwater riſes in the

the county of Monaghan, and, having paſſed through Lough Ramor, unites its waters to thoſe of the Boyne at Navan. —There are alſo ſmall rivers of this name, one in the county of Longford, which joins the Shannon near Laneſborough, and one in the county of Wexford, which flows into St. George's channel at the place where Bannow formerly ſtood. Smith's Cork. Beauſort's Map. Holmes's Tour in the South, &c.

Blackwater *Town*, a ſmall town in the county of Armagh, in Ireland, on the river Blackwater, which has a linen market. Diſtance from Dublin 66 miles.

BLACKWELL, Thomas, in *Biography*, was the ſon of one of the miniſters at Aberdeen, and born in that city in the year 1701. He was educated at the grammar ſchool and mariſchal college of his native place, of which, in 1723, he was appointed Greek profeſſor, and in this office he contributed in no ſmall degree to promote Greek literature, and the ſtudy of the claſſics in general. In 1735, his "Enquiry into the Life and Writings of Homer," 8vo. was publiſhed without his name; and by its popularity ſerved to eſtabliſh his reputation for learning and ingenuity. Of this work, diſcuſſing a variety of topics without any very obvious connection, Dr. Bentley is ſaid to have remarked, "that when he had gone through half, he had forgotten the beginning; and that when he had finiſhed the peruſal of it, he had forgotten the whole." It is reckoned, however, the author's principal performance, and is both curious and entertaining. His "Letters concerning Mythology," 8vo. were publiſhed in 1748; and they were intended to eſtabliſh a regular ſyſtem of ancient fable, as an allegorical repreſentation of the religion, law, and philoſophy of early times. The work is learned, fanciful, and deſultory. In this year Dr. Blackwell was appointed principal of the Mariſchal college, and allowed his office of Greek profeſſor. In 1751, he announced to the public his deſign of publiſhing a new edition of Plato's works; but this deſign was never executed. The firſt volume of "Memoirs of the Court of Auguſtus," 4to, was publiſhed in 1753; the ſecond in 1755; and the third, after the author's death, in 1764. The object of this work is to exhibit, in an elegant and popular form, the principal facts of Roman hiſtory, at the commencement and during the period of the public life and reign of Auguſtus. It is written with vivacity, and was at firſt well received; but the affected caſe and familiarity of the ſtyle, united with a conſiderable degree of that pompous kind of pedantry, which diſplays not only erudition but a knowledge of the world, has contributed to lower its reputation. This work manifeſts alſo a republican ſpirit, not altogether free from party prejudice. The author's affected mode of writing increaſed as he advanced in years; and though it muſt be acknowledged, that he poſſeſſes genius and fancy, and had a reliſh for the beauties of ancient authors, he never acquired that ſimplicity of taſte, which leads to the true eaſe and elegance of compoſition. This peculiar ſtyle and manner of compoſition have been attributed to an injudicious imitation of lord Shafteſbury. Some years before his death Dr. Blackwell's health declined; and his diſorder being of the conſumptive kind, which he is thought to have increaſed by his abſtemious mode of living, he was under a neceſſity of remitting his ſtudies, and adviſed to travel: but with this view he could proceed no farther than Edinburgh, where he died in 1757, the 56th year of his age. His temper was ſingularly mild and equable; and he retained his natural vivacity and chearfulneſs through the whole period of his illneſs, and till the hour of his death. In converſation he was inſtructive and entertaining; and he blended a conſiderable knowledge of the world and urbanity of manners with an extenſive acquaintance with ancient and modern authors. But it was his foible, that he was apt to aſſume the appearance of univerſal knowledge; and this weakneſs betrayed him into converſation on philoſophical and mathematical ſubjects, with which his acquaintance was very imperfect. Among his friends and correſpondents were many perſons of literary eminence; and it is ſaid, that his patrons propoſed to introduce him into the profeſſorſhip of modern hiſtory at Cambridge, if he had not died before a vacancy occurred. Biog. Brit.

Blackwell, Elizabeth, widow of Alexander Blackwell, M.D. author of "A New Method of improving cold, wet, and clayey ground," 1741, London, 8vo. Rejecting dung and other manures, he depended entirely on repeated ploughing and turning the ground. He died a miſerable death in Sweden. His widow, being left in indigence, undertook, by the advice of her friends, to publiſh an account of 500 medicinal plants, to be drawn, engraved, and the greater part of them coloured by herſelf. The plants were furniſhed by Rand and Miller, from the botanical garden, belonging to the company of apothecaries, at Chelſea. They are, in general, Haller ſays, faithfully delineated. In ſome parts, however, ſhe has failed. Not well inſtructed in the Linnæan ſyſtem, ſhe has not delineated the fibres or filaments of the flowers with the accuracy now required. A ſhort account is annexed of the medicinal virtues of each of the plants, ſome of which are extremely rare. The firſt volume of this work was firſt publiſhed in 1737, and the ſecond in 1739, when the whole was publiſhed in 2 vols. fol. under the title of "A curious Herbal, &c.;" and it is creditable to the authoreſs to ſay, that this bulky and expenſive work paſſed through ſeveral editions. The laſt, which came out in 1760, in 5 vols. folio, at Nuremburg, is furniſhed with a preface and conſiderable additions by James Trew. After his death, in 1769, a ſupplemental volume, conducted by Ludwig, Boſc, and Boehmer, was printed in 1773. This work has been in a great meaſure ſuperſeded by Dr. Woodville's SS. Medical Botany, in 4 vols. 4to. Haller. Bib. Bot. Pulteney's Hiſt. and Biog. Sketches of the Progreſs of Botany in England, vol. ii. p. 254.

BLACKWOOD, Adam, was born at Dumferline, in Scotland, in 1539, and educated at Paris under Turnebus and Dorat. He was particularly patronized by Mary queen of Scots; and when he had finiſhed his law ſtudies at Toulouſe, he obtained the office of counſellor to the preſidial of Poictiers, which was Mary's dowry-town. In this place he ſettled and married; and, during the impriſonment of Mary, took ſeveral journies to England with a view of ſerving her. He died in 1613. His religious and political ſentiments may be deduced from the titles of his works, which were written both in verſe and proſe. Of theſe the principal were, "Caroli IX. pompa funebris verſibus expreſſa," Paris, 1754; "De vinculo religionis et imperii, et de conjunctionum inſidiis, religionis fuco adumbratis," 1575; "Adverſus G. Buchanani dialogum de jure regni apud Scotos, &c." Poitiers, 1581; "Martyre de Marie Stuart, reine d'Ecoſſe," &c. &c. His account of the execution of Mary Stuart is a virulent invective againſt queen Elizabeth, her parentage, her right to the crown, her government, &c. His works were collected and publiſhed in a 4to. volume by Gabriel Naudé, in 1644, with an eulogy of the author prefixed. Moreri. Gen. Biog.

BLADDER, in *Anatomy*, is a membranous bag, ſerving as a reſervoir for ſome ſecreted fluid. That which is conſidered as the chief receptacle of this kind, is the urinary bladder. As the anatomy of theſe parts, in general, will be deſcribed with that of the organ which prepares the fluid which they are intended to contain; therefore, for the ſake of uniformity of method, the deſcription of the urinary bladder

bladder is given with that of the kidneys and other urinary organs. See KIDNEY.

BLADDER, *Diſeaſes of the*, in *Surgery*. This *viſcus* being ſupplied with nerves, blood-veſſels, abſorbents, and muſcular fibres, will be neceſſarily liable to all the common diſorders of ſoft parts; ſuch as *wounds*, *inflammation*, *ulceration*, *gangrene*, *palſy*, *contraction*, *dilatation*, *rupture*, &c. But, beſides theſe affections, the bladder is ſubject to other morbid changes, which occur very rarely or not at all in moſt other parts of the body. It is ſometimes included among the contents of a herniary ſac. See HERNIA. Partial bags, or faculi may likewiſe form in the coats of the bladder, ſo as to retain one or more calculous bodies generated in the urine. See CALCULUS, CYSTOTOMY, LITHOTOMY, and STONE. Fungous, painful, and dangerous exceſcences ariſe alſo on the inner ſurface of this organ, which are frequently denominated *cancers*, and are perhaps equally fatal in their conſequences. Theſe diſorders will, in general, produce either a retention or a preternatural evacuation of urine, and require a peculiar plan of treatment adapted to the diverſity of ſymptoms. See URINE, *Retention of*, &c. &c.

BLADDERS, *veſiculæ*, in *Botany*, a kind of air-bags found in ſome ſpecies of fucus.

Vegetable bladders are found every where, in the ſtructure of the bark, the fruit, pith, and parenchyma, or pulp; beſides thoſe morbid ones raiſed on the ſurface of leaves by the puncture of inſects.

BLADDER, *ſwimming*. See AIR-*bladder*.

BLADDERS, *oil*, in the *Anatomy of Plants*. See OIL-*bladders*.

BLADDER, *puceron*, in *Entomology*. See CHERMES.

BLADDER-*nut*, in *Botany*. See STAPHYLÆA.

BLADDER-*nut*, *African*. See ROYENA.

BLADDER-*nut*, *laurel-leaved*. See HOLLY.

BLADDER *ſena*. See COLUTEA.

BLADDER-*ſhaped*, *inflatus*, denotes inflated or diſtended like a blown bladder; ſuch are the cup of the bladder campion, and the bloſſom of the fig-wort.

BLADDER-*ſpout*. See UTRICULARIA.

BLADDER-*wort*, *common*. See UTRICULARIA.

BLADE, in *Agriculture*, a ſpire of graſs, or green ſhoot of corn.

BLADE, in *Anatomy*. See SHOULDER-*blade*.

BLADE *of an Anchor*, denotes that part of the arm on which the palm is ſhut.

BLADE, in *Commerce*, a thin ſlender piece of metal, either forged by the hammer, or run and caſt in moulds, to be afterwards ſharpened to a point, edge, or the like. Sword-blades are made by the armourers, knife-blades by the cutlers, &c. The Engliſh and Damaſcus blades are moſt eſteemed. Among the French, thoſe of Vienne and Danphiny have the preference. The conditions of a good blade of a ſmall ſword are, that it be light and tough, apter to bend than break. When it will ſtand in the bend, it is called a *poor man's blade*.

BLADE *of a Chiſſel*, is the iron or ſteel part, as diſtinguiſhed from the wooden handle.

BLADE *of Mace*, or cinnamon, among apotheearies, are little ſlips or ſlices of thoſe barks.

BLADE *of an Oar*, is that part which is plunged into the water in rowing. On the length of this do the force and effect of the oar, in a great meaſure, depend.

BLADE *of a Saw*, the thin part wherein the teeth are cut, which, to be good, muſt be ſtiff, yet bend equally into a regular bow all the way, without yielding more in one place than another.

BLADE-*mill*, is that contrived for grinding iron tools, as ſcythes, reaping hooks, axes, chiſſels, and the like, to a bright edge.

BLADED, in *Heraldry*, is a term uſed when the ſtalk or blade of any kind of grain or corn is borne of a colour different from that of the ear or fruit: thus, *argent an ear of wheat or* BLADED *vert*.

BLADEN, in *Geography*, a county of North Carolina, in the diſtrict of Wilmington; having 5084 inhabitants, including 1676 ſlaves.

BLADENSBURG, a poſt town of America, in Prince George county, Maryland, on the eaſtern bank of the eaſtern branch of Potowmack river, at the confluence of the N.W. and N.E. branches, 9 miles from its mouth at the Federal city, 38 S.W. from Baltimore, and 12 N.E. from Alexandria, in Virginia. It contains about 150 houſes.

BLADHIA, in *Botany*, ſo named by Thunberg, from Peter John Bladh, a Swede, reſident at Canton. Lin. gen. Schreb. n. 370. Thunb. nov. gen. 6. fl. jap. 7. Claſs and order, *pentandria monogynia*. Gen. Char. *Cal.* perianth one-leafed, very ſhort, permanent, five-parted; parts ovate, concave, ſpreading, torn-ſubſerrate. *Cor.* one-petalled, wheel-ſhaped, five-parted; parts ovate, obtuſe, ſpreading. *Stam.* filaments five, very ſhort; anthers heart-ſhaped, acute, converging into a cone; ſhorter than the corolla. *Piſt.* germ ſuperior; ſtyle filiform, longer than the corolla; ſtigma ſimple, acute. *Per.* berry globoſe, crowned by the permanent ſtyle, one-celled. *Seed* ſingle, globoſe, involved in a membrane.

Eſſ. Char. *Cor.* wheel-ſhaped, deciduous. *Berry* containing one arilled ſeed.

Species, 1. B. *japonica*. Lin. Syſt. 236. Thunb. jap. 95. t. 18. Kœmpf. Amœn. 5. 776. (Quackitz.) "Leaves ſerrate ſmooth." 2. B. *villoſa*. Lin. Syſt. 237. Thunb. jap. 96. t. 19. "Leaves ſerrate, villoſe." 3. B. *criſpa*. Lin. Syſt. 237. Thunb. jap. 97. Kœmpf. Amœn. 5. 776. 2. ic. ſelect. t. 7. "Leaves oblong, curled, ſmooth." All theſe are natives of Japan. Thunberg has another ſpecies among his obſcure plants, jap. p. 350. Martyn.

BLADUM, in *Middle Age Writers*, is taken for all ſorts of ſtanding corn in the blade and ear. The word is alſo written *blatum*, *blava*, and *blavium*. In our old charters, the word bladum included the whole product of the ground, fruit, corn, flax, graſs, &c. and whatever was oppoſed to living creatures. The word bladum was ſometimes alſo applied to all ſorts of grain or corn threſhed on the floor: *tria quarteria frumenti, tria quarteria avenarum, & unum quarterium ſabarum, erunt quieti de ſolutione prædicti bladi in perpetuum*. But the word was more peculiarly appropriated to bread corn, or wheat, called in French *ble*. Thus the Knights Templars are ſaid to have granted to ſir Wido de Merton's wife *duas ſummas bladi*. Kennet's Paroch. Ant. and Du-Cange.

Hence *bladarius* denotes a corn-monger, meal-man, or corn-chandler; and it is uſed in our records for ſuch a retailer of corn. Pat. 1. Ed. III. par. 3. m. 13. And *bladius* ſignifies an ingroſſer of corn or grain.

BLAE, in *Ornithology*, among French writers, an African bird of the falcon tribe deſcribed by Latham under the name of *falco melanopterus*, which ſee.

BLÆRIA, in *Botany*, ſo denominated from Patrick Blair, M.D. Lin. gen. n. 139. Reich. 145. Schreb. 183. Juſſ. 160. Claſs and order, *tetrandria monogynia*. Nat. Ord. *Bicornes*. *Ericæ*. Juſſ. Gen. Char. *Cal.* perianth four-parted; leaflets linear, erect, a little ſhorter than the corolla, permanent. *Cor.* monopetalous, campanulate; tube cylindric, the length of the calyx, pervious; border ſmall, four-cleft;

 diviſions

divisions ovate, reflex. *Stam.* filaments four, setaceous, the length of the tube, inserted into the receptacle; anthers oblong, compressed, erect, obtuse, emarginate. *Pist.* germ four-cornered, short; style setaceous, much longer than the corolla; stigma obtuse. *Per.* capsule obtuse, quadrangular, four-celled, gaping at the angles. *Seeds*, some roundish. *Obs.* The anthers are emarginate, but not horned, as in *erica*, allied to this.

Ess. Char. *Cal.* four-parted. *Cor.* four-cleft. *Stam.* inserted into the receptacle. *Caps.* four-celled, many-seeded.

Species, 1. B. *ericoides*, heath-leaved B. "Anthers awnless, standing out; calyxes four-leaved; bractes the length of the calyx; leaves in fours, oblong-acerose, hairy, imbricate." This has the stature of the common heath. Flowers terminating, white with a tinge of purple; corollas tubulous, erect; anthers two-parted, scabrous; style capillary, longer than the anthers. Introduced into Kew garden in 1774 by Mr. F. Masson. 2. B. *ciliaris*, ciliated B. "Flowers in a head, calyxes ciliate." Resembling the preceding, and readily known by its white calyxes, most distinctly ciliate. 3. B. *articulata*, jointed-leaved B. Penæa Sarcocolla. Berg. cap. 25. "Stamens protruded, two-parted; corollas cylindric." A distorted shrub, of the stature of common heath. Leaves in fours, pressed to the branches; heads of flowers terminating, with white-villose calyxes; corollas flesh-coloured; anthers very narrow, black; differing from the first in having equal stamens, and leaves more imbricated. 4. B. *purpurea*, purple-flowered B. "Stamens included, two-parted; corollas oblong, straight; flowers terminating, aggregate; peduncles erect." Like the third; but the heads are nodding. 5. B. *pusilla*, dwarf B. "Flowers scattered; corollas funnel-form." This has the stature of small heath. Branches pubescent; leaves in fours, rugged, petioled, scored underneath with a line; flowers minute, scattered, shorter than the leaves. 6. B. *muscosa*, moss-leaved B. Ait. Hort. Kew. 1. 150. "Anthers awnless, almost standing out; calyxes one-leafed, hairy; corollas bell-shaped, hairy in the upper part; flowers axillary; stigmas peltate." Found at the cape of Good Hope by Mr. F. Masson, and introduced in 1774; flowering from June to August.

Propagation and Culture. These are all shrubs, inhabitants of the cape of Good Hope, require the same treatment and shelter with other Cape plants in the dry stove, and may be increased by cuttings, like the ericas, or heaths, which they much resemble. Martyn.

BLÆSLING, in *Ornithology*, one of the synonymous names of the *greater coot* of English writers, and *fulica aterrima* of Linnæus. Vide *Günther Nest. und. Eyer.* The common coot, *fulica atra* of Linnæus, is also named by this author *kleiner blaesling*.

BLÆSUS, in *Medicine*. See Stammering.

BLAGAITZKI, in *Geography*, a town of Croatia, 10 miles N.N.W. of Sluin.

BLAGNAC, a town of France, in the department of the Upper Garonne, and chief place of a canton, in the district of Toulouse, on the Garonne; 3 miles N.W. of Toulouse.

BLAGOVETSCHENSKOI, a town of Russia, in the government of Archangel, near the south-east coast of the White sea; 70 miles S.W. of Archangel.

BLAGRAVE, John, in *Biography*, an English mathematician, was born of an ancient and honourable family at Bulmarsh court near Sunning in Berkshire, towards the middle or close of the 16th century, and educated, first at a school in Reading, and afterwards at St. John's college, Oxford. Before he took any degree he retired from the university to his patrimonial seat at South-cote lodge, near Reading, where he diligently pursued his studies, particularly mathematics. His works, of which we have any account, are "A Mathematical Jewel," shewing the construction and use of an instrument so called, and its application to astronomy, cosmography, geography, &c. Lond. 1585, fol.; "The Construction and Use of the Familiar Staff, &c.," performing the geometrical mensuration of all altitudes, Lond. 1590, 4to.; "Astrolabium Uranicum generale," containing the use of an instrument, or astrolabe, Lond. 1596, 4to.; and "The Art of Dialling, in two parts," Lond. 1609, 4to. Mr. Blagrave was distinguished by his benevolence, both during his life, and at his death. Having never been married, he bequeathed 50l. to each of the children of his three brothers, or their posterity, payable at the age of 26; and his bequests in this way were so well adjusted, that near 80 of his nephews and their descendants were thus benefited out of his leasehold estate. He also bequeathed lands for producing an annual donation of 10l. to a maid-servant in the town of Reading, according to the directions of his will. These directions required, that the church-wardens of each of the three parishes should on Good Friday send one virtuous maid, who had lived five years with her master. The three maids were to appear in the town-hall before the mayor and aldermen, and to cast dice. She, whose throw was the greatest, received the ten pounds. The two maids who had lost were to appear the next year, together with a third added to them. Accordingly each maid was to have by his will the chance of three annual throws; but if any failed in three successive years, he orders new persons to be presented. On the same Good Friday, money is distributed to 80 widows in pursuance of his will, who attend a sermon for which the preacher is to receive ten shillings. Mr. Blagrave died Aug. 9th 1611, and was buried in the church of St. Lawrence, Reading, where a sumptuous monument is erected to his memory. Biog. Brit.

BLAGRE, in *Ornithology*. Under this name Levaillant describes the African species of eagle called by Latham *falco blagrus*, which see.

BLAIN, a distemper incident to beasts, consisting in a bladder growing on the root of the tongue against the windpipe, which at length swelling stops the breath.

It comes by great chasing and heating of the stomach; whereby, as some judge, it still grows and increases by more heat.

It is perceived by the beast's gaping, holding out his tongue, and foaming at the mouth: to cure it, cast the beast, take forth his tongue, and then slitting the bladder, wash it gently with vinegar and a little salt.

Blain, in *Geography*, a town of France, and principal place of a district in the Lower Loire. The population of the place consists of 1897 persons, and of the canton of 10,274; its territorial extent is 342½ kiliometres, and it includes 4 communes; 18 miles N.N.W. of Nantes, and 40 S. of Rennes.

BLAINVILLE, in *Biography*, a learned musician of Paris, who proposed, in 1751, a third mode or key, which he called *a mixed mode*, because it participates of the modulations of the two other, or rather from its being compounded of both, a mixture which the author does not regard as an inconvenience, but rather as an advantage and source of variety both in the melody and harmony. Rousseau. Dict. de Musique, published 1768.

Blainville, a performer on the violoncello, and music-master at Paris, who had many symphonies and motets performed at the Concert Spirituel, in the middle of the last century,

century, without ſucceſs; but abandoning the *practice* of harmony or compoſition, in order to try his force in the *theory*, in 1751, he produced "L'Harmonie theorico-practico; in 1754, "L'Eſprit de l'Art Muſical;" in 1765, "L'Hiſtoire générale, critique, et philologique de la Muſique." Theſe works are no better than his ſymphonies. They are compilations without taſte, which teach nothing new to thoſe who know any thing about muſic already; and not enough to thoſe who know nothing. In 1751, he had the courage to publiſh as a diſcovery a pretended *new mode*, a key different from the major and minor, which, he ſaid, was neither major nor minor, but *mixed* of both. He compoſed a ſymphony in this new mode, and had it performed at the Concert Spirituel, which gave birth to many diſſertations and diſcuſſions, &c. Laborde, Eſſai ſur la Muſique, tom. iii. p. 577.

"Who ſhall decide, when doctors diſagree?"

The *new mode*, as it was called, was attacked by the ingenious and ſpeculative writer on muſic, M. Seric of Geneva, and defended by Rouſſeau in his Dictionary. Thirty years after, it became the ſubject of a very long article in M. Laborde's Eſſai ſur la Muſique, merely to attack Rouſſeau for having defended it. In this attack of the dead lion, the abbé Rouſſier was *bottle-holder* to his friend Laborde.

All theſe gentlemen ſeem utterly ignorant of the church muſic of the 15th and 16th century, built on the ancient eccleſiaſtical modes, in which nothing was more common in the maſſes of the old maſters, than for a movement beginning in A minor to end on the fifth of that key, with a ſharp third, which would be called now a *ſemi-cadence*. The melody of the ſeveral parts is equally in the ſcale of C and A natural, which, without accidental flats or ſharps, produces nothing but different ſpecies of octaves in the key of C natural. But calling E the key note inſtead of A, it has a peculiarity in the ſecond, which, inſtead of being a tone major above the key note, is only a major ſemitone.

Now Dr. Pepuſch, who rigidly adhered to the laws of the eccleſiaſtical modes in his "Treatiſe on Harmony," ſo late as 1731, in ſpeaking of the key of E as formed of one of the ſpecies of octave in the ſcale of C natural, has explained the properties of this key with only a major ſemitone for its ſecond, much better than Blainville, or any of his defenders or opponents, and terminates his remarks on this key, by ſaying that "it differs from all others; for *they* are introduced by the ſemitone major *below* them, but this is by the ſemitone major *above* it; *they* by their *ſeventh* major, but *this* by its *ſecond*, which happens to be *minor; that is* from F downwards to E. It is becauſe of this difference and peculiarity in its modulation, which makes what is compoſed in it to be very *ſolemn*, that this key is as it were appropriated to church-muſic, and called by the Italians *tuono di chieſa*." p. 65.

But the doctor does not call it a *new key*, for it is as old as counterpoint; and we ſhould ſuppoſe that Blainville had either ſeen Dr. Pepuſch's treatiſe, or found in ſome old maſs a movement that ended on the fifth, inſtead of the key note, and wiſhed to paſs for an *inventor*. But it is plain, that all the French gentlemen, who took a part in this controverſy, were diſputing about the *dent d'or*, before they had aſcertained its exiſtence. In examining the maſſes of Joſquin, Paleſtrina, and the cantiones of Tallis and Bird, we find movements of the deſcription of Dr. Pepuſch's *tuono di chieſa*. And in Padre Martini's "Saggio di Contrepunto," tom. i. p. 42. he calls this mode *il terzo tuono autentico*, the third authentic mode, which Blainville calls the *new* or *mixed* mode; and P. Martini even calls it *terzo tuono* miſto *del quarto ſuo plagale*, p. 44. He gives the ſame natural ſcale for its intervals as Rouſſeau and Blainville, EFGABCDe, p. 51. An example of this *mixed* mode is given from Paleſtrina, in which no accidental ſharps are marked, though it modulates into G major, A minor, C ♯, and G a ſecond time. A ſharp only is given to G upon the cloſe note, as ſharp third to the final E.

In 1756, Blainville publiſhed what he called "A general, critical, and philological Hiſtory of Muſic;" a work for which the author's materials ſeem to have been ſo ſcanty, that he was reduced to fill two thirds of his thin quarto with an indigeſted treatiſe on compoſition.

Blainville, in *Geography*, a town of France, in the department of La Manche, or the Channel, and chief place of a canton, in the diſtrict of Coutances, 5 miles weſt of Coutances, and 13 north of Granville.

Blainville *ſur l'Eau*, a town of France, in the department of the Meurte, and chief place of a canton, in the diſtrict of Luneville, 4 miles S.W. of Luneville, and 12 S.E. of Nancy.

BLAIR, John, in *Biography*, a chronologer and geographer, was born in Scotland, and educated at Edinburgh. Upon his firſt arrival in England, he was uſher at a private ſchool; and firſt appeared with ſingular advantage before the public by publiſhing, in 1754, a work intitled "The Chronology and Hiſtory of the World, from the Creation to the year of Chriſt 1753, illuſtrated in 56 tables, of which four are introductory, and contain the centuries prior to the firſt olympiad; and each of the remaining 52 contains in one expanded view 50 years, or half a century; by the Rev. John Blair, L.L.D." This comprehenſive work, on which the author muſt have beſtowed a very great degree of attention and labour, was publiſhed by ſubſcription, and dedicated to lord Hardwicke; and the author acknowledges great obligations to the earl of Bath. Dr. Blair appears at this time to have taken orders in the Engliſh church; in 1755, he was elected fellow of the Royal Society, as he was of the Antiquarian Society in 1761. In 1756, he publiſhed a ſecond edition of his Tables; and in 1757, he was appointed chaplain to the princeſs dowager of Wales, and mathematical tutor to the duke of York. In 1761, he obtained a prebendal ſtall at Weſtminſter, and ſeveral church preferments in very quick ſucceſſion. From the vicarage of Hinckley, in Leiceſterſhire, which he held, by diſpenſation, with the rectory of Burton Coggles, in Lincolnſhire, he was promoted firſt to the vicarage of St. Bride's, in London, in 1771, and, in 1776, to the rectory of St. John the Evangeliſt in Weſtminſter, with which he held that of Horton near Colebrooke, in Buckinghamſhire. During the years 1763 and 1764, he accompanied the duke of York in his travels on the continent. In 1768, he publiſhed an improved edition of his "Chronological Tables," which he dedicated to the princeſs-dowager; and to this edition he annexed 14 maps of ancient and modern geography, and prefixed a diſſertation on the riſe and progreſs of this ſcience, which was alſo printed ſeparately in 12mo. His death, which happened June 24th 1782, was probably accelerated by the ſhock that attended the news of his brother, captain Blair's death in the memorable ſea-fight of April 12, 1782; more eſpecially as he then was ſeverely afflicted with an epidemic influenza. After his death, in 1785, his "Lectures on the canon of the Scriptures, comprehending a diſſertation on the Septuagint verſion," were publiſhed; and a new edition of his "Chronological Tables," extended to the year 1790, appeared in that year. Biog. Dict.

Blair, Patrick, practiſed phyſic and ſurgery at Dundee, in Scotland, where he was probably born. He firſt became known in 1706, by his account of the anatomy of an elephant, which he had the opportunity of diſſecting there. It was publiſhed in the Philoſophical Tranſactions, Nos. 326

and 327, in the year 1710. It contains an accurate deſcription of the proboſcis and its muſcles, and confirms, Haller ſays, the opinion formerly given, that the elephant has no gall-bladder. In a ſubſequent number of the Tranſactions, he gives a deſcription of the officula auditus, accompanied with engravings. In the rebellion, in 1715, being ſuſpected, on account of his religious principles, of hoſtility to government, he was for a ſmall time confined. He came afterwards to London, where he re-publiſhed his "Anatomy of the Elephant," in 4to.; and, in 1718, publiſhed a volume of "Miſcellaneous obſervations on the practice of phyſic, anatomy, ſurgery, and botany," in 8vo. This was followed, in 1720, with "Botanical Eſſays," in two parts, alſo 8vo. with figures, in which he treats of the ſexes of plants, confirming the arguments adduced in proof of them by ſound reaſoning, and ſome new experiments of the manner of fecundation, of the circulation of the ſap, &c. This work ſtill retains its credit among botaniſts, although ſome of the author's opinions are abandoned. About the ſame time, he gave an account of the aſbeſtus, found in the county of Angus, in Scotland, printed in the Phil. Tranſ. N° 333; and of the diſſection of an emaciated child, in which he could find no veſtige of the omentum, Id. N° 353; and alſo of a boy, who lived a conſiderable time without food, Id. N° 364; and in the ſame number is alſo a diſſertation on the means of diſcovering the medicinal properties of plants from their external figure. He ſoon after ſettled at Boſton, and publiſhed "Pharmaco-botanologia," or an alphabetical and claſſical diſſertation on all the Britiſh indigenous and garden plants of the London Diſpenſatory, in ſeven decades, 4to. 1723 and 1728, introducing ſome plants, which he had firſt diſcovered growing near Boſton. The work only proceeded to the letter H. The time of his death is not known. Haller. Bib. Anat. et Botan. Pulteney's Sketches, vol. ii. p. 134, &c.

Blair, James, an epiſcopalian divine, was born and educated in Scotland, where he was ordained and beneficed; but meeting with ſome diſcouragements in that country, he quitted his preferments, and removed to England, about the latter end of the reign of king Charles II. Being introduced to Dr. Compton, then biſhop of London, he prevailed on him to go, about the year 1685, as a miſſionary to Virginia, where by his conduct and miniſterial labours he was eminently ſerviceable in promoting the cauſe of religion. In 1689, he was appointed by the ſame prelate as his commiſſary for the province. Intent upon doing good in the office with which he was entruſted, he obſerved with concern, that the want of proper ſeminaries for religion and learning obſtructed every attempt for propagating the goſpel in this colony; and he therefore formed the benevolent deſign of erecting and endowing a college at Williamſburg, the capital of Virginia, for profeſſors and ſtudents in academical learning. With this view he raiſed a conſiderable ſum of money by voluntary ſubſcription; and, in order the more effectually to accompliſh his purpoſe, he came over into England in 1693, to ſolicit the concurring aid of government. King William and queen Mary very much approved the deſign, and accordingly a patent was iſſued for erecting and endowing a college, which was to be denominated from its founders, "the college of William and Mary." Mr. Blair, who firſt projected the ſcheme, was appointed preſident of the college. (See Williamsburgh.) He was alſo rector of Williamſburg and preſident of the council in that colony. Having faithfully and honourably diſcharged the duties of his office as preſident of the college for about 50 years, and thoſe of his miniſterial function for above 60 years, he finiſhed his courſe of laborious and uſeful ſervice in the year 1743. His works, compriſing "Our Saviour's divine Sermon on the Mount explained, and the practice of it recommended, in divers ſermons and diſcourſes, with a recommendatory preface, by the Rev. Dr. Waterland," were publiſhed in 1740, 4 vols. 8vo. Waterland's Preface. Burnet's Hiſt. of his own Times, vol. iii. p. 165. 8vo.
