Blair, Hugh, a diſtinguiſhed preacher and writer, the deſcendant of an ancient family of Ayrſhire, in Scotland, and the ſon of a reſpectable merchant at Edinburgh, was born in that city, April 7th 1718. As his views were at an early period directed towards the church, he entered the univerſity of his native place in 1730, and ſpent eleven years in the aſſiduous proſecution of thoſe literary and ſcientific ſtudies which the church of Scotland preſcribes to ſuch as profeſs themſelves candidates for the miniſterial office. During this period his application and proficiency gained repeated teſtimonies of approbation from the profeſſors under whom he ſtudied. One of his performances at this time, indicating the bent of his genius towards polite literature, was an eſſay Περὶ τοῦ καλοῦ, or "On the Beautiful," which afforded ſuch ſatisfaction to profeſſor Stevenſon, that it was appointed to be publicly read at the concluſion of the ſeſſion. This honour, without doubt, ſtimulated his emulation, and proved the earneſt of his future fame. The method of ſtudy, which he commenced at college, and which he occaſionally practiſed in his maturer years, contributed in a conſiderable degree to the accuracy and extent of his knowledge. It conſiſted in making abſtracts of the moſt important works which he read, and in digeſting them according to the train of his own thoughts. This was the method in which he ſtudied hiſtory in particular; and with this view, aided by ſome of his youthful aſſociates, he conſtructed a comprehenſive ſeries of chronological tables, in which was inſerted every important fact that occurred. In conformity to this plan, his learned friend Dr. John Blair formed his valuable work already noticed under his article. In 1739, Mr. Blair took his degree of maſter of arts; and on this occaſion he printed and defended, in elegant Latin, a theſis, "De Fundamentis et Obligatione Legis Naturæ." Having completed his academical courſe, he paſſed through the cuſtomary trials before the preſbytery of Edinburgh, and was licenſed as a preacher, October 21ſt 1741; and in the following year he was preſented to the pariſh of Coleſſie in Fife, where he was ordained Sept. 23d 1742. Such at this time was his eſtabliſhed reputation as an eloquent preacher, that when a vacancy occurred in the Canongate church of Edinburgh, he was choſen at a conteſted election to ſupply it; and accordingly he returned to his native city in July 1743. In this ſituation he continued for eleven years, exhibiting ſpecimens of thoſe talents for pulpit-compoſitions, which have ſince obtained diſtinguiſhed teſtimonies of public approbation. In 1754, he was tranſlated from the Canongate to lady Yeſter's, one of the city churches; and in 1758, he was promoted to the High Church of Edinburgh, the moſt important eccleſiaſtical charge in North Britain. To this honourable rank he was advanced at the requeſt of the lords of council and ſeſſion, and of other diſtinguiſhed perſons holding public offices, who attend that church; and the wiſdom of their choice was amply juſtified by the prudence, ability, and ſucceſs, with which his miniſterial labours were conducted for a period of more than 40 years. Previouſly to his advancement to this ſtation of public ſervice, Mr. Blair's attention ſeems to have been almoſt wholly devoted to the attainment of profeſſional excellence, and to the regular diſcharge of his parochial duties. Of the productions of his pen, we have only two ſermons, preached on particular occaſions; ſome tranſlations, in verſe, of paſſages of Scripture for the

pſalmody

pfalmody of the church; and a few articles in a periodical publication intitled the "Edinburgh Review." See JOURNAL. From this time he enjoyed greater leiſure for directing his views to other important literary objects, beſides his weekly preparations for the pulpit; and, accordingly, he commenced, Dec. 11, 1759, with the approbation of the univerſity, a ſeries of lectures on compoſition. Of his qualifications for an office of this kind, none could entertain the leaſt doubt; they had been in ſome meaſure ſanctioned by the univerſity of St. Andrews, which, in June 1757, had conferred on him the degree of doctor in divinity, then very rarely beſtowed; and the ſucceſs that attended his firſt courſe, afforded ample evidence of the able manner in which it had been conducted. The patrons of the univerſity determined in the following ſummer to inſtitute a rhetorical claſs, under the direction of Dr. Blair, as a permanent part of their eccleſiaſtical eſtabliſhment; and on the 7th of April 1762, his majeſty was graciouſly pleaſed "to erect and endow a profeſſorſhip of rhetoric and belles lettres in the univerſity of Edinburgh, and to appoint Dr. Blair, in conſideration of his approved qualifications, regius profeſſor thereof, with a ſalary of 70l." The lectures which he delivered on this occaſion, were publiſhed in 1783, under the title of "Lectures on Rhetoric and Belles Lettres," in two volumes, 4to.; and they have been ſince frequently re publiſhed in 3 vols. 8vo. Of theſe lectures it will be ſufficient to obſerve, that the general voice of the public, not only in our own country, but in other nations on the continent into whoſe languages they have been tranſlated, has pronounced them to be a moſt judicious, elegant, and comprehenſive ſyſtem of rules for forming the ſtyle, and cultivating the taſte of youth. By a happy and ſingular union of taſte and philoſophy, the author has ſupplied a great defect in the ſcience of criticiſm, and has made a valuable addition to the polite literature of the preſent age. In the courſe of this Dictionary we ſhall have frequent occaſions for referring to this excellent work, and availing ourſelves of its inſtructive and uſeful contents. In 1763, Dr. Blair publiſhed "A Critical Diſſertation on the poems of Oſſian," which for beauty of language, delicacy of taſte, and acuteneſs of critical inveſtigation, has few parallels. As it was partly by his ſolicitation, that Mr. Macpherſon was induced to publiſh his "Fragments of Ancient Poetry," it is no wonder, that, independently of the teſt of criticiſm, he ſhould be a zealous advocate in favour of their authenticity and antiquity; but, notwithſtanding his able defence, a degree of ſcepticiſm has prevailed on this ſubject.

Dr. Blair's reputation as a preacher, or rather as a compoſer of ſermons, had been for a long time acknowledged by thoſe who had the pleaſure of attending on his miniſtry; but it was not till the year 1777, that he could be induced to favour the world with a volume of the diſcourſes which had ſo long furniſhed inſtruction and delight to his own congregation. The MS. of this volume, it is ſaid, was received by the bookſeller with ſome heſitation; but it was no ſooner publiſhed, than he found it his intereſt to engage the author to furniſh him with other volumes. Accordingly five volumes, in the whole, have been publiſhed at different intervals; and we may venture to affirm, that, liberally as the author was recompenſed, no collection of ſermons has ever been more profitable to the bookſeller, or more acceptable to the public, than Dr. Blair's. The circulation of them was rapid and extenſive. They were tranſlated into ſeveral foreign languages; and they received a royal reward. A penſion of 200l. a year, iſſuing out of the exchequer in Scotland, was conferred, in 1780, on the author, and it was continued without any alteration till his death. Theſe ſermons, though they poſſeſs various degrees of comparative excellence, and ſome muſt be allowed to be much ſuperior to others, are upon the whole models in their kind; and they will long remain as monuments of the piety, the genius, and ſound judgment of the author. Occupying a middle place between the dry metaphyſical diſcuſſions or controverſial ſpeculations of one claſs of preachers, and the looſe incoherent declamations of another, they blend the light of argument with the warmth of exhortation, the elegance of compoſition with judicious obſervations on human life, and practical knowledge with important principles of religion and virtue. The laſt volume was prepared for the preſs by the author after he had completed his eighty-ſecond year, and delivered to the publiſhers about ſix weeks before his death. Although he left many other diſcourſes in manuſcript, he explicitly enjoined that they ſhould be deſtroyed, and thus wiſely prevented that injury to his reputation which has ſometimes been the reſult of poſthumous publications. The author's fame, as a preacher, depended principally, if not wholly, on the intrinſic excellence of his diſcourſes, with reſpect to matter and compoſition; for we are informed, that his delivery, though diſtinct, ſerious, and impreſſive, was not remarkably diſtinguiſhed by that magic charm of voice and action, which captivates the ſenſes and imagination, and which, in the eſtimation of ſuperficial hearers, conſtitutes the chief merit of a preacher. Dr. Blair, in the exerciſe of his profeſſional duties, as far as they regarded the government of the church, was ſteadily attached to the cauſe of moderation. Diffident and unaccuſtomed to extemporary ſpeaking, he declined interfering in eccleſiaſtical politics, and never would conſent to become moderator of the general aſſembly of the church of Scotland; nevertheleſs, his opinion, which was always guided by ſound judgment, uniformly commanded deference and reſpect. Whilſt he was anxious to preſerve the church from a ſervile corrupting dependence on the civil power, on the one hand; it was his wiſh, on the other, to prevent a greater infuſion of democratical influence than he thought to be compatible with good order, and the eſtabliſhed conſtitution of the country. His reputation in public life was well ſuſtained by the great reſpectability of his private character; and he was eminently diſtinguiſhed through life by the prudence, purity, and dignified propriety of his conduct. With a mind free from envy, and yet not inſenſible to the eſtimation in which he himſelf was held; inflexibly upright, and yet condeſcending to his friends, and diſpoſed to enjoy the pleaſures of ſocial intercourſe; few men have paſſed through life more univerſally reſpected by thoſe who knew him, more ſincerely eſteemed in the circle of his acquaintance, or more tenderly beloved by thoſe who enjoyed the benefit of his private and domeſtic connection. His wife, to whom he was married in 1748, contributed for almoſt half a century to his felicity, and was taken from him a few years before his death; and his two children, a ſon and a daughter, died, the former in infancy, and the latter in her 21ſt year. His conſtitution was naturally delicate and feeble; but he enjoyed upon the whole a ſtate of good health; and by habitual chearfulneſs, temperance, and care, ſurvived the uſual term of human life. He retained his faculties to the laſt ſtage; and after a ſhort illneſs of three days, expired on the 27th of December 1800, with the compoſure and hope of a Chriſtian paſtor; and his funeral ſermon was preached by Dr. Finlayſon, who has annexed to the fifth volume of his Sermons a ſhort account of the life and character of the author, from which the preceding article is chiefly compiled.

BLAIR, in *Geography*. See ATHOL.

BLAIREAU, in *Zoology*, the common French name

of *urſus meles*, or badger. A variety of a white colour found in New York is alſo called in France *blaireau blanc*.

Blaireau *puant du Cap de Bonne Eſperance*. Kolbe, and after him Abbé de la Caille, have deſcribed under this title a little quadruped found in the interior of Africa, which exhales a moſt inſupportable odour. Whether it be of the badger kind in reality, or not, is uncertain. Sonnini believes it to be of the civet kind, *viverra Capenſis*; and on the contrary, Gmelin ſuppoſes it to be of the glutton kind, perhaps a variety of *urſus gulo*.

BLAIRIA, in *Botany*. See Verbena.

BLAISE, St., *Order of*, was founded in Armenia, about the commencement of the twelfth century. The habit of the knights of this order was a ſky-blue; and on the breaſt thereof was embroidered their badge, being a *croſs of gold*.

Blaise. *St. Blaiſe and the Virgin Mary* was an order eccleſiaſtical and military. The particular time of its inſtitution is not abſolutely aſcertained; but it is univerſally agreed that it took place ſoon after that of the Knights Templars. The badge of the order was a *red croſs, on the centre of which was a medallion with the image of St. Blaiſe enamelled thereon*. When the knights aſſembled in chapter, or ſet out on any military expedition, they wore on their breaſt the ſame badge embroidered on a white habit.

Blaise, in *Geography*, a town of France, in the department of the Upper Marne, and chief place of a canton, in the diſtrict of Chaumont, 12 miles N.N.W. of Chaumont. —Alſo, a river of France, which runs into the Marne near Larzicour, in the department of the Marne.

Blaise, or Blas, St., a cape on the coaſt of Weſt Florida, in the gulf of Mexico. It is a promontory, which ſeparates the bay of Apalache on the eaſt from that of Penſacola, forming a kind of ſhepherd's crook. N. lat. 29° 40'. W. long. 86°.

BLAISOIS, a province of France before the revolution, bounded on the eaſt by Orleannois, on the ſouth by Berry, on the weſt by Touraine, and on the north by Vendomois and Dunois. The capital was Blois, which ſee.

BLAISON, a town of France, in the department of the Mayne and Loire, and chief place of a canton, in the diſtrict of Angers; 8 miles S.E. of Angers.

BLAKE, Robert, in *Biography*, a celebrated Engliſh admiral, was a deſcendant of an ancient family of the name in the pariſh of Spaxton and county of Somerſet, and born at Bridgwater, in Auguſt, 1589. Having received the rudiments of grammar learning at a free ſchool in his native town, he became a member of St. Alban's hall, Oxford, in 1615, and tranſlated himſelf from thence to Wadham college, where, in 1617, he took the degree of bachelor of arts. In 1619, he loſt a fellowſhip of Merton college, for which he was a candidate, on account of his low ſtature; ſir Henry Savile, the warden, paying particular reſpect to perſonal comelineſs. Soon after the year 1623, in which he wrote a copy of verſes on the death of Mr. Camden, he left the univerſity, where he had been noticed for his early riſing and application to ſtudy, and lived privately at Bridgwater. Adopting at an early period republican principles, and prejudiced againſt the eccleſiaſtical eſtabliſhment, by the ſeverity with which Dr. Laud, then biſhop of Bath and Wells, enforced uniformity in his dioceſe, he inclined alſo to thoſe opinions that were deemed puritanical. Accordingly the puritan party prevailed in procuring his return as a member for his native town, to the parliament of 1640, but for the Long Parliament he loſt his election. Upon the breaking out of the war between the king and parliament, he declared for the latter, and entering into military ſervice, was ſoon appointed captain of dragoons. In this capacity he exhibited proofs of his talents by an obſtinate defence of Briſtol againſt the attack of prince Rupert, which he was at length obliged to ſurrender. In 1644 he was appointed governor of Taunton, which he had ſurpriſed and taken poſſeſſion of for the parliament, and which he defended with a ſmall but well-diſciplined garriſon, during a vigorous ſiege by the king's forces, till he obtained relief. For this ſervice the parliament voted Blake, who was then colonel, a preſent of 500 pounds. After the murder of the king, which he is ſaid to have diſapproved, he cordially joined the republican party, and was reckoned, next to Cromwell, the ableſt and moſt ſucceſsful officer in the ſervice of the parliament. Without affecting the character of a politician, he thought it his duty to ſerve his country to the utmoſt of his power, and to execute any meaſures that were adopted by the party to which he was attached, and by the exiſting government for this purpoſe. Early in the year 1649, he was appointed, in conjunction with Col. Deane and Col. Popham, to the command of the fleet; and his firſt naval expedition was directed, in 1649, againſt prince Rupert and prince Mauriee, to the harbour of Kingſale in Ireland; where he blocked them up for ſome time, and whence he purſued them to Liſbon, whither they had fled for the protection of the king of Portugal. War being declared on this account againſt the Portugueſe, Blake annoyed their trade, and took ſeveral rich prizes; and he afterwards proceeded, firſt to Carthagena and then to Malaga, in purſuit of prince Rupert. At the latter place he burnt and deſtroyed his whole fleet, two ſhips excepted; and in the beginning of the year 1651, he returned with his ſquadron to Plymouth, where he received the thanks of the parliament, and was appointed warden of the cinque ports. In the following year he was conſtituted one of the admirals and generals of the fleet, and employed in reducing the iſles of Scilly and the iſland of Guernſey. Having accompliſhed this ſervice, he was elected one of the council of ſtate; and in 1652, promoted to the rank of ſole admiral for nine months, in the proſpect of a Dutch war. The States, jealous of the naval power of England, determined to reduce it by a very vigorous effort. With this view they diſpatched Van Tromp with 45 ſail of men of war into the Downs, who was met by Blake with a much inferior force of 23 ſhips, and, after a very ſevere action, which took place May 19th 1652, obliged to retreat. After ſeveral ſkirmiſhes with the Dutch ſhips, and the capture of many prizes, during the progreſs of the ſummer, Van Tromp appeared again in the Downs, towards the cloſe of the year, with 80 ſhips, for the purpoſe of renewing his attack upon Blake. The Engliſh admiral, whoſe force was much inferior, and who had the diſadvantage of an unfavourable wind, diſdained however to retreat, and engaged the enemy on the 29th of November. Notwithſtanding every poſſible exertion, he loſt ſix ſhips, and was compelled to retreat into the Thames with his ſhattered fleet; and Van Tromp was left in triumphant poſſeſſion of the channel. Blake loſt no time in repairing and recruiting his fleet; and in February 1653, he ſet ſail in purſuit of his antagoniſt. On the 18th day of the month the Engliſh admiral, with 80 ſhips of war, came up off Portland with Van Tromp, who had 70, and a fleet of 300 merchant-ſhips under his convoy. The engagement was ſuch as ſeldom occurs in the hiſtory of naval combats; it laſted three days, and on both ſides equal valour was diſplayed; at length, however, after a running fight up the channel, the Dutch anchored ſafely in the ſands of Calais, having loſt 11 men of war, 30 merchant-ſhips, and 1500 men who fell in the action, whilſt the Engliſh loſt only one ſhip, but as many lives as the enemy. In this action Blake was wounded in the thigh.

At this time Cromwell diſmiſſed the parliament, and aſſumed the ſupreme power; nevertheleſs, Blake and his colleagues declared their fixed purpoſe to ſerve their country faithfully, and to guard it, by every effort in their power, againſt foreign injury and inſult. "It is not for us," ſaid Blake, "to mind ſtate affairs, but to keep foreigners from fooling us." Accordingly, when generals Monk and Deane, on the 23d day of June, had engaged Van Tromp with a fleet of 120 men of war, with dubious ſucceſs, and with the loſs of ſeveral men, among whom was Deane, Blake on the next day came up to their aſſiſtance with 18 freſh ſhips, and gained a victory ſo complete, that if the Dutch had not again ſaved themſelves on the ſands of Calais, their whole fleet muſt have been ſunk or taken. After this engagement, his health being much impaired, he took his ſeat in the new parliament, ſummoned by the protector Oliver, as a repreſentative of his native town, and he was conſtituted one of the commiſſioners of the admiralty. Cromwell indeed treated him with great reſpect; but he was not unapprized of the admiral's ſtrong inclination to a commonwealth; and he was therefore the more diſpoſed to ſend him, in November 1654, with a ſtrong fleet into the Mediterranean, for the purpoſe of ſupporting the honours of the Engliſh flag, and procuring ſatisfaction for any injury which the Britiſh merchants had ſuffered. Whilſt he lay in the road of Cadiz, he was treated with great reſpect by the Dutch and French, and even by the Algerines. However on the 10th of March in the following year he appeared before Algiers, and demanded ſatisfaction for the piracies committed on the Engliſh, and a releaſe of all Engliſh captives. He then ſailed to Tunis on the ſame errand; but the dey, confiding in the ſtrength of the place, treated Blake's meſſage with contempt; "Here," ſaid he, "are our caſtles of Goletta and Porto Ferino, do your worſt; do you think we fear your fleet?" Blake, curling his whiſkers, as he was accuſtomed to do when in a paſſion, conſulted his officers, and then bore into the bay with his heavy ſhips; demoliſhed the caſtles, burnt all the ſhipping in the haven of Tunis, and forced the haughty and obſtinate dey to an humble ſubmiſſion, and an advantageous peace. This daring action ſpread the ſame terror of his name through Africa and Aſia, which had for a long time prevailed in Europe. He alſo awed the piratical ſtate of Tripoly into a peace with England, and the knights of Malta into a compoſition for the injuries which they had committed. Such was the effect of theſe exploits on the princes and ſtates of Italy, that moſt of them thought fit to pay their compliments to the protector; and the grand duke of Tuſcany, and the free ſtate of Venice, in particular, ſent magnificent embaſſies for that purpoſe. During the war with Spain, which was carried on with great ſpirit at this time, Blake, in purſuance of the protector's order, exerted himſelf in ruining their maritime force in Europe, and Montague being joined with him, on account of his declining ſtate of health, blocked up for ſeveral months a Spaniſh ſquadron in the bay of Cadiz, and detached a part of their fleet to capture the Spaniſh plate fleet. Montague returned to England with the prizes; but Blake, whoſe conſtitution was broken by the dropſy and ſcurvy, ſtaid behind; and in April 1657 ſailed with 25 men of war in purſuit of another plate fleet which had put into Santa Cruz in the iſland of Teneriffe. Upon his arrival, he found that the governor had uſed every poſſible precaution for the defence of the harbour; 16 Spaniſh ſhips were diſpoſed in a circular form within the bay, and ſtrongly barricadoed; and the entrance was guarded by a caſtle and 7 forts, connected with one another, and furniſhed with large cannon. Blake ſteered boldly into the bay, leaving ſome of his ſhips to ſilence the batteries, while with the reſt he attacked the Spaniſh veſſels. Having driven the enemy from all their fortified poſts, he ſet fire to the ſhipping, which it was impoſſible for him to remove, and deſtroyed the whole, to an immenſe amount. Having accompliſhed his object, the wind veered about in his favour, and brought him out again without the loſs of a ſingle ſhip. This exploit has been cenſured by ſome cool politicians as an act of raſhneſs; but ſuch timid reaſoners ſhould conſider that by ſuch acts of valour the Britiſh navy has made the world to tremble. On this occaſion the brother of the admiral was found deficient in ſome ſervice which was expected from him; upon which he was degraded from his command, and ſent home to his own country, though afterwards he ſhared the fraternal regard of Blake, in whoſe mind genuine patriotiſm abſorbed every ſelfiſh and partial intereſt. This great enterpriſe was the laſt act of Blake's public life; the news of it at home was honoured with a public thankſgiving, with a vote of thanks to all the officers and ſeamen, and with a diamond ring, of the value of 500l. to Blake himſelf. He lived to receive this welcome tribute of the gratitude and reſpect of his country, to the proſperity and glory of which he was invariably devoted. As his end approached, he wiſhed to return to his native land; as he drew near, he often anxiouſly inquired for land; but before he could ſee it, he died as he was entering Plymouth ſound, on board his ſhip the St. George, Auguſt the 17th 1657, at the age of about 59 years. His body was embalmed, and interred with ſingular honours in Henry the Seventh's chapel, Weſtminſter; but after the reſtoration in 1661, it was removed and interred in St. Margaret's church yard. Blake was, with regard to his perſon, of low ſtature, of a quick, lively eye, and martial aſpect; he was ſingularly brave, cool in action, and wiſe in the diſpoſition of thoſe deſperate attacks, which men of a colder temperament have judged rather fortunate than expedient. He loved his country, and whatever was the eſtabliſhed government, he was ſolicitous to do his duty; and this duty he performed with the moſt upright and diſintereſted views; for notwithſtanding the high and lucrative poſts which he occupied, and the many rich prizes which he captured, he only added to his own original patrimony about 500 pounds. He was pious without affectation, ſtrictly juſt, and liberal to the extent of his fortune. His officers he treated with the familiarity of friends, and he was truly a parent to his ſailors. Although no epitaph or ſculptured monument records his great and good qualities, all parties have been eager to do juſtice to his memory. Dr. Bates, phyſician to king Charles I., the protector Oliver, and king Charles II., ſums up his character in the following words: "He humbled the pride of France, reduced the Portugueſe to ſubmiſſion, broke the ſtrength of the Dutch, and drove their fleets out of the ſea, ſubdued the pirates in the Mediterranean, and twice triumphed over the Spaniards, blameable only in this, that he joined himſelf with the parricides." Lord Clarendon ſays of him, that he was the firſt man that declined the old track, and diſregarded anciently eſtabliſhed rules, which ſerved merely to keep his ſhip and his men out of danger; he firſt taught ſhips to contemn caſtles on ſhore; he firſt infuſed that courage into ſeamen, which made them learn by experience what mighty things they could do if they were reſolved, and taught them to fight in fire as well as upon water; and though he hath been very well imitated, he was the firſt that gave the example of that kind of naval courage, and bold, reſolute atchievements. Biſhop Burnet mentions a ſtory that is related of him, well known, but worth again recording. Whilſt he lay in the road of Malaga, ſome of his ſeamen being on ſhore, met the hoſt, and treated the proceſſion with neglect and indignity. One of the

the Spaniſh prieſts reſented this inſult, fell upon them, and beat them ſeverely. When they returned to their ſhip, they complained of this uſage; upon which Blake ſent to the viceroy, demanding the ſurrender of the offending prieſt. The viceroy replied that he had no power over the prieſts; to which Blake returned for anſwer, that he would not enquire who had the power to deliver up the prieſt, but if he were not ſent within three hours, he would burn their town. The viceroy ſent the prieſt to Blake, who juſtified himſelf on account of the petulant behaviour of the ſeamen. Blake anſwered, that if complaint had been made to him, he would have inflicted juſt puniſhment, for he would not ſuffer his men to affront the eſtabliſhed religion of any place, at which he touched; but he wiſhed to have it known to the whole world, that an Engliſhman was only to be puniſhed by an Engliſhman. He then treated the prieſt civilly, and ſent him back. When Cromwell received this intelligence, he was highly delighted, and ſaid he hoped that he ſhould make the name of an Engliſhman as great as ever that of a Roman had been. It is ſaid, that when Blake was cruiſing in the Mediterranean, he met with a French ſhip of conſiderable force, and commanded the captain to come on board, no war having been declared between the French and Engliſh. The captain, being aſked whether "he was willing to lay down his ſword and yield," gallantly refuſed, though in his enemy's power. Blake, ſcorning to take the advantage of an artifice, and deteſting the appearance of treachery, told him, "that he was at liberty to go back to his ſhip, and defend it as long as he could." The captain did ſo, and after an engagement of two hours, confeſſed himſelf conquered, kiſſed his ſword, and ſurrendered it. Mr. Granger, ſpeaking of Blake's naval exploits, ſays, "that the very temerity of his enterpriſes ſtruck terror into his enemies, and greatly contributed to his ſucceſs. He not only improved the method of attack, but carried the naval power of Cromwell to a greater height than had been known in any age or nation. "Never man," ſays Mr. Hume, "ſo zealous for a faction, was ſo much reſpected and eſteemed by the oppoſite factions. He was by principle an inflexible republican; and the late uſurpations, amidſt all the truſt and careſſes which he received from the ruling powers, were thought to be very little grateful to him. "It is ſtill our duty," he ſaid to the ſeamen, "to fight for our country, into whatever hands the government may fall." Diſintereſted, generous, liberal; ambitious only of true glory, dreadful only to his avowed enemies; he forms one of the moſt perfect characters of that age, and the laſt ſtained with thoſe errors and violences, which were then ſo predominant. The Protector ordered him a pompous funeral at the public charge; but the tears of his countrymen were the moſt honourable panegyric on his memory." To the above teſtimonies we ſhall add the following lines from Mr. Glover's poem, entitled "London."

———"Thy name
Was heard in thunder through th' affrighted ſhores
Of pale Iberia, of ſubmiſſive Gaul,
And Tagus trembling to his utmoſt ſource.
O! ever faithful, vigilant, and brave,
Thou bold aſſertor of Britannia's fame,
Unconquerable Blake!"

Biog. Brit.

BLAKEA, in *Botany*, ſo named by Dr. Patrick Browne, from Mr. Martin Blake of Antigua, a great promoter of natural knowledge, and patron of the doctor's natural hiſtory of Jamaica. Lin. gen. 593. Reich. 647. Schreb. 810. Brown. t. 35. Juſſ. 328. Claſs and order, *dodecandria monogynia*. Gen. Char. *Cal.* perianth of the fruit inferior, ſix-leaved; leaflets ovate, concave, expanding, the ſize of the flower:—perianth of the flower ſuperior; margin quite entire, hexangular, membranaceous. *Cor.* petals ſix, ovate, expanding, equal. *Stam.* filaments twelve, ſubulate, erect; anthers triangular, depreſſed, concatenated into a ring. *Piſt.* germ inferior, obovate, crowned with the margin of the calyx, ſtyle ſubulate, the length of the flower; ſtigma acute. *Per.* capſule obovate, ſix-celled. *Seeds* very many.

Eſſ. Char. *Cal.* inferior, ſix-leaved; ſuperior entire. *Pet.* ſix. *Capſ.* ſix-celled, many-ſeeded.

Species, 1. B. *trinervia*. "Two-calycled; leaves nerveleſs, very finely ſtriated acroſs." Leaves oblong-ovate, petioled, quite entire, coriaceous, oppoſite; the three nerves underneath protuberant, blackiſh; flowers oppoſite, ſolitary. Generally riſing to the height of 10 or 14 feet; one of the moſt beautiful productions of America: at firſt a climber, but gradually acquiring a more robuſt ſtem, which divides into many weak declining branches, well ſupplied on all ſides with beautiful roſy bloſſoms. A native of Jamaica, in cool, moiſt, ſhady places. 2. B. *triplinervia*. "Uncalycled; leaves triple-nerved." A tree growing to the height of 16 feet; leaves oppoſite, petioled, ſix or ſeven inches long, ribbed underneath, and having a nerve running along the edge: peduncles three-flowered; flowers diſtinct, without any lower perianth; upper perianth three or five-cleft, coriaceous, permanent; petals about ſeven; filaments twelve or fifteen; anthers ovate, parallel, flattiſh at the back, ſhorter than the corolla, truncated, not concatenated; ſtyle club-ſhaped; ſtigma capitate, ſtreaked; fruit a roundiſh, many-celled berry, crowned with the calyx; ſeeds minute; fruit of a yellow colour, and ſapid. A native of Surinam, where it was obſerved by Dalberg; alſo of Guiana, where it flowers and fruits in May.

Propagation and Culture. Theſe trees have not been yet cultivated in Europe. In the Weſt Indies, the firſt ſpecies thrives beſt on the ſides of ponds or rivulets; and when planted in gardens, where its appearance is elegant, it ought to be ſupplied with ſome ſupports, whilſt it continues young and weakly.

BLAKENEY, in *Geography*, a harbour on the coaſt of Norfolk, between Cromer at eaſt by ſouth, and Wells at weſt by north nearly, diſtant from the former 2 leagues, and from the latter 3 leagues.

BLAMONT, a town of France, and principal place of a diſtrict in the department of the Meurthe; containing 1863 inhabitants, and the population of the canton is 10,695. The territory comprehends 212½ kiliometres and 30 communes; 4½ leagues eaſt of Luneville. N. lat. 48° 35'. E. long. 6° 44'.—Alſo, a town of France, in the department of the Doubs, and chief place of a canton; containing 400 perſons, and the canton contains 3589; the territory comprehends 107½ kiliometres and 14 communes; 1½ league north of St. Hippolyte.

BLAMPIN, Thomas, in *Biography*, a Benedictine of St. Maur, was born at Noyon in Picardy in 1640, and taught philoſophy and theology in his own congregation. He is chiefly known as editor of the works of St. Auguſtin, in which he diſplayed much critical erudition and ſagacity, and great accuracy in his collation of MSS. Beſides other preferments in the church, he was appointed in 1708 viſitor of the province of Burgundy, and in conſequence of the auſterities exerciſed in this office he died in 1710. Moreri.

BLANC. See Blank.

Blanc, Francis Le, in *Biography*, diſtinguiſhed himſelf by the ſtudy of belles-lettres, hiſtory, and medals, and was appointed by Louis XIV. to draw up an account of the monies

monies of France from the eſtabliſhment of the monarchy. Accordingly he publiſhed "A Treatiſe on the Monies of France," Paris, 1698, 4to. with figures; reprinted at Amſterdam, 4to. 1692. To this is uſually annexed his diſſertation, publiſhed the preceding year, "On the coins of Charlemagne and his ſucceſſors ſtruck at Rome." He was choſen hiſtorical tutor to the royal children; but died before he entered on his office, at Verſailles in 1698. Nouv. Dict. Hiſt.

Blanc, John Bernard Le, Abbé, hiſtoriographer of the public buildings, and member of the academies of La Cruſca, and of the Arcadi at Rome, was born at Dijon in 1707, and engaging in the literary career, wrote a tragedy entitled "Abenſaid," which, notwithſtanding the harſhneſs of its verſification, was at firſt well received. At Paris, where he ſettled, he obtained friends and patrons; and in 1746 Maupertuis was empowered by the king of Pruſſia to offer him a reſidence, as a man of letters, at his court, which he declined accepting. His "Letters on the Engliſh nation," in 3 vols. 12mo. 1758, are the moſt known of his works, and were occaſioned by his viſit to England. The ſtyle is heavy, and the thoughts trite and vulgar, ſo that they are now little read. He died in 1781. Nouv. Dict. Hiſt.

Blanc, Lewis Le, *Sieur de Beaulieu*, a profeſſor of divinity at Sedan in the 17th century, was born at Pleſſis-Marli, where his father was miniſter, and in the progreſs of his life, of which few particulars are recorded, was diſtinguiſhed by his learning and virtue. He died in 1675, at the age of 60 years and 6 months. His "Theſes Theologicæ" were collected into one volume after his death, paſſed through ſeveral editions, and are highly worthy of an attentive peruſal. The firſt edition was printed at Sedan in 4to, and two other editions were printed in England; the third in 1683. He was eminent for the perſuaſive power of his eloquence, and diſcovered an uncommon degree of penetration and ſagacity in his writings and negociations. Anxious for a reconciliation and union between the Reformed and Romiſh churches, he paſſed in review many of the controverſies that divided them, and ſeemed to prove, with the utmoſt perſpicuity, that ſome of them were merely diſputes about words, and that the others were of much leſs conſequence than was generally imagined. This manner of ſtating the differences between the two churches drew upon him the indignation of thoſe who regarded all attempts to ſoften and modify controverted doctrines as dangerous and detrimental to the cauſe of truth. Among theſe we may reckon Arnauld, Saurin, and Jurieu. On the other hand, the acuteneſs and dexterity with which he treated this delicate ſubject, made a conſiderable impreſſion upon ſeveral perſons, and procured him diſciples who entertained his reconciling ſentiments, but either entirely concealed them, or diſcovered them with caution, as they were known to be diſpleaſing to the greateſt part of the members of both communions. Some of Le Blanc's ſermons were printed at Sedan in 1675. Gen. Dict. art. *Beaulieu*. Moſh. Eccl. Hiſt. vol. v. p. 379.

Blanc, Lewis Le, a ſkilful ſurgeon and lithotomiſt of Orleans, publiſhed in 1764 "A Diſcourſe on the utility of Anatomy;" and in 1768, "Nouvelle Methode d'operer des Hernies," 8vo. He recommends dilating the ring with the finger, if practicable, which it uſually is, he ſays, in recent caſes; in thoſe of long ſtanding, with a pair of forceps he invented for the purpoſe, inſtead of uſing the knife. This doctrine having been oppoſed by Ant. Louis, he was anſwered by Le Blanc in a diſſertation on the ſubject, publiſhed in the fourth volume of the Memoirs of the Academy of Surgery. After reducing the inteſtine, by his method, no truſs is wanted, as is invariably the caſe when the ring is opened by inciſion. The forceps are introduced into the ring, cloſed, and open themſelves by the force of an elaſtic ſpring. He alſo wrote on the operation for the ſtone, on the method of extracting ſmall portions of the placenta left in the uterus, and further obſervations on the cure of hernia. Theſe papers were publiſhed in the 30th, 35th, and 39th volumes of the Journal de Medicine. In 1775 he publiſhed "Precis d'operations de Chirurgie," 2 vol. 8vo. containing the ſubſtance of the above, with ſome additional obſervations. Haller. Bib. Anat. de Chirurg.

Blanc-*manger*, Fr. q. d. *white food*, in *Domeſtic Economy*, is a preparation of diſſolved iſinglaſs, milk, ſugar, cinnamon, &c. boiled into a thick conſiſtence, and garniſhed for the table with blanched almonds. It is cooling and ſtrengthening.

Blancs *manteaux*, in *Eccleſiaſtical Hiſtory*, a name originally given to the *Servites*, or ſervants of the Bleſſed Virgin, on account of their white cloaks; but ſince applied to divers ſorts of religious, who have ſucceſſively inhabited the houſe of the *Servites*, and now to the Benedictines at Paris, though habited in black.

Blanc, *Mont*, in *Geography*, a lofty mountain of Savoy, in the duchy of Faucigny, being part of the ancient "Alpes Penninæ." See Alps. This is reckoned the moſt elevated mountain of the ancient continent, its height above the level of the ſea being, according to the calculations of M. de Luc, 15,304 Engliſh feet; or, according to the meaſurement of ſir George Shuckburgh, 15,662 feet. This accurate obſerver informs us (Phil. Tranſ. vol. lxvii. p. 595), that the height of Veſuvius, eſtimated by Sauſſure at 3,900 feet, placed upon mount Ætna, elevated, according to ſir George, 10,954 feet, would not be equal to the height of Mont Blanc, which he ſuppoſes to be the moſt elevated point of Europe, Aſia, and Africa. This mountain, obſerved from the "Col de Balme," and the vale of "Chamouny," is particularly diſtinguiſhed from other mountains by a mantle of ſnow, which clothes its ſummit and ſides, almoſt without the intervention of the leaſt rock to break the glare of the "white" appearance, from which its name is derived. Thoſe who have ſeen it from the valley of Aoſt obſerve, that on that ſide it does not appear to be covered with a mantle of ſnow, and that it exceeds the Schreckhorn in ruggedneſs and horror. See Schreckhorn. Thoſe who are totally unacquainted with Alpine ſcenes, ſays Mr. Coxe, (Swiſſ. vol. ii. p. 5.) may, perhaps, conceive a faint idea of this gigantic mountain, on being informed, that the mantle of ſnow, which appears to cover its top and ſides, exceeds an altitude of 4000 feet perpendicular, and 9000 feet in an horizontal direction from the dôme of Gouté, to the ſummit; and that the height of the ſnow and ice, eſtimated from the ſource of the Arveron, at the bottom of the glacier of Montanvert, to the ſummit of Mont Blanc, cannot be leſs than 12,000 perpendicular feet, or near three times as high as Snowdon in North Wales. The higheſt point of this mountain appears like a compreſſed hemiſphere, and is called from its form "La Boſſe du Dromedaire;" from that point it gradually ſinks, preſenting a kind of concave ſurface of ſnow, in the midſt of which is a ſmall pyramid of ice; it then riſes into a ſecond hemiſphere, called by ſome "Little Mont Blanc," but more properly by others "Le Dôme du Milieu," or the "Middle Dôme;" thence it deſcends into another concave ſurface terminating in a point, indiſcriminately ſtyled by the natives "Aiguille de Gouté" "Point de Gouté," and "Dôme de Gouté;" from this dome it ends abruptly, and loſes itſelf amid the mountains that bound the vale of Chamouny. Five glaciers extend into this vale, and are ſeparated from one another by foreſts, corn-fields, and meadows; ſo that large tracts of ice are blended with cultivation, and perpetually ſucceed each

other in the moſt ſingular and ſtriking viciſſitude. Theſe glaciers, which lie chiefly in the hollows of the mountains, and are ſome leagues in length, unite at the foot of Mont Blanc.

Of the various attempts that have been made to reach the ſummit of Mont Blanc, the firſt was that of M. Couteran, and three guides of Chamouny, Michael Paccard, Victor Taſſay, and Maria Coutet. On the 13th of July 1776, they ſet off from the priory, about 11 in the evening; paſſed between the glaciers of Boſſon and Tacona; and after ſpending above 14 hours in mounting rugged and dangerous aſcents, and in croſſing ſeveral vallies of ice, and large plains of ſnow, found themſelves on the top next to Mont Blanc. But though at firſt ſight it appeared to be ſcarcely a league diſtant, they ſoon perceived that it ſeemed, on account of the clearneſs of the air, the whiteneſs of the ſnow, and its great height, to be much nearer than it really was, and that it would require at leaſt four hours more to reach the ſummit, even if it were practicable. As the day was far advanced, and the vapours near the ſummit of the mountain began to gather into clouds, they relinquiſhed their enterprize; and returned to Chamouny, not without perſonal danger in leaping over chaſms of ice, after a journey of 22 hours, with this ſatisfaction, that they had approached nearer to Mont Blanc than any former adventurers. The ſummit which they had attained, is, according to ſir George Shuckburgh, more than 13,000 feet above the Mediterranean. After ſome ſubſequent but unſucceſsful attempts, M. Bourrit, accompanied by ſix guides, departed from Bionaſay, and began to "ſcale (as he terms it) the rampart" of Mont Blanc, when he ſuddenly found himſelf ſo exceedingly affected by the intenſe cold, that he was unable to proceed. Maria Coutet, and Francis Guidet, two of his guides, proceeded to the dome of Gouté, which is about 9400 feet in an horizontal direction from the ſummit; but the approach of night obliged them to return. On the 4th of September 1785, Maria Coutet and James Balmat advanced beyond the dome of Gouté towards the ſummit, but a violent ſtorm of hail and wind compelled them to abandon the enterprize. On the 13th of this month Meſſrs. Sauſſure and Bourrit, attended by twelve guides, well provided with barometers, thermometers, and other neceſſary inſtruments, left Bionaſay, and arrived at a hut which was conſtructed by their orders at "Pierre Ronde," 7808 feet above the level of the ſea; and on the next morning they purſued their journey to the dome of Gouté; but a heavy fall of ſnow prevented their progreſs. Sauſſure ſays, that the mercury in the barometer ſunk 18½ inches, and that he reached an elevation of 8256 Engliſh feet. In July 1786, James Balmat, one of ſix guides of Chamouny, being ſeparated from his companions, who failed in another attempt, paſſed the night on a ſpot above the "Dome of Gouté," elevated more than 12,000 feet above the level of the ſea. On his return, however, to Chamouny, he was ſeized with a very ſevere indiſpoſition, the effect of extreme fatigue, and of the intenſe cold; but being attended by Dr. Paccard, a phyſician of the place, he offered, as an expreſſion of gratitude for his attendance, to conduct him to the ſummit of Mont Blanc. Accordingly, on the 7th of Auguſt, theſe two daring adventurers ſallied forth from Chamouny, and reached the mountain of "La Côte," which overhangs the upper part of the glacier of Boſſon. Here they paſſed the night, and at three on the next morning they purſued their route over the ice, aſcended the "Dôme of Gouté," paſſed under the "Middle Dôme," and turning to the eaſt at the laſt pyramid of rock, continued along the ridge which is ſeen from Geneva, and which lies on the left of the ſummit. Here cold and fatigue diſcouraged Dr. Paccard; but being animated by his companion, he determined to advance, ſtruggling with a very violent and piercing wind, till at length they attained the ſummit which no one had viſited before. Here they remained about half an hour, when they found the cold ſo intenſe, that their proviſion was frozen in their pockets, the ink congealed in their inkhorns, and the mercury in Fahrenheit's thermometer ſunk to 18½ degrees. They ſpent 15 hours in aſcending; but found great difficulty in their deſcent, their ſight being much debilitated by the reflection of the ſnow. On their return to Chamouny at eight in the morning, their faces were excoriated, their lips much ſwelled, and Dr. Paccard was almoſt blind. Theſe adventurers prepared the way for the obſervations and diſcoveries of future naturaliſts, and particularly of Sauſſure, whoſe indefatigable zeal would not allow him to reſt, till he had reached the top of Mont Blanc, and made thoſe experiments, which have ſerved in a very conſiderable degree to elucidate the theory of the atmoſphere.

Having arrived at Chamouny, a village at the baſe of the mountain, M. de Sauſſure was detained by continual rains for four weeks; after which, he ſet out on the 1ſt of Auguſt 1787, accompanied by a ſervant and 18 guides, who carried the philoſophical inſtruments and the tents, and other apparatus neceſſary for the intended experiments. Although the diſtance from the priory of Chamouny to the ſummit of the mountain is little more than two leagues, or about 6¾ miles, in a ſtraight line, it requires nevertheleſs 18 hours to gain the ſummit, on account of the difficulties of the road, as well as the neceſſary circuits. In the evening, they arrived at a hut conſtructed for them on the top of the mountain of "La Côte," about a mile perpendicularly above the village. Their ſecond day's journey was attended with many difficulties, owing to the wide, deep, and irregular chaſms interſecting the ice-valley on the ſide of the hill, which can only be croſſed by means of bridges naturally formed of ſnow, and often very ſlender; extended, as it were, over an abyſs. In this perilous valley, they were obliged to purſue a winding road, ſo that they were three hours in croſſing it, though in a ſtraight line its breadth is not above three-quarters of a mile. At length, however, they reached the chain of rocks that border on the perpetual ſnows which cover Mont Blanc, and then mounted, in a ſerpentine direction, to a valley filled with ſnow, and running from north to ſouth, to the foot of the higheſt pinnacle. The ſurface of the ſnow in this valley has numerous fiſſures; penetrating to a great depth, and conſiderably broad; preſenting to view, by their broken ſides, the ſucceſſive horizontal layers of ſnow, which are annually formed. In this ſituation the guides wiſhed to paſs the night; but Sauſſure, obſerving that the loftieſt of theſe rocks is at leaſt 1400 yards perpendicularly lower than the ſummit of the mountain, wiſhed to proceed, and at length prevailed with the guides to accompany him. At four in the afternoon, they arrived at the ſecond of the three plains of ſnow, which they had to paſs; but as the day was far advanced, and they were apprehenſive of expoſing themſelves to the "Avalanches," which are frequently tumbling from the ſummit of the mountain, they determined to proceed no farther. Here they encamped at the height of 9312 feet above the priory of Chamouny, or 12,762 feet above the level of the ſea. For this purpoſe, they dug a deep hole in the ſnow, of ſufficient width to contain the whole company, and covered its top with the tent-cloth. In this ſituation the barometer had fallen to 17 inches, 10 lines $\frac{9}{12}$; and they all felt the effects of the rarefied air. Seven or eight hours' walk, which they had juſt performed, had not in the leaſt affected theſe robuſt and hardy men; but they had ſcarcely raiſed five or ſix ſhovels of ſnow, in forming their intended habitation, before they were under a neceſſity

of

of desisting from labour, and of taking breath at very short intervals. M. de Saussure himself, though accustomed to the atmosphere of mountains, and finding himself, as he says, much better in it than in the air of plains, now felt exhausted with fatigue, only by observing his meteorological instruments. This uncomfortable sensation was heightened by an acute thirst, and water could not be procured, except by melting snow; for the water which they had seen during their ascent, would by this time be congealed; and the small chaffing-dish which they had taken with them, very slowly supplied 20 people languishing with thirst. From the middle of this snowy plain, not far below the top of Mont Blanc, the snow exhibited the most dazzling brightness, and formed a singular contrast with the sky, which, in these elevated regions, appears almost black. No living creature was seen here, nor the least trace of vegetation. The moon shone with the brightest splendour in the midst of a sky as black as ebony. Jupiter, rayed like the sun, arose from behind the mountain in the east; and the light of these luminaries was reflected from the white plain, or rather bason, in which they were situated, and by their dazzling lustre, eclipsed every star, except those of the first and second magnitude. Whilst they were composing themselves to sleep within their tent, incommoded by heat and vitiated air, they were soon alarmed by the noise of an immense mass of snow, or "Avalanche," which fell from the top of the mountain, and covered part of the slope over which they were to climb the next day. The next morning they departed at seven for the third and last plain; turning to the left in their way to the highest rock, which is on the east part of the summit, they found the ascent in some places so steep, that the guides were obliged to hew out their footsteps with hatchets. Their progress was slow, and it took them two hours to climb a hill about 1590 feet high. Having arrived at this last rock, they turned to the west, and climbed the last ascent, about 900 feet high, and inclining about 28 or 29 degrees. Here the air was so rarefied, that Saussure could not take 15 or 16 steps without stopping for breath; and at intervals he found himself faint, so that he was under the necessity of sitting down, until, with the return of respiration, his strength was revived. On his arrival to the summit, at 11 o'clock, a slight vapour, suspended in the inferior regions of the air, prevented him from beholding the lower and more distant objects; such as the plains of France and Lombardy; but he had the less reason for regretting this loss, as he was agreeably surprised by a most distinct and comprehensive view of all these elevated summits, with the organization of which he had so long desired to be acquainted. He thought himself dreaming, when he saw beneath his feet many majestic peaks, especially "Aiguilles," "Le Midi," "l'Argentiere," and "Le Géant," the bases of which he had found it so difficult to ascend. He seized in his mind their mutual proportion and connection, their form and structure; and a single glance removed doubts, and afforded information much more satisfactorily, than whole years of previous study. During this time, his guides pitched his tent, and made preparations for his experiments; but in attempting to dispose his instruments for this purpose, he was obliged, almost at every instant, to desist, and wholly to occupy himself about the means of respiration. Considering that the barometer stood at only 16 inches, 1 line, or 17.145 inches English, and that the air, consequently, possessed little more than half the density of that on the plains, it is manifest that the deficiency was to be supplied by more frequent inspirations. This frequency, of course, accelerated the circulation of the blood, more especially as the arteries, on the surface of the body, were no longer actuated from without by the pressure which they usually experience. When M. de Saussure remained perfectly quiet, he only felt rather uncomfortable, with a slight disposition to be sick; but in any exertion, or when he fixed his attention for a few successive moments, and particularly when, by stooping, he compressed his chest, the necessity recurred of resting himself, and respiring for two or three minutes. His guides also experienced similar sensations. They felt no appetite, and had no inclination to take wine or brandy, having found that strong liquors increased the above indisposition; without doubt, by quickening the circulation of the blood. Nothing but fresh water was coveted and relished, and yet both time and exertion were required to light the fire, without which it was impossible to obtain any. In this situation, Saussure and his companions continued $4\frac{1}{2}$ hours, and in their descent they found fewer difficulties than they expected. They arrived the next morning at the valley of Chamouny, without the least accident; and as they had taken the precaution to wear veils of crape, their faces were not excoriated, nor their sight debilitated.

M. de Saussure has given an ample detail of his observations on the summit of Mont Blanc, in the 4th volume of his "Voyages dans les Alpes;" and a translation of this account by professor Martyn of Cambridge, forms an appendix to his sketch of a tour through Switzerland. We shall here select a few particulars. We learn from this narrative, that the summit of the mountain is a ridge, nearly horizontal, lying east and west; the slope at each extremity inclining from 28 to 30 degrees, the south side between 15 and 20, and the north about 45 or 50. This ridge is so narrow, as scarcely to allow two people to walk abreast, especially at the west end, where it resembles the roof of a house; it is wholly covered with snow; nor is any bare rock to be seen within 150 yards of the top. The surface of the snow is scaly, and in some places covered with an icy crust, under which the snow is dusty, and without consistence. The highest rocks are all granites; those on the east side are mixed with steatites; those on the south and west contain a large quantity of schoerl, and a little lapis corneus. Some of them, especially those on the east, which are about 150 yards below the summit, seem to have been lately shivered with lightning. M. de Saussure saw no animal on the mountain, except two flies, a grey phalæna, and a "Myrtillus," which he supposes must have been driven there by the wind. At the elevation of 11,392 feet above the sea, he observed the "Silene Acaulis," or moss-campion, in flower; and still higher, on the most elevated rocks, the "Lichen Sulphureus," and "Lichen Rupestris" of Hoffman. He has given us the height of the barometer on the top of the mountain: viz. Aug. 3. at noon, 16 inches 0 line, and $\frac{144}{1000}$ of a line, French measure, i. e. 16.181 English; and Reaumur's thermometer was 2.3 below the freezing point, or 27 of Fahrenheit. M. Sennebier, at the same time, observed, at Geneva, the barometer 27 inches 2 $\frac{1044}{1000}$ lines, or 29.020 inches English, and the thermometer 22.6 above freezing, or 82 of Fahrenheit. From these data he makes the height of Mont Blanc 2218 toises, or 14,180 English feet, according to M. de Luc's rule, and 2272 toises, or 14,525 English feet, according to M. Trembley's. To these heights 13 toises, or 83 feet, the height of M. Sennebier's room above the lake of Geneva, must be added, to give the height of the mountain above the level of the lake 14,263 feet, according to M. de Luc, and 14,608 feet, according to M. Trembley. Sir George Shuckburgh made the height of Mont Blanc, by trigonometrical measurement, 14,429 feet above the lake, which is almost the mean between the other two. The result of the observations made at Chamouny, co-temporary with those on Mont Blanc, agrees still more nearly with sir George's measurement. The general mean result makes the summit of Mont

Blanc 2450 toiſes, or 15,673 Engliſh feet, or nearly three Engliſh miles above the level of the ſea. By M. de Sauſſure's experiments with the hygrometer, the air on the top of Mont Blanc contained ſix times leſs humidity than that of Geneva, and to the extreme dryneſs of it he attributes the burning thirſt which he and his companions experienced. But the reſult of his experiments ſeems very different from the ſyſtem of meteorology, publiſhed by M. de Luc. See HYGROMETER. It requires half an hour to boil water on the top of this mountain; whereas 15 or 16 minutes are ſufficient at Geneva, and 14 or 15 by the ſea-ſide. Water boiled at 68.993 degrees of a thermometer, which riſes to 80 with the barometer 27 French inches high. By experiments with the electrometer, M. de Sauſſure found, that the electricity of the air on the ſummit of the mountain was poſitive. The wind on the ſummit was north, and very piercing; but ſouthward of the ridge, the temperature of the air was agreeable. The experiments with lime-water, and with the cauſtic alkali, ſhewed that the air was mixed with atmoſpheric acid, or fixed air.

The difficulty of reſpiration, experienced by M. de Sauſſure and his companions, has been aſcribed by ſome to fatigue, and not to the rarefaction of the air; but his obſervations prove, that the latter was the cauſe both of the difficulty of breathing, and the quickneſs of the pulſe. This, indeed, was ſo conſiderable, that the pulſe of one of the guides, after continuing four hours on the ſummit, was 98, of the ſervant, 112, and of M. de Sauſſure himſelf, 100 in a minute; whereas at Chamouny they were 49, 60, and 72 reſpectively. M. de Sauſſure's obſervations confute an opinion, which is very common, with reſpect to the change of the ſenſes of ſmelling and taſte ſuppoſed to take place on high mountains. He tried the experiment on different mountains, and both the taſte and ſmell of bread, wine, meat, and fruit, appeared to him and to his attendants not at all different. As to ſound becoming weaker, this circumſtance is not to be attributed to any impaired ſtate of the organ of hearing, but to the rarefied air, which both reſiſts leſs and vibrates leſs. Beſides, on an inſulated ſummit there are no echoes, nor ſolid objects to repel the ſound. Theſe concurring cauſes rendered the ſounds on the top of Mont Blanc remarkably feeble; the report of a diſcharged piſtol being equal in ſtrength only to that of a ſmall Chineſe cracker let off in a room.

Soon after M. de Sauſſure's expedition, Mr. Beaufoy, an Engliſh gentleman, ſucceeded in an attempt to aſcend Mont Blanc; but it was attended with peculiar difficulty, ariſing from the enlargement of the chaſms in the ice. An account of this enterpriſe was communicated to the Royal Society, in 1787.

BLANC, *Mont*, gives denomination to a department formed of Savoy. It is bounded on the north by the departments of Leman and of Ain; on the eaſt, by Piedmont; on the ſouth, by Piedmont and the departments of Upper Alps and of Iſere; and on the weſt, by thoſe of Iſere and of Ain. Its ſuperficies is about 1,254,796 ſquare acres, or 640,427 hectares; and its population about 283,106 individuals. It it divided into four communal diſtricts, viz. Chambery, its capital, Annecy, Moutiers, and St. Jean de Maurienne.

BLANC-*en-Berry*, *Le*, a town of France, and principal place of a diſtrict, in the department of the Indre, containing 3850 inhabitants. The population of the canton amounts to 10,602; and its territory comprehends 387½ kiliometres and 10 communes; 6 leagues W. of Argenton.

BLANC-*Courſier Herald*, created by patent on the revival of the moſt honourable military order of the Bath, 1725, "to attend the firſt and principal companion of the order for the time being." He enjoys all rights, privileges, and immunities as any other herald; and his office is annexed, united, and perpetually conſolidated with the office of genealogiſt of the ſaid order. See GENEALOGIST *of the Bath*.

BLANCA, in *Geography*, a ſmall iſland in the Weſt Indies, north of Margarita, low and uninhabited; having ſavannahs of long graſs, plenty of guanas, and ſome trees of lignum vitæ; but chiefly remarkable for its turtle fiſhery. N. lat. 11° 20′. W. long. 64° 10′.

BLANCA, or BLANCHE, an iſland in the gulf of Mexico, near the coaſt. N. lat. 25°. W. long. 62° 14′.—Alſo, a river in the province of Chiapa, in the Audience of Mexico, in New Spain. Its water, though clear, is ſaid to have a petrifying quality.

BLANCARD, STEPHEN, in *Biography*, was ſon of Nicholas Blancard of Leyden, by whom he was initiated into the knowledge of philoſophy and medicine. At a proper age he went to Breda, and thence to Franeker, where he took his degree of doctor in medicine, about the year 1678. We ſoon after find him ſettled at Amſterdam, where he dedicated his time to the practice of his art, but principally to writing or compiling a great variety of anatomical and medical works, of which the moſt valuable, Haller ſays, is his "Anatomia practica rationalis, ſ. variorum cadaverum morbis denatorum anatomica inſpectio," publiſhed 1688, 12mo. But he has, even in this work, introduced many obſervations taken from other writers, without acknowledging it. The caſes here deſcribed are 200 in number, and in general, curious and deſerving notice. Geolicke, however, not only accuſes him of plagiariſm, and of mutilating and ſpoiling the obſervations taken from other anatomiſts, but he blames him for publiſhing ſo many of his works in the Dutch, his native language, which cannot fail, in the end, he ſays, of being highly injurious to the profeſſion of medicine, by enabling perſons to practiſe who have not previouſly received a liberal education. This is, however, now done pretty generally all over Europe, and neceſſarily at the leaſt in this country, where there are ſo many perſons practiſing in every branch of medicine who are incapable of reading any other language than their own, the law here authorizing any perſons who may chuſe it to practiſe medicine, without examination, excepting phyſicians and ſurgeons reſiding in the neighbourhood of London, or of the two univerſities. We ſhall only mention one other of this writer's multifarious productions, his "Lexicon Medicum," containing explanations of all the terms uſed in medicine, ſurgery, and anatomy, firſt publiſhed in 1679, 8vo. This has paſſed through numerous editions, and lately, in 1777, by the care of Jac. Fred. Iſenflam, is increaſed to nearly treble its original bulk, making two large volumes, 8vo.

Blancard's works were collected and publiſhed at Leyden, under the title of "Opera omnia theoretica et practica," in 1 vol. 4to. 1701. Haller Bib. Med. Chirurg. Anat. Botan. Eloy. Dict. Hiſt.

BLANCARDS, a name given to certain linen cloths thus called, becauſe the thread uſed to weave them, has been half-blanched or bleached before it was uſed. They are manufactured in Normandy, particularly in the places which are in the diſtrict, or under the juriſdiction of Pont-Audemer, Bernay, and Liſieux.

BLANCAT, St. in *Geography*, a town of France, in the department of the Upper Garonne, 4 leagues W. N. W. of St. Gaudens.

BLANCH, a cape on the French coaſt, N.W. of Calais, almoſt oppoſite to Dover, on the Engliſh coaſt.

BLANCH, or *White Iſland*, one of the large iſlands on the coaſt of France, lying along the ſhore of the projecting coaſt, to the N. E. of Morlaix.

BLANCH *ferné*, or BLANK *farm*, in *Law*, a *white farm*, that is, where the rent was to be paid in ſilver, not in cattle.

In

In ancient times, the crown-rents were many times reſerved to be paid in "libris albis" called *blanche fermes:* in which caſe the buyer was holden *dealbare firmam;* viz. his baſe money or coin, worſe than ſtandard, was melted down in the exchequer, and reduced to the fineneſs of ſtandard ſilver; or inſtead thereof he paid to the king 12d. in the pound, by way of addition. In Scotland, this kind of ſmall payment is called "blanch holding," or "reditus albæ firmæ."

Blanch-*Lyon Purſuivant of Arms.* This officer took his title from the arms and ſupporters of the Mowbray's, dukes of Norfolk (being ruby, a lion rampant, pearl). Thomas Howard, duke of Norfolk, inſtituted the office of blanch-lyon purſuivant 29 Hen. VIII. and he attended at the funeral of queen Jane. Blanch-lyon was alſo a name to an officer of the crown in the reign of Edward IV.

Blanch *Roſe Purſuivant of Arms,* was a purſuivant created by Edward IV. and ſo denominated from the diſtinguiſhed badge of the houſe of York.

Blanch-*Sanglier Purſuivant of Arms.* This office was inſtituted by Richard duke of Glouceſter during the reign of his brother Edward IV. in alluſion to his badge or cognizance being a white boar.

BLANCHARD, William, in *Biography*, an advocate in the parliament of Paris, was admitted to the bar in 1674, and much employed. Notwithſtanding his profeſſional labour, he found leiſure for literary reſearches, and in 1687, publiſhed a chronological table of the ordinances of the French kings of the third race; which was republiſhed, with improvements, under the title of "A Chronological Compilation, containing a collection of the ordinances, edicts, declarations, and letters patent of the kings of France, relative to public juſtice, police, and the finances, from the year 987 to the preſent time," 2 vols. fol. 1715. The work abounds with accurate reſearches; and a ſupplement to it was preparing by the author, when he died in 1724. Moreri.

Blanchard, Jaques or James, a painter of hiſtory and portrait, was born at Paris in 1600, and having been inſtructed in the firſt principles of painting in his own country, he travelled into Italy, where he ſtudied for ſome time at Rome and Venice, and acquired, from particular attention to the works of Titian and of the Venetian ſchool, diſtinguiſhed excellence in the art of colouring, ſo as to have obtained the flattering appellation of the "French Titian." He was employed a conſiderable time at Turin by the dukes of Savoy and afterwards painted ſeveral pieces at Lyons. Upon his return to Paris he was much engaged, and by his deſcent of the Holy Spirit, and a St. Andrew kneeling, gained high reputation. Colouring was his peculiar excellence, and he was diſtinguiſhed for his judicious management of lights and ſhades. His principal works, beſides thoſe already mentioned, are a gallery at the hotêl de Boullion, of ſubjects from the heathen mythology, and the bacchanals in the ſaloon of M. Morin, with ſome pieces at Verſailles and Trianon. To Blanchard is aſcribed the good taſte for colouring which obtained in France. He is ſaid to have etched ſeveral plates from his own compoſitions. He died at Paris in 1658, and left a ſon *Gabriel,* who was alſo a painter of eminence. D'Argenville. Strutt. Pilkington.

BLANCHE, in *Ornithology.* Sonnini deſcribes a kind of *tern,* or *hirondelle de mer,* under this name, in his additions to Buffon's Hiſtory of Birds. The plumage is entirely white; with the legs and bill black. It inhabits the cape of Good Hope, and may be placed in the Indian and ſouthern ſeas. Latham calls this bird *ſterna alba.*

Blanche *Carte.* See Carte.

Blanche-*Coiffe,* or Blanche-*Coëffe,* in *Ornithology,* is the *corvus cayanus* of Gmelin and Latham, in Buffon's Hiſtory of Birds. It is likewiſe called in the ſame work *geay de Cayenne,* and by Latham the *Cayenne jay.*

Blanche-*Raie,* ſynonymous with *etourneau des terres magellaniques,* names given in Buffon's Hiſtory of Birds to the Linnæan *ſturnus militaris,* a native of Falkland iſland.

Blanche, Fr. for a minim, in *Muſic,* or a white note with a tail to it. See Musical *Characters,* and Time-table.

BLANCHERS, a name given to mechanics employed in blanching, i. e. the art or manner of bleaching or whitening.

BLANCHET, Thomas, in *Biography,* a painter of hiſtory, perſpective, and portrait, was born at Paris in 1617, and firſt manifeſted a genius for ſculpture; but on account of the weakneſs of his conſtitution he was adviſed to direct his attention to painting. Accordingly, having practiſed for ſome time at Paris, he travelled for further improvement into Italy. By the counſel and aſſiſtance of Pouſſin and Andrea Sacchi, he applied to hiſtory painting; and on his return to Paris, he painted ſeveral pieces, particularly a picture at Notre Dame, much admired. At Lyons, where he afterwards ſettled, he became director of an academical ſchool. During his abſence from Paris, he was admitted, in 1676, into the academy of painting. Blanchet deſigned well, and underſtood the principles of perſpective and architecture. His compoſition was rich, and his colouring natural; and though he was not always correct, his deficiency in this reſpect is imputed more to the fire of his genius and the rapidity of his execution, than to want of ſkill. His maſter-piece was the ceiling of the great hall in the hotêl de ville at Lyons, which was unfortunately conſumed by fire; and the accident is ſaid to have affected him ſo deeply, as nearly to have coſt him his life. The magiſtrates of Lyons rewarded him with a penſion, and with apartments in the hotêl de ville. His character was amiable, and his converſation lively and intereſting, ſo that his company was much ſought and valued. He died at Lyons in 1689. Some few of his pieces have been engraved. D'Argenville. Pilkington.

Blanchet, in *Ichthyology,* the familiar French name of a ſort of ſalmon that inhabits the American ſeas; *ſalmo ſatens* of Linnæus.

Blanchet, in *Zoology, l'Amphiſbène blanchet,* a kind of amphiſbæna known among the French naturaliſts of the preſent day by this name. The ſpecies is deſcribed as being of a white colour, without any ſpots; the body as conſiſting of 230 annulations, and the tail of 16: on the head are ſix large ſcales, and about the vent eight very ſmall tubercles. The length is 18 inches, excluſive of the tail, which meaſures an inch and an half. This is a native of South America, where it feeds on ants and other inſects.—Boſc, from whom the above detail is copied, we are convinced, can mean no other than the *amphiſbæna alba* of Linnæus, when he deſcribes this ſpecies. The Linnæan character ſtates the number of rings on the body of this kind at 223, in which particular alone the two deſcriptions ſeem to be at variance; and the inconſtancy of that character is too well known to juſtify the opinion of their being diſtinct, for that reaſon only.

BLANCHING, in *Gardening,* is the art of rendering the leaves and ſtems of various ſorts of plants, as endive (cichorium), celery (apium), &c. white, tender, and eſculent. It conſiſts in producing a kind of vegetable debility or diſeaſe, by depriving them of the ſtimulant effects or influence of light, and is accompliſhed either by earthing them well up, or completely covering them, when perfectly dry, by boards, tiles, or other ſimilar means, as will be more fully

fully explained in treating of the different plants that require this fort of management.

Blanching alſo denotes the operation of covering iron plates with a thin coat or cruſt of tin. See Latten.

Blanching *of copper* for ſale, in imitation of ſilver; or mixing blanched copper with ſilver, or expoſing the ſame to ſale; or any malleable compoſition or mixture of metals, or minerals heavier than ſilver, and which looks, and touches, and wears like gold, but is manifeſtly worſe than ſtandard, is made felony, 8 and 9 W. III. &c. 26.

Blanching *of wax*. See Wax.

Blanching, in *Coinage*, the operation of preparing the pieces before ſtriking, to give them the requiſite luſtre and brightneſs.

The blanching, as now practiſed, is performed by nealing or heating the pieces in a kind of pan or ſhovel, with a wood-fire, in manner of a reverberatory furnace, ſo that the flame paſſes over the ſhovel. The pieces being ſufficiently heated, and cooled again, are put ſucceſſively to boil in two copper pans, wherein are aqua fortis, common ſalt, and tartar of Montpellier; when they have been well-drained of this firſt water in a copper ſieve, they throw ſand and freſh water over them; and when dry, they are all well rubbed.

The ancient method of blanching was, by putting the pieces, after heating, in a large veſſel of common water; and ſome ounces of aqua fortis, but in different proportions for gold and ſilver.—The method is now diſuſed, partly by reaſon of its expenſiveneſs, and partly becauſe it diminiſhes the weight of the metal.

BLANC-JAUNE, in *Ichthyology*. *Salmo niloticus*, of Linnæus, a fiſh of the ſalmon tribe found in the Nile, is called blanc jaune by ſome French authors.

BLANCKAMÉRE, in *Geography*, a town of Brabant, 2 miles S. of Breda.

BLANCKENBERG, Blankenburg, or Blakenberg, a town of Germany, in the circle of Upper Saxony, and county of Schwartzburg-Rudolſtadt, ſeated on the Rinne, 4 miles S. W. of Rudolſtadt.

BLANC-NEZ, in *Zoology*. Under this name the Linnæan *Simia petauriſta* is deſcribed, both in Buffon's Natural Hiſtory, by M. Allamand, and Sonnini, and in the hiſtory of Apes, publiſhed recently in Paris by Audebert. The pervading colour of this animal is a very dark olive; the viſage is black, with the exception of the noſe, a remarkable ſnowy white ſpot of a triangular form being ſituated on the latter, which gives the creature a very ſingular appearance. The appellation of *blanc-nez* or *Guenon blanc-nez*, is very well applied, and might be rendered into Engliſh with much propriety, the white-noſe monkey, if that name had not been previouſly aſſigned to another ſpecies by Mr. Pennant and Dr. Shaw. In the Zoology of the laſt writer we are informed, that the diſtinguiſhing character of his white-noſe monkey (*Simia nictitans*, Linn.) is the tip of the noſe, which is milk-white, while the face itſelf is black. Dr. Shaw obſerves, however, ſhortly after, that the white-noſe, in this ſpecies, is not abſolutely peculiar, but is found in another; alluding, as we imagine, to his vaulting monkey, which anſwers to that deſcription. The laſt mentioned animal he conſiders as the *Simia petauriſta* of Linnæus, and *blanc-nez* of Allamand's edition of Buffon's quadrupeds, as Gmelin ſtates them; and ſo far the countenance of the French naturaliſts appears in favour of his opinion. But, perhaps, it will admit of ſome doubt how far we may be authoriſed in believing ſtill further with Dr. Shaw, that the *Guenon blanc-nez* of Allamand, and Sonnini, in Buffon's Natural Hiſtory, and *Guenon à nez blanc proéminent* of the Supplement of that work, are of the ſame ſpecies. Dr. Shaw thinks the firſt of theſe muſt be the female, and the other the male. Virey, and likewiſe Audebert, are perſuaded that they are certainly diſtinct ſpecies. *Guenon blanc-nez*, they conſider as the Linnæan; *Simia petauriſta*, and *Guenon â nez blanc proéminent*, as *Simia nictitans* of the ſame author.

BLANCO, in *Geography*, the name of a cape of Africa, on the north coaſt of the kingdom of Tunis, called the "White Promontory," or, with the ſame meaning by the inhabitants, "Ras-el-abead;" and ſuppoſed to be the "Promontorium candidum" of Pliny; and the "Promontorium pulchrum" of Livy, where Scipio landed in his firſt African expedition. N. lat. 37° 9′. E. long. 10° 18′.—Alſo, a ſmall point to S. E. of cape Corſo, in the iſland of Corſica.—Alſo, a cape on the weſtern coaſt of Africa, in Negro-land; firſt diſcovered by the Portugueſe in the year 1441. N. lat. 20° 55′ 30″. W. long. 17° 10′. high water 9^h 45′.—Alſo, a cape on the weſtern coaſt of the territory of Tſcheſmé in Aſiatic Turkey, oppoſite to the ſouthern point of the iſland of Scio. N. lat. 38° 20′. E. long. 25° 9′.—Alſo, a cape of South America, on the coaſt of Brazil, between cape Roque on the north, and cape St. Auguſtine on the ſouth. S. lat. 6° 50′. W. long. 35° 33′.—Alſo, a cape of South America, on the eaſtern coaſt of Patagonia, north of port Deſeado. S. lat. 47° 20′. W. long. 64° 42′.—Alſo, the north-weſtern point of the bay of Salinas, on the coaſt of Nicaragua, N. W. from Panama-bay. N. lat. 9° 20′. W. long. 85° 48′.—Alſo, a cape on the north-weſt coaſt of America in New Albion, ſouthward of the mouth of the river called "the river of the weſt," between cape Gregory and point St. George, and at a further diſtance between cape Foulweather and Mendocino. N. lat. 43° 20′. W. long. 128° 20′.—Alſo, a promontory of Peru, in South America, on the coaſt of the South Sea, 120 miles S. W. of Guayaquil. S. lat. 3° 45′. W. long 83°.

Blanco, an iſland on the ſouth-eaſtern part of the peninſula of Yucatan in New Spain. N. lat. 21°. W. long. 88° 5′. See Blanca.

BLANDA, in *Entomology*, a ſpecies of Buprestis, that inhabits South America. The wing-caſes are attenuated, ſerrated, and furrowed; colour braſſy-green, with the furrows coppery. Fabricius.

Blanda, a ſpecies of Tenthredo, found in England. The colour is black; abdomen ruſous in the middle; poſterior thighs marked with a white ſpot. Fabricius, &c.

Blanda, in *Ancient Geography*, a town of Hiſpania Tarragonenſis, mentioned by Mela, Ptolemy, and Pliny, ſituate on the coaſt of the Laletani, ſouth of Garunda.—Alſo, a town of Italy, in the country of the Brutii, according to Pliny and Mela, but called "Blandæ," by Livy, and placed by him in Lucania.

BLANDFORD, commonly called *Blandford-forum*, in *Geography*, is a market town of Dorſetſhire, England. It is ſeated on the eaſtern banks of the Stour, and on the great poſt road from London to Exeter, Cornwall, &c. In the Domeſday book no leſs than nine parcels or pariſhes are included under the name of Blencford or Blancford, of which this is the moſt conſiderable, and was ſtiled a borough in ſome ancient records, though it does not appear to have been repreſented in parliament more than twice; once in the reign of Edward I. and again during the reign of Edward III. James the firſt granted it a charter, and made it a free borough with certain corporate privileges and immunities. The town is governed by a bailiff and ſix capital burgeſſes; a part of whom is inveſted with the power of determining ſuits not exceeding 10l.

Here is a ſmall manufactory of ſhirt and waiſtcoat buttons, and another of thread, but the principal trade of the town depends upon its neighbourhood, and the paſſage of travellers. The town has been deſtroyed ſeveral times by fire.

In

In Camden's time it was moſtly burnt by accident, but was ſoon rebuilt in an improved manner. The years 1676, 1713, and 1731 are recorded as peculiarly calamitous to this town, and in the latter year, nearly the whole of it was deſtroyed. The church, town-hall, alms-houſe, free-ſchool, and all the houſes, but forty, were conſumed. Many lives were loſt, and the diſtreſſing calamity was greatly augmented by the ſmall-pox, which raged in above ſixty families. The computed damage was valued at 100,000l. but the diſtreſs, terror, and miſery that prevailed at the time, and reſulted from the direful cataſtrophe, far exceed all calculation, and defy the powers of verbal deſcription. The town has ſince been rebuilt, and its appearance much improved by ſome reſpectable houſes, a new church, town-hall, &c. The latter is a neat building compoſed with Portland ſtone, and conſtructed on columns of the Doric order. Within the building is a pump which was erected by John Baſtard, who having been a conſiderable ſufferer by the laſt fire, had this pump conſtructed to ſupply the town with water, and thereby to prevent another ſimilar diſaſter. The new church, built in the Grecian ſtyle of architecture, conſiſts of a body, two ailes, a chancel, and a tower. Its interior is very neatly ornamented, and contains ſeveral handſome marble monuments.

The charitable donations to Blandford are numerous and valuable, and are appropriated to endow an alms-houſe, to apprentice and clothe poor boys, to erect and ſupport a charity-ſchool, two free-ſchools, and for other benevolent purpoſes. Blandford is 104 miles W. S. W. from London, and contains 408 houſes, with 2326 inhabitants: at the eaſt end of the town are the remains of a handſome old building, called "Damory-court," which has been poſſeſſed by many noble and diſtinguiſhed perſonages.

Blandford is the birth-place of many celebrated characters: among whom the following are the moſt diſtinguiſhed: *George Ryves*, who was warden of New College, Oxford, in 1599, and Vice-chancellor, in 1601; *Bruno Ryves*, author of the Mercurius Ruſticus, a ſingular book, recording many of the events of the civil wars. He alſo aſſiſted in publiſhing the Polyglot Bible, was dean of Chicheſter and Windſor, and died at the latter place in 1677, aged 81 years; *William Wake*, archbiſhop of Canterbury, &c. was born here in the year 1657, and died at Lambeth in 1736; *Thomas Creech*, the tranſlator of Lucretius, and other ancient claſſic authors, was born here in 1659; *Chriſtopher Pitt*, another tranſlator, dates his birth at Blandford, where he was buried in 1748.

About one mile ſouth of Blandford-forum is Blandford St. Mary, a village noted in the annals of literature as the birth-place of Browne Willis, the celebrated antiquary and topographer (ſee Willis). At the diſtance of one mile weſt of this town is Brianſtone-houſe, the elegant and commodious manſion of Edward Berkeley Portman, eſq. This houſe was erected from the deſigns of James Wyatt, who has diſplayed much judgment and taſte in the diſpoſition of the apartments, the arrangement of the offices, and in the two principal façades. The river Stour winding in a broad ſheet through the grounds, with the plantations, and diſtant ſcenes, combine to render this a charming and delightful reſidence. Hutchins's Hiſtory of Dorſetſhire, ſecond edition, fol. 1796.

Blandford, a townſhip of America, in Lunenburgh county in Mahon bay, Nova Scotia, ſettled by a few families.—Alſo, a townſhip in Hampſhire county, Maſſachuſets, weſt of Connecticut river; about 25 miles, S. W. of Northampton, and 116 W. of Boſton; containing 235 houſes, and 1416 inhabitants.—Alſo, a town in Prince George county, Virginia, about 4 miles N. E. from Peterſburgh, and within its juriſdiction. It contains 200 houſes, and 1200 inhabitants, and is pleaſantly ſituated on a plain, on the eaſtern branch of Appamattox river. Here are many large ſtores, and three tobacco warehouſes, which receive annually 6 or 7000 hogſheads. It is a thriving place; and as the marſhes in its vicinity are drained, the air of this town, and alſo that of Peterſburgh, are much meliorated.

BLANDINA, in *Entomology*, one of the Fabrician ſpecies of Papilio, in the Nymphales ſection; the wings of which are dentated, black, and marked with white ſpots; at the baſe of the anterior pair a blue ſtreak, and another along the margin of the poſterior ones. This rare inſect inhabits India. Vide Donov. Inſ. Ind. Obſ. There is another ſpecies of the *Papilio* genus, that bears the ſame name, that ought by no means to be confounded with the above mentioned inſect. This is alſo deſcribed by Fabricius in his "Entomologia Syſtematica," in the ſection "Satyri;" the wings of this kind are dentated, the colour brown, with a rufous ocellated band; poſterior pair beneath ſuſcous with a cinereous ſtripe. This is *papilio ligea* of Scopoli, *æthiops* of Eſper, and *medea* of the Vienna Catalogue. It inhabits ſeveral parts of Europe, but has not been hitherto diſcovered in Great Britain. The ſame ſpecific name again occurs in Cramer's Papiliones, a ſtrong variety of the Gmelinian *papilio melicerta*, being ſo named by that author.

BLANDRATA, George, in *Biography*, a phyſician and divine of the 16th century, was born in the marquiſate of Saluſſes in Italy, and practiſed phyſic in Poland and Tranſylvania; but upon his return to Italy, he was obliged by the inquiſition to fly, on account of his religious opinions, from Pavia to Geneva, where he declared himſelf a Catholic. Here, however, his ſentiments, which then inclined to Arianiſm, excited the ſuſpicions of Calvin, which obliged him firſt to return to Poland, and afterwards, in 1563, to remove to Tranſylvania, where Sigiſmund, at that time ſovereign of the country, appointed him his phyſician. After the death of Sigiſmund he ſuſtained the ſame office to Stephen and Chriſtopher Battori, and to the former when he obtained the crown of Poland. By his credit and influence the doctrine of Socinus, which Blandrata ſeems to have now adopted, made its way from Poland to Tranſylvania; and it was by his means that Fauſtus Socinus was brought thither from Baſil in 1578, to ſecond his arguments and efforts in counteracting Francis Davides, who zealouſly oppoſed the cuſtom of offering up prayers and divine worſhip to Jeſus Chriſt. It is ſaid, that Blandrata, either through natural levity, or under the influence of an avaricious diſpoſition, abandoned the intereſts of the Unitarians, and he is accuſed by Socinus with inclining towards the Jeſuits, who had obtained credit and influence at the court of king Stephen. His wealth, however, tempted his nephew to ſtrangle him in his bed, at ſome period, not aſcertained, between the years 1585 and 1592; and this unfortunate termination of his life has been charitably interpreted, both by the orthodox and heterodox, as a divine judgment. Of his character as a writer the theologiſts of Geneva expreſs a contemptuous opinion; and his conduct ſeems to have been chargeable with a degree of unſteadineſs and duplicity, which has been partly attributed to the perſecuting ſpirit of the times in which he lived. Gen. Dict. Moſh. Eccl. Hiſt. vol. iv. p. 513, 525. Toulmin's Life of Socinus, p. 6, &c.

BLANES, or Blanda, in *Geography*, a ſea-port town of Spain, in Catalonia, on the Mediterranean, 34 miles N. E. of Barcelona. N. lat. 41° 42'. E. long. 2° 45'.

BLANGIS, or Blangy, a town of France, in the department of the Lower Seine, and chief place of a canton, in the diſtrict of Neufchâtel. The population of the town includes 1749 perſons, and that of the canton 12,879. The territory comprehends 247½ kiliometers, and 31 communes:

34 miles N. N. E. of Neufchâtel, and 20 miles E. of Dieppe.

BLANGY, a town of France, in the department of the Calvados, and chief place of a canton, in the diſtrict of Pont l'Evéque; the place contains 771 perſons, and the canton 10,931. The extent of the territory includes 140 kilometres, and 23 communes; 8 leagues E. of Caen, and 1½ league, S. E. of Pont l'Evéque.—Alſo, a town of France, in the department of the ſtraits of Calais, and chief place of a canton, in the diſtrict of Montreuil, 2 leagues N.E. of Heſdin.

BLANK, or BLANC, in a general ſenſe ſignifies WHITE; and BLANCUS, or BLANCA, is more particularly uſed for a kind of white, or ſilver money, of baſe alloy, coined by Henry V. in thoſe parts of France then ſubject to England, valued at 8d. ſterling. They were forbidden by his ſucceſſor to be current in this realm, 2 Henry VI. c. 9. In ſome ancient charters they were called "ſolidi blanci, or white ſhillings."

BLANK alſo denotes a ſmall copper coin, formerly current in France, at the rate of five deniers Tournois.

They had alſo great blanks or pieces of three blanks, and others of ſix in reſpect whereof the ſingle ſort were called little blanks; but of late they are all become only monies of account.

BLANK, or *Blank-ticket*, in *Lotteries*, that to which no prize is allotted. The French have a game, under the denomination *blanque*, anſwering to our lottery.

BLANK, in *Coinage*, a plate, or piece of gold, or ſilver, cut and ſhaped for a coin, but not yet ſtamped. See COINING.

BLANK-*bar*, in *Law*, is uſed for the ſame with what we call a "common bar," and is the name of a "plea in bar," which, in an action of treſpaſs, is put in to oblige the plaintiff to aſſign the certain place where the treſpaſs was committed. 2 Cro. 594.

BLANKS, in judicial proceedings, certain void ſpaces ſometimes left by miſtake. A *blank* (if ſomething material be omitted) in a declaration, abates the ſame; 4 Ed. IV. 14. 20 H. VI. 18. and ſuch a blank is a good cauſe of demurrer. Blanks in the imparlance-roll aided "after verdict" for the plaintiff. Hob. 76.

BLANK-*verſe*. See VERSE and RHYME.

BLANK-*point*. See POINT-*blank*.

BLANKENBERG, in *Geography*, a ſea-port town and fortreſs of Flanders, ſituate near the ſea-coaſt, between Oſtend on the S. W. and Cadſand iſland to the N. E. N. lat. 51° 18'. E. long. 3° 24'.—Alſo, a ſmall town of Germany, ſeated on a mountain, in a prefecturate of the ſame name, in the circle of Weſtphalia, and duchy of Berg, 20 miles S. E. of Cologn.

BLANKENBURG, a principality of Germany, in the circle of Lower Saxony, belonging, ſince the year 1731, to the reigning houſe of Brunſwick-Wolfenbuttel, for which he holds a ſeat at the diet of the empire, and pays 12 rix-dollars a month. This principality lies partly on and partly near the Hartz mountain, and is about 20 miles long and about 8 wide. The northern part, without the Hartz, conſiſts of very good corn-land, but that which lies on the Hartz abounds in woods, quarries of marble and mines of iron ore. A conſiderable part of the country is watered by the Bode. The capital town is of the ſame name; in which are held the courts of judicature and the conſiſtory, with the ſuperintendance of the principality. Near the town, on an eminence, is the ducal palace. It is 7 miles diſtant from Halberſtadt.

BLANKENHAYN, a ſmall town in the circle of Upper Saxony, and principality of Altenburg, belonging to a lordſhip of the ſame name, which is a fief of the electorate of Mentz, 17 miles E. S. E. of Erfurt.

BLANKENHEIM, a ſmall town in Germany, and capital of a county of the ſame name, in the circle of Weſtphalia, and archbiſhopric of Treves. The prince, reſident here, pays 64 florins a month, and 72 rix-dollars, and 54½ kreutzers to the imperial chamber: 36 miles N. N. E. of Treves. In the French arrangement, it is the principal place of a canton in the diſtrict of Prum, and department of Sarre. The population of the place includes 500 perſons, and the canton 3936. Its territory comprehends 19 communes.

BLANKENSEE, a lake of Germany, in the circle of Upper Saxony, and middle mark of Brandenburg, 6 miles E. of Belitz.

BLANKENSTEIN, a town of Germany in a prefecturate of the ſame name, in the circle of Weſtphalia, and county of Mark, ſeated on an eminence near the Rhur, 19 miles E. N. E. of Duſſeldorp.

BLANKET, in *Commerce*, a warm woolly ſort of ſtuff, light and looſe woven; chiefly uſed in bedding. The manufacture of blankets is principally confined to Witney in Oxfordſhire, where it is advanced to that height, that no other place comes near it. Some attribute a great part of the excellency of the Witney blankets to the abſterſive nitrous water of the river Windruſh, wherewith they are ſcoured; others think they rather owe it to a peculiar way of looſe ſpinning, which the people have about that place. Be this as it will, the place has ingroſſed almoſt the whole trade of the nation for this commodity; inſomuch that the wool fit for it centres here, from the farthermoſt parts of the kingdom. Plott. Hiſt. Oxf. chap. ix. § 163.

Blankets are made of felt wool, i. e. wool from off ſheep-ſkins which they divide into ſeveral ſorts.

Of the head wool, and bay wool, they make blankets of twelve, eleven, and ten quarters broad; of the ordinary and middle ſort, blankets of eight and ſeven quarters broad; of the beſt tail wool, blankets of ſix quarters broad, commonly called cuts, ſerving for ſeamen's hammocks. See HYKES.

BLANKET, *toſſing in a*, a ludicrous kind of puniſhment, of which we find mention in the ancients, under the denomination *ſagatio*. Martial deſcribes it graphically enough. "Ibis ab excuſſo, miſſus ad aſtra, ſago."

A late writer repreſents it as one of Otho's imperial delights. But this is turning the tables; that emperor's diverſion, as related by Suetonius, was not to be the ſubject, but the agent in the affair; it being his practice to ſtroll out in dark nights, and where he met with a helpleſs, or drunken man, to give him the diſcipline of the blanket.

BLANKOF, JOHN TEUNISZ, in *Biography*, a Flemiſh painter, was born at Alkmaar in 1628. After having ſpent ſome years in receiving inſtruction from Arent Tierling, Peter Scheyenburg, and Cæſar van Everdingen, he went to Rome, where he diligently copied the works of the beſt maſters, and was admitted into the ſociety of Flemiſh painters, called Bentvogels, by whom he was diſtinguiſhed by the appellation of Jan Maat, ſignifying, in Dutch, mate or companion, and under which appellation he is moſt generally known. His ſubjects were landſcapes, with views of rivers, or ſea-ſhores, havens, or ports, which he executed with a light, free pencil; and in the repreſentations of ſtorms and calms, he particularly excelled. Thoſe of his pictures that are principally commended, are the Italian ſea-ports, with veſſels lying before them. And his moſt capital performance is a view of the ſea-ſhore, with the waves retiring at ebb-tide; which Houbraken deſcribes as admirably beautiful and natural. His imagination was lively, and his execution rapid. He died in 1670. Pilkington.

BLANQUEFORT, in *Geography*, a town of France,

in the department of the Gironde, and chief place of a canton, in the diſtrict of Bourdeaux, five miles north of Bourdeaux. The place contains 2003, and the canton 9304 inhabitants. The territory comprehends 272½ kiliometres, and 9 communes.

BLANQUILLE, in *Commerce*, a ſmall ſilver coin, equivalent to about 11½*d.* ſterling, current in Morocco, and on the coaſts of Barbary.

BLANZAC, in *Geography*, a town of France, in the department of the Charente, and chief place of a canton, in the diſtrict of Angoulême, 4 leagues S. S. W. of Angoulême. The place contains 546, and the canton 10,440 inhabitants. The territory includes 242½ kiliometres, and 20 communes.—Alſo, a town of France, in the department of the Gard, and chief place of a canton, in the diſtrict of Uzes, 3 miles S. S. W. of Uzes.

BLAPS, in *Entomology*, one of the Fabrician genera of *coleopterous* inſects, the palpi of which are clavated, and four in number; jaws ſtraight and bifid; lip membranaceous and cleft; and the antennæ moniliform at the tip. Fabricius includes in this genus ſome of the *tenebriones* of Linnæus, ſuch as *tenebrio gages* and *mortiſaga*. Gmelin adopts the genus only as a ſubdiviſion of *Pimelia*, in the Syſt. Nat. See PIMELIA.

BLAPSIGONIA, compounded of βλαπτω, *I hurt*, and γονη, *brood* or *iſſue*, a kind of diſeaſe, or defect in bees, when they neglect or fail to produce young, being wholly employed in making honey.

BLARE, in *Commerce*, a ſmall copper coin, containing a little mixture of ſilver, ſtruck at Bern, and valued at much the ſame with the RATZE in other places.

BLARINGHEM, in *Geography*, a town of France, in the department of the North, and chief place of a canton, in the diſtrict of Hazebrouch, 2 leagues S. E. of St. Omer.

BLARNEY, a ſmall market town of the county of Cork, and province of Munſter, Ireland, ſituated on a river of the ſame name, about 4 miles W. of the city of Cork. In the reign of queen Elizabeth, its caſtle was reckoned one of the ſtrongeſt fortreſſes in Munſter, and it has often proved very troubleſome to the inhabitants of Cork. It belonged formerly to the earls of Clancarty, but at preſent is the property of Mr. Jeffries, whoſe father built the town, and eſtabliſhed ſeveral manufactures, of which Mr. A. Young has given a detail in the account of his tour through Ireland. Theſe eſtabliſhments, however, as too generally happens in like caſes, have not been ſucceſsful, and Blarney is not at preſent the flouriſhing town, which Mr. Young's account would lead us to expect. A paper-mill, a ſtamping-mill, a bleach-green, and one or two cotton manufactories ſtill exiſt; and many ſtockings made in the neighbourhood are ſold at the weekly market and in Cork, but all may be conſidered as on the decline. The caſtle and the grounds about it have been conſiderably improved, and the country around, as well as the park, is well watered. There is a ſtone at one of the corners of the top of the caſtle, which is ſhewn to ſtrangers, on account of a ſaying, that any perſon who has kiſſed it is privileged to lie and flatter. The origin of this ſaying, which is often referred to, and from which *Blarney* has become a vulgar ſynonime for flattery, the writer has not been able to diſcover. In the caſtle there is an original painting of Charles 12th of Sweden, at full length, drawn in the dreſs mentioned by Voltaire, brought over by one of the family who had been envoy to that monarch. The adjoining country is moſtly under corn and paſture; the ſoil is a yelloviſh clay, and is moſtly manured with lime-ſtone, of which there is a vein that ſupplies large quantities. Smith's Cork. Young.

BLAS, ST., a cape on the coaſt of the North Pacific ocean, near which, to the S. E., ſtands the town of Compoſtella, in the province of Galicia, in New Spain. N. lat. 21° 30'. W. long. 105° 12'. See BLAISE.

BLAS, a term, in the Helmontian philoſophy, denoting the local and alterative motion of the ſtars; from whoſe influence proceed changes of weather, ſeaſons, ſtorms, and the like.

In imitation of this *blas ſtellarum*, the ſame author framed another in animals, either natural, whereby each *viſcus* is framed according to the model of its particular; or voluntary, which is directed to motion by the will.

BLASCON, in *Ancient Geography*, an iſland of Gaul, mentioned by Pliny, ſituate at the mouth of the Rhone.

BLASE, ST., in *Geography*, a town of Germany, in the archduchy of Auſtria, 8 miles S. W. of Steyr.

BLASENDORF, or BALASFALVA, a town of Tranſylvania, in the diſtrict of Weiſſenbourg, the reſidence of the biſhop of Walachia.

BLASIA, from Blaſio Biagi, an Italian monk, in *Botany*. Lin. Gen. n. 1199. Mich. Gen. t. 7. Claſs, *cryptogamia algæ*. Species, 1. B. *puſilla*. Lin. Spec. 1605. Hudſ. Angl. 519. Dill. t. 31. f. 7. Fl. dan. t. 45. The dwarf blaſia grows on the ſides of ditches and brooks, and in moiſt ſhady places in a ſandy ſoil, in many parts of Europe; with us on Hounſlow-heath, and alſo near Mancheſter and Halifax. It flowers in the beginning of May.

BLASII ZELLA, in *Geography*, a ſmall town of Germany, in the circle of Upper Saxony, and principality of Gotha, ſeparated in 1640 from the bailiwick of Reinhardsbrunn, and added to that of Schwarznot-wald, and famous for its foundery of fire-arms; 16 miles S. of Gotha.

BLASIMONT, a town of France, in the department of the Gironde, and chief place of a canton, in the diſtrict of La Réole, 7 leagues E. of Blamont, or 3½ N. of La Réole.

BLASIUS, GERARD, in *Biography*, ſon of Leonard, phyſician at Amſterdam, who received pupils into his houſe, to inſtruct them in the knowledge of medicine, particularly in the anatomy of brute animals, of which he diſſected a great variety. It was this which probably inclined Gerard to this branch of ſtudy, and gave birth to ſeveral of his works; ſuch as his "Zootomiæ, ſeu Anatomes variorum Animalium," publiſhed 1676; "Obſervata anatomica, in homine, ſimia, equo, vitulo, teſtudine, echino, glire, ſerpente, ardea, variiſque animalibus aliis," Lugduni, 1674, &c.

After making ſome progreſs under his father, he went, for further improvement, to Copenhagen, and at length to Leyden, where he commenced doctor in medicine, about the year 1646. He then returned to Amſterdam, where he acquired ſo much credit and reputation for his ſkill in his profeſſion, that in 1660 he was made profeſſor in medicine in the ſchools of that city, and ſoon after phyſician to the hoſpital.

Beſides a variety of original works, Blaſius publiſhed new editions of parts of the works of Primeroſe, Th. Bartholine, Liceetus, Bellini, Borelli, and Willis, to moſt of which he gave notes and additional obſervations, containing ſuch diſcoveries on the ſubjects treated of, as had been made ſince thoſe works had been originally publiſhed. Of his original works, beſides thoſe mentioned above, we ſhall notice his "Oratio de noviter inventis," Amſt. 1659, 4to. "Obſervationes medicæ rariores, accedit triplicis monſtri hiſtoria," Amſt. 1667, 8vo. in ſix books, containing accounts of the diſſection of numerous morbid bodies, in one of which, the ſpleen, and in another the gall bladder, were found to be miſplaced: in one two ſtomachs were found, in another three teſticles. "Anatome animalium terreſtrium variorum volatilium, aquatilium, ſerpentum, inſectorum, ovorumque

ſtructuram naturalem proponens." Amſt. 1601, 4to. The greater part of this work is collected from Severinus, Harvey, Malpighi, Willis, Bartholine, and other writers and journals. The work has, however, its utility, by bringing into a ſmall compaſs a great number of curious facts, and obſervations, which were only before to be found by recurring to a variety of publications. In a letter publiſhed in the third century of Th. Bartholine's epiſtles, Blaſius claims the diſcovery of the ductus ſalivaris, which he ſays he firſt ſhewed to Steno, then a young man. This has not, however, prevented the diſcovery from being attributed to Steno, the duct taking his name. For the titles of the reſt of the works compoſed or edited by Blaſius, ſee Haller. Bib. Anat. Med. et Chirurg. and Eloy's Dict. Hiſt.

BLASKET Sound, in *Geography*, lies on the weſt coaſt of Ireland, between the Great Blaſket iſland and Dunmorehead, on the mainland of the county of Kerry. In this ſound there is ten fathom water, and in the ſummer time and moderate weather a veſſel may ſtop off the eaſt end of the Great Blaſket; but the ground will not hold well in blowing weather. In paſſing through this ſound, it is neceſſary to attend to a pretty ſtrong tide, and to a rock not far from Dunmore point, which is covered at high water.

BLASKETS, Blasquets, or *Ferriter* iſlands, a cluſter of iſlands on the weſt coaſt of the county of Kerry, Ireland, being the moſt weſterly land in the European part of the Britiſh empire. They are five in number, beſides ſeveral rocks, ſome of which are always above water, and others are covered by high tides. Theſe iſlands were given by the earl of Deſmond to the family of Ferriter, from which one of their names is taken; but at preſent they belong to the earl of Cork and Orrery. The largeſt called, *Inniſmore*, i.e. the Great Iſland, and more commonly the *Great Blaſket*, was viſited by Dr. Smith, who found it inhabited by five or ſix families, and ſpeaks in high terms of the ſalubrity of its air. Ruins of churches, and cells or hermitages, are found in ſome of the others, but when Dr. Smith was there, they were not inhabited. The ſmall rocks are frequented by ſea-fowl, the feathers of which are collected by the people of the neighbouring coaſt. The hawks which are found here are remarkably good, and were formerly in much eſteem. Amongſt other ſea-fowl the *ſtormy petrel*, (*procellaria*, Linn.) is common here. The Greater Blaſket is 9 leagues S. W. by W. from Loughead, the north point of the Shannon, and 5 leagues north of the Skeligs. The whole cluſter lie between 10° 17′. and 10° 31′ W. longitude, and between 51° 58′. and 52° 3′. north latitude. Smith's Kerry. M'Kenzie.

BLASPHEMY, *blaſphemia*, or *blaſphemium*, in *Middle Age Writers*, denotes ſimply the blaming or condemning of a perſon or thing. The word is Greek, βλασφημια, from βλαπτω, *lædo*. Among the Greeks, *to blaſpheme*, was to uſe words of evil omen, or that portended ſomething ill, which the ancients were careful to avoid, ſubſtituting in lieu of them other words of ſofter and gentler import, ſometimes the very reverſe of the proper ones.

Blasphemy is more peculiarly reſtrained to evil or reproachful words ſpoken of the Deity. Auguſtin ſays, "Jam vulgo blaſphemia non accipitur niſi mala verba de Deo dicere."

According to Lindwood, blaſphemy is an injury offered to God, by denying that which is due and belonging to him; or attributing to him what is not agreeable to his nature.

By the Moſaic law, blaſphemy was puniſhed with death. Levit. chap. xxiv. ver. 13—16. As alſo by the civil law. Novel. 77. In Spain, Naples, France and Italy, the pains of death are not now inflicted. In the empire, either amputation, or death, is made the puniſhment of this crime.

By the canon law, blaſphemy was puniſhed only by a ſolemn penance, and by cuſtom, either by a pecuniary or corporal puniſhment. By the Engliſh laws, blaſphemies againſt God and religion, as denying his being, or providence, and all contumelious reproaches of Jeſus Chriſt, &c. to which may be alſo referred all profane ſcoffing at the holy ſcripture, or expoſing it to contempt and ridicule, are offences by the common law, and puniſhable by fine, impriſonment, and pillory. 1 Hawk. P. C. And by the ſtatute law, he that denies any one of the perſons of the Trinity to be God, or aſſerts there are more Gods than one, or, having been educated in, and having made profeſſion of the Chriſtian religion, denies, by writing, printing, teaching, or adviſed ſpeaking, Chriſtianity to be true, or the holy ſcriptures to be of divine authority, for the firſt offence is rendered incapable of any office or place of truſt; and for the ſecond, adjudged incapable of bringing any action, being guardian, executor, legatee, or purchaſer of lands, and to be impriſoned for three years without bail. 9 and 10 W. III. c. 32. To give room, however, for repentance, if, within four months after the firſt conviction, the delinquent will in open court publicly renounce his error, he is diſcharged for that once from all diſabilities.

According to the law of Scotland, the puniſhment of blaſphemy is death. The firſt ſpecies thereof conſiſts in railing at or curſing God, and here the ſingle act conſtitutes the crime. The ſecond conſiſts in denying the exiſtence of the Supreme Being, or any of the perſons of the Trinity; and therein obſtinately perſevering to the laſt. For reiterated denial does not fully conſtitute the crime, becauſe the ſtat. of Charles II. 1661, admits of repentance before conviction as a complete expiation.

This ſtatute of 1661, is ratified by a ſtatute of king William, whereby the calling in queſtion the exiſtence of God, or of any of the perſons of the Trinity, or the authority of Scripture, or the Divine Providence, is made penal. For the firſt offence, impriſonment till ſatisfaction given by public repentance in ſack-cloth. For the ſecond, a fine of a year's valued rent of the real eſtate, and twentieth part of the perſonal eſtate: and the trial in both theſe caſes is competent to inferior judges. The puniſhment of the third offence is death, to be tried only by the juſtices.

Blasphemy *againſt the Holy Ghoſt*. Divines are not agreed with reſpect to the nature of the crime thus denominated, Matthew, xii. 31. Mark, iii. 28, 29. Luke, xii. 10. and the grounds of the extreme guilt aſcribed to it. On this ſubject it may be obſerved in general, that from our Saviour's expreſſion this ſin appears to conſiſt, and to be completed, not in our thoughts, nor in our works, but in our words. Nor, indeed, is the epithet "blaſphemous," or any ſynonymous term, ever joined in ſcripture, as is common in modern uſe, with doctrines, thoughts, and opinions. It is never applied but to words and ſpeeches. A "blaſphemous opinion," or "blaſphemous doctrine," are phraſes, which, however familiar to us, are as unſuitable to the ſcripture idiom, as a "railing opinion," or "ſlanderous doctrine," is to ours. It may be alſo obſerved, that this blaſphemy is not of the conſtructive kind, but direct, manifeſt, and malignant. It is mentioned as comprehended under the ſame genus with abuſe againſt man, and contradiſtinguiſhed only by the object: and it is further explained by being called "ſpeaking againſt," in both caſes. The expreſſions are, in effect, the ſame in all the goſpels, where

it

it is mentioned, and imply ſuch an oppoſition as is both intentional and malevolent. This could not have been the caſe with reſpect to all who diſbelieved the miſſion of Jeſus, and even decried his miracles; many of whom, we have reaſon to think, were afterwards converted by the apoſtles.

The learned Grotius, in order to mollify the ſeverity of the ſentence denounced againſt this ſin, ſuggeſts, that what our Lord expreſſes abſolutely, muſt be underſtood comparatively: and that he only deſigned to intimate, that it is very difficult to obtain the pardon of this ſin, but not that it will admit of no forgiveneſs. But our Saviour here ſays expreſsly of this ſin, whatever it was, both negatively, that it ſhall never be forgiven, and affirmatively, that the perſon guilty of it ſhall be obnoxious to eternal judgment, confirming the whole with an aſſeveration. Dr. Waterland (ſee his Serm. vol. ii. N° 9. p. 177—183.) ſeems to incline to Grotius's opinion; alleging that αδυνατον ſignifies only exceedingly difficult. Dr. Hammond comments upon the words with obſerving, that this ſin ſhall not be pardoned, but upon a particular repentance; but this is true of every ſin as well as of the blaſphemy againſt the Holy Ghoſt. Some have made this crime conſiſt in final impenitency, becauſe that is unpardonable; but it is not eaſy to aſſign a reaſon why this ſhould be called the ſin againſt the Holy Ghoſt. Others have repreſented it as, in its ſpecific nature, a wilful and obſtinate oppoſition to the truth; others again as a malicious oppoſition to the truth, on the part of thoſe who know and are convinced that it is the truth; whilſt ſome have ſuppoſed it to conſiſt in a renunciation of the truth for fear of ſuffering, which made Francis Spira think that he had committed this ſin. Mr. Wakefield, in his Notes on the Tranſlation of the Goſpel of St. Matthew, p. 178, is of opinion, that what is meant by the blaſphemy of the Spirit appears from the context to be perverſely reſiſting and belying with contumacy, againſt plain and ſatisfactory evidence, the operation and interference of the holy ſpirit of God; and he thinks, that thoſe men who reject the Chriſtian revelation, without contemplating its claims with diligence, candour, and exactneſs, upon a precipitate preſumption of its falſehood; and thoſe, who refuſe their aſſent to that degree of moral evidence, of which alone theſe ſubjects are capable, and which they would think ſufficiently ſatisfactory in other caſes, and in the ordinary occurrences of life, are as much guilty of the ſin of blaſphemy in our times, as thoſe cavilling and hypocritical Phariſees were in the days of Chriſt.

Dr. Tillotſon (vol. i. ſerm. xvii.) maintains, that this ſin of which the Phariſees were guilty conſiſted in maliciouſly attributing the miraculous operations which Chriſt performed by the power of the Holy Ghoſt to the devil. This ſenſe is adopted by biſhop Pearce, in his Commentary on the four Evangeliſts, vol. i. p. 85. But Dr. Whitby, with greater probability, refers it to the diſpenſation of the Holy Ghoſt, which commenced after our Lord's reſurrection and aſcenſion; and thoſe were guilty of the crime, who perſiſted in their unbelief, and blaſphemed the Holy Ghoſt, repreſenting him as an evil ſpirit. The crime was unpardonable, becauſe it implied a wilful oppoſition to the laſt and moſt powerful evidence which God would vouchſafe to mankind, and precluded the poſſibility of a recovery to faith and repentance. Whitby's Fourth Appendix to the Goſpel of St. Matthew, in his Paraphraſe, vol. i. p. 289.

Of this ſin, it is ſaid, it ſhall not be forgiven, either in this world or in that which is to come. With regard to the meaning of this expreſſion, it is obſerved both by Lightfoot (Hor. Heb.) and by Grotius (in loc.), that through a fond imagination of the final happineſs of all the ſeed of Abraham, the Jews ſuppoſed, there were ſome ſins that had not been forgiven here, which would be expiated by death, and be forgiven after it; and that our Lord deſigned by this expreſſion to aſſure them, that there was no forgiveneſs for thoſe who ſhould be guilty of this ſin, either before or after death, and that their expectations of forgiveneſs then would prove no other than a deceitful dream. Dr. Whitby, however, has clearly ſhewn, that this was uſed as a proverbial expreſſion, and that it only ſignified, "a thing ſhould never be," when it was ſaid, "It ſhall not be, either in this world, or in the world to come." Others, however, among whom we may reckon biſhop Pearce and Mr. Wakefield, have thought that the expreſſions of "this world," and "the world to come," denote the Jewiſh and the Chriſtian diſpenſations. Ὁ αιων, and ὁ νυν αιων, ſay theſe writers, ſignify in the New Teſtament the Jewiſh age or diſpenſation, which continued till the annihilation of the Jewiſh polity, civil and eccleſiaſtical, by the deſtruction of Jeruſalem under Titus; and ὁ μελλων αιων, or the future age, denoted the Chriſtian diſpenſation. Biſhop Pearce adds, that under the Jewiſh law, there was no forgiveneſs for wilful and preſumptuous ſins; concerning which he refers to Numb. xv. 30, 31. xxxv. 31. Lev. xx. 10. and 1 Sam. ii. 25. With regard to the age to come, or the Chriſtian diſpenſation, the biſhop obſerves, that no forgiveneſs could be expected for ſuch ſinners as the Phariſees were; becauſe, when they blaſphemed the Spirit of God, by which Jeſus wrought his miracles, they rejected the only means of forgiveneſs, which was the merit of his death applied to men by faith, and which under Chriſtianity was the only ſacrifice that could atone for ſuch a ſin; in this ſenſe, as things then ſtood with them, their ſin was an unpardonable one. But, he adds, it is not to be concluded from hence, that, if they repented of this blaſphemy, they could not obtain forgiveneſs. Mr. Wakefield obſerves, that the unreſerved affirmation in Matt. xii. 32. muſt be interpreted, as well as the preceding verſe, with conſiderable qualification. Ουκ αφεθησεται, "will not be forgiven him," muſt ſignify, ſays this writer, "will not *readily* be forgiven—will not be eſteemed a *common* and *venial* fault," agreeably to the eaſtern mode of expreſſion, which conſtantly requires ſuch limitation. Accordingly he thus gives the general ſenſe of this verſe. "Offences of the moſt heinous nature, even reproach and injuſtice againſt the anointed prophet of God, may more readily find pardon, than contumacious blaſphemy of the Holy Spirit." This aggravated ſin, the reſult of obſtinacy, depravity, and malice in the extreme, will have no title to forgiveneſs, even from the clemency and mercy of the Chriſtian revelation, a revelation of pardon and peace, in the fulleſt ſenſe, and to the whole race of man. See Heb. vi. 4—7." Nevertheleſs, "will not any ſins be pardoned on ſincere repentance, and ſtedfaſt purpoſes of amendment, under that conſoling diſpenſation, which breathes nothing but reconciliation and forgiveneſs—nothing but favour, mercy, and peace, from God our Father, and our Lord Jeſus Chriſt?"

BLASQUES Island, in *Geography*, lies on the weſt coaſt of Newfoundland, in about 47° 30' N. lat.

BLASS-ENT, in *Ornithology*. The common wild duck is called by this name in the vicinity of the lake of Conſtance.

BLASSENTE, (*Friſch. av.*) a name ſynonymous with *anas Penelope* of Linnæus, and *common wigeon* of Engliſh writers.

BLAST, *flatus*, in the *Military Art*, a ſudden compreſſion of the air, cauſed by the diſcharge of the bullet out of a great gun. The blaſt ſometimes throws down part of the embraſures of the wall.

Blast is alſo applied, in a more general ſenſe, to any forcible ſtream of wind, or air, excited by the mouth, bellows, or the like.

Blast, in *Agriculture*, a diſeaſe in grain, trees, &c. See Blight.

The ſugar-cane in the Weſt Indies is ſubject to a diſeaſe called the blaſt, and ſaid to be occaſioned by the *aphis* of Linnæus, which is diſtinguiſhed into two kinds, the black and the yellow; and of theſe the latter is the moſt deſtructive. It conſiſts of myriads of little inſects, inviſible to the naked eye, whoſe proper food is the juice of the cane, in ſearch of which they wound the tender blades, and conſequently deſtroy the veſſels. Hence the circulation being impeded, the growth of the plant is checked, until it withers and dies in proportion to the degree of the ravage. It is frequently affirmed, ſays Mr. Bryant Edwards (Hiſt. Weſt Indies, vol. ii. p. 215.) that the blaſt never attacks thoſe plantations where colonies have been introduced of that wonderful little animal, the carnivorous ant, or "formica omnivora" of Linnæus, called in Jamaica the "raffles ant," from its being ſuppoſed to have been introduced there by one Thomas Raffles from the Havannah, about the year 1762. Theſe minute and buſy creatures ſoon clear a ſugar plantation of rats; and their natural food ſeems to conſiſt of all kinds of inſects and animalcules.

Fire Blast. See Blight.

Blasts, among *Miners*. See Damps. See Mines, and Mining.

Blast, the term uſed at iron founderies to denote the column of air introduced into the furnace for the purpoſe of combuſtion. Its velocity is occaſioned by the impelling power of the blowing machine forcing the whole contents of the air-pump through one or two ſmall apertures called noſe-pipes; and, according to the abſolute power of the engine, air of various denſities will be produced, ſo that denſity and velocity are always intimately connected, and mutually implied.

The well known combuſtibility of iron, and the indiſpenſible neceſſity of exciting combuſtion by the introduction of large quantities of condenſed air into the furnace, in contact with ore in various ſtates of maturity as to ſeparation, into contact with iron exiſting in all the modifications of quality as to carbonation, and into contact with an immenſe body of ignited fuel, render this ſubject the moſt important in the major ſcale of our manufactures. Unfortunately for art, as well as for ſcience, few practical deductions can be brought forward to eſtabliſh any one theory of blaſt; one common principle only is acknowledged, that all reduction in the furnace is in conſequence of the combuſtion excited by the column of air introduced.

To take a proper view of this intereſting ſubject, it will be neceſſary to ſubmit it to the following diviſions.

1ſt. Combuſtion, as excited in this particular branch of manufacture.

2d. The nature of the fuel ſubmitted to combuſtion.

3d. The denſity of the air.

4th. The quantity.

5th. The properties which follow as a conſequence of denſity and quality.

1ſt. Combuſtion in the blaſt furnace conſiſts chiefly in the rapid reduction of a given quantity of ſolid fuel, and its accompanying portion of ore, in the ſhorteſt poſſible time. That furnace, and that blaſt, which can, in a given time, reduce the greateſt quantity of fuel, all things elſe being alike, will always manufacture the greateſt quantity of iron. In common, before the introduction of the blaſt, the furnace is previouſly filled with alternate ſtrata of coke, iron-ſtone, and limeſtone, heated by ſimple atmoſpheric preſſure to a bright red or white heat, and the iron-ſtone to a melting heat. This temperature is ſoon increaſed throughout the furnace, after the blaſt is applied. The blowing orifices or tuyeres of the furnace exhibit the fuel increaſing in whiteneſs, and the iron-ſtone rapidly diſſolving before the blaſt, of a blackiſh colour. At this period, the lava which flows from the furnace, in conſequence of the reduction of the ore and lime-ſtone, is conſiderably charged with iron, and is of a black, blackiſh brown, or greeniſh brown colour. Theſe appearances will continue for twelve, twenty-four, or thirty-ſix hours, according to the mode of treatment in bringing forward the furnace after blowing. The tuyere (if a bright tuyere furnace) will appear like a blaze of uncommonly pure light, at times very offenſive to the eye; it ſoon, however, becomes accuſtomed to it, and can with facility diſcern the individual maſſes of coke, as they are forced away, with the rapidity of lightning, before the irreſiſtible force of the air. The concrete ore and lime-ſtone are no longer viſible; but a fine metallic ſpray is conſtantly deſcending, and, forced from the fuel, precipitates itſelf to the bottom of the furnace. The ſcoria formed by the fuſion and union of the lime-ſtone, with the immetallic parts of the ore, is carried before the blaſt in a ſimilar manner and form, but eaſily diſtinguiſhable from the fluid metal by its buoyancy, want of velocity when impelled, and by its dull colour. In this ſtate, the furnace is deemed in excellent ſmelting order. The iron is generally revived with little loſs; and the colour and purity of the cinder or lava ſufficiently indicate the perfection of the ſeparation. When at any time the brightneſs of the tuyere fails, and becomes dull white or reddiſh white, then a change is indicated; the iron-ſtone and lime-ſtone will again appear in the ſolid unſeparated ſtate, and the change of colour in the cinder infallibly betokens an irregularity in the movements of the furnace. Theſe appearances are ſo general, as ſcarcely to admit of an individual exception, and are ſufficient to warrant the following explanation.

At the introduction of the blaſt, the interior of the furnace at the tuyere was ſimply a mixture of ignited maſſes of cokes and iron-ſtone, the latter partly ſemifuſed, but the greateſt part merely heated to a bright red heat. In the deſcent through the furnace, in contact with ignited coke, the particles of metal in the ore may, by parting with the oxygen, have received a diſpoſition to become revived. The increaſed temperature creates an additional tendency, by eſtabliſhing a greater force of affinity betwixt the fuel and the iron. But the metal approaching to its proper ſtate, meeting the current of blaſt, is immediately ſubject to a partial combuſtion. The portion thus oxydated conveys to the lava, in proportion to its quantity and oxygenation, the colour already mentioned.

As ſoon as the continuation of the blaſt conveys a higher temperature to the ſuperior regions of the furnace, the appearance of the ſolid matter at the tuyere ceaſes. The fuſion and ſeparation of the metal from the ore are effected in ſituations more remote from the blaſt, or chief ſource of decompoſition, in a temperature more ſuited to the nature and exiſtence of the metal. The iron, once formed into a fluid, and its fluidity preſerved, its deſcent to the blaſt is attended with little or no injury to its carbonation.

To underſtand this diſtinctly, it will be neceſſary to ſtate two curious facts relative to caſt-iron in a fluid ſtate; and but for the exiſtence of theſe properties, the manufacture of the metal in open furnaces or veſſels would be totally impracticable. 1ſt. Caſt iron, while kept fluid, never decompoſes atmoſpheric air, and never itſelf becomes oxydated. 2d. The degree of carbonation paſſed upon the metal at the moment

moment it enters into complete fuſion, continues without diminution or augmentation throughout the whole operation of the furnace; or, in other words, caſt iron neither receives nor loſes carbon whilſt it preſerves its fluidity. The firſt fact explains the reaſon why the iron is preſerved from combuſtion, when it deſcends oppoſite to the current of blaſt. The ſecond is a proof that the carbonaceous matter is conveyed to the iron in the furnace by a ſpecies of cementation previous to fuſion; and that after this point, caſt iron will not take up any addition of carbon.

To preſerve and eſtabliſh the relation of cementation and fuſion in the furnace enſures uniform products. Combuſtion in this preſents us with a gradation of temperature, diminiſhing from the tuyere upwards through thirty or forty feet of ignited matter. The inferior temperature towards the top of the furnace heats the materials to redneſs; an affinity is here commenced betwixt the carbonaceous matter and the oxygen of the ore; the latter is gradually removed, and a ſecond affinity is inſtituted betwixt the de-oxygenated particles of metal and the carbon: this, as the ore deſcends to higher temperatures, is rapidly increaſed, and by and by the ſaturation of the coally principle is complete. As the ſaturation of carbon always increaſes the fuſibility of iron, the metal of the furnace enters into fuſion at a comparatively low temperature, and ſpeedily precipitates, through the high temperatures in the neighbourhood of the blaſt, to the general reſervoir below.

It is not therefore neceſſary to ſuppoſe, that the great volume of air thrown into the furnace, and the great temperature of courſe excited, are neceſſary to the manufacture of the iron, ſo far as it regards quality; this, it is more than probable, may be injured by it, and even the economy of the manufacture itſelf. Quantity, however, is in general ſecured; but this is more the effect of mechanical reduction, than of any neceſſary operation of the blaſt upon the ore and materials above.

The quicker the body of cokes can be reduced, which occupy that part of the furnace between the point of ſeparation and the tuyere, the greater will be the reduction of the whole, and the greater the quantity of manufactured metal. To this point the whole force of the blaſt is directed; here the chief part of the decompoſition of the atmoſpheric air takes place; and here the deſtruction of the intervening cokes is effected, and that always in proportion to the quantity of air poured upon their highly ignited ſurfaces.

If we aſſume, with a blaſt of a certain denſity, any two points in the furnace, the one as the point of decompoſition, and the other of ſeparation and fluidity of the metal, ſuppoſe the former at the tuyere, and the other at the lower end of the boſhes at A, (See *deſcription of* BLAST *furnace*,) then it muſt be allowed probable, that a change taking place in the denſity, or even in the quantity of the blaſt, that change will affect not only the points themſelves, but alſo their relative diſtances. The point of ſeparation may be brought nearer (and perhaps injuriouſly ſo) to the level of the blaſt, the elevation of which is ſuppoſed to remain the ſame. The contrary may with equal truth be inferred; that if the point of ſeparation is carried to a more elevated ſituation by a change or increaſe of temperature, the ore may enter into fuſion before it has remained ſufficiently long in contact with the ignited fuel, and thereby both the quality and quantity may be injured.

2d. Since pit-coal coke became the ſtaple fuel at the blaſt furnace, the denſity and quantity of air deemed neceſſary to enſure combuſtion and quantity, have been yearly increaſing. The various qualities as to hardneſs or ſoftneſs, purity and effect, have given riſe to a multitude of opinions, which are the moſt appropriate quantity and denſity of air for reſpective qualities of cokes. The blaſt of the furnace, in conſequence, has at different places varied from 1½ to 4 lb. of expanſive force upon the ſquare inch of the air veſſel. Moſt of the Engliſh works are blown with air not exceeding 2 lb. upon the ſquare inch, as being the moſt proper medium of denſity, and beyond which the materials would be overblown. Engliſh coal, in general, is ſoft in its foſſile ſtate, but rich in carbon, and free from mixture. In Scotland, where the coal is found in denſe ſtrata, and forms heavy coke, the blaſt is uſed from 2 lb. to 4 lb. per inch. Thoſe who have adopted denſe blaſts declare, that quantity of iron is incompatible with a column of air inferior to the meaſure of their ſtandard. Either the prejudice is very general, or there really muſt exiſt a direct analogy between the nature of the blaſt and the denſity of the coal.

The operations of the charcoal pig manufactory were conducted with blaſts of a trifling denſity, ſeldom exceeding 1½ lb. upon the inch, and often under this. Denſe blaſt, it was believed, over-ran the furnace, moſt probably by exciting too great a temperature, and frequently had a tendency to diſcharge the materials from the furnace top. There never yet have been any direct experiments made to aſcertain upon what this variety of pit-coal depends; whether excluſively from its denſity, or from containing the carbonaceous matter in more purity or greater diſengagement. Perhaps both are neceſſary to be taken into account, before any ſatisfactory explanation can be given of the facts now ſtated and generally admitted.

3d. The denſity of a column of air depends upon the power of the blowing machine, and the proportion of the area of the ſteam cylinder to that of the blowing cylinder. Tables of the powers of ſteam engines, and the diameters of cylinders requiſite to condenſe air from 1½ lb. to 4 lb. upon the circular inch, will be found under the article BLOWING MACHINE. It will appear evident from theſe tables, that ſteam cylinders of the ſame diameter, and working at the ſame power, when employed to raiſe air of various denſities, do not diſcharge the ſame quantity of atmoſpheric air in any given time. The larger the area of the blowing cylinder, the number of ſtrokes being the ſame, the greater will be the quantity of air diſcharged into the furnace. The reverſe is the caſe with blaſts progreſſively more denſe; ſo that any part of an engine's power may be employed, not in raiſing the true principle of combuſtion—air, but in condenſing a comparatively ſmall body of air, ſo as to give it additional velocity.

To fix the point, or maximum, of the moſt profitable denſity, has hitherto been unattainable. The circumſtances, deemed intimately connected with coal, render it neceſſary to accommodate the blaſt to the combuſtibility of the fuel: were this not the caſe, it would be difficult to overturn the following reaſoning, and to exhibit an inſtance where it might not be found generally applicable. Combuſtion in the furnace will be excited in proportion to the quantity of air introduced. A blowing machine, that with the ſame power of ſteam cylinder threw into the furnace double the quantity of air, though of an inferior denſity, would reduce a greater quantity of combuſtible matter than one oppoſitely conſtructed; or, in other words, 5000 feet of air per minute entering a furnace would produce greater effects than 3000 feet, although the latter were compreſſed into nearly half the bulk of the former.

The moſt plauſible theory of blaſt is to fix upon the loweſt denſity at which the air can be forced into the furnace, and then proportion the diameter of the air-pump to the power of the ſteam end. Suppoſe that this could be effected at half the denſity uſually employed, then that part of the engine's

engine's power uſed formerly to compreſs the air to 3 or 4 lb. would now be employed in a blowing cylinder of larger diameter, raiſing per minute, or indeed per ſtroke, from 100 to 200 cubic feet of air. Oppoſed to this there ſtand two formidable objections, reſulting from the neceſſity of uſing blow-pipes or nozles of increaſed diameters, from which to diſcharge the additional quantity of air, making up in area what is wanting in velocity to diſcharge the air in a given time. The firſt is a re-action of the air, ſo powerful as to iſſue back from the tuyere with a velocity little ſhort of that at which it enters. This, with noſe-pipes of 2, 2½, and from that to 3 inches, is ſcarcely felt when the blaſt is ſoft, and may be entirely obviated by a judicious arrangement of the tuyere iron and noſe-pipe; but with pipes from 3 to 4 and 4½ inches diameter, the recoil increaſes as the ſquares of the diameters of the blowpipes, and even in denſe blaſts the recoil increaſes with the diameter of the diſcharging pipe. It is therefore probable, that to blow with a noſepipe 4 or 5 inches diameter, ſo as to have no recoil, a velocity or denſity of air would be requiſite beyond any thing yet in uſe.

Thoſe who advocate for the uſe of a ſoft blaſt, either upon the plea of their materials, or as being the moſt advantageous method of uſing any given mechanical power, frequently feel the full effects of the recoil of a conſiderable portion of the whole blaſt. But to obviate this, and to gain the advantage of the whole air, the blowpipe is encloſed in a moveable frame or building, which is made air-tight at every caſt, and completely prevents the return of the ſmalleſt portion of it. The combuſtion at theſe furnaces is carried on with equal effect, and the reſulting products in iron equal in point of quantity and quality to thoſe where blaſts of double denſity are uſed.

Again, at other furnaces, where a ſoft blaſt had been originally preferred, the plan of forcing back the recoiled air, in order to make up in quantity what was now deemed to be deficient in denſity or velocity, has been in vain attempted. The tuyere irons have become immediately heated, and burnt back with violence. The materials would not admit of the tuyeres being raiſed ſufficiently high to prevent the cinder from flowing back into the bag, which connects the large and ſmall pipes, and deſtroying it. Even, in more than one inſtance, the entire tuyere ſide of a furnace has been loſt in endeavouring to eſtabliſh this plan of blowing, where either the materials would not anſwer, or from ſome miſconception in the mode of operating. Where a furnace works uniformly with a dark or honey-combed tuyere, this mode of blowing may be attended with the greateſt ſucceſs. In all new erections, however, the blaſt ought to poſſeſs of itſelf ſufficient velocity not only to enter the furnace, but to aſcend through the materials, without admitting of any important recoil.

The ſecond objection, ariſing as a conſequence of the want of velocity, and of being obliged to uſe pipes of a larger diameter to carry in the full complement of air, ariſes from a belief that a large pipe never makes the metal of a good quality. This deduction is perhaps not altogether correct; but it ſeems highly probable, that in the uſe of a comparatively looſe blaſt, only a ſmall portion of the air paſſes through the furnace without decompoſition. The point of ſeparation may by this means be changed, or perhaps be raiſed too high for the preſervation of the metal, immediately previous to ſeparation. As the increaſed temperature prevails upwards, the affinity between the particles of metal in the iron-ſtone, and the carbon of the fuel, may be earlier eſtabliſhed, and no ultimate evil conſequence, in point of reaſoning, ought to enſue. It appears from numerous obſervations, that the quantity of iron-ſtone, which a given weight of cokes ſmelts, and to the metal of which is conveyed the carbonaceous principle, is conſiderably dependent upon the diameter of the blowpipe. Suppoſing the ore of equal richneſs, the ſmaller the pipe, the greater burden will the coke carry, and the cheaper will the iron be made per ton, ſo far as materials are concerned. On the contrary, with large pipes, whatever the denſity of the air may be, the quantity of coals neceſſary to manufacture an equal quality of pig iron will be increaſed, and the coſt of the iron is alſo enhanced. As an equivalent for this, however, the quantity is conſiderably increaſed with nearly the ſame amount of labour; ſo that it remains a queſtion with the manufacturer, whether the additional coſt of coal is compenſated by the extra produce of metal he is enabled to bring to market.

4th. The quantity of air diſcharged into the furnace, under the appellation of blaſt, depends upon the number of ſtrokes or cylinders which the engine makes per minute, and on the area and diameter of the air pump. This is independent of every conſideration of denſity and increaſe of power in the ſteam cylinder, ſo long as the blowing or air cylinder remains the ſame, and the engine performs the ſame diſcharges; the meaſure of atmoſpheric air, which enters the furnace, will remain the ſame. The rapid improvements, which of late years have been made in the blowing machine, have increaſed the quantity from 1000 to 4000 feet per minute per furnace; and the quantity or produce in iron has been alſo conſiderably increaſed. We by no means, however, find that the increaſed manufacture of iron has been in the exact ratio of the quantity of blaſt thrown into the furnace. Many inſtances of late years have been noticed during the tranſition from the old to the improved modes of blowing, wherein the proportion has had little or no ſimilarity.

Fifteen hundred feet of atmoſpheric air in one minute was found in moſt ſituations equal to the manufacture of twenty tons of melting iron; in the ſame ſituations, 3000 feet in the ſame time has never exceeded thirty tons per week; and in one particular trial for two weeks, the diſcharge of 6000 feet, being the whole produce in air of the engine, the produce in iron never exceeded 36½ tons. In the laſt caſe, the quality of the iron was irregular, and the quantity of cokes for each ton of metal thus produced was conſiderably increaſed, although the iron was of inferior carbonation.

Without recurrence to the diameter of the air cylinder, and the particular movements of the engine, the ſame facts have been frequently deduced from the diameters of the noſe-pipes. We have frequently ſeen air diſcharged under a preſſure of 2½ lb. upon each ſquare inch, but with a pipe of 2½ inches diameter, reduce materials, and manufacture good melting iron to the extent of 20, 22, and 25 tons per week; and in the ſame furnace, and with the ſame materials, the air diſcharged by 2 pipes, each 2½ inches, under a preſſure of 3 lb. upon each ſquare inch, the produce never exceeded 30 tons of metal of an equal quality, but more frequently 25 to 28 tons. One obſervation ſtill more direct, and made with a blaſt of a denſity equal to 2½ lb. per inch, and diſcharged by one pipe of 2⅞ inches diameter, frequently manufactured 22 tons fine melting iron weekly; another pipe was added to the oppoſite tuyere of the ſame diameter, and the quantity of metal weekly was never increaſed beyond 32 tons, and upon an average of ſix months only 27 tons. Theſe are curious facts relative to the nature and effects of blaſt, and exhibit the inveſtigation of its principles as a matter of ſingular importance in the economy of the manufacture.

One remark was made relative to the burden of ore in the laſt ſtated fact, that with the ſmall pipe a given weight of cokes ſmelted and carbonated the metal in 3 cwt. of iron-

ſtone;

ſtone; but after the two pipes were added, the weight of iron-ſtone, to produce an equal quality of iron, was reduced to $2\frac{3}{4}$, and afterwards to $2\frac{1}{2}$; producing in the firſt inſtance per charge $1\frac{1}{4}$ cwt. of iron upon an average, but latterly not above 1 cwt. and 10 lb. of iron of equal qualities. Another obſervation, in the ſame caſe, with every attention paid as to velocity, quantity, and temperature of air, may be adduced as of equal importance, though ſomewhat different in its mode of application.

Under a preſſure of 2 lbs. a $3\frac{3}{4}$ pipe was found upon the average of 18 weeks to manufacture 20 : 12 : 0 : 0 tons; a $3\frac{1}{2}$ inch pipe, 20 : 5. Upon an average of 11 weeks, and a $4\frac{1}{4}$ pipe, 22 : 5. Their reſpective areas, and iron produced, will ſtand in oppoſition thus:

$3\frac{3}{4}$ pipe,	area	10.6625	quantity of metal		20.12
$3\frac{1}{2}$ - -		12.25	- - -		20.5
$4\frac{1}{4}$ - -		18.0625	- - -		22.17

It is but fair to ſtate that the effects of combuſtion, ſo far as it related to the reduction of a quantity of fuel, was not in the ſame unequal proportion as the quantity of metal to the meaſure of the air. The quantity of reduction was with the

$3\frac{3}{4}$	pipe equal to 25
$3\frac{1}{2}$ - -	31
$4\frac{1}{4}$ - -	38

But the capacity of the fuel to carbonate the original quantity of iron, diminiſhed in nearly the ſame ratio as the combuſtion increaſed; ſo that the ſame meaſure by weight which carbonated 140 lbs. of iron with the $3\frac{3}{4}$ pipe, was unable to carbonate more than from 96 to 100 lb. of the ſame quality with the $4\frac{1}{4}$ pipe. This obſervation was made previous to the one laſt mentioned, and reaſoning upon the ſubject led to the practice detailed in that experiment. It will appear therefore concluſive, that the ſame body of blaſt may, with greater advantage and economy, be introduced through two pipes than through one, and this for two reaſons. The reduction is equal, and the quantity of fuel reduced, ſmelts and carbonates a larger portion of metal per charge; but it will appear from both caſes equally concluſive, that the capacity of the fuel to convey carbonation is in the ratio of the ſmallneſs of the pipe, or the reduction of the quantity of air.

This is in uniſon with what was ſtated under the particular "Combuſtion;" that a large volume of air, ſo far as it related to the inſtitution of affinity between the coally principle of the fuel, was probably more hurtful to the carbonation than otherwiſe; but that in ſo far as it haſtened the completion of the affinities, the reduction of quantity, and above all increaſe of produce, though merely as an agent deſtroying the ſuperfluous fuel, it may be conſidered as giving the manufacturer a ſuperiority over his proceſs by means, the extent of which he never could formerly command.

Tradition has, though rather imperfectly, conveyed to us ſome facts which our forefathers ſeemed to have underſtood and practiſed with better effect than their poſterity. In operating with charcoal furnaces, and a blaſt proportioned to the ſcanty means then in uſe for the purpoſe of producing forge pigs, the whole air was conveyed into the furnace by means of a pipe 2, or at moſt $2\frac{1}{2}$ inches diameter; but when grey metal was wanted, the ſame body of air was divided and introduced by two pipes, whoſe joint capacity was equal to the former.

It appears therefore an enquiry of ſome importance to thoſe embarked in iron founderies, to aſcertain how far this tendency of the fuel to increaſe the carbonaceous principle proceeds in the ratio of the diminution of the blowpipe. If general obſervation confirmed the particulars here ſtated, the effects of carbonation might be greatly increaſed, and the quantity perhaps little reduced, by introducing the ſame quantity of air by means of four, ſix, or eight ſmall pipes, whoſe conjoint areas ſhould be equal to the original column of blaſt.

5. From quantity and denſity of air, there may and do reſult peculiar properties of blaſt, which may affect the operations of the furnace, and which once fully underſtood may help to explain the facts hitherto unaccounted for, and which we before noticed. Facts reſulting from accurate obſervation would prove an invaluable ſource of information upon this ſubject; and it is with regret that we can furniſh no perfect aerological table of the different temperatures of air under different denſities or degrees of compreſſion. The following, we believe, contains the only collection of temperatures hitherto noted; and as it relates to only one degree of compreſſion, the ſatisfaction it affords muſt be only partial.

TABLE of 30 obſervations made in ſummer upon various temperatures of air before and during the act of compreſſion, compared with the thermometer in the ſhade. The air thus aſcertained, was received into a magazine containing 2500 cubical feet, free from moiſture or damp entirely.

There can ariſe no doubt but that heat is extricated by compreſſion from atmoſpheric air; and that it is further probable, that the quantity of heat diſengaged is in proportion to its condenſation. If, therefore, we are allowed to reaſon upon this ſubject, we ſhould ſtate the following as a conſiderable approximation towards truth. It is univerſally believed and felt, that combuſtion in the blaſt furnace in June, July, and Auguſt, is conſiderably diminiſhed, as a conſequence of the increaſed temperature of the air. The metal, in theſe months, is frequently debaſed in point of carbonation, and diminiſhed nearly one half in point of quantity. We ſhall ſuppoſe that this takes place at a temperature of 100, which has been proved to exiſt under a preſſure of 2½ pounds. The reverſe of this happens in the cool ſeaſon of the year, and particularly in the winter months. The furnace then yields the largeſt quantity of iron, and in the moſt profitable manner. This, with the ſame probability, takes place at a temperature of 50 found in the table.

It would therefore appear to reſult from theſe, that two thirds, or one half of the iron only, is manufactured at a temperature of 100, than in winter at 50. The difference between theſe degrees of temperature amounts to 50, and moſt probably in combuſtion affects the operation as ſenſibly as the human frame is affected by a tranſition of temperature equal or ſimilar. It is not neceſſary now to ſtate the difference between ſummer and the denſer air of our winter, the circumſtances of evaporation and aqueous ſolution; theſe ſhall be particularly attended to in the general proceſs of manufacturing iron. The great difference of temperature ariſing ſimply from compreſſion ſeems to us adequate to explain many phænomena regarding the blaſt furnace. Our knowledge, however, upon this ſubject can only be forwarded by a general collection of facts well aſcertained, ſhewing what are the various degrees of heat made ſenſible by the compreſſion of the blowing machine under every denſity; what the difference in temperature, the denſities being alike, when the air is received over water, in the air-vault, or in the regulating cylinder. From theſe it might moſt probably reſult, that the higher the denſity of the air, the greater would be the degree of heat manifeſted; and it might alſo follow, that in the ratio of this denſity, or temperature, when the air was received over water, ſo would be the evaporation or quantity of water ſuſpended in the air, and of courſe diſcharged into the furnace.

This article may be concluded by the following remarks: —That all iron works are not alike affected by the heat of the ſummer months. Many iron works preſerve the quality of the iron, though at the expence of fuel, and with loſs of quantity; but at other places no extra quantity of fuel will compenſate, either as to quality or quantity, for the want of cool air. Neither ſituation nor denſity of blaſt will explain this curious circumſtance; for with blaſts of equal denſity and quantity, works ſituated not 50 feet above the level of the ſea have been found to manufacture a greater quantity of ſoft iron in ſummer, than at a ſimilar work, not ten miles diſtant, ſituated at leaſt 250 feet higher. At both of theſe works the air is received over water; and no material alteration in the uſe of that air is or can poſſibly be applied. The cauſes of this difference muſt be ſought for in the nature of the coal and iron-ſtone uſed at both works, the inveſtigation of which, however intereſting, would prove a moſt laborious undertaking.

Blast *Furnace*, a large conical or quadrangular building uſed at iron-works for ſmelting iron-ſtones and ores.

Blast *Furnace, Deſcription of.*

Plate (*Chemiſtry*) II. *fig.* 1. repreſents a blaſt furnace, and part of the blowing machine conſtructed upon what at one time was the general plan at iron-works.

A, the regulating cylinder, eight feet in diameter, and eight feet high. B, the floating piſton loaded with weights proportioned to the power of the machine. C, the valve by which the air is paſſed from the pumping cylinder into the regulator; its length 26 inches, and breadth 11 inches. D, the aperture by which the blaſt is forced into the furnace. Diameter of this range of pipes 18 inches. The wider theſe pipes can be with convenience uſed, the leſs is the friction, and the more powerful are the effects of the blaſt. E, the blowing or pumping cylinder, ſix feet diameter, and nine feet high; travel of the piſton in this cylinder from 5 to 7 feet per ſtroke. F, the blowing piſton, and a view of one of the valves, of which there are ſometimes two, and ſometimes four, diſtributed over the ſurface of the piſton. The area of each is proportioned to the number of valves, commonly they are 12 — 16. G, a pile of ſolid ſtone building, on which the regulating cylinder reſts, and to which the flanch and ſtilts of the blowing cylinder are attached. H, the ſafety valve, or cock, by the ſimple turning of which the blaſt may be admitted to or ſhut from the furnace, and paſſed off by a collateral tube on the oppoſite ſide. I, the tuyere

by which the blaſt enters the furnace. The termination of the tapered pipe, which approaches the tuyere, receives ſmall pipes of various diameters from two to four inches, called noſe-pipes. Theſe are applied at pleaſure, as the furnace may be deemed to require an alteration in the volume or denſity of the blaſt. K, the bottom of the hearth, two feet ſquare. L, the top of the hearth, two feet ſix inches ſquare. KL, the height of the hearth, ſix feet ſix inches. L, is the bottom of the boſhes, which here terminate of the ſame ſize as the top of the hearth, only the former are round, and the latter ſquare. M, the top of the boſhes, twelve feet diameter, and eight feet of perpendicular height. N, the furnace-top, at which the materials are introduced, or, as it is commonly called, charged; three feet diameter. MN, the internal cavity of the furnace from the top of the boſhes upwards, 30 feet high. NK, total height of the interior of the furnace, or working part, 44½ feet. OO, the lining. This is done in the niceſt manner with fine bricks, from twelve to fourteen inches long, three inches thick, and tapered to ſuit the circle of the cone. PP, a vacancy which is left all round the outſide of the firſt lining; three inches broad. This is ſometimes filled with coke duſt, but more often with ſand firmly compreſſed. This ſpace is allowed for any expanſion which might take place, either by an increaſed volume of the furnace itſelf in heating, or by the preſſure and weight of the materials when deſcending to the furnace bottom. QQ, the ſecond lining, ſimilar to the firſt. The object of this is to guard againſt the entrance of the flame into the maſs of common building, by rents which may take place in the firſt lining OO. R, a caſt-iron lintel, on which the bottom of the arches is ſupported, eight feet and a half long, and ten inches ſquare. RS, the riſe of the tuyere arch, fourteen feet high on the outſide, and eighteen feet wide. VV, the extremes of the hearth ten feet ſquare. This, and the boſhing ſtones, are commonly made from a coarſe-gritted ſand ſtone, whoſe fracture preſents large rounded grains of quartz connected by means of a cement leſs pure.

Fig. 7. repreſents the foundation of the hearth, and a full view of the manner in which the falſe bottom is conſtructed.

AA, the bottom ſtones of the hearth. B, a ſtratum of bedding ſand. CC, paſſages by which the vapour generated from the damps is paſſed off. DD, pillars of brick. The letters in the horizontal view of the ſame figure correſpond to ſimilar letters in the dotted elevation.

Fig. 8. AA, horizontal ſection of the diameter of the boſhes; the lining and vacancy for ſtuffing at M. C, view of the top of the hearth at L.

Fig. 9. Vertical ſide ſection of the hearth and boſhes, ſhewing the tymp and dam-ſtones, and the tymp and dam plates. *a*, the tymp-ſtone; *b*, the tymp-plate, which is wedged firmly to the ſide walls of the hearth; *c*, dam-ſtone, which occupies the whole breadth at the bottom of the hearth, excepting about ſix inches, which, when the furnace is at work, is filled every caſt with a ſtrong binding ſand. This ſtone is ſurmounted by an iron plate of a conſiderable thickneſs, and a peculiar ſhape, *d*; and from this it is called the dam-plate. The top of the dam-ſtone, or rather the notch of the dam-plate, is from four to eight inches under the level of the tuyere-hole. The ſpace under the tymp plate, for five or ſix inches down, is rammed every caſt full of ſtrong loamy earth, and ſometimes even with fine clay. This is called the tymp ſtopping.

The ſquare of the baſe of this furnace is 38 feet. The extreme height, from the falſe bottom to the top of the crater, meaſures 55 feet.

BLAST *Furnaces, Conſtruction of.*

Theſe furnaces are ſometimes built of an external quadrangular form, entirely of ſand ſtone, and lined, in contact with the fire, of the ſame materials; ſometimes they are built conical, entirely of bricks, or with ſand ſtone on the outſide, and linings of both common and fine bricks within.

One great deſideratum in the conſtruction of furnaces, is to counteract the effects of a powerful expanſion, which always take place, to a greater or leſs extent, after heating, and the introduction of the blaſt, and which has frequently proved fatal to the exiſtence of the entire fabric.

In the general ſtyle of building, all are agreed that the pillars, which ſupport the arches, and of courſe the whole fabric, ought to be done in the moſt ſubſtantial manner. But beyond the arches, a variety of methods has been adopted to enſure a complete fabric, free from large openings or rents after a few weeks blowing.

Some iron-maſters are of opinion, that the ſame degree of firm building, that is beſtowed upon the pillars, ought to be continued to the top, with the addition of binders of flat iron preſſing with their edges againſt the body of the building, or with four ſcrewed bars, ſtill paſſing through the external building, and forming one ſquare binder, if the ſhape of the furnace is quadrangular. Another ſpecies of binder is uſed for ſquare piles, made of caſt iron of a prodigious ſtrength and weight. The individual pieces forming this binder, have, at their extremities, mortiſes, which mutually receive each other, with a conſiderable extra ſpace for the expanſion, which is invariably experienced afterwards. Other iron-maſters, again, prefer rearing a ſubſtantial ſhell of building, and filling the interior ſpace towards the linings, either with dry bricks, or ſtones looſely laid together. When the maſs of building becomes thoroughly heated by the kindling of the fire, and the introduction of the blaſt, the interior of the furnace expands conſiderably, and the action is ſuppoſed to be merely confined to the wedging together of the looſe parts of the building. By the time that this is effected, the expanſion is ſuppoſed to have ceaſed, and the exterior ſhell of the furnace is preſerved entire. Others, equally anxious to form a perfect building, have given an octagonal form to that part of the furnace above the arches, that the binding might be more happily effected. Some have aſſumed this form, with the addition of ſemi-circular receſſes in the ſides of the octagon; their convexes being ſtrongly arched to reſiſt the powerful preſſure expected from within.

Still more determined to defy the all-powerful effects of expanſion, others have hollowed furnaces from the ſolid rock, forty to fifty feet high, and lined theſe immenſe perforations with fine bricks in the uſual form.

Where ſuch a variety of form and of method exiſts in effecting the ſame purpoſe, and where the inſtances of experiment have been very numerous, every mode of conſtruction can boaſt of a ſolitary inſtance of complete ſucceſs, excepting in the caſe of the rock, which was only once attempted, and which, after the introduction of the blaſt, opened from four to ſix inches from top to bottom.

There are ſo many circumſtances to be taken into the account, beſides the mere form of the building, that unleſs theſe are all equally guarded againſt, the chances are in favour of the furnace opening conſiderably. If the building is conſtructed of ſand ſtone, and if this material is carried from the quarry as it is wanted by the workmen, an immenſe proportion of water is thus introduced, which by a little foreſight might have been avoided. Sand ſtones of common denſity as to fracture, contain, when taken immediately from the quarry,

from 8 to 10 per cent. of water, and coarſer-gritted ſtones from 10 to 12. Taking the average 10 per cent., then in a furnace of equal dimenſions to the drawing in *Plate* II. *fig.* 6. the ſand ſtone of which will weigh upwards of 1200 tons, there will be introduced 120 tons of moiſture. This quantity is always conſiderably increaſed by the portion of water neceſſary to reduce the lime to mortar, and frequently augmented by the moiſt ſtate of the weather during building.

The evaporation of this immenſe body of water is the ſource of all the miſchief which takes place in the ſhell of the blaſt furnace; nor is it much to be wondered at, where every precaution is not uſed to bring the heat forward in the moſt gradual manner, preſerving the clearneſs of the vents, and allowing the moiſture inſenſibly to paſs away.

In ſituations where bricks can be obtained, the moiſture of the ſand ſtone is avoided, but the great extra quantity of lime, which is neceſſary to build with bricks, introduces through the medium of the mortar an almoſt equal quantity of water, as with ſand ſtone. This has been obviated in part by uſing ſoft clay in the interior of the walls; but as clay ſeldom binds to any great extent, the general puſh of the furnace muſt be truſted to good binders from without.

In the conſtruction of all blaſt furnaces, a complete ventage ought to be preſerved by means of narrow flues, or paſſages proceeding horizontally from the middle of the ſolid ſhell, or within two feet and a half of the interior to the outſide. Theſe ought to be connected with a circular channel, or gutter, of the ſame dimenſions, proceeding round the circumference of the furnace; ſo that if any one vent were choaked in the general expanſion, the moiſture conducted by it might eaſily vent itſelf among the other openings. The vents cannot well be too numerous; and as they ſeldom exceed four inches ſquare, the building cannot be materially weakened by them.

In addition to the horizontal channel of communication, ſome builders carry up in the main building of the furnace four, ſix, or even eight perpendicular flues, which communicate with it and the openings that proceed horizontally to meet the external air. See *Plate* VIII. *fig.* 1, 2, 3, 4.

Either of theſe methods may be conſidered as juſt precautions to enſure the exiſtence of the furnace, but adopting them in the fulleſt and moſt complete manner, is not always accompanied with ſimilar ſucceſs. If circumſtances formerly noticed concur in occaſioning an extra degree of expanſion, the preſſure of the lining againſt the common building of the furnace often deranges the ſyſtematic order of the vents, puſhes the bricks into contact with each other, and ſmothers for a little while, though to gain more fatal elaſtic effects, the increaſing volume of the vapour.

After ſuch a diverſity of opinion upon a ſubject of ſuch general importance, wherein each reſpective claſs of votaries can boaſt of complete ſucceſs from its peculiar plan, it may be difficult to point out one more generally attended with good effects than another. The following, however, may deſerve the ſerious conſideration of the manufacturer of pig-iron.

Of whatever materials the furnace is conſtructed, let them poſſeſs no more moiſture than is ſufficient for their proper building. The thickneſs of the common building not to exceed, at its greateſt breadth, 6½, or 7 feet. In the middle of the wall, a ſpace of four or ſix inches ought to be left clear all the way to the furnace top. Into this vacuity ſhould be introduced ſmall fragments of ſand-ſtone, about the ſize of an egg and under. When the expanſion, proceeding from the fire building of the interior, cauſes the bricks immediately in contact to puſh outwards, the maſſes of ſand-ſtone are immediately reduced in ſize, and filling the interſtices occaſioned by their former angular ſhape, actually occupy much leſs room; and now preſent to the flame or fire, ſhould it be inclined to penetrate ſo far, a ſolid vertical ſtratum of ſand, after having ſecured the expanſion of the furnace to the extent of ſome inches. The effects of the preſſure are thus diverted from the ſhell of the building, and loſt in the pulverization of the fragments of ſand-ſtone.

The advantages reſulting from this plan may be nearly doubled, by uſing a double lining of fire bricks, as repreſented in *Plate* VIII. *fig.* 3. betwixt each of which, and the common building, a ſimilar vacancy ſhould be left; but filled with ſharp ſand, containing no more moiſture than ſerves to compact it into a firm body. As this moiſture becomes gradually expelled in the ſlow heating or annealing of the furnace, the ſand occupies leſs bulk, or, which is the ſame in effect, is then ſuſceptible of a greater degree of compreſſion when the general expanſion of the furnace comes on. It is evident that the force is here alſo diverted againſt the ſand, in place of acting immediately, with a tendency to enlarge the circumference of the building.

Over and above all theſe precautions, the annealing or drying of the furnace in a progreſſive and regular manner ought to be carefully attended to and continued for two or three months at leaſt. Many are blown much earlier, from an anxiety to get to work, and make returns for the great capital neceſſarily expended in theſe undertakings.

The ſame variety of opinions exiſts in the trade, relative to the determined figure and dimenſions of the blaſt furnace, as ſubſiſt, with regard to the beſt mode of building. Its height has, at different times, varied from 20 to 70 feet; and its diameter, at the boſhes, or wideſt part, from 8 to 15 feet. It will be eaſy to trace the ſource of this indefinite mode of conſtruction, and the uncertainty which muſt neceſſarily pervade operations of ſo much riſk and importance.

At the time when charcoal of wood was the common, and indeed, the only fuel uſed in the blaſt furnace, the volume and extent of the blaſt were proportioned to the very imperfect ſtate of the blowing machinery. Long experience had taught the manufacturer what were the proper ſize and dimenſions of his furnace. Many of them were from 12 to 18 feet high, and ſome of them, where a good water wheel blaſt exiſted, reached as far as 28 feet in height.

When pitcoal was introduced into the blaſt-furnace, in the ſtate of coke, to produce ſimilar effects to the charcoal of wood, it was ſoon found, that in furnaces of equal capacity and height the ſame effects could not be produced. The ore required to remain in contact with the ignited fuel for a longer ſpace of time, in order, unqueſtionably, to produce, by attenuated contact, what was deficient in temperature, for the ſaturation of the ore with coally matter. This would immediately ſuggeſt an increaſe of the height of the blaſt-furnace; and if beneficial effects once reſulted from a ſtep of this nature, it became a matter of difficulty to ſay where the progreſſion of height would ſtop.

Hence, in a few years, aroſe furnaces of 40, 50, 60, and 70 feet in height. Of the laſt dimenſions, one was erected in Wales. The ſize of the artificial crater was ſuch, that the ſtrength of the blaſt was ſcarcely ſufficient to keep the exiſtence of flame viſible at the furnace top. After in vain endeavouring to ignite the immenſe body of materials contained in its vaſt capacity, the height of the furnace was reduced 30 feet by cutting a hole in its ſide, narrowing the mouth, and throwing in the materials at the height of 40, in place of 70 feet from the furnace bottom. This was attended

tended with ſucceſs, and the opertions of the furnace proceeded with their uſual facility.

After the application of ſteam engines to raiſe and condenſe air, the quantity and ſtrength of the blaſt became more a mechanical property in the hands of the manufacturer. It was ſoon diſcovered that an increaſed volume of air, by exciting a much higher temperature throughout the furnace, conſtituted the immediate action of thoſe affinities, which the tall furnace accompliſhed by a long attenuated contact, and that iron equally carbonated and fitted for the purpoſe of melting, could be produced by 30 hours contact, as in four days.

The conſequence of theſe gradual diſcoveries was a general predilection in favour of ſmall furnaces, and at preſent the bias of the manufacturer ſeems inclined to this extreme. Where the maximum will be found it is difficult to conjecture, for the ground which the manufacturer now occupies is materially altered from what it was when ſmelting with coke was firſt introduced. The perfection to which the blowing machine has attained, forms a ſtriking contraſt to the feeble and diminiſhed effects of the bellows in the infancy of the trade. So far as the neceſſary affinity is increaſed, and more inſtantaneouſly produced in high temperatures, than in thoſe inferior, the manufacturer is differently circumſtanced, and commands an extent of means unknown to him in former times. That this ſuperiority will produce equivalent effects in the modification of the blaſt-furnace, requires but little demonſtration. Two facts illuſtrative of this may, however, be mentioned. Caſt ſteel has of late years been formed directly from bar-iron, by a proceſs which only requires an hour or two to complete, and with ſmall quantities of matter the ſame may be performed in a few minutes. This is effected by preſenting the carbonaceous matter to the iron at a melting temperature. In the uſual mode of cementation, bliſtered ſteel, by a more attenuated contact and inferior temperature, requires ſix or ſeven days to complete, what is here produced in two hours. The difference of temperature in the two operations is equal to 60° or 70° of Wedgewood. The firſt operation will be conſiderably ſhortened, if the caſt ſteel is required to hold much carbon; but if this requiſite is neceſſary in the bliſtered ſteel, the length of the cementation muſt neceſſarily be protracted. Again, a piece of malleable iron may, by preſenting it with a proper doſe of carbon, at a high temperature, be converted, in a few minutes, into a maſs of the richeſt carburated caſt-iron, which, in a temperature inferior, would have required ſeveral months.

The ſame facts will apply, in part, to the manufacture of pig-iron in the blaſt-furnace; but an unanimity of opinion and action on this ſubject is precluded, as well by the prejudices of individuals, as from circumſtances ariſing out of the nature of the materials operated upon in different places.

A furnace has lately been tried at Muirkirk in Scotland, only eight feet diameter acroſs the boſhes, in place of its former dimenſions, which were ten feet, and 40 feet high. It was ſoon found, that with the ſame volume of blaſt which was formerly applied to the ten feet furnace, very inferior effects were now produced. The combuſtion apparently was carried to too great an extent, and the materials, owing to this circumſtance, entered into fuſion before the iron had imbibed a ſufficient doſe of the coally principle from the fuel. Another great evil which reſulted from this diminution of diameter, was a friction, or retardation of the deſcent of the materials upon the lining of the furnace. This evil was increaſed and the materials made more bouyant, by the uſual volume of air elevating itſelf in a cone not much more than half its former area. The conſequences were, that the whole mixture of coke, iron-ſtone, and lime-ſtone, would have frequently hung for an hour together, or until the blaſt had cut all the hearth and boſhes clear of materials, a ſlip would have then enſued, and brought with it a large proportion of newly introduced matter. The introduction of this into the fuſing point before being properly heated, and long before any affinity had been eſtabliſhed betwixt the particles of metal and the carbon of the furnace, invariably changed the quality of the metal, and cauſed frequent and ſudden alterations from grey to white iron.

Upon the ſubject of height and width of blaſt-furnaces, it may be finally remarked, that the average height in Britain may be taken at forty feet from the upper ſurface of the hearth bottom, eleven feet diameter at the greateſt width or boſhings, and three feet and a half for the diameter of the tunnel-head, or furnace-mouth.

If the proportions of height and diameter in the dimenſions of the blaſt-furnace have given riſe to a multiplicity of opinions, the internal ſtructure and ſhape of the cavity have been no leſs an ample field for ſpeculation and prejudice. At one time this was conceived ſo eſſential to the ſucceſs of iron-making, that any particular furnace that had made a fortunate run of quantity and quality, was copied with the greateſt accuracy of deſign. The fortunate iron-maſter ingeniouſly attributed to the mechaniſm of his own conſtruction the rich and ſuperior harveſt he had reaped in metal, and ſaw, or fancied he ſaw, in the curvature of a line, or in the inclination of a ſlope, the taliſman of his good fortune. By prolonging the one, or depreſſing the other, he immediately inferred that ſtill ſuperior effects would be produced, and that by obtaining the perfection of art in the mere fabrication of ſtructure, every thing that was great and powerful would enſue. This rage continued for many years, and gave riſe to an endleſs variety of ſhapes, many of which, in their eventual ſucceſs, had only the merit of originality to boaſt.

In the eſtabliſhment of this important and national manufacture, the great fluctuation of opinion as to ſtructure ſeems to have been the prelude to a ſubſidence into approved forms, founded upon general principles; and though we may now ſmile at the indiſpenſible forms which our predeceſſors, or even contemporaries, annexed to the blaſt-furnace, yet theſe alterations of ſhape and ſtructure lay the ſtrongeſt claim to our reſpect and gratitude. The path is now opened, and the ground already beat; from the labours of thoſe who have already gone before us, reſult the happieſt effects; we proceed towards our object, free from the interruption which inexperience always entails; and we may now, by the direct application of principle, perfect with facility what may ſtill be deemed deſiderata in this important branch.

The varieties of ſhape which cuſtom and experiment, from time to time, had annexed to the blaſt-furnace, may be claſſed under four diſtinct kinds. *Plate* VII. and VIII. The following deſcription, characteriſing the reſulting properties and dimenſions in the form of each claſs, will be neceſſary for comprehending the ſubject thoroughly.

Plate VII. *fig.* 1. is the vertical ſection of the blaſt-furnace cut acroſs the top of the boſhes; the internal ſhape entirely conical; the external figure a quadrangular pyramid. The conſtruction of this furnace is truly ſingular; and from this alone great advantages were expected to reſult. The originality of the principle conſiſts in the double ſquare, or throat. One immediately above the hearth, not repreſented in this figure, but ſimilar to the ſquare in *Plate* IX. *fig.* 1. B: and another half way up the cone, four feet in diameter; ſee A.

B, the top of the boſhes, 12 feet in diameter.

C, an inferior diameter of 10 feet, previous to the formation of the throat at A.

D, the top of the ſecond row of boſhes, of the ſame diameter as B.

E, the furnace mouth, or termination of the ſecond cone, four feet diameter, and proportioned to A.

F, funnel top for carrying off the flame occaſioned by the blaſt, ſo as not to interfere with the workmen in filling the furnace.

The dimenſions, as to height, are as follow:

From B to C	height - - - - -	12 feet
C to A	ditto - - - - -	6
A to D	ditto - - - - -	6
D to E	ditto - - - - -	13
Height of the hearth, and firſt row of boſhings, not ſhewn in the figure, but being the ſame as *fig.* 1. *Plate* IX. meaſure - -		15
Height of the bottom ſtones, packing, and falſe bottoms. - - - - -		4
Total height of this furnace from the foundation		56 feet

GG, fire brick lining.

bb, ſpace left for packing.

II, the common building either of ſand-ſtone, or of bricks.

Fig. 2. plan and ſection of the ſame furnace taken acroſs the boſhes at B.

AAAA, ſquare of the common building 29 feet upon the ſide, bound by BBBBBBBB, eight caſt-iron binders; the number or ſetts of theſe requiſite, being proportioned, both in ſtrength and dimenſions, to the height of the furnace. In common, a full binder is applied every ſix feet in the height.

The concentric circles repreſent the various diameters of the interior of the furnace, and are connected each by dotted lines, with their reſpective places in the elevation.

The reaſoning which we believe led to the conſtruction of this furnace, proceeded from a firm belief that the boſhes and throat or ſquare of a blaſt-furnace were of the greateſt importance on two accounts. Firſt, becauſe they ſupported the weight of the materials; and ſecondly, becauſe they concentrated the heat. Theſe acting conjointly, permitted the leaſt poſſible quantity of materials to paſs, till they dropt away in a ſtate of ſemi-fuſion, or complete ſeparation. In furnaces, however, the cones of which were 30 feet high and upwards, this was conceived impoſſible to take place for any length of time, to any conſiderable extent. The height and gravitating preſſure of the materials were more than ſufficient to counteract the moſt favourable conſtruction of boſhes; and as this could not admit of diminution, the ſuſpenſion of the materials, and the concentration of the heat muſt be effected by ſome other means. This, at one time, was believed to have been completely effected by the ſcheme of an additional ſquare, and an extra ſet of boſhes; and there is little doubt but that, by converting perpendicular to lateral preſſure, the ſuſpenſion of the materials was reduced at leaſt to one half of its former intenſity.

It was not doubted but that the proceſs of ſmelting and ſeparation would commence, in part, at A; that what eſcaped fuſion and ſeparation in that quarter, would be eaſily reſolved below; and that the proceſs of combuſtion intenſely at work in two different places at once, would greatly facilitate the general reduction, and add greatly to the produce in iron of the furnace. Theſe ſanguine expectations were unfortunately never realized, the ſolitary inſtance of one furnace only being conſtructed in defence of this theory, and that only for a very temporary endurance, is the beſt proof of the inutility of the plan.

Fig. 3. is the elevated ſection of a blaſt-furnace, of which ſeveral were built, and from which it was at one time conceived that the greateſt advantages were derived. The numerous minute gradations of diameter exhibited in the conſtruction of this furnace, were at one time held in high eſtimation by many iron-makers; and a plan of the preſent furnace circulated from the domains of the lucky projector, with as much care and conſciouſneſs of rich acquiſition, as an antiquary would remove from Herculaneum or Egypt, the precious remains of antiquated obſcurity.

It will be extremely eaſy to trace to its ſource this particular bias to form, ſo univerſally believed in at one time, but now conſigned to that oblivion which experience has taught us it deſerved at a much earlier period.

It often happens, that when repairing or re-lining a blaſt-furnace, the manufacturer avails himſelf of the time thus obtained, to overhaul and repair his engine and blowing machine. The former movements of the machinery may have diſcovered to him many errors both in movement and conſtruction, which the conſtant requiſite motion rendered impracticable for him ſooner to remove. In this way, conſiderable improvements on the engine and blowing apparatus are frequently made; and when again in motion, may, by increaſing the length and number of the ſtrokes in a given time, or by conferring a higher additional working power on the ſteam piſton, increaſe at the ſame time both the volume and denſity of the blaſt. If the produce of the furnace is increaſed, which it is highly probable will be the caſe, then the ſuperior effects are attributed to a few unimportant circles and lines added to the interior of the cone, the acuteneſs and proportion of which do not ſurvive the blowing of the furnace three days.

In like manner, if a work entirely new, commence operations with a greater advantage of blowing power, and with ſomething original in the ſhape of the furnace, the conſequent effects of the former are induſtriouſly attributed to the fortunate conſtruction of the latter, and the grand eſſential blaſt is entirely overlooked, and its next important aſſociates coal and iron-ſtone.

The dimenſions of the preſent furnace are as follow:

Diameter of the cone at A - - -	3	feet
ditto at B - - -	4	
ditto at C - - -	8½	
ditto at D - - -	9½	
ditto at E - - -	10	
ditto at F - - -	11	
ditto at G - - -	10	
From G to F, the diſtance in height meaſures	1	foot
Increaſe of diameter - 1 foot		
F to E, the diſtance is - -	12	
Diminution of diameter - 1 foot		
E to D, the diſtance is - -	1½	
Diminution of diameter 6 inches		
D to C, the diſtance is - -	6	
Diminution of diameter - 1 foot		
C to B, the diſtance is - -	2	
Diminution of diameter - 4½		
B to A, the diſtance is - -	4½	
Diminution of diameter - 1		
Height of the hearth and boſhes not repreſented in the plate - -	13	
Total height of the cavity of the furnace or place occupied by the materials -	40	feet

The former deſcriptions will ſuffice and apply to this plate,

plate, with equal propriety as to the former, regarding the lining, packing, common building, &c.

Fig. 4. is a plan and ſection of the ſame furnace at F in the elevation.

The inner circles repreſent the various diameters of the interior of the cone, the letters in each correſponding. The two external circles deſcribe the packing and lining; and the circle N exhibits the circumference of the common building of the furnace, which, at this particular ſection, is 26 feet in diameter.

Plate VIII. *fig.* 1. is the elevation of the interior of a furnace of a plain conſtruction, and at one time very prevalent at founderies. This faſhion was deemed to poſſeſs its peculiar merits, and ſtill maintains its form unaltered at ſome iron-works where the regular tapering cone is not yet admitted. Its inferiority, as to height, is amply made up by an enlarged capacity ariſing from its diameter.

Diameter at the mouth of the cone	A	3 feet
ditto at	B	11
ditto at the boſhes	C	12
Height from C to B		12 feet
from B to A		14
Height of the boſhings and hearth not repreſented in the figure		11
Total height of that part of the furnace occupied by the materials		37 feet

FF, repreſents a view of the vertical method of carrying off the moiſture and ſteam from the maſs of building, by means of vents. The number of upright flues vary from four to eight, and have regular communications by means of horizontal openings with the external air, GG. They are generally carried up parallel to the lining, and incline with the general diminution of the cone. The former, or vertical openings, are ſix inches ſquare, and the horizontal communications four inches ſquare.

Fig. 2. is a plan and ſection of *fig.* 1. in which are repreſented the lining, the vacuity for packing, and eight vents or openings correſponding to thoſe in the elevation. The letters in each figure correſpond, and the two dotted circles are meant to ſhew, that occaſionally all the vents communicate with each other by means of a horizontal gutter, or channel, carried quite round the building. This precaution is uſed leſt any of the tubes were to fill up and choak the free circulation of the vapour, that its appropriate quantity may get eaſily diſcharged amongſt the other openings.

Fig. 3. is an elevated ſection of a furnace, the interior ſhape of which has now almoſt become univerſal. The regular and uniform deſcent of the materials which follows, as a conſequence of the gradual enlargement of the cone, fully juſtifies the general partiality in favour of this ſhape.

Diameter at the mouth, or opening	A	3 feet
Diameter at the top of the boſhes	B	10
The height from B to A		31½
Height of the hearth and boſhes not ſeen in the plate		11½
Total height of this furnace		43 feet

This form of furnace is not only conſtructed with a double lining of fire-bricks CCCC, and two openings for introducing ſand for packing *bbbb*, but has alſo an opening DD, from top to bottom, about the centre of the common building. From this, in all directions, proceed ſmall vents, which communicate at a ſhort diſtance with the open air, as may be ſeen along the ſides of the building.

Fig. 4. is a plan and ſection of *fig.* 3. cut acroſs at B.

B, diameter over at the boſhes 10 feet.

CCCC, the two circles of fire brick-lining, as ſeen in the elevation.

bbbb, ſpaces for receiving packing.

DD, circular vent, or general gutter, from which ramify the horizontal openings.

Theſe are repeated at intervals of four feet in the height, as may be ſeen in the elevation. In building, DD is filled with fragments of ſoft ſand-ſtone, which are eaſily reduced in the expanſion of the furnace, and tend, by diverting its real preſſure, to preſerve the body of the building entire.

A ſimilar want of unanimity of opinion ſubſiſts among iron-makers, relative to the general conſtruction of the boſhes, their particular height, and moſt beneficial range. Some contend for flat, others for boſhes more vertical, while others again conceive the exertions of thoſe equally ſucceſsful, who adopt the mean of the two extremes. At different places, and to every poſſible range, have been atributed the moſt important conſequences in the ſubſequent proceſs.

Plate IX. *fig.* 1. repreſents boſhes of the ſteepeſt conſtruction.

Diameter at	A	10 feet
Perpendicular height from B to A		8
Square at	P	2½

The opinion relative to this form is, that at firſt blowing, the boſhes are productive of a very proper degree of ſuſpenſion of the materials; but as the preſſure of the deſcent bears in every direction upon the under or bottom part next the ſquare at B, it becomes increaſed ſo much, that the weight of the incumbent materials early begin to preſs too much towards the bottom of the hearth, counteract the regular precipitation which ſhould take place, and impede the aſcent and full effect of the blaſt.

Fig. 4, is a ſection of boſhes approaching to, or indeed may be conſidered as the oppoſite extreme. Here the reverſe of the fact attributable to N° 1. takes place. The preſſure of the deſcending material is equally diſtributed over the very flat inclination of the boſhes, and there is no more weight deemed to be on the ſquare at A than is equal to a full column of the materials of ſimilar dimenſions, left by the direct tendency which the ſtrength of the blaſt to keep them in a ſtate of partial buoyancy. To counteract theſe advantages in part, very ſerious defects are here alſo imputed. If circumſtances unite to increaſe the tear and wear at A in any uncommon ratio, either by *ſcouring*, or from a deficiency in the quality of the ſtone or bricks, the whole of the upper part of the hearth at B B is immediately expoſed, and, though compoſed of a ſuperior quality of ſand, will ſoon follow the direction of the deſcending current. A preſſure of materials then takes place, equal to the whole of the increaſed ſpace, while the effect of the blaſt to bear them up is conſiderably diminiſhed by the enlargement of the original diameter. It will be ſeen from the plate that the weakneſs of flat boſhes at the top is ill calculated to withſtand any accumulating preſſure, and that by confining their part of the proceſs to the hearth, the latter muſt ſoon, by a ſimilar widening, be entirely deſtroyed.

Thoſe who wiſh to ſteer clear of extremes, or profit by the more adventurous ſpirit of their neighbours, more generally adopt a mode of boſhing that occupies the mean of the two former extremes. This is repreſented by *fig.* 3.

Diameter of the boſhes at	A	10 feet
Perpendicular height from B to A		5
Diameter of the ſquare	B	2½

In general, the boſhes of blaſt furnaces are made of the ſame ſand ſtone with the hearths, but of late fire bricks have been introduced with a conſiderable indication of advantage

und permanency. When bricks are uſed, it is found of utility to make the whole part of the building ſolid, back as far as the external ſquare of the hearth, ſo that if the boſhes fail in part as to diſplace one layer of bricks, another ſurface, equally freſh and entire as the former, preſents itſelf to the action of the fire.

Fig. 2. Ground plan of the top of the boſhings of *fig.* 1. A A and B correſpond to the ſame letters in the elevation. The dotted ſquare C deſcribes the form and dimenſions of that part of the hearth immediately above the tuyere, as ſeen in the elevation C C. The large dotted ſquare D D is the external ſize of the hearth, as ſeen alſo in the elevation D D.

Fig. 5. Ground plan of the ſquare and boſhings of *fig.* 4.

While we proſecute the detail and hiſtory of the conſtruction of the blaſt furnace, the ſame diverſity of plans formerly noticed comes under review, in every department of the erection. The importance of the hearth is admitted by every claſs of reaſoners upon this ſubject; and to deviſe a form better calculated for ſmelting than another, has been an object of general concern with the manufacturer. Much as may be deemed to depend upon its form and conſtruction, infinitely more benefit is derived from a proper quality of ſtone, to reſiſt for a given length of time the powerful effects of a continued and unremitting blaſt. To both of theſe important deſiderata much of the manufacturers attention has been from time to time directed.

The firſt ſingularity that ſtrikes us forcibly in the figure of the hearth, is, that in place of being circular, like the upper parts of the furnace, it is conſtructed of a ſquare funnel-form, with angles as acute as repreſented in *Plate* IX. *fig.* 1. This narrowing form is continued on three ſides of the ſquare to the bottom of the hearth, where it generally meaſures from 22 inches to 24 inches. The top of the hearth, at B or A, *fig.* 1. and 4. or as it is commonly called the ſquare, is never leſs than 30 inches, nor more than 33. The height of the hearth from E to B, *Plate* IX. *fig.* 1, 7 feet, and none are made higher. From C to B, *fig.* 3, 6½ feet, which is now reckoned the moſt advantageous height; and from C to A, *fig.* 4, the hearth meaſures 6 feet, under which height there are no hearths ever attempted.

The ſtructure of a hearth, properly ſpeaking, conſiſts of three ſolid ſides only, the fourth, or front, is filled up by the tymp, or key-ſtone. *Plate* IX. *fig.* 1. The block E is generally in one piece, and from four to five feet long, according to the height of the hearth. It deſcends towards the bottom till within two feet or two feet four inches, and then leaves an opening of ſimilar dimenſions as to height, into the centre of the hearth or funnel, as at letter F.

As the ſquare form in which the hearth is finiſhed cannot laſt a day after the blaſt is introduced, and is even frequently deſtroyed in the act of annealing, or heating, it cannot be eſſentially neceſſary to the making of iron. The hearths of all furnaces when blown out, are entirely round, or if waſted more upon the tuyere ſides, oval. The general uſage of the ſquare muſt have been derived from long acquired habit, or perhaps from the conveniency of working and finiſhing thoſe immenſe blocks of ſtone which are ſtill deemed neceſſary to the perfection of a hearth. The interior of charcoal of wood furnaces was at one time entirely ſquare from top to bottom, ſo that in the progreſs of the trade, from ſmelting with wood to the uſe of pit-coal, although the general ſhape of the furnace has been altered, the ſquare figure of the hearth has been retained.

Whatever may have been the utility of this general predilection in favour of eſtabliſhed forms, the advantages hitherto ſuppoſed to be derived from this ſource are now by many doubted, and all thoſe nice ſpeculations relative to the preciſe dimenſions and figure of boſhes and ſquares, threatened with total annihilation. This innovation is not confined to figure alone, but extends to dimenſions, and to the nature and bulk of the material neceſſary for the conſtruction of hearths.

Fig. 1. *Plate* X. is the ſection of a hearth and boſhings, conſtructed upon an enlarged principle as to ſize.

Diameter of the boſhes at A	-	-	-	10 feet
Diameter of the hearth at B	-	-	-	4
Diameter of the hearth at C	-	-	-	3

Theſe enlarged dimenſions, in place of being ſquare as formerly conſtructed, are now entirely round, excepting where the tymp ſtone forms the key to the front of the hearth, as may be ſeen in *Plate* X. *fig.* 2. where the external circle A A repreſents the diameter of the boſhes, B, the termination of them, or the top of the hearth, and the form at C, a plan of the inſide figure of the hearth acroſs the bottom of the hearth at C, *fig.* 1. ſame plate.

The difficulty of always obtaining a ſand-ſtone well calculated to ſtand the violent effects of the blaſt, the frequent great expence incurred, the immenſe loſs of time ſuſtained in cutting out old and putting in new hearths, and afterwards annealing them, has induced more maſters to ſpeculate upon the uſe of bricks of ſhapes larger than the common forms, made from good fire clay. No permanent advantage has hitherto been derived from this ſcheme, although it is abundantly obvious, that a ſucceſsful experiment of this kind would leſſen the expence of a hearth greatly, and ſave at leaſt half the time now required to replace an old one.

Neither have any uncommon advantages reſulted from the hearths laid down in *Plate* IX. *fig.* 6. and in *Plate* X. *fig.* 1, 2, and 3. While ſome approve, more are ready to condemn a meaſure, which has for its object the enlargement of a ſpace before blowing, which too ſpeedily becomes ſo afterwards. There cannot, however, be any objection to the circular, in place of the ſquare form, unleſs a little additional workmanſhip is ſuſtained as ſuch. The matter reſts with experience, accompanied by accurate obſervation, to prove the ſanguine hopes of the projectors, or falſify the prophetic forebodings of thoſe who now condemn the meaſure. The amount of our progreſs hitherto, in the making of pig iron, is aſcertained with certainty; to aſſign limits to its ultimate bounds would be preſumption. Of one fact, however, we may reſt aſſured, that the perfection of the ſteam engine, and the conſequent command of blaſt, has alone done more for the manufacture of this article, than all thoſe nice ſhades of diſtinction as to furnace taken collectively, which relieve each other in a ſucceſſive train of minute gradation from one extreme to the other; to all, or to moſt of which, the moſt wonderful effects have been from time to time aſcribed.

One ſubject of conſiderable importance ſtill remains to be diſcuſſed, relative to the conſtruction of the blaſt furnace; namely, the abſolute and relative heights of the tuyeres, the dam-ſtone, and tymp.

On the ſubject of tuyeres, the general opinion is, that the nearer the cinder the blaſt is introduced, the greater is the effect as to the abſolute quantity of reduction. But this may be productive of conſequences more than ſufficient to counterbalance the doubtful advantage of accelerated reduction, either by blowing the cinder from off the ſurface of the iron, and de-carbonating it, or by the cinder ruſhing back through the blow-pipe at any ſtop of the blowing machine, and deſtroying the leather bag which connects the blow-pipe with the main laying pipes. This never

happens

happens but a conſiderable portion of time is ſacrificed, beſides the expence of the bag.

In common, the ſurface of the tuyere plate is laid eight inches above the cinder, or, which is the ſame thing, above the level of the dam-ſtone. Some blow at a diſtance of four inches, others at ſix and eight, and ſome again as high as twelve and fourteen inches. However, under ſome circumſtances, the height of the tuyere is determined by the nature of the materials. In theſe caſes, if the tuyere is only raiſed one inch above its proper height, the bottom of the furnace lumps up immediately, and will invariably riſe in the ſame progreſſive manner in which the tuyere is heightened.

Plate X. *fig.* 1. repreſents the relative proportions of height betwixt the dam, tuyere, and tymp, in ordinary caſes.

G, the dam, or notch of the dam plate, 17 inches above the level of the bottom at H.

I, the centre of the tuyere 26½ inches from the ſurface of the bottom, and 9½ inches above the level of the dam.

K, the bottom of the tymp plate, 23 inches from the bottom of the furnace, and 6 inches above the level of the dam.

At iron-works where different opinions exiſt as to the proper or working height of the dam, very different relative heights enſue, regarding the tymp and tuyere. The former ſhould always regulate the other two. The height of it is ſeldom uſed leſs than 16 inches, nor more than 28 above the bottom.

Conſiderable advantages reſult from placing the tuyere, as to its horizontal poſition, at a judicious diſtance from the front or back wall. This is, as in the caſe of height, often regulated by the nature of the materials. If the furnace, owing to this circumſtance, tends to work cold and languid, behind, with a propenſity to lump at the back wall, the blow pipe ought to be directed as near to the extremity of the hearth backwards as it is poſſible to get in the tuyere iron; *Fig.* 4. *Plate* X. letter *a*: but where the operations of the furnaces proceed with eaſe and facility, the centre of the tuyere ſhould more generally approach the centre of the hearth, as at *b*.

Of late years a new mode of blowing has been introduced, which, from its great prevalency and good effects, ſeems to bid fair to come into general uſe. Furnaces till lately were only erected with one arch, or tuyere ſide, and the blaſt or column of air introduced by means of one blow pipe; now moſt of the new furnaces are built with double tuyeres, with two ſets of main conducting pipes, and the blaſt introduced by means of two pipes in place of one.

The general effects and ſuppoſed properties of this mode of blowing are attended to under the article blaſt.

In the mean time, the proper height and diſtance of the tuyeres, and their relative poſition to each other, have been ſubject to endleſs diſputation. *Fig.* 4. *Plate* X. *a* and *b* ſhew how, in common caſes, the tuyeres are placed to each other in their horizontal range: *a* is placed with its centre three inches from the extremity or back wall of the furnace, and *b* at the diſtance of nine inches from its centre. That there ſhould be a difference of diſtance in their horizontal poſition none are inclined to diſpute; but that this ſhould take place in their vertical ſituation, is by ſome contended; while others inſiſt that the difference ought never to be leſs than four inches. *Fig.* 6. *Plate* IX. *e e*.

Some leſs faſtidious aſſert, and with many evidences of ſound reaſoning on their ſide, that if the blaſt is introduced into the furnace, and at a proper diſtance, to keep the back wall clear, thoſe nice diſtinctions as to inches go for nothing, in a region where an inſtantaneous increaſe of volume muſt deſtroy all repulſion or mechanical contact. This philoſophical reaſon is flatly denied, and the contrary minutely and gravely aſſerted, that were two pipes placed every way immediately oppoſite to each other, the action of the oppoſite columns would retard the velocity of the air, and diminiſh the real elevated quantity in the furnace, by locking up in mutual oppoſition a portion of their reſpective quantities in the laying pipes. There might be ſome foundation for this conjecture, were the reſpective nozles or blow pipes brought into actual contact, or inſerted into each other; but to thoſe who conſider, that in moſt furnaces there is never leſs than four feet of diſtance between nozle and nozle, and the moſt of the intervening ſpace filled with a column of ſemifuſed materials, ignited to the higheſt pitch of whiteneſs, this ſuppoſition will appear to reſt upon very unſatisfactory grounds.

A leſs ſcrupulous claſs of obſervers and reaſoners upon this ſubject even go the length to aſſert, that the tuyeres ought to be put in direct oppoſition, and that this, ſo far from being detrimental, would be found to poſſeſs unqualified advantages. This it is ſaid would reſult from a certain degree of coolneſs which the extremity of each column of air confers upon its oppoſite tuyere iron, and prevent the ſame from heating and burning. To whatever cauſe it is attributable, the fact ſtands in many inſtances unqueſtioned, that not half the tuyeres are loſt or burnt out, with the double blaſt, that was formerly deſtroyed, where the ſingle blaſt was in uſe.

Fig. 7. *Plate* X. repreſents a tuyere iron, 16 inches wide, and 12 inches high at the wide end, 18 inches long and narrowing at the other end to 4 inches wide, and 4½ inches in height. *Fig.* 6. is a plan of the under ſurface of the tuyere iron. *Fig.* 5. repreſents the ſize and dimenſions of the tuyere plate, which when bedded receives upon its ſurface the tuyere iron, *fig.* 7. This plate is firſt laid upon a bed of fire clay, with its narrow end towards the hearth, and inclined to riſe a little. The tuyere is then introduced upon its ſurface, height and diſtance being attended to in the diſpoſition of the plate, and the ſpace betwixt its ſurface, and the ſand-ſtone of the furnace, rammed very perfectly with balls of good fire-clay mixed with ſmall fragments of fire bricks. When about to blow, the noſe or inner end of the tuyere is covered with a very plaſtic clay, to prevent it from heating and burning away. This is always carefully attended to, and the blaſt put off at any time to replace it. Should it be neglected at any time, the iron would inflame with ſuch rapidity, that an opening would be inſtantly made, by which the cokes and ignited matter of the furnace would be recoiled with the greateſt violence imaginable.

Fig. 2. *Plate* XIII. The dam-ſtone. This is actually the dam, or barrier, which prevents the fluid contents of the furnace from advancing, and making their eſcape into the ſand of the caſting houſe. It is generally made from the ſame ſtone as the hearth, but is found ſtill more difficult to ſtand for any length of time the action of the fluid iron, than the hearth to reſiſt the ravages of the blaſt.

Fig. 3. dam plate. This is laid againſt the dam ſtone with a bed of fire clay interpoſing, and cloſes the front of the furnace. Its form is double, ſo that by turning it ſerves the purpoſe twice. It often fails, owing to the conſtant current of lava paſſing over the curvature *a*, and deepening it, till the iron flows over along with the cinder.

Fig. 4. the tymp plate. This embraces the under end of the tymp ſtone, and the ſides of the hearth for three feet up. The thickneſs at bottom, called the heel, or cod, is preſerved from the action of the fire by a ſtrong ſtopping of clay.

This

This is replaced at leaſt every caſt, and prevents the flame and heated materials of the furnace from being blown forward.

Plate IX. *fig.* 4. is a ground plan of the arch pillars, hearth, tuyeres, and vents of a blaſt furnace.

A, the hearth, or particular ſpot where the fluid metal is collected.

B, the dam-ſtone.

c, the fall, or opening, by which the metal is diſcharged. After the caſt it is filled with ſand, which ſoon hardens and preſents a very cloſe texture to the fluid metal within. At the following caſt it is cut carefully down, till the bar penetrates to the quick. A circular inciſion is then made, and the metal flows out of the orifice in a connected round ſtream, into the runner or channel made in the ſand.

dddd, four vents or openings which communicate with the falſe bottoms. *Plate* I. *fig.* 2. Theſe ſerve to convey the damp from the furnace bottom, and by being run out into the external air, two in the front of the hearth, and one at each tuyere, indicate by their temperature, and the quantity of ſteam or vapour which they emit, the real ſtate of the bottom below.

DD, the two pillars which ſupport the front arch; they, at the ſame time, ſerve as abutments to one leg of each of the tuyere arches. The arch at the front is 15 feet wide and 15 feet high, and inclines to the centre of the furnace, in the ſame manner as the ſide walls of the pillars approach.

E, main or back pillar built entirely ſolid.

FF, vent holes ſix inches ſquare, carried up from the foundation, and brought forward to meet the open air every four or five feet.

GGGGGG, tops of the pillars covered with caſt iron plates, for receiving three large caſt iron lintels, 10 feet long, and 10 inches ſquare. Theſe ſerve to give ſolidity to the arch, and ſupport the lining and boſhes of the furnace. *Fig.* 8, 9, different forms of tuyere pipes.

BLAST-*Furnace.—Hiſtory of its Origin and Progreſs.*

In detailing the progreſſive hiſtory of the blaſt furnaces, it is neceſſary to premiſe, that in this country it has undergone a revolution, of which we meet with no ſimilar inſtance in other countries.

The moſt natural and abundant fuel which preſents itſelf to mankind in their progreſs towards civilization, is that furniſhed by the numerous and extenſive foreſts, which generally occupy the ſurface of a wide and uncultivated country. Theſe, in the hiſtory of all nations, have been early appointed to domeſtic uſes, and to the comfort of individuals. As a country became more populous, and the ſpirit of civilization increaſed, other advantages reſulted from the general uſe of wood as fuel. The amelioration of climate, and the clearing of large tracts of land, making it ſubſervient to the purpoſes of agriculture, were not the ſmalleſt benefits thus derived. As the progreſs of knowledge began to deviſe and eſtabliſh regular manufactories, to ſupply the wants of the thriving community, the ſame ſources of combuſtion were opened to the manufacturer and the artizan. Theſe, as they became ſucceſsful, were only preludes to other eſtabliſhments more extenſive, more lucrative, and entailing wants more difficult to ſupply. Among others the ſmelting of metals was no doubt of early origin, and equally dependent upon the woodland counties, in the immediate neighbourhood of the ores. In this claſs we can trace no metallurgical operation ſo hoſtile to the exiſtence of wood, as an extenſive manufacture of iron. If this manufacture, owing to the great and unexampled proſperity of the country, in place of remaining ſtationary, or exhibiting ſymptoms of decline, ariſing from a want of conſumption of the article, has increaſed in capital, in extent, and riches beyond all precedent, wood, the baſe of the manipulation itſelf, depending only upon a ſtock rapidly declining, the exiſtence of which was frequently incompatible with the views and intereſt of the landed proprietor, muſt ſoon have been annihilated, and the art of making iron loſt to the community.

In this ſingular ſituation was Great Britain placed from the reign of Charles II. to the middle of the laſt century. The increaſing manufactures, commerce, and general proſperity of the country called loud for an additional ſupply of articles fabricated from iron, while wood, the foundation of the whole art, was rapidly declining in point of quantity, without the moſt diſtant proſpect of ever being again renewed. Pit coal had been long before the latter period ſuggeſted as a ſubſtitute, but prejudice, intereſted views of eſtabliſhed capitaliſts, and above all, a want of command of mechanical power, had prevented any ſucceſsful operation from being eſtabliſhed in this new department of iron making. No ſooner, however, were theſe barriers to improvement broken through, and a change of fuel in the blaſt furnace found to be attended with profitable effects, than the languiſhing ſtate of the trade began to revive, and improvements ſucceeded each other, with a facility new and aſtoniſhing. In fifty years the revolution was complete, whether the conſideration regards the increaſe of the manufacture, the general uſe of pit coal in the blaſt furnace, or the almoſt total annihilation of the charcoal mode of making iron.

It is uncertain at what period the manufacture of iron commenced in Britain. It is probable, that the working of the tin mines of Cornwall, by the Phœnicians, would introduce into the country a claſs of men ſkilled in all the then known metallic ores, capable of appreciating their true value, by converting the riches of an unexplored country, either to their own immediate neceſſities, or to the conveniences of the unſkilful inhabitants. The invaſion of England by the Danes, and their conſequent eſtabliſhment, would moſt likely add to the former ſtock of knowledge, in the art of mining and ſuſing iron ores. Whatever truth there may be in this conjecture, the fact ſtands unqueſtioned, that in ſeveral counties in England large heaps of ſcoria are found, with an accumulation of ſoil ſufficient to bear large trees. Theſe have been from time immemorial called "Danes cinders." So early as 1620, Dudley remarks, that large oaks were then found in a ſtate of decay upon the tops of ſome of theſe hills of ſcoria. It is not, however, probable, that theſe cinders were the product of the blaſt furnace. At a period ſo remote as that, wherein theſe heaps of ſcoria muſt have been accumulated, the labours of the iron maker were chiefly directed to the fabrication of ſmall portions of malleable iron in *foot blaſts* and *bloomeries*. The art of moulding and caſting in iron was either totally unknown, or ſo very rude, as to excite no intereſt in favour of proſecuting this fine branch of art. If pig or caſt iron was at all formed, it was merely of the moſt infuſile nature, for being ſpeedily converted into malleable iron. It was not till long afterwards, when improvements had taken place in the rude machinery of the times, and a diviſion of labour ſeemed to be productive of many advantages, that different furnaces exiſted: one for the making of pig iron, and another for the converſion of it into malleable iron. This firſt gave riſe to the blaſt furnace, which, properly ſpeaking, was an improvement reſulting from the knowledge of the advantages derived from a diviſion of labour. After the appropriation of the blaſt furnace to the excluſive manufacture of pig iron, the manufacturer would ſoon diſcover, that the products of his

his furnace were frequently different from each other. Experience and obſervation would ſoon enable him to decide, from whence this had its origin. A ſmall additional quantity of fuel, beyond that he formerly uſed for forge-pig-iron, he found, would confer a degree of fuſibility upon the metal that immediately pointed out the practicability of caſting it into ſhape. Moulding from thence would moſt likely enſue, and become equally an appendage to the blaſt furnace as was the bar-iron forge. As this new manufacture became familiar to the proprietor, he would immediately find his intereſt in dividing the product of his blaſt furnace into grey melting iron or into forge pigs, as the exigencies of his moulding ſhop, or forge required.

If credit could be given to the "Metallum Martis" of Dudley, in the 12th year of James, anno 1615, there were at that period not leſs than 300 blaſt furnaces for ſmelting iron-ore with charcoal, each of which had fuel, upon an average, for 40 weeks per annum. The average produce in pig-iron at each furnace of 15 tons per week, or 600 tons per annum, makes the total yearly quantity 180,000 tons, being a greater quantity than has ever ſince been manufactured in Britain.

However much this quantity may be exaggerated, yet it is highly probable, that even at this early period, the iron buſineſs in general, and the particular operations of the blaſt furnace, had obtained an eminent rank in the manufactures of the country. The progreſs of agriculture, and the increaſe of population under the reign of the peaceable James, had taught the huſbandman and the proprietor the value of cultivated fields. The great conſumption of wood for the navy and iron-works had greatly exhauſted the principal foreſts of ſupply; tracks of country became cleared, and as the ſpirit of cultivation increaſed, the annual quantity of fuel for the manufacturing of iron diminiſhed.

It is probable that Mr. Dudley, in eſtimating the quantities produced from each furnace, formed his average from the winter and ſpring months, when water was plentiful, and he ſeems not to have made ſufficient allowance for the occaſional ſtoppages in ſummer, during the time of cutting and collecting the wood for the enſuing wet ſeaſon. If, therefore, in place of making 600 tons yearly, the furnaces of theſe days are ſuppoſed to have made each, upon an average, five tons per week, or making a little allowance, 250 tons yearly, which is ſurely nearer the truth, this ſtill leaves an annual amount of manufactured pig-iron equal to 75,000 tons, which, excluſive of the operations of the forge, forms a very reſpectable ſtaple at that early period of the hiſtory of our manufactures.

Pit coal had been long known before this period, and wrought at Newcaſtle prior to the year 1272. Annually vaſt quantities of it were exported to Holland and the Low Countries, for the uſe of the ſmithy, and other manufactures requiring an intenſe and continued heat. Yet in England prejudices ran ſo ſtrong againſt its application to the manufacture of caſt-iron, that the projectors of this original undertaking met with every obſtacle which the narrow unenlightened minds of the eſtabliſhed manufacturers could deviſe.

James granted ſeveral patents for the excluſive right of manufacturing iron with pit coal. None of the projectors, however, were ſucceſsful, till the year 1619, when Dudley ſucceeded in making coak pig-iron in a blaſt furnace, though only at the ſparing rate of *three tons per week*. At this period many of the iron works were at a ſtand for want of wood, and the conſequence was an advance upon the price of iron: this rendered it a lucrative buſineſs to thoſe manufacturers whoſe ſupply of wood was ſtill undiminiſhed, and of courſe made them hoſtile to any innovation, whereby the preſent price of iron was likely to meet with a reduction.

This period of prejudice, ſo unfavourable to innovation in the iron buſineſs, was followed by one more general and more calamitous for the nation: amidſt the diſtraction occaſioned by civil war, neither innovation nor improvement could be expected. Patents, however, were granted to ſome during the common-wealth, for the excluſive manufacture in the new way, in one of which, it was at the time believed, that Cromwell was a partner: theſe partly ſhared the ſame fate with the firſt inventor, and none ſucceeded in eſtabliſhing a manufactory either of extent or certainty. In 1663, we find Dudley applying for his laſt patent, and ſetting forth, that at one time he was capable of producing ſeven tons of coak pig iron weekly, with an improved furnace 27 feet ſquare, and bellows, which one man could work for an hour without being much tired.

It was not, till impelled by neceſſity, ariſing from the rapid decline of the annual growth of timber, that pit coal became an object of univerſal eſtimation. When improvements on machinery had attained a pitch of certainty, and experience had taught the mechanic the manifold advantages of the ſteam engine; the adventurous manufacturer found he poſſeſſed an extent of means to which he was formerly a ſtranger. Small furnaces, ſupplied with air from leathern bellows, blown by oxen, horſe, or human labour, became exploded, and an increaſe of ſize took place, together with an increaſe of the column of blaſt neceſſary to excite combuſtion.

At this eventful era in the hiſtory of the blaſt furnace, when the ameliorating hand of agriculture was progreſſively ſweeping before it, what remained of the once immenſe tracts of woodland dedicated to the ſupply of the blaſt furnace; when the general improvement in machinery, and the introduction of the ſteam engine threatened to give new life and impulſe to manufactures in general, the iron-buſineſs ſeemed dwindling into inſignificancy and contempt. The demand of the country increaſed for the manufactured article, particularly bar-iron, while every year ſaw a gradual but ſteady diminution of the annual quantity. Recourſe to foreign markets was had for a ſupply of that article, of which this country once was the greateſt exporter, and the immenſe annual importations from Ruſſia and Sweden may date their origin from that period. The flouriſhing and extenſive detail of Dudley no longer exiſted, and the 300 blaſt furnaces of his day were now diminiſhed to 59 in all; the total amount of whoſe annual produce was 17350 tons, or nearly 300 tons to each furnace.

LIST of the Blaſt Furnaces in England and Wales immediately before the introduction of pit coal, as a ſubſtitute for the charcoal of wood; the particular counties in which they were ſituated; the collective quantity of iron manufactured in each county, and the produce of each particular blaſt furnace.

Annual average for each furnace 294 1 1

By this ſtatement it is evident, that the manufacture of pig-iron had diminiſhed during one hundred to one hundred and thirty years preceding, upwards of 50,000 tons annually. Fortunately for the exiſtence of the trade, the application of good going, and what, at that time, would be reckoned powerful, ſteam engines, about the year 1750, for raiſing and compreſſing air, were introduced at ſome places where abundance of materials was found without water for turning machinery. The manufacturer now found that his produce could be increaſed by enlarging the diameter of his ſteam cylinder, or perfecting the vacuum under the piſton; and it was ſoon diſcovered, that theſe increaſed effects alone were requiſite to the formation of pig-iron, in profitable quantity from the coke of pit coal; nor is it to be wondered that this ſecret remained ſo long a myſtery. The ſmall quantity of air that was formerly requiſite to ignite a charcoal furnace, whether from the great inflammability of the fuel, or the ſmallneſs of its capacity, was conſtantly before the eyes of the manufacturer. He had more often felt the effects of over-blowing, than under-blowing his furnace; and it is highly probable, that pit coal, being deemed every way inferior,

inferior, an unuſual timidity would precede any movement that might have for its object the enlargement of the column of air or the increaſe of its denſity.

This, however, once done away, there ſeemed no end to the quantity of air that a coke blaſt furnace could with propriety receive before any bad conſequences enſued. Denſity, however, was found inimical to quantity, and the ſame law was at laſt diſcovered to hold good regarding pit coal as with wood, that the ſofter qualities could be over-blown, while the more denſe and compact ſtrata remained undiminiſhed before a heavier blaſt.

The celebrated foundery of Carron was begun about the year 1760, and as was the cuſtom of the times, the operation of blowing was performed by large bellows moved by means of a water wheel. Pit coal was the ſtaple fuel in view, but the ſcanty ſupply of air, and its want of denſity, ſeldom permitted the produce of the furnace to exceed 10 or 12 tons weekly, and frequently, in ſummer, the quantity was reduced even below this. The company collected immenſe quantities of charcoal wood, and found their blaſt much better calculated for the operation of ſmelting with it, than the uninflammable pit coal obtained in their neighbourhood. Experience, however, gradually unfolded means of adopting machinery, more calculated to the nature of the coal fuel, more powerful wheels were conſtructed, the bellows was abandoned, and in their place large iron cylinders were introduced blowing both up and down. A larger column of air of triple or quadruple denſity was obtained, and effects equivalent to theſe great improvements followed at the blaſt furnaces. The ſame furnaces that formerly yielded 10 and 12 tons weekly, now ſometimes produced 40 tons in the ſame ſpace, and on the average in one year not leſs than 1500 tons of metal.

From the period (1750 to 1760) that pit coal coke was applied as a ſubſtitute for wood charcoal in the blaſt furnace, the iron trade began immediately to revive, and its progreſs in England and Wales, in a period of 30 years, was truly aſtoniſhing. The general uſe of pit coal, moſt unqueſtionably, occaſioned an earlier relinquiſhment of many of the charcoal works, than would have otherwiſe been the caſe, but the collective manufacture had ſo much increaſed, as to render this an object of trifling importance.

The following is a correct ſtatement of the annual manufacture of pig-iron in England and Wales in the year 1788:

Charcoal Blaſt Furnaces.	No. of Furnaces.	Tons at each.	Total in each County.
Glouceſterſhire	4	650	2600

Total quantity of pig-iron made in England and Wales	77		61300
	85		68300
Annual quantity manufactured immediately preceding the introduction of pit coal for furnace fuel	59		17350
Annual increaſe in 30 years	26		50950

The period of 1788 or 1790 may be called a new æra in the manufacturing of pig-iron. The double power engine of Mr. Watt had now become more general, and was yearly

yearly finding its way into blaſt furnace works. The regular and increaſed effects of this very powerful machine were ſoon felt in moſt of the iron counties. The produce of the furnaces in metal greatly increaſed as to quantity, and as they became more proſperous, ſtimulated others to engage in ſimilar undertakings. New works were yearly projected, and ſeveral blowing furnaces annually added to the former liſt: ſo that in eight years the manufacture of pig-iron had nearly doubled itſelf.

The following table is a curious illuſtration of this fact. It was drawn up as an authentic document of the returns made from all the blaſt furnace proprietors in Britain, of the number of their furnaces, and the annual quantity of pig-iron manufactured at their reſpective founderies. Theſe returns were made at a time when it was in the contemplation of the legiſlature to impoſe a tax upon pig-iron, and are copied from Dr. M‘ Nab's letter to the chairman of the committee of the houſe of commons upon the ſubject of the coal trade.

Ditto of each of the Scotch Furnaces, 946

The demand for iron articles of all kinds in this country not only continued unabated after the period of 1796, but kept increaſing in a greater ratio than formerly; ſo that, in the ſhort ſpace of five years, ſituations were occupied for nearly 50 additional furnaces, or addltions made to eſtabliſhed works of that extent. Betwixt 1801 and 1802, it was aſcertained that the following new furnaces were either building or actually in blaſt, in England, Wales and Scotland.

In England and Wales.

Total of new Blaſt Furnaces	22	25

Blowing and building in Great Britain; the produce of which ſuppoſing them all to have gone to work at the rate of 1000 tons per annum, from each furnace, would amount to, from 47 furnaces, 47,000 tons.

Manufactured at, and previous to 1796, in 121 furnaces, 125,079

168 furnaces, 172,079 tons.

The reſpective proportions of this aſtoniſhing produce in pig iron manufactured in England and Wales, and in Scotland, will ſtand thus:

	Furnaces.		Tons.	
England and Wales, in 1796,	104		108,993	
Ditto, ſince that period,	40		40,000	
		144		148,993
Scotland, in 1796	17		16,086	
Ditto, ſince that period,	7		7,000	
		24		23,086
Grand Total in Britain,		168 making		172,079

In recapitulating the intereſting facts which will reſult from a review of the gigantic progreſs of this manufactory, the regular progreſſive quantity made at a furnace is remarkable, or, which is the ſame, a diminution of the number of furnaces to perform the ſame quantity of labour.

Dudley repreſents, that in his day, 1620, there exiſted, in England and Wales alone, 300 blaſt furnaces, for the ſole making of pig iron, to each of theſe have been aſſigned the yearly produce of - - - - 250 tons.

At a period conſiderably after this, and before the uſe of pit-coal was found profitable in the furnace, 59 furnaces produced yearly 17,350 tons of charcoal iron, or each furnace average, - 294

In 1788, there ſtill exiſted in England 24 charcoal furnaces, which yearly manufactured 13,100 tons of metal, or from each furnace, on an average, - - - - - 545

At the ſame period, in England and Wales, 53 blaſt furnaces, at which coke was uſed, manufactured yearly 48,100 tons, which upon an average was nearly, from each furnace, - - 907

The ſame year, in Scotland, 8 furnaces produced 7000 tons of iron, or from each furnace, - 875

In 1796, the number of furnaces in England and Wales amounted to 104, and yielded 108,993 tons of metal, which from each furnace was equal to - - - - 1048

The ſame year, in Scotland, 17 furnaces manufactured 16,086 tons of pig iron, which is from each furnace, - - - - 946

Theſe are by no means ſufficient data to form an accurate opinion of the real progreſs or improvement of our blowing machinery in Britain. In the collection of furnaces in 1796, a number of charcoal blaſts were included, which, from their general ſmall produce, blowing only four, ſix, or nine months a year, reduces the average conſiderably on the whole. It may now be ſafely aſſerted, that the average produce in iron at pit-coal blaſt furnaces in England and Wales, is at melting iron works, - 1200 tons

Do. at forge pig works, - - 2000

This bears a very ſtriking contraſt to the early exertions of the manufacturers in the ſixteenth and ſeventeenth centuries, and exhibits a wonderful example of the general and rapid improvement of machinery in the laſt 50 years. With the improvements of machinery, the advancement of the manufacture of iron in general, and particularly of coke pig iron, has kept equal pace. Nor have we ſacrificed quality to quantity, but the reverſe; for the melting pig iron of our time is much more calculated for every variety of caſting, than iron, equally ſaturated with the coally principle, made with wood charcoal.

By comparing the value of a ton of pig iron at different periods for the laſt 200 years, a pretty accurate opinion may be formed of the increaſed price of labour at iron works, and of the increaſed value of an object of univerſal utility in all our arts and manufactures.

About the year 1620, charcoal pig iron ſold for 6l. per ton.
1788, ditto for melting, - 8l.
1798, ditto - - 9l. 10s.
Coke pig iron, when firſt invented by Dudley, was ſold at - - - 4l.
In 1788, it ſold for - 5l. 10s.
1798, ditto - - 7l. 10s.
1802, melting iron was - 8l. 10s.
And ſmooth-faced N° 1. ſold at - - 9l. 10s.

One thing is here worthy of remark, that in a period of 170 years one ton of coke pig iron roſe in value only 30 s. i. e. betwixt 1620 and 1788; but that in the ſhort period of 14 years following 1788, an advance of 4l. per ton took place. One thing only may be offered in extenuation of this immenſe riſe, that part of it was owing to the miſunderſtanding that took place betwixt this country and ſome of the Baltic powers, which was no ſooner adjuſted than pig iron fell in price. The article ſtill, however, maintains itſelf at 8l. 10s. per ton, being double the riſe in point of value in fourteen years that took place in the one hundred and ſeventy preceding the commencement of that period.

To point out proper channels, whereby to account for the annual conſumption of ſuch an immenſe quantity of raw materials, would prove a ſatisfactory ſource of information. The endleſs detail into which the foundery trade has now branched itſelf, the almoſt univerſal fabrication which it embraces, and the extenſive diffuſion of the ſcites of manufactories themſelves, preclude the poſſibility of obtaining this with ſtrict accuracy. The following ſtatement, however, will tend to throw ſome light upon the ſubject.

	Tons.	
It is reckoned, that the bar iron forges in Britain manufactured annually from pig iron 40,000 tons of finiſhed bars, which, at the rate of 35 cwt. of pigs for every ton of iron bar produced, will account for - - - - -		70,000
Conſumed yearly in the erection of new furnaces, forges, machinery, &c. - - -		5,000
Purchaſed by the board of ordnance in the ſtate of cannons, mortars, carronades, ſhot, and ſhells, &c. on an average of 1794, 5, 6, -	10,935	
Waſte in melting from the pig, boring, &c. - - - - -	1,300	
		12,235
Purchaſed by the navy board in the ſtate of ballaſt, &c. - - - - - -		2,664
India Company's annual ſupply in guns, ſhot, ſhells, carcaſes, &c. -	5,000	
Waſte melting, boring, &c. -	700	
		5,700
Merchant guns, carronades, ſhot, &c. for arming trading veſſels, - -	10,000	
Waſte in melting and boring, -	1,000	
		11,000
Ballaſt for Merchantmen and India men, -		5,000
	Tons	111,599

For the difference betwixt this and the total manufacture, recourſe muſt be had to the large exportation to Ireland, and to the numerous and extenſive caſting founderies of London, Liverpool, Manchester, Birmingham, Workington, Newcaſtle, Edinburgh, Glaſgow, &c. none of which melt under 2000 tons yearly, and many of them from 4 to 5000 tons of melting pig iron.

We ſhall now leave this intereſting ſubject with ſome general obſervations upon the origin and progreſs of the pig iron manufacture, and its early uſe in the fabrication of caſtings.

It appears from Dudley, that towards the cloſe of the reign of queen Elizabeth, blaſt furnaces had been conſtructed of ſize, and with machinery ſufficient to produce upwards of two tons of charcoal iron per day. Such great products in iron were moſt probably confined to ſituations where there was abundance of water, and where water-wheels and bellows of a conſiderable magnitude were uſed. The more common modes of operation were confined to furnaces of an inferior ſize, which were ſupplied with air by means of hand-bellows, excited by cattle, or the labour of men. At the ſame period England enjoyed a conſiderable export trade, ariſing from her ſuperior manufacture of iron guns, mortars, &c. As pit-coal had not been applied in any branch to the manufacturing of iron, it is probable, that theſe articles would be caſt from the large blaſt furnaces; the flame of wood poſſeſſing but feeble effects compared to that of pit-coal, would render the application of the reverberating furnace, if then known, of no uſe in the caſting of guns and mortars.

The non-application of pit-coal in every department of the melting foundery, would greatly retard the perfection, or even improvement of the art of moulding, and caſting ſmaller and more general articles. The want of it, as the ſmelting fuel in the blaſt furnace, was long ſeverely felt by the general backward ſtate of the art of moulding and caſting in this country, and allowed other nations with fewer advantages to get the ſtart of us. It is highly probable, that long before the period formerly alluded to, the application of pit-coal had been ſpeculated upon, either as an auxiliary, or as a ſubſtitute in every branch of the iron buſineſs. Its well known inflammability and tendency to form a cinder, and the general decay of wood, would furniſh ample grounds for what, to many at the time, would be conſidered as idle and viſionary ſpeculations. The advantages ariſing from the trade, as it was then ſituated, had been rigidly aſcertained, and fully appreciated by the eſtabliſhed manufacturers. The buſineſs, in point of extent, ſeemed only limited by the ſupply of wood. New erections, for want of a proper ſupply of materials, became impracticable; thoſe already engaged were more anxious to preſerve their ſupply, however much circumſcribed, than liſten to innovation, which, by ſubſtituting pit-coal for the charcoal of wood, would likely give to the ſpeculatiſt a great ſuperiority in the market. It is alſo highly probable, that many of the iron works then eſtabliſhed were at a conſiderable diſtance from pit-coal, the general introduction of which would prove fatal to their intereſts.

In this view of the ſubject, the adventurer with capital had every thing to hope, the eſtabliſhed manufacturer every thing to fear, by change. Under theſe circumſtances, the diſcovery, or rather the aſſertion of the practicability of making iron with pit-coal, was announced by Simon Sturtevant, eſq. in the year 1612, who, upon application, was favoured with a patent from king James, for the excluſive manufacture of iron with pit-coal, in all its branches, for the long period of thirty-one years. In return, the ſaid Simon Sturtevant bound himſelf to publiſh a faithful account of his diſcoveries, which afterwards appeared in quarto, under the title of his "Metallica." It is uncertain to what cauſes his failure was at the time attributed, but in the execution of his diſcoveries upon a large ſcale, he had found difficulties amounting to utter impracticability; for in the year following, he was obliged to make a ſurrender of his letters of monopoly.

The

The ſecond adventurer in this unexplored path we find to have been John Ravenſon, eſq. who, like Sturtevant, was ſucceſsful in obtaining a patent for the new manufacture, but, like him alſo, was inadequate to the completion of it upon a profitable ſcale. Ravenſon was alſo enjoined to publiſh his diſcoveries under the title of his "Metallica," which was printed for Thomas Thorp, anno 1613. Several other adventurers ſtepped forth, all of whom had the mortification of reſigning their patents, without having contributed to the ſucceſs of their arduous undertaking.

In 1619, Dudley obtained his patent, and declared, that although he made only at the rate of three tons per week, he made it with profit.

This diſcovery was perfected at his father's works at Penſent, in Worceſterſhire. This gentleman's ſucceſs in the various manufactures of iron with pit-coal, had united not only all the proprietors in the charcoal iron trade, but many new adventurers, who wiſhed to ſhare in the emoluments, or to acquire part of the fame of the new diſcovery. Their intereſt was ſufficient to limit the duration of Dudley's patent from 31 to 14 years. During the greateſt part of this period, according to his own ſtatement, he continued to make pig and bar iron, and various caſtings; all of which he ſold much lower than the charcoal manufacturers. In the article of caſtings he muſt have had greatly the ſtart of the charcoal founderies, as the quality of melting coke pig iron is far ſuperior to that of charcoal, particularly that made in this country for the general purpoſes of caſting. Nor was the ſuperior genius of Dudley always an object of paſſive indifference in the narrow eſtimation of the new adventurers and the eſtabliſhed manufacturers. The envy occaſioned by his uncommon ſucceſs, produced at laſt a ſpirit of combination, which terminated in a hoſtile attack upon his devoted works. His improved bellows, furnace, forge, &c. all fell a prey to a lawleſs banditti, betwixt whom and its furious leaders no ſhades of diſtinction were viſible, but thoſe of avarice, ignorance, and the moſt contemptible prejudice.

To evade the mode of operation diſcovered by Dudley, or to introduce the making of coke pig iron with greater advantages, a new plan was adopted by captain Buck, major Wildman, and others, in the foreſt of Dean, where they erected large air-furnaces, into which they introduced clay pots reſembling thoſe uſed at glaſs-houſes, filled with the neceſſary preparations of ore and charcoal. The furnaces were heated with the flame of pit-coal; and it is probable, that by tapping the pots below, it was expected that the ſeparated metal would flow out. This rude proceſs of aſſaying on a large ſcale, was in the end found utterly impracticable; the heat was inadequate to perfect ſeparation; the pots cracked; and, in a ſhort time, the proceſs was abandoned altogether.

The misfortunes which befel the ſanguine, but unfortunate Dudley, were an irreparable loſs to the perfection of the coke pig proceſs. The hoſtile rivalſhips he had to encounter, in conſequence of the new ground he had occupied as a manufacturer, together with a zealous attachment to the royal cauſe during the civil war which followed his diſcovery, completely prevented his improvements from attaining a pitch of permanency and general utility. The refuſal of a new patent after the reſtoration, prevented him from again entering the laborious paths of diſcovery and improvement, although it appears, that his former application to the perfecting of this branch of manufacture had not been unſucceſsful, for in place of three tons of coke pig weekly, in his petition praying for a renewal of his ancient rights, he ſtates, that he could now manufacture ſeven tons by means of a large furnace, and an improved bellows.

No greater pitch of improvement took place for nearly one hundred years after this period. The practicability of the manufacture was diſcovered; but the mode of obtaining quantity, to enſure in general a profitable return, depended upon other circumſtances than the proportioning of the raw materials together. Had machinery received the ſame improvements in the time of Dudley, it is more than probable that the rapid progreſs of the coke pig trade would have dated its origin from that period. But this great æra in the hiſtory of our manufactures was reſerved for a much later date: and in the improvements of the ſteam engine, we ſee new life and exiſtence conferred upon every ſpecies of art that can be made ſubject to motion or mechanical control.

Blast *Furnace Works*, are large and expenſive buildings for the manufacturing of pig iron. An erection upon the ſmalleſt ſcale muſt conſiſt of a furnace, caſting-houſe, bridge-houſe, and blowing engine. The latter is ſometimes, though ſeldom, worked by means of a water-wheel. The moſt univerſal mode of blowing is by means of a ſteam engine. See Blowing *Machine*.

There is no general plan laid down for building a blaſt furnace work. The ſingular ſituation which ſhould be occupied, to inſure every convenience, renders this dependent upon the nature of the ground.

It is always reckoned a great advantage to place the blowing machine at as ſhort a diſtance as poſſible from the furnace or furnaces, that the air may have the leaſt poſſible travel in the conducting pipes. When this cannot be conveniently effected, the diameter of the pipes ought to be made ſufficiently large to admit of the blaſt paſſing without any material friction.

The uſual appendages to blaſt furnaces are mines of coal, iron-ſtone, and lime-ſtone. And theſe form no inconſiderable portion of the whole expence.

In ſituations where blaſt furnace building materials are at a moderate price, and where no uncommon difficulty occurs in the progreſs of the general operations, 15000l. of funk capital may be deemed requiſite for one furnace; and for every furnace after this, 10,000l. may be added.

This great capital for many years kept the trade in the hands of a few; but of late, ſince capitaliſts have become more common, the number and extent of the blaſt furnace erections have become truly aſtoniſhing.

The following deſcriptions of plates illuſtrative of the plan and arrangement of blaſt furnace works will convey a tolerable idea of the nature of theſe buildings.

Plate XI. *Blaſt Furnace Works*, repreſents the ground plan of an entire fabric, conſiſting of

A ſteam-engine for blowing two furnaces.
2 Blaſt furnaces.
2 Bridge-houſes.
1 Caſting-houſe.
1 Boiler-houſe.
2 Boilers.
1 Chimney for boiler flues.

A, Engine-houſe, 40 feet long, 18 feet wide.

B, Pedeſtal for ſteam cylinder; 7 feet ſquare at baſe, and 4 feet at top.

C, Pedeſtal for blowing, or air cylinder. Baſe 10 feet ſquare, top 7 feet ſquare. Theſe are generally built of ſolid hewn ſtone, and bedded with the greateſt accuracy. From centre to centre of the two pedeſtals is 24 feet, which is alſo the diſtance betwixt centre and centre of the ſteam and air cylinders.

D, Door or opening through the lever wall. This wall at bottom is built 5½ feet thick, but is occaſionally reduced

in point of thickneſs to 3½ feet at top, as may be ſeen at the correſponding letter in the ſection.

F, Door or opening from the engine into the boiler-houſe. An opening above this ſerves to conduct the ſteam pipe from the boiler to the ſteam apparatus at the cylinder.

E, Door or opening for carrying through the blaſt pipes from the top and bottom of the air cylinder to the water receiver below.

G, The boiler-houſe, 40 feet by 30 within the walls. As this is excavated from the ſolid hill to the depth of 30 feet, it is requiſite to have the walls uncommonly ſtrong. Thoſe in the plan are 6 feet thick at bottom, and are reduced at three different heights in thickneſs, as repreſented by the interior lines.

H H, Two boiler ſeats for boilers, 18 feet long, 9½ feet high, and 7 feet wide.

I I, Fire-places, 6 feet ſquare.

K K, Dead-plates before the bars or grates.

L L, Openings where the furnace doors are hung.

M M, Semi-circular openings formed beyond the dotted line, or termination of the boiler, in which the flame from the grates riſes to enter the iron flue or tube, which is placed in the centre of the boiler.

N, Chimney, 2½ feet ſquare within, and 50 feet in total height; from the bottom of the flue 42, and 8 feet from the foundation.

O O, Coal pits for containing ſmall coals for the engine's ſupply. Theſe are 8 feet by 6 at bottom, and widen gradually as they approach the ſurface of the coke yard. The coals are there emptied from the cart into theſe receivers, and the engine-man eaſily ſupplies his wants from the ſmall openings which communicate with O into the boiler-houſe.

P P, Bridge-houſes for containing cokes, iron-ſtone, and lime-ſtone, for filling the furnace. Meaſurement within 42 by 40 feet.

Q Q, Doors or entrances from the coke yard into the bridge-houſes.

R R, Openings from the bridge-houſe, which is here connected with the furnace, by means of an arch and parapet walls. This is more fully ſeen in the elevation ſection P. Along this bridge the materials are carried or wheeled into the mouth of the furnace.

S S, Two blaſt furnaces, 34 feet ſquare in the baſe.

T, Caſting-houſe 102 feet long by 48 in width, from the front wall or arch of the furnace, or 88 feet wide from the front wall of the engine and bridge-houſes, and 24 feet high in the ſide walls.

W, Water receiver for receiving and equalizing the column of blaſt. Length 40 feet, and breadth 18 feet.

V, The ſpace in which the equivalent column of water riſes, 3 feet wide. The exterior line denotes the inverted iron cheſt; the interior lines, the different baſements formed by the ſtone work laid upon the cheſt to prevent it from riſing when the engine is at work.

Y, Termination of the blaſt conduct pipes from the air cylinder into the iron receiver, 2 feet 6 inches diameter.

Z, Poſition for the horizontal range of pipes to branch off, which are meant to convey the blaſt to the oppoſite tuyeres, *a a*, betwixt the back wall of the furnace, and the bridge-houſe.

b b, The two tuyere ſides next the water preſſure. From Y proceeds a ſtraight pipe along the centre line *b*, for conveying the blaſt to that ſide of the furnace.

c c, Front arches, under which the furnace workmen perform all the labour of tapping, caſting, and cleaning the furnace.

d d, The ſpaces incloſed within theſe dotted lines are called pig beds. They are kept conſtantly filled with ſand, and in them the operation of moulding and running the pig metal is conſtantly performed.

Plate XII. *Blaſt Furnace works.*

Elevated ſection of the ground plan, *Plate* XI. through N F B D C E and X.

A, Inſide of the blaſt engine-houſe.

B, Steam cylinder pedeſtal.

C, Blowing or air cylinder pedeſtal. Both of theſe are built upon 4 or 6 inch planking, laid upon ſtrong logs, which are again ſupported upon the ſolid ſtone buildings, *a a*, running from the lower wall along the ſide wall of the engine-houſe, to the wall perpendicular to E. The binding down bolts that paſs through the flanges of the cylinders are ſtrongly keyed upon the under ſide of the logs, and are at all times eaſily acceſſible.

D, The lever wall and opening of communication betwixt the ſteam and blowing end of the engine-houſe.

F, Door or opening into the caſting houſe and water regulators.

E, Door to the boiler houſe.

G, The boiler-houſe.

H, One of the boiler ſeats.

I, One of the boilers, 18 feet long, by 9½ wide, by 7 high.

K, Manhole door for entering the boiler.

L, Thorough arch in the foundation of the chimney.

M, Throat, or opening into the chimney, for the paſſage of the flame and ſmoke.

O, Coal pit for containing fuel for the engine.

P, Arched paſſage of communication betwixt the bridge-houſe and furnace mouth. The opening in the bridge-houſe is more diſtinctly ſeen at R, *Plate* XI.

S, Side view of one of the blaſt furnaces, as connected with its correſponding bridge-houſe.

W, Water vault, or ciſtern, for receiving the inverted cheſt. In rocky foundations this is cut out of the rock, but in ſoft ground the excavation is made and lined with well jointed maſon work, puddled behind with clay to prevent the loſs of water.

T, Caſting-houſe and roof.

b, The tuyere arch.

c, The ſow, or lintel of caſt-iron, 12 inches ſquare.

d, The oriſice at which the blaſt enters, called the tuyere.

e, Spring beams of the engine houſe, A. Theſe are compoſed of two logs 14 inches ſquare. The main gudgeon, ſeat, and beam reſt upon theſe.

f, Stay logs for the ſteam cylinder.

g, Ditto, for the blowing cylinder.

Deſcription of *Plate* XIII. *Blaſt Furnace Works.*

Croſs ſection and elevation of *Plate* XI. through S Y S.

S S, Section of two blaſt furnaces, and their ſituation as connected with the blowing apparatus.

Y, The branch pipe for communicating the air to the inſide tuyeres of the furnace. This pipe has another branch of communication behind, which connects it to the blaſt pipes which deſcend from the blowing cylinder at A, and to the double column of pipes which are carried round behind the furnace to the oppoſite tuyeres.

C C, View of the pipes which convey the air to the oppoſite tuyeres, where double blaſts are in uſe.

D, Front wall of engine and bridge-houſes.

X, Iron cheſt inverted in the water receiver, and connected with the blaſt pipes.

V V, Opening all round for the water to aſcend, as it becomes expreſſed from the cheſt by the impelling force of the blaſt.

O, Logs on which the cheſt is inverted, to preſerve it from the floor of the water receiver, from 12 inches to 18 of ſpace.

Deſcription of *Plate* XIV. *Blaſt Furnace Works.*

Ground plan of an extenſive blaſt furnace foundery, conſiſting of four furnaces and two blaſt engines. The peculiar conſtruction of this plan is, that only one furnace may be erected at a time, and afterwards the whole number; ſtill preſerving that regularity and uniformity of deſign which will at any time make the blowing machinery of one part ſubſervient to the whole, in caſe of accidents, ſtoppages for repairs, &c.

A, Engine houſe, with cylinder, pedeſtals, lever wall, openings, &c.

B B, Two boiler-ſeats and boilers.

C C, Water regulators for the blaſt, which conveniently communicates, by means of pipes, with the blowing cylinders, placed upon the pedeſtals behind A, I.

D D, &c. Centre line of the whole blaſt pipes. This extenſive column may be ſo arranged, as to enable the furnaces to be blown each with two tuyeres; and the blaſt of one engine made to paſs through the whole. The general communication is effected by carrying the chief column either behind the furnaces, or, as in the plate, through the main pillar of the furnace, by means of an arched opening 3 feet wide.

E, Ground plan of the hearth, ſquares, and pillars of four blaſt furnaces.

F F F F, Bridge-houſes for materials, and filling or charging the furnace.

G G G G G, Openings into the furnace top.

H, Caſting-houſe.

I, Second blaſt-engine, upon the ſame plan as A. Each of theſe two engines ought to be calculated to blow two furnaces, and occaſionally, when any thing goes wrong with one, the blaſt of the other could be eaſily diſtributed for a time among all the furnaces.

BLASTED, in *Antiquity*, ſomething ſtruck with a *blaſt*.

Among the Romans, places blaſted with lightning were to be conſecrated to Jupiter, under the name of *bidentalia*, and *putealia*. It was alſo a ceremonial of religion to burn blaſted bodies in the fire.

BLASTING *of ſtones*, in *Agriculture*, the operation of tearing aſunder large ſtones or rocks, which are in the way of the plough or other inſtruments employed in breaking up ground, by means of gun-powder. The method of performing this buſineſs is by boring a large hole, eight, ten, twelve, or more inches deep, according to the nature and ſize of the ſtone or rock to be blaſted, by means of a chiſel for the purpoſe, and then introducing a ſufficient quantity of gun-powder, and afterwards carefully ramming the hole up with ſmall fragments of ſtone or other ſolid materials, only leaving a very ſmall aperture, by placing a ſteel pricker of ſufficient length and ſuitable dimenſions, with a handle at the top, at firſt into the powder, and frequently turning it round while the hole is ramming up. After the hole is quite filled, by forcing the hard materials in with a proper inſtrument, the pricker is withdrawn, and the aperture left by it filled to the top with gun-powder, and then a match of tow, ſtraw, or other light inflammable material laid to it, and ſet on fire.

It is obſerved by Mr. Headrick, in the ſecond volume of "Communications to the Board of Agriculture," that in order to perform this operation properly ſome experience is neceſſary, and that a ſkilful workman can frequently rend ſtones into three equal pieces, without cauſing the fragments to fly about. This, he ſays, depends upon the depth and poſition of the bore. It is alſo remarked, that a ſmall portion of quick-lime, in fine powder, is found to increaſe the force, and conſequently to diminiſh the expence of blaſting ſtones. On theſe grounds the following is offered as a ſubſtitute for gun-powder, which is now become very expenſive, though, as is freely confeſſed, without any experience of its effects. Suppoſing *fig.* 1, *Plate* III. (*Agriculture*) to be a large ſtone to be blaſted or rent; *a b*, a bore ſent down into it in the uſual manner. This bore being then well cleaned out and dried, is to be filled from *b* to *c* with the pureſt quick-lime, or ſuch as ſwells moſt in ſlaking. That it may be perfectly quick, it ſhould be taken red hot from the kiln, or the ſmall furnace where it has been burnt; being then rammed in hard with the jumper or punch *a c*, the upper part of the bore is to be crammed with rotten rock in the ordinary way. The pricker being removed leaves the aperture at *b*; *a b*, a ſmall pipe of copper, of leſs diameter than the needle or pricker, having an orifice about the dimenſions of the ſtraw, uſed to convey the fire down to the gun-powder, with a funnel *d* to receive water, is introduced into the aperture. Perhaps a ſtraw or ſmall reed ſtuck in the lower part of the funnel, among tallow or beeswax, might ſerve the purpoſe of a copper-pipe. Things being thus prepared, pour water into the funnel *d*; and if the pipe be not too high, ſo as to prevent the air from eſcaping from the aperture, left by the pricker, it will deſcend and cauſe the lime to ſlake in the bore *c b*. Every one knows how irreſiſtibly the pureſt quick-lime attracts water, and with what prodigious force it expands in ſlaking into three or four times its former bulk. From theſe data it is therefore inferred, that the ſlaking of lime, in ſuch circumſtances, would burſt or rend the ſtone *f* in pieces; but the ſucceſs of ſuch an experiment, it is obſerved, muſt depend entirely upon uſing lime of the utmoſt purity, and having it very hot, and perfectly cauſtic when it is put in.

It is further remarked, that if the bore *c b* were filled with water, and the aperture afterwards rammed up, the water being made to freeze by cold, would rend the ſtone; for when water paſſes from a fluid to a ſolid form, it expands with irreſiſtible force, though froſt cannot be depended upon in this climate.

BLASTOLOGY, from βλαστος, *bud*, and λεγω, *I gather*; the regular and ſtated pruning of vines.

BLATNA, in *Geography*, a town of Bohemia in the circle of Prachalitz, near which is an inland lake, which is the ſource of the river Uſlava.

BLATTA, in *Middle Age Writers*, denotes a purple in the wool or ſilk, dyed with the liquor of the blatta.

This was otherwiſe denominated *blatta ſerica*, or *blatta ſericum*; whence alſo *blattiarius*, uſed in ancient writers for a dyer in purple.

BLATTA, in *Entomology*, a genus of *hymenopterous* inſects, called in England *cock-roaches*, or *black beetles*. The head is inflected; antennæ ſetaceous; feelers unequal and filiform; wing-caſes and wings ſmooth, the former ſomewhat coriaceous; thorax flattiſh, orbicular, and margined; legs formed for running; abdomen terminating in two articulated appendages above the tail.

The blattæ, conſidered in a collective point of view, are a very troubleſome race of inſects. Certain kinds, that are happily for us ſtill peculiar only to the hotter parts of the world, are ſo formidable both in reſpect of number and talents for doing miſchief, that they are really conſidered as a peſt to ſociety in thoſe countries which they infeſt. Theſe noxious creatures enter houſes and commit various depredations on the furniture, devour proviſions of every kind, tear or gnaw holes in clothes, torment the inhabitants with their bite, and otherwiſe do conſiderable injury. The ſort of blatta moſt abundant in

England

England was originally a native of the eaſtern parts of the glob', or, as ſome ſuppoſe, of America, from whence it was long ſince imported into Europe, and is now completely naturalized to our climate. This is the *blatta orientalis* of ſyſtematic writers. Another creature of this kind, *blatta Americana*, was alſo introduced with the raw ſugars brought ſome years ago to Europe from America.

All the known ſpecies of *cock-roaches*, whether in the larva, pupa, or perfect winged ſtate, ſecrete themſelves in the day time, and wander about during the night in ſearch of food. In alluſion to this circumſtance, the ancients called them lucifugæ. inſects that ſhun the light. The common cock-roach will eat almoſt any ſort of proviſion, preferring, however, bread, meal, ſugar, and ſtale meat, either of which it is obſerved to devour with the greateſt eagerneſs. Except in being completely deſtitute of wings and wing-caſes the larva reſembles the perfect inſect, and in the pupa ſtate nothing more than the rudiments of the wings are perceptible. In the dark they are remarkably active and briſk in all their motions, and on the leaſt diſturbance, or the return of light, retreat again to their lurking places with timidity and precipitation. They can fly ſwiftly, but they ſeldom uſe their wings for this purpoſe; even when moſt cloſely purſued they are known to truſt rather to their legs, with which they are able to run with no ſmall celerity. The fumes of charcoal, we are told, may be employed with ſucceſs in deſtroying theſe unwelcome inmates.

The following ſpecies of the *blatta* genus, are deſcribed by Linnæus, Fabricius, Gmelin, &c. viz. *gigantea*, *maderæ*, *ægyptiaca*, *occidentalis*, *ſurinamenſis*, *americana*, *auſtralaſiæ*, *erythocephala*, *capenſis*, *indica*, *nivea*, *irrorata*, *viridis*, *braſilienſis*, *petiveriana*, *orientalis*, *cincta*, *picta*, *variegata*, *lapponica*, *germanica*, *ruficollis*, *maculata*, *marginata*, *oblongata*, *nitidula*, *fuſca*, *deuſta*, *chlorotica*, *latiſſima*, *terrima*, *perſpicillaris*, *aſiatica*, *ſchæfferi*, *ſylveſtris*, *penrſylvanica*, *livida*, *rufa*, *griſea*, *minutiſſima*, *aptera*, *punctulata*, *ocellata*, which ſee, reſpectively.

Blatta, according to ſome writers, was alſo uſed for a particular kind of kermes, or chermes; or, according to others, for "the purple-worm," by which the *coccus cacti*, or *cochineal* inſect was moſt likely meant. But both of theſe acceptations are ſuſpicious. We know that the word blatta was anciently uſed for a kind of moth, whoſe fat was reputed excellent for the ears. This laſt was called the book-worm moth. See Book-worm.

Blatta *Americana* of Cateſby is of the *ſilpha* genus with modern entomologiſts. Gmelin ſpeaks of it under the name of *Silpha Americana*.

Blatta *byzantina*, in *Phyſiology* and *Pharmacy*, the *operculum*, or lid of a turbinated ſhell, whoſe fiſh yields a purple dye.

The *blatta* differs from the lid of the *buccinum* or *purpura*, in figure; the firſt being oblong, the latter round: but in the ſhops they are ordinarily confounded, and ſold for each other. The *blatta byzantina* is alſo confounded by apothecaries with the *unguis odoratus*, from which it ought to be diſtinguiſhed, as belonging to another kind of ſhell-fiſh.

Dr. Liſter takes the *blatta byzantina* to have ſucceeded the *unguis odoratus*, and to have been brought into the ſhops in its place. In Dioſcorides's time, the beſt was brought from the Red Sea, viz. the paleſt and fatteſt; the blacker and leſs, from Babylon, or the Perſian gulf: but it ſeems, latter times took up with thoſe found about Conſtantinople; whence the preſent ſhop-*blatta* had its name.

The name *blatta* ſeems to have been given to this *operculum* from the colour; as being of a dark hair-colour, as the common *blatta orientalis*, or common *cock-roach*, ſo frequent in London, is.

The *blatta byzantina*, when exhibited internally, renders the body ſoluble, ſoftens the ſpleen, and diſcuſſes peccant humours. When uſed externally, by way of fumigation, it reſtores epileptic patients, and women labouring under a ſtrangulation of the *uterus*. In other diſorders its effects are the ſame with thoſe of moſt teſtaceous ſubſtances.

BLATTARIA, in *Botany*. See Celsia, Lythrum, Pentapetes, and Verbascum.

BLATTERIÆ, Affinis. See Lysimachia.

BLATTINUS, in *Entomology*, a ſpecies of *ſtaphylinus* that inhabits Auſtria; the colour is black; thorax broad; wing-caſes and the legs teſtaceous and gloſſy. Shranck. Inſ.

BLATUM-Bulgium, in *Ancient Geography*, a promontory of Britain, mentioned in Antonine's Itinerary, concerning the ſituation of which antiquarians have entertained different opinions. Camden, Gale, Baxter, and ſome others, have fixed it at Boulneſs, on the ſouth coaſt of Solway firth, at the end of Severus's wall; yet Mr. Horſley aſſigns its ſituation at Middleby in Annandale. Here, as at the moſt remote limit of the province of Britain, Antonine commences his ſecond route. A military way led from Blatum-Bulgium to Luguvallium, or Carliſle.

BLAU, in *Geography*, a river of Germany, in the circle of Swabia, which riſes near the foot of a hill in the Blautopfe, as it is called, and runs into the Danube at Ulm.

BLAUBEUREN, a town of Germany in the circle of Swabia and duchy of Wirtemberg, in a ſmall diſtrict of the ſame name, ſeated on the river Blau, 7 miles W. of Ulm.

BLAUDRUSELUS, in *Zoology*. (olaſſen iſl.). *phoca criſtata* of Erxleben and Gmelin, and *hooded ſeal* of Pennant.

BLAUENTHAL, in *Geography*, a town of Germany, in the circle of Upper Saxony.

BLAUER-Bock, in *Zoology*, one of the names given by authors to the blue antelope, *antilope leucophæa*. Vide Kolbe Vorgeb.

BLAVET, in *Biography*, a celebrated performer on the German flute, the firſt, perhaps, who greatly diſtinguiſhed himſelf by that inſtrument after it ſuperſeded the common flute, and became in general uſe. He was born at Beſançon, and coming to Paris in 1723, ſoon acquired a great reputation. The prince of Carignon, who knew his merit, enliſted him in his ſervice; gave him an apartment in his hotel, and a penſion. He was afterwards appointed ſuperintendant of the comte de Clermont's band, and remained in that nobleman's ſervice to the end of his life.

To his admirable talents, Blavet joined the reſpectable virtues of ſociety; his manners and conduct were blameleſs, his temper tranquil, and his probity ſcrupulous. He married at eighteen, and lived upwards of fifty years with his wife in uninterrupted harmony and affection. We are always glad when to great profeſſional abilities, ſuch an eſtimable character can be joined.

Blavet's excellence on the German flute had been heard of all over Europe, before the character of Weideman was eſtabliſhed in England, or that of Quantz in Germany.

About the end of 1765 he was attacked with the ſtone, which was a malady then more dangerous than it became afterwards, by the ſkill, experience, and ſucceſs of eminent ſurgeons; but determining too ſoon, like our poor countryman Dr. Worgan, to ſubmit to the operation, he died under it in 1768, leaving behind him the eſteem and regret of all who knew him.

Blavet, in *Geography*, a river of France, which runs into the ſea oppoſite Belle Iſle. This forms a good harbour and ſpacious road.

BLAUFELCHEN, in *Ichthyology*, the name under which *Salmo Wartmanni* of Bloch and Gmelin is described by Wartmann Besch. Berl. Naturf. Fr. 3. p. 184.

BLAVIGNAC, in *Geography*, a town of France, in the department of the Lozére, and chief place of a canton in the district of St. Chely d'Apcher; 6 miles south of St. Chely.

BLAUKOEPFIGE Rothe Amsel *Frisch*, one of the synonymous names of *lanius minor*, Gmel.

BLAUMEISE, in *Ornithology* (Frisch. Hist. of Birds), the blue titmouse of English writers, and *parus cæruleus* of Linnæus.

BLAUSLUYS, in *Geography*, a town of Holland, 2 leagues west of Gertnefdenburg.

BLAUSPECHT, in *Ornithology*, the name of the common nut-hatch; *sitta Europæa* in Frisch. Hist. of Birds.

BLAYE, Blavia, or Blavutum, in *Geography*, a seaport town of France, in the department of the Gironde, and chief place of a district of the same name seated on the Gironde, or Garonne, near its conflux with the Dordogne. Its citadel is situate on a high rock, and it is defended by a fort constructed on an island in the river, which is here 1900 toises wide; and on the other side of the river, in the country of Mendoc, is another fort. All ships that are going up the river to Bourdeaux, deposit their arms and cannon at Blaye, before they pass the river, and take them up on their return. The town contains 3580, and the canton 13,819, inhabitants. The territory comprehends 160 kiliometres, and 14 communes. It is distant 20 miles north from Bourdeaux. N. lat. 45° 9′. W. long. 0° 45′.

BLAYMARD, or Bleymard, a town of France, in the department of Lozére, and chief place of a canton, in the district of Mende. The place contains 546, and the canton 11,802, inhabitants. Its territory comprehends 347½ kiliometres, and 11 communes; 3½ leagues east of Mende.

BLAZE, in the *Manege*. See Star.

BLAZEGNIES, in *Geography*. See Malplaquet.

BLAZEY Bay, a bay in the English channel, on the south coast of Cornwall, between Fowey and Deadman point.

BLAZING Star. See Comet.

BLAZON, or Blason, in *Heraldry*. To *emblazon* is a term signifying the description of things borne in coat-armour, in such manner as they ought to be represented, according to the rules of heraldry. To *blazon*, originally signified the blowing or winding of an horn by the heralds, at justs and tournaments, when they proclaimed and recorded the atchievements of the combatants.

BLEA, in *Vegetables*, is that part of a tree, which lies immediately under the bark, and between that and the hard wood, and is the first progress of the alteration of the bark into wood by the natural growth and strengthening of the fibres. See Botany.

While the blea remains yet soft, and retains something of the nature of bark, it may maintain a feeble vegetation; but when it is grown absolutely hard and woody, it can contribute nothing to the growth of the tree. The vegetation of the young branches of trees is the most lively and vigorous, and the only one that goes as far as the flowers and fruit, because these branches are little else but bark.

BLEACHING. The art of bleaching consists in removing the coloured matters intermixed with vegetable and animal substances in their natural state, or such as they have subsequently imbibed by accident, or some artificial process. Edward Hussey Delaval, esq. F.R.S. has shewn, by a number of accurate experiments on the cause of the permanent colours of opake bodies, published in the second volume of the second edition of the Memoirs of the Literary and Philosophical Society of Manchester, "that when the colouring matter of plants is extracted from them, the solid fibrous parts, thus divested of their covering, display that whiteness which is their distinguishing character. White paper and linen are formed of such fibrous vegetable matter, which is bleached by dissolving and detaching the heterogeneous coloured particles." He further observes, "it appears that the earth, which forms the solid substance of plants, is white; that it is separable from the colouring matter by several means; that whenever it is either pure and unmixed, or diffused through transparent colourless media, it exhibits its whiteness, and is the only vegetable matter which is endued with a reflective power; that the colours of vegetables are produced by the light reflected from this white matter, and transmitted from thence through the coloured coat or covering, which is formed on its surface by the colouring particles; that whenever the colouring matter is either discharged or divided by solution into particles, too minute to exhibit any colour, the solid earthy substance is exposed to view, and displays that whiteness, which, as before noticed, is its distinguishing character.

He states that in all those animal matters which do exhibit colours, the colouring particles are endued with the same properties, and are regulated by the same laws, which prevail in vegetable substances.

A reference to the original paper can only do justice to the observations of this excellent philosopher, confirmed by numberless experiments; but what is already said will be sufficient to give an idea of the nature of the process of bleaching, and that it depends on the removal of the matter interposed betwixt the air and this white substance.

The national importance of bleaching is so great, that it comprehends nearly the whole of the cotton and linen manufacture, and goes to an extent beyond most other arts.

Its operation in these branches may be considered under two points; viz. 1st, the separation of extraneous substances from linen and cotton, which is effected by steeping, fermentation, or weak alkaline leys; 2d, the separation of the constituent or inherent colouring matters of those substances, which is effected by different modes, and by various modifications of each method, as exposure to the air, light, the use of alkaline leys, soap, oxygenated muriatic acid, combinations of oxygenated muriatic acid with other matters, sulphuric acid, hepar sulphuris, &c.

To impress upon the mind the nature of the bleaching business, it will be proper first to describe the vessels used in the sundry operations of steeping, boiling, bucking, washing, souring, &c. then proceed to shew the management of each process, with some observations on its effects; and, lastly, how to make or procure the articles necessarily employed in this art, and the method of ascertaining the qualities of each, adding some observations on the theory of the operations.

Bleaching of goods, particularly cotton manufactures.

1st, *On Steeping*.

The vessels generally used in bleaching are made of such wood as will not communicate any colour to the liquors they are to contain, and therefore deal or fir wood is preferable to most others. The vessels employed for steeping the goods when received from the loom are usually of the form A, *fig.* 1. *Plate* I. *Bleaching*. The goods when received from the weaver contain not only the natural colouring matter of the cotton, which is of an oily nature, and which prevents the cloth from easily imbibing water, but also a substance called sowins, being a paste made of flour and water, used during the weaving, and applied with brushes upon the warp, in order to give a firmness to the threads by glueing

or

or parting together the loose fibres of the threads, and thus allowing them to pass more freely through the reed and harness. To remove this substance, and to open the fibres of the cotton, so as to give full effect to the subsequent operations, it is proper to steep the goods in a vessel of the above form in lukewarm water, till a gentle fermentation takes place, which will usually be effected in 24 hours. The cloth should then be taken out, and well washed in a current of clear water, which will thus separate a considerable quantity of filth without the expence of using alkaline leys; and the cloth is then ready to be boiled or bucked as may be preferred by the bleacher.

2d, *On Boiling.*

For boiling, a copper vessel is to be preferred, and the goods prepared, as above mentioned, by steeping and washing, are put into the vessel containing hot water only, or warm alkaline ley; a winch is placed over the vessel, and the piece goods attached to the ends of each other, are, when put in motion by the handle of the winch, dragged or rolled over it till the whole are passed; the winch is then turned with a retrograde motion, and the cloth gradually thus returned back, in order that every part of each piece may be thoroughly impregnated with the liquor, which is raised to and kept at a boiling heat, as long as it appears to extract any colouring matter from the cloth; the goods are then taken out and well washed in water.

Fig. 1. *Plate* IV. shews a section of the boiling pan A, of copper, set in brickwork; the winch C, with its handle D: E, uprights of wood, on which the winch turns; F, a cock to empty the pan; G, the fire-place; H, the ash-hole.

The use of this process depends upon the properties which alkaline salts have of uniting with the oily and resinous matters which are either attached to or are a constituent part of vegetable fibres, and which contain their colouring particles, forming with them a saponaceous matter, soluble in water, and by that means easily extricated from the cloth.

3d, *On Bucking.*

As this is one of the most general operations in bleaching, it will be necessary to describe it more particularly. *Fig.* 1. *Plate* I. under the word *bucking*, shews at A the form of the bucking tub or kier, in which the goods are to be laid; B is an iron boiler, in which the alkaline salts, as pot-ashes or pearl-ashes, are to be dissolved in boiling water; C is the fire-place, in which a fire is constantly kept up; D is the ash-hole; E, a cock through which the boiling ley is let out upon the goods closely placed together in the bucking tub, A. A sufficient quantity of boiling ley is let into the bucking tub, till all the goods in the tub are thoroughly impregnated with it; the ley liquor is then allowed to pass by a cock at H into an iron vessel placed in the ground at F, and from thence raised by the pump G into the iron boiler B, and thence returned hot again upon the cloth. This operation is continued for several hours, till the ley, by the separation of the colouring matter in the cloth, acquires a colour almost black, a very offensive smell, and nearly the consistence of molasses or treacle. The cloth is then taken out, well washed from its impurities, and, in the old mode of bleaching, it is then laid upon the ground to be whitened by exposure to the atmosphere, but, in the new mode of bleaching, is submitted to the action of the oxygenated muriatic acid, to procure a similar whiteness. It may be proper here to notice, that the old and new methods of bleaching are yet much the same as formerly, only in the substitution of the use of the oxygenated muriatic acid in those parts of the process, where a long exposure to the atmosphere was formerly employed after the alkaline leys.

The operation of bucking acts on a similar principle to that of boiling, but in a much more forcible manner, as a greater quantity of ashes is added in proportion to the water made use of, and more heat is received and retained in the large bulk of cloth placed in the bucking tub, which expands the fibres of the cotton, and admits the more powerful action of the alkali, as is easily demonstrated by observing the very dark colour of the alkaline leys which have been used in bucking, in comparison with those which have been employed in boiling goods. To those persons who wish for a full and minute account of the absorption and power of heat, we recommend a perusal of count Rumford's interesting essays on the subject of heat.

The black alkaline ley which remains after bucking should be preserved, as it will answer, after evaporating and calcining, as hereafter mentioned, to form again fresh alkaline salts of good quality. With a view to preserve as much of the ley as possible, it will be advisable to wring it out into a tub from the cloth or yarn, after it is bucked, by the method shewn in *Plate* IV. *fig.* 3. where R R are two strong posts, fixed firm in the ground, S T two wringing hooks, upon which the cloth U is twisted, to force out the liquor, by W, a winch handle, which turns the hook round on the post R. The two hooks are kept at a proper distance from each other, one by a collar at X, the other by an iron pin at Y, which runs through a hole in the square part belonging to the hook T, which square has several holes in it to bring this hook nearer to the hook S when required.

4th, *Souring.*

This process consists in immersing, for the space of twelve hours, or more, the yarn or cotton in a mixture of water and sulphuric acid (vitriolic acid), well incorporated; the proper strength of which mixture is about the acidity of lemon juice, and is usually directed by the taste. The sour kettle should be made of lead, of a form which can be heated; the heat of the liquor should not be greater than the hand can bear with ease. This sour kettle should be half sunk within the ground, as shewn in *Plate* IV. *fig.* 2. where M is a section of the souring vessel; N, the level of the ground; O, the brickwork; P, the fire-place, which is a half circle, or arch, without any grate; I I I, a space filled with dry ashes, betwixt the lower part of the sour vessel and the brick-work, in order to preserve the heat of the liquor in that part of the vessel below the surface of the ground; K, a brick hearth, on which part of the fire is made; L, a cast iron plate, bending in the form of the sour kettle, which is intended to prevent the fire placed on the floor at P K, from acting upon the lead of the sour vessel; Q, the space betwixt the vessel and brick-work, through which the smoke goes to the chimney.

The construction of this apparatus is upon the same principle as the warm vats made use of by the blue dyers, the intent not being to make the liquor boil, but to keep it at a degree of heat which the hand can long and easily bear. There are no grate or bars necessary in this fire-place, as the coals will burn with sufficient rapidity without them.

The goods may be put into this acid liquor either in a wet or dry state. The best plan is to immerse the goods in the evening in the acid liquor cold, let them remain covered with it all night, then in the morning make a fire and bring the liquor to a blood heat, in which state having a winch over the vessel, similar to that represented at C, *fig.* 1. give the goods a few turns over it, that every part of them may be exposed to the action of the liquor. The goods may then be lapped round the winch to drain a little, to prevent an unnecessary waste of the acid liquor, and afterwards carried to the wash-wheel, or river, to be well washed from

the

the acid, ſo that the cloth may be perfectly taſteleſs to the tongue. It is a remarkable circumſtance, that cloth may remain immerſed a very conſiderable time in a ſtrong acid liquor without rotting, but that if expoſed to the air or heat of a ſtove, if a very ſmall portion of acidity remains in the cloth, it becomes ſo concentrated by heat, as to damage the cloth immediately; therefore too much attention cannot be paid to this point.

The uſe of the acid liquor above-mentioned is to diſſolve any earthy or metallic matters inherent in the cloth, or which may have been communicated to it accidentally, or which it may have derived from the impurity of the alkaline ſalts uſed in the bucking or boiling.

A conſiderable quantity of the acid liquor may be preſerved by paſſing the goods which have been ſoured through a tub of clean cold water, previous to waſhing them, and repleniſhing the ſour kettle with this acidulated liquor, rather than water only.

5th, *Waſhing*.

After every operation in which acids or alkaline ſubſtances are uſed in bleaching, it is neceſſary that the goods ſhould be well waſhed in clear water; it is therefore of the greateſt conſequence that the water of a bleach ground ſhould be pure, and in conſiderable quantities, ſuch, for inſtance, as is perfectly tranſparent, will not curdle with ſoap, nor yield any degree of blackneſs with powdered gall nuts, or, which is a more accurate teſt, with a tincture of galls by infuſion in ſpirits of wine.

Various methods have been invented for the purpoſe of waſhing out the impurities of the articles to be bleached; ſuch as cleanſing them in a large current of water by ſhaking them with the hand in the ſtream, beating them on blocks of wood with a flat paddle, or hand-bruſh, beating them on a large flat ſtone with long wooden levers, flatted underneath, paſſing them over winches placed above veſſels of water, or rivers, as *fig.* 1. and 3. *Plate* II. paſſing them betwixt plain or fluted rollers, as *fig.* 5. and 6. putting them under fulling mills, or fulling ſtocks, as *fig.* 7. or within waſh-wheels, as *fig.* 1. and 2. and by many other modes, few of which are equal, and perhaps none ſuperior, to thoſe of which engravings are here given, for doing the buſineſs ſimply, effectually, and with eaſe to the workmen; the latter point of which is of conſequence to be attended to, as it will be univerſally found in every mechanical employment, that if the leaſt additional labour or care is required from the workmen, however great the effects produced, prejudice or indolence will prevent their doing juſtice to the invention. Under theſe circumſtances, the waſh-wheel repreſented in *Plate* II. *fig.* 1, 3, 4, is the beſt machine for general uſe, and the leaſt liable to occaſion damage to the goods. The front of the waſh-wheel repreſented at A, *fig.* 1. is ſuppoſed to be eight feet diameter, excluſive of the buckets B, ſhewn by dotted lines on its periphery, which give it motion from the water falling into them. This wheel is divided within into four parts or quarters, by the ſtrong arms projecting from the ſhafts D, to the outer circle; in each of theſe ſeparate quarters or boxes, repreſented by dotted lines, one or more pieces of goods which require waſhing, are put looſely folded together through one of the holes C, of 14 inches diameter.

Fig. 2. ſhews the back part of the ſaid waſh-wheel, which is made of ſolid planks, excepting a grate of ſlender iron bars marked R, which encircles the wheel underneath the ſeparation boards or bottoms of the buckets; the uſe of this grating is to admit within the wheel a current of clear water from the pipe Q. When an equal number of piece goods have been introduced into each of the four diviſions of the wheel by the holes, C, &c. above mentioned, a current of clear water is permitted to run through a cock from the pipe Q, againſt the grating R, which allows it to flow freely through into the boxes, or thoſe parts of the wheel which contain the goods; a valve is then opened from the trough P, communicating with a large reſervoir or ſtream of water, a ſufficient quantity of which is let into the outſide buckets from the valve, to give the proper motion to the waſh-wheel containing the goods. In every revolution of the wheel, the goods in each quarter of it are thrown twice, by the ſimple motion of the wheel, with great force againſt the arms which form the four diviſions of it; viz. once in going down, and once in riſing up. The ear can diſtinguiſh by the firmneſs of the ſound when the wheel moves with proper velocity; and a greater or leſs quantity of water is allowed to act upon the buckets till that is attained, which uſually is when the wheel makes 15 or 16 revolutions in a minute. During the whole time the wheel is in motion, the ſtream of clear water from the pipe Q flows upon the goods within the wheel in every direction; and the dirty water, produced from thus waſhing the goods, runs out of the wheels from a number of holes bored through the wood-work near the axle, and a few made in the front near the outer circle of the wheel. *Fig.* 4. ſhews an end view of the waſh-wheel, about thirty inches wide, with the manner that the bucket-work is made

It has been found to anſwer equally well to make uſe of a greater number of waſh wheels of a ſmaller ſize, as ſix feet diameter and two feet wide, of which ſeveral may be put in motion at once by a large water-wheel, horſes, or a ſteam engine.

The goods, when taken out of the waſh-wheel, are to be unfolded, and taken to the river to be ſtreamed, or may be waſhed from any impurities which may remain in the folds by means of a winch N, *fig.* 1 and 3. *Plate* II. where ſix pieces of cloth are repreſented in the action of waſhing in a large wooden back divided into ſix partitions, to prevent the pieces of goods entangling with each other. *Fig.* 1. is a ſide view of the operation, where the dotted lines repreſent the partitions which ſeparate the goods; I, a trundle wheel, which being put in motion by the cogs, H, of the waſh-wheel, turns the winch on its axle, which winch may at any time be detached from it by the handle M drawing the catch K from the hook, as is ſhewn in the top view *fig.* 3. where alſo is explained, at the letters OOOOOO, the manner in which each piece of goods is kept in its proper place on the winch, by the partitions above mentioned, and by angular ſlips of wood nailed to the back and partitions.

To aſſiſt the drying of the goods after waſhing, they are uſually paſſed betwixt two ſmall rollers, commonly called ſqueezers, repreſented at *fig.* 5, where G is a ſolid wooden frame, containing two wooden rollers, each from 10 to 16 inches long, on an iron axis, which rollers receive a proper preſſure by means of the two ſcrews T acting on an iron bar V, which reſts on the two ends of the axis of the top roller, as ſhewn by the dotted lines. In proportion as the ſcrews preſs the iron bar upon the axle of the top roller, it brings that roller cloſer in contact with the bottom roller, and occaſions more water to be preſſed out of the cloth, which is paſſed betwixt them looſely drawn together, ſomething like a rope, and the goods therefore require leſs time in the ſubſequent drying. In this plate the ſqueezers are connected with the waſh-wheel above mentioned by a ſquare iron ſocket, which, as is ſhewn at F, ſlides occaſionally upon the ſquares of both axles. *Fig.* 4. ſhews at S the buckets of the waſh-wheel, on which the water falls to give it motion; H, the cogs round its axle, which work the trundle wheel I.

Fig. 6. *Plate* II. ſhews two views of another machine uſed for cleanſing cotton goods, conſiſting of two fluted or grooved

grooved rollers, in the ſection of which *a* repreſents the ſills, or bottom timbers; *b b*, the two ſupports or ſide pieces; *c*, one of the upright pieces in which the axles of the rollers are placed; *dd*, the two croſs pieces to ſecure the frame work below; *e e*, the two rollers with grooved channels which fit to each other; *h*, one of the levers, which, from a point *i*, ſhewn by dotted lines, preſſes on the round end of the axle of the top roller, more or leſs, according as the weight *k* is placed on the lever further from or nearer to the axis of the roller.

In the geometrical elevation of the ſame machine, *e e* ſhews a front view of the two rollers; *f g*, the winch to turn it, with a hollow wood handle upon the iron work; *l*, the axis of the upper roller projecting beyond the ſide timber, ſo as to admit one of the levers *h* above mentioned to preſs upon it.

The wet goods, by being paſſed backwards and forwards through theſe fluted rollers, which are conſtructed at a much leſs expence than waſh-wheels, are conſiderably cleanſed, but not ſo perfectly as by the waſh-wheels above mentioned.

Fig. 7. *Plate* II. explains another mode of cleanſing goods, and is applicable to cotton, linen, or woollen goods, but more generally to the two laſt, as, without great care in its management, it is very apt to tear or damage cotton goods. This machinery is uſually termed falling ſtocks, or falling hammers. N° 1. is the axle of the water-wheel, in which are fixed tappets at 2, to raiſe alternately the levers 3, 4, furniſhed with large wooden mallets or hammer heads 6, 8, channelled at the lower part as at 8. Theſe lever hammers or fallers, work from a pin fixed in the upright at 7; 9 is a ſtrong piece of timber hollowed out at 10, to receive the goods to be cleanſed; 11, a piece of timber fixed a-ſlant to keep the fallers in their proper place, and direct their motion; 12, a chain faſtened to each faller, ſerving by means of the hook 13, to ſuſpend the faller whilſt the goods are put in or taken out of the cavity 10.

When the goods to be cleanſed are placed in a looſe bundle in this cavity, the hammers are let down upon them, and put in motion alternately by the tappets 2, in rotation, which raiſe the levers to a certain height, and then quitting them, the hammer heads by their great weight, fall with great force on the goods in the cavity below them; and a current of clear water being admitted upon the goods from a cock above them, the dirty water runs out at a hole in the bottom of the cavity. The falling of the hammers gives a ſlow circular motion to the goods in the cavity, ſo as to expoſe the ſeveral parts in rotation to the action of the hammers.

Having noticed the veſſels made uſe of in bleaching, and the general nature of the ſeveral operations, we ſhall now proceed to mention the origin of the ſeveral improvements made in this art, and their application to practice.

Under the operation of ſteeping, we have ſhewn the method of removing the colouring matters not natural to the vegetable, but acquired in the manufacture, and which may probably be beſt done by water alone, though ſometimes ſome of the old leys, which have been previouſly uſed to other cloth, are employed to this purpoſe. After the ſteeping, and indeed after every application of bleaching agents, it ſhould be laid down as a general rule, that the cloth or goods be carefully waſhed in cold water.

In the old method of bleaching, alkalies, ſuch as pearl or pot-aſhes, were, after ſteeping, applied by bucking or boiling, with alternate expoſure to the atmoſphere.

Alkalies acting ſo important a part, it is neceſſary to deſcribe the bleachers' mode of uſing them, which conſiſts in diſſolving them in clean water, and thus forming what is termed an aſh-ley. To which the more intelligent bleacher, if he does not make uſe of American pot-aſh, or that of a ſimilar quality, adds ½ of quicklime, whereby the aſhes are rendered cauſtic, and their power materially augmented. But in order that no inconvenience may ariſe from cauſticity, after mixture, the whole is allowed to ſettle, and from the pure liquor thereof the work is afterwards ſupplied; the bleacher, in drawing it off, reducing it by the addition of water to the different ſtrengths which the goods may require.

The ley being prepared, the bleacher proceeds to apply it to the cloth by bucking or by boiling.

In bucking, the alkaline ley is put into the boiler before deſcribed, near to and below which is the wooden veſſel called a kier, in which the goods are looſely and regularly arranged. After this, a fire is put under the boiler, and beginning whilſt the ley is yet cold, it is made to circulate through the cloth in the kier, from which it runs into the iron veſſel placed in the ground, from this it is pumped up into the boiler, and again returned upon the cloth in the kier; and this circulation is maintained, and the heat at the ſame time increaſed, until the ley be ſo far concentrated by evaporation, as at laſt to remain almoſt wholly in the cloth. This is generally the operation of a day, and the cloth is allowed afterwards to remain thus impregnated with the concentrated ley until next morning.

In boiling in alkaline leys, the mode of which has been before deſcribed, the operation is continued from one hour to five or ſix hours, but it is more tedious and leſs effectual than bucking, where much buſineſs is to be done.

After bucking or boiling, the goods were, by the old bleaching proceſs, expoſed for at leaſt a week to the air, before they were again ſubmitted to the action of alkaline leys, and this proceſs alternately repeated many times, till the goods were perfectly white, and the goods at laſt foured and waſhed off.

To explain the *old method of bleaching* more particularly, we ſhall add the following proceſs for bleaching linen cloth.

Steep your raw linen cloth in a wood veſſel all night, then change the water, and add freſh till you perceive the water to be no longer diſcoloured by it; rinſe, wring, and lay it on the ground, and water it if you have opportunity. When it has thus lain on the graſs three or four days, and is dry, take hold of each piece one after the other by the ſelvedge, and draw the cloth to you, ſtill holding it in the moſt even manner you can, until you get the further end, with the corners of which further end you tie the cloth very looſely in the middle of the folds, and ſo lay it in the bucking tub, with the two ſelvedges upwards.

Thus proceed till you have placed as much cloth in your tub as will cover the bottom of it, taking care not to pack the cloth ſo cloſe but that your ley may penetrate every part equally. When you have laid the firſt range of cloth in your tub, pour upon it as much milk-warm ley as will ſufficiently ſoak through all parts of your cloth. Then lay another range in the ſame manner upon the firſt, and pour on more ley till that be ſoaked as the other was, and continue ſo to do till your bucking tub be full of cloth.

That done, you muſt begin to buck for twelve hours together, the remainder of your ley having been put in the pan with a ſlow fire underneath. For the firſt five hours the ley ſhould not be of a boiling heat; you muſt from time to time allow ſome of the ley to run out of the pan upon the cloth in the bucking tub; then increaſe your fire gradually and ſlowly, ſo as in four hours more to bring it to a boil, continuing to put on the ley, and draw it off your cloth in ſmall quantities at a time. When your ley begins to boil, you muſt let it boil on for three hours, during the whole time

time pumping your ley up to the boiler from the reſervoir, into which it runs from the cloth, and returning it boiling hot upon the cloth, ſo that the hot ley may act powerfully and equally upon every part thereof.

After each bucking your cloth muſt be laid upon the graſs in the bleach-field for ſome days. The bucking, and expoſure on the ground, muſt be repeated about ten times ſucceſſively, according to the nature of your cloth; it ſhould then be dried up, foured, and waſhed well in clean water; if the water is rather warm, the better.

Your two firſt buckings ought to be from a ſtrong cauſtic ley of pot-aſhes; but afterwards you ſhould abate of that ſtrength, leſt it ſhould injure your cloth. Mild ley, or pearl-aſh, ſhould be uſed for the latter buckings, as the cloth becomes nearer white.

This was the management during the ſummer months; but for four months in winter bleaching was ſuſpended, the operations being periodically interrupted, and the capital of the manufacturers or proprietors of the goods locked up. Even during the bleaching months, their property was long in preparing for ſale; as cotton goods, which required from four to ſix applications or repetitions of alkaline leys, conſumed ſo many weeks in bleaching, whilſt linens, which could not be bleached by leſs than from twelve to twenty applications, could not be brought in a marketable ſtate to the proprietor hardly in ſix months.

Such was the ſtate of bleaching till Mr. Scheele, a Swede and eminent chemiſt, diſcovered the properties of oxygenated muriatic acid, procured by mixing manganeſe with marine acid, in rendering vegetable matter white; and M. Berthollet, the celebrated French chemiſt, improved this operation, and actually applied its powers in bleaching cotton goods by interpoſing its action between the different alkaline operations inſtead of the tedious expoſure of the goods to an uncertain atmoſphere; the ſame effect being produced by immerſion of the cloth in this acid, as by laying the goods upon the graſs in the bleach-field, expoſed to air and light.

Diſcovery of and Variations in the Mode of procuring the Oxygenated Muriatic Acid.

By the addition of vitriolic acid to common ſalt, an elaſtic aeriform fluid, or muriatic gas, is diſengaged, from which with water a marine acid is produced. The mineral ſubſtance manganeſe, or what the modern chemiſts call oxyd of manganeſe, contains what was formerly denominated vital air, pure air, or dephlogiſticated air, but now named oxygen. Manganeſe yields oxygen, when marine acid is added to it, and ſubmitted to diſtillation; the liquor produced by the contact of this oxygen with water, is the oxygenated marine or muriatic acid diſcovered by Mr. Scheele, about the year 1774, when he obſerved and applied its effects in rendering colourleſs vegetable ſubſtances of various kinds, more as a matter of curioſity than uſe.

M. Berthollet, in the year 1786, improved the proceſs of its preparation, applied its power to bleaching or deſtroying the vegetable colours natural to cloth, the reſult of which experiments he gave to the world in the year 1789; but, without derogating from the merit of this excellent chemiſt, it is juſtice to ſtate, that, previous to any publication by M. Berthollet, Mr. Scheele communicated to Mr. Kirwan the properties of the dephlogiſticated marine acid in whitening vegetable ſubſtances, and Mr. Kirwan, then reſiding in Newman-Street, London, ſuggeſted to Mr. C. Taylor, the preſent ſecretary to the Society of Arts, &c. the probability of its uſe in bleaching; and a whole piece of callico, in the ſtate received from the loom, was, in the ſpring of 1788, actually bleached white, printed in permanent colours, and produced in the Mancheſter market ready for ſale, having undergone all theſe operations in leſs than 48 hours, by the joint efforts of Mr. Cooper, Mr. Baker, and Mr. Taylor, which is perhaps the firſt entire piece, either in France or England, that fully aſcertained the real merits of the new mode of bleaching, and a certainty that it might be generally uſeful in commerce. This experiment was immediately followed by the eſtabliſhment of a large bleaching concern by Mr. Cooper, Mr. Baker, and Mr. Horridge, at Raikes, near Bolton, in Lancaſhire, and before any conſiderable bleaching work was actually at work in France.

The ingenious Mr. Watt we believe to be the firſt perſon who ſimplified the proceſs of preparing the oxygenated muriatic acid, by means of a mixture of common ſalt and manganeſe, previous to the addition of the vitriolic acid. Soon afterwards the operations of the bleacher were farther facilitated by the ſubſtitution of large and commodious ſtills of lead, inſtead of glaſs veſſels, and both theſe improvements have ſince been in general uſe.

We ſhall now proceed to mark the various treatment of the oxygenated muriatic acid when obtained, and the different means which have been adopted to fit it for application in bleaching.

It having been found in the earlier ſtages of diſtillation, that common marine acid was produced inſtead of the dephlogiſticated or oxygenated muriatic acid; and from the violence of the ebullition, that manganeſe itſelf was ſometimes thrown over from the ſtill, M. Berthollet had recourſe to an intermediate veſſel, containing water, to abſorb the marine acid gas, and ſtop other impurities which might contaminate the oxygenated muriatic gas in its paſſage through this veſſel to the receiver.

It will here be neceſſary to diſcriminate the various modes in which the oxygenated muriatic gas has been treated, after paſſing the intermediate veſſel laſt mentioned.

Mr. Scheele ſeems generally to have operated with the acid in the ſtate of gas; but M. Berthollet ſought to condenſe it in water, with which he filled his receiver, or wooden veſſel, and which water he kept agitated during the diſtillation, to accelerate the ſolution or combination of the gas.

The oxygenated muriatic acid, thus prepared, was drawn from the receiver into kiers, or large wooden veſſels, where its ſtrength was regulated by the addition of water; after which, the goods to be bleached were immerſed therein from ſix to twelve hours, but moſt frequently during the night; and though theſe periods may ſeem ſhort, they were ſufficient to allow the cloth to become more white than could be done by as many days' expoſure to the atmoſphere and a ſummer's ſun, and were then ready for a freſh application of the alkaline leys.

Such was the bleaching liquor of M. Berthollet; but it was found in practice yet defective, as the volatility of the gas occaſioned its ſpeedy ſeparation from the aqueous ſolution; a decompoſition even by light alone in glaſs veſſels took place; a rapid loſs in the ſtrength of the liquor when expoſed; and much danger to the health of the workmen from its ſuffocating quality; at the ſame time, that in extracting the natural colours of the cloth, it alſo tended to diſcharge the colours dyed in the yarn, and were along with the gray cotton an imperfection which precluded its uſe in an infinite variety of Britiſh manufactures.

Similar circumſtances probably led ſome bleachers reſident at Javelle, in France, to add a ſolution of cauſtic alkali to the water in the receiver, and by this means to remedy many of the defects complained of.

But M. Berthollet continued to recommend his proceſs, conſidering ſuch ſubſtance as impairing the bleaching powers;

an idea that was generally maintained by the chemiſts, but contradicted by the bleachers, whoſe experience taught them, that though the acid thus combined whitened with ſomewhat leſs rapidity, yet it was not eventually in an inferior extent; and the advantages of preſerving the colours dyed in the yarn, compelled them to have recourſe to the expenſive addition of pot-aſhes, in preference to M. Berthollet's mode.

Here we ſhall obſerve, that, according to the doctrine of the modern chemiſts, the oxygenated muriatic acid bleaches in conſequence of yielding to the colouring matter of the cloth that oxygen which, in the diſtillation, the acid abſorbed from the manganeſe; or; in the language of Stahl and Becher, that the dephlogiſticated marine acid abſorbed the colouring matter from the cloth, and was reſtored to its original ſtate of common marine acid, by regaining that phlogiſton which it had, in its preparation, yielded to the manganeſe.

In the mixture of an alkali with the acid, we have noticed that the bad conſequences ariſing from its volatility have been corrected, and the requiſite protection afforded to dyed colours, yet ſtill that its power of whitening cloth was not diminiſhed, nor much more time taken up by the operation; yet, in part from deference to M. Berthollet's opinion, and in part owing to the expence of the alkali, other means to produce the effect were attempted.

One of the firſt of theſe, practiſed by the bleachers of cotton-hoſe, at Nottingham, was to receive the dephlogiſticated muriatic gas into a ſmall air-tight chamber, in the upper part of which the goods were ſuſpended from a frame, whilſt at ſome diſtance below was water, ſometimes impregnated with ley of pot-aſh, and ſometimes with lime-water, or water mixed with lime. The gas was introduced betwixt the fluid and the goods, amongſt which it aſcended and mixed; at the ſame time, by occaſionally immerſing the goods in the fluid below, it was ſought to modify the action of the acid. This was effected by means of a pole, or long lever, connected with the frame on which the goods were ſuſpended, the centre of which pole moved on a ſwivel fixed in a hole in the partition, occaſionally ſtopped with clay, and enabled a perſon to let the goods down into the fluid, not always however without inconvenience, which occaſioned it the name of the *Bedlam Proceſs*.

Reſpecting the above proceſs it muſt be obſerved, that the acid is much more powerful or active in the ſtate of gas than in any other way; and though the occaſional immerſion of the goods into the fluid below, corrected in ſome degree its violent effects, yet the dyed colours diſappeared more rapidly in this than in any other proceſs, and the fabric itſelf was ſometimes injured.

The next proceſs attempted by the bleachers, was to put into the receiver, filled with water, a quantity of pulverized lime, then the goods themſelves, and the whole agitated during the admiſſion of the gas; the conſequence of which was, that the goods thus mixed with lime were partially coated with it; and this coating being unequal, the action of the acid upon it was irregular, leaving at the ſame time the parts uncoated to receive the whole action of the bleaching powers; hence inequality of bleaching enſued, and an inſurmountable difficulty in preſerving the dyed colours of the goods to be bleached.

Having noticed the imperfections of the two laſt proceſſes, we ſhall obſerve that lime-water, or a pure chemical ſolution of lime in water, has been ſometimes ſubſtituted inſtead of a ſolution of alkalies in the receiver, but was not, when uſed in that manner, found to anſwer ſo well as the alkaline ſolution.

That lime-water could produce no valuable effect beyond what was derived from M. Berthollet's mode, or from ſimple water, muſt be evident, when it is conſidered that water can diſſolve no more than $\frac{1}{700}$th part of its weight of lime, a quantity wholly inſignificant in neutralizing the oxygenated muriatic acid for the purpoſe of the bleacher; nor could pulverized lime, merely thrown into the water of the receiver, ſerve a better purpoſe, ſince, from its being ſpecifically heavier than the water, all beyond the quantity in chemical ſolution ſubſided and remained nearly uſeleſs at the bottom of the receiver.

It has been already mentioned, in noticing the application of alkaline leys in bleaching, that the more intelligent bleachers, in preparing their aſh-leys, made uſe of quicklime to augment the power of the alkali, when ſuch alkali was in a mild ſtate, or, in other words, combined with fixed air, or, as it is now termed, carbonic acid; the attraction of cauſtic lime for the carbonic acid being ſtronger than that of aſhes. Hence, on cauſtic lime being thrown into mild aſh-ley, the carbonic acid, by which the aſhes were rendered mild, abandons the alkali to combine with the lime, leaving the aſhes in their cauſtic ſtate.

But, although the attraction of carbonic acid is ſtronger for lime than for alkali, the contrary is the caſe with the oxygenated muriatic acid, as it abandons lime to combine with aſhes, leaving the lime to precipitate.

This obſervation is made in order to guard the ignorant bleacher from miſtakes, who, from having mixed lime with his aſh-ley in the receiver, in the preparation of the oxygenated marine acid, may ſuppoſe it acts in a ſimilar manner; but not a particle of lime is acted upon by the acid, whilſt aſhes remain to combine with it; the only effect of the lime there, being to abſtract from the aſhes any fixed air they may contain, and ſo diſpoſe the alkali to abſorb more of the oxygenated muriatic acid.

Beſides the proceſſes above mentioned, the bleachers attempted to unite the oxygenated muriatic acid with clay; but as the clay has ſcarcely any affinity with it, the liquor thus made was little, if at all, ſuperior to that of M. Berthollet.

Such were the attempts made from the year 1786; and the oxygenated muriatic acid combined with pot-aſh was in general uſe by the bleacher until 1798, when Mr. Tennant, of Glaſgow, by a well-conducted ſeries of experiments, formed what may not improperly be called a new æra in bleaching.

Mr. Tennant, having ſeen ſo long a period elapſe without any material improvement in bleaching, and the alkali, though an expenſive ingredient, regarded by the bleacher as an indiſpenſible article to unite with the oxygenated muriatic acid in the receiver, made ſome trials with the earths ſtrontites and barytes, and with ſucceſs. Their ſolubility in water enabled him to combine them with a ſufficient quantity of oxygenated muriatic acid to ſerve the purpoſe; but the ſcarcity of ſtrontites, and the difficulty of ſeparating barytes from the vitriolic acid, with which it is uſually found in combination, rendered theſe diſcoveries rather objects of curioſity than uſe.

Mr. Tennant had previouſly made experiments to combine the oxygenated muriatic acid with lime and lime-water, in the modes above-mentioned, but found they were not adequate to the purpoſes intended; the lime in general remaining at the bottom of the receiver uncombined with the gas, which was the neceſſary conſequence of the lime being ſpecifically heavier than the water, and the gas much lighter; the water, by its interpoſition betwixt the two ſubſtances which ought to be combined, namely the oxygenated muriatic gas and the lime, preventing their union. To bring the pulverized lime into contact with the gas as quickly as

it entered the receiver, became then the object of his attention; and for this purpoſe he found it was neceſſary to keep the lime floating, or diffuſed through the fluid, which he ſucceeded in accompliſhing by two different methods; one of which was by increaſing the ſpecific gravity of the water in the receiver, by the addition of common ſalt, and thus retarding the lime from ſubſiding; the other mode was by conſtant agitation of the lime in the water in the receiver, to keep the lime diffuſed through the fluid, during the time the oxygenated muriatic gas was introduced; and by this means he ſucceeded in uniting and retaining a much greater quantity of gas with the mixture, than by any method heretofore uſed, and without the addition of any aſhes or alkaline ſubſtances.

A very material advantage was gained by this diſcovery; namely, that it uniformly afforded ſecurity to the dyed colours in a ſuperior degree to the alkaline ley.

It is well known, that in the alkali of commerce, ſuch as pot-aſh or pearl-aſh, a large and very irregular proportion of neutral ſalts is intermixed, which are ſoluble along with the alkali in water, thereby ſo far contaminating the ley, that the bleacher is always uncertain what quantity of pure and active alkali it contains. In bucking or boiling cotton goods, the detriment from theſe neutral ſalts is not ſo great, as a repetition of the proceſs may compenſate for thoſe admixtures in the ley: but in the bleaching liquor formed by the mixture of the oxygenated muriatic gas with ſuch ley, if there is a deficiency of alkali, the uncombined oxymuriatic acid immediately attacks the dyed colours of the goods, and diſcharges them, and thus conſiderable damage frequently occurs before the real origin of the evil is aſcertained and corrected. The bleacher is kept in a conſtant ſtate of alarm reſpecting the quality of the aſhes he makes uſe of, beſides the great coſt of their purchaſe. In uſing lime for the ſame purpoſe, the expence is a mere trifle; what is not combined with the oxymuriatic acid precipitates, after the agitation is over, leaving a pure liquor free from all uncombined acid.

Simple as the combination of the lime with the oxygenated muriatic acid may now appear, yet it was a long time attempted in vain; but this, perhaps, will not be ſo much a matter of ſurprize, when we reflect that the French chemiſts, whoſe opinions were regarded generally as law by the common bleachers, and whoſe treatiſes on the ſubject of bleaching were almoſt the only accounts publiſhed, conſidered lime as no further uſeful in bleaching, than in abſorbing the carbonic acid or fixed air uſually combined with alkalies or aſhes; and thus rendering the alkaline ley more diſpoſed to unite with the oxygenated muriatic gas, when expoſed to its contact in the receiver, to form, as it is called, the liquor de Javelle; or, when intended for uſe as a mere alkaline ley, to render its action more powerful on the oily particles in the vegetable fibre, on a ſimilar principle to the formation of ſoap.

An excellent treatiſe on the ſubject of bleaching, in the Engliſh language, viz. "The Report on Experiments made by order of the right honourable the truſtees of the linen and hempen manufactures, to aſcertain the comparative merits of ſpecimens of oxygenated muriatic bleaching liquids," publiſhed at Dublin in the year 1791, in claim of a bounty offered by the truſtees, appears to convey no further knowledge of the uſe of lime in bleaching at that time, than in promoting the ſeparation of the carbonic acid from the leys, whether they were afterwards to be uſed alone, or in the preparation of the oxygenated muriatic acid. Mr. Roſe's experiments in this report contain, however, much uſeful information, which we ſhall further notice.

The ſimplicity of Mr. Tennant's invention of retaining a greater quantity of the oxygenated muriatic gas, by agitation of a ſufficiency of lime in the water of the receiver, ſhould be no derogation to its real merit. In ſubſtituting lime for pot-aſh, an article, not only of foreign produce, but expenſive, he has benefited this country to an extent almoſt beyond conception; it having been proved upon oath, that by the uſe of Mr. Tennant's proceſs, the conſumption of aſhes at a ſingle bleaching-green has been reduced three thouſand pounds ſterling in value in one year. A patent for Mr. Tennant's invention was granted him in the year 1798; but, as frequently happens in patent cauſes, on a late trial of its validity, ſome circumſtances aroſe, from which the jury thought themſelves juſtified in reverſing the patent; we have therefore, with conſiderable pains, collected for the public benefit an account of his proceſs, and the moſt approved mode of putting it in practice, either on a ſmall or an extenſive ſcale, as will be ſeen by a reference to *Plate* I. of *Bleaching* hereafter deſcribed.

Mr. Tennant's method of uſing calcareous earth for neutralizing the muriatic acid gas, and forming the oxy-muriat of lime employed in bleaching, is as follows; viz.—In a receiver capable of containing one hundred and forty gallons wine meaſure, diſſolve thirty pounds of common ſalt, which appear uſeful only in giving an additional degree of ſpecific gravity to the water, and by that means making it eaſier to keep the lime to be afterwards added, in ſuſpenſion; when this ſalt is diſſolved, add ſixty pounds of finely powdered quicklime, and into the retort of the apparatus put thirty pounds of powdered manganeſe, mixed up with thirty pounds of common ſalt, upon which pour thirty pounds of ſulphuric acid (oil of vitriol), previouſly diluted with its bulk of water, and the uſual precaution of luting the veſſel being taken, proceed to diſtillation. When the gas begins to appear, the agitation of the lime and water in the receiver muſt commence, which ſhould be continued by means of a wooden paddle or rake, or ſimilar contrivance, without intermiſſion, until the materials in the retort, after heat being employed as uſual, will not yield any more oxygenated muriatic acid gas. Then the whole ſhould be allowed to remain at reſt for two or three hours, when the clear liquor in the receiver may be drawn off for uſe, and mixed with water in ſuch proportions as may be found neceſſary, previous to the immerſion of the goods to be bleached.

The principal point of attention in preparing this oxygenated muriat of lime is, to obtain a complete diffuſion of the lime through the mixture, or a mechanical ſuſpenſion of it in the water during the operation, ſo that every particle of the lime may, by agitation, be expoſed to the action of the gas, inſtead of merely its upper ſurface, as had been formerly practiſed. By the preſent means, the oxygenated muriatic acid gas is abſorbed with eaſe, and meets with a ſufficient quantity of lime to produce a ſtrong ſolution of oxygenated muriat of lime, without any uncombined oxygenated muriatic acid; a thing which could not be otherwiſe effected. The addition of the common ſalt in the receiver may even be omitted, without prejudice, if the agitation of the lime be well managed.

Plate I. *fig.* 2. of *Bleaching*, ſhews a longitudinal ſection of a method, which has been practiſed in Ireland for diſtillation of the oxygenated muriatic acid, and the formation of the oxygenated muriat of lime. *a*, the aſh-hole; *b*, the fire under the iron pot or veſſel; *c*, the aperture through which it is ſupplied with coals; *d*, the entrance to the aſh hole, which may be provided with a ſtopper of burnt clay, or earthen ware, to regulate the draught of the fire, by means of the handle ſhewn by dotted lines; *e*, a caſt-iron pot or veſſel

veſſel, nearly filled with water, in which the leaden retort is placed; *f*, a tripod of iron, on which the retort ſtands; *gg*, the leaden retort, from which the gas is to be diſtilled; *h*, a tunnel of bent lead, through which the oil of vitriol (ſulphuric acid) is to be introduced into the retort; *i*, a leaden cover, fitted and luted to the neck of the retort, having three apertures, viz. for the introduction of the tunnel, the rod of the agitator, and the tube of the condenſer; *k*, the agitator, formed of a rod of iron coated with lead, having ſome arms at its lower end to ſtir the materials within the retort. At the part where the rod paſſes through the cover, a leaden collar or cap is ſoldered, to prevent the agitator from deſcending too low; theſe two parts are made in a conical form, to fit exactly, and thus prevent the eſcape of the gas; *l*, a leaden tube or pipe, of three inches bore, to conduct the gas into the tubulated reſervoir; *m*, the leaden reſervoir, formed upon the principle of Wolfe's apparatus; the tube, *l*, deſcends by the firſt aperture, *m*, to the bottom of the reſervoir, which is about two thirds full of water. The ſmall portion of ſulphuric acid, which riſes in diſtillation, unites with this water; the oxygenated muriatic acid, which traverſes this water, paſſes by the pipe, *n*, into the receiver or condenſer, *oo*, which is a wooden veſſel, in the midſt of which is placed an agitator, *p*, the arms of which raking up the lime cauſe it to combine with the gas, in proportion as it ariſes in bubbles from the lower extremity of the leaden pipe, *n*.

The projections of wood, *qqqq*, fixed to the ſtaves within the tub, counteract the rotatory motion of the arms of the agitator, and thus aſſiſt the combination of the gas with the lime and water. The cover of this tub is fixed cloſe upon the edge of it at *r*; the cover having a groove in it to unite them tighter together; *s*, a cock, to draw off the liquor, when ſufficiently impregnated for uſe; *t*, a wooden handle to give motion to the agitator. The joints may be luted with clay, to prevent the eſcape of the gas.

Fig. 3, and 4, ſhew Mr. Tennant's improved machinery for preparing the oxy-muriat of lime. The outline, A, (*fig.* 3.) is the ſtill, made of lead, of a circular form, having a double flange at the top, which is filled with water, to prevent the gas from eſcaping in that direction. B, the leaden cover of the ſtill, having a flange on the under ſide, which goes into the double flange of the ſtill, and having a double flange on the upper ſide, which is filled with water; the inner part of this double flange conſiſts of a ſhort tube, which goes quite through the cover, opening by this means a communication with the ſtill, and allowing the gas to eſcape through the long leaden pipe inſerted into it, and from thence into the receiver, as explained at *fig.* 4, where there is a ſection of the ſtill, furnace, and receiver; *a*, the ſtill; *b*, an iron pan in which the ſtill is placed on an iron ſtand; this pan is then nearly filled with water; *c*, the fire-place; *d*, the furnace door; *e*, the aſh-hole; *f*, double flange filled with water; *g*, the cover, with flanges on the upper ſide filled with water. D, the receiver, made of wood, and lined with lead; *i*, a double flange filled with water, the interior pipe communicating with the inſide of the receiver, and bent horizontally as at *k*, from whence the gas iſſues into the receiver; *l*, *l*, two ſhort pipes inſerted in the top of the receiver, through which the rods of the agitators have a free motion; *m*, *m*, a ſtopper in the top of the receiver, cloſed when the receiver is at work, but ſufficiently large, if removed, to admit a perſon into the inſide to repair or cleanſe it, when neceſſary; *n*, *n*, two paddles, or agitators, generally of a ſquare form, and of a ſimilar conſtruction to the head of a churn ſtaff; *o*, *o*, the rods of the agitators attached by iron pins to the lever, *q*, which lever has ſlits at the place of junction, to allow the rods to riſe and fall perpendicularly; *p*, the fulcrum or ſupport of the lever; *q*, the lever, which, by a proper motion communicated to it, alternately raiſes and depreſſes the agitators in the receiver; *r*, a rod connecting the lever *q*, with the lever *s*, which laſt lever is put in motion by the wheel E; *t*, a balance weight placed at the other end of the lever; the beam ſupporting the fulcrum of the lever being near the letter *s*. E, the wheel to be put in motion by water, or in any other way, having a crank, *u*, communicating by an upright ſhaft with the lever *s*.

It will be found that the flanges, filled with water, preclude the neceſſity of the application of any lute, and occaſion the operation to be conducted in a cleaner, cheaper, and more expeditious mode, than formerly employed.

To deſcribe the proportions of the ſeveral articles uſed in the proceſs of bleaching, would carry us far beyond the bounds which can be allotted in the preſent publication; we ſhall, therefore, give the following ſhort but clear account of the mode we recommend to be practiſed, to procure the moſt perfect and durable white on cotton goods, after their being taken from the weaver; which is, firſt, to wet them thoroughly in cold water; then to allow them to ſteep in cold, or lukewarm water, from 12 to 36 hours, according as they are of a ſtrong or thin fabric; then to waſh them well in clean cold water; afterwards to buck or boil them in a cauſtic alkaline ley; then to waſh the goods well in clean water, and afterwards immerſe them in diluted oxymuriate of lime, and waſh them, repeating the operations of the alkaline leys, and the oxymuriate of lime, till the goods are perfectly white; then to paſs the goods through the diluted ſulphuric acid liquor, waſhing them well afterwards; laſtly, to paſs them through a weak ley of pearl-aſhes, or of ſoap, and again through clean water, before drying and finiſhing them; which finiſhing of the goods conſiſts in ſtarching, bluing, rolling, or calliendering them as faſhion directs, or the particular market for which they are intended, may require.

It is to be remarked, that the immerſion of the goods in the vitriolic ſours, and alſo in pearl-aſh, or ſoap liquor, is neceſſary at the end of the proceſs, to prevent a brown hue which the cloths that are bleached white from the oxygenated muriatic acid, without ſuch precaution, are apt to revert to.

By experiments made at Rouen on cotton thread, with a view to aſcertain whether the old or new mode of bleaching was more prejudicial to the fabric, it was proved that the cotton thread bleached in the new mode bore, without breaking, conſiderably more weight than that bleached in the old method, and was leſs injured in texture.

In the report on experiments, made by order of the truſtees of the linen and hempen manufactures at Dublin, in the year 1791, with a view to aſcertain the comparative merits of ſeveral ſpecimens of bleaching liquids ſent for their examination, the following mode of bleaching appeared to be the beſt for linens, and though executed on a ſmall ſcale, will convey the principal neceſſary information.

May 11th, 1791. The linen was ſteeped, in the ſtate received from the loom, into water of a heat ſufficient to bear the hand, and left in the veſſel.

May 16th. The linen was waſhed out of the liquor, in which a pretty ſtrong fermentation was obſerved to have taken place.

May 17th. Finiſhed making a mother-ley, which was made in the following manner: three pounds and a half of lime were ſlaked, and mixed with ten gallons of water; fourteen pounds of Dantzic pearl-aſh were diſſolved in ſome of this water; then mixed the whole; when it had ſettled, it

was filtered through a coarſe cloth, and the reſiduum waſhed repeatedly in four gallons of water, to obtain the whole ſtrength of the alkali; the whole fourteen gallons being then carefully mixed, the ley proved, by very accurate weighing, to contain twelve ounces of cauſtic alkaline ſalt to the gallon. From this, a ley was made from the work, by adding ſix parts of water to one of the mother-ley; thus each gallon of the working ley contained one ounce, five drachms, and forty-three grains of cauſtic alkali.

The boiler being charged with this ley, the linen, which had been ſpittle waſhed, was ſteeped in it cold for one hour; then brought up by a very gentle heat to a ſimmering boil, which was continued for three hours; the cloth was then well waſhed out, and left in ſteep for that night.

May 18th. Waſhed out the above linen in freſh water; hung it on cards in the open air, watering it ſeveral times in the day.

May 19th. Finding the cloth not ſo well cleared as could be wiſhed, the boiler was again charged with one of mother-ley, to four of water, which made the ſtrength two ounces, three drachms, twelve grains of cauſtic alkali to the gallon. In this was boiled another piece of linen which had been ſpittle waſhed as the others; and after it was boiled, it was well waſhed out.

May 20th. Steeped the whole of the linens for ſix hours in the liquid prepared with the oxymuriatic acid of the ſeveral claimants; afterwards waſhed them well out, and left them ſteeping in cold water all night.

May 21ſt. Waſhed out all the above linens, and when dry, boiled the whole parcel as before in one of the mother-leys, to five of water, containing two ounces of cauſtic alkaline ſalt to the gallon; waſhed them well out of the ley, and left them to ſteep in pure water till Monday morning, the 23d inſtant.

May 24th. Steeped the linens for the ſecond time in the oxygenated muriatic acid for ſix hours; then waſhed them out, and left them to ſteep all night in cold water.

May 25th. Having charged the copper with a ley made from one of mother-ley, to ſix of water, containing one ounce, five drachms, and forty-three grains of cauſtic alkaline ſalt to the gallon, the linens were boiled in this for the third time, with a very gentle ſimmering heat for three hours; they were then waſhed out, and left to ſteep.

May 27th. Steeped all the linens for the third time ſix hours in oxygenated muriatic acid as before; waſhed them out, and left them in water all night.

May 28th. Immerſed all the linens which had been ſteeped yeſterday in the oxygenated muriatic acid, in a weak vitriolic acid for four hours; then waſhed them out, and left them ſteeping in cold water.

May 29th. Waſhed and dried the linen cloth which had been ſoured yeſterday.

June 1ſt. Boiled all the linen which had been ſoured in a ſtrong lather of ſoap.

June 2d. Soured and waſhed out all the linen which had been boiled in a ſoap lather yeſterday. This operation finiſhed that experiment, in which the above linens were firſt ſteeped in water; then boiled in cauſtic alkaline ley, and ſteeped in oxygenated muriatic acid alternately four times; then ſoured in vitriolic acid, ſoaped and ſoured again.

The above experiments were made, with various others, by Mr. John Arbuthnot, and Mr. John Clarke; and on the trials of the different ſpecimens of the oxygenated muriatic acid, the preference was given to that prepared by Mr. Robert Roe, of Bing's End, on the principle of the javelle liquor mentioned by Mr. Barthollet, by adding a ſolution of alkali in water in the receiver. Mr. Roe's beſt preparation, of which was made by adding thirty-eight pounds of quicklime to 114lb. of pearl-aſh, which made a cauſtic ley of about nine pounds weight per gallon; he found cauſtic ley more ſuſceptible of imbibing the gas and retaining it, than mild ley of equal ſtrength.

From the different experiments made to bleach various articles at the above time, the following inferences may be deduced, viz. that allowing cotton or linen, when raw from the the loom, to ferment, by ſteeping in warm water a conſiderable time before boiling the cloth in an alkaline ley, is of conſiderable ſervice.

That cloth or yarn is not injured by ſteeping for ſix hours together in oxygenated muriatic acid.

That ſtrong alkaline leys anſwer better than weak ones, at the commencement of uſing the leys.

That the white colour of bleached cloth can be better judged of wet than when dry.

That very minute attention in excluding light and air is not abſolutely neceſſary in bleaching with oxygenated muriatic acid.

That purging or clearing yarn or cloth in an alkaline ley, previous to ſteeping in oxygenated muriatic acid, is abſolutely neceſſary.

That the bleaching liquids made from oxygenated muriatic acid, in which alkaline ſalt is blended in the compoſition, require the cloth to be frequently ſteeped in vitriolic acid; and that the oxygenated muriatic acid made with water only, make more frequent boilings of the cloth in alkaline leys neceſſary.

That the loſs of the cloth in weight, when bleached by the new method, is only one fourth, but by the old method one third.

That ſteeping in warm water is infinitely better to extract the ſowen and dirt from the raw cloths, than boiling them with ſoap or ley immediately as they come from the loom.

The liquors of the oxygenated muriatic acid, and alſo thoſe made from the vitriolic acid, may be repeatedly uſed without detriment, till the whole ſtrength is exhauſted.

The cloth or linen, in the acid bleaching liquors, ſhould be moved in the liquor every hour, that every part may be equally cleared.

It is difficult to aſcertain the ſtrength of the leys proper for uſe in bleaching cotton or linen, as the alkalies or aſhes differ ſo greatly in purity, and the admixture generally found in them of neutral ſalts prevents the hydrometer from being a regular teſt. The common allowance for bleaching linens in Ireland, is ſtated by Mr. Higgins, in his ingenious memoir in the Tranſactions of the Dublin Society, to be for ſixty gallons of water, ſix pounds of barilla, or four pounds of pot-aſh at the leaſt, and moſt bleachers uſe more than this.

To diſcover adulterated pot-aſh, Mr. Higgins recommends the following method. The ſpecimen of aſhes being firſt weighed, is digeſted for a few minutes on a ſand bath, in twice its weight of water, in a heat of about 212 degrees, and inſtantly ſtirred. It is then removed from the ſand-bath, and before it is cooled to the temperature of the atmoſphere, it muſt be filtered through paper. When all the liquor has paſſed through the filter, a ſmall quantity of cold water is gradually poured upon the ſaline reſiduum or the filter, in order to waſh through the whole of the alkali. The undiſſolved ſalt ſulphate of pot-aſh (vitriolated tartar,) remaining on the filter, is afterwards dried and weighed, to aſcertain the quantity.

To determine whether any common ſalt is ſuſpended in the liquor which has been filtered, evaporate the clear ſolution a little on a ſand-bath, and ſet it in a cold place for 24 hours;

hours; at the end of which time, any common falt it contains will be found cryftallized in regular cubes at the bottom of the veffel; pour off the clear liquor, and repeat the procefs, till no more cubic cryftals are produced. If it is defired to be very accurate in the analyfis, before the common falt (muriate of foda) thus procured is weighed, fome muriatic acid may be poured upon it, in order to take up any of the pure pot-afh which may have adhered during its cryftallization. The muriatic acid, with fuch of the alkali as it has diffolved, may be then drained off and thrown away, and the muriate of foda dried and weighed.

The fum of the impurities being then fubtracted from the weight of the fpecimen, the quantity of the pure pot-afh is afcertained.

To fhew what quantity of mere alkali is contained in 100lb. avoirdupois of feveral different alkaline falts examined by Mr. Kirwan, we fhall add the following table, publifhed by him in the Irifh Tranfactions, in 1789.

One hundred Pounds.		Mineral Alkali.
Cryftallized foda -	yielded -	20lbs.
Sweet Barilla - -	-	24
Mealy's cunnamara kelp -	-	3.437
Do. defulphurated by fixed air	- -	4.457
Strangford kelp - -	-	1.25
One hundred Pounds.		**Vegetable Alkali.**
Dantzic pearl-afh -	yielded -	63.33lbs.
Clarke's refined afh - -	-	26.875
Caffiup - - -	-	19.376
Common raw Irifh weed-afh	-	1.666
Do. flightly calcined -	-	4.666

It is much to be regretted that, confidering the immenfe quantities of pure marine alkali which could be procured at a cheap rate from the Eaft Indies, that fo little attention fhould be paid by the Eaft India company to an article which would be fo profitable a branch of commerce to them, and prevent a confiderable fum being paid to other nations. The mineral alkali procured from the Eaft Indies, is much purer than what is obtained from Barilla; and a preparation exactly fimilar in appearance and quality to the Alicant Barilla, may be made with great advantage to the manufacturer, from a mixture of the Eaft India mineral alkali with the common Scotch kelp, for the purpofes of the bleacher, the foap maker, or the Turkey-red dyer. To fhew the importance of this object, the following table of the imports into Great Britain are annexed for feven years.

	Barilla.	Pot-Afhes.	Pearl-Afhes.
1796	86.723 cwt.	62.829 cwt.	45.290 cwt.
1797	51.105	57.826	36.674
1798	123.990	81.482	60.691
1799	146.163	77.246	51.792
1800	175.629	135.400	45.161
1801	63.210	90.523	54.835
1802	151.796	48.054	64.288

When it is confidered that 20 pounds of the mineral alkali brought from India in a powdery ftate, as it ufually is, will, by mere folution in water, yield 100lbs. of the cryftallized foda fold in the fhops, it will be feen, that the purchafe of the mineral alkali from the Eaft India company, will be an object well deferving the attention of the bleachers and foap-boilers; and far preferable to the ufe of Spanifh kelp or Barilla.

Mr. Kirwan, by means of muriatic acid, precipitated the colouring matter from an alkaline ley, faturated with the colouring matter of linen yarn, and found it to poffefs the following properties. When fuffered to dry for fome time on a filter, it affumed a dark green colour, and felt fomewhat clammy, like moift clay. His obfervations in the Irifh Tranfactions for 1789, are as follow:

"I took, fays he, a fmall portion of it, and added to it 60 times its weight of boiling water, but not a particle of it was diffolved. The remainder I dried in a fand-heat; it then affumed a fhining black colour; became more brittle, but internally remained of a greenifh yellow, and weighed one ounce and a half."

"By treating eight quarts more of the faturated ley in the fame manner, I obtained a further quantity of the greenifh depofit, on which I made the following experiments:

1ft. Having digefted a portion of it in rectified fpirits of wine, it communicated to it a reddifh hue, and was, in a great meafure, diffolved; but by the affufion of diftilled water, the folution became milky, and a white depofit was gradually formed; the black matter diffolved in the fame manner.

2d. Neither the green nor the black matter was foluble in oil of turpentine or linfeed oil, by a long continued digeftion.

3d. The black matter being placed on a red hot iron, burned with a yellow flame and black fmoke, leaving a coaly refiduum.

4th. The green matter being put into the vitriolic, marine and nitrous acids, communicated a browniſh tinge to the two former, and a greenifh to the latter, but did not feem at all diminifhed.

"Hence, it appears, that the matter extracted by alkalies from linen yarn, is a peculiar fort of refin, different from pure refins only by its infolubility in eſſential oils, and in this refpect refembling lacs. I now proceeded to examine the powers of the different alkalies on this fubftance, eight grains of it being digefted in a folution of cryftallized mineral alkali, faturated in the temperature of 62°, inftantly communicated to the folution a dark brown colour; two meafures (each of which would contain eleven pennyweights of water), did not entirely diffolve this fubftance. Two meafures of the mild vegetable alkali diffolved the whole."

"One meafure of cauftic mineral alkali, whofe fpecific gravity was 1.053, diffolved nearly the whole, leaving only a white refiduum."

"One meafure of cauftic vegetable alkali, whofe fpecific gravity was 1.039, diffolved the whole."

"One meafure of liver of fulphur, whofe fpecific gravity was 1.170, diffolved the whole."

"One meafure of cauftic volatile alkali diffolved alfo a portion of this matter."

The colouring matter of cotton is much more foluble in alkali, than that of linen: hence the greater facility with which cotton is bleached.

The theory of bleaching vegetable matter, as we have before obferved to have been defcribed by Mr. Delaval, depends on removing the colouring matters, whether natural or accidental, which cover their folid fibrous parts, which are the only parts endued with a reflective power.

Raw cotton or linen, boiled in a a diluted folution of cauftic alkali, gives to the liquor a deep brown colour, and deftroys its cauſticity; and freſh portions of clear ley applied a fecond or third time, will produce a fimilar effect, but in an inferior degree. If the cotton or linen be now plunged into the oxymuriatic acid, and allowed to remain a fhort time, they will become white; and if they are then plunged into an alkaline ley, the liquor will again become brown, and lofe its cauſticity.

On faturating either the firft or laft of the alkaline folutions with an acid, a fimilar precipitate is obtained from each, of a dark coloured matter, almoft infoluble in water, but foluble in cauſtic alkali.

Hence.

Hence it appears, that after raw cotton or linen has been acted upon by alkalies for two or three times, they have no further effect upon it, till the cloth comes in contact with oxygen or pure air, either by immerſion in the oxygenated muriatic acid, or by expoſure to the atmoſphere; and it is on account of the ſpeedy action of the acid, in compariſon with that of the atmoſphere, that the new mode of bleaching is now generally adopted.

M. Berthollet, and the modern chemiſts ſuppoſe, that the colouring matter of linen is compoſed principally of carbon and hydrogen; and they conclude, that linen, bleached by the oxymuriatic acid, becomes yellow, on this principle, that when the oxymuriatic acid renders linen white, a quantity of oxygen has combined with the colouring particles; but that this oxygen gradually enters into a combination with the hydrogen, and forms water which paſſes off; that then the carbon becomes predominant, and the linen, in conſequence, aſſumes a yellow colour.

The old chemiſts, on the principles of Stahl, would ſay, that a part of the dephlogiſticated marine acid, (oxymuriatic acid,) after the cloth had been acted upon by the alkali, abſorbed ſuch phlogiſtic colouring matter from the cloth, as the alkali had no affinity for; and thus became diluted common marine acid, which has a great attraction to cotton or linen, and, if expoſed to a moderate heat, will act upon the texture of the cloth, and render it of a yellow colour.

We notice this circumſtance in two different points of view, that the bleacher may be aware of the neceſſity of applying, in either caſe, a weak ley of pearl-aſh, ultimately after the uſe of the muriatic acid, to prevent this yellowneſs from occurring; and alſo that the reader may comprehend the reaſoning of Home, and other perſons who have written upon the ſubject of bleaching, previous to Mr. Scheele's diſcovery.

To recover the pure alkali from the black coloured leys which have been uſed in bleaching, and to render them equally proper for the ſame purpoſe, has been for a conſiderable time a material object in the neighbourhood of Manchester, and practiſed with great ſucceſs.

To effect this, the black or brown ſtrong leys, which have been left after bucking linen, or cotton yarn, or goods, or ſaved after wringing them, is put into an oblong flat ſhallow iron pan, made of plate-iron, rivetted together. (See *Plate* IV. *fig.* 4, 5.) Under this pan a fire is made, and the old leys gradually evaporated, till they become of a conſiſtence nearly reſembling tar; the matter is then put into caſks, and carried to the reverberatory furnace, *Plate* IV. *fig.* 6, 7. where it is laded or poured into the cavity or bed within the furnace; the fire being then made, acts powerfully on the alkaline maſs; gradually dries the water left amongſt it; then acts on the colouring matter the ley has abſtracted from the cloth, which is partly diſſipated in a black, offenſive ſmoke, and partly deſtroyed by combuſtion; the calcination of the aſhes is aſſiſted from time to time, by raking them up with a long iron rod, in order to expoſe freſh ſurfaces to the flame; the heat is continued and increaſed till the inflammable matter amongſt the alkali is diſſipated, and the aſhes brought to a perfect fluid ſtate; they are then let out by an aperture in the ſide of the furnace, into an old iron pot put into the ground, and when cold, broken into ſmall pieces for uſe, being frequently in a purer ſtate then when firſt imported.

Fig. 4. *Plate* IV. is a ſection of the evaporating pan for the waſte leys, where A repreſents a flat iron pan, of an oblong ſquare form, about ſix inches deep, and of a ſize proportionate to the quantity of leys to be evaporated; B, the fire-place; C, the aſh-hole; D, the flue in which the fire acts under the pan; E, the chimney for the ſmoke; F, the brick work.

Fig. 5. *Plate* IV. is a bird's eye view of the ſame evaporating pan, which is made of plates of beaten iron rivetted together, as ſhewn in the plan; the fire-place underneath it is marked by dotted lines at B, and the chimney flue at E.

Fig. 6. *Plate* IV. repreſents a longitudinal ſection of the reverberatory furnace uſed in the preparation of aſhes, or ſolid alkaline ſalts from the old leys after evaporation, to a proper conſiſtence; *a*, the brick work; *b*, the aſh-hole; *c*, a channel, or paſſage under the furnace, to admit a free current of air; *d*, the fire-grate; *e*, the fire-place; *f*, the inner part of the furnace; *g*, the bed of fire-proof brick, on which the matter is calcined; *h*, the alkaline ley to be calcined; *i*, a door through which the ley is introduced by an iron ladle into the furnace, and through which door the matter, during calcination, is ſtirred from time to time; *k*, the paſſage for the ſmoke, or chimney, which chimney ſhould be from 20 to 30 feet high; *l*, the upper part of the furnace, arched like an oven: *p*, the ſeparation wall between the fire and matter to be fluxed or calcined.

Fig. 7. *Plate* IV. repreſents the upper plan of the furnace, of which *fig.* 6. is a ſection; *a*, the outer walls; *b*, the aſh-hole and draught-hole; *e*, the iron grate of the fire-place; *g*, the baſon in which the leys are calcined; *m*, the door through which foſſil coal is thrown into the fire place; *n*, an iron tube through which the aſhes in fuſion flow out of the furnace when ſufficiently calcined; *o*, an iron pot into which the melted aſhes flow, and where they are ſuffered to cool; *p*, a wall of fire-brick between the fire-place and baſon, over which wall the fire paſſes; *r*, the ſteps leading down to the aſh-hole.

It is neceſſary to remark, that all the interior part of the reverberatory furnace ſhould be made of Welſh brick, or ſuch as will withſtand the action of a ſtrong fire; the whole building ſhould be well bound together by iron bars, or cramps. If ſo conſtructed, it will laſt for ſeveral years; and when it then wants repair, the aſhes, which will be found accumulated in the interſtices of the brick-work, will defray the expence of ſuch repairs.

Having ſhewn the methods generally uſed in bleaching linen and cotton, we ſhall notice a proceſs lately diſcovered by Mr. W. Higgins of Dublin, for uſing the ſulphuret of lime, as a ſubſtitute for pot-aſh in bleaching. The ſulphuret is prepared in the manner following, viz. ſulphur or brimſtone in fine powder, four pounds; lime well ſlaked and ſifted, twenty pounds; water ſixteen gallons; theſe are all to be well mixed, and boiled for about half an hour in an iron veſſel, ſtirring them briſkly from time to time. Soon after the agitation of boiling is over, the ſolution of ſulphuret of lime clears, and may be drawn off free from the precipitate, which is conſiderable, and which reſts upon the bottom of the boiler. The liquor, in this ſtate, is nearly of the colour of ſmall beer, but not quite ſo tranſparent.

Sixteen gallons of water are afterwards to be poured upon the remaining precipitate in the boiler, in order to ſeparate the whole of the ſulphuret from it; the matter is then well agitated, and muſt, when ſettled, be drawn off, and mixed with the firſt liquor; to theſe again thirty-three gallons more of water may be added, which reduce the liquor to a proper ſtandard for ſteeping the cloth.

Though either lime or ſulphur, ſeparately, are very little ſoluble in water, yet this ſulphuret of lime is highly ſoluble.

This preparation has been applied, in the following manner, to the bleaching of linen in Ireland.

The linen, as it comes from the loom, is charged with the weaver's paſte or dreſſing, to diſcharge which, the linen muſt be ſteeped in water for about 48 hours, and afterwards taken out and well waſhed; in order to ſeparate the reſinous matter inherent in the vegetable fibre, the linen muſt then be ſteeped in the cold ſolution of ſulphuret of lime (prepared as above), for about 12 or 18 hours; then taken out and well waſhed; when dry, it is to be ſteeped in the oxymuriate of lime, prepared by Mr. Tennant's proceſs, for 12 or 14 hours, and then waſhed and dried. This proceſs is to be repeated by ſix alternate immerſions in each liquor, which are ſufficient to whiten the linen.

Though we muſt confeſs, that we have ſome doubts reſpecting the application of ſulphuret of lime to ſuperſede the uſe of aſhes, in bleaching goods intended to remain perfectly white, yet we think it incumbent upon us to ſtate, that for goods previouſly bleached for dying, it poſſeſſes advantages over thoſe where alkalies have been uſed, and which has been actually proved above 30 years ago, by the practice of Mr. Peter Henry Otterſen, communicated by him to the late Mr. John Wilſon, of Ainſworth, near Manchester. Mr. Wilſon's memory deſerves every mark of reſpect from the cotton manufacturers of England, for his numerous improvements in the bleaching, dying, and finiſhing of cotton goods.

For the uſe of private families, where the linen is dirtied by perſpiration or greaſe, it will be of great ſervice towards rendering it white, to ſteep it for ſome time in a clear liquor, made by mixing one quart of quicklime in ten gallons of water, letting the mixture ſtand 24 hours, and then uſing the clear water drawn from the lime. After the linen has been ſteeped in this liquor, it ſhould be waſhed as uſual, but will require much leſs ſoap to be uſed.

Cotton goods, after bleaching, were formerly dried in the open air, on frames or tenter rails, or on rails in covered buildings, or in large rooms or ſtoves heated for the purpoſe, all which modes were attended with great delay and diſadvantages.

Theſe difficulties were removed in 1797 by an apparatus, ſimple in its conſtruction, eaſily managed, and of ſingular uſe in facilitating the proceſs of the bleacher. For this uſeful invention the public are indebted to John Burns, eſq. of Paiſley.

By this diſcovery the bleacher can erect a drying machine, equally uſeful at all ſeaſons, and in all weathers, at leſs than one-tenth of the expence of former conſtructions, for doing buſineſs to the ſame extent. There is no riſk of damage from wind or rain, leſs chance of injury from ſervants, owing to the ſimple manner in which the goods are prepared. They receive a fine gloſs during the proceſs of drying, the colour is as well preſerved as if dried in the open air, and they cannot be injured by the heat.

A contrivance ſo obviouſly beneficial and complete, was ſoon introduced into general practice in the weſt of Scotland; and ſo undoubted were the claims of the above gentleman to the originality of invention, that the bleachers in the neighbourhood preſented him with a handſome donation of ſilver plate, ſuitably inſcribed, in teſtimony of their ſenſe of his merit, and as ſome reward for communicating his plan to the public.

We are more particular in noticing this circumſtance, as ſome other perſons have ſubſequently taken out a patent for the ſame principle, with a little variation in the conſtruction of the machine, but which alteration has not been found to anſwer the purpoſe as expected. We ſhall therefore now more particularly deſcribe Mr. Burns's apparatus for drying.

Fig. 1. *Plate* III. A is the boiler or ſteam veſſel; B, the ſafety valve; C, the hollow leaden pipe which conveys the ſteam from the boiler to the rollers; D, a braſs cock hollowed to receive the pivot of the roller, repreſented in *fig.* 2. one of which cocks is fixed to the pipe under each roller, and by opening which the ſteam is admitted into the roller; E repreſents twelve rollers placed upon the cocks, one of which, next to D, has the cloth upon it in the operation of drying; FFF, the wood frame in which the machinery is placed; GGG, the ſupporters of the leaden ſteam pipe, and of the trough HH, which trough is 15 inches broad at top, to receive the water formed by the condenſed ſteam as it drops from the bottom of the rollers, E, and to conduct it to I, a ſmall pipe extending from the trough, H, to the funnel, K, which funnel has its lower pipe reaching to within eight inches of the bottom of the boiler, to prevent the ſteam from iſſuing out at its mouth, and which funnel keeps the boiler ſupplied with water to its proper height, or ſhews when any is wanted, as the ſteam would ariſe through it if water ſhould be wanting in the boiler.

Fig. 2. *Plate* III. ſhews one of the rollers ſeparate from the frame. It is uſually five feet long, one foot in diameter, and made of double tinned ſheet iron, and hollow in the middle, for containing the ſteam; *a* is the lower pivot of the roller, which is an open tube at the end for receiving the ſteam conveyed through it from the cock. This pivot riſes a foot within the roller, at the under part of the roller; at *d* is a ſmall hole for allowing the condenſed ſteam to drop into the trough placed below it as above-mentioned; *b*, the other pivot or axis of the roller, which is faſtened to the top bar of the frame by a latch, as repreſented in *fig.* 1.; *c*, a row of teeth fixed into a ſmall ſlip of tinned ſheet iron, ſoldered to the roller, and thereby elevated to prevent the teeth from tearing the cloth.

Fig. 3. *Plate* III. a machine about three feet in height, for the purpoſe of lapping the cloth upon the rollers. A, the box in which the cloth is firſt laid; B, the fartheſt wooden roller, over which the cloth paſſes from A, and from thence under the wooden roller C, to the tin roller D, on which it is lapped by turning it with the handle E; F, the cloth paſſing under the roller C, to the tin roller D, on which, when it is lapped, it is ready to be carried and placed in the drying machine; G, a weight hung from the projection in the frame at H, over the roller B, to keep the cloth ſufficiently tight as it paſſes from the box A, over that roller to be lapped on the drying roller D.

Fig. 4. *Plate* III. ſhews another method of lapping the cloth on the tin roller, previous to its being dried. A, a perpendicular frame in the front of which is placed the tin roller B, with a handle for turning it at C; the cloth D extends from the roller B over the wooden roller E, in a frame F to G, where its other end is attached by a wire run acroſs it to ſome wrapper or linen cloth, faſtened to a board H, fixed below the roller B. L L are upright poſts fixed to the outer ſide of the bottom frame KK, having wooden pegs NN in them, on the ſide neareſt the tin roller B. Rails or rods are laid acroſs from theſe to ſimilar pegs oppoſite, to prevent the cloth touching the ground when it is adjuſting in the beginning of the operation, and the number of theſe poſts neceſſary, therefore, are in proportion to the length of the cloth.

At the commencement of lapping the cloth on the tin roller B, the frame F, moveable on ſmall rollers II, running in grooves on the frame KK, is drawn ſo far back, that when the cloth is faſtened to the wrapper G, one half of the piece reaches to the roller F, the other half paſſed over that roller, reaches to the tin roller B, to which it is then to be faſtened. On turning the handle C, the cloth is gradually lapped round

the roller B, the moveable frame F being drawn forward by the cloth; for as the cloth is lapped on the roller B, the frame F is drawn towards it betwixt the uprights LL, and by means of a projecting wood forming an inclined plane fixed at M, on each ſide, near the top of the frame F, the rails O are raiſed off the pegs NN, and carried forward on the part M of the frame F, without impeding its progreſs to the tin roller B, till the wrapper G, to which the cloth is faſtened, paſſes over the roller, and the wire at G, which attaches it to the cloth, is withdrawn, leaving the whole of the cloth to be dried on the tin roller B, which roller is then taken out and placed in the drying frame.

To aſcertain the ſtrength of the oxygenated muriatic acid uſed by the bleachers in France, Monſ. Deſeroizilles made uſe of a ſolution of indigo in the vitriolic acid, for which purpoſe he takes one part of finely pulverized Guatimala indigo, and eight parts of concentrated vitriolic acid, which mixture ſhould be put in a glaſs veſſel, and kept of a gentle heat by ſtanding near the fire or in warm water all night, and repeatedly ſtirred with a glaſs rod or tube. When the ſolution is complete, it is diluted with a thouſand parts of water. One meaſure of this ſolution is put into a graduated tube of glaſs, and oxygenated liquor is added, until the colour of the indigo is completely deſtroyed, and the ſtrength of the oxygerated liquor is aſcertained by its power in diſcharging the colour.

Mr. Roſe has recommended a method which is better adapted for general uſe; which is, "to have ſmall meaſures properly proportioned to each other, and when the liquid is ſtrong, to prevent waſte of the indigo liquor prepared as above, and a tedious repetition of meaſures, let a ſmall meaſure of the liquor to be tried be put into a meaſure containing 24 of the ſame meaſures of water (it then becomes diluted to a twenty-fifth part); to a meaſure of this diluted liquor add as many meaſures of the blue teſt as it will diſcharge, which multiplied by 25, gives its whole ſtrength. It will be proper to have a meaſure of five for the ſake of diſpatch, in adding the blue teſt liquor. It is neceſſary that the experimenter ſhould ſit low enough to view his meaſures horizontally, in order that they may not be overfilled, otherwiſe he may be deceived.

Great care ſhould be taken in the choice of the indigo and the vitriolic acid employed, for unleſs the indigo is of the Guatimala kind, or beſt Eaſt India, and the vitriolic acid highly concentrated and pure, the colour produced will be a greeniſh brown, inſtead of a bright blue.

Mr. Chaptal has employed the oxygenated muriatic acid to the purpoſe of bleaching paper, both by applying it to the rags before worked down, and to the pulp or paſte; he alſo reſtored the white to prints diſcoloured by time, by immerſing them in the oxygenated muriatic acid liquor, or expoſing them to the action of its vapour. And ſeveral patents have been granted in this kingdom for bleaching pulp or paper, amongſt which Meſſrs. Clement and George Taylor, of Maidſtone, in Kent, have obtained one for bleaching the pulp, by incloſing it with a liquor of oxygenated muriate of pot-aſh, in a veſſel reſembling a churn, eight feet diameter at the great end, three feet four inches diameter at the little end, and two feet ten inches in the clear. This veſſel revolves upon an axis at each end, and the pulp, by this motion, and projecting parts within the veſſel, is conſtantly expoſing freſh ſurfaces to the liquor, till the whole pulp is ſufficiently whitened.

Mr. Bigg, of Iping, in Suſſex, has ſince obtained a patent for bleaching paper, and reſtoring to whiteneſs damaged or mildewed paper, by expoſing in cloſe wooden veſſels paper, in quantities of ſix or eight ſheets together, on wooden frames placed at ſmall diſtances from each other, to the action of oxygenated muriatic gas, and after the paper is taken out, preſſed, and dried, previous to its being ſized, wetting it in a ſolution of alum water.

Another method he propoſes, is by wetting and ſoaking the paper in oxygenated muriatic acid liquor, till it is properly bleached; after which it ſhould be well preſſed and dried, and wet out in the alum water, as in the other proceſs.

A patent has likewiſe been granted to Mr. Elias Carpenter, of Bermondſey, London, for a method of bleaching paper in the water leaf or ſheet, and ſizing it without drying; he uſes for this purpoſe a ſtout deal box or caſe, which muſt be carefully cloſed, and capable of confining water or ſteam within this. The paper to be bleached is to be hung on ſtrips of glaſs, about 15 inches long, placed in grooves within the box, about four ſheets on each ſtrip; the paper is taken for this purpoſe when preſſed in the packs in its wet ſtate, and when the box is filled and cloſed, it is expoſed to the action of oxygenated muriatic gas for eight or ten hours, and when ſufficiently bleached, ſized with a preparation made from one hundred weight of pieces of ſkins boiled in water and ſtrained, then fourteen pounds of alum, ſeven pounds of white vitriol, and one pound of gum arabic added; theſe ingredients will make ſize enough for about 50 reams of foolſcap paper; the paper when ſized and preſſed, is finiſhed in the uſual way. To prevent the noxious qualities of the gas to the workmen, he directs a ſolution of pot-aſh in water to be placed at the bottom of the bleaching box, to abſorb the elaſtic vapours which would otherwiſe affect them on opening the box.

Mr. Tennant of Glaſgow, ſubſequent to the patent granted him for his bleaching liquid, has obtained a patent for preparing the oxygenated muriate of lime in a dry form, by which means bleachers may be cheaply and conveniently ſupplied with it by him, and ſave much of the trouble, expence, and hazard which attend the preparation of the former bleaching liquor.

To bleach ſilk from its natural gummy ſtate, whether in ſkain or manufactured, it ſhould be put into a thin linen bag, and thrown into a veſſel of boiling water in which good white ſoap has been diſſolved; the ſilk ſhould boil two or three hours in this liquor, and the bag of ſilk frequently preſſed with a ſtick, and turned, ſo that the gummy matter may ſeparate from it, and riſe to the ſurface of the liquor, from whence it ſhould be ſkimmed off, and thrown away; the bag ſhould then be taken out, and if it contains ſilk goods, they ſhould be well waſhed in clean cold water, to prepare them for printing or dying; but if the bag contains ſilk in the ſkain, after it has been well waſhed in clean water, beaten, and ſlightly wrung, it may be put the ſecond time into the copper veſſel, filled with cold water mixed with ſoap, and a little indigo blue, if you wiſh it tinged a little of the blueiſh hue.

The ſilk, when taken out of the ſecond water, ſhould be wrung hard with a wooden peg, to preſs out all the liquor; then ſhaked, to ſeparate the threads; then ſuſpended on poles, in a cloſe room or ſtove where ſulphur is burnt, which improves the whiteneſs of the ſilk.

Woollen cloths or ſtuffs may be bleached and made white by ſoap and water; by the vapour of ſulphur; or by chalk, indigo, and ſulphuric vapour. In the firſt caſe, after the ſtuffs have been cleaned at the fulling mill, they are again worked in warmiſh ſoap and water, to render them whiter, and afterwards waſhed in clear water and dried; in this ſtate they are fit for dying any light colours.

To deſtroy or remove the reddiſh hue ariſing from boiling printed cottons in madder decoctions, which prevents the printed

printed colours appearing to advantage, the goods are uſually boiled for ſome time in bran and water, and then expoſed to the air, by laying them on the graſs, and throwing upon them clear water from time to time. Mr. Grimſhaw, in the year 1796, obtained a patent for clearing printed goods coming from the madder copper, by uſing the grains after brewing malt liquors, inſtead of bran; the plan he recommends is, that the grains ſhould be previouſly ſour, and that three or four buſhels thereof, more or leſs, according to the colour of the cloth, ſhould be put into a copper of hot water, containing 200 gallons or upwards, and four or five pieces of the printed cotton goods then immerſed therein, and worked over a winch backwards and forwards, for ten or fifteen minutes; the pieces are then taken out of the copper, and well waſhed in clear water, and laid ſtraight upon the ground for two or three days, till the parts which ſhould be white become clear. The ſame liquor, with the addition of a few grains, will ſerve to clear other printed goods, till the whole number wanted to be cleared, have been completed; a ſufficient quantity of clear water being added to repleniſh what has been abſorbed by the goods, or evaporated in boiling. After either of the operations above-mentioned, the immerſion of the printed goods in dilute oxygenated acid, will anſwer the purpoſe of the expoſure to the air.

Bleaching *of Books, Prints*, and *Paper*. See Books, &c. and Bleaching; *ſupra*.

Bleaching *of Hair*. See Hair.

Bleaching *of Wax*. See Wax.

BLEAK, in *Ichthyology*, the Engliſh name of Cyprinus Alburnus, a ſpecies diſtinguiſhed from the other fiſhes of its genus by having twenty rays in the anal fin.

The bleak is a very abundant fiſh in many of the Engliſh rivers, and in thoſe of the northern countries of Europe in general. The fleſh is in ſome eſteem; but it is chiefly taken for the ſake of the beautiful ſilvery ſcales, which artiſts make uſe of in the manufactory of artificial pearl. The credit of this invention is claimed by the French; and it is ſaid, that they have arrived at ſuch a degree of perfection in this art, that, independent of the plain ſilvery hue of the beads in common, they can vary the colour to blue, green, or any other vivid tint they may deſire. The proceſs is very ſhort; the ſcales are ſcraped off, waſhed, and then reduced to a fine powder; this is diluted with water, and introduced into a thin bubble of glaſs, where it forms an internal coating; the cavity is then filled with wax, through which a hole is bored, and the bead is finiſhed.

Gmelin ſpeaks of this ſpecies being from four to ten inches in length; but theſe do not commonly exceed ſix inches. This fiſh is infeſted in the ſummer-time with a creature of the vermes tribe, that lives in the inteſtines, and which oftentimes increaſes to ſuch a vaſt ſize as to occaſion the death of the bleak. Fiſhes ſo infeſted riſe to the ſurface of the water, where they leap and tumble about in the greateſt agonies, and in that ſtate are well known to the fiſhermen by the name of mad bleaks. The white bait taken in the Thames at Blackwall and Greenwich, in the month of July, is believed to be the fry of this ſpecies. Vide Donov. Brit. Fiſhes, pl. 18.

BLEB, a ſmall bliſter, or bubble.

Naturaliſts have obſerved ſmall purple blebs on all the plants of the *hypericum* kind. Phil. Tranſ. N° 224. Thick pieces of glaſs, fit for large optic glaſſes, are rarely to be had without blebs. Ibid. N° 4.

BLECHINGLEY, or Bletchingley, in *Geography*, an ancient but ſmall borough town of Surrey, in England; has had the privilege of returning members to parliament from time immemorial. The right of voting is veſted in burgage tenure; and the lord of the manor's bailiff was the returning officer till 1723, when, by a reſolution of the houſe of commons, he was deprived of that office; and the borough has now the ſingularity of ſending two members to parliament, without a mayor, conſtable, or any other legal returning officer. Sir Robert Clayton is the proprietor of the borough, and has conſequently the power of appointing the repreſentatives. The town occupies the ſummit and ſide of a hill, and commands ſome fine and extenſive proſpects into Kent, Hampſhire, &c. Here was formerly a caſtle, which is nearly obliterated, and its ſcite is overgrown with coppice wood. An alms-houſe and free ſchool are the only charitable foundations of this place. The church is large and handſome; but its ſpire was deſtroyed by lightning in 1606, at which time the bells were melted by the electric fire. Fuller's earth and a ſpecies of iron-ſtone are obtained in the vicinity of this town. Blechingley is 21 miles ſouth from London. The town and ſuburbs within the pariſh, contain 186 houſes, and 1344 inhabitants.

BLECHNUM, in *Botany*. Lin. gen. n. 1175. Reich. 1292. Schreb. 1627. Claſs, *cryptogamia filices*, or ferns. Gen. Char. Fructifications diſpoſed in two lines, approaching to the rib of the frond, and parallel.

Species, 1. B. *occidentale*, South American B. "Fronds pinnate; pinnas lanceolate, oppoſite, emarginate at the baſe." This ſpecies riſes by a ſimple undivided ſtalk to the height of 13 or 18 inches; leaves long and narrow; many pinnas, with two ſmall auricles at the baſe. A native of the Weſt India iſlands, and the continent of South America. Introduced here about 1777. 2. B. *orientale*, Chineſe B. "Fronds pinnate; pinnas linear, alternate." Frond three feet long; ſtipe covered at the baſe before, with large grey briſtles; the anterior ſide ſcored with three longitudinal grooves; leaflets linear-lanceolate, ſeſſile, ſmooth, entire, ſtreaked at an acute angle, the length of the finger. Found in China by Oſbeck, and alſo in the Society iſles. 3. B. *auſtrale*, Cape B. "Fronds pinnate; pinnas ſubſeſſile, cordate-lanceolate, quite entire, the loweſt oppoſite." Stipes a foot long, green; fronds entire, about the edge rugged; the barren ones with broader pinnas, truncate at the baſe; the fertile, with lanceolate pinnas, heart-ſhaped at the baſe; having two lines of fructification, longitudinal, and diſtant both from the edge and rib. A native of the cape of Good Hope. Introduced here, in 1774, by Mr. F. Maſſon. 4. B. *virginicum*, Virginian B. "Fronds pinnate; pinnas multifid." Having the ſtature of polypodium filix mas or male fern; frond ſmooth; pinnas lanceolate, ſeſſile, ſemipennatifid, acute; diviſions obtuſe, quite entire. A native of Virginia and Carolina. Cultivated, in 1774, by Dr. John Fothergill. 5. B. *japonicum*, Japoneſe B. "Frond bipinnatifid; pinnules ovate, obtuſe, ſerrated." Stipe convex at the back and ſmooth, before flat and ſtreaked; the whole ſmooth, flexuoſe, equal; pinnas oblong, acute, pinnatifid; the lower ſubpetioled, the upper ſeſſile; differing from the *orientale* in having an erect frond and blunt pinnules. A native of Japan. 6. B. *radicans*, rooted-leaved B. "Fronds bipinnate; pinnas lanceolate, crenulated; the lines of fructification interrupted." Frond rooting; pinnas ſeſſile, ſlightly concurrent at the baſe, ſerrate with a very fine callus, acuminate, more veined beneath; the line of fructification is next the nerve, but interrupted as it were by long points. A native of Virginia and Madeira, where it was obſerved by Kœnig. Introduced, in 1779, by Mr. F. Maſſon.

Propagation and Culture. The fourth ſpecies alone will abide the open air in England; the firſt muſt be kept in the bark ſtove; the reſt require only the protection of the dry ſtove, or conſervatory; they are increaſed by parting the roots. Martyn.

BLEDSOE Lick, in *Geography*, lies in the ſtate of Teneſſee, in America, 32 miles from Big Salt Lick garriſon, and 36 from Naſhville.

BLEEDA, or Blida, in *Geography*, a town of Africa, in the kingdom of Algiers, and province of Titeri, is ſituate in the interior of the country, over-againſt the mouth of the Ma-Saffran, at five leagues diſtance, under the ſhade of a ridge of mountains, forming a part of mount Atlas. It is about a mile in circuit, encompaſſed by a wall chiefly of mud perforated by hornets, and tolerably populous, but without much trade; ſome of the houſes are flat-roofed, and others tiled; it is well-watered, as a branch of an adjacent rivulet may be conducted through every houſe and garden, and it is ſurrounded by very fruitful gardens and plantations. As Bleeda and Medea (ſee Medea) lie nearly in the ſame meridian, and are ſituated at a proper diſtance from the Hamam Mereega, the Aquæ Calidæ Colonia of the ancients, and as their modern and ancient names reſemble one another, Dr. Shaw ſuppoſes that we may take one for the Bida Colonia, and the other for the Lamida of Ptolemy. That part of mount Atlas which lies between theſe towns, and reaches as far as mount Jurjura, is inhabited by numerous clans of Kabyles; few of which, from their rugged ſituation, have been made tributary to the Algerines. The Beni Sala and Halcel overlook Bleeda, and the rich plains of Mettijah; whilſt the Beni Selim and Haleeſa ſometimes deſcend into the paſture ground, near the banks of the Biſhibelh, or river of fennel, of which a great quantity grows on its banks. Shaw's Travels, p. 36.

BLEEDING, or Blood-letting, in *Medicine*, a ſpecies of evacuation frequently reſorted to, as a principal remedy in inflammatory affections, ſuch as pleuriſy, peripneumony, phrenitis, quinſey, enteritis, acute rheumatiſm, &c.; and in diſorders accompanied with plethora, ſuch as mania, apoplexy, &c. See theſe diſeaſes ſeparately. In all theſe caſes, the earlier this remedy is employed the better, and eſpecially in thoſe inflammatory diſorders, ſuch as phrenitis and peripneumony, where, from the great vaſcularity of the part, the progreſs of the inflammatory action is extremely rapid, and the injury done to organs ſo eſſential to life, often becomes irreparable.

Nor is the *timing* of this remedy the only circumſtance that requires attention. Other circumſtances of equal moment are to be attended to; viz. *the quantity of evacuation, and the ſuddenneſs with which it is effected*. The quantity muſt be regulated by the degree and ſeat of inflammatory action, and the age and conſtitution of the patient. The appearances of the blood, when drawn (ſee Blood), are commonly regarded as a good criterion for regulating the repetition of the lancet, and the quantity to be taken away each time; but the ſtate of the pulſe affords a much better guide; and veneſection will often be found neceſſary in caſes where the buffy coat or ſizy appearance of the blood is not preſent in any conſiderable degree.

The impreſſion produced upon the ſyſtem is very different, according as the blood is drawn from a large or a ſmall orifice; i. e. according as it is evacuated ſuddenly or ſlowly. The former method is to be practiſed in all violent inflammations of parts eſſential to life; ſuch as the brain, the lungs, the ſtomach, &c; for thus the increaſed action of the vaſcular ſyſtem is ſubdued almoſt on the onſet; a momentary deliquium is induced (a ſtate the oppoſite to that in which the morbid condition conſiſted), from which the moſt beneficial conſequences reſult.

Provided equal quantities of blood be drawn in equal times, it matters not whether it be taken from the *right* or the *left* arm; in other words, ſuppoſing, in the caſe of pleuriſy, the ſeat of the pain and inflammation to be in the *right* ſide, thoſe ſymptoms will be as ſpeedily removed by taking away in the whole thirty ounces of blood at three different times from the left arm, as they would be, if the ſame quantity were taken away from the *right* arm, in the ſame number of times, and from orifices equally large; becauſe in both caſes there is the ſame quantity abſtracted from the whole maſs of blood, and conſequently from the quantity circulating through the lungs, and their inveſting membranes; whence the *general* and *local* effects in both caſes are ultimately the ſame. Hence the futility of the doctrine of *Revulſion*, about which ſuch warm diſputes were at one time carried on.

Hitherto we have merely hinted at the *general effects* produced upon the ſyſtem by blood-letting. It will now be expected that we ſhould ſpecify what they are. The firſt and moſt obvious effect is upon the heart and arteries. The blood is to them a ſtimulus; conſequently, by withdrawing a quantity of that fluid from them, we withdraw a proportionate quantity of ſtimulus, and bring down their action ſo much nearer to their natural ſtandard. The abſorbents participate in this change; whence a leſs impeded exhalation takes place. At the ſame time a diminution of the animal heat ſucceeds. But the cerebral ſyſtem and the vaſcular ſyſtem are ſo intimately connected, that the one cannot be materially affected without producing a correſponding effect upon the other. This is proved by the deliquium and convulſions which ſucceed to ſudden and profuſe hæmorrhages. Thus it appears that the beneficial effects of blood-letting, in the diſorders to which it is applicable, are not owing merely to the abſtraction of a quantity of the circulating maſs, and conſequent abatement of activity in the ſanguiferous veſſels; but alſo to the abſtraction of a quantity of the ſuperfluous *Animal Heat*, and to the impreſſions at the ſame time made upon the lymphatic veſſels, and finally upon the ſyſtem of brain and nerves.

From this view of a remedy ſo powerful and ſo extenſive in its operation, it is eaſy to perceive what miſchievous and even dangerous conſequences muſt reſult from its abuſe. Being the moſt ſpeedily debilitating of all remedies, it is obvious that what is termed *general bleeding* ought never to be reſorted to, but in caſes where the pulſe denotes an increaſed degree of ſtrength, as well as exceſſive activity. It has been from attending merely to its increaſed activity, and the accompanying accumulation of heat, without a due eſtimation of the ſtrength of the pulſe, in fevers and other diſorders ſuppoſed to be inflammatory, that ſo much abuſe has been committed in the employment of the lancet. See Fever; under which article, the propriety and impropriety of blood-letting will be fully conſidered, with remarks on the practice of Fernelius, Botallus, Sydenham, Pringle, and other celebrated phyſicians, who puſhed this remedy to an extravagant length.

Although *general* bleeding be only admiſſible under the conditions above mentioned, yet *topical* bleeding may be ſometimes employed with good effect in caſes of partial inflammation, exiſting in ſtates of the body where vigour in the ſyſtem at large is wanting; eſpecially when the veſſels belonging to ſome organ eſſential to life, are obſtructed, overloaded, or inflamed.

Bleeding was formerly employed for the purpoſe of *preventing* plethoric and inflammatory conditions of the body. Hence many of the old writers recommend it to perſons in health both in ſpring and autumn, to pregnant women, &c.; but this practice is very properly diſcontinued, and other modes of counteracting a tendency to over-repletion are adopted in its place; ſuch as a vegetable diet, regular exerciſe, occaſional purging, and the like.

BLEEDING, or BLOOD-LETTING, in *Surgery*, is the artificial extraction of blood from an ARTERY or VEIN, for medicinal purpoſes. The operation of cutting an artery is named ARTERIOTOMY; that of opening a vein is called VENESECTION, or PHLEBOTOMY.

The inſtrument uſed in this country for bleeding the human ſubject, is denominated a LANCET; though a *phleme*, or *fleam*, was formerly employed, and is ſtill very commonly uſed by farriers in England, and even by the beſt ſurgeons in Germany, &c. See the *Plate* of *Surgical Inſtruments*. The lancet, on theſe occaſions, is uſed ſingle; but where the intention is to puncture numerous ſmall blood-veſſels at the ſame inſtant, rather than any one conſiderable vein or branch of an artery, ſurgeons have recourſe to an inſtrument containing many lancets, which is known by the name of SCARIFICATOR.

Leeches are often applied to a part of the body requiring the local evacuation of blood; and in this caſe, as well as in ſcarifying, the operation is termed *local* bleeding, in contradiſtinction to *general* blood-letting by the lancet.

Some nations, eſpecially thoſe which have ſcarcely emerged from a ſtate of barbariſm, are accuſtomed to draw blood by making one or more inciſions or punctures at random, with a knife, a ſtone, a tooth, or a needle. See ACUPUNCTURE, PHLEBOTOMY, ARTERIOTOMY, LEECHES, and CUPPING.

The art of bleeding may be traced back to the remoteſt antiquity, and ſeems to have been common among the Egyptians, Aſſyrians, Scythians, &c. at a time when anatomy had never been cultivated. The Greeks boaſt that Podalirius, the ſon of Eſculapius, was the firſt who practiſed bleeding, ſoon after the ſiege of Troy; but the fact itſelf is related by only one author (Steph. Byzan. in voce *Syrna*), who lived too long afterwards to be credited implicitly. It is therefore much more likely, that bleeding had been performed previouſly to the time alluded to. Pliny, indeed, ſuppoſes that phyſicians firſt learnt this operation from having obſerved the hippopotamus draw blood by puſhing ſharp reeds into its body (Hiſt. Nat. lib. viii. cap. 26.); but this is a very improbable thing, as there is very little analogy between the artificial opening of a vein with a lancet, and the random wounding of an animal by friction againſt a broken reed.

We ſhall, however, not enlarge on the hiſtory of this practice, but proceed to deſcribe the common modes of opening a vein in ſeveral parts of the body; after which we ſhall treat of ARTERIOTOMY.

When we reſolve to perform veneſection, we muſt, beſides the inſtruments required for that operation, have in readineſs one or two well-rolled blood-letting bandages, or tapes, from four to eight feet in length, and of two fingers breadth, with pins, or elſe needles and thread. Thoſe bandages are, by foreigners, reckoned the beſt, which have narrow ſtraps at their ends.

In general, veneſection is practiſed at the bend of the elbow, or upon the foot. When the patient is to be bled at the arm, we place him, with his face towards the light, upon a chair of a moderate height; draw his ſhirt as high as is neceſſary above the elbow; let him extend his arm to a certain degree, but not too much; after which, the ſurgeon, in order that the veins may become turgid by checking the circulation, applies a bandage (which is often made of fine red cloth), of the breadth of three or four fingers, twice round the arm above the elbow, with the ends of which, after having previouſly drawn them moderately tight, he ties a bow with a ſingle knot, at the poſterior part of the arm. Whether this bandage has been properly applied, we know by the circumſtance, that the veins become elevated and tumid, whilſt the pulſation of the artery at the wriſt is diſtinctly perceptible.

We then chooſe a vein in the bend of the elbow, which muſt be done with caution. The upper is the cephalic vein, and this a beginner ought, if poſſible, always to chooſe, as little or no danger is to be apprehended from opening it; but it is very ſeldom to be ſeen or felt, and commonly is too ſmall. The median vein is moſt eaſily ſeen and felt; but generally the tendon of the biceps muſcle is ſituated under or at the ſide of it, which we muſt take great care not to puncture. The inner vein of the arm, or the baſilic (which in the right arm is by ſome termed the hepatic vein, and in the left the ſplenic), is indeed commonly very eaſy to be ſeen, and ſtill more eaſy to be felt; ſometimes, however, it is alſo very ſmall, or lies ſo cloſe upon the artery as to render it hazardous to open it.

Some recommend blood-letting upon the back of the hand, although this is an inconvenient place, and, in certain caſes, not very ſafe for the operation. But if it is to be performed, we tie the red bandage two fingers breadth above the wriſt, round the fore-arm; and, in order to raiſe the vein, let the patient then hold his hand in warm water. The moſt common vein upon the hand is the cephalic of the thumb, which lies between the bones of the carpus, with which the thumb and the fore-finger are joined. But the vena ſalvatella of the middle finger, which lies between the two metacarpal bones with which the middle and the ring fingers are joined, is at preſent but very rarely opened, and only when no other is to be ſeen; eſpecially as it does not diſcharge much blood, is difficult to be tied, and, if cut quite through, forms a thrombus.

In bleeding theſe veins, the patient muſt be placed in a ſomewhat oblique poſition againſt the light; ſo that when the hand is half cloſed, and laid upon the edge of the veſſel, the fingers are directed towards the light, in order that the inſtrument may throw no ſhade upon the place of the vein where we intend to open it.

Bleeding at the foot is generally performed upon the vena ſaphæna, which lies upon the firſt metatarſal bone, connected with the great toe, running along it and the tarſus, over the inner ancle. Where it lies cloſe upon the ankle, it is inconvenient to open, and we muſt be very careful leſt we cut through it and injure the periofteum, or even thruſt the fleam or lancet into the bone itſelf. If poſſible, it will be better to open it one, two, or three fingers' breadths farther from the ancle towards the great toe. We may alſo open a branch far forwards, almoſt cloſe upon the great toe; and here we are required often to open it with pregnant women who have ſwelled legs.

The other pretty ſafe vein upon the foot is the cephalica pedis, that lies between the two tendons which extend the great and the ſecond toes; only we muſt be cautious not to injure the tendon lying beſide it. The other veins ſituated upon the back of the foot ſhould never be opened, but in caſes of extreme neceſſity; for the operation is attended with danger, on account of the contiguous tendons; beſides, they do not diſcharge a ſufficient quantity of blood, and they almoſt always form a thrombus, which a beginner ſhould be careful to avoid.

When we bleed at the foot, the patient ſhould firſt place the limb in a pail of warm water, in order that the veſſels may be ſeen and felt; and it is alſo neceſſary with ſmall veins to apply the red bandage, which, however, in order that the purpoſe of checking the flow of the blood may be attained, and no inconvenience occaſioned, muſt be applied in the middle of the calf, eſpecially with lean perſons, in

the ſame manner as on the arm; but the bow and its knot muſt not lie upon the tibia.

On the arm, therefore, we chooſe either the cephalic or the median vein, and, if the tendon lying below it ſhould occaſion heſitation, the baſilic, eſpecially if this lies more convenient and ſuperficial. When the ſurgeon, then, has brought his eye to the proper diſtance from the vein, he wets the point of his middle finger, preſſes gently with this finger upon the vein at the places where he thinks he can beſt open it, and accurately marks the place with which he was ſatisfied in trying by the feel; after which he ſuffers the arm to fall down again into the patient's lap.. In the ſame manner he chooſes a vein upon the hand.

For blood-letting at the right foot, the patient is placed upon a chair of a moderate height, in the moſt enlightened part of the room, with his face directed towards the window, and his feet immerſed in a veſſel filled with warm water, ſo that the water covers all the veins of the whole foot. When therefore the foot is warm, and the veins ſufficiently tumid, the ſurgeon lays hold of the foot with his left hand, and places it with the middle of the ſole upon the edge of the veſſel which is the moſt remote from the body, in ſuch a manner, however, that the foot is not extended, but forms a right angle with the leg. With the middle finger of the right hand he examines thoſe veins which lie the moſt elevated, and makes, according to the rules before laid down, a ſcientific ſelection; but he muſt always firſt direct his attention to the vena ſaphæna.

The moſt convenient attitude for the ſurgeon is when he kneels down with one knee; as in this poſition the eye is near to the vein, the poſition is firm, and can be better ſupported for the requiſite length of time. If any other vein beſides the ſaphæna be choſen, the patient is directed to move his toes, whilſt we are examining the vein, in order that we may feel how near a tendon may be ſituated below it; and here the caution ſhould be obſerved, not to make all the fingers wet, for the warm water diminiſhes the ſenſe of touch, and conſequently renders it indiſtinct. We therefore uſe at firſt only one hand, becauſe, in caſe of a failure, or from ſome other cauſe, we may be under the neceſſity of taking alſo the other foot.

The vein may be opened either longitudinally, that is to ſay, in the direction of its courſe, or we open it rather obliquely or tranſverſely. The firſt is the ſafeſt, eaſieſt, and moſt convenient method; but it is admiſſible only with large veins, and when we foreſee that during the operation they will not ſlip or twiſt, as it were, out of the way of the inſtrument. Commonly the veins are opened ſomewhat obliquely, and in this manner we may generally open the veins on the arm, and in moſt caſes upon the foot. But when the veins are too ſmall, there is reaſon to apprehend that we may not hit them, or that they will not diſcharge a ſufficient quantity of blood; and when their ſituation requires it, as is the caſe with the cephalic of the foot (where it lies over the tendon that elevates the great toe), the orifice muſt be made quite tranſverſely.

When therefore we have properly examined the vein with the moiſt finger, we hold the phleme in readineſs (if we uſe this inſtrument); that is to ſay, we draw up the ſpring, take it in the right hand, ſo that the thumb lies upon the ſlider, the fore-finger upon the bridge, and the middle finger upon the preſſer, exactly over its ſpring, and the ring finger upon the round part of the bottom plate. With the fore finger and thumb of the left hand, which are moiſtened with a little ſaliva, we move the iron as high up in the groove as we think it neceſſary to make the orifice deep; and place the box (after having again elevated the arm, or taken the foot or hand out of the water, and ſupported them, in the manner above deſcribed, upon the margin of the veſſel) in ſuch a manner upon the ſkin, that the iron has exactly the proper direction toward the place where the oriſice is to be made, and then, by a gentle preſſure with the middle finger, let the ſpring fly looſe.

If a perſon ſhould be ſo fat as to render bleeding impracticable, and with ſuch it is at leaſt very difficult to do it on the foot, we may in ſome meaſure attain our purpoſe, if we direct the patient, as he gets out of bed, to hold his foot or hand in warm water; after which the veins will generally become ſufficiently perceptible to the eye or touch of an experienced ſurgeon.

But though the phleme is uſed for blood-letting, eſpecially in Germany, it is however an univerſally acknowledged truth, that the *lancet* is the ſafeſt and beſt inſtrument for the purpoſe. We run leſs hazard with it of doing damage, and the ſurgeon is always able, according as the circumſtances require, to make the orifice either ſmall or large. When therefore we let blood with the lancet, we place it ſo that the handle forms a ſomewhat acute angle with the blade. The ſurgeon next lays hold of the limb upon which he is to perform the operation, ſuppoſe the right arm, with his left hand; and at the ſame time preſſes with the left thumb upon the vein, about two fingers' breadth below the place which is choſen for the orifice: he then takes the lancet between the thumb and fore finger of the right hand, ſo that ſomething more of the blade is uncovered than he thinks neceſſary to introduce. At the ſame time he lets his hand reſt upon the middle, ring, and little finger, which muſt be placed as conveniently as poſſible below the vein that is to be opened. He then puſhes the point of his lancet carefully through the ſkin and integuments into the vein, and carries the inſtrument in an oblique direction a little forwards, till the orifice is ſufficiently large. But, during the introduction of the lancet, the operator muſt hold the point as ſteady and even as poſſible, in order that it may not penetrate into the ſubjacent parts. Should he, however, not be able to depend ſufficiently upon the ſteadineſs of his hand, he will do well to leave no more of the point of the lancet uncovered than is to penetrate into the vein. The ſurgeon having withdrawn his right hand, at the ſame time removes the thumb of his left hand from the vein, in order that the blood may flow out freely.

If the blood will not flow properly, notwithſtanding the vein has been properly hit, either the orifice is too ſmall, or fat perhaps gets into the orifice of the integuments and ſtops it. The fat is to be preſſed back, by ſtroking with a wet and warm ſponge, or by means of an inſtrument. The impediment, indeed, may lie in the motion of the part; when, for example, the arm is bent obliquely, or the foot is placed in the water, the orifice of the vein may eaſily be diſplaced, and ſome of it be cloſed by the ſound part of the ſkin. But, finally, the circumſtance may alſo be occaſioned by the viſcid conſiſtence of the blood. To this latter cauſe it is often to be attributed, after the firſt few minutes; on which account it will be proper to wipe the arm, over the orifice of the vein, with a ſponge filled with warm water, and let the hand reſt in a ſomewhat higher ſituation than the orifice, upon a ſtick, which the patient may alſo turn round, or preſs firmly with his fingers.

When a ſufficient quantity of blood has flowed from the vein (for example, in the arm), and we are to tie it up, we take the ſponge, moiſtened with warm water, in the right hand, the bandage in the left, and the linen compreſs between the thumb and middle finger of the ſame hand; we hold againſt the vein with the ſponge, and with the left hand

remove

remove the red bandage and hang it over the chair, or the ſhoulder of the patient. The aſſiſtant takes away the veſſel into which the blood has been received, and the operator now with a moderate preſſure draws the ſponge from the vein towards the hand in a right line with the orifice that has been made; and it will be proper, whilſt he brings the lips of the wound together with the thumb of his left hand from the ſide, to repeat the wiping with the ſponge once more, in order completely to remove the blood that may have been left in the orifice.

When the ſurgeon now ſees the vein well cloſed, he lays upon it the compreſs, with the fingers of his right hand, whilſt he draws it towards the thumb of the left hand upon the ſkin; and when the middle of it is upon the orifice, he preſſes it down with the fore and middle fingers of the right hand, and immediately changes theſe for the thumb of the left hand. With the right hand he waſhes the blood from the limb, by means of the ſponge; after which, he lays the ſponge aſide. He then takes the bandage out of his left hand, lays hold of it with the fore and middle fingers of the right hand at the inner part of its head, and the thumb upon the outer, and places it upon the compreſs in ſuch a manner that the fingers of the left hand make way for it, whilſt the two fingers of the right hand continue the preſſure in their place. But, immediately after, theſe are again changed for the left, fore, and middle fingers, which now preſs at the ſame time upon the one turn of the bandage and the compreſs. The right hand carries the bandage croſs-ways round the arm, whilſt the fore fingers of the two hands always alternate, till the laſt, when both ends of the bandage are either ſewed, tied, or pinned together.

Notwithſtanding we have given theſe very preciſe directions, a young ſurgeon will learn better by ſeeing the operation performed by a ſkilful hand, than by any verbal inſtructions.

Tying the vein upon the thumb is performed in the following manner: — Preſſing with the compreſs, which here muſt be pretty narrow and thick, is like that performed on other veins; and therefore, whilſt we hold it faſt upon the wound of the vein with the two fore fingers of the left hand, we let the bandage, (which is rolled upon one head, an inch in breadth, four feet in length from the end to the place where it touches the compreſs), hang about half a foot down over the back of the hand, obliquely from the wriſt outwards; carry the head of the bandage, after preſſing it over the compreſs with two fingers of the left hand, through between the thumb and the fore-finger, over the palm of the hand; and, proceeding over the back of the hand, cover the end of the bandage; then go round the wriſt, again over the back of the hand, under the thumb, and now round the ball of the thumb; again over the turn that has juſt been made acroſs the back of the hand; and after having once more carried it half round the wriſt, pin both ends together on the back of the hand. We may alſo apply this bandage with varied turns. In a ſimilar manner, with turns round the little finger, and circular turns round the wriſt, the bandage is applied, when the vena ſalvatella is opened.

With the veins of the foot, the common bandaging is made by the Staples, which, however, ſometimes requires a peculiar method, that every one will eaſily be able to adapt according to circumſtances. The bandage may be applied ſomewhat tighter than upon the arm: however, on account of the injurious conſequences, which may even be attended with danger, the bandage muſt not be drawn too tight; but it will be better ſome hours after to examine it again, and if neceſſary, draw it ſomewhat tighter. Upon the whole, it is to be recommended, if poſſible, in all bloodletting operations, eſpecially in arteriotomy, that the ſurgeon ſhould ſee the patient again ſome hours after; as he may obviate ſeveral ſmall inconveniences, which afterwards frequently occaſion unpleaſant complaints.

Veneſection is more rarely performed upon the frontal vein, the veins under the tongue, and upon the neck. For the frontal vein, when it requires to be opened, we apply a bandage, or a garter or cloth, round the neck, lay the middle of the bandage upon the back of the neck, carry both extremities over the throat, and round again to the back of the neck, where an aſſiſtant takes one end in each hand. This the patient may alſo perform himſelf; only then the middle of the bandage muſt be applied to the throat, the two ends carried round the neck till they meet at the throat again; there the patient holds them with both his hands, and, according to circumſtances, draws the bandage tighter, or relaxes it, ſo as ſtill to retain ſufficient ſpace for reſpiration. A ſtill more convenient mode of diſtending the veins of the neck, &c. is to paſs the bandage over the ſides of the neck, and under the oppoſite arm-pits, ſo as not to preſs upon the trachea, which may impede reſpiration; then hold the ſwelled vein down with the thumb or finger of your left hand, a little below the part allotted for the operation. The inciſion is to be made, when the vein is ſufficiently tumid, with a lancet.

In order that the blood may not run down upon the face, we preſs a card bent crooked under the orifice upon the ſkin, and thereby conduct the blood into a veſſel. After a ſufficient quantity of blood has been diſcharged, we remove the bandage from the neck, when the bleeding generally ceaſes immediately, and the orifice is ſecured with ſticking plaiſter, or, if it ſhould be neceſſary, with a compreſs and Discrimen bandage.

When we have to open a ſublingual vein, we muſt promote the efflux of the blood, as in bleeding at the forehead, by the application of a cloth under the arms and acroſs the ſides of the neck. The orifice is made with the lancet, and the inciſion is continued till it ſeems large enough. In order more conveniently to get at it, we hold back the tongue with a wooden fork, or ſpatula. We may draw a ſilk thread through the wound, in order to clear it from the blood, which here eaſily coagulates, and at the ſame time to prevent the lips of the wound from adhering together, and conſequently to obviate whatever might impede the flow of the blood. When its flow muſt be ſtopped, we take off the bandage, and let the patient hold ſome ſpirit of wine, or common brandy, in his mouth. If the blood flows more copiouſly, we may diſpenſe with the thread, and immediately remove the bandage from the neck; alſo, when it is to be ſtopped, apply a little alum or agaric to the wound, and preſs it down for a time; or apply Lampe's compreſſory, deſcribed in I. Val. Heinr. Kochler Anleitung zum Verbande, &c. Leipzig, 1796, 8vo. *Tab.* VI. *fig.* 5.

To bleed at the external jugular vein, the bandage is likewiſe applied round the neck; againſt the clavicle, and upon the vein that is to be opened, a thick compreſs is placed, and the bandage drawn ſomewhat together. The thumb is placed upon the compreſs which lies upon the vein, and the fore-finger over it, in order to ſecure it and to ſtretch the ſkin; we then take a pretty large lancet, and with it open the vein in the ordinary manner; only with this difference, that we muſt introduce it deeper, and make the external orifice larger. To catch the blood, we make uſe of a card, as in bleeding at the forehead. When a ſufficient quantity of blood has been drawn, we remove the bandage; after which, the lips of the wound generally cloſe ſponta-

neouſly. But ſhould a bandage be neceſſary, we may ſecure a compreſs upon it by means of two circular turns round the neck. As this bandage, on account of the preſſure upon the trachea and veſſels, &c. of the neck, is always very troubleſome; and alſo the preſſure, as it never muſt be ſtrong, is frequently inſufficient; we may moſt conveniently uſe the inſtrument invented by Mr. Chabert for compreſſing the veins of the neck. In want of it, we muſt let an aſſiſtant cloſe the orifice by preſſure with his finger, till the danger of hæmorrhage is over.

Some moiſten the compreſſes with brandy, vinegar, &c. and thereby, on account of the irritation, occaſion ſome inconvenience at the orifice of the vein, in which ſometimes inflammation, and even a ſuppuration is excited. It is better to apply the compreſs dry, or to ſtick upon it a piece of gold-beater's ſkin, whereby the lips of the wound, if they have been well brought together, are retained in that ſtate, ſo that the burſting open of the vein is more effectually prevented.

Eaſy and inſignificant as ſome young ſurgeons think the operation of phlebotomy, it nevertheleſs often requires the greateſt accuracy, and is on that account one of the moſt delicate operations. To a true ſurgeon, therefore, it is always of importance, and the more ſo as his honour and reputation are endangered by committing an error in it. Frequently the faults which the patient commits during and after the operation, ſuch as incautious motion of the limb whilſt the operation is performing, violent exertion of it, drawing on boots, &c. after blood-letting at the feet, are aſcribed to the negligence or ignorance of the ſurgeon. Inaſmuch alſo as no operation occurs ſo frequently as this, and as it ſo very often endangers the life of a man, or at leaſt an error committed may give riſe to ſuch danger; the ſurgeon muſt well conſider the ſymptoms which occur in it, and may ſuperinduce more important conſequences dangerous to health, in order that he may timely obviate or remove them.

Sometimes there ariſes, as the moſt common bad conſequence of blood-letting, an inflammation of the external integuments, and of the ſubjacent cellular ſubſtance. Sometimes it is chronic, but little painful, ſuppurates ſlowly, and produces a circumſcribed abſceſs. Sometimes it is more diffuſed, and has the appearance of an erylipelatous inflammation: ſometimes it is violent and acute, and reſembles a phlegmon. This generally occurs when the inſtrument is a bad one, and rather tears than cuts; when the patient is of a very irritable habit, and much diſpoſed to inflammation; when the requiſite precautions for healing the wound by the firſt intention are neglected, and the arm is ſuffered to be moved; when the wound is externally rubbed, preſſed, &c. The nature of this inflammation cannot be miſtaken, and it muſt be treated like a common wound.

It may ſometimes happen, that when the wound of the vein does not ſoon cloſe, an inflammation of the vein takes place, which however varies with reſpect to its violence, its extenſion, and progreſs. In a milder degree, this inflammation is followed merely by a ſlight ſwelling of the vein, and an adheſion of its ſides. A violent inflammation induces ſuppuration. The common method of treatment is the antiphlogiſtic. As the internal membrane of the veins is continued to the heart, and as inflammations in ſuch membranes ſpread eaſily and rapidly, where they are not prevented by an adheſion of the ſides of the vein, it is in moſt caſes adviſable to produce ſuch an adheſion by the application of external preſſure at ſome diſtance above the orifice. If, as may very eaſily happen, ſuch an inflamed vein ſhould paſs into ſuppuration, it would (if known) then be neceſſary to cut open the vein, in order to prevent the pus from mixing with the circulating fluids.

When a vein has been cut entirely through, the pain is not greater than common, nor does the patient experience any inconvenience whilſt the blood is flowing; but a greater or leſs quantity of it deſcends under the vein into the adipoſe membrane, remains there incloſed, and during the firſt twenty-four hours occaſions a tenſion. The external orifice of the ſkin may be diſplaced from the orifice of the vein, likewiſe, when the orifice of the integuments is ſmaller than that of the vein; when the patient moves the arm too much, in conſequence of which ſome blood is indeed diſcharged from the wound, but more penetrates between the vein and the ſkin into the cellular texture; and when the operation has been abſurdly performed where two veins anaſtomoſe; from all theſe cauſes an effuſion of blood may take place, in conſequence of which the part acquires a blueiſh black colour, and ſometimes an ecchymoma, ſometimes a ſugillation, and at other times a thrombus is produced. Although the appearance frequently ſeems to indicate greater danger than really exiſts, the ſpeedy application of remedies is nevertheleſs neceſſary.

In the firſt caſe, cataplaſms, with warm vinegar, wine, and other ſpirituous or diſcutient remedies, are ſerviceable. When ſuch extravaſated blood is not again taken up, or when the veſſels are inadequate to its re-abſorption, on account of its great quantity, an abſceſs is generally formed, which muſt be treated according to the rules of art, and the ſpirituous remedies laid aſide. See Abscess. In the ſugillation, we muſt endeavour to remove the obſtacles that may impede the circulation of the blood: theſe are either external ones, ſuch as a too tight bandage, by looſening which the complaint is removed; or they are internal ones, and occaſioned by a contraction of the veſſels. In a recent ſugillation, we may combine the reſolvent means above-mentioned with mild aſtringents; and when the ſtagnating blood has been again diſſolved and removed, we at laſt apply cold, diſcutient, and ſpirituous remedies.

When an aponeurotic part (for example, the faſcia of the fore-arm) is wounded, the patient ſometimes experiences a more violent pain than uſual, eſpecially when he moves the limb; and this he feels preſently after the blood-letting has been performed. A compreſs, moiſtened with cold Goulard's water &c. is of ſervice, whilſt at the ſame time the bandage is left applied for three or four days, and the limb kept completely at reſt, and wetted many times a day with ſuch remedies. When this is neglected, there very often takes place a ſerious inflammation, which muſt be treated according to the antiphlogiſtic plan. Repoſe of the limb, which is to be kept in a bent poſition, and relaxation of the inflamed parts by means of warm emollient applications, are abſolutely neceſſary. As ſoon as the inflammation abates, it is proper every day to attempt moving the joints, in order to prevent a ſtiffneſs. But if the tenſion and inflammatory ſymptoms run very high, it may even be requiſite to divide the faſcia completely.

When a nerve is injured, the patient experiences a ſtill more violent pain, which extends itſelf throughout the whole limb, and the patient is alſo apt to faint, the muſcles of the affected part contract, and the blood ſometimes does not flow ſo freely as uſual, although the vein has been well opened. The orifice of the vein does not become violently inflamed, and the pain continues. In order to prevent inflammation and other ſymptoms, a larger quantity of blood muſt be let run out, the limb muſt at leaſt for ſome days be left completely at reſt, and we muſt take care that the muſcles of the part remain as much relaxed as poſſible. More-

over,

over, we muſt treat the patient antiphlogiſtically, preſcribe a ſpare diet, and alſo, if the caſe ſhould require it, adminiſter opiates and laxatives. For leſions of the nerves, the application of warm ſpirit of turpentine is commended; but it would probably be uſeful only in caſe the nerve ſhould lie above, but hardly when under, the vein. Over the orifice we apply ſome lint and a mild plaiſter, and over this and the whole limb, emollient and diſcutient cataplaſms, with which anodyne remedies are mixed.

If, notwithſtanding this treatment, the ſymptoms ſhould become more violent, the lips of the wound acquire a hardneſs, and become more inflamed, affected with pain and tumor, with a full and quick pulſe, blood muſt be drawn by leeches, or at another place by veneſection. Inſtead of the warm emollient fomentations and cataplaſms, which are recommended in ſuch caſes, Mr. B. Bell extolls, from his own experience, cooling aſtringent remedies. Preparations of lead he has found moſt ſerviceable. The parts which ſuffer the moſt may be covered alternately with cloths wetted with a ſolution of ſaccharum Saturni, and with pledgits ſpread with ceratum Saturni. The fever muſt alſo be particularly attended to, and the above mentioned cooling treatment continued. When the pains are ſo violent, that they entirely deprive the patient of ſleep and reſt, we muſt uſe antimony and opium; but in order that the opium may prove ſerviceable, it is adminiſtered always in conſiderable doſes. The limb muſt be alſo kept continually at reſt, and in a horizontal poſture.

But frequently the firſt affection is neglected, or improper remedies are employed, ſo that opium, and all the remedies that have been mentioned, have not the ſmalleſt effect. This is particularly to be ſuppoſed, when the nerve is cut in ſuch a manner, that only a part of its fibres ſtill remains entire, and theſe are preternaturally ſtretched; in which caſe the whole body ſuffers, and the moſt violent convulſive affections take place, which indicate the moſt imminent danger. The only remedy under theſe circumſtances is the diviſion of the nerve by a tranſverſe inciſion above the inflamed part, that is to ſay, higher than the orifice of the vein. As the nerve certainly lies within the breadth of the orifice of the vein, the inciſion needs not be long, and it muſt penetrate only down to the faſcia of the fore-arm, for all its cutaneous branches always lie on the outſide of this faſcia.

Mr. Benjamin Bell has given very extraordinary directions on this ſubject, which have (moſt unaccountably) been tranſcribed by many ſurgeons in France and Germany: he directs, among other things, an extenſive tranſverſe inciſion to be made through the original wound, and even down to the bone! which Mr. Abernethy has very properly reprobated as "dangerous and unneceſſary."

When the branch of an artery has been wounded, the patient does not feel more pain than uſual; but the ſurgeon immediately concludes from the colour and ſpouting of the blood what fault he has committed. See Aneurism.

In veneſection, a bone may alſo be injured, chiefly with lean perſons, who generally have very thin veins, eſpecially on the feet; which, though they are very viſible, lie, however, ſo cloſe upon the bones and tendons, that the inſtrument paſſes through and injures the ſubjacent bone. In moſt caſes, this only occaſions a pain which the patient feels during the operation, and no bad conſequences enſue. Frequently the ſurgeon himſelf would not know it, did he not find, on examining the inſtrument, that the point is entirely wanting, or at leaſt bent round, and its edge ſpoiled. This, however, applies only to the caſe where none of the iron is left in it; but when this happens the caſe is worſe. We may know that it has taken place from the cutting blade being wanting, or in part broken off; from the pain which the patient feels, and which is generally of a pulſating kind: from the divided ſtream of the blood; from the feel with the fingers, when they are ſtroked over the orifice of the vein, and from the rebounding which the ſurgeon feels in the fingers at the ſtroke. If it is not ſeated very firmly, the ſtream of blood generally drives it out, if we draw the orifice gently aſunder with two fingers. But when it is more firmly ſeated, we muſt endeavour to draw it out with a fine pair of forceps as cautiouſly as poſſible, that it may not break in extracting, and the point remain ſticking in the bone. When it has been ſucceſsfully extracted, we muſt endeavour to prevent the ſymptoms, ſuch as inflammation, tumor, &c. by moiſtening the compreſs and the bandages with a diſcutient lotion, and afterwards alſo keep the bandages moiſtened with ſuch remedies throughout the day. This accident is only liable to occur in uſing the fleam.

But the breaking off the blade may alſo happen with muſcular ſubjects, and this the ſurgeon can certainly in general prevent, by always inſpecting his inſtruments carefully, and providing them with good blades. The beſt blades are thoſe which are very ſharp and finely poliſhed, and theſe are generally very thin, and conſequently moſt liable to fly off. Before we uſe any blade, eſpecially a thin one, we ought always to put it to the following teſt. We ſcrew the new blade into the phleme, and let it fly two or three times without any object oppoſed to it. If the blade remains as it ſhould, we are then ſo much the more ſecure againſt its flying off in bloodletting, becauſe it has a reſiſtance oppoſed to it. This precaution ſhould never be neglected, and the loſs of a few blades ſhould not be regarded, in order to ſecure ourſelves againſt the danger to which we are expoſed, if we neglect it. Theſe obſervations and precautions will ſcarcely be wanted for *Engliſh* ſurgeons, who have laid aſide that inſtrument.

Sometimes a lymphatic veſſel is wounded; in which caſe the patient experiences no extraordinary pain, nor does the ſurgeon foreſee the injury that is ſtill to ariſe, and conſequently cannot be immediately diſcovered. After the bandaging, the vein heals up, no inflammation is left behind, but there daily flows out of the orifice of the ſkin a quantity of clear pellucid lymph, which continually keeps the dreſſings wet. This circumſtance often gives the ſurgeon much trouble. Here we may apply with advantage Goulard's ſaturnine water, or a ſolution of alum, or mere cold water. The cure is beſt completed by means of dry lint, applied daily once or twice in the form of a tent. We may alſo ſprinkle pulverized alum, or apply a ſtrong preſſure upon the veſſel; and ſometimes we may uſe the lapis infernalis with advantage. Mr. Jaeger, however, thinks (Funfzig. chirurg. prakt. Cantelen. &c. Frankf. a M. 1788, p.3.) that the cure may moſt ſpeedily be effected by immediately promoting ſuppuration.

It may happen, that in letting blood at the arm a lymphatic veſſel becomes inflamed; in which caſe we feel upon examination, a hard abſorbent veſſel both above and below the wound of the vein, which laſt, however, is not yet healed, but generally uninflamed: if the affected limb is uſed, the pains become more violent, and ſometimes extend themſelves into the axilla, where alſo the glands ſwell; generally the fore-arm likewiſe ſwells and becomes painful, and at laſt abſceſſes take place in different parts. Beſides keeping the affected arm at reſt, we muſt cover the wound with an emollient ointment, and apply to the hard veſſels and tumors, cataplaſms of emollient, diſcutient, and anodyne remedies, upon which they are generally diſcuſſed. When abſceſſes have already been formed, they muſt be opened and healed, according to the rules of the art. See Abscess.

The

The moſt common ſymptom conſequent upon blood-letting is fainting, which, however, is in moſt caſes unattended with danger, eſpecially when it does not ariſe from a too copious evacuation of blood. It may often be prevented, by keeping the patient engaged in converſation, by letting him take a ſpoonful of vinegar, or a glaſs of cold water into his mouth or ſprinkling him and waſhing his hands and face with it. But if it nevertheleſs ſupervenes, we muſt immediately place the patient in a horizontal poſition, throw open the chamber window, and apply ſtrong ſtimulating ſubſtances, ſuch as volatile alkali, to his noſtrils; and when he has come to himſelf, we may give him a glaſs of wine, provided it be not contra-indicated by his ill ſtate of health.

With perſons who always faint whenever they are bled, and who on this acccount, however neceſſary the operation may be for them, always dread it, the beſt method of preventing their fainting, is to lay them immediately in a horizontal poſition, with the head low, and at the ſame time frequently to ſtop the diſcharge of blood by holding the vein. This caution is particularly to be recommended with pregnant women, as faintings and convulſions in them, if they continue too long, may prove very injurious to the fœtus, or produce abortion.

We have hitherto confined our remarks to the opening of a Vein: it therefore now remains for us to deſcribe the operation of Arteriotomy, which is the artificial opening of an Artery.

This operation was very frequently practiſed by the ancients; who, perhaps, from having incorrect ideas of the nature of theſe blood-veſſels, were not always aware of the dangerous conſequences which follow from this practice, if injudiciouſly managed. Thoſe who are deſirous of reading a full account of the ancient practice in this branch of ſurgery, may peruſe what Oribaſius has collected from Galen and Antyllus; to which they may add the obſervations of Paulus Ægineta, and Proſper Alpinus, the latter of whom deſcribes the operation as it was performed in Egypt.

The ſuppoſed advantages of opening an artery, rather than a vein, are 1ſt, that the blood flows with greater velocity than from a vein; and therefore affords a larger quantity in a given time: 2dly, that it prevents the accumulation of blood in any local inflamation more effectually, becauſe it intercepts the fluid in its paſſage towards the affected part: 3dly, that its ſalutary effects more ſpeedily follow, on this account, than from the operation of phlebotomy; and, therefore, it is preferable in caſes of a very urgent nature, ſuch as apoplexy and phrenitis, ariſing from the preſſure of blood upon the brain.

But theſe advantages are ſpeculative, rather than practical, for the following reaſons: 1ſt, No ſurgeon who is acquainted with the ſerious conſequences of opening a large branch of an artery, and the difficulty of reſtraining the effuſion of blood in many inſtances, will perform this operation in the ſame parts of the body, and in the ſame dauntleſs manner, as the ancients did. And in opening only very ſmall branches, (ſuppoſe of the temporal artery,) it rarely happens that the blood flows rapidly, and never with the ſame freedom as it does from a large vein: 2dly, That we may ſometimes, by this means, intercept the blood as it paſſes towards an inflamed part is certain, by cutting through the principal artery which conveys the blood; but this advantage is not often obtained, becauſe we dare not divide any conſiderable ramification, and there are always more arterial branches than one to ſupply an important organ: 3dly, We admit, that in certain caſes, (in ophthalmia, or inflammation of the eyes, for example,) the good effects of blood-letting by arteriotomy near the affected part, is far more uſeful than by phlebotomy, in a remote part; but, unfortunately, the ſurgeon cannot always evacuate a ſufficient quantity of blood by this means, on account of the difficulty of finding a ſuitable branch of an artery, which may be eaſily as well as ſafely inciſed.

Therefore, conſidering all the diſadvantages of this operation, it is now very rarely practiſed, except in the temples, where the pulſation of a ſmall branch of the artery may be often felt with eaſe; and there is little or no danger in attempting to divide it. If we do not ſucceed in our attempts, or do not procure ſo much blood as is requiſite, the operation of phlebotomy may then be had recourſe to. It ſhould, however, be mentioned as an undoubted fact, that acute inflammations of the eyes, are more effectually relieved by arteriotomy, (when it properly ſucceeds,) than by opening a vein in the arm; and that the excretion of four ounces of blood in this way, is as uſeful as twenty or even thirty ounces taken from the venous ſyſtem!

As arteriotomy is now ſcarcely ever performed in any other part of the body beſides the temple, we ſhall content ourſelves with deſcribing this operation alone. In that ſituation, the artery lies near enough upon the cranium to be compreſſed readily, when we wiſh to ſtop the current of blood; though, in general, the blood does not flow ſo freely, as to cauſe any difficulty in reſtraining it by moderate preſſure.

The patient being placed in a good light, the operator feels for a pulſating veſſel in the temple, nearly oppoſite the outer angle of the eye. When he has diſcovered it, he endeavours to trace the direction in which it runs; and then he places the two foremoſt fingers of his left hand upon the artery, leaving a ſpace of about half an inch between them for the place of the inciſion. The veſſel is ſo ſmall, in general, that it cannot be opened by an oblique, or a longitudinal puncture, as in bleeding the veins of the arm; but muſt uſually be cut acroſs, by a ſingle ſtroke of the lancet, or ſcalpel. A lancet is not ſo convenient as a ſmall knife for this purpoſe, becauſe its fine point is apt to be broken; and it will be found beſt to draw the inſtrument over the artery, inſtead of endeavouring to ſtrike it with the point, (which Dr. Butter, Mr. B. Bell, and others, direct to be done,) as in phlebotomy. It may be convenient to make a little impreſſion with the finger-nail, or with ink, on the exact ſpot we determine upon for the inciſion, leſt we loſe our object in operating; for a ſurgeon cannot always enſure the diviſion or wounding of the artery on his firſt attempt, eſpecially if the inciſion be made with timidity, or heſitation.

When a ſufficient quantity of blood has flowed, (which it does by a florid and ſalient ſtream,) we cloſe the wound; and apply a long bandage over a very firm, thick compreſs of linen, in which may be included a piece of coin, or ſome other hard ſubſtance. It is a matter of ſmall importance whether or no we firſt uſe an adheſive plaſter, except when the bleeding is likely to prove troubleſome: but the different modes of arreſting arterial hæmorrhages, are deſcribed under the articles Hæmorrhage, Ligature, Styptic, and Aneurism.

Frequently it is neceſſary that the ſurgeon ſhould make himſelf acquainted with the ſtate of the blood, and often alſo it is required of him to paſs his opinion upon it. As long as the blood is warm and flows out of the vein, it exhibits a pretty uniform red colour, and has a viſcid gluey feel; but when it grows cool, it coagulates into a maſs varying in colour and denſity. After ſome hours, there gradually exudes from this coagulated maſs a fluid, which ſeparates the more ſolid parts from the ſides of the veſſel, ſo that it ſwims in it. This water is called *ſerum*, but the coagulated red cake is named *cruor* or *craſſamentum*.

Good

Good venous blood, expoſed to the air, is of a dark red colour: when it cools, it ſeparates a thin and almoſt colourleſs ſerum, and a thick cake, which has no cruſt of a different colour from the blood below it; and of which the ſerum forms a proportion, amounting to between the third part and the half. Such blood has no preternatural acrimony, or ſaline quality; and in it are found all its conſtituent parts in the proper proportions. From this condition of the healthy blood, we may form a judgment of its preternatural ſtate, if it be materially changed.

When the blood remains ſo fluid that it will not coagulate, it indicates a deficiency of the gelatinous part, and a great redundance of ſerum. Such blood is to be found in many fevers, eſpecially in malignant ones, or when the patient is in a very debilitated condition.

If there be too much ſerum in the blood, dropſy and other ſimilar diſeaſes are to be apprehended; for ſuch diſſolved blood always indicates a weakneſs of the veſſels, and of the muſcular fibre.

When the ſerum is yellow, it indicates an obſtructed flow of the bile, and its regurgitation into the maſs of the circulating fluids.

When the blood has much ſerum and little of the red part, the blood is overloaded with mucus, and it indicates that a cachectic diſeaſe is impending; eſpecially when the ſerum has various different colours, and the texture of the cruor is very ſlender.

If the blood has its proper and ſufficient redneſs and fluidity, but at the ſame time exhibits a greaſy pellicle, it indicates a ſuperfluity of oleaginous particles.

When it ſeparates and yields a very compact, tenacious, yellow, or buffy ſurface, it is too thick; and if the ſerum be at the ſame time ſmall in quality, it ſhews a great degree of vaſcular action and inflammation. This is a fact very generally admitted.

Finally, it is to be obſerved, that we need not be alarmed when the thicker part of the blood ſeems to ſwim in a milky fluid; for it commonly happens, in drawing blood only a few hours after a meal, when it proceeds from the chyle, which, about this time, is imperfectly mixed with the blood.

We have thrown out theſe few hints for the attention of practical ſurgeons; but they are by no means to be regarded as complete or abſolutely incontrovertible. There is a great deal of fallacy in judging from the colour, and other ſenſible qualities of the blood; and the moderns have, therefore, learnt to give their opinion with diffidence. This ſubject is conſidered more at large in a ſubſequent article. See Blood, and its properties.

Bleeding *a Horſe*, a frequent operation in the *Veterinary Art*, principally intended to diminiſh the maſs of blood, and thereby deſtroy the too great fulneſs or over-action of the heart and arteries.

When this operation is intended to affect the general ſyſtem, the evacuation is uſually made from the jugular vein. For the relief of particular parts, the veſſels which belong to it, or which are adjacent to it, may be opened; as the vein running down the inſide of the fore-arm is commonly opened when it is conceived the ſhoulder is affected: the neceſſity of this operation, on account of injuries of this part, is leſs frequent than is generally imagined: the vein itſelf in general gives out but little blood, and is very apt to ſwell after the operation.

Affections of the feet are more frequent, and we have often opened the coronary veins with obvious good effects; by puncturing with a lancet various parts of the coronary ring, the blood flows copiouſly, and at length ſtops of itſelf without the leaſt ill conſequences.

The vein which encircles the coffin bone is alſo, without much difficulty, opened in inflammations of this part; the blood flows freely, the artery which accompanies it being in general opened along with it. It is neceſſary, in performing this operation, to remove the horn covering the veſſels with a drawing knife till the blood flows in ſufficient abundance. The horn round the point of ſection ſhould be thinned conſiderably, to prevent irritation, and mild reſinous dreſſings ſhould afterwards be laid over the part, to exclude the air, &c.

This operation we have heard condemned by ſome, as producing ill conſequences, and a ſore difficult to heal. We have only to remark, after having frequently performed it, we have not met with an inſtance of theſe ill effects following it.

The angular veins of the eye are often opened with good effects in inflammations of this part, as alſo the veſſels which are ſeen paſſing over the ſclerotic coats of the eye, and over the duplicature of the *membrana conjunctiva* on the inſide of the eye-lids, both of which admit of eaſy ſection with the lancet.

The *temporal* artery alſo preſents itſelf very conveniently for opening in the horſe; and in inflammations of the brain, or its coverings, or where a ſudden depletion of the ſyſtem is deſired, it is productive of manifeſt good effect. If this veſſel ſhould bleed too freely, and apprehenſions are entertained of the loſs of too much blood, it is moſt eaſily ſtopped by preſſure, or by a deep inciſion, which completely ſevers the veſſel: in this caſe its ends ſoon retracting, ſtop the farther effuſion of blood.

The veins of the palate are conveniently ſituated for opening, by making a tranſverſe inciſion in this part with a lancet, and this is often had recourſe to in the relaxation of the palate, termed lampers, and with apparently good effect. Some are deterred from the operation, by having experienced a difficulty in ſtopping the flow of blood; a circumſtance that in a few times when we have performed this operation, has not occurred to us.

We ſhall now briefly ſtate the mode of operating, and the conſequences which ſometimes follow the opening of the jugular vein in horſes.

It is moſt uſual to bleed with the fleam, or the lancet; the former, on account of the thickneſs of the ſkin of the horſe, and the reſiſtance afforded by the hair, is generally had recourſe to. It is alſo next to impoſſible to drive the blade into the neck ſo deep as to be injurious, on account of the ſhoulder to which it is affixed; it is perhaps, on this account, the ſafeſt and moſt certain inſtrument, eſpecially in the hand of grooms and helpers in ſtables, as it cannot be much abuſed. In the ſtructure of it, the back ſhould be particularly attended to, for in general this is too narrow, inſomuch, that the inſtrument being ſtruck, it ſinks into the channel of the vein, the prominent muſcles of the neck receive the ſtroke, and the vein is not opened. To remedy this, which is a very common inconvenience, the back of the fleam ſhould be at leaſt three quarters of an inch broad, in which caſe the operation very rarely fails.

The lancet is alſo very convenient in thin-ſkinned horſes, and performs the operation very well. It requires, however, on account of the reſiſtance of the ſkin and hair, to be uſed rather boldly, as to the length it is preſented with, and the force employed, at leaſt when a copious flow of blood is deſired.

It is uſual to wet the hairs over the part intended to be

punctured, and then if they are drawn parallel to the direction of the vein, the lancet paſſing between them, there is leſs reſiſtance than if they preſented themſelves tranſverſely to the blade, in which caſe they muſt neceſſarily be divided before the inciſion can take place.

The jugular vein, after bleeding, often ulcerates, and is attended with the moſt ſerious ill conſequences, the miſchief extending in both directions along the internal ſurface of the vein, from the point of the inciſion; the cavity of the vein, or its canal becomes obliterated, and the irritation occaſions a thickening of the cellular membrane ſurrounding the vein, often to ſome inches in depth. This, in general, if no external irritation happens, ſubſides gradually, and diſappears without any farther ill conſequences, and the vein is totally loſt on that ſide: at other times, an oozing and diſcharge of thin lymph takes place from the injured part, and a ſinus forms, running moſtly againſt the courſe of the vein up the neck, which, being freely opened, ſoon heals without farther inconvenience. At other times, conſiderable abſceſſes form, which are opened without danger, and the thickening of the cellular membrane gradually ſubſides, and the part heals. Again, in others, the inflammation and ulceration extend along the courſe of the vein to the head, forming abſceſſes, which burſt and diſcharge blood, and the ulceration extending to the head becomes fatal.

As prevention is often much eaſier than cure, to avoid this accident great care ſhould be taken to uſe a clean inſtrument, with a ſmooth, keen edge, not to ſtrike where the vein has been already opened, where very often is an enlargement, and the vein becomes thinner in that part, and more extended, not to include any thing but the ſkin in pinning it up, and not to leave the pin remaining in the neck too long, to become cankered and ruſty, and thus produce irritation. The pin ſhould be clipt as ſhort as poſſible, to prevent the horſe rubbing it out againſt the manger, &c.

The wound will in general cloſe of itſelf after a few minutes, if all preſſure upon the vein be removed, and ſufficiently firm to ſtop the eſcape of the blood, if the lips of the orifice are preſſed together, without any pinning, and the horſe's head, to render it more certain, ſhould be tied rather high to the rack for a ſhort time; where, however, the orifice is very large, or the veins very tumid, and diſpoſed to bleed, pinning is the ſureſt practice.

Lancets are often made with a ſpring, ſuddenly to plunge them into the vein, and are uſefully and commodiouſly employed for this operation, as they do it with great ſuddenneſs and effect, more ſo than the hand or the blow of a bloodſtick. The only objection is, that the inſtrument, from the preſſure againſt the neck required in uſing it, cannot be ſo ſuddenly withdrawn as might be deſirable, ſo that if the horſe plunges at the moment he might ſeverely cut himſelf, which we have ſeen happen. To prevent the poſſibility of ſuch an occurrence, the inſtrument might be provided with a ſecond ſpring to bring back the lancet to its ſheath, or caſe, immediately after the ſtroke, which would render this inſtrument very uſeful and perfect.

Bleeding *from the noſe*. See Epistaxis.

Bleeding *from the lungs*. See Hæmoptysis.

Bleeding *by meaſure*, is where an account is taken of the quantity as it flows from the vein, in order to put a ſtop to the flux when the requiſite portion is had.

Bleeding *at large*, where the flux is continued without regard to the quantity, till ſuch time as ſome expected effect is perceived. This method is ſometimes uſed in caſes of apoplexies, comata, &c.

Bleeding *of a corpſe, cruentatio cadaveris*, is a phenomenon ſaid to have frequently happened in the bodies of perſons murdered, which, on the touch, or even approach of the murderer, began to bleed at the noſe, ears, and other parts; ſo as formerly to be admitted in England, and ſtill allowed in ſome other parts, as a ſort of detection of the criminal, and proof of the fact. Phil. Tranſ. N° 77. p. 3012. But this kind of evidence derives its weight merely from ſuperſtition and credulity. Numerous inſtances of theſe poſthumous hæmorrhages are given by Webſter, Lemnius, Libavius, and eſpecially Horſtius, who has a diſcourſe expreſs on this point, under the title, "De Cruentatione Cadaverum."

Bleeding is alſo applied, in a leſs proper ſenſe, to a flux of ſap out of the wounded veſſels of plants, either ſpontaneouſly at certain ſeaſons, or by art, and the help of inciſion.

BLEGNY, Nicolas, in *Biography*, a bold, and, for a time, ſucceſsful adventurer in medicine, to which he was not regularly educated. Dionis ſays, he married a midwife, which probably firſt ſuggeſted the idea of becoming a rupture doctor, and of contriving an elaſtic bandage for that complaint. In 1676, he publiſhed at Paris, "L'art de guerir des hernies," 12mo. which has paſſed through ſeveral editions. He uſed to cauterize the ſkin of the groin with aqua fortis, or the muriatic acid; when the wound healed, a firm cicatrix was left, which contributed in preventing the further deſcent of the gut. This remedy was invented by the prior De Cabeveres. He relates ſeveral remarkable cures performed by him: in one caſe, part of the urinary bladder had ſlipped into the ring. In 1679 he publiſhed, "Hiſtoire anatomique d'un enfant, qui a demeuré vingt cinque ans dans le ventre de ſa mere," Paris, 12mo. The fœtus was ſaid to be petrified. It had acquired, from its long reſidence in the abdomen, and from the preſſure of the neighbouring viſcera, an almoſt cartilaginous hardneſs, and retained very little of the human form. About the ſame time, he commenced the publication of a medical journal, under the title of "Les nouvelles decouvertes, ſur toutes les parties de la medicine," of which one number came out every month, and he ſolicited and obtained aſſiſtance from a variety of practitioners; he alſo contributed conſiderably to it from his own ſtock. His name appeared as the editor for the firſt three years, but was afterwards omitted. Bouet thought the journal deſerving of being tranſlated into Latin, and publiſhed it at Geneva, in 4to. under the title of "Zodiaci medico-Gallici." He had before this made himſelf known by a treatiſe on the venereal diſeaſe; "L'Art de guerir les maladies veneriennes expliqué par les principes de la nature, et de la mecanique," 12mo. 2 vols. Paris. This was ſoon republiſhed, tranſlated into German, Engliſh, and other languages. He ſays, the diſeaſe was known to the ancients, and even to Moſes. It may be brought on, he thinks, by immoderate venery. He objects to the uſe of aſtringent injections in the gonorrhœa, and profeſſes to cure the lues, equally certainly, and more ſafely, with decoctions of guiacum and ſarſaparilla, than with mercury. He had alſo publiſhed, by order of his ſovereign, "Remede Anglois, pour la gueriſon des fievres," 1682, 12mo. The principal part of this remedy was the Peruvian bark. He had now attained to very high rank in his profeſſion, having been made, in ſucceſſion, ſurgeon to the queen, to Philip duke of Orleans, and, in 1687, one of the phyſicians in ordinary to the king. Soon after he undertook the management of an hoſpital, for the reception of the ſick poor at Pincourt, but for ſome immoral practices, encouraged in this place, a report of which was made to the king, he was removed from all his appointments, and

and confined in prifon for eight years. Releafed at length from his confinement, he went and fettled at Avignon, where he continued to the time of his death, about the year 1722, being 70 years of age. Haller. Bib. Chirurg. Anat. et Med. Eloy Dict. Hift.

BLEICHERODE, in *Geography*, a town of Germany, in the circle of Upper Saxony, county of Hohenftein, and lordfhip of Lora; though fmall, it is populous and thriving, has fome manufactures, and carries on a good trade; 20 miles north of Mulhaufen.

BLEIDENSTATT, a town, or large village of Germany, in the circle of the Upper Rhine, and principality of Naffau-Saarbruck-Ufingen, feated on the Aar, 9 miles N.N.W. of Mentz.

BLEISTEIN, or PLESTAIN, a town of Germany, in the circle of Bavaria, and principality of Newburg, with an annexed lordfhip, a fief of the kingdom of Bohemia; 22 miles E.N.E. of Amberg.

BLEKEDE, a fmall town of Germany, in the circle of Lower Saxony, and principality of Luneburg-Zell, feated on the Elbe, to which belongs a toll on the river of conficderable produce; 20 miles E.N.E. of Luneburg.

BLEKINGEN, called by the Swedes *Blekingh*, by the Danes *Blegind*, and by the inhabitants *Blegen*, a province of Sweden, bounded on the north by Smoland, on the fouth and eaft by the Baltic, and on the weft by Scania, Schonen, or Skone, is about 100 Engliih miles in length, and about 26 in breadth. It is a mountainous country, but various parts of it are more pleafant than any other provinces of the kingdom. It abounds with foreits of oak, beech, pine, and birch trees, and carries on a conliderable trade in pot-afh, tar, tallow, hides, leather, beams, deal-boards, and maits. The inhabitants alfo employ themfelves in fifhing and hunting. The fhallow foil does not admit of much tillage, but the paftures afford the beft cheefe in Sweden; the cattle, however, are of a fmaller fize than thofe of Schonen. This country has feveral lakes and fix principal rivers, which furnifh good falmon. Its iflands belonging to this jurifdiction are numerous, and the whole province contains 29 parifhes. The clergy are fubject to the fee of Lund. As to its political divifion it confifts of four harads, or diftricts, and its principal town is Carlfcrona, which fee.

BLEMISH, in *Horfe dealing*. By this term, among the venders of horfes, is underftood any appearance by which the horfe is disfigured, as broken knees, a blind eye, fcars of various kinds, &c. The term blemifh, by fome, may be extended even to any unlightly natural markings of the horfe. Thefe blemifhes, however, for the moft part are conlidered as in no wife of themfelves conftituting an unfoundnefs.

BLEMISH, a term in *Hunting*, ufed when the hounds, or beagles, finding where the chace has been, make a proffer to enter, but return.

BLEMMYES, or BLEMYES, among the *Ancient Geographers*, a fabulous fort of people, fuppofed without heads; having eyes and mouths on their breafts; faid to have inhabited part of Ethiopia, on the borders of Egypt.

Some authors imagine, that this fable had its origin in a cuftom which prevailed among this people of depreffing their heads between their fhoulders, which they forced upwards, fo that their necks were very fhort, and their heads were concealed partly by their fhoulders, and partly by their long and thick hair. To this purpofe it is alleged, that the Egyptian, or bearded Bacchus, has the head funk in his breaft. We learn from Vopifcus, that fome Blemmyan captives, taken prifoners by Probus, in an expedition againft them, about the year of Chrift 278, made a very odd appearance at Rome. But at this time they could not be quite unknown at Rome, as fome of them had appeared there before, on occafion of Aurelian's triumph. In the time of Diocletian, the number of the Blemmyes, fcattered between the ifland of Meroe and the Red fea, was very inconfiderable, their difpofition was unwarlike, and their weapons rude and inoffenfive; yet, in the public diforders, thefe barbarians, whom antiquity, fhocked with the deformity of their figure, had almoft excluded from the human fpecies, prefumed to rank themfelves among the enemies of Rome. With a view of oppofing to the Blemmyes a fuitable adverfary, Diocletian, in his attack on the rebellious Egyptians, A. D. 296, perfuaded the Nobatæ, or people of Nubia, to remove from their ancient habitations in the deferts of Lybia, and refigned to them an extenfive but unprofitable territory above Syene, and the cataracts of the Nile, with the ftipulation, that they fhould ever refpect and guard the frontier of the empire. We find, however, that at a fubfequent period they fent ambaffadors to the court of Conftantine. The Blemmyes were fubdued by Florus, the lieutenant of Marcian, A. D. 450.

Bochart derives the word *Blemmyes* from בְּלִי, which implies a *negation*, and מוֹחַ, *brain*; in which fenfe, the Blemmyes fhould have been people without brains. See Strabo, l. xvii. p. t. 172. Pomponius Mela, l. 1. c. 4. His words, in defcribing thefe favages of Ethiopia, are curious; "Intra, fi credere libet, vix homines magifque femiferi; Ægipanes, et *Blemmyes*, et Satyri."

BLENAU, in *Geography*, a town of France, in the department of the Yonne, and chief place of a canton in the diftrict of Ioigny, containing 1065 perfons; the number of people in the canton amounts to 5976: the territory comprehends 290 kiliometres and 9 communes; 2 leagues N.W. of St. Fargeau.

BLENCH, in *Law*, a fort of tenure of land; as to hold land in blench is by payment of a fugar-loaf, a couple of capons, a beaver-hat, &c. if the fame be demanded in the name of *blench*, i.e. *nomine albæ firmæ*. See ALBA FIRMA.

BLENDE, in *Mineralogy*, called alfo black-jack, or pfeudo-galena, the native fulphuret of zinc. See ZINC, *ores of*.

BLEND-*metal iron*, a coarfe fort of iron from the Staffordfhire mines, ufed for making nails and heavy ware; in fome places alfo for horfe-fhoes.

BLEND-*water*, a diftemper incident to black-cattle, which comes feveral ways. 1. From blood. 2. From the yellows, which is a ringleader of all diieafes. And 3. From the change of ground: for being hard, it is apt to breed this evil, which if not remedied in fix days, will be paft help.

BLENHEIM, in *Geography*, a village of Germany, in the circle of Bavaria, and principality of Newburg, 2 miles N.E. of Hockftedt, famous for a victory obtained there by the Engliih and their allies over the French and Bavarians, Auguft 13th 1704. For an account of the battle, fee HOCKSTEDT.

BLENHEIM, a new town of America, in the ftate of New York, in Schoharie county, incorporated in 1797.

BLENNA, or BLENA (βλέννα) in *Medicine*, a term ufed by Hippocrates, and fubfequent medical writers, to denote a phlegm or mucus excreted from the noftrils. This fort of excretion occurs not unfrequently in acute diieafes, and is generally a favourable fymptom.

BLENNIUS, in *Ichthyology*, a Linnæan genus of jugular

fiſhes, the character of which is thus defined; head ſloping, ſix rays in the gill-membrane; body lanceolate; ventral fins of two united rays; anal fin diſtinct.

The ſpecies of this genus are enumerated in the Gmelinian Syſt. Nat. under two ſections, the firſt comprehending thoſe having the head creſted; the ſecond, ſuch as have the head ſmooth, or without a creſt. Galerita, criſtatus, cornutus, ocellaris, faſciatus, gattorugine, ſupercilioſus, tentacularis, ſimus, and phycis, are the creſted kinds; the ſpecies of the ſecond ſection are pholis, gunnellus, punctatus, muſtelaris, viviparus, lumpenus, raninus, murænoides; which ſee reſpectively.

Boſc propoſes an arrangement very different from the preceding, for the ſpecies included in his genus blennius. Theſe he divides into four ſections; the firſt including le blennie lièvre (*blennius ocellaris* Linn.), and le blennie phycis, becauſe theſe have two dorſal fins, and filaments or appendages upon the head. The ſecond diviſion, comprehending thoſe with only one dorſal fin and filaments upon the head, includes le blennie méditerranéen (*gadus mediterraneus* Linn.), le blennie gattorugine, le blennie ſourcilleux, le blennie cornu, le blennie tentaculé, le blennie fujéfin (*blennius ſimus* Linn.), le blennie coquillade (*blennius galerita* Linn.), le blennie ſanteur (a ſpecies diſcovered by Commerſon in the South ſeas), and le blennie pinaru (*blennius criſtatus* Linn.) The third and fourth ſection has no appendage upon the head, but are diſtinguiſhed from each other by having either two dorſal fins, or only one. Thoſe with two are le blennie gadoïde (*gadus albus* Linn.), le blennie belette, and le blennie tridactyle. Laſtly, in the fourth ſection are le blennie pholis, le blenne boſquien of Lacépède, le blennie ovovipare (*blennius viviparus* Linn.), le blennie gunel, le blennie pointillé of Lacépède, le blennie garamit, (*gadus ſalarias* of Forſkal), le blennie lumpène, and le blennie torſk.

BLENNORRHAGIA, in *Surgery*, is a term lately introduced to expreſs the varieties of a morbid affection, more generally called Gonorrhœa. This term is derived from βλεννος, *mucus*, and ῥεω, *fluo*; and is therefore equivalent to the Latin word *Mucifluxus*; but it is diſtinguiſhed from Blennorrhœa, which denotes the ſymptom uſually called Gleet. The author who has principally endeavoured to introduce this new epithet, is Dr. Schwediauer. His claſſification is as follows:

Claſſis, *Locales*.

Ordo, *Phlogoſes*, or *Mucifluxus*.

Genus, Blennorhagia. Anglis, *Clap*; Germanis, *Tripper*; Gallis, *Chaude-piſſe*; Italis, *Gonorrhœa*.

Character in Viris.—Titillatio, præcipue in urethræ parte anteriore in lacuna Morgagni ſub frænulo; ſubſequente poſt biduum aut quatriduum, phlogoſi locali, cum ardore et dolore in mingendo; accedente ſtillicidio materiei purulentæ vel puriformis ex urethra; corpore cavernoſo urethræ præternaturaliter turgeſcente, plerumque cum erectionibus membri virilis ſolito frequentioribus dolorificis.

In Fœminis.—Titillatio ad orificium vaginæ externum; ſubſequente poſt biduum aut quatriduum dolore, rubore et tumore præternaturali, præcipue (ad rapham) prope commiſſuram labiorum vulvæ inferiorem; accedente ardore et dolore ejuſdam partis in mingendo; cum ſtillicidio materiei puriformis ex vulva.

Gonorrhœa
——— virulenta
——— maligna
——— venerea
Fluor albus venereus, ſ. malignus
Leucorrhœa venerea
} auctorum.

Variat ratione ſedis. *Materia fluens:*

Blennorrhagia balani — ex glande,
——— urethralis — ex urethra,
——— veſicalis — e veſica,
——— labialis — e labiis vulvæ,
——— vaginalis — e vagina,
——— uterina — ex utero,
——— naſalis — e naribus.

Species ſunt,

Blennorrhagia ſyphillitica,
α. Simplex,
β. Complicata, ſ. ulceroſa.
Blennorrhagia a manuſtupratione.
——— ab acri externe applicato.
——— a ſtimulo interne applicato.
——— arthritica.
——— a calculo veſicæ.
——— a cancro uteri aut vaginæ.

Sequela Blennorrhagiæ eſt,

Blennorrhœa. Anglis, *Gleet*; Germanis *Nachtripper*, *weiſſer Flus*; Gallis, *Gonorrhée inveterée*.

Character.—Stillicidium humoris puriformis, aut muci limpidi, ex urethra in viris, ex orificio vaginæ in fœminis, præternaturalis, ſine libidine aut dyſuria.

Gonorrhœa benigna
——— inveterata
Fluor albus benignus
Leucorrhœa
} auctorum.

Variat ratione ſedis ut Blennorrhagia.

Species practico notatu neceſſariæ ſunt,

In viris: Blennorrhœa ſimplex a relaxatione vaſorum.
——— complicata.
α. Cum ulcere urethræ,
β. Cum ulcere aut ſcirrho proſtatæ.

In fœminis: Blennorrhœa a relaxatione aut debilitate vaſorum uteri aut vaginæ.
——— ex blennorrhagia prægreſſa.
——— ex diæta laute et vita ſedentaria.
——— a manuſtupratione
——— ab ulcere aut cancro uteri vel vaginæ.

Sequelæ Blennorrhagiæ ſyphiliticæ retropulſæ ſunt:

Tumor teſticulorum.
Iſchuria urethralis.
Bubo?
Ophthalmia.
Dyſecœa.
Fluxus puriformis ex oculis.
——— ex auribus.
——— e naribus.
Syphilis.

Genus, Gonorrhœa.

Character.—Excretio ſeminis aut muci proſtatæ præternaturalis, potiſſimum ſine erectione et libidine; accedente dolore lumborum et atrophia.

Gonorrhœa vera
Pollutio nocturna debilitans
Excretio ſeminis involuntaria
} auctorum.

Species ſunt:

Gonorrhœa a debilitate aut relaxatione vaſorum.
——— ab ulcere aut eroſione ductuum excretoriorum proſtatæ et veſicularum ſeminalium.
——— a nimia irritabilitate, potiſſimum per manuſtuprationem inducta.

BLENNUS, in *Ichthyology*, a name given by Schonfelt to the *fyngnathus typhle* of Linnæus, and *fhorter pipe fifh* of Engliſh writers.

BLENNY. See Blennius.

BLENOD, in *Geography*, a town of France, in the department of the Meurthe, and chief place of a canton, in the diſtrict of Toul, 5 miles ſouth of Toul.

BLEONNE, a river of France, which runs into the Durance near Mees, in the department of the Lower Meuſe.

BLERA, in *Ancient Geography*, *Gravina*, a ſmall town of Italy, in Apulia, eaſt of Venuſia. The *Blera* of Ptolemy is a place in Etruria, near Tarquina.

BLE'RE', in *Geography*, a town of France, in the department of the Indre and Loire, and chief place of a canton, in the diſtrict of Tours, containing 2519 inhabitants; the population of the canton is 13185; the territory comprehends 372½ kiliometres, and 15 communes; 4 leagues E.S.E. of Tours.

BLERGIES, a town of France, in the department of the Somme, 8 miles S. W. of Poix.

BLESCHINO, a town of Bohemia, in the circle of Konigingratz, 3 miles eaſt of Konigingratz.

BLESLE, a town of France, in the department of the Upper Loire, and chief place of a canton, in the diſtrict of Brioude, ſeated on the Alaignon, and containing 1329 inhabitants; the population of the canton is 5706; the territory comprehends 167½ kiliometres and 12 communes; 3½ leagues W. of Brioude.

BLESS, Henry, in *Biography*, a painter of hiſtory and landſcape, was born at Bovine, near Dinant, in 1480, and, without any inſtruction, rendered himſelf eminent in his art, by his own genius, and a diligent ſtudy of the works of Peteuier, particularly by his landſcapes. His ſtyle of compoſition, in hiſtorical ſubjects, reſembled the ſtyle of the Flemiſh artiſts of that age, and crowded ſeveral ſubjects into one deſign; and yet his pictures were ſo delicately pencilled and finiſhed, and his landſcapes ſo agreeably varied and well executed, that even in Italy his works were highly eſteemed, and diſtinguiſhed by the appellation of the owl pictures, for he fixed an owl, as his peculiar mark, in every picture he painted. He died in 1550. Pilkington.

BLESSINGTON, in *Geography*, a market town in the county of Wicklow, and province of Leinſter, Ireland, which, before the union, ſent two members to parliament. It is pleaſantly ſituated on a riſing ground near the Liffy, 14 miles S.W. of Dublin; and was founded by primate Boyle, one of whoſe deſcendants, the marquis of Downſhire, is the preſent proprietor. The number of inhabitants, according to Mr. Frazer, does not exceed 400. N. lat. 53° 9′ 45″. W. long. 6° 34′. Dr. Beaufort. Frazer's Wicklow.

BLESTIUM, or Blestio, in *Ancient Geography*, a place of Britain, in the rout from Iſca to Caleva, according to the itinerary of Antonine, between Burrium and Aricomium, ſuppoſed by Mr. Horſley to be Monmouth. Mr. Camden, and Drs. Gale and Stukeley, have placed this ſtation at Old Town, in Herefordſhire.

BLESTRISMUS, in the *Ancient Phyſic*, (βλησιρισμος, from βαλλω, *to throw*), a term employed by medical writers to expreſs that reſtleſſneſs and toſſing about of the body, which takes place in febrile diſorders.

BLETA Alba, a barbarous term employed by Paracelſus to denote a milky appearance of the urine in ſome diſeaſes of the kidneys.

BLETTERAND, in *Geography*, a town of France, in the department of Jura, and chief place of a canton, in the diſtrict of Lons-le-Saulnier, 6 miles N.W. of Lons-le-Saulnier; containing 732 inhabitants. The population of the canton is eſtimated at 10,007; the territory comprehends 150 kiliometres, and 13 communes.

BLETTERIE, John Philip Rene de la, in *Biography*, a diſtinguiſhed profeſſor of the congregation of the oratory, was born at Rennes; and quitting the congregation, he removed to Paris, and obtained the rhetorical chair in the Royal College, and a ſeat in the Academy of Belles Lettres. Among his moſt eſteemed works may be reckoned his "Hiſtory of Julian the Apoſtate," Paris, 1735, 1746, 12mo.; "Hiſtory of the emperor Jovian, and a tranſlation of ſome works of the emperor Julian," Paris, 1748, 2 vols. 12mo. which Gibbon (Decl. and Fall of the Rom. Emp. vol. iv. p. 206.) characteriſes as "a work remarkably diſtinguiſhed by elegance of ſtyle, critical diſquiſition, and religious prejudice." The abbé de la Bletterie alſo publiſhed a tranſlation of the "Life of Agricola," and the "Manners of the Germans," of Tacitus, and a life of that hiſtorian, his favourite author, in 1755; and a tranſlation o the ſix firſt books of the "Annals," in 1768. The ſtyle of this work has been charged with the vulgarity of religious ſectarianiſm; for the author had adopted the opinions of the quietiſt Queſnel, and publiſhed a defence of the famous madame Guyon. He died in 1772, at an advanced age, with an excellent character for both underſtanding and morals. Nouv. Dict. Hiſt.

BLETUS, in the *Ancient Phyſic*, (βλητος, from βαλλω, *to ſtrike.*) This term is uſed by Hippocrates and other medical writers to ſignify a livid appearance or ecchymoſis on the ſides of the cheſt, as if from a blow, which ſometimes occurs in thoſe who die of pleuriſy. The epithet βλησιος has alſo been applied to thoſe who die ſuddenly (as if ſtruck by lightning) in acute diſeaſes.

BLEU, in *Ichthyology*, the French trivial name for the ſpecies of ſhark called by Linnæus *ſqualus glaucus*.

BLEUET, in *Ornithology*, is the name by which the common king's fiſher, *alcedo iſpida*, is called in Provence.

BLEU-VERT. The *merops cæruleſcens* of Latham is known among the Freneh naturaliſts by this title.

BLEVY, in *Geography*, a town of France, in the department of the Eure and Loire, 3 leagues S.S.W. of Dreux.

BLEXEN, a town of Germany, in the circle of Weſtphalia, and county of Oldenburgh, 3 miles N.N.E. of Oldenburgh.

BLEYL, a village of Bohemia, near the town of Bregnitz, in the circle of Soatz, or Saaz; famous on account of its manufactory for the preparation of ſulphuric acid, by ſeparating it from ſulphat of iron by diſtillation. The manufactory has two ſheds for this operation; one with three galleries, each containing 29 retorts on each ſide; the other with two galleries, each holding on each ſide 21 retorts. In the galleries of this manufactory there is likewiſe a diſtillation of aqua fortis, or nitric acid.

BLEYMARD. See Blaymard.

BLEYNE, in *Farriery*, a French word, now obſolete in the Engliſh language, for a *ſand crack*, which ſee.

BLEYSWELCH, in *Geography*, a town of Germany, in the circle of Weſtphalia, and biſhopric of Paderborn, 4 miles S. of Wunnenberg.

BLEYSWICK, a town of Holland, 8 miles north of Rotterdam.

BLIARUS, or Membriarus, in *Ancient Geography*, an iſland of the Mediterranean, near that of Thera, ſaid by Steph.

Steph. Byz. to have derived its name from one of the companions of Cadmus.

BLIEGG, in *Ichthyology*, a name given by the Germans to the fiſh we call the *bleak*. See BLEAK, and A BURNUS.

BLIESCASTEL, in *Geography*, a town of France, in the department of Sarre, and chief place of a canton, in the diſtrict of Sarrebruck; containing 1278 inhabitants; the population of the canton includes 10,084 perſons; and the territory has 30 communes.

BLIESNA SALENSI, a harbour on the coaſt of Lapland, between the river Kola and Kilduyn iſland.

BLIGH'S *Cap*, a name given by captain Cook, on account of its ſhape, to an iſland in the ſouthern Pacific ocean, near Kerguelen's land, before called by Kerguelan "the iſland of Rendezvous." It is a high round rock acceſſible only to birds. S. lat. 48° 29'. E. long. 68° 4'.

BLIGHT, in *Agriculture*, a general name for various diſtempers incident to corn and fruit-trees.

It affects them variouſly, the whole plant ſometimes periſhing by it, and ſometimes only the leaves and bloſſoms, which will be ſcorched and ſhrivelled up, the reſt remaining green and flouriſhing. Some have ſuppoſed, that blights are produced by eaſterly winds, which bring vaſt quantities of inſects' eggs along with them from diſtant places. Theſe being lodged upon the ſurface of the leaves and flowers of fruit-trees, cauſe them to ſhrivel up and periſh.

Mr. Knight, however, obſerves, that blights are produced by a variety of cauſes; by inſects, by an exceſs of heat or cold, of drought or moiſture; for theſe neceſſarily derange and deſtroy the delicate organization of the bloſſoms; but he believes the common opinion, that they ariſe from ſome latent noxious quality in the air, or from lightning, to be totally unfounded. The term blight is very frequently uſed by the gardener and farmer, he remarks, without any definite idea being annexed to it. If the leaves of their trees be eaten by the caterpillar, or contracted by the aphis; if the bloſſoms fall from the ravages of inſects, or without any apparent cauſe, the trees are equally blighted; and if an eaſt wind happen to have blown, the inſects, or at leaſt their eggs, whatever be their ſize, are ſuppoſed to have been brought by it.

The true cauſe of blights ſeems to be, continued dry eaſterly winds for ſeveral days together, without the intervention of ſhowers, or any morning dew, by which the perſpiration in the tender bloſſom is ſtopped; and if it ſo happen that there is a long continuance of the ſame weather, it equally affects the tender leaves, whereby their colour is changed, and they wither and decay.

The beſt remedy, perhaps, is gently to waſh and ſprinkle over the tree, &c. from time to time, with common water; and if the young ſhoots ſeem to be much infected, let them be waſhed with a woollen cloth, ſo as to clear them, if poſſible, from this glutinous matter, that their reſpiration and perſpiration may not be obſtructed. This operation ought to be performed early in the day, that the moiſture may be exhaled before the cold of the night comes on: nor ſhould it be done when the ſun ſhines very hot. Mr. Forſyth recommends their being waſhed well with urine and ſoap-ſuds, as ſoon as poſſible after the diſeaſe appears.

Another cauſe of blights in the ſpring, is ſaid to be ſharp, hoary froſts, which are often ſucceeded by hot ſun-ſhine in the day-time. This is the moſt ſudden and certain deſtroyer of fruit that is known. The chief remedy to be depended upon in this caſe is, that of protecting the fruit-trees during the night-time with nets. This mode, where regularly and correctly performed, has been found highly beneficial.

But, in order to cure this diſeaſe, ſome have adviſed the burning of wet litter on the windward ſide of the plants, in order that the ſmoke of it may be carried to them by the wind, which they ſuppoſe will ſtifle and deſtroy the inſects and thereby cure the miſchief. Others direct the uſe of tobacco-duſt, or the waſhing of the trees with water in which tobacco-ſtalks have been infuſed for twelve hours, which they ſay will deſtroy thoſe inſects, and recover the plants. Pepper-duſt, ſcattered over the bloſſoms of fruit-trees, &c. has been recommended as very uſeful in this caſe; and there are ſome who adviſe the pulling off the leaves that are affected.

What is termed the blight is frequently, however, no more than a debility, or diſtemper in trees. Mr. Forſyth obſerves, that "this is the caſe when trees, againſt the ſame wall, and enjoying the ſame advantages in every reſpect, differ greatly in their health and vigour, the weak ones appearing to be continually blighted, while the others remain in a flouriſhing condition. This very great difference, in ſuch circumſtances, can be attributed only to the different conſtitutions of the trees, proceeding from want of proper nouriſhment, or from ſome bad qualities in the ſoil; ſome diſtemper in the ſtock, buds, or ſcions; or from ſome miſmanagement in the pruning, &c. all of which are productive of diſtempers in trees, of which they are, with difficulty, cured. If the fault be in the ſoil, it muſt, he ſays, be dug out; and freſh mould put in its place; or, the trees muſt be taken up, and others, better adapted to the ſoil, planted in their room. It will be found abſolutely neceſſary always to endeavour to ſuit the particular ſorts of fruit to the nature of the ſoil; for it is in vain to expect all ſorts of fruit to be good in the ſame ſoil. If the weakneſs of the tree proceed from an in-bred diſtemper, it will be adviſeable to remove it at once, and after renewing the earth, to plant another in its place." But if the weakneſs is brought on by ill management in the pruning, which is frequently the caſe, he would adviſe more attention to the method of pruning and training.

Beſides this, "there is another ſort of blight that ſometimes happens pretty late in the ſpring, as in April or May, which is very deſtructive to fruit-trees in orchards, and open plantations, and againſt which we know of no effectual remedy. This is what is called a *fire-blaſt*, which, in a few hours, hath not only deſtroyed the fruit and leaves, but often parts of trees; and ſometimes entire trees have been killed by it." This, Mr. Forſyth obſerves, "is generally thought to be occaſioned by certain tranſparent flying vapours, which may ſometimes take ſuch form, as to converge the ſun's rays in the manner of a burning-glaſs, ſo as to ſcorch the plants they fall upon; and this, in a greater or leſs degree, in proportion to their convergency. As this generally happens in cloſe plantations, where the vapours from the earth, and the perſpiration from the trees, are pent in for want of a free circulation of air to diſperſe them, it points out to us the only way, yet known, of guarding againſt this enemy to fruits; namely, to make choice of a clear healthy ſituation for kitchen-gardens, orchards, &c. and to plant the trees at ſuch a diſtance, as to give free admiſſion to the air, that it may diſpel thoſe vapours before they are formed into ſuch volumes as to occaſion theſe blaſts." But blaſts may alſo be occaſioned by the reflection of the ſun's rays from hollow clouds, which ſometimes act as burning mirrors, and occaſion exceſſive heat. Againſt this there is no remedy yet diſcovered.

Mr. Marſhall, in the Rural Economy of midland counties, obſerves, that it is well known that this diſeaſe is moſt injurious

jurious to grain crops in wet ſeaſons; hence, principally, the ſcarcity and advanced price of wheat after ſuch ſeaſons. It is alſo remarked to affect the north ſide of fields, much more than the ſouth, and that the effect is governed by the ſtate of ripeneſs; conſequently, a few days of forwardneſs may be ſufficient to prevent the effect. It is evident, that the forward wheats are leaſt liable to be blighted; for, having paſſed ſome certain ſtage of maturation, they become invulnerable to the attack of this miſchievous enemy; at leaſt, no obvious injury is incurred. It is alſo obſervable, that no perceptible blight takes place while a dry ſeaſon continues. The only guard a farmer has againſt the attack of this ſecret enemy, appears to be that of ſowing early.

Blight *of corn* is called Smut.

BLIGNY-SUR-OUCHES, in *Geography*, a town of France, in the department of the Côte d'Or, and chief place of a canton, in the diſtrict of Beaune, 3 leagues N. W. of Beaune, containing 1169 inhabitants; the canton contains 6398; and comprehends 265 kiliometres, and 23 communes.

BLIKOOSKOI, a ſmall iſland in the Frozen ſea. N. lat 71° 30'. E. long 125° 14'.

BLIND. See Blindness.

Blind, *Pore*, or *Pur*, denotes only a great degree of ſhort-ſightedneſs. Phil. Tranſ. N° 37. p. 731.

Blind, is alſo uſed for occult, or imperceptible. Hence blind rampart, *cæcum vallum*, among the ancients, was that beſet with ſharp ſtakes, concealed by graſs or leaves growing over them.

Blind *teſtimonies*, *cæca teſtimonia*, thoſe given by abſent perſons in writing.

Blind is alſo uſed in ſpeaking of bodies without apertures.

Hence,

Blind *wall*, *cæcus paries*, that without windows. In a like ſenſe we meet with *blind* chamber, *cæcum cubiculum*.

Blind is alſo uſed in ſpeaking of veſſels which are not perforated. In this ſenſe the chemiſts ſay a blind alembic. A tube is ſaid to be blind, when it is cloſed a-top. Some anatomiſts alſo call the third cavity of the ear cœcum, as having no iſſue; but it is more uſually denominated labyrinth, which ſee.

Blind *harbour*, or *Murderer's bay* of Taſman, in *Geography*, a deep bay at the N. W. part of the ſouthern iſland of New Zealand, having two ſmall iſlands near the bottom of it on the weſt ſide; 6 leagues to the eaſt of cape Farewell.

Blind, in the *Military Art*, ſignifies, generally, every material which ſerves to cover and protect the beſiegers from the fire of the enemy; as wool packs, ſand-bags, earth-baſkets, &c. Blinds ſometimes conſiſt only of canvas ſtretched, ſo as to intercept the view of the garriſon from the walls. Sometimes they are planks erected, and in this caſe are more properly called mantlets. They are alſo occaſionally conſtructed with a number of baſkets or barrels.

More particularly taken, blinds denote wooden frames of four pieces, either round or flat. Two of them are ſix feet long, and pointed at the extremities; the others, about three or four feet in length, ſerve as ſpars, to faſten the two former together. Theſe blinds are fixed upright in the ground againſt the ſides of the ſaps, to hinder the earth from falling in, and to faſten faſcines upon the upper part. They are likewiſe of uſe in covering the ſaps, and ſupporting a roof of faſcines to ſecure the troops from ſtones and granades.

Blinds, of another ſort, are commonly made of oziers, or branches interwoven and laid acroſs between two rows of ſtakes, about the height of a man, and four or five feet aſunder.

Blinds are of eſſential ſervice at the heads of trenches, or ſaps, when they are extended in front towards the glacis; and when, from the ſuperior elevation of the enemy's works, he may overlook, and pour his fire in upon the beſiegers. They are alſo indiſpenſable, in caſe the nature of the ground ſhould oblige the approaches to be carried on in a ſtraight direction, and the workmen and the guard to be neceſſarily expoſed to the batteries of the garriſon. But in this caſe, the ſaps can only be carried on in the night, as the loſs of men would otherwiſe prove extremely ſerious.

Blind is alſo ſometimes uſed for Orillon.

Blind *granado*, that which does not light or take fire.

Blind *faith*. See Faith.

Blind *gut*. See Coecum.

Blind *worm*. See Slow-*worm*.

BLINDING, a ſpecies of corporal puniſhment anciently inflicted on thieves, adulterers, perjurers, and others; and from which the ancient Chriſtians were not exempt. Sometimes lime in vinegar, or barely ſcalding vinegar, was poured into the eyes, till their balls were conſumed; ſometimes a rope was twiſted round the head till the eyes ſtarted out. Solin. Polyhiſt. c. 4. Lamprid. in Alex. Sev. c. 17. Val. Max. lib. vi. c. 5. Lactant. de Mort. Perſec. c. 36.

In the middle age, they changed total blindneſs for a great darkneſs, or diminution of ſight, which they produced by holding a red hot iron diſh or baſon before the eyes, till their humours were dried, and their coats ſhrivelled up.

The inhabitants of the city Apollonia executed it on their watch whom they found aſleep. Democritus, according to Plutarch, Cicero, and A. Gellius, put out his own eyes, that he might be leſs diſturbed in his mental contemplations, when thus freed from the diſtraction of the objects of ſight. Herodot. lib. vi. c. 92. Aul. Gell. Noct. Att. lib. x. c. 71. Cicero Tuſc. Qu. 5.

Blinding, *obcæcatio*, in the *Black Art*, denotes a ſpecies of necromancy, whereby a viſible body may be concealed, or hidden by an inviſible power. See Necromancy.

Blinding *of a caſemate*, ſignifies erecting a battery againſt it, in order to diſmount its cannon and render them uſeleſs.

BLINDNESS, in *Surgery*, the privation or want of ſight. This defect may ariſe from a variety of cauſes, exiſting either in the organ of ſight, or in the circumſtances neceſſary to produce viſion. See Optics, and Eye. Blindneſs will be complete, when the light is wholly excluded; or partial, when it is admitted into the eye ſo imperfectly as to convey only a confuſed perception of viſible objects. Blindneſs may again be diſtinguiſhed into periodical or permanent, tranſient or perpetual, natural or accidental, &c.; but theſe diſtinctions do not ſerve to communicate any idea of the cauſes of blindneſs, which are to be ſlightly mentioned in the preſent article. For a more particular account of the cauſes and remedies of blindneſs, the reader will conſult the articles which give an account of the doctrine of viſion, and the diſeaſes of the eye.

The ordinary cauſes of blindneſs are as follow:

1. *In the eyelids and muſcles.* By a coheſion of the eyelids; by an elongation of the upper eye-lid; by a paralytic ſtate, which diſables the patient from raiſing it ſufficiently; by an irregular or defective action in the muſcles which are attached to the eye-ball.

2. *In the membranes of the eye.* By their opacity, ſo as to exclude the rays of light; by their exquiſite ſenſibility, ſo as to render viſion intolerable; by their blood-veſſels aſſuming a morbid action, and effuſing a fluid (ſuppoſe pus, for example) into any of the cavities of the eye.

3. *In*

3. *In the humours of the eye.* By their defective quantity; by the turbid ſtate, or imperfectly tranſparent condition, of the humours; by the loſs of any one of them, through accident or violence; by an altered figure of the cryſtalline lens.

4. *In the brain or optic nerve.* By compreſſion, producing palſy or Gutta Serena (which ſee); by a ſtate of debility or inertneſs in the viſual organ, ſo as to require an uncommonly ſtrong light; by too great ſenſibility in the optic nerve, enduring but a very feeble impreſſion from the light, and tranſmitting only a confuſed perception of viſible objects to the mind; by ſome unknown change in the nervous power, cauſing depraved viſion, and exciting imaginary ſcenes, which no perſon can obſerve beſides the patient himſelf.

It has been generally ſuppoſed, that blind perſons have not any idea of viſible objects, though they can diſtinguiſh them by the touch: thus the gentleman couched by Mr. Cheſelden, though he knew the colours aſunder in a good light during his blind ſtate; yet when he ſaw them after couching, the faint ideas he had of them before, were not ſufficient for him to know them by afterwards. Phil. Tranſ. N° 403. p. 447.

It was even a conſiderable time before he could remember which was the cat and which the dog, though often informed, without feeling them. Add, that he had no idea of diſtance; but thought all the objects he ſaw touched his eyes, as what he felt did his ſkin.

But a caſe is recorded by Mr. Ware in the Philoſophical Tranſactions (read to the ſociety June 11th, 1801), which does not accord with Mr. Cheſelden's obſervation on this ſubject. It was the caſe of a young gentleman, who (by a ſurgical operation) recovered his ſight when ſeven years of age; after having been deprived of it by cataracts, before he was a year old. Mr. Ware gives the following account of the facts in queſtion: "I performed the operation on the left eye, on the 29th of December laſt, in the preſence of Mr. Chamberlayne, F.A.S. Dr. Bradley, of Baliol college, Oxford, and Mr. Platt, ſurgeon, in London. It is not neceſſary, in this place, to enter into a deſcription of the operation. It will be ſufficient to ſay, that the child, during its performance, neither uttered an exclamation, nor made the ſmalleſt motion, either with his head or hands. The eye was immediately bound up, and no inquiries made on that day with regard to his ſight. On the 30th, I found that he had experienced a ſlight ſickneſs on the preceding evening, but had made no complaint of pain, either in his head or eye. On the 31ſt, as ſoon as I entered his chamber, the mother, with much joy, informed me that her child could ſee. About an hour before my viſit, he was ſtanding near the fire, with a handkerchief tied looſely over his eyes, when he told her that under the handkerchief, which had ſlipped upward, he could diſtinguiſh the table by the ſide of which ſhe was ſitting: it was about a yard and a half from him; and he obſerved that it was covered with a green cloth (which was really the caſe), and that it was a little farther off than he was able to reach. No further queſtions were aſked him at that time; as his mother was much alarmed, leſt the uſe thus made of his eye might have been premature and injurious. Upon examination, I found that it was not more inflamed than the other eye; and the opacity in the pupil did not appear to be much diminiſhed. Deſirous, however, to aſcertain whether he was able to diſtinguiſh objects, I held a letter before him, at the diſtance of about twelve inches, when he told me, after a ſhort heſitation, that it was a piece of paper; that it was ſquare, which he knew by its corners; and that it was longer in one direction than it was in the other. On being deſired to point to the corners, he did it with great preciſion, and readily carried his finger in the line of its longeſt diameter. I then ſhewed him a ſmall oblong band-box covered with red leather, which he ſaid was red and ſquare, and pointed at once to its four corners. After this, I placed before him an oval ſilver box, which he ſaid had a ſhining appearance; and, preſently afterwards, that it was round, becauſe it had not corners. The obſervation, however, which appeared to me moſt remarkable, was that which related to a white ſtone mug; which he firſt called a white baſon, but, ſoon after, recollecting himſelf, ſaid it was a mug, becauſe it had a handle. Theſe experiments did not give him any pain; and they were made in the preſence of his mother, and of Mr. Woodford, a clerk in his majeſty's treaſury. I held the objects at different diſtances from his eye, and inquired very particularly if he was ſenſible of any difference in their ſituation; which he always ſaid he was, informing me, on every change, whether they were brought nearer to, or carried further from him. I again inquired, both of his mother and himſelf, whether he had ever, before this time, diſtinguiſhed by ſight any ſort of object; and I was aſſured by both that he never had, on any occaſion; and that, when he wiſhed to diſcover colours, which he could only do when they were very ſtrong, he had always been obliged to hold the coloured object cloſe to his eye, and a little on one ſide, to avoid the projection of the noſe. No further experiments were made on that day. On the 1ſt of January, I found that his eye continued quite free both from pain and inflammation, and that he felt no uneaſineſs on the approach of light. I ſhewed him a table knife; which at firſt he called a ſpoon, but ſoon rectified the miſtake, giving it the right name, and diſtinguiſhing the blade from the handle, by pointing to each as he was deſired. He afterwards called a yellow pocket-book by its name, taking notice of the ſilver lock in the cover. I held my hand before him; which he knew, but could not at firſt tell the number of my fingers, nor diſtinguiſh one of them from another. I then held up his own hand, and deſired him to remark the difference between his thumb and fingers; after which, he readily pointed out the diſtinctions in mine alſo. Dark-coloured and ſmooth objects, were more agreeable to him than thoſe which were bright and rough. On the 3d of January, he ſaw, from the drawing-room window, a dancing-bear in the ſtreet; and diſtinguiſhed a number of boys that were ſtanding round him, noticing particularly a bundle of cloths which one of them had on his head. On the ſame evening, I placed him before a looking-glaſs, and held up his hand: after a little time he ſmiled and ſaid he ſaw the ſhadow of his hand, as well as that of his head. He could not then diſtinguiſh his features; but, on the following day, his mother having again placed him before the glaſs, he pointed to his eyes, noſe, and mouth, and ſeemed much gratified with the ſight.

Having thus ſtated the principal obſervations that were made by Maſter W. I ſhall now make a brief compariſon between this ſtatement, and that which is given in the XXXVth volume of the Philoſophical Tranſactions, of M. Cheſelden's patient, who was ſuppoſed to be born blind, and obtained his ſight when he was between thirteen and fourteen years old.

It ſhould be obſerved, that though Maſter W. was ſix years younger than Mr. Cheſelden's patient, he was remarkably intelligent, and gave the moſt direct and ſatisfactory anſwers to every queſtion that was put to him. Both of them, alſo, if not born blind, loſt their ſight ſo very early, that, as Mr. Cheſelden expreſſes it, "they had not any recollection of having ever ſeen."

My firſt remark is, that, contrary to the experience of Mr. Cheſelden's patient, who is ſtated "to have been ſo far from making any judgment of diſtance, that he thought all objects touched his eyes, as what he felt did his ſkin," Maſter W. diſtinguiſhed, as ſoon as he was able to ſee, a table, a yard and a half from him; and proved that he had ſome accuracy in his idea of diſtance, by ſaying, that it was a little further off than his hand could reach. This obſervation, ſo contrary to the account we have received of Mr. Cheſelden's patient, would have ſurpriſed me much more than it did, if I had not previouſly, in ſome ſimilar inſtances, had reaſon to ſuſpect that children, from whom cataracts had been extracted, had a notion of diſtance the firſt moment they were enabled to ſee. In the inſtance particularly of a young gentleman from Ireland, fourteen years old, from each of whoſe eyes I extracted a cataract, in the year 1794, in the preſence of Dr. Hamilton, phyſician to the London hoſpital, and who, before the operation, aſſured me, as did his friends, that he never had ſeen the figure of any object, Dr. Hamilton and myſelf were much aſtoniſhed by the facility with which, on the firſt experiment, he took hold of my hand at different diſtances, mentioning whether it was brought nearer to, or carried further from him, and conveying his hand to mine in a circular direction, that we might be the better ſatisfied of the accuracy with which he did it. In this caſe, however, and in others of a like nature, although the patients had certainly been blind from early infancy, I could not ſatisfy myſelf that they had not, before this period, enjoyed a ſufficient degree of ſight to impreſs the image of viſible objects on their minds, and to give them ideas which could not afterwards be entirely obliterated. In the inſtance of Maſter W. however, no ſuſpicion of this kind could occur; ſince, in addition to the declaration of himſelf and his mother, it was proved by the teſtimony of the ſurgeon who examined his eyes in the country, that the cataracts were fully formed before he was a year old. And I beg leave to add further, that on making inquiries of two children, between ſeven and eight years of age, now under my care, both of whom have been blind from birth, and on whom no operation has yet been performed, I find that the knowledge they have of colours, limited as it is, is ſufficient to enable them to tell whether coloured objects be brought nearer to, or carried further from them; for inſtance, whether they are at the diſtance of two inches or four inches from their eyes; nor have either of them the ſlighteſt ſuſpicion, as is related of Mr. Cheſelden's patient, that coloured objects, when held before them, touch their eyes.

But the judgment which Maſter W. formed of the different diſtances of objects, was not the only inſtance in which he differed from Mr. Cheſelden's patient; who, we are informed, "did not know the figure of any thing, nor any one thing from another, however different in ſhape and magnitude;" for Maſter W. knew and deſcribed a letter, not only as white, but alſo as ſquare, becauſe it had corners; and an oval ſilver box, not only as ſhining, but alſo as round, becauſe it had not corners: he likewiſe knew, and called by its name, a white ſtone mug, on the firſt day he obtained his ſight, diſtinguiſhing it from a baſon, becauſe it had a handle. Theſe experiments were made in the preſence of two reſpectable perſons, as well as myſelf; and they were ſeveral times repeated, to convince us that we could not be miſtaken in them. I mention the circumſtance, however, with much diffidence, being aware that the obſervations not only differ from thoſe that are related of Mr. Cheſelden's patient, but appear, on the firſt ſtatement, to oppoſe a principle in optics, which I believe is commonly and juſtly admitted, that the ſenſes of ſight and feeling have no other connection than that which is formed by experience; and, therefore, that the ideas derived from feeling can have no power to direct the judgment, with reſpect either to the diſtance or form of viſible objects. It ſhould be recollected, however, that perſons who have cataracts in their eyes, are not, in ſtrictneſs of ſpeech, blind, though they are deprived of all uſeful ſight. The inſtances I have adduced prove, that the knowledge they have of colours is ſufficient to give them ſome idea of diſtance, even in their darkeſt ſtate. When, therefore, their ſight is cleared by the removal of the opaque cryſtalline, which intercepted the light, and the colour of objects is thereby made to appear ſtronger, will it be difficult, or unphiloſophical, to conceive that their ideas of diſtance will be ſtrengthened, and ſo far extended as to give them a knowledge, even of the outline and figure of thoſe objects with the colour of which they were previouſly acquainted?"

The miſeries of blindneſs are feelingly deſcribed both by Homer and Milton, in the following impreſſive paſſages. The venerable father of epic poetry, who is ſaid, in the perſon of Demodocus the Phœacian bard, to have deſcribed his own ſituation, proceeds thus:

"Τὸν περὶ Μοῦσ' ἐφίλησε, δίδου δ' ἀγαθόν τε, κακόν τε,
Ὀφθαλμῶν μὲν ἄμερσε, δίδου δ' ἡδεῖαν ἀοιδήν"

Odyſſ. l. Θ. v. 63, 64.

"Dear to the muſe, who gave his days to flow
With mighty bleſſings mix'd with mighty woe,
In clouds and darkneſs quench'd his viſual ray,
Yet gave him pow'r to raiſe the lofty lay." Pope.

In ſimilar ſtrains does Milton bewail his calamity, in his addreſs to light:—

"Taught by the heav'nly muſe to venture down
The dark deſcent, and up to re-aſcend,
Though hard and rare; thee I reviſit ſafe,
And feel thy ſov'reign vital lamp: but thou
Reviſit'ſt not theſe eyes, that roll in vain
To find thy piercing ray, and find no dawn:
So thick a drop ſerene hath quench'd their orbs,
Or dim ſuffuſion veil'd. Yet not the more
Ceaſe I to wander, where the muſes haunt
Clear ſpring, or ſhady grove, or ſunny hill,
Smit with the love of ſacred ſong: but chief
Thee, Sion, and the flow'ry brooks beneath,
That waſh thy hallow'd feet, and warbling flow,
Nightly I viſit; nor ſometimes forget
Thoſe other two, equall'd with me in fate,
So were I equall'd with them in renown,
Blind Thamyris and blind Mæonides,
And Tireſias and Phineus prophets old:
Then feed on thoughts, that voluntary move
Harmonious numbers; as the wakeful bird
Sings darkling, and in ſhadieſt covert hid
Tunes her nocturnal note. Thus with the year
Seaſons return; but not to me returns
Day, or the ſweet approach of ev'n or morn,
Or ſight of vernal bloom, or ſummer's roſe,
Or flocks, or herds, or human face divine:
But cloud inſtead, and ever during dark,
Surrounds me, from the chearful ways of men
Cut off, and for the book of knowledge fair
Preſented with an univerſal blank
Of nature's works to me expung'd and ras'd,
And wiſdom at one entrance quite ſhut out."

Paradiſe Loſt, b. iii.

Thus alſo does he deplore, in the moſt affecting accents, the misfortune of blindneſs in his "Sampſon Agoniſtes:"—

——"But chief of all,
O loſs of ſight, of thee I muſt complain!

Blind among enemies, O worſe than chains,
Dungeon, or beggary, decrepid age.
Light, the prime work of God, to me is extinct,
And all her various objects of delight
Annull'd, which might in part my grief have eas'd,
Inferior to the vileſt now become
Of man or worm. The vileſt here excel me:
They creep, yet ſee; I dark in light expos'd
To daily fraud, contempt, abuſe, and wrong,
Within doors, or without, ſtill as a fool,
In power of others, never in my own;
Scarce half I ſeem to live, dead more than half.
O dark, dark, dark, amid the blaze of noon,
Irrecoverably dark, total eclipſe
Without all hope of day!
O firſt created beam, and thou great word,
Let there be light, and light was over all;
Why am I thus bereav'd thy prime decree?
The ſun to me is dark,
And ſilent, as the moon
When ſhe deſerts the night,
Hid in her vacant interlunar cave.
Since light ſo neceſſary is to life,
And almoſt life itſelf, if it be true
That light is in the ſoul,
She all in every part; why was the ſight
To ſuch a tender ball as th' eye confin'd?
So obvious, and ſo eaſy to be quench'd?
And not, as feeling, throughout all parts diffus'd,
That ſhe might look at will through ev'ry pore?
Then had I not been thus exil'd from light,
As in the land of darkneſs, yet in light
To live a life half dead, a living death:
And buried; but yet more miſerable!
Myſelf the ſepulchre, a moving grave;
Bury'd, yet not exempt
By privilege of death and burial
From worſt of other evils, pains, and wrongs,
But made hereby obnoxious more
To all the miſeries of life."

The degree in which the calamity of blindneſs is felt and lamented by thoſe to whom it occurs, may be alſo partly gueſſed at by the extaſies into which perſons have fallen on their recovery from it.

Mr. Boyle mentions a gentleman, who, having been blind, and brought to ſight at eighteen, was very near going diſtracted with the joy. See a remarkable caſe of this kind, Tatler, N° 55. vol. i. Boyle's Works abr. tom. i. p. 4.

We find various recompenſes for blindneſs, or ſubſtitutes for the uſe of the eyes, in the wonderful ſagacity of many blind perſons recited by Zahnius in his "Oculus Artificialis," and others. In ſome, the defect has been ſupplied by a moſt excellent gift of remembering what they had ſeen; in others, by a delicate noſe, or the ſenſe of ſmelling; in others, by an exquiſite touch, or a ſenſe of feeling, which they have had in ſuch perfection, that, as it has been ſaid of ſome, they learned to hear with their eyes; as it may be ſaid of theſe, that they taught themſelves to ſee with their hands.

Some have been enabled to perform all ſorts of curious and ſubtle works in the niceſt and moſt dexterous manner. Aldrovandus ſpeaks of a ſculptor who became blind at twenty years of age, and yet ten years after made a perfect marble ſtatue of Coſmo II. de Medicis; and another of clay like Urban VIII. Bartholin tells us of a blind ſculptor in Denmark, who diſtinguiſhed perfectly well, by mere touch, not only all kinds of wood, but all the colours; and F. Grimaldi gives an inſtance of the like kind; beſides the blind organiſt living in Paris, who is ſaid to have done the ſame.

The moſt extraordinary of all is a blind guide, who, according to the report of good writers, uſed to conduct the merchants through the ſands and deſarts of Arabia. James Bernouilli contrived a method of teaching blind perſons to write. Leo Afr. Deſc. Afr. lib. vi. p. 246. Caſnub. Treat. of Enthuſ. chap. ii. p. 45. Fonten. Elog. des Acad. p. 114.

An inſtance no leſs extraordinary is mentioned by Dr. Bew in the "Tranſactions of the Mancheſter Society." It is that of a perſon, whoſe name is John Metcalf, a native of the neighbourhood of Mancheſter, who became blind at ſo early an age as to be altogether unconſcious of light and its various effects. His employment in the younger period of his life was that of a waggoner, and occaſionally as a guide in intricate roads during the night, or when the common tracks were covered with ſnow. Afterwards he became a projector and ſurveyor of high-ways in difficult and mountainous parts; and in this capacity, with the aſſiſtance merely of a long ſtaff, he traverſes the roads, aſcends precipices, explores valleys, and inveſtigates their ſeveral extents, forms, and ſituations, ſo as to anſwer his purpoſe in the beſt manner. His plans are deſigned, and his eſtimates formed, with ſuch ability and accuracy, that he has been employed in altering moſt of the roads over the Peak in Derbyſhire, particularly thoſe in the vicinity of Buxton, and in conſtructing a new one between Wilmſlow and Congleton, ſo as to form a communication between the great London road, without being obliged to paſs over the mountain.

Although blind perſons have occaſion, in a variety of reſpects, to deplore their infelicity, their miſery is in a conſiderable degree alleviated by advantages peculiar to themſelves. They are capable of a more fixed and ſteady attention to the objects of their mental contemplation, than thoſe who are diſtracted by the view of a variety of external ſcenes. Their want of ſight naturally leads them to avail themſelves of their other organs of corporeal ſenſation, and with this view to cultivate and improve them as much as poſſible. Accordingly they derive relief and aſſiſtance from the quickneſs of their hearing, the acuteneſs of their ſmell, and the ſenſibility of their touch, which perſons who ſee are apt to diſregard; and many inſtances have occurred, that ſeem to verify the opinion of Rocheſter;

"That if one ſenſe ſhould be ſuppreſs'd,
It but retires into the reſt."

To this purpoſe we may obſerve, that Democritus is ſaid to have put out his eyes, that he might think more intenſely.

Many contrivances have alſo been deviſed by the ingenious for ſupplying the want of ſight, and for facilitating thoſe analytical or mechanical operations, which would otherwiſe perplex the moſt vigorous mind and the moſt retentive memory. By means of theſe they have become eminent proficients in various departments of ſcience. Indeed, there are few ſciences in which, with or without mechanical helps, the blind have not diſtinguiſhed themſelves. The caſe of profeſſor Saunderſon at Cambridge is well known. His attainments and performances in the languages, and alſo as a learner and teacher in the abſtract mathematics, in philoſophy, and in muſic, have been truly aſtoniſhing; and the account of them appears to be almoſt incredible, if it were not amply atteſted and confirmed by many other inſtances of a ſimilar kind, both in ancient and modern times. Cicero mentions it as a fact ſcarcely credible, with reſpect to his maſter in philoſophy, Diodotus, that "he exerciſed himſelf

in

in it with greater aſſiduity after he became blind; and, which he thought next to impoſſible to be performed without ſight, that he profeſſed geometry, and deſcribed his diagrams ſo accurately to his ſcholars, as to enable them to draw every line in its proper direction.'^ Jerom relates a more remarkable inſtance of Didymus in Alexandria, who, "though blind from his infancy, and therefore ignorant of the letters, appeared ſo great a miracle to the world, as not only to learn logic, but geometry alſo to perfection, which ſeems (he adds) the moſt of any thing to require the help of ſight." Profeſſor Saunderſon, who was deprived of his ſight by the ſmall pox, when he was only twelve months old, ſeems to have acquired moſt of his ideas by the ſenſe of feeling; and though he could not diſtinguiſh colours by that ſenſe, which, after repeated trials, he ſaid, was pretending to impoſſibilities, yet he was able with the greateſt exactneſs to diſcriminate the minuteſt difference of rough and ſmooth in a ſurface, or the leaſt defect of poliſh. In a ſet of Roman medals he could diſtinguiſh the genuine from the falſe, though they had been counterfeited in ſuch a manner, as to deceive a connoiſſeur who judged of them by the eye. His ſenſe of feeling was ſo acute, that he could perceive the leaſt variation in the ſtate of the air; and it is ſaid, that in a garden where obſervations were made on the ſun, he took notice of every cloud that interrupted the obſervation, almoſt as juſtly as thoſe who could ſee it. He could tell when any thing was held near his face, or when he paſſed by a tree at no great diſtance, provided the air was calm, and there was little or no wind: this he did by the different pulſe of air upon his face. He poſſeſſed a ſenſibility of hearing to ſuch a degree, that he could diſtinguiſh even the fifth part of a note; and by the quickneſs of this ſenſe he not only diſcriminated perſons with whom he had once converſed ſo long as to fix in his memory the ſound of their voice, but he could judge of the ſize of a room into which he was introduced, and of his diſtance from the wall; and if he had ever walked over a pavement in courts, piazzas, &c. which reflected a ſound, and was afterwards conducted thither again, he could exactly tell in what part of the walk he was placed, merely by the note which it ſounded. See SAUNDERSON.

Sculpture and painting are arts which, one would imagine, are of very difficult and almoſt impracticable attainment to blind perſons; and yet inſtances occur, which ſhew that they are not excluded from the pleaſiug creative and extenſive regions of fancy. We have known caſes in which the form and features of the face have been delineated wholly by the touch, and in which it has been moulded with the utmoſt exactneſs. De Piles (Cours de Peint. p. 329.) mentions a blind ſculptor, who thus took the likeneſs of the duke de Bracciano in a dark cellar, and made a marble ſtatue of king Charles I. with great juſtneſs and elegance. However unaccountable it may appear to the abſtract philoſophers, yet nothing is more certain in fact, than that a blind man may, by the inſpiration of the muſes, or rather by the efforts of a cultivated genius, exhibit in poetry the moſt natural images and animated deſcriptions even of viſible objects, without deſervedly incurring the charge of plagiariſm. We need not recur to Homer and Milton for atteſtations to this fact; they had probably been long acquainted with the viſible world before they had loſt their ſight; and their deſcriptions might be animated with all the rapture and enthuſiaſm which originally fired their boſoms, when the grand and delightful objects delineated by them were immediately beheld. We are furniſhed with inſtances in which a ſimilar energy and tranſport of deſcription, at leaſt in a very conſiderable degree, have been exhibited by thoſe on whoſe minds viſible objects were never impreſſed, or have been entirely obliterated. Dr. Blacklock affords a ſurpriſing inſtance of this kind; who, though he had loſt his ſight before he was ſix months old, not only made himſelf maſter of various languages, Greek, Latin, Italian, and French, but acquired the reputation of an excellent poet, whoſe performances abound with appropriate images and animated deſcriptions. See BLACKLOCK.

Another inſtance, which deſerves being recorded, is that of Dr. Henry Moyes in our own country, who, though blind from his infancy, by the ardour and aſſiduity of his application, and by the energy of native genius, not only made incredible advances in mechanical operations, in muſic, and in the languages, but acquired an extenſive acquaintance with geometry, optics, algebra, aſtronomy, chemiſtry, and all other branches of natural philoſophy. From the account of Dr. Moyes, who occaſionally read lectures on philoſophical chemiſtry at Mancheſter, delivered to the Mancheſter ſociety by Dr. Bew, it appears, that mechanical exerciſes were the favourite employment of his infant years; and that at a very early age he was ſo well acquainted with the uſe of edge-tools, as to be able to conſtruct little windmills, and even a loom. By the ſound, and the different voices of the perſons that were preſent, he was directed in his judgment of the dimenſions of the room in which they were aſſembled; and in this reſpect he determined with ſuch a degree of accuracy, as ſeldom to be miſtaken. His memory was ſingularly retentive; ſo that he was capable of recognizing a perſon on his firſt ſpeaking, though he had not been in company with him for two years. He determined with ſurpriſing exactneſs the ſtature of thoſe with whom he converſed, by the direction of their voices; and he made tolerable conjectures concerning their diſpoſitions, by the manner in which they conducted their converſation. His eyes, though he never recollected his having ſeen, were not totally inſenſible to intenſe light; but the rays refracted through a priſm, when ſufficiently vivid, produced diſtinguiſhable effects upon them. The red produced a diſagreeable ſenſation, which he compared to the touch of a ſaw. As the colours declined in violence, the harſhneſs leſſened, until the green afforded a ſenſation that was highly pleaſing to him, and which he deſcribed as conveying an idea ſimilar to that which he gained by running his hand over ſmooth poliſhed ſurfaces. Such ſurfaces, meandering ſtreams, and gentle declivities, were the figures by which he expreſſed his ideas of beauty; rugged rocks, irregular points, and boiſterous elements, furniſhed him with expreſſions for terror and diſguſt. He excelled in the charms of converſation; was happy in his alluſions to viſual objects; and diſcourſed on the nature, compoſition, and beauty of colours, with pertinence and preciſion. This inſtance, and ſome others which have occurred, ſeem to furniſh a preſumption, that the feeling or touch of blind perſons may be ſo improved, as to enable them to perceive that texture and diſpoſition of coloured ſurfaces by which ſome rays of light are reflected and others abſorbed, and in this manner to diſtinguiſh colours. But the fact is ſtill undecided; and farther trials are neceſſary, in order to ſet aſide high authorities to the contrary, and abſolutely to decide it. Dr. Reid, in his "Inquiry into the Human Mind on the Principles of Common Senſe" (ch. vi. § 2.), deduces evidence from acknowledged facts, as well as reaſoning, in order to ſhew, that there is very little of the knowledge acquired by ſight, that may not be communicated to a man born blind. One who never ſaw the light may be learned and knowing in every ſcience, even in optics; and may make diſcoveries in every branch of philoſophy. He may underſtand as much as

another man, not only of the order, diſtances, and motions of the heavenly bodies, but of the nature of light, and of the laws of the reflection and refraction of its rays. He may underſtand diſtinctly, how thoſe laws produce the phenomena of the rain-bow, the priſm, the camera obſcura, and the magic lanthorn, and all the powers of the microſcope and teleſcope. Nevertheleſs, as to the appearances of colour, a blind man muſt be more at a loſs, becauſe he has no perception that reſembles it; though, by a kind of analogy, he may ſupply even this defect. To thoſe who ſee, a ſcarlet colour ſignifies an unknown quality in bodies, that exhibits to the eye an appearance which they have often obſerved, and which they well know; but to a blind man, it denotes an unknown quality that exhibits an appearance, with which he is unacquainted. But he can conceive the eye to be variouſly affected by different colours, as the noſe is by different ſmells, or the ear by different ſounds: thus, he can conceive ſcarlet to differ from blue, as the ſound of a trumpet does from that of a drum; or, as the ſmell of an orange differs from that of an apple. It is impoſſible to know whether ſcarlet colour has the ſame appearance to me which it has to another man; and if its appearances to different perſons differed as much as colour does from ſound, they might never be able to diſcover this difference. Hence it is plain, that a blind man might talk for a long time about colours diſtinctly and pertinently; and if you were to examine him in the dark about the nature, compoſition, and beauty of them, he might be able to anſwer, ſo as not to betray his defect. After all, as a blind man has never had any ſenſation of light and colour, his knowledge concerning them, however extenſive and accurate, muſt be the reſult of previous inſtruction; it muſt depend on the force of genius, or on the ſtrength of memory; and his language concerning coloured objects muſt be like that of a parrot, without any preciſion of meaning, and without any correſponding ideas. On this diſputed ſubject the reader may derive information from Diderot's "Lettre ſur les Aveugles a l'uſage de ceux qui voyent," or "A Letter concerning the Blind for the uſe of thoſe who ſee," in his "Works," vol. ii.; and they alſo may conſult Cheſelden's "Anatomy," and Locke's "Eſſay on the Human Underſtanding."

With regard to the ſcientific and practical departments of muſic, every age has ſupplied numerous inſtances of blind perſons who have attained to great excellence. They will occur among the articles of muſical biography in the courſe of this work.

Of the contrivances that have been deviſed for the aſſiſtance of the blind, we have already mentioned thoſe of profeſſor Saunderſon, and of Mr. Grenville, under the article *Palpable* Arithmetic. We ſhall here ſubjoin, from a letter addreſſed by Dr. Moyes to the editor of the "Encyclopædia Britannica," an account of the palpable notation generally uſed by him for twenty years, for the purpoſe of aſſiſting his memory in numerical computations. With this view he made uſe of a ſquare piece of mahogany, a foot broad and an inch thick, repreſented by A B C D (*Plate* I. *Algebra, fig.* 3.); he divided each of the ſides AB, BC, CD, DA, into 24 equal parts; joined each pair of oppoſite diviſions by a groove cut in the board of ſufficient depth to be felt with the finger; and perforated the board at each interſection with an inſtrument $\frac{1}{10}$th of an inch in diameter. Having thus divided the ſurface of the board into 576 ſmall ſquares, perforated at each of their angles, he fitted to the holes in the board three ſets of pegs or pins, reſembling thoſe in the plate, *figs.* 4, 5, 6, in ſuch a manner, that when fixed in them they kept their poſition, and required ſome force to turn them round. The head of each peg belonging to the firſt ſet is a right-angled triangle, about $\frac{1}{10}$th of an inch thick; the head of each peg belonging to the ſecond ſet differs from the former merely in having a ſmall notch in its ſloping ſide or hypothenuſe; and the head of each peg of the third ſet is a ſquare, the breadth of which ſhould be equal to the baſe of the triangle of the other two. Theſe pegs ſhould be kept in a caſe conſiſting of three boxes or cells, each cell being allotted to a ſet; and the caſe muſt be placed cloſe by the board before the commencement of every operation. Each ſet ſhould conſiſt of 60 or 70 pegs, at leaſt when employed in long calculations; and when the work is finiſhed, they ſhould be collected from the board, and carefully reſtored to their reſpective boxes. When a peg of the firſt ſet is fixed into the board, it will acquire four different values, according to its poſition with reſpect to the calculator. When its ſloping ſide is turned towards the left, it denotes *unit*, or the firſt digit; when turned upwards, or from the calculator, it denotes 2, or the ſecond digit; when turned to the right, it repreſents 3; and when turned downwards, or towards the calculator, it denotes 4. The number 5 is denoted by a peg of the ſecond ſet, having its ſloping ſide turned to the left; 6, by the ſame turned upwards; 7, by the ſame turned to the right; and 8, by the ſame turned directly down, or towards the body of the calculator. The figure 9 is expreſſed by a peg of the third ſort, when its edges are directed to right and left; and the ſame peg expreſſes the cypher 0, when its edges are directed up and down. By theſe different pegs the relative values of the ten digits may therefore be diſtinctly expreſſed with facility; and by a ſufficient number of each ſet the ſteps and reſult of the longeſt calculation may be clearly repreſented to the ſenſe of feeling. For an example, let it be required to expreſs the year of the Chriſtian æra 1788. Take a peg of the firſt ſet, and fix it in the board, with its ſloping ſide turned towards the left, which repreſents 1; take a peg of the ſecond ſet, and fix it in the next hole in the ſame groove, proceeding as uſual from left to right, with its ſloping ſide turned to the right, and this expreſſes 7; take again a peg of the ſame ſet, and fix it in the next hole, with its ſloping ſide turned downwards, and this will repreſent 8; and laſtly, take another peg of the ſame ſet, and place it in the next hole in the ſame poſition, which will denote 8; and thus the whole will expreſs the number required. In order to expreſs a vulgar fraction, the numerator is placed in the groove immediately above, and the denominator in that immediately below the groove in which the integers ſtand; and in decimal arithmetic, an empty hole in the integer groove repreſents the comma, or decimal point. By ſimilar breaks are alſo denoted pounds, ſhillings, pence, &c.; and by the ſame expedient, the diviſor and quotient in diviſion are ſeparated from the dividend. "This notation," ſays the ingenious inventor, "which ſupplies me completely with co-efficients and indices in algebra and fluxions, ſeems much ſuperior to any of the kind hitherto made public in the weſt of Europe. That invented and deſcribed by Mr. Grenville, having no leſs than ten ſets of pegs, is by much too complicated for general practice; and that which we owe to the celebrated Saunderſon, is apt to puzzle and embarraſs the calculator, as the pegs repreſenting the numerical digits can ſeldom or never be in the ſame ſtraight line."

It redounds very much to the honour of modern times, that the public attention has been directed to the improvement of the condition of blind perſons; and that inſtitutions have been formed in different countries for providing them with ſuitable employment, tending not only to alleviate their calamity, but to render them uſeful. The firſt regular and ſyſtematic

ſyſtematic plan for this purpoſe was propoſed by M. Haüy in an "Eſſay on the education of the Blind," printed at Paris in the year 1786, under the patronage of the Academy of Sciences. An Engliſh tranſlation of this eſſay is annexed to "Dr. Blacklock's Poems," printed at Edinburgh in 1793, 4to. The object of this plan is to teach the blind reading, by the aſſiſtance of books, in which the letters are rendered palpable by their elevation above the ſurface of the paper; and by theſe means to inſtruct them, not only in the liberal arts and ſciences, but likewiſe in the principles of mechanical operations, ſuch as ſpinning, knitting, book-binding, &c. ſo that thoſe who are in eaſy circumſtances may be capable of amuſing employment, and thoſe of the lower ranks of life, and ſuch as have no genius for literary improvement, may nevertheleſs, become reſpectable, uſeful, and independent members of ſociety, in the ſituation of common artiſans. By theſe palpable characters, they are taught to read, to write, and to print; and they are likewiſe inſtructed, according to their ſeveral talents and ſtations, in geometry, algebra, geography, and every branch of natural philoſophy. The inſtitution encourages and cheriſhes a taſte for the fine arts; it teaches the blind to read muſic with their fingers, as others do with their eyes; and it does this with ſo much ſucceſs, that though they cannot at once feel the notes and perform them upon an inſtrument, yet they are capable of acquiring any leſſon with as much exactneſs and rapidity, as thoſe who enjoy all the advantages of ſight. Of this curious and intereſting eſſay, now before us, we ſhall give ſuch an account as may ſerve to gratify thoſe of our readers, who are concerned in the ſupport of plans, ſomewhat reſembling that which it deſcribes, in our own country. The author, after ſtating the object of his plan, and obviating the ſcruples of thoſe who demur againſt allowing its general utility, in the two firſt chapters, proceeds, in the third chapter, to illuſtrate the method of reading, as adapted to the practice of the blind. This method conſiſts, as we have already obſerved, in the uſe of typographical characters, whoſe elevation above the ſurface of the paper renders them obvious to the touch, without the intervention of ſight. From the perception of typographical characters, the tranſition is not difficult to that of written characters; i. e. of characters not written with ink, but formed by impreſſions made upon ſtrong paper with an iron pen, whoſe point is not ſlit. The characters, thus produced, are diſtinctly ſeparated and inverted; and they are marked on the ſide of the paper contrary to that which is read, and in ſuch a manner that the poſition and order of the letters may appear right and in relievo, when the page is turned. The blind may thus be able to form and decypher muſical characters, mathematical diagrams, and all the neceſſary proceſſes of arithmetic and geography, as well as thoſe that are printed and written. In the fourth chapter the author replies to ſeveral objections that are urged againſt the method of reading he has propoſed. The fifth and ſixth chapters contain an account of the art of printing, as it is practiſed by the blind, for their peculiar uſe, and alſo as it is performed for the uſe of thoſe who ſee. In the proceſs of printing, the blind compoſitor has a box for every alphabetical character in uſe; on the outſide of theſe boxes are palpably marked the peculiar character belonging to each; theſe are filled with types, which he ſelects and ſets as they are wanted, but in a contrary poſition to that in which they are read. When the types have been arranged and fixed, a page of very ſtrong paper is moiſtened, ſo as to be capable of receiving and retaining impreſſions, and laid upon the types; and then by the operation of the preſs, or by the eaſy ſtrokes of a ſmall hammer frequently repeated over the ſurface, the impreſſion of the type is made to riſe on the oppoſite ſide of the paper; and it continues, when dry, not only obvious to the ſight but to the touch, and is not eaſily effaced. On the upper ſide of the paper the letters appear in their proper poſition; and by their ſenſible elevation above the common ſurface, the blind may eaſily read them with their fingers. The ſeventh chapter explains the method of teaching the blind to write; which we have already noticed. The eighth chapter ſhews how they are taught arithmetic; for this purpoſe they are provided with a board pierced with different lines of ſquare holes, proper for receiving moveable figures, and bars for ſeparating the different parts of an operation. To render this board more uſeful, a caſe is added, compoſed of four rows of little boxes, which contain all the figures proper for calculation, and which are placed at the right hand of the blind perſon while he operates. In order to obtain characters for expreſſing all the poſſible fractions, 10 ſimple denominators are caſt, in the order of the figures 0, 1, 2, &c. to 9 incluſively, and likewiſe 10 ſimple numerators in the ſame order, moveable, ſo as to be adapted at the head of the denominators. By means of this combination, the blind are able to expreſs any fraction. The ninth chapter treats of geography; and in teaching it, M. Weiſſenbourg and Mad. Paradis marked the circumference of countries by a tenacious and viſcid matter, and covered the different parts of their maps with a kind of ſand mixed with glaſs, in various modes; and diſtinguiſhed the order of towns by grains of glaſs, of a greater or leſs ſize. M. Haüy ſatisfies himſelf with marking the limits of the maps, for the uſe of the blind, by ſmall iron wire rounded; and it is always a difference, either in the form or ſize of every part of a map, which aſſiſts his pupils in diſtinguiſhing the one from the other. For the purpoſe of teaching muſic, the ſubject of the tenth chapter, muſical characters are caſt; and theſe are ſo numerous, as to repreſent upon paper, by elevations on its ſurface, all the poſſible varieties that occur. The eleventh chapter contains an account of the mechanic arts, in which the blind are employed, and of the method in which they are formed for ſuch occupations. Accordingly they have been ſucceſsfully employed in ſpinning, in making pack-thread of the thread they have ſpun, in weaving girths with this pack-thread, in making nets, in ſewing, in binding books, &c. In the twelfth chapter we have a view of the proper mode of inſtructing the blind, together with a parallel between their education and that of the deaf and dumb. This operation, it is ſaid, is eaſy in itſelf, and requires in a maſter more courage than knowledge. "By the aid," ſays M. Haüy, "of our books in relievo, every one can teach them to read. Upon the muſical works found in our preſs, every profeſſor of that art may give them leſſons. With an iron pen, with plates and moveable characters, executed according to our models, the firſt maſter in writing may teach them that art, and arithmetic." The thirteenth chapter contains a brief account of the elementary books of languages, mathematics, and hiſtory, which ſhould compoſe the library of the blind perſon. The eſſay terminates with an hiſtorical ſummary of the riſe, progreſs, and actual ſtate of the inſtitution for blind children. The ſucceſs of this inſtitution has fully anſwered the expectations of its founder, and amply compenſated the expence beſtowed upon it by the liberal and well-diſpoſed. We are happy to add, that inſtitutions of a ſimilar kind have been eſtabliſhed in our own country; and to render our particular tribute of reſpect to the founders and ſupporters of the "School for the Indigent Blind," inſtituted in London in 1799. It is now ſituated in St. George's-fields, but will ſpeedily be removed to Gray's Inn-lane, as ſoon as the neceſſary buildings for its accommodation are erected. The object, with a view to which this ſchool was founded, is unqueſtionably one of the moſt important and intereſting kind

that

that can excite compaſſion, or demand encouragement. It provides inſtruction for the indigent blind, in a trade, by which they may be able to provide, either wholly or in part, for their own ſubſiſtence; and thus, inſtead of being altogether a burden to the community, they will be of ſome ſervice to it; and inſtead of being depreſſed and cheerleſs themſelves, under a ſenſe of their total dependence, and for want of regular employment, habits of induſtry will relieve their ſpirits, and produce the moſt beneficial effects on their ſtate and character. The children of this inſtitution, amounting in the preſent year (1804) to 32, are completely clothed, boarded, lodged, and inſtructed, gratis. The articles at preſent manufactured in the ſchool are ſhoemakers'-thread, fine and coarſe thread, window faſh-line, and cloaths'-line (of a peculiar conſtruction, and made on a machine adapted to the uſe of blind perſons), by the females; and window and faſh-line, cloaths'-line, hampers, and wicker baſkets, by the males. The ſucceſs that has crowned the efforts of the friends of this inſtitution, ſince its firſt eſtabliſhment, affords ſufficient evidence of the degree in which the ſituation and faculties of the blind are capable of improvement; and a view of it in its preſent proſperous ſtate, muſt be gratifying to perſons of humane and compaſſionate feelings. Here they will not find the ſcholars ſitting in liſtleſs indolence, which is commonly the caſe with the blind, or brooding in ſilence over their own defects, and their inferiority to the reſt of mankind; but they will behold a number of individuals, of a claſs hitherto conſidered as doomed to a life of ſorrow and diſcontent, and to be provided for merely in alms-houſes, or by donations of charity, not leſs animated in their amuſements, during the hours of recreation, and far more cheerfully attentive to their work in thoſe of employment, than perſons poſſeſſed of ſight. This important and uſeful inſtitution is under the direction of a preſident, eight vice-preſidents, a treaſurer, and a committee of 24 members. A ſubſcription of one guinea annually, or of not leſs than 20 guineas at once, or within one year, conſtitutes a member.

To this article we ſhall ſubjoin the following directions given by Mr. Thickneſſe, for teaching the blind to write:

"Let any common joiner make a flat board, about 14 inches long, and 12 wide; in the middle of which let a place be ſunk, deep enough, when lined with cloth, to hold only two or three ſheets of fool's-cap paper, which muſt quite fill up the ſpace: over this muſt be fixed a very thin falſe frame, which is to cover all but the paper, and faſtened on by four little pins, fixed in the lower board: and acroſs the lower frame, juſt over the paper, muſt be a little ſlider, an inch and a half broad, to ſlip down into ſeveral receſſes made in the upper frame, at a proper diſtance for the lines, which ſhould be near an inch aſunder; and this ruler, on which the writer is to reſt his fourth and little finger, muſt be made full of little notches, at a quarter of an inch diſtant from each other; and theſe notches will inform the writer, by his little finger dropping from notch to notch, how to avoid running one letter into another. When he comes to the end of the line, he muſt move his ſlider down to the next groove, which may eaſily be ſo contrived with a ſpring to give warning that it is properly removed to the ſecond line, and ſo on."

Blindness, in the *Veterinary Art*, a diſeaſe very frequently happening to horſes. The eye of the horſe is ſubject to various diſeaſes which may occaſion blindneſs, as the *cataract*, the *gutta ſerena*, opacity of the cornea or its coverings, &c.

The diſorder, however, generally inducing blindneſs among horſes is the *cataract*, and the inflamation of the external parts of the globe of the eye, which precedes the obſcuration of the cryſtalline, is termed blindneſs, as though the diſeaſe was really confirmed; and horſes ſo affected are conſidered as ſuch, and denominated blind, though at this period of the diſeaſe the ſight is only rendered imperfect.

This deſtructive diſorder, in general, commences with an inflammation of the outer coats of the eye, as the *membrana conjunctiva*, or *cornea*, or both together, and extending gradually to the interior, inflames and deſtroys the tranſparency of the cryſtalline, and obſtructs the admiſſion of light.

Theſe attacks of inflammation not unfrequently diſappear for a time, or, at leaſt, become much leſs diſtinguiſhable, and then return again, obſerving ſomething like regular periods of acceſſion and remiſſion; and from hence the diſeaſe has been termed by ſome the *moon blindneſs*, and theſe changes were conſidered as under the influence of this planet, and correſponding with the periods of its change; there are, however, other cauſes more powerful in their influence, to which theſe changes in this diſorder may, with more appearance of truth, be attributed, as improper expoſure to exceſſive cold, or drafts of air; to a cloſe, low, over-heated ſtable, or ſudden alternations from the one to the other; violent exerciſe and ſweating; then waſhing with cold water, leaving the hair drenched with it; acrid volatile ſalts riſing from the dung; overfeeding with too hot, dry, and ſtimulating food, and all other cauſes inducing an increaſed action of the heart and arteries, naturally tend to induce a recurrence of this complaint.

As this diſeaſe is one of the moſt intereſting in the veterinary art, and the moſt neceſſary to be well underſtood, as well by profeſſional men, as by dealers and poſſeſſors of horſes, we ſhall deſcribe at ſome length the appearances by which it is known to exiſt, and the means that have hitherto been employed, as far as they have come to our knowledge, for the removal of it. Thoſe who may deſire to be acquainted reſpecting the information poſſeſſed by the ancients of this complaint, and their practices for its cure, may be referred to the writings of Abſyrtus and Vegetius: the latter, in his elegant work *de arte Veterinaria*, lib. 2. cap. xvi. *de ſuffuſione oculorum*, has divided this diſorder into three kinds, under the titles *ſtenochoriaſis*, *protochoriaſis*, *hypochoriaſis*; by his definitions, however, of theſe three kinds, it appears that he only meant the different ſtages of the formation of the cataract, from the firſt inflammation of the eye, to the cryſtalline becoming perfectly opake and burſting its capſule; ruſhing to the anterior chamber of the eye, and reſting, like a white opake ball, againſt the cornea; occaſioning a total loſs of ſight, and which he compares to the yolk of an egg burſting from its ſituation in the centre of the egg, and to which it can never be again reduced. He conſiders the cauſe of this complaint to be the rupture of the membrane containing the ſight; by exceſſive heat, or more certainly from the fatigue of a long journey, or the neglected injury of the eye, from the inattention of the maſter. His *hypochoriaſis*, which appears to be the firſt ſtage of this diſorder, he ſays, deſcends from the head, and often ſhews itſelf in one eye, and then migrates to the other, and is attended with a flow of water or tears. His treatment, in this caſe, is to bleed often from the eye-brow, or rather the eye-lids, and from the temples; to foment frequently with warm water in which rue and fennel ſeeds have been boiled; to anoint the eye "*cum collyrio opopanato et opobalſamato.*" He alſo recommends applying the actual cautery to the temples above the veins. This author, in another chapter, recommends, in this complaint, that you ſhould inſpect the noſtril on the ſame ſide with the morbid eye, and you will find

find a small opening, through which, by inserting a pipe, you may fill the eye with wine, and relieve the disorder; a remarkable proof of the minute and accurate observation of the ancients. The existence of such an opening (for it is, in reality, the opening of the lacrymal duct that is alluded to), is not known to many who profess to practise on the diseases of horses at this day.

Absyrtus, a Greek writer, who lived about the reign of Constantine the Great, and prior to Vegetius, recommends, in this disorder, and which he calls *ναλωμα*, that the ear should be pierced with an awl, and a piece of white hellebore should be inserted in the perforation for its relief.

The following we venture to give as a more natural and true description of the appearances of the eye, during the presence of this complaint, than what has before been exhibited; though, no doubt, subject to many omissions and imperfections, which future observations may lead us to rectify.

The earliest indication of this disease is exhibited by the external transparent parts of the ball of the eye becoming obscured, assuming a blackish glassy hue; sometimes blue, or brown, or a dull white, and streaked with blood, according to the degree of inflammation or distension of the blood-vessels; admitting, according to their capacity, the different parts of the blood which are not transparent; and this inflammation, it may be remarked, takes place more frequently in young horses of five or six years old, than in those of a more advanced age, and the upper half of the *cornea* generally appears more obscured than the lower; this, however, may be a deception, arising merely from the point of vision, the observer being placed below the eye, and seeing directly through the lower part, and more obliquely through the upper. The blood-vessels also may be observed increased in number and size, passing over the opake white surface of the sclerotica, to the *cornea* and *conjunctiva;* for it has not, as far as we know, been ever ascertained from actual dissection or experiment, whether it is the cornea that is inflamed, or the conjunctiva, or both; nor is it absolutely necessary for the treatment, that this should be known.

The eye and eye-lids feel hotter to the hand than usual; and often times there is a deposit of a white matter resembling pus, in the bottom of the anterior chamber of the eye, which, perhaps, proceeds from the vessels of the ciliary fringe, or uvea, which are large in the horse.

After this opacity of the cornea has existed some time, the eye of itself, or still more certainly if antiphlogistic means are used, returns to its natural brilliancy, and the disorder seems removed; a few weeks or months may elapse before its return; and if these remedies are had recourse to very early, the disorder may even be permanently removed; it very frequently, however, returns, and again disappears, and this several times before the inflammation of the crystalline, and the destruction of sight take place. In other subjects, one uninterrupted course of inflammation, without any interval, takes place, till the cataract is fully formed.

When this morbid process begins in the crystalline, the inflammation of the exterior parts of the eye often disappears, and they assume their usual brightness, and afford us an opportunity of distinctly observing the changes which take place in the lens.

And, with respect to the cataract itself, or this opacity of the lens, we may remark, that the whole crystalline shall assume this milky appearance at once, or a small speck only near the centre shall be seen, which often remains for years, without the least perceivable increase, and without producing blindness, or any sensible detriment to the animal: again, in other cases, no speck is observable but whitish lines which reflect the light, stretching like rays from the centre of the lens to its circumference; and sometimes the capsule containing it is said to be only affected.

The cataract, as it is called, being fully formed, the complete opacity of the lens being established, and light no longer admitted, the iris begins to lose its properties, nearly closing up the opening of the pupil; from its relaxation, the whole eye becomes diminished, and apparently sunk in the head; and the capsule, especially in draft horses, bursts, and the lens is forced from its situation, and falls to the anterior chamber of the eye, resembling, as we have before observed, an opake white ball.

As perfect clearness and distinctness in all parts of the eye, with a due contraction of the pupils, are the most certain indications of its goodness, so the slightest dulness or opacity in the external coats, or diminution of the pupil, should lead the purchaser to be cautious; for it cannot be too often observed, that this opacity, after it has been of some standing, is almost certain destruction to the eye; and there are no remedies at this time known that can prevent its fatal termination, though numerous attempts and experiments have been instituted with this view; and the operation for the cataract is useless in the horse; for if it succeeds, the vision is still so imperfect, that blindness itself is preferable.

Though various useful offices can be found for horses that have lost their sight; yet it is of importance, for most of the purposes to which they are applied, that it should be preserved. We cannot recommend with too much force, the necessity of an early recurrence to the prescribed remedies for destroying the inflammation; for, at its very commencement, it has probably only the characters of common inflammation, and might be entirely and effectually subdued as in other parts; but neglected, this disorder soon assumes its peculiar properties, arising, perhaps, from the particular structure and functions of the parts affected, and in a short time becomes perfectly beyond the reach of any remedy; for though, no doubt, there are a few insulated instances where this disorder has been removed, yet, as the termination of the generality of cases is of an opposite nature, it would be unwarrantable to make a conclusion from such cases of the general possibility of cure in this complaint.

Where the inflammation has not yet received the specific properties above described, the following remedies will frequently remove it; and in more confirmed cases, we shall mention the means that have been unsuccessfully employed to remove it, that we may shew the insufficiency of such attempts, and promote farther experiment and research respecting it.

In the commencement of this complaint, the use of abstinence from heating food, or hard exercise; exposure to stables of cooler temperature, and well aired, not from partial drafts, but their loftiness only; exclusion of too much light, or the light altogether; diluent drinks, and purgatives; such may be employed to the general system. To the part itself, washes of cold water, or ice and water, or litharge water, or with a small portion of opium dissolved in it; others think more favourably of stimulating, or caustic washes, as weak solutions of vitriolated zinc, very dilute acids, and even spirits and water.

Blisters applied to the cheek, or over the masseter muscle, produce an irritation which is very successful in removing this inflammation, and, in particular, the insertion of a seton or two in the muscular parts surrounding the eye, care being taken that the fascia over the muscle is divided, otherwise

otherwiſe there is no ſuppuration; theſe will tend, as we have experienced, powerfully to carry off an attack of this diſorder. Firing with a hot iron has alſo been employed with the ſame view, on the ſurrounding ſkin; and likewiſe blood-letting from the jugular vein, or from the temporal artery, or locally from the veſſels proceeding from the inner canthus, or anterior angle of the orbit; as alſo the veſſels paſſing over the ſclerotic coat, which become very much enlarged and viſible in this diſeaſe, as well as thoſe in the lining of the lids.

Mr. Coleman, the very ingenious profeſſor of the veterinary college, ſeared up the veſſels of the ſclerotica with a hot iron, forming an entire circle round the ball of the eye, at ſome diſtance from the cornea, to prevent all acceſs of blood to this part, and ſo endeavoured, mechanically, to put a ſtop to the inflammation; it was found, however, inſufficient to deſtroy the diſorder, and we believe that any hope of relief from this mode of treatment has ſince been abandoned; and for this reaſon, perhaps, this experiment has proved inſufficient, that when communication is ſtopped from the exterior veſſels, there are others whoſe trunks are ſhort of theſe, which ſupply the ſubſtance of the cornea; and others again, out of our reach, on the inſide of the cornea; but above all, the habit in the parts to diſeaſe, and the diſpoſition in the ſyſtem to generate it, are not overcome, and the morbid tendency is not thereby deſtroyed.

The farriers, who practiſe medicine, in treating this complaint, often remove the lacrymal gland, which they call the haw, from its ſuppoſed reſemblance to this fruit; and as this part partakes of the inflammation, and is much ſwelled, they miſtake it for the ſource of the diſorder. The removal of it, which is eaſily done, by drawing it out with a hook, and cutting it off, occaſions a copious diſcharge of blood, which, in ſlight attacks, relieves the eye, and encourages them in this practice; but from our own perſonal experience we have learned, that in caſes of any duration, it is totally inadequate to the removal of the complaint, and the eye muſt obviouſly ſuffer from the loſs of a part that is neceſſary to its well-being: and means leſs injurious to the eye may be equally well employed with as much ſucceſs, ſuch as we have before pointed out.

An infuſion of the *polygonum hydropiper* injected into the noſtril, ſo as ſlightly to inflame the membranes, produces very good effects in this complaint.

It has been obſerved, that in the human eye, long continued inflammations of the exterior coats rarely produce cataracts, as they do in the horſe; and the reaſon that has been aſſigned for this is, that the ſame blood-veſſels which ſupply the *tunica conjunctiva* and *cornea*, alſo ſupply the lens and the humours of the eye, which they ſay is not the caſe with the human, as theſe parts are ſupplied from the eyelids and integuments; there is, however, in the horſe, a ſingular propenſity to inflammatory complaints, and to this diſpoſition, perhaps, it is rather to be attributed.

In the inflammation of the cornea, which is attended with a black, gloſſy appearance of this part, there is ſeldom any increaſed diſcharge of tears from the eye and noſe; but in the other kinds which we have before enumerated, there is, in general, a conſiderable increaſe of this ſecretion. When blood-ſtreaks, or blotches appear, it is probable that the veſſels are ruptured, and that this blood is really in a ſtate of extravaſation.

BLINK *of the ice*, in *Sea Language*, denotes that bright, white appearance produced by the ice near the horizon, and perceptible, in approaching the ice, long before it is itſelf ſeen. This phenomenon has been often remarked by mariners, and is particularly mentioned in Phipps's (lord Mulgrave's) voyage to the North Pole, p. 70.

BLINKS, in *Botany*. See MONTIA.

BLINKS, among *Ancient Sportſmen*, denoted boughs broken down from trees, and thrown in the way where deer are likely to paſs, to hinder their running, or rather to mark which way a deer runs, in order to guide the hunter.

BLINKING *of beer*, in Lincolnſhire, ſignifies letting the wort ſtand for ſome time in the vat, till it hath acquired ſome degree of acidity, in order to diſpoſe it to fine, and be the ſooner ready for drinking.

BLISSOM, among *Huſbandmen*, corruptly called *bleſſom*, is the act of a ram when coupling with an ewe.

BLISTER, in *Pharmacy*. Bliſters are raiſed on the ſurface of the body for medicinal purpoſes, by applying, for a number of hours, ſome of the moſt active of the animal or vegetable ſtimulants. Of theſe, by far the moſt convenient, and that which is almoſt univerſally employed, is the *cantharis*, or *Spaniſh fly*, (MELOE *Veſicatorius*.) Theſe inſects are found in Spain, Italy, and the ſouth of Europe; they have a longiſh body, beautifully brilliant with green and gold. They are gathered, by ſhaking the trees which they frequent, and are killed by the vapour of ſpirit of wine burnt beneath them, or by the fumes of vinegar, after which they are dried in a ſtove. In this ſtate they are brought over without further preparation.

Cantharides poſſeſs ſo much acrimony, that in reducing them to powder, the face ſhould be covered with a maſk, to prevent the troubleſome ſneezing and excoriation of the fauces, from the finer duſt flying about. Taken internally, in an over-doſe, they inflame the whole inteſtinal canal, in a greater or leſs degree; and they have a peculiar tendency to irritate the urinary organs. Applied to the ſkin, they firſt inflame the part, but often, with ſcarcely any attending pain; after which they produce a very copious bliſter of clear, yellowiſh ſerum beneath the cuticle, which riſes in a large bag. This inſect appears to poſſeſs this veſicating property in a much larger degree, in proportion to the pain excited, than any other ſtimulant; and hence its peculiar utility in producing this ſerous diſcharge with the leaſt poſſible inconvenience to the patient. It is not exactly known in what part of the inſect the veſicating property reſides, or whether it does not equally belong to every part. It is not eaſily deſtroyed, or impaired by long keeping, if the inſect be unbruiſed, and preſerved in a dry place.

For bliſtering the ſkin, the cantharides are firſt finely powdered, and then incorporated, with ſome labour, with a ſimple mixture of wax and reſin melted together, to which ſome add a little vinegar, and allowed to grow nearly cold before the flies are added. This is a neceſſary precaution, ſince it is certainly known that a conſiderable heat impairs the bliſtering property. The plaſter, thus made, ſhould be of ſuch a conſiſtence, as readily to ſoften with a moderate heat. When uſed, it is generally ſpread uniformly upon leather, of the requiſite ſize and ſhape, by the aſſiſtance of an iron ſpatula, warmed ſcarcely more than the hand can bear.

To increaſe the effect, ſome apothecaries ſprinkle the plaſter with powdered cantharides, after it is ſpread on the leather, but this is not neceſſary, where the plaſter itſelf is good; and the powder is apt, after veſication, to lodge on the tender cutis, and produce much needleſs irritation. As the bliſtering plaſter adheres very looſely to the ſkin, it is uſeful in applying it to children, to maniacal perſons, and wherever it is danger of being too ſoon pulled off, to ſurround the bliſter with a margin of ſtrong adheſive plaſter.

The plaſter of cantharides ſeldom fails to produce a large bliſter, in ten or twelve hours; but its operation continues ſometimes longer, ſo that it may be conveniently ſuffered to remain for twenty-four hours, the large cuticular bags being punctured to let out the fluid. When the plaſter is taken off, and the ſerum moſtly diſcharged, the bliſtered part ſhould be dreſſed with ſpermaceti, or ſome other mild ointment, unleſs it be intended to keep up the ſerous diſcharge by ſtimulating applications.

The pain produced by the action of cantharides varies greatly, according to the part affected, the thickneſs of the ſkin, and the general irritability of the conſtitution, and in particular of the ſurface of the body. Moſt frequently the pain is very ſlight, often amounting to no more than a ſenſe of heat on the part. When very acute, it is of great ſervice to remove the plaſter, when it has been on about two hours, to anoint the part with oil or cream; and about an hour or two after, to replace the bliſtering plaſter, which will then often proceed to veſicate without much further irritation.

The operation of cantharides is much affected by the thickneſs of the ſkin beneath; and hence the ſcalp reſiſts veſication more than the ſofter ſkin of the abdomen; and particularly by the heat of the body, ſo that the plaſter ſhould be ſtronger, and its conſiſtence ſofter, when applied to an unuſually cold ſurface.

Sometimes, though rarely, the ſymptoms of ſtrangury produced by this active medicine, follow even its external application.

A more active veſicatory is ſuppoſed to be made, by adding other ſtimulating ſubſtances to the cantharides plaſter. In the Paris Pharmacopœia, euphorbium (the moſt acrid of all the medicinal gums) is added in equal quantity with the cantharides: in the Edinburgh, verdigris, muſtard, and black pepper are uſed.

It is often of advantage to keep up a diſcharge from a bliſtered part for a conſiderable time. It then becomes gradually purulent. For this purpoſe, a milder form of cantharides is highly uſeful, and a ſofter conſiſtence is given to it. This may be done by mixing a ſmall portion of the flies in powder, with any ſimple ointment; but this is liable to act unequally, and the entire particles of the fly ſometimes create trouble, by lodging upon the tender cutis. To remedy this, the London college uſe a watery infuſion of cantharides, mixed with a ſtimulating reſin ointment, melted, and continued over a ſlow fire, till all the water is evaporated, leaving a ſmall portion of extractive matter of the flies, equally diffuſed through the ointment, and ſtrongly increaſing its ſtimulating power.

A few other ſubſtances have been occaſionally uſed to produce veſication. One of theſe is the inner bark of the *Mezereon*, (Daphne *Mezereum*) and of another plant of the ſame genus, the *Thimelæa Laureola*, or *Spurge Laurel*, (Daphne *Laureola*) both ſhrubby plants, well known in gardens. The uſe of the latter (which will equally apply to the mezereon) is thus directed in the Paris Pharmacopœia. Small twigs of the plant, about the ſize of a pen, and ſmooth, are ſelected, and cut tranſverſely into portions of the requiſite length. Theſe are ſteeped in milk-warm water, or in vinegar, for about half an hour, to looſen the bark, which is then peeled off with a pen-knife, and the wood is thrown away. This bark is applied to the ſkin to be bliſtered, previouſly rubbed with vinegar.

In twenty-four hours a perfect veſication is produced, with little pain, and without the poſſibility of thoſe ſymptoms of ſtrangury, which now and then attend the uſe of cantharides.

BLISTERED, *bullatus*, in *Botany*, is applied to the ſurface of a leaf, which riſes high above the veins, ſo as to appear like bliſters.

BLISTERING *of horſes*, in the *Veterinary Art*, a remedy much in uſe for promoting the removal of a great variety of diſorders; more eſpecially, however, in reducing morbid enlargements of bone, or morbid thickenings of any of the ſofter parts, where its utility is principally obvious.

The veſication of the ſkin of the horſes is attended with ſome remarkable circumſtances, in which it differs from the human, eſpecially in the greater irritability of the ſkin; for the cuticle of the horſe is raiſed by a bliſter of leſs ſtrength, than is required in raiſing the human cuticle; whence, perhaps, it may be inferred, that its ſenſation alſo is more acute. It is probable that the ſkins of animals covered with hair are, in general, more irritable than naked ſkinned animals; the ſpirits of turpentine producing a moſt painful irritation, both in the horſe and the dog, when applied to the ſkin, but not ſo in the human.

Irritants, however, of the ſkin, without any bliſtering, or veſication, may be had recourſe to with very great advantage, in the veterinary art, as they can, without injury to the parts, be very frequently renewed, and with the happieſt effects.

The mildeſt applications of this deſcription, are the animal and vegetable oils; as hog's-lard, and the oil expreſſed from linſeed, or olives: where more irritation is thought requiſite, the addition of the eſſential oil of origanum, or the ſpirits of turpentine, will readily afford it.

Lard alone, rubbed on the ſkin of the horſe, we have often obſerved to produce a ſenſible irritation and increaſed warmth in the part, ſo ſuſceptible is this part in theſe animals; and may ſerve as a baſis from which we may proceed to the higher degrees of ſtimulus, firing the ſkin with the actual cautery, in lines more or leſs cloſe, being the higheſt degree of irritation to which we can or ought to proceed.

That irritation which is produced by the cantharides, is, of all others, we believe, the moſt uſeful in its effects. It ſhould be applied, mixed with lard, or olive-oil; to which it is uſual to add the dried juice of the euphorbium; as, however, it is ever deſirable to avoid unneceſſary complication in the remedies we preſcribe, by which our effects are rendered more certain, and the inductions more eaſy and clear, ſo we propoſed to try this medicine by itſelf, to aſcertain its preciſe effects; and being mixed with olive-oil, it was applied to the ſkin of the leg of the horſe: no diſtinct veſication of the part followed, but it produced a conſiderable heat, and formed a brown ſcab, with very little diſcharge of ſerum; but, on the contrary, was particularly dry and irritating to the horſe. We have ſince omitted it in the bliſter, and, we believe, without the ſmalleſt detriment to its operation; for the cantharides, when they act properly, and are not applied too ſtrong, produce a plentiful veſication, and a copious diſcharge of thick ſerum, almoſt of the conſiſtence of honey.

We have found alſo the pyro-ligneous acid, or the acid obtained by the diſtillation of wood, in cloſe veſſels, and properly concentrated, a cutaneous irritant, of very uſeful qualities. After the ſkin has been ſimply wetted with it, it ſlightly inflames it; and the cuticle, after two or three days, comes away dry, bringing with it any foulneſs of the ſkin, for the removal of which it is moſt particularly ſerviceable.

We have known ſome, from motives of economy, omit the cantharides in their bliſter, and uſe, inſtead of it, vitriolic acid. It, in general, as far as we have ſeen, forms a dry, black ſcab, and is by no means ſo agreeable in its effects as the former.

It is a common habit with farriers practiſing medicine, to mix corroſive ſublimate with their bliſter; and, where it may be deſirable to deſtroy the ſkin, this ſhould be uſed, but not otherwiſe; for it is no veſicatory, but a moſt violent cauſtic, ſoon deſtroying any living matter with which it comes in contact; and we have ſeen, from the ignorant uſe of it, the moſt deplorable effects, by its bringing off extenſive ſloughings of the ſkin, and even penetrating to the parts beneath, and ſo injuring them, as ever after to render the horſe unſerviceable.

There is an effect produced by the cantharides on the ſkin of the horſe, which, as far as we know, has not met with much attention; though it is very remarkable, and not analogous to its effects on the human ſkin: it is that prodigious thickening of the integuments, after the operation of the bliſter, which ſometimes does not ſubſide for many weeks, being a great diſfigurement: a bliſter, therefore, if one could be deviſed not producing theſe effects, would be a deſirable thing in the veterinary Pharmacopœia. This effect, we ſhould, however, remark, is not conſtant.

BLITAS, Las, in *Geography*, a cluſter of ſmall iſlands in Nicaragua lake, in Spaniſh North America.

BLITH. See Blyth.

BLITHE, a river of England, which runs into the Trent, 4 miles N. E. of Litchfield.

BLITUM, from Βλιτον, *abjiciendum, fit only to be thrown away*, in *Botany*. Lin. Gen. n. 14. Schreb. 18. Juſſ. 86. Chenopodio-Morus, Boerh. Morocarpus, Rupp. Eng. *Blite*. Fr. *Blète*. Claſs and Order, *Monandria digynia*. Nat. Ord. *Holoraceæ*. *Atriplices*, Juſſ. Gen. Char. *Cal.* perianth three-parted, ſpreading, permanent; diviſions ovate, equal, two more gaping than the other. *Cor.* none. *Stam.* filaments ſetaceous, longer than the calyx, within the middle diviſion, erect; anther twin. Piſt. germ ovate, acuminate; ſtyles two, erect, gaping, the length of the ſtamen; ſtigmas ſimple. *Per.* capſule very thin, rather the cruſt of the ſeed, ovate, a little compreſſed, contained within the calyx now become a berry. *Seed* ſingle, globular, compreſſed, the ſize of a capſule.

Eſſ. Char. *Cal.* trifid. *Pet.* none. *Seed* one, with a berried calyx.

Species 1. B. *capitatum*, berry-headed ſtraw-berry blite, Lin. Spec. 6. Reich. 11. Hall. helv. n. 1571. Morocarpus capitatus. Scop. Carn. n. 3. Atriplex. Bauh. pin. 119. n. 7. Prodr. 58. n. 2. Ger. emac. 326. n. 8. Park. 748. f. 1. Mor. hiſt. 2. 606. f. 5. t. 32. f. 11. Raii hiſt. 197. n. 5, 7. "Heads ſpiked terminal." An annual plant, with leaves reſembling thoſe of Spinach, and ſtalk riſing, in gardens, about 2½ feet high; but in a wild ſtate, upright and only about a foot high; flowers on the upper part iſſuing in ſmall heads at every joint, and terminated by a cluſter of the ſame; when the flowers are paſt, theſe heads ſwell to the ſize of wood-ſtrawberries, and when ripe have the ſame appearance, full of a purple juice, which ſtains the hands, and formerly much uſed in cookery, for colouring puddings, &c. ſeed black when ripe: commonly called ſtrawberry blite, ſtrawberry ſpinach, or bloody ſpinach, and, by ſome, berry-bearing orach. A native of Swiſſerland, the Griſons, Auſtria, the Tyrol, Spain, and Portugal; cultivated by Parkinſon, in 1633. 2. B. *virgatum*, ſlender-branched ſtrawberry blite. Lin. ſpec. 7. Reich. 12. Gmel. ſib. 3. 16. Atriplex. Bauh. pin. 119. n. 6. Mor. t. 32. f. 10. Raii hiſt. 197. n. 6. "Heads ſcattered, lateral." Seldom growing more than one foot high, with ſmaller leaves than the former; flowers produced from the axils, almoſt the whole length of the ſtalk; ſmall, and collected into little heads, ſmaller than the firſt, and not ſo deeply coloured, but of the ſame ſhape. A native of the ſouth of France, Spain, Italy, and Tartary. 3. B. *tataricum*. Mill. Dict. n. 3. B. fragiferum maximum polyſpermum. Amm. ruth. "Leaves triangular, ſharply toothed; heads ſimple, lateral." Riſing near three feet high; flowers axillary, in ſmall heads; fruits of the ſame ſhape and colour with thoſe of the firſt, but ſmaller; differing from it in the ſhape and indentures of the leaves; and in having leaves placed between the fruits the whole length of the ſtalk, not terminated by heads, as the firſt, but having leaves above the heads. Probably a variety of the ſecond ſort. The ſeeds were ſent to Mr. Miller by Dr. Amman, profeſſor of botany at Peterſburgh. 4. B. *chenopodioides*. Linn. Syſt. Reich. 12. Mant. 170. "Heads in whorls, juiceleſs." A low plant, reſembling chenopodium. A native of Tartary; now in Sweden. Probably only a variety; and in reality the four ſorts ſeem to be but one.

Propagation and Culture. All are annual plants, which drop their ſeeds, that will produce plentifully the following ſpring; or if the ſeeds of any one of them be ſown in March or April, upon a bed of common earth, in an open ſituation, the plants will come up in a month or ſix weeks, and remaining in the ſame place, will require no other care beſides being kept from weeds, and thinned out to the diſtance of ſix or eight inches apart; and in July the plants will begin to ſhew their berries, which will make a pretty appearance. By many they are tranſplanted into the borders of the flower garden, and by others planted in pots, ſo as to be ready for removal into the court-yard, or for being placed upon low walls for ornament. When theſe plants are deſigned to be removed, they ſhould be tranſplanted before they ſhoot up their flower-ſtems, for they will not bear tranſplanting afterwards; and when planted in pots, they muſt be watered in dry weather; and, as the flower-ſtems advance, they ſhould be ſupported by ſticks. Martyn.

Blitum. See Achyranthes, Amaranthus, Chenopodium, and Gunnera.

BLOATED *fiſh*, or *herring*, in our *Statutes*, are thoſe which are half dried. Vide Stat. ann. 18 Car. II. c. 2.

Bloated herrings are made by ſteeping them in a peculiar brine, and then hanging them in a chimney to dry.

BLOATING, in *Medicine*. See Leucophlegmatia, and Œdema.

BLOCH, Mark Eleazar, in *Biography*, a Jewiſh phyſician at Berlin, and a celebrated ichthyologiſt, was born at Anſpach in Franconia. His parents were in a condition ſo obſcure and deſtitute, that they were ſcarcely able to maintain him during his infancy, and much leſs to procure for him any ſuitable means of education. At the age of 19 he underſtood neither German nor Latin; and as he had read only a few Rabbinical books, he ſpoke a kind of Franconian gibberiſh, intermixed with the Jewiſh jargon. About this time, however, he was taken into the houſe of a ſurgeon at Hamburgh, who was a Jew, and employed by him in the inſtruction of his children; and in this ſituation he acquired a competent knowledge of the German language. The ſavings of his ſcanty ſalary enabled him to procure aſſiſtance in the ſtudy of Latin. Having alſo gained ſome knowledge of ſurgery, he repaired to Berlin, where his relations lived, with a view of proſecuting the ſtudy of anatomy. After ſtruggling with various difficulties, he was admitted as doctor in the univerſity of Franckfort, and returned to Berlin for the exerciſe of his profeſſion. Here he became acquainted with M. Martini, who recommended him to be elected a member of the Society of the Friends of Nature. In order to promote the objects of this inſtitution, he undertook a natural hiſtory of the muræna, a fiſh caught, as it was ſuppoſed, only in the lakes of Pomerania. He alſo began to form a cabinet of natural hiſtory; and having made a conſiderable collection

of

of aquatic animals from all parts of the globe, he determined to write a natural hiſtory of fiſhes; and in this deſign he was encouraged and aided by obtaining poſſeſſion of the original MSS. of father Plumier, who had made three voyages to America, and brought with him many objects highly intereſting to the natural hiſtorian. M. Bloch firſt publiſhed, in German, four numbers of an "Economical Natural Hiſtory of Fiſhes, particularly thoſe in the ſtates of Pruſſia, with figures from original drawings;" Berlin, 1781 and 1782, large 4to. In the following years appeared an "Economical Natural Hiſtory of the Fiſhes of Germany," in 3 volumes, conſiſting of 108 plates, and including the three numbers already mentioned. He afterwards publiſhed, in 9 volumes, "The Natural Hiſtory of foreign Fiſhes;" ſo that his whole work was comprehended in 12 volumes, and contained 432 plates. The laſt appeared in 1795. He alſo, at his own expence, procured a French tranſlation of his work, by C. Laveaux, then at Berlin, which he publiſhed under the title of "Hiſtoire general et particuliere des Poiſſons," Berlin, 1785—1788, in 6 vols. folio, with 216 plates. In order to defray the expence of this work, his only ſon, a young man diſtinguiſhed by his talents, undertook a tour through France and England for the purpoſe of procuring ſubſcriptions; and in the proſecution of his journey died at Paris, in 1787. This loſs, and the embarraſſment of his circumſtances, preyed upon the ſpirits of this ingenious naturaliſt, and ſunk him into the deepeſt affliction. However, he ſtill continued to employ himſelf in his favourite work, the hiſtory of fiſhes, and having completed it, undertook a journey to Paris. He died at Carlſbad in Bohemia, Auguſt 6th 1799. Beſides the above voluminous works, Mr. Bloch publiſhed many memoirs on ſubjects of natural hiſtory, in the tranſactions of different ſocieties. That on the muræna, in the Memoirs of the Friends of Nature, has been already mentioned; he alſo communicated, in the ſame Memoirs, "Obſervations on the regular depreſſions in vitriform ſtones;" "On the worms in the inteſtines and lungs of birds;" "An Eſſay towards the natural hiſtory of the worms which live in other animals;" "On worms of the bladder;" "Deſcription of the buſtard, and ſome kinds of birds found in marſhes;" "On the oil of herrings;" "On the vulgar opinion that the organ of generation in the ray and ſhark is double;" "On the myxina glutinoſa of Linnæus," &c.

BLOCK, Daniel, an eminent portrait-painter, was born at Stettin in Pomerania, in 1580, and educated for his profeſſion under Jacob Scherer. As a painter of portraits, he gained great reputation, and had the honour of painting the portraits of Chriſtian IV. king of Denmark, and of Guſtavus Adolphus, king of Sweden. His merit recommended him to the prince of Mecklenburg, in whoſe ſervice he was retained for 44 years, and for whom he painted the portraits of his whole family, at full length, as large as life, and in the antique habit. By the agreeable manner of his colouring, and the eaſy attitudes of his figures, he obtained ſo much employment, as to enable him, before the decline of his life, to amaſs a large fortune; of which, however, he was unfortunately deprived by a plundering party, preſerving, with great difficulty, his own life. He died in 1661. Pilkington.

Block, Jacob Roger, was born at Gouda, where he acquired the art of painting, particularly in reference to perſpective and architecture, which he principally cultivated. Having ſpent ſeveral years in Italy, where he imbibed that taſte of grandeur and elegance in his compoſitions, by which he was advanced in the public eſteem above all his contemporaries, he returned to his own country, and was appointed ſtate-painter to the archduke Leopold, whom he attended in all his campaigns; but whilſt he was paſſing a ſmall rivulet, over a bridge of planks to view the fortifications of St. Vinox in Flanders, his horſe ſlipped, and he was unfortunately drowned. Whilſt he lived at Gouda, he was viſited by Reubens, who, having examined his works, teſtified to his honour, that he had not ſeen any painter in the Netherlands, who could ſtand in competition with him for the ſubjects he painted. The time of his birth and death are not aſcertained. Pilkington.

Block, Benjamin, ſon of Daniel Block, was born at Lubeck in 1631, and, with a view of improving himſelf in colouring and deſign, reſided for ſome time at Rome, Venice, and Florence. Having thus acquired a good taſte, and a pleaſing tone of colouring, he was introduced to the court of Saxony, where he painted ſeveral portraits of the elector and prime nobility; and he alſo painted ſeveral altar-pieces for the churches and convents of Hungary, which are much commended. His capital performance is the portrait of Kircher the Jeſuit, which, even at Rome, was exceedingly admired. The time of his death is not aſcertained. Pilkington.

Block is uſed for a piece of marble as it comes out of the quarry, before it has aſſumed any form from the hand of a workman.

Block, in the *Mechanic Arts*, a large piece of ſolid wood, whereon to faſten work, or to faſhion it; ſtrength and ſtability being the requiſite properties.

In this ſenſe we ſay a chopping block; a ſugar-ſiner's block; a ſmith's block, on which his anvil is faſtened; an executioner's block, on which the criminal's head is laid to be ſtruck off.

Block, *Mounting*. See Anabathra.

Block, among *Cutters of Wood*, is a form made of pear-tree, box, or other hard and cloſe grained wood, free from knots, on which they cut their figures in relievo, with knives, chiſſels, &c. The like are in uſe for card-making; and from the ſame firſt aroſe the modern art of printing. Phil. Tranſ. N° 310. p. 2398.

Block, among *Bowlers*, the mark which is aimed at, being a ſmall-ſized bowl laid on the green for this purpoſe; it is called alſo the *jack*.

Block, in *Falconry*, denotes the perch whereon a bird of prey is kept. This is to be covered with cloth.

Block *Iſland*, in *Geography*, called by the Indians "Maniſſes," lies about 21 miles S.S.W. of Newport, in Newport county, and ſtate of Rhode iſland. It was erected into a townſhip, named "New Shoreham," in 1672. This iſland is 46 miles in length, and its extreme breadth is 38 miles. It has 682 inhabitants, including 47 ſlaves. It is famous for cattle and ſheep, butter and cheeſe; and round its coaſts are caught conſiderable quantities of cod-fiſh. The ſouthern part of it is in N. lat. 41° 8′.

Block, in *Naval Architecture*, denotes an eight ſquare, or round part below the heeling of the main and fore top-maſts.

Blocks are ſhort pieces laid under a maſt to raiſe it from the ground.

Blocks are alſo pieces of wood belonging to ſhips, in which the ſhivers, or ſheaves, of pullies are placed, and wherein the running ropes go. Accordingly they poſſeſs the properties and powers of pullies, and they have from one to eight ſheaves. The blocks in general uſe are the ſingle block, the double block, the treble block, and the four-fold block; but when heavy weights or bodies are to be raiſed or moved, blocks with a greater number of ſheaves are applied, the increaſing power being as two to one for every ſheave moving with the object. See Pulley.

Blocks differing from the common ſhape are the bee-block, the check-block, the long-tackle-block, the main-ſheet-block, the monkey-block, the nine-pin-block, the rack-block, the

ſhoe-block, the ſhoulder-block, the ſiſter-block, the ſnatch-block, the ſtrap-bound-block, the viol-block, and the warping-block. The principal parts of blocks are their ſhells, ſheaves, and pins, which are of various ſizes and powers, according to the effect which they are to produce. The dimenſions of the ſhells, and the thickneſs and number of the ſheaves, are proportioned to the ſize of the ropes working in them, and the powers required. The ſheaves turn abreaſt of each other in the ſhell, on one axis or pin, or one above another, on ſeparate pins. The ſhell is made of elm or aſh, and hollowed between the cheeks, with one or more ſheave-holes to receive the ſheave or ſheaves. On the outſide of the cheeks of blocks that are to be ſtrapped, one ſcore is cut towards the ends, in which part of the ſtrap is buried; if they are double-ſtrapped, they have two ſcores. A hole is bored through the centre to admit the pin; which, paſſing through both ſides of the ſhell, forms the axis for the ſheaves. The ſheave is a ſolid cylindrical wheel, and round its circumference is a groove, one-third of the thickneſs of the ſheave deep, in which the rope works. It is commonly made of lignum vitæ; but for laborious purpoſes, it is coaked in the middle with metal, or elſe made of caſt metal; if the ſheave is iron, it is coaked with braſs, and if of braſs, with the hardeſt bell-metal. The hole in the centre is ſomewhat larger than the pin. The pin is made of lignum vitæ, cocus, greenheart, which is a wood imported from the Weſt Indies, or iron, and it is the axis on which the ſheaves turn.

The proportions for ſingle, double, treble, fourfold blocks are as follow; viz. the length is eight times the breadth of the ſheave-hole, which is one-ſixteenth of an inch more than the thickneſs of the ſheave; and this is one-tenth more than the diameter of the rope for which it is intended, and the diameter of the ſheave is five times the thickneſs. The breadth of the block is ſix times the thickneſs of the ſheave, and the thickneſs about one half the length. Flat thin blocks are three-eighths of the length thick; but all blocks, having more than one ſheave, are increaſed in thickneſs more than in the above proportion by the additional number of ſheave-holes, and middle-parts or partitions; the thickneſs of each partition being one-ſixth leſs than the breadth of the ſheave-hole. Theſe dimenſions are variable, according to the uſes for which blocks are intended. Very large and four-fold blocks are formed of ſeparate pieces, as the cheeks, partitions, &c.; and when thus made, they are denominated "made-blocks." The ſhells of blocks are firſt ſawed to their length, breadth, and thickneſs; and the corners or angles are taken off. The workman then gauges the ſize of the ſheave-hole in the middle, one ſixteenth larger than the thickneſs of the ſheave, and once the thickneſs longer than the diameter, for a ſingle-ſheaved block. In blocks of two ſheaves, the partition is kept in the middle, and is one-ſixth leſs than the ſheave-hole; each ſheave-hole is gauged equally on each ſide, and ſo for all blocks with a greater number of ſheaves. The blocks are then jambed up edgeways with wedges in a clave, and the ſheave-holes are made in this manner: the length and breadth are firſt gouged out, and holes are bored half way through the block, along the part gouged out, with an augre of the ſize of the ſheave-hole; then the ſheave-hole is gouged and bored on the oppoſite ſide in the ſame manner, ſo as to meet the oppoſite holes. Blocks from 10 inches and upwards have one hole bored at each end, and cut through with a chiſſel; and the wood is ſawed out with a rib-ſaw. All blocks have the ſheave-holes cleared through by chiſſels, and by burrs at the corners. Blocks that are to have iron ſtraps, ſhould have the ſtrap fitted on before the wood is cut out of the middle. The hole for the pin is bored through the middle of the block, one-tenth leſs than the diameter of the pin. The outſides and edges of the ſhell are next rounded off by the ſtock-ſhave, and neatly finiſhed by the ſpoke-ſhave. In the royal navy, blocks are left thick upon the edges of the cheeks; but in the merchant-ſhips, the edges are ſometimes thinned off to a ſmall ſquare, and ſometimes rounded off. The ſcores for the ſtraps are gouged out along the outſides of the cheeks, and taper in depth from nothing at the pin to half the thickneſs of the ſtrap at the ends of the block, for a ſingle ſcore, and the ſame on each ſide of the pin for a double ſcore. The ſcores are gouged down, acroſs the breaſt of the block, to half the ſize of the ſtrap, in order to allow for the ſerving. After the ſcore is cut, the ſheaves are fitted; they are one-tenth thicker than the diameter of the rope intended for running on them, and five times that thickneſs in diameter. The hole for the pin ſhould be bored through the centre by a bitt fixed in the mandrel of a turning lathe, or with a ſtock and bitt, and reamed with an augre one ſixteenth larger than the diameter of the pin, that it may eaſily turn; they are then put in a lathe and turned ſmooth, and the outer circumference hollowed one-third of its thickneſs, that the rope may embrace it cloſely. The diameter of the pin is the thickneſs of the ſheave, and is turned in a lathe, except its head, which is left eight ſquare, to prevent its turning in the block, and is driven through the holes in the block and ſheaves. After the ſheaves are fitted, the inſide of the ſheave hole, at the arſe of the block, is gouged hollow, to admit the rope, and correſpond with the ſheave; and a ſmall neat chamfer is taken off the edges.

Blocks, *Bee*, are made of elm, in length ſeven-ninths the length of the bee, in depth two inches for every foot of length, and in thickneſs ſeven-eighths of the depth. A block of this kind is trimmed ſquare, chamfered on the outſide edges, and fitted with a ſheave in one end; and in the other end is cut a hole, to be fitted with a ſheave, in caſe the other ſhould fail. The ſheave-hole is $\frac{2}{7}$ths of the length of the block, and $\frac{1}{4}$th the length of the ſheave-hole in breadth, and half the length of the ſheave-hole within the end. Bee-blocks are bolted to the outer ends of bowſprits, under the bees, and the bolts ſerve like the axis or pin for the ſheaves to work upon; the fore-top-maſt ſtay reeves through the ſheave-hole at the fore-maſt end of the ſtarboard bee-block, and the fore-top-maſt preventer, or ſpring-ſtay, through the ſheave-hole at the after-end of the larboard bee-block.

Blocks, *Brail*, in rigging the mizen-yard, are ſtrapt together in one ſtrap, and lie over the yard, and ſeize together underneath; the throat-blocks next the cleats to the maſt; the middle-blocks in the middle between the throat-block and peek; the peek-blocks about three or four feet within the cleats at the peek.

Blocks, *Bunt-line*, are laſhed in rigging the lower-yards like the leech-line blocks in the middle between them and the ſlings of the yard. Theſe, in rigging the top-ſail yards, are ſpliced round the ſtrap of the top-ſail-tye-block upon the yard.

Block, *Cat*, is employed to draw the anchor up at the cat-head. See Cat-heads.

Blocks, *Cheek*, or half-blocks, are made of elm-plank; the length being twice and a half the depth of the top-maſt head; the breadth is ſeven-eighths of the depth of the top maſt head, and the thickneſs half that depth. The depth of each tenon, and thickneſs of the cheek, when the ſheave-hole is cut, is each three-eighths of the whole thickneſs, ſo that the remaining two-eighths are the ſheave-hole. The three tenons are each two inches ſquare, one in the middle, and one at each end; and the length of the holes is more than the breadth of the block, by the thickneſs of the ſheave. The back of the block is divided into three parts, and one-third on each ſide is bearded down to one-third the thickneſs of the cheek on each edge. Pins of iron are made for faſten-

faſtening them to the top-maſt head, and for durability the ſheave-holes are coppered. Cheek-blocks are bolted to the thwart-ſhip ſides of top-maſt heads, cloſe up under the cap, the bolts ſerve as the pin or axis for the ſheaves to work on; the jib-ſtay and haliards, and fore-top-maſt ſtays, ſail-ſtay, and haliards reeve through the cheek-blocks at the fore-topmaſt-head, and the main-topmaſt-ſtay ſail haliards, and middle-ſtay ſail-ſtay, and haliards reeve through the cheek-blocks, at the main-topmaſt-head.

Blocks, *Clue-garnet*, ſerve to draw the clues, or lower corners of the courſes up to the yards, and are faſtened to the clues of thoſe ſails. In rigging the lower-yards, theſe laſh through the eyes upon the yard; the blocks hanging underneath, four feet without the middle cleats on each ſide. See Clew-*garnet*.

Block, *Clue-line*, in rigging the sprit-ſail yard, are ſtrapped with two eyes, and are laſhed through thoſe eyes round the yard, three feet without the ſlings; the laſhing to be upon the yard. In rigging the ſprit-ſail top-ſail yard, theſe blocks are ſtrapped with two eyes, and are laſhed through thoſe eyes round the yard, about two feet without the ſlings. The clue-line blocks, in rigging the top-ſail yards, are ſtrapt with two laſhing eyes, and laſh upon the yard three feet without the ſlings; the blocks hanging underneath the yard, through which the clue-line reeves, and is ſtrapt with a knot, and leads down upon the deck. In rigging the top-gallant yards, theſe blocks are ſtrapt with two laſhing eyes, and laſh upon the yard three feet without the ſlings. The blocks hang under the yard, through which is reeved the clue-line, which is ſtopt with a knot. The leading-part leads down the maſt, and into the lower ſhrouds. Some ſloops and light-rigged veſſels have no clue-line blocks; they lower the yard.

Blocks, *D*, are lumps of oak in the ſhape of the letter D, from twelve to ſixteen inches long, and eight or ten inches wide. They are thirded and bearded on the back, and the edges beaded. A ſheave-hole is cut through the middle fore and aft. It is bolted to the ſhip's ſide, in the channels, to reeve the lifts, &c.

Blocks. *Deep-ſea-line*, are the ſame as a wooden ſnatch-block (which ſee,) only ſmaller; generally from nine to eleven inches long.

Block, *Derrick*, in rigging the mizen-yard, is ſtrapt with eyes, that go round the yard, and laſh underneath, between the ſlings and the outer yard-arm or peek; the other block is croſs-ſeized into the ſtrap, has an eye ſpliced in each end, and lies upon the mizen cap, and ſeizes or hangs through the eyes under the cap, or upon the upper ſide of it.

Block, *Fiſh*, is hung in a notch at the end of the davit, and ſerves to haul up the flukes of the anchor to the ſhip's bow.

Blocks, *Girt-line*, in rigging the fore-maſt, and main and mizen maſts, are laſhed round the maſt-head, above the ſtop of the cap, one to hang on each ſide. The girt-lines that reeve through them lead down upon deck, for hoiſting the rigging-tops, and croſs-trees, and the perſons employed to place the rigging over the maſt-head.

Blocks, *Leech-line*, in rigging the lower yards, are laſhed round the yard, and through the eye of the ſtrap, ten feet within the cleats on each yard-arm; the blocks hang on the fore part of the yard.

Blocks, *Lift*, in rigging the lower yards, are ſpliced into the ſtrap of the topſail-ſheet blocks; the lifts reeve through the block in the ſpan round the maſt-head, between that and the top-maſt, then lead down abreaſt the ſhrouds, and reeve through a block faſtened to the ſide, and are there belayed. In rigging the topſail-yards, the lift-blocks are ſtrapt with an eye to the ſide of the yard-arm. The lift reeves through the lower ſheave in the ſiſter-block in the topmaſt-ſhrouds, and through the block on the yard-arm. The ſtanding part hooks to a becket round the topmaſt-cap, and the leading part leads down the ſide of the maſt, and belays to the dead-eyes in the lower ſhrouds.

Block, *Long-tackle*, reſembles two ſingle-blocks joined together endways, one being two-thirds leſs than the other. The ſhell is made of aſh or elm, two-thirds longer than the proportion for a ſingle block. Theſe blocks are uſed for tackles, and are made according to the ſize of the rope, as other ſingle blocks. They are uſed in the Royal Navy and Eaſt India ſervice as yard-tackles; but in the merchant ſervice as loading-tackles.

Blocks, *Made*, have the ſhell formed of ſeveral pieces of elm-plank, ſuited to the thickneſs of the cheeks, ſheave-holes, and middle parts, and are ſtrongly bolted together with three bolts at each end, driven through and clenched on a ring at the points. Theſe blocks have flatter cheeks and more ſquare edges than other treble and fourfold blocks. Of this ſort are large treble and four-fold blocks, for heaving down ſhips, or other heavy purchaſes. Smaller made blocks, of modern invention, are formed of two pieces, joining in the middle; the pin working on patent rollers, let into the inſide of the cheeks, which are bolted or rivetted together at the ends. Theſe blocks are thought too complex for the Royal Navy, and are not ſo eaſily remedied in caſe of failure.

Block, *Main-ſheet*, is uſed for the ſheet-tackle of the mainſail-booms of ſmall veſſels, and is ſingle or double; the ſheet or fall being always belayed round the pin. The ſhell is made of aſh or elm, one half longer than the proportion for ſingle or double blocks; the additional length is tapered, and a hole bored through between the ſheaves and the end, to admit the ſtrap; the length of the pin is the length of the block, and is ſimilar to a belaying pin, for which purpoſe it is ſometimes uſed.

Blocks, *Monkey*, are ſometimes uſed on the lower yards of ſmall merchant ſhips, to lead (into the maſt or down upon deck) the running rigging belonging to the ſails. The ſhells are made of aſh or elm; ſome are only ſmall ſingle blocks, attached by a ſtrap and iron ſwivel to iron-ſtraps that embrace and nail to the yard, the block turning to lead the ſmall running-ropes in any direction; others are nearly eight-ſquare, with a roller working in the middle, the ſame as a ſheave, with a wooden ſaddle beneath, to fit and nail to the yard.

Blocks, *Nine-pin*, are uſed to lead the running-ropes in an horizontal direction. The ſhells, made of aſh or elm, reſemble the form of a nine-pin, though flatted on the ſides; their lengths are generally confined to the place in which they are fixed, and this is for the moſt part under the croſs-pieces of the fore-caſtle and quarter-deck bitts. The breadth of the block, ſheave, &c. is governed by the rope, and tapers at the ends to three-eighths of the breadth of the middle; the pin at each end, ſerving as a vertical axis, is two-thirds of the bigneſs of the end. The thickneſs is five-eighths of the breadth. Theſe blocks may be turned in a lathe, and flatted afterwards with a ſpoke-ſhave.

Block, *Quarter*. See *Thick and thin* Block.

Blocks, *Rack*, are a range of ſmall ſingle blocks, made from one ſolid, by the ſame proportions as ſingle blocks, with ends, in form of a dove's tail, for the laſhing, by which they are faſtened athwart the bowſprit, to lead in the running ropes. They are ſeldom uſed.

Blocks, *Shoe*, are two ſingle blocks, cut in a ſolid piece, tranſverſely to each other. They ſerve for legs and falls of the bunt-lines, but are ſeldom uſed.

Block, *Shoulder*, is a large ſingle block, left nearly ſquare at the lower end, or arſe of the block, and cut ſloping

in the direction of the ſheave. Shoulder-blocks are uſed on the lower yard-arms, to lead in the topſail-ſheets; and, on the topſail-yards, to lead in the topgallant-ſheets; and by means of the ſhoulder, are kept upright, and prevent the ſheets from jambing between the block and the yard: they are alſo uſed at the outer end of the boomkins, to lead in the fore-tacks.

Blocks, *Sifter*, are made of aſh, ſimilar to two ſingle blocks, and are turned out of a ſolid piece, about twenty inches long, one above the other; between the blocks is a ſcore for a middle ſeizing: a round head is turned at each end, and hollowed underneath, to contain the end-ſeizings; along the ſides, through which the pins are driven, is a groove, large enough to receive part of the topmaſt-ſhroud, in which it is ſeized. In theſe blocks reeve the lifts, and reef-tackle-pendents, of the topſail-yards.

Blocks, *Slab-line*, in rigging the lower-yards, are ſtrapt with a ſhort laſhing-eye, that ſeizes to the ſpan of the quarter-blocks underneath the yard.

Blocks, *Snatch*, are proportioned by the rope, as a ſingle block, leaving twice the length for the ſcore and laſhing; they taper from the ſheave to the laſhing end, to half the breadth and thickneſs at the ſheave; one ſide of the ſhell is cut acroſs above the ſheave, large enough to admit the rope or fall. In the Royal Navy, ſnatch-blocks are iron-bound, terminating at the ſmall end with a ſwivel-hook, or an eye, large enough to receive ſeveral turns of laſhing; that part of the ſtrap, over the notch in the ſide, lifts up with a hinge, and is confined down, when the rope is in the block, by a ſmall iron hook, or latch, that hooks in the eye of a toggle-holt, and that ſecures the upper end of the ſtrap; the hinged part of the ſtrap goes over the bolt, with a hole in the end; the ſtrap is let into the block its thickneſs, and is confined by the pin and nails; they are uſed for heavy purchaſes, and where a warp, or hawſer, is brought to the capſtern. Snatch-blocks, not iron-bound, have a large hole bored through the tapering end of the ſhell, for the laſhing. They are uſed for the main and fore ſheet blocks of ſquare-rigged veſſels.

Block, *Spring*, a new kind of block, invented by Francis Hopkinſon, eſq. of Philadelphia, and deſigned to aſſiſt a veſſel in ſailing, by increaſing the acting ſpring of her rigging. It is propoſed to apply it to all ſuch parts of the rigging as will admit of it with ſafety and convenience, and where its operation will be moſt advantageous; but particularly to the ſheet ropes, and, if practicable, to the dead-eyes, in lieu of what are called the chains. A (ſee *Plate of Ship*) is a block made in the uſual manner, having a ring, or eye, B, at one end. C, is a ſpiral ſpring, linked at one end to the hook DE, and at the other to the ring F, which is to be annexed by a ſtaple to the timber-head, or by ſome other means to the place where it is to be applied. The ſpring C muſt be of well-tempered ſteel, and proportioned in ſtrength to the ſervice it is to perform. Within the cavity or pipe, formed by the ſpiral ſpring, there muſt be a chain of ſuitable ſtrength, called a check-chain (repreſented ſeparate at G), connected by the links to the hook DE and ring F. When the ſpring is not in action, this chain is ſlack; but when the ſpiral ſpring is extended, by the force of the wind, as far as it can be without danger of injury, the check-chain muſt then begin to bear, to prevent its farther extenſion, and, if ſtrong enough, will be an effectual ſecurity againſt failure.

Fig. 2. repreſents part of the gun-wale of a ſloop, with the ſpring-blocks in action, one of them hooked to a ſtaple in the timber-head, and the other to the corner of the jib.

The inventor of this machine apprehends, that a veſſel thus furniſhed will be leſs liable to heel; and that ſhe will receive the impulſes of the wind to better advantage, and ſail with a more lively and equable motion than if rigged in the common away. Tranſactions of the American Philoſophical Society, vol. III. art. 40.

Blocks, *Strap-bound*, are ſingle blocks, with a ſhoulder left on each ſide, at the upper part, to admit the ſtrap through, a little above the pin. Theſe blocks are uſed at the clues of the ſquare-ſails, for the clue-garnets or clue-lines, and under the yards; the ſhoulder preſerves the ſtrap from chaſing.

Block, *Thick and thin*, or *Quarter*, is a double block, with one ſheave thicker than the other, and is uſed to lead down the topſail-ſheets and clue-lines. In the merchant ſervice they are uſed ſingle, thick and thin. In rigging the lower yards, they are ſtrapt with a long and ſhort leg, with a laſhing eye ſpliced in the ends, and laſh to the yard within the cleats, in the middle of the yard, the block hanging downwards. The long leg comes up the aft-ſide, and meets the ſhort leg on the fore-ſide, and there laſhes through the eyes. Although theſe are uſed for the topſail-ſheets, and intended for the clue-lines, a ſingle block would be cheaper and better; as the thin ſheave is ſeldom uſed for the clue-line, it being found rather to impede than to facilitate. Small ſhips, in the merchant ſervice, have a double block laſhed in the middle of the yard, as the quarter-block, through which the ſheets reeve, and lead down on oppoſite ſides. Large ſhips, in the merchant ſervice, have a ſingle block laſhed on each ſide of the middle of the yard, and the ſheets reeve on their reſpective ſides, and lead down by the maſt. A quarter-block, in rigging the croſs-jack-yard, is ſtrapt with a double ſtrap, with an eye in each of the four ends, and is laſhed upon the yard in the middle between the cleats.

Block, *Top*. See Top-Rope.

Blocks, *Top-Gallant-Sheet*, in rigging topſail yards, are ſtrapt with two laſhing-eyes, and laſh upon the yard, cloſe within the clue-line-blocks on each ſide.

Blocks, *Topſail-Sheet*, in rigging the lower yards, are put over the yard-arms, ſtrapt with an eye of the ſize of the yard-arm.

Blocks, *Tricing*, for the yard-tackles, are ſtrapped with a ſhort laſhing-eye, that ſeizes round the yard about one third of the length within the arm-cleats; the blocks hanging under the yard.

Blocks, *Tye*, in rigging the topſail-yards, laſh at the topmaſt-head cloſe up to the rigging, under the collar of the ſtay, as the lower ones; and the blocks on the yards laſh under the fore-part of the yard, as the lower ones, and reeve with a double tye, in large ſhips, and with a ſingle tye, like the lower, in ſmall ones. The ſtanding-parts of the double tyes clinch round the maſt-head, then reeve through the double block upon the yard, and up again, and reeve through the block on each ſide of the maſt-head. The blocks are then ſpliced in their lower ends, and connected by their haliards to a ſingle block, that is ſtrapt with a long ſtrap, with a hook and thimble, that hooks to a ſwivel-eye-bolt in the channel on each ſide; the leading-part comes in through a block laſhed on each ſide; the foremoſt ones abaft the forecaſtle, and the after ones on the quarter-deck.

Block, *Voyol* or *Viol*, is a large ſingle-ſheaved block; the length is ten times the thickneſs of the ſheave-hole, which is three-eighths more than the thickneſs of the ſheave; the thickneſs of the ſheave is one tenth more than the diameter of the viol, and the diameter of the ſheave is ſeven times the thickneſs. The breadth of the block ſhould be eight times the thickneſs of the ſheave, and the thickneſs two-ſevenths of the length. This block is double ſcored, the

the ſheave is coaked with braſs, and the pin is iron, and nearly as thick as the ſheave. It is uſed in heaving up the anchor. The viol paſſes round the jeer-capſtern, and through the block, which is laſhed to the main-maſt; and the cable is faſtened in a temporary manner to the viol in ſeveral places. It is ſeldom uſed except in the largeſt ſhips of the Royal Navy.

Block, *Warping*, is made of elm or aſh board, ſhaped like the body of a bellows; the ſides or cheeks are $8\frac{1}{2}$ inches broad in the middle, and tapered to 2 inches broad at the ends; the back, or longeſt cheek, is 16 inches long, and $\frac{3}{8}$ths of an inch thick, with a hole bored through the upper end to receive a leathern ſtrap; the upper cheek is 12 inches long, and $\frac{1}{8}$ths of an inch thick, except the lower end, which is $1\frac{1}{8}$ inch thick, and forms the ſheave-hole. The ſheave is $1\frac{1}{4}$ inch thick, and $7\frac{1}{2}$ inches in diameter, made of lignum vitæ, coaked with braſs; it is let into the cheeks one eighth of an inch, to prevent the yarn from getting between the ſheave and the cheeks. The cheeks are faſtened together at the lower end with three ſcrews and nuts; and the pin, which is iron, is ſeven inches long, driven through the middle of the block, with a ſhoulder on the upper ſide, and clinched at the point on the lower ſide of the ſhell; the upper part of the pin is tapered ſmall, and a wooden handle rivetted upon it. The cheeks have a broad chamfer round the outer edges; the inſide edges, and inſide of the block above the ſheave, are lined with thin iron neatly ſcrewed on, to prevent the block from wearing. This block is finiſhed in a neater manner than blocks in general, and is ſeldom uſed but by rope-makers, to warp off the yarn into hauls for tarring.

Blocks, *ſingle*, *double*, or *treble*, in *Rope-making*, are ſtrapped with a hook and thimble, and reeved with a rope, called the tackle-fall, which is uſed to ſtretch the yarn to its full extent, before the preſs is put on, by a capſtern, or crab, at the lower end of the rope-walk. The fall is then belayed, until every yarn is hove through the ſtrands and brought down, ſo that the rope may not exceed the circumference intended. For other blocks, ſee Bulls-*eyes*, Dead-*eyes*, and Euphroes. See *Plates* of *Ships*.

Blocks, *Strapping of*. A ſeventeen-inch block has a five-inch rope ſtrap, and every inch in length above or under, to a twelve-inch block, has half an inch more or leſs ſized rope allowed for the ſtrap; a 11-inch block has a 3-inch ſtrap; a 10 and a 9-inch block, $2\frac{1}{2}$ inches; an 8 and 7-inch block, 2 inches; a 6-inch block, $1\frac{1}{2}$ inch; a 5-inch block, 1 inch; and a 4-inch block, $\frac{3}{4}$ of an inch. The ſcore round iron-bound blocks is taken out to the ſize of the iron ſtrap, ſufficient to bury it, except at the pin. Iron ſtraps are from $\frac{1}{4}$ of an inch to 1 inch in thickneſs, and nearly three times the thickneſs in width; the thickneſs of theſe ſhould correſpond to the ſtrain which they are to reſiſt. The cat-block muſt have a ſtrong ſtrap and large iron hook, which hooks the ring of the anchor in catting. The top block ſhould have a ſtout iron binding, with a ſtrong ſhort hook. Top tackle blocks have ſtrong iron bindings, the upper block with a tackle-hook, and the lower block with a ſwivel-hook. The ſwivel, in iron-bound blocks, ſerves to turn it occaſionally, in order to untwiſt the parts of the rope that form the tackle, as the mechanical power is greatly reduced thereby.

In rigging, the whole length of all the different ſizes of block-ſtrapping is got upon the ſtretch, and hove out tight for worming and ſerving; it is then wormed and ſerved, and cut into ſhorter lengths, to ſuit the different blocks. The ſtrapping of jeer-blocks is wormed, parcelled, and ſerved; ſtrapping of 4 inches diameter, and above, is wormed and ſerved; and all under four inches is only ſerved with ſpun yarn; except the ſprit-ſail brace, bunt-line, and leech line blocks, that are laſhed under the tops, which are only ſerved with ſpun-yarn over the ſplice, and the tail left half a fathom in length. Jeer-blocks are double ſcored, and the double and treble blocks are ſtrapped with a double ſtrap, thus: it is ſpliced together at the ends, and, when doubled, to be the ſize of the block and circumference of the yard; it is then doubled, and the block ſeized in the bight, with a long and ſhort leg; the ſplice lying in the arſe of the block.

The ſcores of all blocks are to be well-tarred, and the pin and ſheave examined, before the ſtrap is put on. The block is ſet well into the ſtrap with wedges, thus: the four parts are frapped together with rope-yarn under the block, with a chock between, and the wedges are ſet between the breaſt of the block and chock. Then the ſtrap is nippered, with a heaver, round the block; the wedges, chock, and frapping, taken away, and the block hung upon the ſtake-head, or poſt, and the ſtrap well ſeized together, cloſe under the block, with nine under and eight riding turns, every turn ſtrained tight round by a heaver, and croſſed each way with two turns.

Jeer-blocks, for the maſt-heads, are ſtrapped with long eyes, to receive many turns of the laſhing; and the block is ſeized into the ſtrap as before, as are all ſeizing blocks, in proportion to their ſizes. The ſtraps are cut agreeable to the following table.

A TABLE of the Dimenſions of Straps for Laſhing and Seizing Blocks.

Size of the Blocks.	Circumf. of the Straps.	Length of the Straps.	
Inches.	Inches.	Feet.	Inches.
17	5	7	4
16	$4\frac{1}{2}$	6	8
15	4	6	0
14	$3\frac{1}{2}$	5	4
13	$3\frac{1}{2}$	4	11
12	$3\frac{1}{2}$	4	6
11	3	4	2
10	3	3	9
9	$2\frac{1}{2}$	3	4
8	$2\frac{1}{2}$	3	0
7	$2\frac{1}{2}$	2	9
6	2	2	6
5	$1\frac{1}{2}$	1	9
4	$0\frac{3}{4}$	1	6

Blocks, ſtrapped with eyes or thimbles ſpliced in the ends, are ſeized tight into the bight, and the legs left long enough to laſh through the eyes, round a maſt, yard, &c. as the top-ſail clue-lines, clue-garnets, and ſpritſail clue-lines, &c.

Blocks ſtrapped with a thimble, or hook and thimble, have the ſtrap ſpliced together at the ends. The block is fixed in one bight, for the ſplice to lay on the arſe of the block, and the thimble in the other bight; the ſeizing is put on, between the block and thimble, with eight under and ſix riding turns, according to the ſize of the block, each turn ſtrained tight by a heaver; the turns double croſſed, and the end ſtopt with a wall-knot crowned.

Blocks ſtrapped with double tails, are fixed in the ſtrap, ſimilar to blocks with eye-ſtraps; and thoſe with a ſingle tail are ſpliced in, and ſerved with ſpun yarn over the ſplice.

Girtline blocks are ſtrapped in the houſe, and the girt-lines reeved. See Elements and Practice of Rigging, &c. vol. i.

Block-*and-Block*, in *Sea-Language*, denotes the ſituation of a tackle, when the effect is deſtroyed by the blocks meeting together.

Block-*wood*, is a name ſometimes given in our laws to logwood. 23 Eliz. c. 9.

BLOCKADE, in the *Military Art*, ſignifies the method adopted in cutting off all communication between a town which it is intended to reduce by famine, and the neighbouring country. It is effected by poſting troops on all the paſſages and avenues leading to and from the place; preventing any ſupplies of proviſions or reinforcements from being thrown in by the enemy, and thus, in courſe of time, ſtarving the garriſon into a ſurrender. A blockade differs from a regular ſiege, inaſmuch as there are no trenches or attacks. Blockades are principally formed by the cavalry. The term probably owes its origin to the German expreſſion *blochus*, or *blockhauſe*, a *bulwark*, or *houſe of wood*; or to the Gauliſh *blocal*, a *barricade*; though others derive it from the Latin *baculare*, ſignifying *to ſtop a paſſage*.

The word is ſometimes uſed in ſpeaking of the commencement of a ſiege, when detachments are ſent forward to ſeize the principal avenues, and occupy the ground on which the beſiegers intend to fix their quarters.

To *raiſe a blockade* is to force the troops, which keep the place blocked up, from their poſts.

The only method of reducing fortreſſes in the more remote ages of antiquity, was by blockade. The town was completely inveſted by a wall of maſonry conſtructed around it, and furniſhed at certain diſtances with redoubts and places of arms; or the beſiegers contented themſelves in ſurrounding it with a deep ditch and intrenchment, well palliſaded, to prevent the garriſon from making ſorties, or any ſuccour or proviſions from being introduced by the adverſary without. In this ſituation the inveſting army tranquilly waited until famine brought about what at that period art and force were unable to accompliſh. From hence proceeds the extreme length of thoſe ſieges chiefly ſpoken of in the more early pages of profane hiſtory; that of Troy, which laſted ten years; that of Azotus, by Pſammetichus, which continued twenty-nine; and that of Babylon, by Cyrus, who, according to Xenophon (Cyrop.), would have been much longer detained before its walls, if a lucky ſurprize had not rendered him maſter of the place. See Babylon.

The ancient Greeks, on foreſeeing that the ſiege of a fortreſs would prove a work of time, often changed it into a blockade. They environed the town with a foſſe and rampart againſt the attempts of the garriſon, and drew another ditch round it towards the country, to oppoſe ſuch troops as might advance to ſuccour the place. The beſiegers eſtabliſhed their camp between the two lines, and thus, in proceſs of time, ſtarved their adverſaries into a capitulation.

In the inſtance of the blockade of Platæa, carried on during the third year of the Peloponneſian war, the works conſtructed by the Lacedæmonians were of a more complex nature. They conſiſted in two walls of ſolid maſonry, built at the diſtance of ſixteen feet from each other, of a reaſonable thickneſs, and covered in at top by a kind of roof or platform. The intervening ſpace formed a ſuite of apartments, in which the troops, deſtined to carry on the blockade, were lodged during the winter. Each of theſe walls was furniſhed with a parapet and battlements, and, at the diſtance of every ten of theſe laſt, was erected a turret with a flat roof, of the breadth of the whole terrace, and capable of making reſiſtance at the ſame time againſt an enemy from within or without. The only method of communication between the different chambers, was by traverſing theſe towers.

The approach to the walls on either ſide was defended by a deep ditch, the earth of which had been uſed in conſtructing the rampart. During the night, guards were kept on the ſeveral towers; centinels were eſtabliſhed at different poſts round the whole extent of the circumvallation; and a corps de reſerve of three hundred men remained always under arms, ready to march on the firſt ſignal wherever there might be occaſion for their ſervices.

This is the moſt remarkable inſtance of a blockade we meet with in the Grecian hiſtory. Notwithſtanding, however, all the precautions above related, and the ſeeming impracticability of flight, the intrepid garriſon of Platæa found means to elude the vigilance of their beſiegers, and, by a well concerted ſortie, about one half of them effected an eſcape acroſs the formidable works of the Peloponneſians, and reached Athens in ſafety. The event is related in a very intereſting and circumſtantial manner by Thucydides in his ſecond book. The Romans firſt imitated, and finally ſurpaſſed the Greeks in this as well as in every other branch of ſcientific warfare. As early as the ſiege of Agrigentum, in the firſt Punic war, we find them dividing their forces, and forming two encampments to block up the place on both ſides; connecting theſe encampments by lines of circumvallation, and braving within theſe defences every effort made to relieve the town by the enemy from without. But theſe lines were equally badly guarded againſt a ſortie with thoſe of Platæa. The Carthaginian garriſon, imitating the former example, ſucceeded in a like manner in forcing a paſſage by night over the intrenchments of the beſiegers. (Polyb. lib. i. c. 17.) The famous blockade of Lilybæum, during the ſame war, which laſted for nearly ten years, is a remarkable inſtance of Roman perſeverance in military undertakings, although, the place being open to receiving ſupplies from the ſea, the aſſiduity of the beſiegers was not attended with ſuch complete ſucceſs as it deſerved. By degrees, however, the Romans improved in the art of reducing fortreſſes by blockade. Syracuſe, which the abilities of Archimedes rendered impregnable by open force, had been thus reduced by Marcellus, but for the treachery of a townſman, which in a great meaſure abridged his labour; and all the military ſcience and manœuvre of the formidable Hannibal was in vain exerted for the preſervation of Capua, during the twelve months the ſiege laſted. (Polyb. Livy.)

The works conſtructed by Scipio Æmilianus for the reduction of Numantia, exceeded in magnitude all which had been raiſed on any former occaſion, and beſides ſurpaſſing them in ſtrength, embraced a much greater extent of ground, than the intrenchments of the Lacedæmonians before Platæa. Numantia was eighty-four ſtadia, or nearly a league in circuit. Scipio, after having inveſted it, drew a circle incloſing twice the area of the circumference of the town; and this work being compleated, he threw up his lines of circumvallation and contravallation at a reaſonable diſtance from each other. Each of theſe fortifications was compoſed of a rampart eight feet thick, and ten in height, defended by ſharp palliſades, and flanked with turrets at a hundred feet diſtant from each other. We can hardly comprehend or credit the immenſe labour of ſuch a circumvallation; but nothing can be better atteſted than theſe facts. (Appian. de Bell. Hiſp.)

Among the numerous exploits of Cornelius Sylla, the blockade of Prænеſte, during his civil war with the party of Marius in Italy, is not to be reckoned the leaſt. The inflexible aſſiduity, with which it was kept up during a long period of time, and preſerved unbroken againſt the bloody and almoſt unintermitted attacks of ſeveral hoſtile armies, ſuperior in number to his own, conveys the higheſt idea of

his

his martial abilities. It was, however, under the auſpices of Julius Cæſar, that this branch of military ſcience attained its higheſt point of perfection among the Romans; and whether we conſult the annals of ancient or modern warfare, we find no example to equal the talents diſplayed by that unrivalled general, in the formation of his immenſe works before Aleſia, and at Dyrrhachium, which have deſervedly excited the wonder and admiration of poſterity.

In the former inſtance, he undertook the arduous taſk of blocking up an army of 80,000 Gauls, doubly ſuperior in number to his own forces, commanded by a general of the greateſt military knowledge, Vercingetorix, and entrenched under the walls of a fortified city, ſituated itſelf on an almoſt inacceſſible mountain. Cæſar's line of contravallation, extending nearly eleven miles, was compoſed of a ditch fifteen feet broad, and as many deep, defended by a rampart twelve feet in height, furniſhed with a parapet, and fortified all round by turrets, at the regular diſtance of eighty feet. The front of the rampart, looking towards the town, was protected by a palliſade of ſharp ſtakes and boughs of trees, interlaced, cut ſharp, and pointing outwards. Before the foſſe were planted five different rows of *cippi*, or large branches ſharpened at the ends, fixed in trenches five feet in depth, and ſo ſtrongly interwoven, as not to be removed or plucked up, without infinite labour. In front of theſe were arranged eight other rows of *lilia*, or pits, three feet deep, diſpoſed in the form of a quincunx, ſtuck thick with ſtrong ſharp ſtakes, and covered over with buſhes to deceive the enemy. Before theſe again were ſcattered up and down numerous ſtakes of a foot in length, faſtened in the earth, and headed with barbed iron hooks, called by the Romans *ſtimuli*. Farther advanced than theſe laſt, at 400 paces diſtance from the rampart, Cæſar drew another ditch, twenty feet broad and deep, to keep the garriſon at a diſtance, and prevent them from annoying his ſoldiers while employed on the contravallation. Not contented with ſuch immenſe labours, he conſtructed the like fortifications towards the country, for the purpoſe of fruſtrating any attempts the expected Gauliſh ſuccours might make for the relief of their beſieged countrymen. Between the lines, a ſpace of nearly half a mile in breadth, was diſpoſed the inveſting army, and their principal encampment was pitched in the moſt convenient ſituation for communicating with every part of the circumvallation. Behind theſe defences did Cæſar baffle the utmoſt efforts of a new army of 250,000 Gauls, ſent to extricate Vercingetorix; and, after a ſeries of the moſt brilliant atchievements ever recorded, obliged the town of Aleſia, and the army incloſed within its walls, to ſurrender at diſcretion. Cæſ. de Bel. Gal. lib. vii.

No leſs famous in hiſtory, though not productive of equal ſucceſs, were the celebrated lines at Dyrrhachium, carried over a tract of fifteen miles, and within which, Cæſar flattered himſelf, to ſurround, and compel to a capitulation, an army exceeding his own in ſtrength, and commanded by the great Pompey. But in this inſtance the conqueror of Gaul had to do with Romans, and the enterprize proved too vaſt for his ſtrength. Pompey, by a ſudden and well-directed effort, broke through the blockade, when it was on the very point of being completed; and had he briſkly followed up the advantage, might, according to Cæſar's own confeſſion, have converted his adverſaries' hopes of ſucceſs into total defeat. Cæſ. de Bel. Civ. lib. iii.

The works thrown up by Auguſtus at Peruſia, and the entrenchments within, which Stilico at Fœſula encloſed, and deſtroyed an inundation of 400,000 Goths, are proofs that in after ages the Romans retained a remembrance of the means by which Cæſar had triumphed at Aleſia, and were ſtill capable of practiſing them for the extermination of their numerous enemies. App. de Bel. Civ. Zozim. Proſp. Marc. Chron.

In modern warfare, there are two ways of forming blockades. The firſt, and moſt ſimple, conſiſts in fortifying and occupying different poſitions at a ſmall diſtance from the place, principally upon all the highways and avenues, and along the banks of rivers, both above and below the town. Theſe poſts are guarded by diſtinct corps of infantry and cavalry, who take care to keep up an eaſy communication with one another, and to prevent all ſupplies of proviſions from being conveyed into the fortreſs blockaded. This, by degrees, reduces the garriſon to great neceſſity, cauſes them to deſert, and frequently occaſions ſuch murmurings and mutinies among the inhabitants, as to force the governor to a premature capitulation. Such a ſpecies of blockade is extremely tedious; for it is almoſt impoſſible to prevent proviſions from being ſometimes introduced in ſmall quantities, and reviving the courage and patience of the beſieged. But it is of advantage, after having thus for ſome time inveſted a town at a diſtance, to convert the operations into a regular ſiege, as the garriſon are then generally unprovided with the materials neceſſary for protracting their defence.

The ſecond kind of blockade is much cloſer and nearer. It is effected by means of lines of circumvallation and contravallation, between which the army lies encamped, and is adopted only in particular caſes. If, for example, after the loſs of a battle, the enemy ſhould retire into a town which is well known not to be over-abundantly ſupplied with proviſions, and, it is preſumed, muſt be obliged to ſurrender in a few days. But as it would be the height of imprudence in a beaten general to expoſe the remains of his army to certain ruin, by ſhutting them up in a place ſo ill-circumſtanced, (a fault, nevertheleſs, committed by marſhal Wurmſer in 1796, after the loſs of the battles of Baſſano and Roveredo, and which all the importance attached by the imperialiſts to the preſervation of Mantua can hardly excuſe,) this kind of blockade is ſeldom put in practice.

It is rarely a fortreſs is reduced to ſurrender, by the mere proceſs of blockading; but ſieges are often greatly accelerated by it, on account of that ſcarcity of neceſſaries, whether for the ſubſiſtence or defence of the garriſon, which, in a greater or leſs degree, is its never failing conſequence.

The blocking up of towns by corps principally of cavalry, poſted in the neighbouring places of ſtrength, is more convenient than any other method; becauſe the troops forming the inveſtiture, are not ſo fatigued as they would be in occupying open poſitions, and unfortified villages. In the latter caſe, it is neceſſary to be always on the alert, not only againſt the garriſon, who, by a well directed ſortie, may interrupt the communication, and cut off ſome of the detachments; but, againſt the enemy from without, who, by ſecretly marching a ſtrong force, may ſurprize, beat up one of the beſieger's quarters, and introduce a convoy, or reinforcement into the town. On account of theſe inconveniencies, it is eſſentially neceſſary to aſcertain the quantity of proviſions and ſtores contained in the magazines of a place blockaded, in order to compute how long it may hold out, and to have an army in the field ſufficiently ſtrong to protect and cover the blockade. For, ſhould the enemy ſucceed in ſurpriſing and cutting off one detachment, its defeat might occaſion the ſucceſſive deſtruction, or capture of all the others, before they could aſſemble in competent force to repulſe the collected attacks of an enterprizing and vigorous adverſary. (Feuquieres, Mem. chap. lxxxii. p. 377.)

It is chiefly, ſince the conteſt for the imperial ſucceſſion in

in 1740, that the expedient of blockading fortreſſes of the moſt formidable ſtrength, has been preferred to the leſs tedious, but more deſtructive plan of carrying them by a regular ſiege. In the latter caſe, every outwork belonging to the place muſt be taken, or battered down inch by inch, with an immenſe loſs to the beſieging army, and frequently at the hazard of its being ſo reduced in numbers, as not to be capable of undertaking any action of moment during the remainder of the campaign. On the other hand, a blockade, well kept up, muſt, ſooner or later, reduce the garriſon to the laſt extremity for want of proviſions, or ammunition. The number of troops engaged in the enterprize is comparatively ſmall. The loſs of men, neceſſarily conſiderable in the frequent and bloody attacks on the fortifications of a well defended place, is entirely avoided; and the major part of an army is ſtill at liberty to continue its advances into the heart of the enemy's country, and to follow up a previous ſucceſs, without the tedious proceſs of ſtopping to reduce every ſtrong hold in its way. The inconveniences which might otherwiſe reſult from leaving a hoſtile garriſon in the rear, are, in a great meaſure, obviated, if the blockade is kept up with proper alacrity and cloſeneſs. The enemy within the town have enough to do to attend to procuring proviſions for themſelves, without troubling the convoys deſtined for the main army of their beſiegers; and by this means, the operations of a campaign, ſo far from being retarded, are frequently accelerated, by having recourſe to a blockade. Had the allied powers, inſtead of mouldering away their armies before the walls of Mayence and Valenciennes, and afterwards completing their ruin, by the impotent and bloody attempts upon Dunkirk and Maubeuge, adopted this method during the ſummer of the year 1793, they poſſibly might have made greater impreſſion on the territory of the French republic. Had, on the contrary, the generals Jourdan and Pichegru endeavoured, in 1794, to carry Landrecy, Valenciennes, Condé, and Luxembourg, by regular ſieges, inſtead of contenting themſelves with leaving thoſe fortreſſes in a ſtate of blockade, it is very evident that the ſucceſſes of the French, during the latter part of that memorable campaign, would have been by no means ſo rapid and important as they actually turned out.

When the directory formed, in 1796, the reſolution of invading Germany, their armies made no attempt to attack in front the towns of Manheim, or Mayence, but proceeded to effect a paſſage over the Rhine, at a diſtance from thoſe places; and, inſtead of conſuming their time, and waſting their ſtrength in long and tedious ſieges, they advanced rapidly into Suabia and Franconia. They wiſhed to become maſters of Ehrenbreitſtein, Mayence, Manheim, and Philipſburg, by the ſame method by which, in 1794, they had recovered the towns of Landrecy, Queſnoy, Valenciennes, and Condé, and to atchieve, by a ſingle manœuvre, that which would, in former times, have been the reſult of two or three ſucceſſive campaigns. Purſuant to this ſyſtem, they forbore to undertake any ſiege, and ventured to leave fortified places at a great diſtance behind them. Their generals foreſaw, that by carrying the war away from theſe towns, they ſhould, by force, detach the enemy from them; and judged that if they could obtain and keep poſſeſſion of the country ſituated beyond theſe fortreſſes, they would, in the end, fall into their hands perfectly undamaged, and without having coſt them either blood or treaſure. They propoſed to acquire the fortified places, by making themſelves maſters of the ſurrounding country; as formerly theſe countries were ſecured by getting poſſeſſion of the fortified places. Theſe had hitherto been the means of conqueſt; they now meant to make them its reſult. This method, by which the French acquired ſo great a number of fortified towns in 1794, met not with the ſame ſucceſs in 1796; but their failure did not ariſe from the ſtrong places which they left behind them; and as theſe had not impeded the progreſs of Jourdan and Moreau, neither were they the cauſes of their firſt diſaſters. If the troops of the republic had been victorious at Amberg, or at Wurtzburg, the fortreſſes of Ehrenbreitſtein, Manheim, Mayence, and Philipſburg, would, no doubt, have ultimately fallen, as Luxembourg did in 1795. Hiſt. of the Camp. of 1796, Lond. 1796, 8vo.

As a proof of the little danger attending this method of carrying on war, we ſhall only add, that the garriſons of Philipſbourg and Mayence remained ſo cloſely blockaded by a ſmall part of the French forces, as not to be capable of affording the archduke any eſſential aſſiſtance in cutting off the retreat of the invaders, notwithſtanding the rapid and diſorderly manner in which more particularly that of Jourdan was conducted. During the ſame year, Buonaparte, although the reduction of Mantua was the principal object of the campaign in Italy, did not for a moment diſcontinue his other operations in the field. On the contrary, this did not hinder him from carrying his arms into the middle ſtates of that beautiful country; from laying Parma and Modena under contribution; obliging the pope and duke of Tuſcany to agree to a neutrality; forcing the Engliſh from Leghorn, and fighting the imperialiſts almoſt inceſſantly, on every point of a very extended line, to the deſtruction of no leſs than four of their armies ſucceſſively detached againſt him.

Notwithſtanding the tardy proceedings of a blockade are far from being congenial to French vivacity, yet, where the ſtrength, or peculiarly inacceſſible ſituation of a fortreſs, have precluded all hopes of ſucceſs from a coup de main, they have often had recourſe to this means. That they are poſſeſſed of ſufficient perſeverance on theſe occaſions, the three blockades of Luxembourg, Mantua, and Ehrenbreitſtein, in 1795, 1796, and 1798, are convincing proofs.

The moſt famous blockades which, during the laſt century, have diſtinguiſhed the military hiſtory of Europe, are the following: That of Prague by the Auſtrians in 1742, is renowned for the gallant defence made by the French forces under the marſhals Belliſle and Broglio, for the ſpace of five months, during which time they were driven to the laſt neceſſity for want of proviſions; and for the daring retreat by which the former of theſe generals preſerved the remains of his army from falling into the hands of the enemy. The late war has produced ſeveral remarkable inſtances. The two already mentioned of Luxembourg and Ehrenbreitſtein reflect equal honour on the beſiegers, whom no obſtacle could deter from continuing, with invincible patience, their plan of reduction; and the garriſons, whoſe reſiſtance was in the higheſt degree meritorious.

In 1796, public attention was every where engroſſed by the blockade of Mantua, which gave occaſion for the utmoſt exertion of that military talent by which the firſt conſul of France has ſo eminently diſtinguiſhed himſelf, and for the veteran marſhal Wurmſer to add freſh laurels to thoſe he had already acquired, and draw even from his conqueror a flattering acknowledgment of the ability he had diſplayed in its defence. The different exploits of theſe generals; the entire deſtruction of four imperial armies, in vain attempts to relieve the place; the bloody battles of Caſtiglione, Roveredo, Arcole, and Rivoli, the reſult of thoſe attempts; and the conqueſt of all Italy by the

French,

French, the conſequence of its fall, ſecures to the blockade of Mantua everlaſting fame.

The conduct of general Maſſena, when blocked up in 1800 within the walls of Genoa, may juſtly be compared with the moſt glorious actions of the war. Surrounded on all ſides by enemies; cut off from every hope of ſuccour by land or ſea, and almoſt deſtitute of proviſions or ammunition, he maintained, for ſixty days, a poſt the Auſtrians had flattered themſelves to reduce by famine in ſix; deſtroyed immenſe numbers of them in his different attacks on their poſts; and having defended the place to the laſt extremity, obtained a negociation (for Maſſena would not ſuffer the word capitulation to be inſerted in the treaty), equally honourable to himſelf, and advantageous to his country. It was advantageous, inaſmuch as it obliged the enemy to divide and ſcatter their forces, entangle themſelves among the defiles of the Apennines, and, beſides loſing a number of men before Genoa, drew them to ſuch a diſtance from what the French government intended to make the principal ſeat of action during the campaign, as enabled the firſt conſul to paſs the great St. Bernard unoppoſed, occupy the plains of Piedmont, throw himſelf in the rear of general Melas, and, by the battle of Marengo, extinguiſh at once the hopes of the Auſtrians in Italy.

BLOCK-*battery*, in the *Military Art*, denotes a wooden battery on four wheels, moveable from place to place, whereby to fire *en barbe*, or over the parapet; ſometimes alſo uſed in galleries and caſemates, where room is wanted.

Block-*bruſh*, a term uſed in *Heraldry*, to expreſs a bundle or bunch of knee-holm, or baſtard myrtle, formerly uſed by butchers to clean the ſurface of their chopping-blocks, which forms a part of the armorial enſigns aſſigned to the company of butchers of London.

Block-*carriage*, in the *Artillery*, denotes a carriage uſed for conveying mortars and their beds from one place to another.

Block-*houſe*, in the *Military Art*, a kind of wooden fort or battery, either mounted on rollers, or on a veſſel, and ſerving either on the water, or in ſome counter-ſcarps and counter-approaches. The name is ſometimes alſo given to a brick or ſtone fort, built on a bridge, or the brink of a river, ſerving not only for its defence, but for the command of the river, both above and below. Such was that noted *block-houſe* anciently on the bridge of Dreſden, ſince demoliſhed on enlarging the bridge.

Block-*printing*. See Printing.

BLOCKING, in *Middle Age Writers*, denotes a kind of burial uſed for perſons dying excommunicated.

Blockings, *circular*, in *Architecture*, are baſes to the dome, repreſented in the *Plate* of *Archit.* (title *Baſilic*) QQQ; which, by their apparent ſolidity, ſeem to ſtrengthen the dome, and at the ſame time taking from its height, add a peculiar gracefulneſs to its appearance.

Blockings, *ſquare*, are repreſented at S (title *Baſilic*), in *Plate* of *Archit.* Theſe, when enriched with baſe and cap, obtain the appellation of pedestals.

Blocking-*courſe*. See Course.

BLOCKLAND, Anthony de Montfort, in *Biography*, a painter of hiſtory and portrait, was born of a noble family at Montfort in 1532, and acquired his art in the ſchool of Francis Floris, whoſe manner he always followed. By endeavouring principally to imitate the taſte of the Roman ſchool in deſign and compoſition, he became a diſtinguiſhed artiſt. He well underſtood the principles of perſpective, and he diſpoſed his figures with judgment and accuracy. The ſtyle of his colouring was agreeable, and his pencil mellow. He deſigned every object after nature, and gave to the contours of his figures conſiderable elegance. His genius was beſt adapted to grand compoſitions, of which he deſigned many, both at Delft and Utrecht. Several of his works, particularly a Venus, and the hiſtory of Joſeph and his brethren, are in ſo good a taſte, that they ſeem to have been painted by a maſter educated in the ſchool of Florence. Pilkington.

BLOCKLEY, in *Geography*, a townſhip in Philadelphia, in the county of Pennſylvania.

BLOCKY, among *Jewellers*, a name given to a diamond when its ſides are too upright, by its table and collet being larger than they ought to be.

BLOEMAERT, Abraham, in *Biography*, the moſt diſtinguiſhed of a family of Dutch artiſts, was the ſon of Cornelius, an architect, engineer, and excellent ſtatuary of Dordrecht, who, during the troubles of the low countries, removed to Utrecht. He was born at Gorcum in 1567; and reſided chiefly at Utrecht, where he probably died, A.D. 1647. In his youth, he diligently copied the deſigns of Francis Floris; but the excellence to which he attained was chiefly owing to his own genius, which enabled him to acquire a ſtyle of painting peculiar to himſelf. He painted hiſtory pieces, ſacred and profane, landſcapes, and animals; but though he poſſeſſed a facility of invention, and a free-ſpirited touch, and well underſtood the chiaro-ſcuro, his taſte and ſtyle are ſaid to have too much of the Flemiſh, and he is charged with having indulged his own fancy, and deviating from nature in his figures. The hiſtorical picture of the death of Niobe and her children, gained him great reputation; the figures in the compoſition being as large as life. Some ſlight, maſterly etchings are attributed to this artiſt, which are executed in a manner imitating drawings with a pen, from his own compoſitions. He alſo publiſhed ſome ſpirited chiaro-ſcuros, the outlines of which, contrary to the uſual cuſtom, were not cut on blocks of wood, but etched upon copper. Of this kind are two large prints by him, repreſenting Moſes and Aaron, both ſitting figures. He left four ſons, all artiſts. His ſon *Frederic* worked chiefly from his father's deſigns, and imitated his ſtyle in his etchings and chiaro-ſcuros. He alſo, conjointly with his father, made a large drawing book, conſiſting of figures, animals, landſcapes, &c. *Henry* and *Adrian*, were both painters; and they are alſo mentioned as engravers: the moſt eminent, as a painter, was the latter.

Cornelius, the moſt diſtinguiſhed as an engraver, was Abraham's youngeſt ſon, and born at Utrecht in 1603. Devoting himſelf wholly to the art of engraving, he firſt ſtudied under Criſpin de Paſs, and then went to Rome, where he died, at a very advanced age. The manner of engraving adopted by this artiſt was original, and the ſource of that ſtyle, in which the beſt French maſters excelled, or thoſe of them who worked merely with the graver. He covered the lights upon his diſtances, and the other parts of his plates which required tinting, with great care: whereas, before his time, the lights on the diſtant hills, trees, buildings, or figures, had been left quite clear; and by ſo many white ſpots, ſcattered in various parts of the ſame deſign, the harmony was deſtroyed, the ſubject confuſed, and the principal figures prevented from relieving with any ſtriking effect. By this judicious improvement, Bloemaert gave to his prints a more clear and finiſhed appearance, than all the laboured neatneſs even of Jerom Wierix had been able to produce. He drew correctly; but as he executed entirely with the graver, the extremities of his figures are heavy; and his heads are not always beautiful or expreſſive. In the mechanical part of the work few have excelled him,

either as to clearneſs, or freedom of execution. His great fault, however, is want of variety. The naked parts of his figures, the draperies, and the back ground, are equally neat, and engraven preciſely in the ſame manner. Hence the effect is flat, and the fleſh, for want of diſtinction, appears cold and ſilvery.

His works, which are numerous, are juſtly held in high eſtimation, and cannot be eaſily procured. The following are particularly noticed, and the firſt impreſſions of ſome of them are very rare: the "Chaſtity of Joſeph," from Blanchart; the "Adoration of the Shepherds," from Raphael; the ſame ſubject from Pietro de Cortona; the "Holy Family" of the "Spectacles," as it is called, from Joſeph's holding a pair of ſpectacles in his hand, from Annibale Caracci; another "Holy Family," from Parmegiano; the "Virgin and Child," the child ſleeping, from Guido; "St. Luke painting the Virgin and Child," from Raphael; "St. Peter raiſing Tabitha from the Dead," from Guercino; "St. Marguerita" leaning on a pedeſtal, and ſetting her foot upon the dragon, after Annibale Caracci; the "Four Fathers of the Church," from his father A. Bloemaert; "Chriſt appearing to St. Ignatius," from the ſame; "Meleager preſenting the boar's head to Atalanta," from Rubens; ſeveral "prints for a miſſal," after Ciro Ferri and others; a ſet of ſmall prints of "Ruſtics, &c." from his father; "Heads" from the ſame; &c. &c. Pilkington and Strutt.

BLOEMEN, John Francis Van, a painter of landſcapes, called by the Italians, from the delicate manner in which he painted his diſtances, "Horizonti," or "Orizonti," was born at Antwerp in 1656; and as he ſtudied at Rome, and alway reſided in ſome part of Italy, he is generally conſidered as an Italian artiſt. His works have been very much admired in every part of Italy, and bought at very high prices by the beſt judges. His firſt manner reſembled that of Vander Cable; but he afterwards made nature his model, and more particularly the views about Tivoli, the ſubjects of many of his landſcapes, in which he repreſents, with extraordinary truth and beauty, the miſts ariſing from the agitated ſurface of the river below. His pictures are generally well deſigned, and well handled; and thoſe of his beſt time are now conſidered as an ornament to the moſt ſelect cabinets in Europe. A very capital picture of this excellent artiſt, in which the figures were inſerted by Sebaſtian Conea, is in the collection of the earl of Moira. By this artiſt we have five ſmall etchings, probably done for his amuſement. They are "perſpective views," apparently near Rome. Pilkington and Strutt.

Bloemen, Peter Van, brother of the preceding, was born at Antwerp, and after living ſeveral years with his brother at Rome, and ſtudying the works of the greateſt maſters, returned to his native city, where, in 1699, he was appointed director of the academy. The ſubjects of his pictures are the marchings of ſquadrons of cavalry, encampments, artillery, battles, Italian fairs, markets, and feſtivals, in which he manifeſts correctneſs of deſign and drawing, and an elegance in the manner of dreſſing his figures. His horſes are deſigned in an admirable ſtyle, and in his battles they exhibit great ſpirit, graceful attitudes, and an expreſſion full of life and nature. His landſcapes are enriched with elegant architecture, with baſſo-relievos, and mutilated ſtatues, in a noble taſte; and they are rendered the more agreeable by a good tone of colour, animals of different kinds, and excellent figures. His beſt works are admired in all parts of Europe, and afford high prices; but ſome of them are too laboured, and leſs valuable. Pilkington.

Bloemen, Norbert Van, brother of the preceding, was born at Antwerp in 1672, and being allured by the reputation of his brothers to viſit Italy, he there devoted all his hours to ſtudy. He principally painted converſations and portraits; but the colouring of his pictures is too glaring, and wants more truth and nature. Pilkington.

Blois, in *Geography*, lat. *Bleſæ*, a city of France, was, before the revolution, the capital of "Le Blaiſois," the ſee of a biſhop, ſuffragan to the archbiſhop of Paris, and formerly the reſidence of the kings of France; but is now the capital of the department of the Loir and Cher, and divided into eaſt and weſt Blois, the former containing 5400 inhabitants, and its canton 12,885, and the latter 7912, and its canton 11,862: the whole territory comprehends 237½ kiliometres, and each canton has eight communes. Blois is ſeated in a pleaſant country, on a ſmall eminence near the river Loir, over which is a handſome ſtone-bridge. The caſtle is the principal ornament of the city, and has, on the firſt view, the appearance of two diſtinct buildings, which are joined by a paſſage cut out of a rock. That part of the caſtle, which was built by the duke of Orleans, inſtead of that which he demoliſhed in 1632, is a ſuperb, but unfiniſhed edifice. The court before it, where the church of St. Saviour is ſituated, is very large, and was formerly uſed for tournaments. The adjoining gardens are magnificent and beautiful. On every gate of the city is exhibited an image of the Virgin Mary, who is thought to have delivered the inhabitants from the plague in 1631. In this caſtle, famous as the birth-place of Louis XII., are ſhewn the chambers where the duke of Guiſe, and his brother the cardinal, were murdered by order of Henry III., December 23, 1587. The church of St. Solenne is the cathedral, which is a beautiful ſtructure. The front of the Jeſuits' college is decorated with the Doric, Ionic, and Corinthian orders of architecture. About three quarters of a mile from the city, water in great abundance deſcends through the clefts of a rock, in a large aqueduct, by which it is conveyed to a reſervoir near the walls, and it is then diſtributed by leaden pipes to the ſeveral parts of the city. The trade of Blois conſiſts chiefly of wine and brandy; though it has manufactures of ſerges and ticken. Several kings have kept their courts at Blois, and the French language is ſpoken in the greateſt perfection by its inhabitants. N. lat. 47° 35′ 20″. E. long. 1° 20′ 10″.

Blois, Peter *of*, *Petrus Bleſenſis*, in *Biography*, an eminent writer of the 12th century, was born about the year 1120 at Blois in France, whence he derived his name; and as his parents were opulent, he enjoyed all the neceſſary means of a learned education. In his youth he ſtudied in the univerſity of Paris, where he manifeſted a ſtrong inclination to poetry, and in his more advanced life, he applied with peculiar ardour to the ſtudy of rhetoric. At Bononia in Italy, whither he removed from Paris, he acquired eminence by his knowledge of the civil and canon laws; and he appears alſo, by his writings, to have cultivated an acquaintance with medicine, and with various branches of the mathematics. But the principal object of his attention, and in which he is ſaid to have particularly excelled, was theology, or the ſcholaſtic theology of the times, which conſiſted in vain attempts to prove and explain the numerous abſurd opinions, which prevailed in the church, by the ſubtleties of Ariſtotelian logic. To him ſome have aſcribed the firſt uſe of the term "tranſubſtantiation," which was ſoon after adopted in the church of Rome. Being appointed preceptor to William II. king of Sicily, A.D. 1167, he obtained the cuſtody of the privy-ſeal, and, next to the archbiſhop of Palermo, the prime miniſter, he had the greateſt influence in all affairs. However, his

power

power ſoon terminated; for, upon the baniſhment of the archbiſhop, A. D. 1168, he left the court of Sicily, and returned into France. From France he was invited into England, by Henry II. who employed him as his private ſecretary, made him archdeacon of Bath, and gave him ſome other benefices. After having ſpent a few years at court, he conceived a diſguſt at that mode of life, and retired into the family of Richard, archbiſhop of Canterbury, who made him his chancellor, about A.D. 1176. After the death of this prelate, A. D. 1183, he acted as ſecretary and chancellor to archbiſhop Baldwin, his ſucceſſor; and was deputed by him on an embaſſy to Rome, A. D. 1187, in order to plead his cauſe before pope Urban III. in the famous controverſy between him and the monks of Canterbury, about the church of Hackington. When Baldwin departed into the Holy Land, A.D. 1190, he was involved in various troubles in his old age, the cauſes of which are not diſtinctly known, and died about the end of the 12th century. From his works, which may be juſtly reckoned among the moſt valuable monuments of the age in which he flouriſhed, and ſome of which may even now be read with profit, he appears to have been a man of approved integrity and piety, as well as of a lively inventive genius, and uncommon erudition. He is ſaid to have dictated letters in Latin to three different ſcribes, on different ſubjects, and to have written a letter in the ſame language himſelf, at the ſame time. His printed works conſiſt of 183 letters, which he collected together at the deſire of Henry II.; of 65 ſermons, delivered on various occaſions; and of 17 tracts on different ſubjects; "Opera P. Bleſenſ. Paris, edit. A.D. 1667," fol.; and afterwards printed in the Bibliotheca Patrum, tom. 24. Cave Hiſt. Lit. vol. ii. p. 333. Henry's Hiſt. vol. vi. p. 147, &c.

BLOKZYL, in *Geography*, a town and fort of Overyſſel, ſituated at the mouth of the Steenwyk, or Old Aa, where it enters the Zuyder ſea, with a harbour capable of containing 200 veſſels; defended by ſix baſtions, and erected by the Dutch, at the commencement of their republic, to defend them from the invaſions of the Spaniards. N. lat. 52° 45'. E. long. 5° 45',

BLOMARY, or Bloomary, the firſt forge in an iron-work, through which the metal paſſes after it is melted out of the ore. (See Iron.) They are alſo called *blomary-hearths*.

BLOMBERG, in *Geography*, a town of Germany, in the circle of Weſtphalia, and county of Lippe, which obtained its firſt privileges, in the beginning of the 14th century, from count Simon I.; 8 miles S.E. of Lemgow.

BLOMESHOLM, a manor of Sweden, in the diſtrict of Bohus, about 3 Swediſh miles from Stromſtadt, in which is a very ancient monument, conſiſting of large ſtones, ſet up perpendicularly, and arranged in the form of a ſhip.

BLONAI, a barony and caſtle of Swiſſerland, near Vevay, and about 1½ mile from the lake of Geneva.

BLOND, Le, Christopher, in *Biography*, a painter, was born in 1670, but little noticed in the more early part of his life. He became known at Rome in 1716, and eſtabliſhed his reputation in Italy, as a good painter of portrait in miniature. At Amſterdam he diſtinguiſhed himſelf by painting ſmall portraits, for bracelets, rings, and ſnuff-boxes, firſt in water colours, with a very lively and natural colouring, and afterwards in oil. From the Low countries he came over to England, and projected a new manufactory for impreſſing colours on paper with copper-plates, which promiſed to be advantageous, but in the end proved detrimental to himſelf and his aſſociates, to which his own diſſolute life and manners very much contributed. His ſcheme was to copy the moſt capital pictures in England, of the greateſt maſters, ſo as to give his prints the appearance of paintings in oil. Many of his prints were well executed, are ſtill extant, and are held in eſtimation. It is ſaid, however, that he was not the original inventor of this method of managing colours; but that he took it from Laſtman, and others, who, with equal capacities and more diſcreet conduct, had undertaken it before him, but failed of ſucceſs. Pilkington.

BLONDEL, David, a French proteſtant miniſter, eminent for his acquaintance with eccleſiaſtical and civil hiſtory, was a native of Chalons in Champagne, admitted miniſter in 1614, and ſettled at Houdan near Paris. His firſt work in favour of the Proteſtants was printed at Sedan in 1619, under the title of "Modeſte Declaration, &c." or, "A Modeſt Declaration of the ſincerity and truth of the reformed churches in France;" and intended as a reply to the invectives of the party of the biſhop of Luçon, afterwards cardinal Richelieu. This work eſtabliſhed his reputation among the Proteſtants, and occaſioned his being much employed in their ſynods. He was not diſtinguiſhed as a preacher; and his ſtyle, as a writer, was perplexed, and encumbered with parentheſes; but his judgment was penetrating, his memory tenacious, and his erudition extenſive. As an honorary profeſſor, with a penſion, to which office he was appointed by the ſynod of Charenton in 1645, he had opportunity to devote his time to literature; but though he undertook to refute Baronius's annals, it does not appear that he did much beſides writing a few notes in his own copy of the work. His works were "Explications on the Euchariſt;" a treatiſe concerning "The Primacy of the church;" "Pſeudo-Iſidorus et Turrianus vapulantes," againſt the Decretal epiſtles; a "Treatiſe on the Sibyls," diſproving the truth of their oracles, and refuting the ancient practice of praying for the dead; and a treatiſe "De Epiſcopis et Preſbyteris." By his treatiſe againſt the ſtory of pope Joan, which he rejected as fabulous, he offended ſome Proteſtants, who did not wiſh to be deprived of this topic of ſatire againſt the Romiſh church. Among Blondel's works on civil hiſtory, we may reckon his "Genealogy of the kings of France againſt Chifflet," written in Latin, and printed at Amſterdam in 1654, 2 vols. fol. which is ſaid to have been undertaken at the deſire of chancellor Seguier; and his piece "De formula regnante Chriſto." On the death of Gerard Voſſius, he was choſen to ſucceed him as profeſſor of hiſtory in the ſchola illuſtris of Amſterdam, and took poſſeſſion of his office in 1650; but his aſſiduity in the proſecution of his ſtudies, and change of air, occaſioned the loſs of his ſight, after which, it is ſaid, that he dictated his work intitled "Genealogy, &c." At Amſterdam his ſituation was rendered uneaſy by a charge of Arminianiſm; and he died in 1655. Gen. Dict.

Blondel, Francis, an eminent mathematician and military engineer, was born in 1617, at Ribemont in Picardy. In 1652, he was travelling governor to the young count of Brienne, and after a tour of three years he publiſhed an account of it in Latin. After his return he was advanced to conſiderable poſts both in the army and navy, and he was employed in various negotiations with foreign princes. In 1659, being deputed by Louis XIV. as his envoy-extraordinary to Conſtantinople, he viſited Egypt; and at the termination of his embaſſy, he was appointed counſellor of ſtate, tutor in mathematics and belles-lettres to the dauphin, and one of the mathematical profeſſors at the royal college. In 1665, he began to diſplay his talents for architecture, when the court employed him to conſtruct a bridge over the Charente at the town of Saintes. In 1669, he became member of the Academy of Sciences; and in 1670 he was honoured

honoured with letters patent from the king for the superintendence of all the public works in Paris. To him were intrusted the repair and decorations of the gates of St. Antony and St. Bernard; and the gate of St. Denis, one of the most finished pieces of French architecture, was designed and erected by himself. In the office of director and professor of the Academy of Architecture, established in 1671, he gave "A Course of Architecture," which was published in large folio, in 1698, and which was long considered as a standard book. In 1675, he presented to the king his treatises "On the art of throwing bombs," printed in 1685, 4to. and "On a new method of fortification," which procured for him the rank of marshal de camp. His other works were "Notes on the architecture of Savot;" the "Resolution of four principal problems of architecture," Paris, 1676, fol.; "A Course of mathematics," Paris, 1683, 4to.; the "History of the Roman calendar," Paris, 1682, 4to.; and a "Comparison between Pindar and Horace." He also communicated several ingenious pieces to the Royal Academy of Sciences, which are inserted in their Memoires, particularly for the year 1666. He died at Paris, Feb. 1. 1686. Gen. Dict.

Blondel, Francis, was admitted doctor in medicine at Paris, the place of his birth, in 1632. As he had acquired considerable reputation as a scholar, he was engaged, on the death of Chartier, to assist in completing his magnificent edition of the works of Hippocrates and Galen, three volumes of which were left unfinished. He was an avowed opponent to the admission of antimony, and of all chemical preparations, into the practice of medicine, coinciding in that respect with his contemporary and coadjutor, Guy Patin. In 1658, he was made dean of the faculty of medicine, which office he held the following year. In 1660, he published "Statuta facultatis medicinæ," Paris, 12mo.; and in 1665, an epistle to Alliot, "De cura carcinomatis, absque ferro et igne," 4to. Alliot used for the purpose a medicine prepared from the arsenicum rubrum, dissolved in aqua fortis, and precipitated with the acetum saturni. The precipitate was then washed, by repeated affusions of warm water, and its causticity further mitigated by burning spirits of wine, in which it was immersed, until the powder became perfectly insipid. Blondel died Sept. 5th, 1682. Haller. Bib. Chirurg. et Med. Eloy Dict. Hist.

Blondel, Francis, born at Liege in 1613, studied medicine at Cologne, and was for some time physician to the elector of Treves. On the death of that prince, in 1652, he went to Aix, and was appointed physician and superintendant of the baths in that city. In 1662, he published "Lettre de Francis Blondel a Jaques Didier, touchant les eaux minerales chaudes d'Aix, et de Borset, et les cures qui se sont faites par son usage," Brux. 12mo.; and in 1671, "Thermarum, aquisgranensium, et porcetanarum descriptio," which was reprinted in 1688, in 4to. with engravings, and considerable additions. He died in 1703, much regretted by the inhabitants of Aix, having, by his writings, so recommended the waters, as considerably to increase the resort of patients there. Eloy. Dict. Hist.

Blondel, James Augustus, of a French family, but born in England, and admitted licentiate of the college of physicians in London about the year 1720; published, in 1727, "The strength of imagination in pregnant women examined, and the opinion that marks and deformities in children arise from thence, demonstrated to be a vulgar error," 12mo. Though Dr. B. had not put his name to this work, yet his neighbour and colleague, Dr. Turner, discovering that he was the writer, and considering it as an attack upon what he had said on the subject, in the 12th chapter of his treatise on the diseases of the skin, in which he gives numerous instances of marks and deformities in the bodies of children, impressed on them by the disturbed imaginations of the parents, thought himself called upon to explain and to defend what he had there advanced. He therefore, in an appendix to his treatise on gleets, published the following year, gave some additional observations on the subject, in further proof of the influence of the affections of the mother over the fœtus in utero. To this Dr. Blondel replied, in 1729, and with much humour, as well as argument, shewed the absurdity and fallacy of the opinion maintained by his antagonist; who, if he insisted on his point, must admit that animals, and even plants, are under the influence of the same affections; their fœtuses being frequently produced equally defective and monstrous as those of the human species. The answer is entitled, "The power of the mother's imagination over the fœtus examined, in answer to Dr Daniel Turner's book, entitled, 'A Defence of the 12th chapter of his treatise, de morbis cutaneis.'" This drew a more serious reply from Dr. Turner, addressed immediately to his opponent, under the title of "The force of the mother's imagination upon the fœtus in utero still farther considered, in the way of a reply to Dr. Blondel's last book, by, &c." 1730, 8vo. But though the doctor supports himself with the authority of Schenckius, Hildanus, Horstius, and many other collectors of wonderful and extraordinary stories, the good sense of his antagonist prevailed, and he has the merit of having contributed very largely towards removing the prejudices on this subject, which had prevailed for ages, and, with them, the solicitude and anxiety which never failed to torment the minds of such women as had the misfortune, while pregnant, to see or hear any thing, strongly affecting their imaginations, lest their offspring should be born with some defect or deformity. It is now pretty generally known, that no such consequences follow, and that the few cases in which children are produced defective, with redundant parts, or in any way distorted, happen indifferently, where the mother has or has not, in the course of her pregnancy, received some shock or alarm. The power of the imagination in marking, distorting, or deforming the fœtus in utero is vanished, with the witches, ghosts, and hobgoblins, formerly equally objects of distress and terror. Haller. Bib. Chir. et Med. Pract. Eloy Dict. Hist.

There is another writer of the name mentioned by bibliographers.

Blondel, Jaques, surgeon of Lisle in Flanders. He translated the Chirurgia militaris of Nicolas Godin, under the title of "La Chirurgie militaire, tres utile a tous ceux qui veulent suivre un camp, en tems de guerre, pareillement a tous autres en condition pestilente ou dysenterique, ecrite en latin, par Nic. Godin," Anvers, 1558, 8vo.

Blondel, John Francis, was born at Rouen in 1705; and was known, not only as architect to the king, member of the Academy of Architecture, and royal professor of the art at the Louvre, but by several useful publications; as "A Discourse on Architecture," 12mo.; "A Treatise on the decoration of buildings," 1738, 2 vols. 4to.; "A Course of Architecture," 6 vols. 8vo. 1771—1773. The two last were published in 1777, 3 years after his death. M. de Bastide also published, in 1774, a posthumous work of Blondel, entitled, "L'homme du monde eclairé, par les Arts," 8vo. 2 vols. Blondel was the author of the articles relating to architecture in the Encyclopedie. He died Jan. 9, 1774. Encycl.

BLONDIN Peter, a native of Picardy, born Dec. 18th 1682, was a disciple of Tournefort, by whose advice he travelled over Picardy, Normandy, and the isle of France, to improve himself in botany. In the course of his excursion, he disco-

diſcovered upwards of an hundred and twenty plants, which had not been before deſcribed, and ſeveral others, which had been ſuppoſed peculiar to America. In 1708, he was admitted doctor in medicine at Rheims; and, in 1712, he was received into the French academy, in quality of eleve of M. Reneaume, an honour he did not long enjoy, being cut off in the following year, by an inflammation of the lungs. M. Fontenelle, who ſpoke his funeral eulogium, attributed to him a ſmall work, publiſhed in his life-time, in which he had made ſome corrections in Tournefort's arrangement of certain ſpecies of plants; he alſo ſays, he left ſome curious memoirs on the ſubject of botany, intended for publication, and which were prevented being printed by his premature death. But his name does not appear in Haller's Bib. Botan. nor in the catalogue of botanical works contained in the ſplendid library of ſir Joſeph Banks, lately publiſhed by Dr. Dryander. Eloy Dict. Hiſt.

BLONDVAURY, in *Geography*, a town of France, in the department of the Charente, 5 leagues eaſt of Confolens.

BLONDUS, or Biondi, Michael Angelo, in *Biography*, was born at Venice, May 4th 1497. After ſtudying under Auguſtin Niphus, a celebrated teacher of that time, he ſettled at Naples. He was a voluminous writer. The titles of the moſt diſtinguiſhed of his works follow. "Epitome ex libris Hippocratis de nova et priſca arte medendi deque diebus decretoriis," Romæ, 1528, 1545, 8vo.; "Libellus de morbis puerorum," Venetiis, 1539, 8vo.; "De partibus ictu ſectis citiſſime ſanandis, et medicamento aquæ, nuper invento. In plurimorum opinionem de origine morbi Gallici, deque ligni Indici ancipiti proprietate," Venetiis, 1542, 8vo. For wounds made with a cutting inſtrument, and recently inflicted, he recommends the application of ſimple water, as a moſt valuable and uſeful remedy. He does not admit that the venereal diſeaſe was a new complaint, originating in the Weſt Indies, but believes it to have been known to Hippocrates, and other ancient phyſicians, and deſcribed in their writings. He had uſed the lignum ſanctum in his attempts to cure the diſeaſe, but ineffectually; the diſeaſe returning, he ſays, after diſcontinuing the medicine, with increaſed violence. He placed his principal dependence on mercury, but does not give the rationale, or method of uſing it. This work is inſerted by Conrad Geſner in his "Collectio ſcriptorum optimorum de chirurgia," 1555, fol. For the titles of the remainder of his works, ſee Eloy's Dict. Hiſtor. Med. Aſtruc. de Morb. Vener. Haller. Bib. Med. Pract. et Botan.

BLONSK, in *Geography*, a diſtrict of Poland, belonging to the territory of Warſaw, in the palatinate of Czerſk, or Maſovia.

BLOOD, is the nutritive fluid of animals. In the human ſubject it circulates through the arteries and veins (ſee Circulation), being of a ſcarlet colour in the former, and of a purple colour in the latter; it is of conſiderable conſiſtence; of a ſlightly ſaline taſte, and peculiar ſmell; its ſpecific gravity is eſtimated at 1.0527. When blood is drawn into a baſon, it firſt congeals into a tremulous, jelly-like maſs; and then ſpontaneouſly ſeparates into a ſolid, heavier ſubſtance termed the craſſamentum, cruor, or the clot of the blood, and a ſupernatant pale liquor called the ſerum. If the craſſamentum of the blood be waſhed with water, all the red colour may be waſhed out of it, and a firm whitiſh ſubſtance will remain. This ſubſtance, which did exiſt in a ſtate of ſubtile fluidity, ſo as to be capable of permeating the minute veſſels of the body, and which thus ſpontaneouſly concretes, has been, therefore, called the coagulating lymph of the blood. If the blood be ſtirred with a wiſp, this ſubſtance concretes in a fibrous form round about it, and it was in conſequence formerly termed the fibrous part of the blood. By this latter denomination, it is alſo now generally known and deſcribed. Thus it appears, that there are three parts readily diſtinguiſhable in the blood; the ſerum; the fibrous part or baſis of the craſſamentum; and the colouring matter; to the more particular conſideration of theſe we now proceed.

Of the Serum.

The Serum of the blood is of a light greeniſh yellow colour, and its mean ſpecific gravity is eſtimated at 1.0287. It coagulates at about 160° of Fahrenheit's thermometer, the ſame form becomes converted into a tremulous ſolid ſubſtance, which being cut in pieces and compreſſed, there can be ſqueezed out of it a muddy and ſomewhat glutinous fluid, which is termed the ſeroſity of the blood. If the remainder be boiled, part of it will be found to be inſoluble; and this has all the properties of albumen, or that inſoluble matter which is contained in the white of the egg: for an account of which, ſee the article Albumen. That part of the ſerum which is diſſolved in boiling water, becomes a jelly, if the water be evaporated to a certain degree, and it be ſuffered to become cold. It is again ſoluble, if more water be added. This modification of animal matter is now termed gelatine, and to that article the reader is referred for a more full account of its properties. The ſeroſity of the blood appears to contain animal mucilage, but no accurate chemical examination has as yet been made of it. The ſerum of the blood turns the ſyrup of violets green; which effect is owing to ſoda, that is contained in it. If coagulated ſerum be heated in a ſilver veſſel, the ſilver becomes blackened by being converted into a ſulphuret; in conſequence of the ſerum containing ſulphur. If the ſalts of the ſerum be diſſolved in boiling water, and afterwards cryſtallized, they are found to be carbonat of ſoda, muriat of ſoda, phoſphate of ſoda, and phoſphate of lime.

Of the fibrous Matter of the Blood.

This matter ſpontaneouſly concretes in open and in cloſe veſſels, in the temperature of the animal, or in a much lower degree of temperature, though with ſome little variation as to the time in which the coagulation happens. Dilution of albumen by water prevents its coagulation, even by thoſe chemical agents which ſuddenly and firmly coagulate it in its natural ſtate, ſuch as heat, ſpirit, and acids. No dilution of the blood by water has hitherto prevented even the ſpontaneous coagulation of its fibrous part. The baſis of the craſſamentum, or fibrous part of the blood, is found to be a whitiſh ſolid elaſtic ſubſtance, of greater ſpecific gravity than the ſerum. This ſubſtance, which is inſoluble in water or alcohol, and which reſembles the muſcular fibres in its chemical properties, has been denominated by the French chemiſts fibrine or fibrina, to which article the reader is referred for a more particular account of it. It is right however here to remark, that chemical analyſis ultimately converts all animal ſubſtances into azot, hydrogen, and carbon; and that the proportion of the former is greater in the fibrous part of the blood than in albumen, or perhaps in any other animal compound.

Of the colouring Matter of the Blood.

The colouring matter of the blood has an attraction to water and diſſolves in it, forming a tranſparent red liquor. This attraction is perceived in macerating fleſh in water; for the colouring part, which is ſpecifically heavier than any other part of the blood, and readily ſinks in the ſerum, yet riſes up and becomes diſſolved in the water. The watery ſolution of this part of the blood turns the ſyrup of violets green, and contains both ſoda and albumen. If the red

part

part of the blood be incinerated by fire, it is found to contain much iron, which Fourcroy and Vauquelin diſcovered was combined with phoſphoric acid in the ſtate of ſubphoſphate of iron; and this is the only part of the blood which is found in analyſis to contain any of that metal. Fourcroy examined the blood of the fœtus, and found that the colouring matter was darker and more abundant than in the adult ſubject. He alſo found that the blood of the fœtus contained no fibrine, but much more gelatine than in the adult.

The colouring matter of the blood is found, by examination with the microſcope, to be compoſed of very minute globular particles. They were particularly attended to by Leeuwenhoeck, and afterwards examined and deſcribed by others, chiefly by Senac, Hewſon, and Fontana. They are ſo ſmall as ſcarcely to admit of an accurate examination in this climate by the common microſcope. This aſſertion will probably be readily admitted, if it be granted that they do not exceed a 200,000th part of an inch in diameter; yet ſuch dimenſions may be ſtated as the average eſtimate of their ſize, drawn from the accounts of various obſervers. Haller ſays, that he ſaw them as large as peas by the ſolar microſcope, and it was by the aid of that inſtrument that we are enabled to give the following account of them. A drop of blood, much diluted with water, was put upon a micrometer or piece of glaſs, ruled by a diamond in ſquares of $\frac{1}{50}$th of an inch, and put before the lens of the ſolar microſcope. The ſquares were magnified upon the ſcreen to eight inches diameter. The globules of the blood were ſeen undulating to and fro in vaſt numbers; they all appeared exactly of the ſame ſize; and a few which were ſeparated from the reſt were attentively examined. Theſe had all the appearance of globules; they were circular in their diſk, and were regularly illumined on one ſide, and ſhaded on the other, with the priſmatic colours arranged in the middle or greateſt convexity; the violet being next to the light, and the red next to the ſhade. On varying the focal diſtance of the lens, indeed, an alteration of appearance took place, ſome ſhading appeared in the middle juſt in the manner repreſented by Fontana. Upon again varying the poſition of the lens, the globules appeared as at firſt. This ſhadowy appearance in the middle probably led Mr. Hewſon to ſuppoſe that they contained a central ſolid particle. It is, however, generally admitted, that the colouring particles of the blood are ſpherical; and if their ſize be calculated from the preceding account, they will be found to be leſs in diameter than the 200,000th part of an inch.

If, for inſtance, the ſquare of $\frac{1}{50}$th of an inch be magnified to a ſquare of eight inches, and the globules appear $\frac{1}{8}$th of an inch in diameter, then 64 may be placed in a line on one ſide of the ſquare, and $64 \times 64 = 4096$, is the number that will ſtand within that ſurface. Now, this ſquare is but $\frac{1}{50}$th of an inch, magnified on the ſcreen to a ſquare of 8 inches; then, multiply 4096 by 50, and it gives 204,800, as the number of theſe globules which would ſtand in the ſquare of one inch.

The preceding account of the blood, imperfect as it is, yet affords us much ſatisfactory information. We perceive that there are contained in the blood, in a ſtate of ſubtile fluidity, the materials of which the body is conſtructed, and which are capable of becoming ſolid fibres of various degrees of ſolubility. We find in it alſo that aqueous liquor which fills all the interſtices of the ſolid parts. It is true, that we find in the animal body many ſubſtances which do not exiſt formally in the blood, and which are new compounds of matter made out of that fluid; and for an account of which the reader is referred to glandular ſecretion.

With reſpect to that change which the animal matter undergoes from a fluid to a ſolid ſtate, and which is called coagulation, but little is ſatisfactorily known. It ſeems to have been a problem amongſt chemiſts. Scheele attributed it to the agency of caloric; Fourcroy, to that of oxygen; and Dr. Thomſon has of late accounted for it, without ſuppoſing the addition of any other ſubſtance to the coagulated matter. With reference to the laſt opinion, it ſhould be obſerved, that in coagulation, a change in the chemical properties of the coagulated ſubſtance takes place, which implies, that a chemical alteration has alſo taken place; and that even if the theory were true with reſpect to albumen, it will not account for the coagulation of the fibrine of the blood. Where chemiſtry fails to explain phænomena incident to living bodies, it is fair to inquire if life may not have ſome ſhare in their production.

Mr. Hunter thought that the coagulation of the blood depended on its living powers, and ſupported his opinion by many ingenious arguments. To remove any objection which might be made to a fluid or unorganized ſubſtance being alive, he adverts to what happens with reſpect to the yolk and white of the egg, which, in conſequence apparently of their poſſeſſing a principle of life, are preſerved from putrefaction during incubation, and which reſiſt the effects of heat and cold in a degree and manner ſimilar to the lower kinds of animals. His chief arguments in evidence of the coagulation of the blood depending upon life are, that in ſome caſes where death has been cauſed by lightning, or by violent fatigue in running, as in animals who are hunted to death, or by blows on the ſtomach, the irritability of the muſcles has been deſtroyed, and the blood has remained fluid, and never coagulated. Mr. Hunter alſo mentions, that he mixed infuſions of bitter vegetables, which are generally conſidered as tonics, with blood, and theſe did not retard its coagulation, but that a ſolution of opium had that effect. As a proſecution of this hint, the writer of the preſent article cauſed blood to be much diluted with water, and infuſions of noxious vegetables to be ſtirred into it; yet in theſe experiments the fibrine ſtill coagulated, and that in a ſudden manner.

The vegetable infuſions were theſe of opium, tobacco, and the atropa belladonna. It may be proper to relate the particulars of one of theſe experiments, in order to give a general idea of the whole. Eight ounces of blood were drawn from the arm into ten pints of water of 95° of Fahrenheit's thermometer, containing a ſtrong infuſion of the atropa belladonna. It was ſtirred with a glaſs rod; the two fluids appeared tranſparent and homogeneous. In eight minutes, the temperature being 93°, a conſiderable quantity of floculent coagulum at once ſuddenly formed, and no additional coagulation afterwards took place. The thermometer was attentively obſerved, but no change was remarked in it during this coagulation. The gentleman who performed theſe experiments, wiſhing to repeat them with ſome variety in the mode of conducting them, obſerved, however, that heat was given out during the coagulation of the blood, as will be ſeen in the following experiment.

Ten ounces of blood were drawn into a wooden bowl, in which a thermometer was held. The temperature of the blood, while flowing from the vein, was 93°. In ſix minutes the thermometer had ſunk to 89°, and coagulation commenced on the ſurface; on elevating the bulb of the thermometer to the coagulum on the ſurface, the quickſilver roſe to 90 and $\frac{1}{2}$; on depreſſing it to the bottom of the bowl, it ſunk to 89. This was repeated twice with nearly the ſame reſult, and on the third trial the quickſilver roſe to 91°; and on depreſſing it again, it was perceived that the blood was

coagulated throughout. After this, the quickſilver regularly continued to deſcend, and was no longer influenced by changing the ſituation of the bulb of the thermometer.

With reſpect to the uſe of the red particles, Boerhaave ſuppoſed, that they might tend to keep the diſſimilar parts of the blood incorporated, as ſhot agitated in a mixture of ſand and water would prevent the ſubſidence of the former from the latter. It ſeems, however, no improbable opinion, that this is the matter which has the very peculiar properties of forcibly attracting oxygen gas, even through the medium of the blood veſſels, and combining with it, and becoming in conſequence of a ſcarlet colour, yet of holding it ſo looſely as to part with it in the round of the circulation to carbon and probably to hydrogen, and thus contributing to the production of animal heat. The writer of the preſent article is of this opinion, becauſe he has expoſed the red parts of the blood to air containing oxygen gas, and always found the oxygen gas diminiſhed in proportion to the quantity of blood which had acquired a ſcarlet colour by expoſure to it. On the contrary, he has expoſed the ſerum of the blood to ſimilar kinds of air, and never perceived any abſtraction of oxygen gas by that fluid. Thus probably we diſcover the principles of nutrition of the body and the cauſe of its heat. For a further account of the effects of reſpiration on the blood and its conſequences, ſee Lungs, *function of*.

Haller's elements of phyſiology may be conſulted for an account of all that had been done reſpecting the inveſtigation of the nature of the blood till his time; the works of Mr. Hewſon and Mr. Hunter may be referred to for additional information on this ſubject; the works of Fontana, for microſcopical obſervations; and for novel chemical experiments, the writings of Fourcroy, Vauquelin, &c. in the Annales de Chimie, and thoſe of Deyeux and Parmentier in the Journal de Phyſique, and Dr. Thomſon's excellent ſummary contained in his Syſtem of Chemiſtry.

Blood, *tranſuſion of*. See Transfusion.

Blood, *injecting liquors into it*. See Injection.

Blood, *ſpitting of*. See Hæmoptysis.

Blood, *cooling of*. Lord Bacon has ſuggeſted that the proſecution of experiments on this ſubject might poſſibly lead to the means of prolonging life. But this great philoſopher appears to have entertained erroneous notions reſpecting the animal economy, on this and ſome other points. Nothing accurate was known, in thoſe days, on the ſubject of animal heat. If the blood were cooled below a certain ſtandard, diſeaſe and death, and not longevity, would be the conſequence. However, when the quantity of animal heat exceeds what is natural, the exceſs is carried off by an increaſed evaporation from the ſurface of the body, in other words, by perſpiration. And in this way, or by the direct application of water of a low temperature to the ſkin, the blood, as well as every other part of the body, may be ſaid to be cooled, and diſeaſe prevented or removed. But this is not what lord Bacon meant in his propoſal for cooling the blood.

Blood, *Depuration of*. See Secretion.

Blood, *Flux of*, is called an Hæmorrhage. The periodical ones of women, Menses. Thoſe after child-birth, Lochia. That ordinarily happening on the firſt coition is by ſome called and conſidered as the teſt of virginity.

Blood, *ſtaunching of*. See Styptic.

Blood, *vomiting of*. See Hæmatemesis.

Blood, *Circulation of the*. See Circulation.

Blood, *morbid alterations of*. The alterations which the blood undergoes in various diſeaſes, are ſuch as claim the attentive obſervation of phyſicians. But, in order to form a juſt conception of them, it is neceſſary previouſly to conſider what are the component parts of this vital fluid, and their relative proportions, in the natural and healthy ſtate.

By the accurate analyſes of modern chemiſts it has been proved, that, beſides water, and various ſaline matters (ſuch as ſoda, phoſphates of lime, of ſoda, and of ammonia, and muriates of ſoda and ammonia), the blood conſiſts of what is termed fibrin, albumen (coagulable lymph), and a colouring principle, viz. oxyd of iron combined with phoſphoric acid. Theſe ſeveral materials conſtitute the fluid called blood, which, in its natural ſtate, is kept in conſtant motion, under a temperature of 98° or 100° (in ſome animals the temperature is rather higher) of Fahrenheit's thermometer. A large proportion of fibrin, ſome albumen, and the colouring matter, conſtitute the cruor, or craſſamentum; while the ſerum is compoſed of water, with a large proportion of albumen, and the ſaline ſubſtances above mentioned.

Now, it is probable, that conſiderable alterations take place in the relative proportions of theſe ingredients, whenever the living body, whether of man or brute, becomes long or violently diſturbed in its action, and eſpecially (as Mr. Hewſon has ſhewn) whenever the energy of the vaſcular action is much increaſed. But in accounting for any remarkable alterations in the blood, there are ſeveral other circumſtances, beſides that of vaſcular action, which require to be noticed; and particularly the circumſtances connected with reſpiration, ſuch as the temperature, and purity or impurity of the ſurrounding air, its greater or leſs degree of humidity, &c. Theſe, by their chemical agency, muſt have a conſiderable influence in the production of the various morbid alterations which take place.

Many variations, however, in regard to the relative proportion of the conſtituent parts of the blood, and other chemical changes in its qualities, which in all probability frequently take place, are not obvious to the ſenſes, in ſome diſeaſes, whilſt in others they are very conſpicuous: for inſtance, in pleuriſy, peripneumony, acute rheumatiſm, &c. In theſe diſorders, the blood drawn from the veins, and ſuffered to ſtand in the cup until it is cold, becomes covered with a tough buff-coloured coat, or ſize, and is uſually called *inflamed*, or *inflammatory blood*. This ſize is formed (ſays Mr. Hewſon) by the coagulable lymph (which conſiſts of albumen and a portion of fibrin) being fixed or coagulated, after the red particles have ſubſided. The blood in theſe caſes does not appear to be thicker, but on the contrary thinner than natural. It is ſlower in coagulating than healthy blood. The coagulation is owing to the action of the air. Perhaps in pleuriſy, acute rheumatiſm, and other diſorders belonging to the phlegmaſiæ of noſological writers, ſome chemical change is produced in the fibrous matter of the blood (ſee Fourcroy, Connoiſſances Chimiques, article *Sang*), whereby it is preternaturally ſoftened or liquefied; or there may be an over-proportion of albumen, and that of an altered quality. Whatever be the real chemical difference, we cannot think with Mr. Hewſon, that it is wholly occaſioned by the increaſed force or energy of vaſcular action, ſince it ſometimes occurs in caſes where the action of the heart and arteries is not more vigorous than natural, and even where their action appears to be below the natural ſtandard. Thus a ſize has been ſometimes obſerved upon the blood drawn from patients affected with typhus (Parmentier and Deyeux in Fourcroy, as above referred to), and even on the blood taken from ſcorbutic patients. (Ibid.) And Mr. Hewſon himſelf remarks, that it is a common occurrence in pregnant women. Increaſed energy of vaſcular action is doubtleſs a principal cauſe of the changes obſerv-

able in fizy blood; but much is alſo to be aſcribed, in this buſineſs, to the circumſtances connected with reſpiration as before mentioned.

This fizy blood being ſo conſtantly ſeen in pleuriſy, peripneumony, acute rheumatiſm, and other inflammatory diſeaſes, it has been conſidered as a proof of the exiſtence of inflammatory action in all other caſes, wherein it has been obſerved; and has accordingly been deemed by many practitioners the beſt and ſureſt teſt or index when veneſection ſhould be repeated or withheld, as alſo concerning the quantity of blood which ſhould be drawn at each operation. But this is a very wrong mode of proceeding. We have ſhewn that this appearance (the fize or buffy coat of the blood) is not reſtricted to diſorders belonging to the claſs of phlegmaſiæ, but that it occurs in other inſtances, where the free and frequent employment of phlebotomy would be uſeleſs, or even pernicious. Indeed, we have often found it neceſſary to repeat the uſe of the lancet, where this appearance of the blood has been wanting; and to abſtain from a repetition of it, where it has been preſent. In regulating, therefore, the abſtraction of blood, it is neceſſary to attend not only to the appearances of the blood, but more eſpecially to the kind of inflammatory action, to the ſtate of the pulſe and reſpiration, to the degree and ſeat of the pain, and to the age and conſtitution of the patient. Further, the term inflammatory blood, as being liable to miſconception and abuſe, ſhould be diſcontinued; and the expreſſion *fizy blood*, or *blood with a buffy coat*, ſhould be employed in its place. But if the term *inflamed blood* be improper, that of *putrid blood* is much more ſo. This was never yet drawn from any living animal, man or brute. Putridity is eaſily known. The ſmell affords an obvious teſt; but the chemical products obtained from animal ſubſtances in a ſtate of putrefaction, are the ſureſt teſts. Yet thoſe expert chemiſts, Meſſrs. Parmentier and Deyeux, could trace no marks of putridity in the blood taken from patients labouring under the worſt forms of typhus, or what are commonly called putrid fevers. Such blood did not yield, by diſtillation in a water bath, any volatile alkali; nor in a moderate temperature did it run into putrefaction ſooner than the blood of a healthy perſon. The blood in theſe caſes, however, has its peculiar appearances; which, until we arrive at ſomething more certain in regard to the cauſe thereof, we ſhould be content to call *typhus-fever blood*. In like manner, the dark-coloured blood of ſcorbutic patients (which ſome aſcribe to a deficiency of oxygen, and we would add of albumen alſo,) we ſhould be content to call *ſcorbutic blood*, until we have better data to proceed upon. Again, it is conjectured that the pale colour and dilute quality of the blood, in chlorotic and dropſical patients, may be owing to a deficiency of the colouring matter (iron) of the blood, as well as an under-proportion of the fibrous and albuminous matter. But we know not of any experiments by which this has been demonſtrated. Hence we muſt for the preſent be content to name ſuch blood *chlorotic* and *hydropic blood*; taking care at the ſame time to have it underſtood, that in uſing theſe terms, it is by no means intended to convey the idea, that ſuch a ſtate of the blood is the cauſe of chloroſis or dropſy, but merely the concomitant of thoſe diſorders. Whoever wiſhes to inveſtigate the ſubject of the morbid appearances of the blood more fully, ſhould conſult the writings of Hewſon and John Hunter; and for what relates to the chemical part of the inquiry, Fourcroy.

Blood, *Uſes of the*, are either in the animal œconomy (ſee Blood *ſupra*, and Lungs,), or in medicine, religion, diet, arts, manufactures, &c.

Blood, *mechanical and commercial uſes of the*, are chiefly in agriculture, where it is found an excellent manure for fruit-trees; among lapidaries; in the manufacture of ſugar, &c.; in building, boards are ſometimes rubbed with blood to turn them brown. Some alſo pretend it has anciently been uſed in the mortar of old walls. Blood is the baſis of that noble colour called by painters *Pruſſian Blue*. See Prussic Acid.

Blood, *eating of*. This practice appears to have been prohibited to Noah (Gen. ix. 3. 4), which prohibition was renewed by Moſes (Lev. xvii. 10—14.), and obſerved by the Jews, principally with a view to the uſe of ſacrifices in divine worſhip, and as a token of reſpect to the altar, at which the blood of every victim was preſented before God. The prohibition was repeated by the apoſtles at the council of Jeruſalem (Acts, xv. 28, 29.), confirmed and defended by all the fathers except St. Auguſtin, and the univerſal practice both of the eaſtern and weſtern churches till his time; and in many churches, even of the Weſt, much longer, as low as the middle of the 10th, ſome ſay the 11th and even the 12th century. The practice of the primitive Chriſtians ſeems to intimate that they underſtood the apoſtolical prohibition to be abſolute and perpetual, as they abſtained from the uſe of blood for many centuries. When they were charged with meeting in the night, and drinking blood, by way of binding one another to ſecrecy, in ſome immoral practices, Tertullian replies to this charge, that it was well known that no Chriſtian would eat blood at all; inſomuch, that it was uſual with heathens, when they wanted to know whether any perſon was a Chriſtian, to ſet blood-puddings before him as a very ſufficient teſt. Moreover, blood is not eaten by Chriſtians in any part of the Eaſt, or by the Greeks, or Ruſſians, who are of the Greek church, to this day; and it has been alleged, that the uſe of blood was not introduced into this weſtern part of the world till a very late period. When the Pomeranians were converted to Chriſtianity, in 1120, they were particularly enjoined to abſtain from blood, as a badge of their profeſſion. It was not allowed to be eaten in the Weſt in the time of Bede, or a century afterwards; and blood was not eaten in any part of Switzerland, till Calvin introduced the practice from ſome other place. Dr. Lardner, however, ſays (ubi infra), that little regard was paid to theſe regulations of the apoſtolical decree by the Latin Chriſtians, from the end of the fourth century.

The queſtion is, whether the apoſtolical precept to abſtain from blood, ſhould be conſidered as only temporary and occaſional, a ſort of accommodation to the weakneſs of the Jewiſh converts; or perpetual, founded on moral principles, and conſequently ſtill obligatory. The former opinion ſeems the more probable, and is the moſt generally received. For the prohibition in the law of Moſes, two reaſons have been aſſigned; one is, that the blood was appointed to make atonement on the altar for offence againſt the law. The prohibition, according to this reaſon of it, muſt be reſtricted to Jews and others circumciſed after the manner of Moſes; for no other perſons could offer ſacrifices, or be cut off for tranſgreſſing the Levitical laws, but ſuch as were of that people. The other reaſon is thus expreſſed: "It is the life of all fleſh; the blood of it is for the life thereof" (Lev. xvii. 14.); that is, as ſome have interpreted the paſſage, it is the nouriſhment of the animal, and not fit for your nouriſhment; and becauſe it was not fit for food, and was uſeleſs and offenſive, therefore it was to be poured out upon the earth, or covered with duſt, that is, buried in the earth; and this order is frequently repeated. Lev. xvii. 13. Deut. xii. 16, 24; xv. 23. Hence we may account for the conduct

duct of David, when his three warriors brought him water from the well of Bethlehem, at the extreme hazard of their lives (1 Chron. xi. 18.); conſidering the water as if it were their blood, which they hazarded to obtain it, he refuſed to drink it; and there being no rule or reaſon for offering ſuch water upon the altar, he did what ſeemed to be next to offering it; "he poured it out before the Lord." The Jewiſh ordinance anſwered two obvious ends; it ſerved, with other regulations and reſtrictions, to keep the Jewiſh people ſeparate from other nations; and it alſo promoted their bodily health and vigour. But there is no foundation, either in the reaſon of the thing, or in the prohibition, to ſupport the opinion of thoſe who imagine the eating of blood to be an immoral thing; if this had been the caſe, God would not have permitted the Iſraelites (Deut. xiv. 21.) to ſell a creature that died in his blood to an alien or ſtranger, that he might eat it. If, therefore, the eating of blood cannot be reckoned an immorality, the prohibition in the apoſtolical decree cannot be binding upon all men in all times, but only at ſome ſeaſons, when the circumſtances of things render forbearance or abſtinence expedient. Accordingly, if blood be thought diſagreeable and unwholeſome, as food, the uſe of it may be avoided, for the ſake of health; but we are not obliged to abſtain from it upon a religious account, or in virtue of this decree, which would be no better than ſuperſtition. It has been ſuppoſed, by ſome approved writers, and eſpecially by Dr. Lardner, that this was only a temporary proviſion, deſigned to prevent giving offence to the believing Jews, and to facilitate civil converſe and religious communion between believing Jews and Gentiles. Dr. Lardner alſo ſuppoſes, that the decree is not to be underſtood as a precept or commandment, but as delivering advice and counſel concerning ſome matters of prudence and expedience, conſidering the circumſtances of things and perſons in that time. It has been farther urged as an argument againſt the perpetuity of the apoſtolical decree, that the apoſtle Paul never quotes, or alludes to it in his writings.

On the other hand, it has been argued, that the prohibition to eat blood, given to Noah, ſeems to be obligatory on all his poſterity; and as it accompanied the firſt expreſs grant of animal food, it ſeems to be reſerved, by way of acknowledgment to God, as the giver of life, and of the food which ſupports it. This reſpect paid to blood, which is ſhed when animals are killed for food, and which is the moſt apparent vehicle of life, may alſo be intended to inculcate a reſpect for life, as the moſt valuable gift of God, and to warn us not to deprive any animal of it, and much leſs man, without neceſſity. It has alſo been pleaded, as an additional argument for abſtaining from blood, that it is not a wholeſome aliment, eſpecially in hot countries, promoting leprous and ſcorbutic diſorders. The advocates of this opinion farther argue, that blood is prohibited becauſe it tends to make men ſavage; that the prohibition is joined with that of fornication, which is an immorality in the common ſenſe of the term, but which Dr. Lardner underſtands as denoting marriage with heathens, from which the apoſtle Paul ſo earneſtly diſſuades the Chriſtians at Corinth; and that God has enjoined abſtinence from blood on all Chriſtians, in order to manifeſt his ſupreme dominion over all their enjoyments. Selden, de Jure Gentium, &c. l. vii. c. 1. Shuckford's Conn. vol. i. p. 93, &c. Lardner's Remarks on Dr. Ward's Diſſertations in Works, vol. xi. p. 329, &c. Prieſtley's Inſtitutes, vol. ii. p. 439, &c.

Blood, *religious uſes of.*—Among the ancients, blood was uſed for the ſealing and ratifying of covenants and alliances, which was done by the contracting parties drinking a little of each other's blood; for appeaſing the manes of the dead, in order to which blood was offered on their tombs, as part of the funeral ceremony. Thus we read, that twelve youths were ſacrificed at the funeral of Patroclus; and eight at that of Pallas. Homer. Il. Φ. ver. 27. Virgil. Æn. lib. x. ver. 518.

The blood of victims was the portion of the gods, both among Jews and Heathens; and accordingly was poured or ſprinkled on the altars, in oblation to them.

Some have aſſerted, that the Romans offered human blood to appeaſe their deities, which is denied by others.

The prieſts made another uſe of blood, viz. for divination: the ſtreaming of blood from the earth, fire, and the like, was held a prodigy, or omen of evil.

The Roman prieſts were not unacquainted with the uſe of blood in miracles; they had their fluxes of blood from images, ready to ſerve a turn; witneſs that ſaid to have ſtreamed from the ſtatue of Minerva at Modena, before the battle at that place. But in this their ſucceſſors have gone beyond them. How many relations in eccleſiaſtical writers of Madonas, crucifixes, and wafers bleeding! At leaſt the liquefaction of the blood of St. Januarius, at Naples, repeated annually for ſo many ages, ſeems to tranſcend by far all the frauds of the Grecian or Roman prieſthood. But the chemiſts are got into the ſecret, and we find M. Neumann at Berlin performed the miracle of the liquefaction of dried blood, with all the circumſtances of the Neapolitan experiment. See Januarius.

Blood, in the *Romiſh Church*, is uſed in ſpeaking of the wine in the euchariſt; which they ſuppoſe miraculouſly converted, by the prieſt's conſecration, into the real blood of Chriſt. See Transubstantiation, &c.

Blood is alſo uſed abuſively for the ſap of plants; as having much the ſame office in the vegetable, as the other in the animal œconomy. In a ſenſe not unlike this, wine is ſometimes alſo denominated the *blood of the grape.*

Blood is alſo applied, in *Pharmacy*, to certain vegetable juices, tears, &c. as dragon's blood gum. Dragon's blood, *ſanguis draconis*, is alſo uſed by the Arabs for the juice of the anchuſa.

Blood, *ſatyrion*, a ruddy liquor produced from the roots of *ſatyrium*, baked with bread; and liquefied, as it were, into blood, by a long digeſtion.

Blood, in *Chemiſtry* and *Alchemy*, is a denomination given to ſeveral artificial compoſitions, chiefly on account of their red colour.

Blood is more peculiarly uſed by the alchemiſts for the tincture of a thing. In which ſenſe we meet with *blood of mercury*, denoting the tincture of it; dragon's blood, denoting the tincture of antimony.

Blood, *Dragon's.* See Sanguis *Draconis.*

Blood is alſo uſed, in *Middle Age Writers*, for ſupreme juriſdiction, exerciſed by the lord of the fee, in caſes where blood is ſpilt. This is alſo called "judgment of blood," "juſtice of blood," ſometimes "cognizance of blood."

Blood, *avenger of*, among the Jews, was the next of kin to the perſon murdered, who was to proſecute the murderer. Eccleſiaſtical judges retire when judgment is to be given in caſes of blood, becauſe the church is ſuppoſed to abhor blood: it condemns no perſon to death; and its members become irregular, or diſabled from their functions, by the effuſion of blood.

Blood *of Chriſt*, is the denomination of a military order inſtituted at Mantua, in 1608, by Vinc. Gonzangua IV. Its device was "Domine probaſti me;" or, "Nihil hoc triſte recepto." Hermant ſpeaks of this order, and obſerves that it took its name from ſome drops of the blood of Chriſt

faid to have been preſerved in the cathedral church of Mantua. The number of knights was reſtrained to twenty, beſides the grand-maſter; the office whereof was annexed to himſelf and his ſucceſſors.

Blood, in *Farriery*, denotes a diſtemper in cattle's backs, which makes them in going draw their heads aſide, or after them: the cure is by ſlitting the length of two joints under the tail, and thus letting the beaſt bleed plentifully. If he bleed too much, the farriers knit his tail next the body, and then bind ſalt and nettles bruiſed on the part.

Blood-*running itch*, is a ſpecies of itch in a horſe, proceeding from an inflammation of the blood by over-heating, hard riding, or other ſore labour; which getting between the ſkin and fleſh, makes the beaſt rub and bite himſelf; and, if let alone, ſometimes turns to a grievous mange, highly infectious to all nigh him.

Blood, *field of*, in Syriac *aceldama*, was a field purchaſed by the Jews, with the thirty pieces of ſilver which had been given to Judas for betraying his maſter, and which he had reſtored. It ſtill ſerves for a burial-ground, in which all pilgrims, who die in their pilgrimage at Jeruſalem, are interred. See Aceldama.

Blood-*flower*, in *Botany*. See Hæmanthus.

Blood-*hound*. See Hound.

Blood-*letting*. See Bleeding.

Blood, *precious*, in *Eccleſiaſtical Hiſtory*, a denomination given to a reformed congregation of Bernardine nuns at Paris, firſt eſtabliſhed under that name in 1661.

Blood, *Princes of the*, in France, are thoſe deſcended from the blood royal.

Blood-*ſhotten*, in *Surgery*, a diſtemper of the eyes, wherein the blood-veſſels are greatly diſtended, ſo as to make the eyes appear red. See Ophthalmia.

Blood-*ſtone*. See Hæmatites.

Blood *of ſulphur*, *ſanguis ſulphuris*, is a preparation of liver of ſulphur, ground with the oil of tartar *per deliquium*, then digeſted with dulcified ſpirit of nitre. It is reputed a good pectoral and diuretic, but rarely preſcribed.

Blood-*veſſels*, in *Anatomy*, uſually include only the veins and arteries; though, in a larger ſenſe, all the veſſels in the body, as the nerves, lymphatics, &c. to the very hair, may be comprehended under the denomination. See Artery, and Vein.

Blood-*ſnake*. See *Blood*-Snake.

Blood-*wite*, in *Ancient Law Writers*, ſignifies blood, and a cuſtomary amercement paid as a compoſition for the ſhedding or drawing of blood.

The word is alſo written *blodwite*, *blodwita*, *blodwyta*, *bloodwit*, *blodwit*, *bloudwit*, and *bluidweit*; and is formed from the ancient Saxon *blud*, *blood*, and *wite*, or *wite*, a *fine* or *penalty*.

The word alſo denotes an exemption from this penalty, granted by the king to certain perſons and communities, as a ſpecial favour. Thus, king Henry II. granted to all tenants within the honour of Wallingford—"Ut quieti ſint de hidagio et blodwite et bredwite."

Blood *wood*. See Hæmatoxylon.

Blood-*wort*, or *Bloody Dock*, in *Botany*. See Rumex.

Blood, *Corruption of*, in *Law*. See Corruption *of Blood*.

Blood, *inheritable*, denotes ſuch a regular deſcent as gives a perſon legal right to inherit the eſtate of an anceſtor. See Attainder, Escheat, Inheritance, &c.

Blood, *Reſtitution in*. See Corruption *of Blood*, and Pardon.

Blood, *Royal*, is applied to the regular deſcendants of the royal family. See Royal *Family*.

Blood, *whole* and *half*; a kinſman of the whole blood is he that is derived from the ſame pair of anceſtors; whereas a perſon of half blood deſcends from either of them ſingly, by a ſecond marriage. Blackſt. Com. vol. ii. p. 227. See Descent.

Bloody Crime, *Sanguineum Crimen*, in *Writers of the Middle and Barbarous Age*, that which is puniſhed with the blood or life of the offender.

Bloody *Flux*, in *Medicine*. See Dysentery.

Bloody *Hand*, in *Law*, one of the four kinds of treſpaſſes in the king's foreſt, by which the offender being taken with his hands or other part bloody, is judged to have killed the deer, though he be not found either hunting or chaſing. In Scotland, in ſuch crimes, they ſay, taken in the fact, or with the red hand. See Backberond.

Bloody-*hal Cock*. See Heeler.

Bloody *Iſland*, in *Geography*, an iſland in the harbour of Port Mahon, in the iſland of Minorca.

Bloody *Point*, a cape on the ſouth-weſt coaſt of the iſland of St. Chriſtopher's. N. lat. 17° 24′. W. long. 62° 41′.

Bloody *Bay*, a bay on the north ſide of the iſland of Egmont, or New Guernſey.

Bloody-*Farland Point*, a remarkable head-land on the northern coaſt of the county of Donegal, Ireland, nearly oppoſite to Tory iſland. N. lat. 55° 9′ 30″. W. long. 8° 11′. M'Kenzie. Beaufort.

Bloody *Rains*. See Rain.

Bloody *Sweat*. Many inſtances of this are recorded, in which it has been owing to bodily diſorder, or extreme mental agitation and agony. See particularly Ariſtotle's Hiſt. Animal. lib. iii. cap. 19. apud Oper. tom. ii. Thuanus Hiſt. Temp. &c. lib. ii. apud Oper. tom. i. Melanges d'Hiſtoire et de Literature, &c. par M. V. Marville, tom. iii. p. 149. Acta Phyſico-Med. Norimbergæ, vol. i. p. 84. and vol. viii. p. 428. See Agony.

Bloody *Urine*, in *Medicine*. See Hæmaturia, and Urine.

Bloom, in the *Iron Works*, a term uſed by the miners for a four-ſquare maſs of hammered iron, about two feet long, and three quarters of a hundred weight, made from part of a ſow of caſt iron. The bloom, however, is not yet become iron fit for the ſmith's uſe, but muſt undergo many hammerings, and be firſt made what they call the *ancony*; which ſee.

Bloom, *half*, a round maſs of metal, which comes out of the finery of an *iron-work*. See Blomary.

Blooms, in *Sea Language*, hot burning winds, blowing from the land to the ſea.

Bloomfield, in *Geography*, a townſhip of America, in Ontario county, New York. By the ſtate cenſus of 1726, 151 of the inhabitants were electors.

Blooming Vale, a tract of land, in the townſhip of Manlius, and ſtate of New York, or Butternut creek.

Blossom, in a general ſenſe, denotes the flower of any plant. See Flower. In a more proper ſenſe, the word is reſtrained to the flowers of trees, which they put forth in the ſpring, as the forerunners of their fruit, otherwiſe called their *bloom*. The office of the bloſſom is partly to protect, and partly to draw nouriſhment to the embryo fruit, or ſeed. Phil. Tranſ. N° 399. p. 329.

Blossom, in *Botany*, denotes one of the parts of a flower. See Corolla.

Blossom is alſo uſed, in the *Manege*, for the colour of a horſe, which has his hair white, but intermixed all over with ſorrel and bay hairs, called alſo *peach-coloured*.

Horſes of this colour generally are hard and inſenſible both in the mouth and the flank; ſo that they are little valued; beſides they are apt to turn blind.

Blossom, in reſpect of ſheep. See Blissom.

BLOT L'EGLISE, or *Blot le Roche*, in *Geography*, a town of France, in the department of the Allier, 10 miles W. of Gannat.

BLOTED *China Ware*, a name given by ſome to a ſort of china that is loaded with colours in an irregular manner. This pleaſes ſome people, but it is a defective ſort of ware, the large blotches of colours having been only laid on to cover the blemiſhes or faults in the firſt baking.

BLOTNO, in *Geography*, a town of Lithuania, in the palatinate of Wilna, on the river Rawie, 16 miles N. of Lida. N. lat. 54° 5′. E. long. 25° 34′.

BLOTTING PAPER, a ſpecies of paper, made without ſize or ſtiffening, ſerving to imbibe the wet ink in books of account, and prevent its ſetting off, or blotting the oppoſite page.

BLOTTING-*book*, a ſort of minute book, or memorandum book, uſed by ſome merchants for making imperfect entries in a preſent hurry, which are to be copied out fairer and fuller at night into the journal.

BLOUNT, THOMAS, in *Biography*, a learned Engliſh writer, was born at Bordeſley, in Worceſterſhire, in 1619; and, without the advantage of an univerſity education, made a conſiderable progreſs in literature. By profeſſion he was a barriſter of the Inner Temple. Upon the breaking out of the popiſh plot in the reign of Charles II., he was much alarmed on account of his being a zealous Roman Catholic, and ſeized with a palſy, which terminated in his death, in 1679. His works were numerous, and are as follow: viz. "The Academy of Eloquence;" "Gloſſographica, or a dictionary interpreting ſuch hard words, Hebrew, Greek, Latin, Italian, &c. introduced into the Engliſh tongue," 1656, 8vo; "The Lamps of the Law, and the Light of the Goſpel, &c.;" "Boſcobel, or the Hiſtory of his Majeſty's Eſcape after the battle of Worceſter," 1660, 8vo; the ſecond part was printed in 1681, 8vo; "The Catholic Almanac for 1661, 62, 63, &c.; "Booker refuted," or Animadverſions on Booker's Ephemeris, 1665, 4to.;" "A Law Dictionary," 1671, fol.; "Animadverſions upon ſir Richard Baker's Chronicle, &c." 1672, 8vo.;" "A World of Errors diſcovered in the New World of Words, &c." 1673, fol.; "Fragmenta Antiquitatis, ancient tenures of lands, &c." 1679. Biog. Dict.

BLOUNT, SIR HENRY, was born at the ſeat of his father ſir Thomas Pope Blount, at Tittenhanger, in Hertfordſhire, in 1602; and having completed his education at Trinity college, Oxford, he commenced the ſtudy of the law at Gray's Inn. Being reſolved to travel, he ſet out on his tour in 1634, and viſited the Turkiſh dominions in Europe, and alſo ſeveral parts of Egypt. After a long ſtay at Grand Cairo, he returned to England, in 1636, and publiſhed an account of his travels under the title of "A Voyage into the Levant, &c." Lond. 1636, 4to. which had a rapid ſale, though it was not held in high eſtimation by the moſt competent judges. Charles I. appointed him one of the band of penſioners; and, on his father's death, in 1638, he ſucceeded to the family ſeat at Blount's hall in Staffordſhire, and a conſiderable eſtate. In the civil war he joined the royal party; but abandoning the royal cauſe, he was well received in London by perſons in power. In 1651, he became one of the committee for reforming the practice of the law; and he was very zealous againſt tythes, and for the reduction of the ſtipends of all pariſh miniſters to an equal and moderate proviſion. His general knowledge recommended him to the office of one of the commiſſioners for advancing the trade and navigation of the commonwealth. His brother's death, in 1654, made way for his ſucceſſion to the Hertfordſhire eſtate. At the Reſtoration he was favourably received by the king; and in 1661 he ſerved the office of high-ſheriff for the county of Herts. From this time, till his death in 1682, he lived as a retired Engliſh gentleman; but he ſeems to have acquired from his travels an inclination to freedom of opinion, and to have adopted ſeveral ſingular and paradoxical notions. Six comedies, entitled "Court Comedies," and publiſhed under the name of John Lilly, have been aſcribed to him. Biog. Brit.

BLOUNT, SIR THOMAS POPE, eldeſt ſon of the preceding, was born at Upper Holloway, near London, in 1649, and educated under the immediate inſpection of his father. Having eſtabliſhed an early reputation for learning and worth, he was created a baronet by Charles II. in 1679. He repreſented firſt the borough of St. Alban's, and afterwards the county of Herts, and was always eſteemed as a friend of liberty, and a true patron of literature. Of his erudition he gave evidence in his learned work, entitled, "Cenſura Celebriorum Authorum," printed at London, in 1690, folio, and reprinted at Geneva in 1694 and 1710, 4to. This work is an accurate and uſeful compilation, containing an account of the characters and writings of both ancient and modern authors. His work "De Re Poetica," publiſhed in 1694, 4to. is a ſimilar compilation, comprehending an account of ancient and modern poets. His "Natural Hiſtory," printed 1693, 12mo. is a kind of common-place book, containing obſervations, many of which are uncommon, ſelected from the beſt modern writers. Of his talents as an original writer, we have a ſpecimen in his "Eſſays on ſeveral ſubjects," 8vo. in which he diſcuſſes many curious points; ſuch as the influence of the prieſthood; the regard due to the ancients; the variety of opinions; the uncertainty of human knowledge; the effects of cuſtom and education, &c. He died at Tittenhanger in 1697, and left a numerous family. Biog. Brit.

BLOUNT, CHARLES, brother of the preceding, was born at Upper Holloway in 1654, and poſſeſſed diſtinguiſhed talents, which were aſſiduouſly cultivated by his father, who aſſumed the direction of his ſtudies. As he was the favourite of his father, he encouraged his marrying and ſettling in an independent eſtate at the early age of eighteen years. If we except a little treatiſe, publiſhed without his name, and entitled "Mr. Dryden vindicated, &c." his literary career commenced in 1678 or 1679, with the publication of his "Anima Mundi, or an hiſtorical narration of the opinions of the ancients concerning man's ſoul after this life, according to unenlightened nature;" in the compoſition of which he is ſaid to have been aſſiſted by his father. This work contained free opinions, which gave great offence; and though it had been previouſly licenſed, was ſuppreſſed by order of Compton, biſhop of London; and during his abſence burned by ſome officious zealot. Several anſwers to it were written; and it was particularly animadverted upon in the ſecond volume of Nichols's Conference with a Theiſt. In the ſame year Mr. Blount publiſhed ſome extracts from Hobbes's Leviathan, in a ſingle ſheet, entitled "Mr. Hobbes's laſt Words and dying Legacy;" and intended to expoſe, probably, the political principles of this writer. To theſe, his ardent zeal for liberty rendered him peculiarly adverſe; and his zealous attachment to this cauſe was ſoon after manifeſted in a pamphlet, under the ſignature of "Junius Brutus;" deſigned to alarm the nation with regard to a popiſh plot, and the proſpect of a popiſh ſucceſſor to the crown. In 1680 he publiſhed his tranſlation of "the Two Firſt Books of Philoſtratus, concerning the life of Apollonius Tyanæus, with philological notes on each chapter," fol. which, being conſidered as a dangerous attempt to reproach and injure the Chriſtian religion, was immediately ſuppreſſed, ſo that few

few copies of it could be obtained. This was followed, in the same year, by a work entitled "Great is Diana of the Ephesians, or the Original of Idolatry, together with the political institutions of the Gentiles' Sacrifices;" which, though professedly written against the impositions of the Heathen priests, was thought to be aimed at the Christian priesthood, and indirectly against all revelation. The author was now considered as the head of the Deistical sect, and he is charged with having taken great pains, by conversation and correspondence, to propagate and defend his opinions. In a letter to Dr. Sydenham, however, he acknowledged, that in point of practice, Deism was less satisfactory than the Christian scheme. The clamour occasioned by his former publications made him somewhat more cautious and reserved; and accordingly he studiously concealed his being the author of a treatise, entitled "Religio Laici;" published in 1683, and said, by Dr. Leland, in his Deistical writers, vol. i. p. 37. to be little more than a translation of Lord Herbert's work, under the same title; and he also abandoned the design which he had formed of writing a life of Mahomet. From this time he seems to have changed the objects of his study; for in 1684 he published "Janua Scientiarum; or an Introduction to Geography, Chronology, Government, History, Philosophy, and all genteel sorts of learning;" 8vo. which was intended to assist young persons at an early age in the acquisition of principles of philosophy and science, without pursuing the tedious course that had been usually prescribed to them in schools.

Mr. Blount was one of those who cordially concurred in the revolution: and in a letter addressed to W. Levefon Gower concerning corporations, and inserted in the "Oracles of Reason," he expresses his wish, that those counsellors of the late king, who had injured the independence of parliament, might be punished, justly considering the purity of representation as the essence of a free constitution. About this time he wrote his treatise entitled "A Just Vindication of Learning, and of the Liberty of the Press;" which is esteemed one of his best performances, and a summary of all the principal arguments that can be urged upon this topic. In his zeal for the cause of king William, he wrote a pamphlet in 1693, intended to prove the right of William and Mary to the crown, on the ground of conquest; and in explanation of this design, so dissonant, one would imagine, with his principles, and no less obnoxious than ill-founded, he declares that he wrote "with an especial regard to such as have hitherto refused the oath, and yet allow of the title of conquest, when consequent to a just war." By this performance he gave such offence, that, on a complaint being brought before the house of commons against this pamphlet, entitled "William and queen Mary Conquerors," it was ordered to be burnt by the hands of the common hangman; and in the same censure was involved a pastoral letter of bishop Burnet, in which the same notion was advanced, probably with the same views.

Mr. Blount, having lost his wife, became ardently enamoured of her sister, a lady of great beauty and merit, who seemed disposed to return his affection; but as the ecclesiastical laws opposed their union, he drew up a case strongly argued, and referred it to certain divines, who of course gave their opinions against his wishes. As the lady refused to comply, after such a determination, Mr. Blount sunk into despair, and at length shot himself through the head.

After this act of phrensy, he languished for some days, receiving no nourishment but from the hands of the object of his affection, till at last death released him, August 1693. Many of his private letters and some small tracts were published, together with a preface, by Gildon, in 1693, before the author's death, in a work entitled "The Oracles of Reason;" which was afterwards re-printed, with some additional pieces, after his decease, in 1695, in a collection of "The Miscellaneous Works of Charles Blount, esq." by the same Mr. Gildon, who prefixed to it an account of the life and death of the author. The learning of Mr. Blount is unquestionable, and he seems to have possessed a strong and ardent mind; but his early dislike of superstition precipitated him into some very considerable errors, and inclined him to believe all revealed religion to be priestcraft, because he perceived that some priests had converted religion to their own secular advantage. His sentiments on the subject of religion were divulged in his writings without disguise, and sufficiently warrant our referring him to the class of deists; but the charge of atheism alleged against him by some foreign divines, is certainly unfounded. See an account of Mr. Blount's writings by Dr. Leland, in the fourth letter of his View of the Deistical Writers, vol. i. By this author we are informed that Mr. Gildon, who published the "Oracles of Reason," and communicated them to the world, was afterwards, upon mature consideration, convinced of his error, and in 1705 published his retractation in a book, entitled "The Deist's Manual." The greatest part of this book is intended to vindicate the doctrines of the existence and attributes of God, his providence and government of the world, the immortality of the soul, and a future state. And his avowed reason was, because many of the deists, with whom he was well acquainted, did really deny those great principles, which lie at the foundation of all religion, or, at least, represented them as doubtful and uncertain. And their not admitting natural religion in its just extent, formed some of their principal prejudices against the Christian revelation. Biog. Brit.

Blount, in *Geography*, a new county of the State of Tenessee, in America.

BLOUNTSVILLE, a town of America, in North Carolina, on the post-road from Halifax to Plymouth, 49 miles from Plymouth, and 55 from Williamstown.

BLOW, in a general sense, denotes a stroke given either with the hand, a weapon, or instrument. The effect of a blow is estimated like the force of percussion, and accordingly it is expressed by the velocity of the body multiplied by its weight.

In *Fencing*, blows differ from thrusts, as the former are given by striking, the latter by pushing. We say to give, to return, to parry a *blow*. (See Parrying.) Blows on the sword make a kind of pursuit, called beating.

Blow, *blind*, *ictus orbus* or *cæcus*, is that which does not appear, or is not attended with effusion of blood; in contradistinction from that followed by a wound, discolouring, *tumor*, or the like, called *ictus apertus* or *apparens*, an open *blow*.

In the ancient laws, we find blows for remembrance, given to make persons remember some transaction, and enable them to become better witnesses of it in future times.

Blow, *military*, *alapa militaris*, that given with the sword on the neck or shoulder of a candidate for knighthood, in the ceremony of dubbing him. The custom seems to have taken its rise from the ancient ceremony of manumission.

In giving the blow, the prince used this form: "esto bonus miles;" upon which the party rose a complete knight, and qualified to bear arms in his own right. Sometimes a double or even triple blow was given, called *trina percussio*.

Blow, Dr. John, in *Biography*, born at North Collingham, in Nottinghamshire, was one of the first set of children of the chapel royal after the restoration, that was brought up under captain Cook. He likewise received instructions

from Hingeſton, domeſtic organiſt to Oliver Cromwell, and Dr. Chriſt. Gibbons. In 1673, he was ſworn one of the gentlemen of the chapel; and in 1674, upon the deceaſe of Humphrey, appointed maſter of the children. In 1685, he was nominated one of the private muſic to king James II. and in 1687, he was likewiſe appointed almoner and maſter of the choriſters in the cathedral church of St. Paul; but, in 1693, he reſigned this laſt place in favour of his ſcholar Jeremiah Clark.

Blow had his degree of doctor of muſic conferred on him by the ſpecial grace of archbiſhop Sancroft, without performing an exerciſe for it in either of the Univerſities. On the deceaſe of Purcell, in 1695, he was elected organiſt of St. Margaret's, Weſtminſter; and, in 1699, appointed compoſer to the chapel of their majeſties, king William and queen Mary, at a ſalary of 40l. a year, which afterwards was augmented to 73l. A ſecond compoſer, with the like appointment, was added in 1715, when John Weldon was ſworn into that office; at which time it was required that each ſhould produce a new anthem on the firſt Sunday of his month of waiting.

That Blow was a compoſer of anthems, while a finging-boy in the chapel royal, appears from Clifford's Collection of the Words of the Services and Anthems uſed in our collegiate and cathedral churches, 1664; for among the eccleſiaſtical compoſers mentioned in this book, amounting to upwards of ſixty, are included the names of Pelham Humphrey, John Blow, and Robert Smith, children of his majeſty's chapel. Humphrey was born in 1647, and Blow in 1648; ſo that at the reſtoration, the firſt being only thirteen, and the ſecond but twelve, their compoſing anthems fit for the chapel royal, before they had attained the age of ſixteen or ſeventeen, would now be regarded as wonderful proofs of precocity, if Purcell, ſoon after, at a more early period of his life, had not produced compoſitions that were ſtill ſuperior to theſe.

Dr. Blow died in 1708, at ſixty years of age; and though he did not arrive at great longevity, yet, by beginning his career, and mounting to the ſummit of his profeſſion ſo early, he enjoyed a proſperous and eventful life. His compoſitions for the church, and his ſcholars who arrived at eminence, have rendered his name venerable among the muſicians of our country.

Though his church muſic was never collected in a body, yet, beſides the three ſervices and ten full and verſe anthems printed by Boyce, in Dr. Tudway's MS. collection, nineteen of his choral productions have been preſerved; and in Dr. Aldrich's collection in Chriſt-church there are five more. The aggregate of which, amounting to upwards of forty different compoſitions of this elaborate kind, is but a ſmall part of what might be found in the chapel and choir-books of our cathedrals.

Some of his choral productions are doubtleſs in a very bold and grand ſtyle; however, he is unequal, and frequently unhappy, in his attempts at new harmony and modulation; but, as a compoſer who ranked ſo high among our moſt claſſical maſters ſhould not be praiſed or cenſured indiſcriminately, we ſhall point out a few inſtances of his great, and, to our conceptions, unwarrantable licentiouſneſs, as a contrapuntiſt.

We are as ſorry to ſee, as to ſay, how confuſed and inaccurate a harmoniſt he was; but as it is neceſſary to ſpeak of an artiſt ſo celebrated and honoured by his contemporaries, to diſſemble his faults would ſurpaſs candour, and incur the cenſure of ignorance and partiality; for it is as much the duty of an hiſtorian to blame as to praiſe, when juſtice and integrity require it. Indeed, upon whatever ſubject a man writes, he ſhould aſpire at nothing ſo much as ſpeaking truth, if he wiſhes for the approbation of his conſcience, which is not only the moſt comfortable of all praiſe, but, luckily, the moſt within his own power. The abilities of the dead, we can have no intereſt in depreciating; and if our opinion ſhould be unjuſt, the miſchief will recoil on ourſelves; for the dead have more friends than the living, who are ever ready to vindicate ſuch wrongs.

Though there are ſtrokes of pathetic and ſubjects of fugue in Blow's works that are admirable; yet we have examined no one of them that appears to be wholly unexceptionable, and free from confuſion and crudities in the counterpoint. Of the two-part anthem with choruſes, "Lord how are they increaſed," the firſt movement is very plaintive and expreſſive; but there are licences in the harmony which look and ſound quite barbarous. Indeed, theſe crudities are ſo numerous as to throw a doubt on his learning, as well as genius. Whether they are notes of paſſion, effuſions of an unruly ſpirit, or of ignorance and affectation, we will not venture to determine; but, to our ears, they have the full effect of jargon and want of principles.

It does not appear that Purcell, whom he did himſelf the honour to call his ſcholar, or Crofts, or Clark, his pupils, ever threw notes about at random, in his manner, or inſulted the ear with lawleſs diſcords, which no concords can render tolerable.

In an anthem, "Turn thee unto me, O Lord," printed by Henry Playford in the ſecond collection of Divine Harmony, there are ſo many wanton violations of rule, particularly in the laſt chorus, that it would be endleſs to point them out; but they ſeem ſuch as no rule, authority, or effect, can juſtify; 7ths reſolved on the 8th, aſcending and deſcending; 2ds treated with as little ceremony as 3ds. Indeed, we never ſaw ſo ſlovenly a ſcore in print, and it may, in general, be ſaid of his faults in counterpoint, that there are unaccounted millions of them to be found in his works.

He has been celebrated by Dr. Boyce, for "his ſucceſs in cultivating an uncommon talent for modulation;" but how ſo excellent a judge of correct and pure harmony could tolerate his licences, or reconcile them to his monumental character, and the additional praiſe he has himſelf beſtowed upon him, is as unaccountable as any thing in Blow's compoſitions, conſidering the knowledge and known probity of the late worthy editor of Cathedral Muſic.

Many of his ballads, though only in two parts, are full of crude diſcords unprepared and unreſolved; the cauſe of which, in ſome meaſure, may be aſcribed to the *ground-baſes*, on which it was now the faſhion to write: for melody being ſcarce, both that and the harmony were frequently injured by this Gothic reſtraint. But the paſſing-notes and notes of embelliſhment of the compoſers, in general, of this period, were uncouth in melody, and licentious in harmony. Perhaps thoſe of the preſent times, in leſs than a century, will be equally unpleaſing to the ears of poſterity; and yet we fancy that both melody and harmony have received their laſt poliſh.

The ballads of Dr. Blow are in general more ſmooth and natural than his other productions, and, indeed, than any other ballads of his time; there is more melody than in thoſe of Henry Lawes, or any compoſer of the preceding reign; yet it is not of that graceful kind in which the Italians were now advancing towards perfection, with great rapidity. It is either of a Scots caſt, or of a languid kind, that excites no other ſenſation than fatigue and drowſineſs.

His paſtoral, "Since the Spring comes on," is, however, as *chantant* as any mongrel mixture of Scots, Iriſh, French, and Engliſh, that has been ſince compiled.

piled. The firſt movement, particularly, ſeems to have been the model of moſt of the Vauxhall ſongs of the laſt fifty years.

"Fill me a bowl," p. 52, has the ſame kind of merit.

The collecting of his ſecular compoſitions into a folio volume in 1700, under the title of "Amphion Anglicus," was doubtleſs occaſioned by the great ſucceſs of the "Orpheus Britannicus," a ſimilar collection of Purcell's dramatic and miſcellaneous ſongs, publiſhed by his widow, in 1698. But whether Dr. Blow was ſtimulated to this publication by emulation, envy, or the ſolicitation of his ſcholars and friends, by whom there are no leſs than fifteen encomiaſtic copies of verſes prefixed to the work, the ungrateful public ſeems to have remained always inſenſible to theſe ſtrains of the modern *Amphion*, which were not only incapable of building cities, but even of ſupporting his own tottering fame.

Some of his innumerable deformities from the Amphion Anglicus are added to thoſe of his church muſic, in the third vol. Gen. Hiſt. Muſ. "Go perjured man," is the beſt of all his ſecular productions; but that, which was an imitation of a duet by Cariſſimi, "*Dite, O cieli*," is overloaded, in his "Amphion Anglicus," with a laboured and unmeaning accompaniment. P. 44 and 46 of this collection, contain two of his beſt ballads, "Sabina has a thouſand charms," and "Philander do not think of arms." In theſe ballads the union of Scots melody with the Engliſh, is firſt conſpicuous. The ſubject of a ſong, p. 168, "Orithea's bright eyes," is likewiſe broad Scots.

Blows, in *Common Law*. See Battery.

Blows, *fly*, the *ova* of flies depoſited on fleſh, or other bodies proper for hatching them.

Blow, in the *Sea Language*: when the wind increaſes from a moderate breeze, it is ſaid to blow; and, according to the various degrees of ſtrength with which the wind blows, it receives different appellations.

Blow-pipe, *Tubus ferrumnatorius*, Lat.; *Löthrohr*, *Blaſerohr*, Germ.; *Chalumeau*, Fr. A blow-pipe is a wind inſtrument for the purpoſe of increaſing the heat of a candle or lamp, in the ſame manner as a pair of bellows is employed for raiſing the temperature of a common fire or furnace. It is not known at what time or by whom this very uſeful inſtrument was invented, but it appears to have been employed by glaſs-workers, enamellers, and jewellers, long before it was adopted as an article of chemical apparatus. The firſt intimation of its value to the chemiſt is to be found in Kunkel's treatiſe on glaſs-making.

The common glaſs-blower's lamp is repreſented in *Plate* X. *fig.* 1. (*Chemiſtry*). A, is a wooden table, within the frame of which is fixed a pair of double bellows B, that are worked by the foot of the artiſt; from the nozle of the bellows proceeds a pipe of lead, or tinned iron, CC, which, firſt riſing perpendicularly, is then brought under the top of the table to D, where it penetrates the wood, and terminates on its upper ſurface, in a recurved hollow cone E, the apex of which is pierced with a minute round hole. A ſhoe-lamp, F, is placed on the table, ſo that its wick is ſomewhat below, and about half an inch diſtant from the aperture of the pipe; the bellows being then worked, a conſtant ſtream of air is thrown upon the wick of the lamp, producing a long conical horizontal flame, G, of very conſiderable intenſity. The increaſed heat of the flame appears to depend, in part, on a more rapid and complete combuſtion of the oil, and in part, alſo, on the concentration of the flame, by the action of the blaſt. The flame, upon examination, will be found to conſiſt of an exterior yellow cone, incloſing another of a lighter yellow colour, at the extremity of which laſt is the focus of greateſt heat.

The ſhoe-lamp (more diſtinctly repreſented in *fig.* 2.) is ſo called from its reſemblance to a ſhoe. It is made of tinned iron, and conſiſts of two parts; the exterior, *a*, ſerves to hold the proper lamp, and to retain the oil, which occaſionally drops from the wick; the lamp, *b*, has a fixed cover, except at the tip, *c*, where a circular aperture is left for the wick, *d*, which conſiſts of a bundle of cotton threads, about an inch in diameter; at *e* is a hinge, by which that part of the lid neareſt the wick may be raiſed, in order to pour in freſh oil, or to renew or raiſe the wick.

The glaſs-worker's blow-pipe is, however, not ſufficiently portable for the uſe of the chemiſt and mineralogiſt, and it was a happy thought of Swab, the Swediſh mineralogiſt, to ſubſtitute the lungs for the bellows. Gahn, Engeſtroem, and Bergman ſuggeſted various improvements in the conſtruction of this inſtrument, which now appears to have attained as great a degree of perfection, as it is perhaps capable of.

The common chemical blow-pipe conſiſts of five parts; (*Chemiſtry*, *Plate* XI. *fig.* 3.) the mouth-piece, *a*; a plain tube, *b*; a bulb, *c*; a curved tube, *d*; and a nut, *e*

The mouth-piece (more diſtinctly repreſented by *fig.* 5.) is made of ivory, the reſt of the apparatus being of braſs, and fits cloſely into the pipe, *b*, ſo as to be air-tight; the bulb, *c*, is divided into two hemiſpheres, which ſcrew into each other, and is deſigned to collect and condenſe the moiſture of the breath; into the lower hemiſphere is fixed the recurved tube, *d* (as repreſented in *fig.* 4.), in ſuch a manner as to prevent the condenſed vapour from eſcaping out of the bulb; the nut, *e*, is a hollow cylinder ſufficiently wide at one end to receive the extremity of the curved tube, and perforated at the other with a ſmall round hole, to allow a paſſage for the air; each blow-pipe has generally three of theſe nuts (*fig.* 6.), with apertures of different ſizes, the largeſt of which does not exceed the diameter of the ſmalleſt pin.

In uſing the portable blow-pipe, the only difficulty is to keep up a conſtant ſtream of air; which is to be done by performing the function of reſpiration through the noſtri's alone, diverting from time to time a portion of the *expiration* into the mouth for the ſupply of the blow-pipe, and forcing it through the tube by the action of the muſcles of the cheek. This knack is by ſome acquired in an inſtant, while others are a long time in making themſelves maſters of it. To thoſe who experience any difficulty in the free uſe of this inſtrument, the following directions may be of ſervice. Firſt, let the learner accuſtom himſelf to breathe freely with the mouth ſhut; then in making an expiration, let him tranſfer the air into the mouth, till the cheeks are moderately inflated, and retaining it there, let him diſcharge the ſurplus of the expiration through the noſtrils, and then make two or three eaſy inſpirations and expirations through the noſtrils, without allowing the air in the mouth to eſcape. When practice has rendered this eaſy, which may be effected in half an hour, let the nut with the ſmalleſt aperture be fixed on the curved tube of the blow-pipe, and introduce the mouth-piece within the lips; then inflate the cheeks by an expiration, and continue breathing eaſily through the noſtrils, till nearly the whole of the air has paſſed out of the mouth through the tube; then renew the air as before, and, after a few days' practice, the muſcles of the mouth will be accuſtomed to this new mode of exertion, and an uniform uninterrupted ſtream of air may be kept up for half an hour without any extraordinary fatigue. A wax candle, *f*, having burnt long enough to allow the wick to be turned down, in the manner repreſented in the plate, the nut of the blow-pipe is to be applied to the arch of the wick, and the air, as it comes through, will bend the flame into a neat horizontal cone, the exterior part of which is yellow, and the interior

interior blue. The ſubſtance under examination being reduced to the ſize of a peppercorn, is to be placed in the platina ſpoon, *fig.* 7. or into a ſhallow cavity in a piece of compact charcoal, and being firſt gradually heated by the yellow flame, *g*, is afterwards to be expoſed to the full intenſity of the blue focus, *h*.

An important uſe of the blow-pipe in the laboratory is to ſoften glaſs-tubes, &c. in order to bend them to any ſhape that may be required, for which purpoſe the blow-pipe juſt deſcribed is not very well qualified, the flame not being large enough, and, from its intenſity at the blue focus, acting very unequally. It may, therefore, in theſe, and ſimilar caſes, be advantageouſly ſuperſeded by the alcohol blow-pipe.

This inſtrument, the invention of which is due, we believe, to M. Paul and profeſſor Pictet of Geneva, has received ſome improvements from Engliſh artiſts, and is figured in *Chemiſtry*, *Plate* XI. *fig.* 1. and 2. It is made of braſs, and conſiſts of the following parts: A is an oval baſe, in which are two round holes, for the reception of the two ſpirit lamps, B, and C, the latter of which has a conſiderably thicker wick than the former. D is a pillar that ſcrews into the baſe, and ſupports a moveable braſs collar, E, which may be retained at any convenient height by the ſcrew, F. L is the boiler hanging looſely, but ſecurely, in the collar, E; M is a ſcrew accurately cloſing an aperture in the boiler, through which it is filled with alcohol; I is a conical plug, ſerving as a ſafety-valve, the reſiſtance of which to the expanſion of the vapour is regulated by the ſteel ſpring H, compreſſed between the ſcrew nuts G and K; O is the delivering pipe, ſeen more particularly at *fig.* 2. It conſiſts of a plain tube, *e*, ſomewhat longer than the depth of the boiler, of a ſhoulder and ſcrew, *b*, by which it is fixed in the bottom of the boiler, of a ball and ſocket joint (compoſed of the ſphere, *c*, *d*, incloſing the perforated bulb and ſtem *e*, *f*), and of the nut *g*, terminated by a ſmall aperture, &c. ſcrewing on the ſtem, *f*. N (*fig.* 1.) is a hollow cap, ſcrewing into the boiler, and receiving the head of the tube, *a*, to prevent any liquid alcohol from being thrown into it. This blow-pipe works in the following manner: The boiler being filled with alcohol, and the ſcrews and valve ſecured, the lamps, B and C, are lighted. The alcohol in the boiler being brought to ebullition by the lamp B, the vapour aſcends into the cap N, whence it paſſes down the tube O, and is diſcharged at P, upon the wick of the lamp C, producing a long bulky horizontal flame Q, whoſe extreme temperature is nearly equal to that of melting copper, and is admirably fitted for the working of glaſs.

Mr. Benjamin Hooke, lately an ingenious mathematical inſtrument-maker in Fleet Street, has made ſome improvements in the blow-pipe by alcohol; for a deſcription and drawing of which we refer to Nicholſon's Journal, vol. iv. p. 106, 8vo.

The blow-pipe is of conſiderable uſe to the mineralogical chemiſt, from its being very portable, and ſhewing, in a few minutes, upon a very ſmall quantity of any mineral ſubſtance, the effect that would be produced by its expoſure to the heat of our moſt powerful furnaces. It is alſo a valuable inſtrument in the analyſis of minerals, by indicating their principal contents, rudely and imperfectly indeed, yet ſo as to afford a clue to the chemiſt in his ſubſequent operations.

The efficacy of the blow-pipe, in fuſing the moſt refractory ſubſtances, is, however, greatly increaſed by charging it with oxygen gas; a heat is thus produced, fully equal to that of the ſolar rays concentrated by the beſt lenſes. The apparatus for this purpoſe conſiſts of the common blow-pipe, with the mouth-piece taken out, and connected to a gazometer, by a flexible tube of elaſtic gum; the curved tube and terminating nut of the blow-pipe ought, however, to be made of platina, the heat produced being ſo intenſe as frequently to fuſe and inflame thoſe parts of the inſtrument, if made of braſs. The operator ſhould alſo be careful to wear ſpectacles of green glaſs, in order to protect his eyes from the intolerable white glow, which is ſo intenſe as to cauſe even the flame of a common wax candle to caſt a very ſenſible ſhade. Sometimes a double blow-pipe is made uſe of in experiments with oxygen gas, by which the effect is conſiderably increaſed. A repreſentation of this is ſeen in *Chemiſtry*, *Plate* X. *fig.* 3. The part, *a*, which joins the tube of the gazometer, turns air-tight in a collar, *b*, on the end of the tube, *b*, *c*. On this tube are two braſs boxes, *d*, *e*, into which are fitted the tubes, *f*, *g*, which alſo turn in air-tight ſockets, for the purpoſe of enabling the operator to move the blow-pipes, *h*, *i*, nearer to or further from each other. The blow-pipes, *h*, *i*, are alſo moveable at *k*, *l*, by which the direction of the blaſts may be varied, ſo as to meet on the charcoal, *m*, at any angle that may be required.

The cauſe of the great heat which is produced by the blow-pipe, has generally been attributed both to a concentration of the flame in a ſmall focus, and a more rapid combuſtion than uſual. Count Rumford, however, (Eſſays, vol. ii. p. 69.) ſuppoſes that the effect of this inſtrument is entirely due to the former of theſe cauſes; and in ſupport of this hypotheſis, he mentions the reſults of ſome experiments made by himſelf, which are ſo contrary to daily experience, and were conducted in ſo inaccurate a manner, as to deſerve, in our opinion, very little confidence.

He begins by ſaying, "A current of air cannot *generate* heat, without, at the ſame time, being decompoſed; and, in order to its being decompoſed in a fire, it muſt be brought into actual contact with the burning fuel, or at leaſt with the uninflamed inflammable vapour which riſes from it. But can it be ſuppoſed that there can be any thing inflammable, and not actually inflamed, in the clear, bright, and perfectly tranſparent flame of a wax candle? A blow-pipe has, however, as ſenſible an effect when directed againſt the clear flame of a wax candle, as when it is employed to increaſe the action of a common glaſs-worker's lamp." To this it may be replied, in the firſt place, that flame is not tranſparent; and, ſecondly, that a conſiderable quantity of "uninflamed inflammable matter" is contained in the flame, as is evident from the ſoot that may be collected by holding a plate of glaſs or metal over it, ſo as juſt to touch the ſummit. The count proceeds to relate that carbonic acid being driven by a blow-pipe through the "clear, brilliant flame of a wax-candle juſt ſnuffed," melted a ſmall tube of glaſs in the ſame time as when the pipe was charged with atmoſpheric air, or even with oxygen gas. We have repeated theſe experiments, and obſerved, that when the blaſt was directed to the whiteſt part of the flame, no well defined horizontal cone was produced by any of the three gaſes; that when carbonic acid, or the breath, was paſſed through the flame juſt above the wick, a well defined cone was produced, the interior of which was of a light blue, and the exterior of a pale yellow; when atmoſpheric air was employed, the whole cone was of a bright yellow; and, with oxygen gas, the whole flame was of a dazzling white. The effect of the ſecond in melting glaſs was greater than that of the firſt, and the laſt was much more powerful than the ſecond. Neri, art de la Verrerie. Bergman's Eſſ. vol. ii. Philoſophical Magazine, vol. viii. p. 325.

BLOWER, *ſouffleur*, an appellation of contempt, ſometimes given to an alchemiſt.

In the French king's kitchen, there was anciently an of-

ficer under the denomination of *fufflator*, or *fire-blower*. The Roman mint-men were diſtinguiſhed by the appellation of blowers of gold, ſilver, and braſs, &c. *flatores auri, argenti*.

Blower, among dealers in horſes, a term uſed for ſuch horſes as wheeze much, without wanting wind. See Wheezing.

BLOWING, in *Medicine*. One method of adminiſtering medicines is by inflation, or blowing them into the part by a tube: thus it is they ſometimes convey powders into the eye, and ſometimes up the noſe, for the cure of a polypus.

Blowing, *exſufflatio*, was alſo a ceremony in the ancient adminiſtration of baptiſm, whereby the catechumen, upon rehearſing the renunciation, blew three blaſts with his mouth, to ſignify that he rejected or caſt the devil abſolutely off.

Something like this is ſtill retained in the Ruſſian church. In the ſacramentary of St. Gregory, the prieſt who adminiſters baptiſm, is enjoined to blow thrice on the child's face, making the ſign of the croſs with his hand, and pronouncing the words *exi ab eo Satan*. Juſtin Martyr, Tertullian, St. Cyril, and St. Auguſtin ſpeak of this ceremony as uſed in their times.

Blowing *of a fire-arm*, is when the touch-hole is run or gulled, and become wide, ſo that the powder will flame out.

Blowing is alſo uſed in ſpeaking of the natural motion or courſe of the wind.

In the *Sea-Language*, the wind is ſaid to *blow home*, or *blow through*, when it does not ceaſe, or grow leſs, till it comes paſt the place where the ſpeaker is. To *blow through* is ſometimes alſo uſed to denote, that the wind will be ſo great as to blow aſunder the ſails. When a wind increaſes ſo much that they cannot bear any top-ſails, they ſay, they were *blown into their courſes*, i. e. they could only have out the ſails ſo called. To expreſs an extraordinary great wind, they ſometimes ſay, it will blow the ſail out of the bolt-ropes.

Blowing is alſo uſed in ſpeaking of the force and effect of kindled gunpowder on bodies which happen to be over it. In this ſenſe we ſay to blow up a houſe. Engineers at ſieges make mines wherewith to blow up walls, baſtions, and other defences. Powder-mills are apt to blow up by the iron gudgeons growing hot, and ſetting fire to the powder duſt flying about.

Blowing, among *Gardeners*, denotes the action of flowers whereby they open and diſplay their leaves. In which ſenſe, blowing amounts to much the ſame with flowering and bloſſoming.

Blowing of Glass, one of the methods of forming the divers kinds of works in the glaſs manufacture. It is performed by dipping the end of an iron ponteglio, or blow-pipe, in the melted glaſs, and blowing through it with the mouth, according to the circumſtances of the glaſs to be blown.

Blowing *of tin*, a term uſed by the Corniſh miners for the fuſion or reduction of tin-ore to the metallic ſtate, after having been roaſted to get rid of the ſulphur and arſenic.

Blowing *Machine*, is uſed in metallurgical operations on a great ſcale, for the purpoſe of exciting combuſtion in furnaces appropriated for the ſmelting and reducing of ores.

The hiſtory and improvement of machinery of this nature have kept pace with the other branches of our national manufacture, and, in many inſtances, may be juſtly ſaid to have gone beyond them.

In the ſmelting of lead and tin ores, the ſize and powers of the blowing machine have been leſs a ſubject of alteration and improvement, than thoſe uſed at furnaces and works where iron ore is ſmelted.

The natural fuſibility and eaſy volatilization of the former metals, in temperatures beyond a bright red heat, have preſcribed the ſize of the furnace, the meaſure of the blaſt, and the nature of the fuel.

In the manufacture of copper, air-furnaces are generally uſed, except where precipitated oxyd of copper is revived in ſmall blaſt-furnaces, reſembling thoſe called cupolas, uſed at iron founderies.

The conſtruction of a lead ſmelting machine, or what is commonly called a "Lead Mill," is extremely ſimple. A water wheel is erected in the middle of a ſquare building. To the ſhaft of this wheel are attached four ſmall wheels of caſt iron, about 18 inches diameter. Four pairs of bellows, two pairs on each ſide of the ſhaft, are placed at equal diſtances, and ſupported upon a ſtrong framing of wood. As the water wheel ſhaft revolves, the ſmall wheels are carried round, and alternately, or two and two together, depreſs the extremity of a lever attached by an iron chain to an equipoiſed beam. The deſcent of this lever elevates the oppoſite end of the beam, to which is alſo attached, by means of another iron chain, the upper or moveable ſurface of the bellows. The blaſt produced in this way is in general ſoft, much inferior in point of either quantity or denſity to what is found neceſſary at iron furnaces. The bellows in common meaſure 10 feet in length, and 5 or 6 feet acroſs the breach, moving about 30 ſtrokes per minute.

In the manufacture of iron it has always been, particularly ſince the introduction of pit-coal, the unceaſing object of the iron-maker to improve his blowing apparatus; for uniformly he has found, that in proportion as he can raiſe air, and make it enter the furnace, ſo will his weekly quantity of metal be increaſed.

In the early hiſtory of this intereſting manufacture, when charcoal of wood was the matter of fuel made uſe of, the affinities betwixt the latter and the ore were eſtabliſhed with more facility. Small furnaces, called bloomeries, were ſufficiently large, and deemed of profitable capacity, if they produced a bloom or two of iron per day, of 90 to 120 lbs. each.

Hand bellows, and what were called fuel blaſts, were ſufficiently large for the minor operations. After the general introduction of the refinery furnaces, and the diviſion of the manufacture into the making of pig iron, and the refining of this into bar or malleable iron, the advantages of a powerful blaſt were immediately perceived. Water wheels, working two pairs or more of leather bellows, were found to produce powerful effects, and, in conſequence, almoſt every ſituation that preſented a command of materials and a waterfall, became the ſeite of an iron-mill.

The ſimple mode of blowing furnaces by means of a trompe, was at the ſame time introduced; but in general it was found, that much greater advantage could be derived from the deſcent of water upon a wheel, either as to denſity or quantity, than by means of the beſt conſtructed trompe.

The uſe of water wheels and leather bellows continued general throughout the iron buſineſs, until the principles and mechaniſm of the ſteam engine were eſtabliſhed upon unerring grounds. This wonderful invention was ſoon applied with the happieſt effect in many ſituations rich with mineral treaſures, but to which nature had denied the advantage of water ſufficient to turn machinery. Cylinders, compoſed of wood, firmly jointed and hooped, were firſt introduced as a ſubſtitute for leather bellows: theſe were ſoon after replaced by bored cylinders of caſt iron; and

with this great diſcovery and application of the art of caſting, the blowing machine aſſumed a general and well-proportioned form.

This took place nearly 40 years ago, and continued with a few temporary deviations until the introduction of Bolton and Watt's highly improved engine. The following may ſerve for an outline of the old blowing ſteam engine.

A ſteam cylinder, working with atmoſpheric preſſure from 3 to 7 lbs. upon every ſquare inch of the area of the piſton. The diameter of the cylinder for one furnace varied from 25 to 36 inches, and for two furnaces from 36 to 50 inches. Upon the oppoſite of the main or working beam, ſometimes at equal, and ſometimes at unequal diſtances from the centre, was placed the air-pump or blowing cylinder. This was, in common, equal to four or five times the area of the former; and, with the ſmall working power of the ſteam cylinder, ſeldom condenſed the air beyond $1\frac{1}{2}$ to $1\frac{3}{4}$ lbs. per ſquare inch. The air-pump was commonly conſtructed open below, as may be ſeen in *Plate* II. *fig.* 1. (*Chemiſtry*). The plan was ſometimes deviated from, and the cylinder inverted. The blowing piſton was loaded with weights, and the air expreſſed by its deſcent. In this mode of working, the act of the ſteam piſton, deſcending in vacuum, raiſed the air-pump piſton loaded with weights. Upon the return of the ſtroke, or while the ſteam piſton aſcended in the cylinder, this piſton loaded with weights ſunk the whole length of the ſtroke, and by means of this loading, proportioned to the powers of the engine, forced the air either into the regulator or the furnace.

Above, or parallel to the air-pump, was placed the regulating cylinder, as may be ſeen in the plate above mentioned. This had a valve of communication, which opened every ſtroke the engine made, and admitted the whole diſcharge of air. The piſton of the cylinder, frequently called the fly piſton, was loaded with weights, and kept conſtantly vibrating; ſo that when any deficiency of preſſure aroſe from the remitting action of the air-pump piſton, the blaſt was comparatively equalized by the preſſure of the fly piſton upon the included air. The ſize of this cylinder was generally in the proportion of 9 to 6 of the air-pump.

The chief objections to this mode of blowing, even when in univerſal uſe, were founded upon the great inequality of the blaſt, and a very conſiderable waſte of air that took place at the *ſnort*, or ſafety valve, to prevent the fly piſton being blown entirely out of the cylinder. The ſnort was an opening made in the top of the air-pump cylinder, on which reſted a heavy iron valve, faced with leather ſtuffed with wool; this was, by means of an upright iron rod, attached to a lever, which run acroſs the top of the regulating cylinder. As ſoon as the fly piſton aroſe to a certain height, a block of wood, or other contrivance, lifted the one end of the lever, and along with it the valve, to a certain height, and permitted a quantity of the denſeſt air to eſcape, ſufficient to inſure the ſafety of the piſton. Notwithſtanding theſe precautions, many accidents and ſtops enſued; the breaking of a pin, or the looſing of a key, frequently ejected the piſton from its cylinder, though loaded with ſeveral tons of weight.

Some iron maſters, more ingenious than others, contrived to take the ſpare or waſte air from the ſnort, to receive it in an inverted cheſt above water, and blow to its extent ſmithy and finery fires. Endeavours of this kind to huſband and economiſe air, raiſed and condenſed at a great expence, were ſufficient proofs that a method was ſtill wanting to complete the blowing machine, to render its motions ſteady and uniform, and to equalize the denſity of the blaſt throughout the whole ſtroke.

This was completely accompliſhed by inverting large cheſts, or cylinders, in ciſterns of wood, ſtone, or iron. The ſpace betwixt the inner and outer ciſterns was conſtructed of ſufficient capacity to oppoſe to the expanſive force of the blaſt a column of water of equal or ſuperior reſiſtance.

This invention was called the water blaſt, water preſſure, water regulator, &c. The dimenſions differed materially from from each other; this circumſtance being much regulated by conveniency, opinion, and the ſize of the engine.

Plate XIV. *fig.* 1. (*Chemiſtry*) repreſents a ground plan of a very capacious water regulator, ſunk in the ground, and built of ſtone and bricks.

A, the inverted cheſt made of plates of caſt iron, 40 feet long, 12 feet wide, and 12 feet high. The ſquare ſuperficies of this cheſt is equal to 480 feet, and its cubical contents are 5760 feet. Its weight will amount to nearly 30 tons.

B, the opening to which the air-pipe is attached; 2 feet diameter.

CCCC, open ſpace betwixt the inverted cheſt and ſtone ciſtern, for the column of water to aſcend; $3\frac{1}{2}$ feet wide.

D D D D, ſtone or brick-work, of which the great ciſtern is built. This work requires to be well jointed, as the motion of the water has a great tendency to open the ſpaces betwixt the ſtones. This ciſtern is 47 feet feet long, 19 feet broad, and 14 feet high; its cubical meaſurement amounting to 12,500 feet, and capable of containing 93,500 gallons wine meaſure.

e e e e, an opening of one foot in breadth left in the middle of the building. This is compactly filled with well trod clay, called puddling, and prevents the eſcape or circulation of water through the building. Beyond this the common building extends to a ſufficient thickneſs to give general ſecurity to the whole.

Fig. 2. is a croſs ſection of the water regulator at B, *fig.* 1. The letters in this view correſpond with thoſe in the plan.

F, the blaſt pipe from the cylinder entering the cheſt, and branching to the two blaſt furnaces.

G G, large hewn ſtones, on which the cheſt is ſupported, about two feet from the bottom of the ciſtern, at intervals of ſix feet from each other.

H, loading of hewn ſtone, which for this ciſtern requires to be equal in all to 90 tons. If the cheſt weighs 30, then 60 tons of loading will be requiſite. This is ſuppoſing that the power of the blowing machine is calculated to preſs equal to 3 lbs. upon every ſquare inch, which many of them are conſtructed to perform.

To comprehend diſtinctly in what manner the water regulator performs its functions, and upon the ſuppoſition that the compreſſing power of the engine is equal to 3 lbs. upon every ſquare inch, we ſhall ſuppoſe the engine at reſt, and water introduced into the regulator, till it riſe to the level of the dotted line *h*, 5 feet from the lower edge of the cheſt, and 7 feet in total depth of water. As ſoon as the engine is ſet to work, the compreſſion of the air immediately ſets the water in motion; every ſtroke making the water riſe in the ſpace CC, and proportionally falling towards G G, in the interior of the cheſt.

When the inverted cheſt becomes filled with air, and the condenſation has reached the maximum of the power of the blowing machine, the water will be found elevated $3\frac{1}{2}$ feet to *i*, and the gauge will exhibit a depreſſion in the interior of the cheſt, from *h* to *k*, $3\frac{1}{2}$ feet, making in all 7 feet from *k* to *i*.

At every turn of the engine ſtroke, the water maintained at *i* falls a few inches, and elevates itſelf above *k* in the in-

terior of the cheſt, a ſimilar height. This deſcription takes it for granted, that the ſpaces C C are equal to the area of the inverted cheſt; ſo that every inch of water forced out of the cheſt adds exactly one inch to the height of the column.

A blowing machine, capable of blowing to purpoſe two blaſt furnaces, ought to have the inverted cheſt of the regulator equal to three or four hundred ſquare feet of area. There cannot ariſe any error from having this large enough; the want of ſpace and capacity frequently proves a real detriment.

In calculating the proportions and dimenſions of water regulators in general, the principle is, to allow the ſpace around the inverted cheſt equal in point of ſuperficial meaſurement to the area of the interior of the cheſt, that the deſcending column of water may diſplace no more in the perpendicular aſcent, than it is itſelf abſolutely depreſſed.

If the area or ſpace, in which the water riſes and falls, is only equal to half the area of the inverted cheſt, then for every foot of water which is depreſſed in the bottom of the cheſt, a column of two feet will be raiſed and maintained on the outſide. On the contrary, if the outſide ſpace for water be equal to twice the area, then every foot of water depreſſed in the cheſt will only elevate the external column ſix inches.

It will appear evident from theſe general facts, that a conſiderable latitude may at any time be aſſumed in conſtructing the water regulator, particularly in old eſtabliſhed works, where local circumſtances and conveniency confine its ſituation to one ſpot.

Where it is not inconvenient to uſe a high perpendicular column of water, the inverted cheſt may be increaſed one half, double, or even triple the ſuperficial meaſurement of the outſide ſpace; ſo that if the power of the blowing machine is equal to 3 lbs. upon the ſquare inch, the water in the cheſt will be depreſſed $3\frac{1}{2}$ feet nearly, and raiſed in the perpendicular column 5 feet 3 inches in the firſt, 7 feet in the ſecond, and $10\frac{1}{2}$ feet in the laſt caſe. This plan to ſuit former eſtabliſhments may be adopted with conſiderable modifications, always keeping in mind, that every foot of area gained upon the ſurface of the water is a material acquiſition to the equalizing powers of the regulator.

One imperfection attends this want of equilibrium on the two ſpaces for the action and re-action of the water.—Whatever ſpace the waters would fall, at the return of the ſtroke, ſuppoſing the inſide and outſide columns exactly balanced, would in this caſe be increaſed one half, double, or triple.

Again, where ſituation does not admit of the perpendicular column being raiſed beyond, or not even to the extent of the depreſſion, that takes place within the inverted cheſt, and where an additional ſpace cannot be procured for an increaſe of its diameter, an inverted cheſt of much leſs height than common may be uſed, loaded with a material of great weight, ſuch as iron. The water in that caſe would diſtribute itſelf over the ſurface of the cheſt, inſtead of riſing in perpendicular height.

One ſerious objection, however, is made to cheſts or cylinders, where the eduction pipe approaches within a ſhort ſpace of the ſurface of the water; namely, water riſing in the pipes, and being conveyed along with the air into the furnace. This may take place in two ways; by an inſenſible and uniform diſcharge of water into the furnace, making the blaſt at the tuyere viſible, like the reſpiration of the human body in a froſty day; or in quantity, threatening utter deſtruction to the furnace and buildings. The former is occaſioned by the air from the eduction pipe, at the commencement of the ſtroke, impinging violently upon the ſurface of the water, and raiſing a portion of it in the ſtate of ſpray. This is ſpeedily diſſolved or entangled in the maſs of condenſed air before the return of the next ſtroke, and becomes expreſſed along with the blaſt into the furnace. The other hazardous conſequence is occaſioned chiefly by undulation in the column of water, when the blowing machine is, by derangement or accident, working under its proper power or number of ſtrokes. In theſe caſes, when the pauſe at the end of the ſtroke is prolonged, an exhauſtion ſometimes takes place in the air-pipes, the water riſes and is carried in a ſtream through the blow-pipe into the furnace.

The ſame caſualties may more readily occur, if the ſurface of the water is upon a level, or nearly ſo, with the tuyere.

In judicious erections this is moſt carefully avoided; the ſurface of water in the inverted cheſt or cylinder is kept at leaſt 8, 9, and 10 feet under the level of the tuyere, even at the laſt period of return, when the water has riſen to its greateſt height within.

This very proper precaution enſures an advantage of much importance. A large ſpace is obtained betwixt the top of the cheſt and the depreſſed ſurface of the water; this becomes a ſpacious reſervoir for the condenſed air, and, by generating a conſiderable portion of elaſticity, prevents any violent perturbation upon the water at any period of the ſtroke. The increaſed diſtance betwixt the ſurface of the water, and the pipe which conducts the air from the cylinder, has a complete tendency to prevent the elevation of the aqueous particles, and always enſures a quantity of air comparatively free from moiſture.

Upon the principles formerly noticed, it is poſſible to conſtruct a blowing apparatus of this nature, wherein there could be little or no viſible motion in the perpendicular column of water even with the ſame engine.

Let us ſuppoſe a machine of this nature at work, with an accurately balanced column of water, the fall of which, at the return of the ſtroke, was equal to 12 inches. It is evident, that if the outſide ſpace was enlarged ſo much over its ſurface as to contain this foot of water, without adding any perceptible height to the column; that included within the cheſt would, at the return of the ſtroke, being fed from a more capacious limb, riſe a foot, without any ſenſible diminution taking place in the perpendicular height of the external fluid. It is equally obvious, in this as in every caſe with water regulators, that the riſe and fall of the inſide column of water will remain the ſame, under every modification and form, while the pace and powers of the engine remain the ſame.

The application of water regulators to blowing machines was ſoon followed by an attempt to further improvement, by the introduction of the air-vault; the principle of which was to form a receiver of ſuch capacity, that the elaſticity or ſpring of the condenſed air would be ſufficient to expreſs and equalize the blaſt during the return of the ſtroke.

To effect this, an immenſe magazine was requiſite; to erect which of any metallic ſubſtance would have been ruinouſly expenſive, and, if conſtructed of wood, inſufficient for retaining the air. It became therefore requiſite to try the experiment upon building, or by excavation from the ſolid rock. In both theſe ways has the air-vault been tried, and found to produce an excellent effect, as to equalizing the denſity of the blaſt; but it has been conceived with ſuch indifferent conſequences as to quantity, that the plan is for the preſent given up.

Air-vaults were conſtructed both at the Clyde and Muirkirk iron works in Scotland, and a conſtant current of air produced; but nearly one half the quantity lifted by the air-pump eſcaped through the walls and arches of the building. This was at any time made viſible by rubbing ſoapy water upon the external walls.

At Devon iron works in Scotland, an air-vault was excavated from the ſolid rock, 72 feet long, 14 feet wide, and 13 feet high; equal to 13,000 feet of cubical meaſurement. This immenſe excavation was made comparatively air-tight, by cauking the ſeams and fiſſures of the rock, plaſtering and then covering the whole with alternate layers of pitch and cloſe wove paper.

This was the moſt perfect experiment ever tried upon the air-vault; and if an opinion is to be formed of the perfection of the apparatus by the quantity of iron at one time manufactured, a very trifling portion of air indeed muſt have been loſt.

It has been frequently noticed in Scotland, that at works where the materials were in any degree ſimilar, 3000 to 3500 cubical feet of air per minute will, in the courſe of a week, produce from 30 to 35 tons of pig iron, whatever may be the denſity at which it is thrown into the furnace.

The Devon furnace at one time averaged 33 tons weekly for 9 months running, and conſumed of air, per data furniſhed by Mr. Roebuck in his paper publiſhed in Nicholſon's Journal, vol. iv. nearly 3400 cubical feet per minute, under a preſſure of $2\frac{3}{4}$ lbs. per ſquare inch. Notwithſtanding this powerful demonſtration, ſtrong prejudices were entertained to its diſadvantage; and many believed, that had any other mode of regulator been attached to the blowing machine, abundance of air would have been obtained to have blown two furnaces equally well. That this idea was incorrect, may be eaſily gathered by calculation from the area of the air-pump, the length of the working ſtroke, and the number of ſtrokes per minute, all of which are particularly ſtated by Mr. Roebuck.

For the general conſtruction of an air-vault formed by building, ſee *Plate* XV. (*Chemiſtry.*)

Fig. 1. is a ſection of the vault conſtructed under the bridge-houſe, or place where the materials are proportioned, previouſly to their being thrown into the furnace. One half a blaſt furnace outline, is ſeen as connected in point of ſituation and blaſt to the air magazine.

A, the termination of the blaſt pipes that convey the air from the blowing cylinder into the receiver, 3 feet diameter; the length depends upon the contiguity of the engine to the vault.

B B B B, four vaults, 13 feet wide each, 25 feet deep, and 10, 11, 12, and 13 feet high to the ſpringing of the arches; total height to the crown of the arches, $16\frac{1}{2}$, $17\frac{1}{2}$, $18\frac{1}{2}$, and $19\frac{1}{2}$ feet. Theſe cells communicate with each other by arched openings in the croſs-walls, which may be diſtinctly ſeen in the ground plan at L.

C C, the eduction pipes that carry the air to the furnace; 18 inches diameter.

D, end view of the range of laying pipes at the tuyere of the furnace. The dotted lines betwixt D and C are meant to repreſent the horizontal range of the pipes.

E, part of the outline of a blaſt furnace to ſhew its proper ſituation to the air vault.

F F F F, floor of the reſpective vaults, compoſed of a mixture of two parts of boring duſt, two of fine riddled lime, and one part of fine roaſted iron ſtone, mixed up into plaſter with water containing a conſiderable portion of ſalt.

G G, end walls of bricks or ſtone, four feet thick.

H H H, lining of brick-work, built in the moſt accurate manner, with fine riddled mortar, and run every ſecond or third courſe with mortar made thin and very liquid. Theſe walls are two feet and a half in thickneſs, are carefully plaſtered, and afterwards covered with ſeveral layers of ſtrong paper and pitch, to prevent the eſcape of air. The roofs of the vaults are finiſhed in the ſame manner.

I, door arch into the vaults; entrance obtained by means of a ladder or wooden ſtairs ſuſpended within.

K, ſpace above the arches, filled with rubbiſh, to prevent any ſpring, and to raiſe the floor to the level of the furnace top.

L, the range of the floor, or acclivity to the furnace mouth.

Fig. 2. is a ground plan of the bridge-houſe containing the air-vaults, and exhibits one half the ground plan of the furnace through the centre of the tuyere arches.

B B B B, correſponding to the ſame letters in the elevation.

C C, pipes for taking off the blaſt into the furnace.

D, correſponding to the ſame letter in the ſection.

E, main pillar of the furnace, ſame as E in the ſection.

G G G G, and H H H, correſpond with the ſame letters in the elevation.

I, ſquare for receiving the furnace hearth.

K, part of the ground view of the hearth, and the approaching blaſt pipes.

L L L, openings of the croſs arches, which communicate the vaults with each other.

The cubical contents of a vault, conſtructed according to theſe dimenſions, will amount to 20,000 feet.

In general, it may be remarked upon the conſtruction of the blowing machine, that ſince the period of the introduction of Mr. Watt's engine, the air-pump, or blowing cylinder, has been conſtructed ſo as to diſcharge a cylinder full of air every aſcent and deſcent of the piſton. This, inſtead of travelling 4 to 5 feet per ſtroke, more generally moves 8 feet; and the number of cylinders per minute are ſeldom under 24.

Formerly, in the common atmoſpheric engine, the movement of the piſton from top to bottom, and back again, produced only one cylinder full of air from the air-pump, and the number of cylinders diſcharged per minute ſeldom exceeded 16. A ſteam cylinder of 40 to 44 inches diameter, and an air-pump of 6 feet diameter, the piſton moving about 5 feet per ſtroke, were deemed ſufficient in the conſtruction of a blowing machine for two blaſt furnaces. The quantity of air pumped up and thrown into the furnaces by ſuch an engine ſeldom exceeded 3000 cubical feet per minute. This, and even a larger quantity, is now thrown into one furnace, and the produce by ſuch means increaſed from 15 to 35 tons weekly.

The firſt ſet of tables following are calculated to ſhew the quantity of air that would be diſcharged by blowing cylinders of various diameters, the length and number of the ſtrokes being given.

The ſecond ſet, to ſhew what diameter of blowing cylinder is requiſite, with a given ſteam power, to raiſe the air to a certain denſity per ſquare inch. See ENGINE, WATER REGULATOR, and REGULATING VAULT.

TABLE I. of Blowing Cylinders, their Capacity, Area, and Quantity of Air discharged by a Four-Feet Stroke, &c.

Diam. of Cylinders in Inches.	Area in Circular Inches.	Area in Square Inches.	Capacity of the Stroke in Cubic Feet.	Air discharged at the Rate of 50 Cylinders per Minute.	Air discharged at the Rate of 40 Cylinders per Minute.	Air discharged at the Rate of 30 Cylinders per Minute.	Air discharged at the Rate of 25 Cylinders per Minute.	Air discharged at the Rate of 20 Cylinders per Minute.	Air discharged at the Rate of 15 Cylinders per Minute.	Air discharged at the Rate of 12 Cylinders per Minute.	Air discharged at the Rate of 10 Cylinders per Minute.

TABLE II. of blowing Cylinders, their Area, Capacity, and Quantity of Air, discharged by a Five-Feet Stroke.

Diameters of Cylinders.	Area in Circular Inches.	Area in Square Inches.	Capacity of the Stroke in Cubical Feet.	Air discharged at the Rate of 50 Cylinders per Minute, in Cubical Feet.	Air discharged at the Rate of 40 Cylinders per Minute in Cubical Feet.	Air discharged at the Rate of 30 Cylinders per Minute in Cubical Feet.	Air discharged at the Rate of 25 Cylinders per Minute in Cubical Feet.	Air discharged at the Rate of 20 Cylinders per Minute in Cubical Feet.	Air discharged at the Rate of 15 Cylinders per Minute in Cubical Feet	Air discharged at the Rate of 12 Cylinders per Minute in Cubical Feet.	Air discharged at the Rate of 10 Cylinders per Minute in Cubical Feet.

TABLE III. of blowing Cylinders, their Area, Capacity, and Quantity of Air discharged by a Six-Feet Stroke.

Diameter of Cylinders.	Area in Circular Inches.	Area in Square Inches.	Capacity of the Stroke in Cubical Feet.	Air discharged at the Rate of 50 Cylinders per Minute in Cubical Feet.	Air discharged at the Rate of 40 Cylinders per Minute in Cubical Feet.	Air discharged at the Rate of 30 Cylinders per Minute in Cubical Feet.	Air discharged at the Rate of 25 Cylinders per Minute in Cubical Feet.	Air discharged at the Rate of 20 Cylinders per Minute in Cubical Feet.	Air discharged at the Rate of 15 Cylinders per Minute in Cubical Feet.	Air discharged at the Rate of 12 Cylinders per Minute in Cubical Feet.	Air discharged at the Rate of 10 Cylinders per Minute in Cubical Feet.

TABLE IV. of Blowing Cylinders, their Area, Capacity, and Quantity of Air discharged by a Seven-Feet Stroke.

Diameters of Cylinders.	Area in Circular Inches.	Area in Square Inches.	Capacity of the Stroke in Cubical Feet.	Air discharged at the Rate of 50 Cylinders per Minute in Cubical Feet.	Air discharged at the Rate of 40 Cylinders per Minute in Cubical Feet.	Air discharged at the Rate of 30 Cylinders per Minute in Cubical Feet.	Air discharged at the Rate of 25 Cylinders per Minute in Cubical Feet.	Air discharged at the Rate of 20 Cylinders per Minute in Cubical Feet.	Air discharged at the Rate of 15 Cylinders per Minute in Cubical Feet.	Air discharged at the Rate of 12 Cylinders per Minute in Cubical Feet.	Air discharged at the Rate of 10 Cylinders per Minute in Cubical Feet.

TABLE V. of Blowing Cylinders, their Area, Capacity, and Quantity of Air discharged by an Eight-Feet Stroke.

Diameters of Cylinders.	Area in Circular Inches.	Area in Square Inches.	Capacity of the Stroke in Cubical Feet.	Air discharged at the Rate of 50 Cylinders per Minute in Cubical Feet.	Air discharged at the Rate of 40 Cylinders per Minute in Cubical Feet.	Air discharged at the Rate of 30 Cylinders per Minute in Cubical Feet.	Air discharged at the Rate of 25 Cylinders per Minute in Cubical Feet.	Air discharged at the Rate of 20 Cylinders per Minute in Cubical Feet.	Air discharged at the Rate of 15 Cylinders per Minute in Cubical Feet.	Air discharged at the Rate of 12 Cylinders per Minute in Cubical Feet	Air discharged at the rate of 10 Cylinders per Minute in Cubical Feet

TABLE I. of the Powers of Steam Engines working at the Rate of 5 lbs. Avoirdupoiſe upon every Circular Inch, or 6.3656 lb. upon every Square Inch of the Steam Piſton applicable to Blowing Machinery; and the Areas and Diameters of Blowing Cylinders requiſite to raiſe Air of various Denſities from 1½ lb. to 4 lbs. upon each Circular Inch, or from 1.90 lb. to 5.092 lbs. Avoirdupoiſe upon each Square Inch of the Air Receiver.

Diameter of Steam Cylind.	Area of Ditto.	Power of the Engine in Pounds	Blaſt 1¼ lb. per Circular Inch, or 1.90 lb. per Square Inch		Blaſt 1⅓ per Circular Inch, or 2.12 lb. per Square Inch.		Blaſt 1½ lb. per Circular Inch, or 2.54 lb. per Square Inch.		Blaſt 2 lb. per Circular Inch, or 2.80 lb. per Square Inch.		Blaſt 2½ lb. per Circular Inch. or 3.18 lb. per Square Inch.		Blaſt 2⅔ lb. per Circular Inch. or 3.44 lb. per Square Inch.		Blaſt 3 lb. per Circular Inch or 3.81 lb. per Square Inch.		Blaſt 3⅓ lb. per Circular Inch, or 4.13 lb. per Square Inch.		Blaſt 3½ lb. per Circular Inch, or 4.45 lb. per Square Inch.		Blaſt 3⅔ lb. per Circular Inch, or 4.77 lb. per Square Inch.		Blaſt 4 lb. per Circular Inch, or 5 .09 lb. per Square Inch

TABLE II. of the Powers of Steam Engines working at the Rate of 6 lbs. Avoirdupoiſe upon every Circular Inch, or 7.639 lb. upon every Square Inch of the Steam Piſton, applicable to Blowing Machinery; and the Areas and Diameters of Blowing Cylinders requiſite to raiſe Air of various Denſities from 1½ lb. to 4 lbs. upon each Circular Inch, or from 1.90 lb. to 5.092 lbs. Avoirdupoiſe upon each Square Inch of the Air Receiver.

Diameters of the Steam Cylind.	Areas of Ditto.	Power of the Engine in Pounds.	Blaſt 1½ lb. per Circular Inch, or 1.92 lb. per Square Inch.		Blaſt 1¾ lb. per Circular Inch, or 2.22 lb. per Square Inch.		Blaſt 2 lb. per Circular Inch, or 2.54 lb. per Square Inch.		Blaſt 2¼ lb. per Circular Inch, or 2.86 lb. per Square Inch.		Blaſt 2½ lb. per Circular Inch, or 3.18 lb. per Square Inch.		Blaſt 2¾ lb. per Circular Inch, or 3.49 lb. per Square Inch.		Blaſt 3 lb. per Cir. Inch, or 3.81 lb. per Square Inch.		Blaſt 3¼ lb. per Cir. Inch, or 4.11 lb. per Square Inch.		Blaſt 3½ lb. per Cir. Inch, or 4.45 lb. per Square Inch.		Blaſt 3¾ lb. per Cir. Inch, or .77 lb. per Square Inch.		Blaſt 4 lb. per Cir. Inch, or 5.09 lb. per Square Inch.

: III. of the Powers of Steam Engines working at the Rate of 7lbs. Avoirdupoise upon every Circular Inch, or 8.91lb. upon every Inch of the Steam Piston, applicable to Blowing Machinery; and the Areas and Diameters of Blowing Cylinders, requisite to raise various densities from 1½lb to 4lbs. upon each Circular Inch, or from 1.90lb. to 5.092lbs. Avoirdupoise upon each Square Inch of : Receiver.

ower of the Engine in Pounds.	Blast 1¾lb. per Cir. Inch, or 1.95lb. per Square Inch.		Blast 1¾lb. per Cir. Inch, or 2.22lb. per Square Inch		Blast 2lb. per Cir. Inch, or 2.54lb. per Square Inch.		Blast 2¼lb. per Cir. Inch. or 2.86lb. per Square Inch.		Blast 2½lb. per Cir. Inch, or 3.18lb. per Square Inch.		Blast 2¾lb. per Cir. Inch. or 3.41lb. per Square Inch.		Blast 3lb. per Cir. Inch, or 3.81lb. per Square Inch.		Blast 3¼lb. per Cir. Inch, or 3.63lb per Square Inch.		Blast 3½lb. per Cir. Inch, or 4.45lb. per Square Inch.		Blast 3¾lb. per Cir. Inch, or 4.77lb. per Square Inch.		Blast 4lb. per Cir. Inch, or 5.09lb. per Square Inch.

TABLE IV. of the Powers of Steam Engines working at the Rate of 8lbs. Avoirdupoife, upon every Circular Inch, or 10.18lbs. upon ev Inch of the Steam Piston, applicable to Blowing Machinery; and the Areas and Diameters of Blowing Cylinders requifite to r various Denfities from 1½ lb. to 4 lbs. upon each Circular Inch, or from 1.90 lb. to 5.092 lbs. Avoirdupoife upon each Square Inch Receiver.

Diameters of Steam Cylind.	Area of Ditto.	Power of the Engine in Pounds.	Blaft 1½ lb. per Circular Inch, or 1.490 lb. per Square Inch.		Blaft 1¾ lb. per Circular Inch, or 1.862 lb. per Square Inch.		Blaft 2 lb. per Circular Inch, or 2 54 lb. per Square Inch		Blaft 2¼ lb. per Circular Inch, or 2.863 lb. per Square Inch.		Blaft 2½ lb. per Circular Inch, or 3. 8 lb. per Square Inch.		Blaft 2¾ lb per Circular Inch or 3 44 lb. per Square Inch		Blaft 3 lb. per Circular Inch, or 3.81 lb per Square Inch.		Blaft 3½ lb. per Circular Inch, or 4 45 lb. per Square Inch.		Blaft 3¾ lb. per Circular Inch, or 4 77 lb. per Square Inch		Blaft 4 lb. per Circular Inch. or 5 09 lb. per Square Inch.

TABLE VI. of the Powers of Steam Engines working at the Rate of 10lbs. Avoirdupoise upon every Circular Inch, or 12.73lbs. upon ev Inch of the Steam Piston, applicable to Blowing Machinery; and the Areas and Diameters of Blowing Cylinders requisite to ra various Denfities from 1½ lb. to 4 lbs. Avoirdupoise upon each Circular Inch, or from 1.90 lb. to 5.092 lbs. upon each Square Inch Receiver.

Diameters of Steam Cylind	Areas of Ditto.	Power of the Engine in Pounds.	Blast 1¼lb. per Circular Inch, or 1.90 lb. per Square Inch		Blast 1½lb. per Circular Inch, or 2.22 lb. per Square Inch.		Blast 2 lb. per Circular Inch, or 2.54 lb per Square Inch.		Blast 2¼lb. per Circular Inch, or 2.86 lb. per Square Inch.		Blast 2½lb. per Circular Inch, or 3. 8 lb. per Square Inch.		Blast 2¾lb. per Circular Inch, or 3 44 lb. per Square Inch.		Blast 3 lb. per Circular Inch, or 3.81 lb. per Square Inch.		Blast 3¼lb. per Circular Inch, or 4.18 lb. per Square Inch.		Blast 3½lb. per Circular Inch, or 4.45 lb. per Square Inch.		Blast 3¾lb. per Circular Inch, or 4.77 lb. per Square Inch.		A o

BLOWING *of a Flower*, among *Floriſts*, an artificial proceſs in order to bring a flower to diſplay itſelf with greater perfection and beauty than it would arrive at in the natural way of blowing. The uſual method is thus: about April, when the flower ſtems begin to put forth, or *ſpindle*, as the gardeners call it, they place by each flower a ſtrait ſtick four feet long, and tie the ſpindles to it as they ſhoot. As ſoon as the flower-buds appear, they leave only one of the largeſt on each flower-ſtem to bloſſom. About ten days before the flowers open themſelves, the round-podded kinds will begin to crack their huſks on one ſide, when the careful gardener, with a fine needle, ſplits or opens the huſk on the ſide oppoſite to the natural fraction; and about three or four days before the complete opening of the flower, cuts off with a pair of ſciſſars the points on the top of the flower-pod, and ſupplies the vacancies or openings on each ſide of the huſk with two ſmall pieces of vellum or oil-cloth, ſlipped in between the flower-leaves and the inſide of the huſk; by ſuch means, the bloſſom will diſplay its parts equally on all ſides, and be of a regular figure. Beſides this care, when the bloſſom begins to ſhew its colours, they uſe to ſhade it from the extreme heat of the ſun with a trencher-like board, or other device of the like nature, faſtened to the ſtick which ſupports it; for the flowers, as well as fruits, grow larger in the ſhade, and ripen and decay ſooneſt in the ſun.

In *Heraldry*, a fleur de lys is ſaid to be blown, *eſpanoui*, when its leaves are opened, ſo that buds appear among the fleurons. The arms of the city of Florence are *argent, a fleur de lys blown, gules*.

BLOWING-*ſnake*, in *Zoology*, a name given by the people of Virginia to a ſpecies of ſerpent much reſembling the European viper, but conſiderably larger, and very remarkable for its inflating and extending the ſurface of its head before it bites. Its wound is very fatal.

BLOWN RED, in the manufacture of porcelane. See RED.

BLUBBER, in *Phyſiology* and *Trade*, the fat which inveſts the bodies of all large cetaceous fiſh, ſerving to furniſh an oil.

The blubber is properly the *adeps* of the animal: it lies immediately under the ſkin, and over the muſcular fleſh. In the porpoiſe, it is firm and full of fibres, and inveſts the body about an inch thick. In the whale, its thickneſs is ordinarily ſix inches; but about the under lip, it is found two or three feet thick. The whole quantity yielded by one of theſe animals ordinarily amounts to forty or fifty, ſometimes to eighty or more hundred weight. Phil. Tranſ. N° 77. p. 2275.

The uſe of the blubber to the animal ſeems to be partly to poiſe the body, and render it equiponderant to the water; partly to keep off the water at ſome diſtance from the blood, the immediate contact whereof would be apt to chill it; and partly alſo for the ſame uſe that cloaths ſerve us, to keep the fiſh warm, by reflecting or reverberating the hot ſteams of the body, and ſo redoubling the heat; ſince all fat bodies are, by experience, found leſs ſenſible of the impreſſion of cold than lean ones.

Its uſe in trade and manufactures is to furniſh train-oil, which it does by boiling down. Formerly this was performed aſhore in the countries where the whales were caught; but of late the fiſhers do not go aſhore, they bring the blubber home, ſtowed in caſks, and boil it down there.

BLUBBER-*livers*. The livers of cods, which having been barrelled, yield ſpontaneouſly a conſiderable quantity of oil, which being ſkimmed off, the reſidue are called blubber-livers, to be boiled down for more oil.

BLUBBER, *ſea*, a denomination given by our navigators to the *urtica marina*, or ſea-nettle. Phil. Tranſ. N° 349.

BLUDENTZ, in *Geography*. See PLUDENTZ.

BLUE, one of the ſeven primitive colours of the rays of light, into which they are divided, when refracted through a glaſs priſm. See COLOURS, and REFRACTION.

Anciently blue was the ſymbol of the ſea; for which reaſon, in the Circenſian games, the combatants who repreſented the ſea were clad in blue; and thoſe who had diſtinguiſhed themſelves by any notable exploit at ſea, were rewarded with a blue enſign.

Mr. Boyle has given us the following method of making tranſparent blue, nearly equal to ultramarine. The principal ingredient of this beautiful colour is the *cyanus*, or blue corn-bottle flower, which abounds almoſt in every corn-field, and may eaſily be had during four of the ſummer months. It may be gathered by children about the verges of corn-fields, without doing any damage to the corn. This flower has two blues in it, one of a pale colour in the large outer leaves; and the other of a deeper blue, that lies in the middle of the flower. Both theſe will do, being ſeparated from the buttons or caſes in which they grow; but the deep blue leaves in the middle produce much the beſt colour: this may be obſerved by rubbing the leaves while they are freſh upon a piece of writing-paper, ſo hard as to expreſs the juice, which will yield an excellent colour, that by the experience of two or three years has not been found to fade. A ſufficient quantity of theſe middle leaves being procured, let the juice be preſſed from them; to which a little alum being added, will give a laſting tranſparent blue, ſcarcely inferior in brightneſs to ultramarine. It is very probable, that if the chives of theſe flowers were cured in the ſame manner with ſaffron, they would produce a much greater body of colour, from which a tincture might be drawn with more eaſe than when preſſed freſh from the field.

Mr. Boyle alſo recommends another fine blue, produced from the blue leaves of rue beaten in a ſtone mortar with a wooden peſtle, and then put in water for fourteen days or more, waſhing them every day until they are rotten. Theſe beaten up at laſt, water and all, until they become a pulp, and then dried in the ſun, will make a fine blue for ſhading.

BLUE *Aſhes*, *Cendres bleues*. See VERDITER.

BLUE *bice*, is a colour of good brightneſs, next to Pruſſian blue; it is alſo a colour of a body, and flows well from the pencil. See BICE.

BLUE, in *Dying*. See DYING, INDIGO, and WOAD.

BLUE *black*. See BLACK.

BLUE *enamel*. See *Azure* ENAMEL.

BLUE, *Flanders*, is a colour ſeldom uſed but in landſcapes, as being apt to turn green. The French call it *cendre verte*, or green aſhes.

BLUE *for painting or ſtaining glaſs*. See GLASS.

BLUE *Japan*. See JAPANNING.

BLUE *Indigo*. See INDIGO.

BLUE *Litmus*, or *Lacmus*. See LITMUS.

BLUE, *Painters'*, is made differently according to the different kinds of paintings. In limning, freſco, and miniature, they uſe indifferently ultramarine, blue aſhes, and ſmalt; theſe are the natural blues, excepting the laſt, which is partly natural, partly artificial. See each under its proper head. In oil and miniature they uſe indigo, blue bice, blue verditer, lapis armenus, ſmalt, and litmus, alſo a counterfeit ultramarine. Enamellers and painters of glaſs have blues peculiar to themſelves; each preparing them after his own manner. See ENAMELLING, *Painting on* GLASS, and Neumann's Chem. Works, by Dr. Lewis.

Blue, *Pruſſian.* See Prussic *Acid.*

Blue, *Saxon*, a ſolution of indigo in ſulphuric acid. See Indigo.

For an account of the proceſſes for obtaining blue liquors from oak-duſt and vitriol, from log-wood and verdigriſe, from log-wood and blue vitriol, from an eſſential oil and volatile ſpirit; ſee Dr. Lewis's Commercium Philoſophico-Technicum, ed. 4to, ann. 1773, p. 382. 407. 436.

Blue, *Stone*, or *Powder*, uſed in waſhing of linen, is the ſame with ſmalt, either in the lump, or powdered.

When the ſmalt is taken from the pot, it is thrown into a large veſſel of cold water: this makes it more tractable and eaſily powdered. Afterwards, when examined after cooling, it is found to be mixed with a greyiſh matter reſembling aſhes, which they call *eſchel.* This grey matter it ſeparated by waſhing, and then the blue ſubſtance is powdered and ſifted through fine ſieves, to bring it to what we call *powder-blue.* Phil. Tranſ. N° 396. See Cobalt.

Blue, *turnſol*, is a blue uſed in painting on wood, made of the ſeed of that plant. It is prepared by boiling four ounces of turnſol in a pint and a half of water wherein lime has been ſlacked. See Turnsol.

Blue, *ultramarine.* See Lazulite.

There is a blue ſubſtance, ſomething like what Kentman mentions under the name of *cæruleum patavinum.* It was diſcovered in a peat-moſs in Scotland. This earth is at firſt of a white colour, and only grows blue by being expoſed to the air. It has alſo ſome reſemblance to what Mr. de Coſta in his Nat. Hiſt. of Foſſ. p. 103. calls *ochria friabilis cærulea.* It is deſcribed very minutely by Mr. Douglas, who gives an account of his various experiments upon it, and recommends it as a cheap paint in gum water, particularly as it is levigated and prepared by nature. See Phil. Tranſ. vol. lviii. N° 27. an. 1768.

Many ſimilar ſpecimens of blue earth have been diſcovered in England and Ireland, and ſeveral parts of the continent.

Blue-*ball*, a name given in ſome countries to the *Cone-*Wheat.

Blue-*bottle*, in *Botany.* See Centaurea.

Blue-*Cap*, in *Ichthyology.* See Blew-*Cap.*

Blue *John*, the common appellation, among the Derbyſhire miners, of Fluor-Spar.

Blue *Mantle Purſuivant of Arms.* This officer is by patent a member of the corporation of heralds. Sir Henry Spelman conjectures, that the title was taken from the colour of the mantle of the French kings. This office is ſaid to have been inſtituted by Henry V., and probably might be coeval with that of Garter, and erected with reference to that order; but although the catalogues place John Wrexworth and others by this title under the reign of Henry V.; Anthony Wood aſcribes the creation of this office to Henry VI., in whoſe 26th year *Bluemantle Purſuivant* waited on Bruges, Garter king of arms, into France, and alſo on the biſhop of Chicheſter and others, ambaſſadors thither. Previous to that date there are not any entries on record relating to this officer; but from thence to the preſent time the ſucceſſion hath been carried on without any interruption.

Blue *Nuns*, *filles blues*, thoſe of the order of the Annunciation.

BLUEFIELD's Bay, in *Geography*, a bay in the iſland of Jamaica, lying S.E. of Savannah-la-Mar, and having good anchorage for large veſſels. N. lat. 18° 10′ 30″. W. long. 78°.

Bluefield's, or *Blewfield's Bay*, a bay on the weſtern coaſt of Nicaragua, in New Spain, into which a river of the ſame name is diſcharged. N. lat. 11° 40′. W. long. 83°.

BLUEHILL, a townſhip of America, in Hancock county and diſtrict of Maine, on the weſt ſide of Union river, 344 miles N.E. of Boſton, and 13 E. of Penobſcot; having 274 inhabitants.

Bluehill *Bay*, a bay of America, formed by Naſkeag point on the weſt, and Mount Defart iſland on the eaſt, and extending northerly to a mountain on the eaſt of Penobſcot river, which, from its appearance at ſea, is called "Bluehill." Union river diſcharges itſelf into this bay.

Blue *Hills*, a range of mountains in New England, the firſt ridge of which in New Hampſhire paſſes through Rocheſter, Barrington, and Nottingham.

Blue *Mountains*, are mountains of America, in Northampton county, and ſtate of Pennſylvania, extending from S.W. to N.E. and through a ſmall interval acroſs the Delaware.—Alſo, a range of mountains, which run from S.E. to N.W. through Surry county, in the iſland of Jamaica. Blue mountain peak is ſaid to riſe 7431 feet above the level of the ſea; and the precipices are interſperſed with beautiful ſavannahs.—Alſo, a mountain in Ruſſia, part of the Altay mountains. See Sinnaia Sopka.

Blue *Ridge*, or *South Mountain*, is the firſt ridge of the Alleghany mountains in Pennſylvania, Virginia, and North Carolina, diſtant from 130 to 200 miles from the ſea, and, meaſured from its baſe, about 4000 feet high. Between this and the north mountain is a large fertile vale. The paſſage of the Potowmack river through this ridge is one of the moſt ſtupendous ſcenes in nature. See Alleghany *Mountains*, and Potowmack *River.*

Blue *Licks*, lie on the main branch of the Licking river in Kentucky, and are ſituated about 8 miles weſterly from the Upper Blue Licks. Both of them are on the N.E. ſide of the river; and the latter is about 15 miles N.E. of Millers.

Blue *Spring*, lies between Big Barren and Little Barren river, ſouthern branches of Green river, in Mercer's county, Kentucky, about 22 miles ſouth-weſterly from Sulphur ſpring, and 13 ſouth of Craig's fort, on the north ſide of Green river.

Blue *Stone Creek*, a ſmall weſtern branch of the Great Kanhaway.

BLUENESS, that quality which denominates a body blue, depending on ſuch a ſize and texture of the parts that compoſe the ſurface of a body, as diſpoſe them to reflect the blue or azure rays of light, and thoſe only, to the eye.

With reſpect to the blueneſs of the ſky, M. de la Hire, after Leonardo da Vinci, obſerves, that any black body viewed through a thin white one, gives the ſenſation of blue; and this he aſſigns as the reaſon of the blueneſs of the ſky, the immenſe depth of which being wholly devoid of light, is viewed through the air illuminated and whitened by the ſun. For the ſame reaſon, he adds, it is that ſoot mixed with white makes a blue; for white bodies, being always a little tranſparent, and mixing themſelves with a black behind, give the perception of blue. From the ſame principle he accounts for the blueneſs of the veins on the ſurface of the ſkin, though the blood they are filled with be a deep red; for red, he obſerves, unleſs viewed in a clear, ſtrong light, appears a dark brown, bordering on black: being then in a kind of obſcurity in the veins, it muſt have the effect of a black; and this, viewed through the membrane of the vein and the white ſkin, will produce the perception of blueneſs.

In the ſame way did many of the early writers account for the phenomenon of a blue ſky; ſuch as Fromondus, Funccius, Otto Guericke, and many others: their opinion long prevailed, and has been adopted by ſome in more modern times, eſpecially by Wolfius and Muſchenbroek. But in the explanation of this phenomenon, ſir Iſaac Newton obſerves, that all the vapours, when they begin to condenſe and coaleſce into natural particles, become firſt of ſuch a bigneſs as to reflect the azure rays, before they can conſtitute clouds of any other colour. This, therefore, being the firſt colour which they begin to reflect, muſt be that of the fineſt and moſt tranſparent ſkies, in which the vapours are not arrived to a groſſneſs ſufficient to reflect other colours.

M. Bouguer, without having recourſe to the vapours diffuſed through the atmoſphere, in order to account for the reflection of the blue-making rays, aſcribes it to the conſtitution of the air itſelf, whereby theſe fainter-coloured rays are incapable of making their way through any conſiderable tract of it. And he accounts for thoſe blue ſhadows, which were firſt obſerved by M. Buffon in the year 1742, by the aërial colour of the atmoſphere, which enlightens theſe ſhadows, and in which the blue rays prevail; whilſt the red rays are not reflected ſo ſoon, but paſs on to the remoter regions of the atmoſphere. The abbé Mazeas, in a Memoir of the ſociety in Berlin, for the year 1752, accounts for the phenomenon of blue ſhadows by the diminution of light; having obſerved that, of two ſhadows which were caſt upon a white wall from an opaque body illuminated by the moon, and by a candle at the ſame time, that which was enlightened by the candle was reddiſh, and that which was enlightened by the moon was blue. However, the true cauſe of this appearance ſeems to be that aſſigned by M. Bouguer, which agrees with the ſolution given of it about the ſame time by Mr. Melville. But inſtead of attributing the different colours of the clouds, as ſir Iſaac Newton does, to the different ſize of thoſe globules into which the vapours are condenſed; Mr. Melville ſuppoſes, that the clouds only reflect and tranſmit the ſun's light; and that, according to their different altitudes, they may aſſume all the variety of colours at ſun riſing and ſetting, by barely reflecting the ſun's incident light, as they receive it through a ſhorter or longer tract of air: and the change produced in the ſun's rays by the quantity of air through which they paſs, from white to yellow, from yellow to orange, and laſtly to red, may be underſtood agreeably to this hypotheſis, by applying to the atmoſphere what ſir Iſaac Newton ſays concerning the colour of tranſparent liquors in general, and that of the infuſion of *lignum nephriticum* in particular. Edinb. Eſſ. vol. ii. p. 75. Bouguer Traité d'Optique, p. 368. Newton's Optics, p. 228; or Prieſtley's Hiſt. of Viſion, &c. p. 436—449.

BLUFF-Head, or *Bluff-headed*, in the *Sea-Language*, is when a ſhip has but a ſmall rake forward on, being built with her ſtem too ſtraight up.

Bluff-headed ſhips are oppoſed to thoſe that are ſharp-headed. They are ſhorter, leſs maſted, and ſail cheaper.

BLUING of Iron, a method of beautifying that metal ſometimes practiſed; as for mourning buckles, ſwords, or the like. The manner is thus: take a piece of grind-ſtone, and whet-ſtone, and rub hard on the work to take off the black ſcurf from it; then heat it in the fire, and as it grows hot, the colour changes by degrees, coming firſt to a light, then to a dark gold colour, and laſtly to a blue. Sometimes they grind alſo indigo and ſallad-oil together, and rub the mixture on the work with a woollen rag, while it is heating, leaving it to cool of itſelf.

Among ſculptors we alſo find mention of bluing a figure of bronze, by which is meant the heating of it, to prepare it for the application of gold leaf, becauſe of the bluiſh caſt it acquires in the operation.

BLUM, Joachim Christian, in *Biography*, an eſteemed German poet, was born at Rathenau, in 1739, and received the early part of his education in his father's houſe, from a lady, who was the governeſs of his ſiſters. At the age of eleven years he loſt his father, and became maſter of a library, of which he availed himſelf to great advantage. During his reſidence with his mother and ſiſters, he amuſed himſelf with playing hymns on the harpſichord, and with reading moral authors, and reciting orations, which he did in a manner ſo affecting as to cauſe his hearers to ſhed tears. His mother concluded, that he had an inclination to become a clergyman, and with this view placed him, in 1754, at a ſchool in Brandenburg, where he manifeſted by his courſe of reading, and alſo by his performances, a ſtrong turn for poetry. In 1757, he removed to the gymnaſium at Berlin; and giving up all thoughts of the miniſterial office, he devoted himſelf to the ſtudy of philoſophy and the belles lettres, indulging himſelf occaſionally in his favourite purſuit. From Berlin he proceeded, in 1759, to Frankfort on the Oder, where he ſtudied for ſome time under Baumgarten, for whom he profeſſed the higheſt reſpect; but when this city fell into the hands of the Ruſſians, he retired to the houſe of his mother; and as his health was in an infirm and declining ſtate, in conſequence of an accident which had almoſt proved fatal to him in his youth, he determined to continue with his mother, and to devote the remainder of his days to the muſes in his native place. Here he cloſed his life, Auguſt 28, 1790. His poetical works were "Lyric Poems," and "Idylls," publiſhed at various periods after the year 1765. A dramatic piece, in praiſe of his native town, entitled "Rattenau delivered," was often repreſented at Berlin with applauſe, but forbidden in compliance with the requeſt of the Swediſh ambaſſador. Blum's poetry is ſaid to be characterized by ſoftneſs, ſimplicity, and correctneſs, and he ranks among the beſt poets of Germany. He alſo publiſhed ſome volumes under the title of "Walks;" two volumes of "Orations;" and a collection of "German Proverbs." His works in general were much read, and approved by perſons of the firſt diſtinction. The late king of Pruſſia, Frederick William, honoured him with a very particular token of favour. As Blum's health required his reſidence in the country, he purchaſed, in 1787, a ſmall eſtate, upon which was a manſion in a very ruinous condition; but having in the purchaſe exhauſted almoſt the whole of his property, he could not repair his houſe without aſſiſtance; and, therefore he addreſſed a poetical epiſtle to the king, in which he introduced the following lines:

"O aid thy poet, gracious prince,
And free his breaſt from care;
All that he aſks is competence
His manſion to repair.

Thoſe mould'ring walls, which long have ſtood
Offenſive to the eyes,
A temple then to gratitude,
Shall renovated riſe.

His groves, near yonder wand'ring ſtream,
Whoſe banks with reeds are crown'd,
Thus conſecrated groves ſhall ſeem,
And ſhade the hallow'd ground."

With this addreſs his majeſty was ſo much pleaſed, that he ordered for him 2000 rix-dollars. Blum expreſſed his gratitude in a ſecond epiſtle, to which the king returned his beſt

wiſhes. Beſides the Greek and Latin, he well underſtood the French, Italian, and Engliſh languages; and he had ſtudied with great attention the hiſtory of the Chriſtian church. Gen. Biog.

BLUMBERG, in *Geography*, a ſmall town of Germany, in the landgravate of Baar.

BLUMENAU, a bailiwick of Germany, in the principality of Calenberg, ſeated on the Leine.

BLUMENFELD, a town of Germany, in the circle of Swabia, and commandery of Minau, ſeated on the river Ach; 8 miles N.N.E. of Schaffhauſen.

BLUMENSTRAST, J. Deodatus, in *Biography*, took his degree of doctor in medicine in Leyden. Returning thence to Ruſſia, his native country, he was ſoon diſtinguiſhed by the emperor, who made him archiator, or principal phyſician to his court. He had alſo the honour of being appointed the firſt preſident of the Royal Academy of Sciences at Peterſburg, which had been inſtituted, Haller ſays, by his exertions. He died at Moſcow at an advanced age, in April 1755, leaving only one publication, which was firſt printed in the year 1700, 4to. "Medicus Caſtrenſis Exercitui Moſcovitarum." Haller Bib. Med. Pract. Eloy. Dict. Hiſt.

BLUMENTHAL, in *Geography*, a bailiwick of Germany, in the duchy of Bremen.

BLUMLIS Alp, a majeſtic eminence of the Alps, in the canton of Bern, in Swiſſerland, terminating the valley of Lauterbrunnen, and having at its feet a large glacier, which ſtretches towards the valley of Gaſter. The Blumlis Alp, and alſo the feet of the Alpſchelenhorn, are covered with black ſchiſtus; but the granite is not apparent, except at a conſiderable height. The ſides of the Blumlis Alp, bordering the glacier, are black ſlate, in which have been found ſeveral belemnites, and a fragment of a Cornu Ammonis, a foot in diameter.

BLUNDERBUSS, in the *Military Art*, a ſhort ſort of fire arm, with a large bore contrived to carry a number of muſket or piſtol bullets at once. The blunderbuſs is proper to do execution in a crowd, or to make good a narrow paſſage, as the door of a houſe, ſtair-caſe, or the like.

BLUNT, in *Fencing*. To fight with blunts, is to exerciſe or parade with weapons without points or edges.

BLUNTING *the angles of a battalion*, in the *Military Art*, ſignifies to retrench the four corners, and turn the ſquare into an octagon. This is done in order to give an opportunity for preſenting the pikes, or firing on all ſides, and was a military evolution formerly much in uſe, but now diſuſed.

BLUSHING, a ſuffuſion or redneſs of the cheeks, excited by a ſenſe of ſhame, on account of conſciouſneſs of ſome failing or imperfection. See Enchymoma.

Bluſhing is ſuppoſed to be produced from a kind of conſent or ſympathy between ſeveral parts of the body, occaſioned by the ſame nerve being extended to them all. Thus the fifth pair of nerves being branched from the brain to the eye, ear, muſcles of the lips, cheeks, palate, tongue, and noſe; a thing ſeen or heard, that is ſhameful, affects the cheeks with bluſhes, driving the blood into the minute veſſels thereof; at the ſame time that it affects the eye and ear. For the ſame reaſon it is, as Dr. Derham obſerves, that a ſavoury thing ſeen or ſmelt, affects the glands and parts of the mouth: if a thing heard be pleaſing, it affects the muſcles of the face with laughter; if melancholy, it exerts itſelf on the glands of the eyes, and occaſions weeping, &c. And to the ſame cauſe Dr. Willis aſcribes the pleaſure of kiſſing.

BLUSTERING *weather* is that where the wind blows with various degrees of ſtrength, attended with a dark ſky, rain, ſnow, &c.

BLUTEAU, Don Raphael, in *Biography*, a religious theatine, was born of French parents in London in 1638. After having diſtinguiſhed himſelf in ſacred and profane literature, he viſited Portugal and acquired ſuch knowledge of the language as to be able to preach in it with applauſe. From Portugal he returned to Paris, and was for ſome time preacher to Henrietta-Maria, queen of England. Upon reviſiting Portugal, he obtained an office in the inquiſition, and became member of the Royal Academy of Hiſtory. Of his works, the moſt eſteemed is "A Portugueſe and Latin Dictionary," in 8 vols. fol. Coimbra 1712—1721, to which he added a Supplement in 2 vols. fol. Liſbon, 1727, 1728. He died at Liſbon in 1734, at the advanced age of 96. Moreri.

BLUTFINK, in *Ornithology*, one of the ſynonymous names of *loxia pyrrhula*, the common bulfinch. Friſch. Av.

BLYSOOG, in *Geography*, a river of South Wales, which runs into the Tivy, about 3 miles S.S.E. of Cardigan.

BLYTH, in *Geography*, a ſmall market town of Nottinghamſhire, in England, has been the ſeat of a caſtle and a priory; but theſe buildings, with their endowments and privileges, being entirely demoliſhed at the diſſolution, the town alſo ſunk in the general wreck, and has never ſince been renovated. The whole pariſh conſiſts now only of 157 houſes, with 589 inhabitants. Here are a ſmall market on Wedneſdays, and two annual fairs. The church is a large handſome ſtructure, and contains ſeveral ancient monuments. Some of the Creſſy family built an hoſpital here, which bears the name of Blyth-ſpittle.

Blyth, or *South Blyth*, a ſmall ſea-port town of Northumberland, in England, is a place that has obtained its ſole conſequence ſince the reſtoration; for, previous to that period, here were ſcarcely any houſes. In the year 1728, its trade had ſo much increaſed that above 200 veſſels were entered in the cuſtom-houſe books as ſailing from this port. It is conſidered as a creek to the port of Newcaſtle, and its principal trade is in coals. Blyth is 14 miles N. E. of Newcaſtle, and 288 miles N. of London. The townſhip contains 183 houſes, and 1170 inhabitants, of whom 234 are employed in trade. Here is a ſmall market on Saturdays. About three miles ſouth of Blyth is Seaton Delaval, a ſeat belonging to lord Delaval, whoſe grandfather, ſir Francis Blake Delaval, was an able admiral in the beginning of the laſt century. He was often projecting ſome improvements in the ports near his ſeat, and after ſurmounting great difficulties, conſtructed one upon a new plan, which now bears his name.

BMI, in *Muſic*. See Gamut.

BOA, in *Zoology*, a genus of the Serpent race, diſtinguiſhed by having plates, or undivided ſcuta, both on the belly, and beneath the tail; the latter of which, unlike the crotali, does not terminate in a rattle.

Such is the Linnæan character of this genus, the ſpecies of which are not very numerous. Gmelin enumerates the following kinds in the Syſtema Naturæ: contortrix, canina, hipnale, conſtrictor, cenchris, ophryas, enydris, murina, ſcytale, and hortulana. But in addition to theſe, we are to mention a few other ſpecies deſcribed by Dr. Patrick Ruſſel in a recent publication on the ſerpents of India, with the obſervations of Dr. Shaw upon the newly diſcovered kinds, and ſeveral others lately ſpoken of by continental writers.

Dr. Ruſſel, in the work above cited, has four new ſpecies

of boa, called, in the Indian language, *bungarum pamah*, *padain cootoo*, *geedi paragoodo*, or in the young ſtate *cobra monil*, and the *horatta pam*. Theſe are the ſpecies, faſciata, viperina, lineata, and horatta of Dr. Shaw's zoology. Dr. Shaw has likewiſe increaſed the number of the boæ by the addition of a fifth ſpecies, *crotalus mutus* of Linnæus, which he is induced to remove from the crotali to this genus, becauſe it is not furniſhed with a genuine rattle like the reſt of that tribe.

But the French writers of the preſent day have regarded the arrangement of the Swediſh naturaliſt in the amphibious claſs of animals with much leſs indulgence, their alterations tending to little leſs than the ſubverſion of his ſyſtem. The boa genus, as eſtabliſhed by Linnæus, is obviouſly defective, in one point at leaſt, where nature had herſelf preſcribed thoſe characters which ought not to have eſcaped the diſcrimination of the naturaliſt. Nothing, we muſt admit, can be more improper, if it could have been avoided, than to include in the ſame natural family both the venemous and inoffenſive kinds of ſerpents; or, in other words, to unite, under one head, thoſe which, having fangs for the conveyance of poiſon into the wound inflicted with their bite, are highly dangerous, and ſuch as have no fangs for this purpoſe, and are therefore comparatively harmleſs. The firſt innovation upon the Linnæan genera was made by Lacepede, whoſe method has been followed by others; and laſtly, by Latreille, with ſome improvements, in his Natural Hiſtory of Reptiles.

Latreille retains among his boæ thoſe only of the Linnæan ſpecies which have no venemous fangs; for the reception of the remainder he eſtabliſhes the new genus SCYTALE. This genus forms an intermediate link between the two Linnæan genera boa, and crotalus; having, in common with both, the abdominal plates, and either plates alone, or plates and ſcales beneath the tail; the poiſonous fangs removing them from the boæ, and the naked tail from the crotali, or ſnakes that have a rattle at the extremity of that part. The boæ of Latreille contain the following ſpecies: *le boa devin* (conſtrictor, Linn.), *le boa géant* (a ſpecies hitherto confounded with the former), *le boa bojobi* (boa canina, Linn. and Lacepede), *le boa hipnale* (hipnale, Linn.). *le boa cenchris* (cenchris, Linn.), *le boa enhydre* (enydris, Linn.), *le boa ophrie* (ophrias, Linn.), *le boa ſcytale* (ſcytale, Gmel. Scheucher), *le boa brodé* (hortulana, Linn.), *le boa rativore* (Seba, v. 2. pl. 29. 1.), and *le boa turc*, a native of the Grecian iſlands, deſcribed by Olivier in his "Voyage dans l'Empire Ottoman."—Thus the Linnæan *boa comertrix*, a poiſonous ſpecies, *le ſcytale a groin* of this writer, is removed from among the boæ to the genus SCYTALE, together with another ſpecies not before deſcribed, *le ſcytale a tête plate*, and the four new ſpecies mentioned by Dr. Ruſſel belong unqueſtionably to the ſame genus, being all of the venemous kind. We have, therefore, ſix ſpecies of the SCYTALES confounded with the natural family of boa.

The boæ, taken collectively, exceed in magnitude all the other tribe of ſerpents. The powers of certain ſpecies, like their ſtature, are prodigious. Theſe enormous kinds are principally the inhabitants of the burning regions of Africa, whoſe fame, in this reſpect, was celebrated in ages of remote antiquity. Hiſtory ſpeaks of theſe tremendous ſerpents in terms that ſtagger credibility; but travellers of our own times, who have had the opportunity of obſerving theſe creatures in their native haunts, and whoſe relations deſerve every rational degree of credit, afford ſo much collateral evidence, that we are not allowed to reject the authority of the ancients in many of the moſt material points. When Valerius Maximus relates, upon the authority of Livy, the conteſt between an army of Romans under Attilius Regulus, and an enormous ſnake, that diſputed with them, for a conſiderable time, the paſſage acroſs the river Bagdara in Africa, and was at laſt only overcome, after killing many of the ſoldiers, by means of the battering machines employed in attacking fortreſſes, we are inclined to ſuſpect the whole as fabulous. If, however, we reflect at the ſame time upon the ſize and power of this monſter, the ſkin of which, when taken off, was 120 feet in length, we need not be aſtoniſhed at the reſiſtance it was capable of making. Something muſt be allowed on this occaſion for the luxuriance of fancy, or the fictions of the battle between the Phœnicians, and the ſacred ſnake of Mars, would almoſt ſhrink from compariſon with this ſurpriſing adventure.

> Ille volubilibus ſquamoſos nexibus orbes
> Torquet, et immenſos ſaltu ſinuatur in arcus:
> Ac media plus parte leves erectus in auras
> Deſpicit omne nemus:———————
> ———————————————
> Nec mora: Phœnicas (ſive illi tela parabant,
> Sive fugam; ſive ipſe timor prohibebat utrumque)
> Occupat; hos morſu, longis complexibus illos;
> Hos necat afflatos funeſti tabe veneni. Ovid.

The ſerpent mentioned by Livy is believed to have been an overgrown creature of the boa genus, the *conſtrictor* of Linnæus; a kind which, from the ſuperiority of its ſize, is emphatically denominated the "King of Serpents." This ſpecies, of which we ſhall ſpeak more largely in another place (vide CONSTRICTOR), is found occaſionally in Africa, India, and South America, from 20 to 30 feet in length, and even more; and of a ſtrength ſo great, as to be able to deſtroy moſt of the larger animals by the violence of its preſſure only. We have ſeen the ſkins of this particular ſpecies almoſt 20 feet in length, and of a bulk proportionate. Among the articles of Natural Hiſtory, collected in South America for the National Muſeum at Paris, but intercepted, and ſold in this country, there were ſeveral ſpecimens: dried ſkins of this kind are alſo preſerved in the Britiſh and Leverian muſeums, and in moſt of the public muſeums on the continent, which at once remove every unreaſonable degree of ſuſpicion as to the actual exiſtence of ſuch a monſtrous kind of ſerpent.

If, therefore, according to the ideas of latter writers, the true boæ are deſtitute of poiſonous fangs, nature has more than amply ſupplied the deficiency by the powers they are endowed with for the deſtruction of their prey. The elephant, the rhinoceros, the hippopotamus, and the lion, are the only animals that can reſiſt them with ſucceſs. The ſtag, the leopard, and even the buffalo, entangled once within the coils of the body of the boa, muſt fall an eaſy victim to its voracity. The boæ are, among ſerpents, what the elephant and the lion are among quadrupeds: like the elephant, they ſurpaſs the reſt of the ſerpent race by their ſize; and, like the lion, excel them in their addreſs, their courage, and their force. They ſeldom attack their prey by artifice, decoying their unwary adverſary, and, by a wound as ſudden as inſenſible, paralyzing its efforts with the deadly torpor of their poiſon. Confident in their powers, they attack them openly; oppoſe their ſtrength to the reſiſtance of their enemy with ardent intrepidity; and when they conquer, it is by the manifeſt ſuperiority of bodily vigour over that of their opponent.—It ſhould be obſerved, that theſe traits of character relate only to the largeſt of the boa genus, of which no more than two ſpecies are correctly aſcertained, although there is reaſon to believe the number muſt be greater. Much confuſion prevails among travellers who have deſcribed theſe ſerpents: they have entered largely into the prodigies of their hiſtory, without paying any due regard to the deſcription

tion of the animals themſelves, a circumſtance that has hitherto involved this matter in obſcurity, and leaves us in conſiderable doubt as to the real number of diſtinct ſpecies already diſcovered, and mentioned by thoſe travellers. See CONSTRICTOR, &c.

BOACRÆ, in *Ancient Geography*, a place of Italy, on the Aurelian way, in the route from Rome to Arelato, through Etruria and the Maritime Alps. Anton. Itin.

BOAD, in *Geography*, a town and fort of Hindoſtan, in the country of Oriſſa, near the Mahanuddy river; 55 miles S. E. of Sumpulpour, and 100 weſt of Cattack. N. lat. 20° 40'. E. long. 84° 10'.

BOADICEA, BOUDICIA (Tacitus), or BUNDUICA (as ſhe is called by Dion), in *Ancient Britiſh Hiſtory*, a queen of the Iceni, celebrated for her misfortunes, and for her formidable, though unſucceſsful, reſiſtance to the Roman power in Britain.

At the time when the revolt, of which Boadicea was the principal mover, took place, the ſouthern part of the iſland had tranquilly ſubmitted to the government of the Cæſars. Although ſcarcely 18 years had elapſed ſince the invaſion of Claudius, Britain was already conſidered an important acquiſition. Several flouriſhing colonies were founded; numerous ſettlers flocked from the more diſtant provinces of the empire, and the only expedition which employed the legions, was that undertaken againſt the ſequeſtered iſland of Mona, the principal remaining ſeat of Druidical ſuperſtition. But amidſt this ſeeming ſecurity, the oppreſſion exerciſed by individuals excited indignation among the natives. The procurator, Catus Decianus, who, in the abſence of the proprætor, poſſeſſed the excluſive adminiſtration of government, behaved with the moſt inſufferable tyranny; and, according to the confeſſion of Tacitus himſelf, the great men of the nation were treated as ſlaves, and deprived injuriouſly of their eſtates by this upſtart governor. The fear, however, of incuring the imperial reſentment, reſtrained them from expreſſing their diſſatisfaction otherwiſe than by murmurs, till the deceaſe of Praſutagus, king of the Iceni, brought matters to a criſis. This monarch, by his attachment to the party of the invaders, had merited the title of friend and ally of the Roman people, and by his laſt will, had bequeathed his eſtates as a joint inheritance between the emperor Nero and his two daughters. His policy, if intended as ſuch, failed of the deſired effect. The procurator, under pretence of carrying the teſtament into execution, ſeized on all the poſſeſſions of Praſutagus without exception; and as Boadicea dared to murmur againſt ſuch flagrant injuſtice, he actually cauſed herſelf to be publicly ſcourged as a ſlave, and the chaſtity of her daughters to be violated by his officers.

Such outrages were beyond ſufferance. The Iceni to a man roſe up in arms, headed by Boadicea in perſon, who to a maſculine ſpirit joined a gift of natural eloquence calculated to inflame the paſſions of a barbarous multitude. The Trinobantes, and other neighbouring nations, alike incenſed at the extortions of the procurator, followed the example, and an army of 120,000 iſlanders being rapidly formed, marched directly againſt Camalodunum, (ſuppoſed to have been Maldon,) the neareſt Roman colony. As Decianus could only ſpare a few ſoldiers to aſſiſt the inhabitants in its defence, the place was almoſt inſtantly ſtormed, and, with a temple lately erected to the divinity of Claudius Cæſar, reduced to aſhes, all within it being previouſly maſſacred. The ninth legion, which had ventured to take the field againſt the inſurgents, was next attacked and defeated. The infantry were almoſt totally deſtroyed. The commander, Petilius Cerealis, at the head of his cavalry, with difficulty regained his camp, where he carefully intrenched himſelf; while Catus Decianus, terrified at the conſequences of his infamous conduct, made his eſcape into Gaul, covered with univerſal odium.

After ſuch a ſeries of ill-fortune, the only hope of the Romans remained veſted in the proprætor Suetonius Paulinus, at this time occupied in exterminating the Druids of Mona. On receiving news of the progreſs made by Boadicea, he immediately marched, though by a dangerous route, and through the midſt of an hoſtile country, to Auguſta (London), already a conſiderable place, though not yet dignified with the name of a colony. As he judged this poſt untenable, he retired to unite his ſcattered forces, accompanied by ſuch of the inhabitants as choſe to follow his fortunes; but the women and children, the old and infirm, who were left behind, without any other protection than their ſex, their age, or their ſituation afforded, were indiſcriminately ſacrificed to the fury of the Britons. Verulamium, another colony, ſhared the ſame fate. All foreigners were every where put to the ſword, and the cruelties, ſaid by Dion to have been exerciſed upon ſome of the ſufferers, are ſhocking beyond deſcription.

The rebellion had now attained its utmoſt height. Three Roman ſtations laid in aſhes, and the blood profuſely poured of 70,000 of her perſecutors, had amply revenged the wrongs of Boadicea. The whole eaſtern part of the iſland was in poſſeſſion of her partizans, and her forces in arms had increaſed to the amazing number of 230,000, when Suetonius, having taken every meaſure prudence could ſuggeſt in his circumſtances, prepared to check this torrent in its courſe. The proprætor, although accuſed, and perhaps with juſtice, of pride and exceſſive cruelty, yet poſſeſſed the moſt ſplendid military talents. During the laſt reign he had ſignaliſed himſelf, when commander in Africa, by a complete victory over the rebellious Mauritanians. Nero rewarded his bravery by naming him to the government of Britain. The late reduction of Mona had increaſed his celebrity; and he appears to have been the only general then in the empire, Corbulo probably excepted, equal to the taſk of reducing the inſurrection raiſed by Boadicea. His ſituation was, however, extremely critical. It was in vain that he diſpatched inſtructions to Pænius Poſthumus, who commanded the ſecond legion, to march to his aſſiſtance. Pænius, in conſequence of ſome difference with his general, or actuated by a ſecret jealouſy, refuſed to move, in direct diſobedience to orders. Thus Suetonius ſaw his whole force reduced to the fourteenth legion, Gemina, and the Vexillarii of the twentieth, which, added to a few auxiliary cohorts, only amounted to about 10,000 men. With this army, ſmall as it was, he determined on hazarding a battle, and therefore waited the approach of the Britons on a narrow ſpot of ground, opening in his front into an extenſive plain, while his rear was protected by a thick wood. According to the uſual diſpoſition obſerved by the Roman armies, the legionaries were ſtationed in the centre, flanked by the light armed and auxiliary cohorts; the wings being compoſed of cavalry. Suetonius did not tarry long in expectation of the enemy. The Britons ſoon appeared, covering the plain in immenſe numbers. Their wives and children, who had accompanied them to become ſpectators of a victory already conſidered as certain, were mounted in heaps on waggons, encircling the field in their rear, like an amphitheatre. Boadicea, with her two daughters, drove in a chariot along the ranks, encouraging her troops in animated language. She renewed the detail of Roman injuſtice; beſought vengeance for the wrongs ſuſtained by herſelf and her family; magnified the importance of the victory ſhe had already gained, and aſſured her followers

lowers that their enemies, forſaken by all the gods, would never be able to endure even their ſhouts of onſet. She finiſhed by exhorting them to conquer or die, which, ſhe added, was her own reſolution. Suetonius on his ſide did not neglect to animate his men by a ſuitable oration, and the acclamation and cheerful countenance with which it was received, convinced him that he had every thing to hope from the bravery and diſcipline of his ſoldiers.

The Britons came on, uttering loud ſhouts, menaces, and ſongs of victory, while the Romans, cloſely drawn up, awaited the onſet in perfect ſilence, and at the requiſite diſtance, made a firſt diſcharge of the pilum with terrible effect. Preſerving the advantage of the ground, they received the attack of the barbarians with ſuch firmneſs, as checked its impetuoſity; till, having expended all their javelins, not without dreadful carnage of the enemy, they ruſhed forward from all parts at once, obſerving the form of a wedge, the more eaſily to penetrate ſuch an immenſe multitude. This charge was ſeconded by the allies with equal ardour. The firſt ranks of their opponents were inſtantly borne down, and hewn in pieces; but the reſt crowding to ſurround the Romans, a bloody conteſt commenced. The Britiſh war-chariots, wherever they ſucceeded in breaking in among their enemies, occaſioned terrible annoyance, till Suetonius, ordering his men to direct their blows at the naked bodies of the drivers, by degrees diſembarraſſed himſelf of theſe troubleſome invaders. The action was long maintained with fury on both ſides, the Britons, though deſtitute of order or diſcipline, fighting with great obſtinacy and deſperation; but, finally, the ſuperior ſkill, coolneſs, and bravery of the Romans, bore down every oppoſition. Prodigious numbers periſhed beneath the ſwords of the legions, or by the charges of the cavalry, who trampled all before them; while the crowds that endeavoured to ſave themſelves by flight, met with an inſurmountable impediment in their own waggons, which encloſed them in form of a ſemicircle. Here the ſlaughter was terrible, for mercy, in the circumſtances of Suetonius, would have been in the higheſt degree imprudent. The Romans, in the heat of their fury, ſpared neither age nor ſex. Even the beaſts of burden, ſtruck through with darts, increaſed the horrors of the ſcene, and the heaps of dead, which covered the plain, the fields, and the ſurrounding foreſts. Upwards of 80,000 Britons are computed to have periſhed on this occaſion; while of the Romans about 400 were killed, and ſcarcely ſo many wounded.

Few victories, even in the moſt flouriſhing ages of the republic, deſerved to be compared with this of Suetonius. Never had any been more deciſive. The remaining rebels, terrified at the dreadful chaſtiſement they had received, diſperſed into their reſpective diſtricts, and Boadicea herſelf periſhed ſoon after the battle, either through chagrin, or, as is the prevailing opinion, ſhe ended her days by poiſon. Pænius Poſthumus, whoſe diſobedience had prevented the ſecond legion from ſharing in the triumph of their countrymen, fell upon his own ſword, thus avoiding the puniſhment and diſgrace which awaited his conduct. The vigour with which, though accompanied by acts of the moſt terrible ſeverity, Suetonius purſued the revolters, reſtored tranquillity to the whole iſland before the enſuing ſpring. The intrigues of individuals, and the jealouſy of his execrable ſovereign, occaſioned his ſubſequent recal from his government; yet the triumphs obtained under his auſpices, conferred everlaſting honour and renown both on his own name and that of the legion he commanded.

Boadicea is deſcribed by Dion Caſſius as a woman of large ſtature, ſtrong and well proportioned in her limbs, of a manly and ſtern countenance, harſh, authoritative voice, and poſſeſſing beautiful golden hair, which reached down below her waiſt. That ſhe was poſſeſſed of uncommon abilities, or at leaſt had perſons of extraordinary talents to aſſiſt her, is evident from the rapidity with which ſhe cut off the Roman garriſons one after another; the diſpoſition of her forces, ſo as entirely to interrupt the communication between the quarters of the legions; the victory ſhe obtained over Cerealis, famous himſelf for his military knowledge, and the extremities to which ſhe reduced Suetonius, the greateſt general of the age. Dion is loud in praiſe of her eloquence, and puts into her mouth ſeveral elaborate orations. We have preferred the authority of Tacitus, reſerving, however, ſuch paſſages of Dion as are moſt neceſſary to elucidate the narration. The defeat and death of Boadicea are ſaid to have happened A. D. 61. Tacit. Annal. xiv. c. 31—37. Dion Caſſius, Hiſt. Rom. lib lxii. cap. 1—12.

BOADJOOS, in *Geography*, called alſo *Oran laut*, or men of the ſea, are a ſort of itinerant fiſhermen in the Eaſt Indies, ſaid to come originally from Johore, at the eaſt entrance of the ſtraits of Malacca, though ſome are of opinion, that they muſt have come either from China or Japan. They live chiefly in ſmall covered boats, on the coaſts of Borneo, Celebes, and the adjacent iſlands. Others dwell near the ſea, on theſe iſlands; their houſes being raiſed on poſts, at a little diſtance in the ſea, and always at the mouths of rivers. They are Mahometans; and have a language of their own, but no written character. Many Boadjoos are ſettled on the north-weſt coaſt of Borneo, who not only fiſh, but make ſalt, and trade in ſmall boats along the coaſt. Some of their boats are from 12 to 18 and 20 tons burden, and carry from 16 to 20 men, and form, in ſome places, a fleet of a hundred ſail. Others of them are about 5 or 6 tons burden, which are managed by women, even in heavy ſeas. Their method of making ſalt is as follows: they gather ſea-weeds, burn them, make a ley of aſhes, filter it, and form a bitter kind of ſalt in ſquare pieces, by boiling it in pans made of the bark of the aneebong, or cabbage-tree; theſe pieces of ſalt are carried to market, and paſs as a currency for money. Thoſe that are ſettled on the north-weſt coaſt of Borneo uſed to ſupply the Engliſh at Balambangan with rice, fowl, and other proviſions. Many of them are ſettled at the mouth of the river of Paſſir, who employ themſelves chiefly in catching ſmall ſhrimps with hand-nets, which they puſh through the mud; the ſhrimps, after being well waſhed with water, are expoſed to a hot-ſun. They are then beat in a mortar, and made into a kind of paſte, called *blatchong*, which has a ſtrong ſmell, and is much in requeſt all over India. Theſe laſt Boadjoos may be conſidered as ſtationary or fixed, compared with thoſe who live always in their boats, and who, as the monſoon ſhifts on the iſlands Borneo and Celebes, ſhift their ſituation to leeward, ſo as to be always under the lee of the land, for the ſake of fine weather. Moſt of thoſe who rove round Celebes, though they change their ſituation with the monſoon, conſider Macaſſer as their home. Whilſt the Boadjoos lie at anchor, in boats managed by their women, they are dextrous in fiſhing for *tripangs*, i. e. ſwallows, or ſea-ſlugs, which they take in ſeven or eight fathoms water. When they ſee the ſwallow in clear water, they ſtrike it with an inſtrument, conſiſting of four-bearded iron prongs, fixed along an almoſt cylindrical ſtone, rather ſmaller at one end than at the other, about 18 inches long; an iron ſhot is fixed at the end of the ſtone, next the point of the prongs. The ſwallow is dried in the ſmoke, and ſent to the China market. They alſo dive for it, the beſt being found in deep water. The black is reputed the beſt; but there is ſome of a lighter colour, found only in deep water, which is more valued

valued in China than the black, and ſold even for 40 dollar a picol: ſome of the pieces weigh half a pound. The white, caught in ſhoal water and on the dry ſand, among coral rocks, is the worſt; its value being about four or five dollars a picol. The Boadjoos are very uſeful to the Dutch Eaſt India company, in carrying intelligence ſpeedily from place to place. Stavorinus's Voyages, vol. ii. p. 240.

BOADODA *Baſhaw*, in the *Turkiſh Military Orders*, an officer of the *janizaries*, whoſe buſineſs it is to walk every day about the principal parts of the city, with a number of janizaries to attend him, to keep order and ſee that all things are regular, even to the dreſs. This office is for three months, and from this the perſon is uſually advanced to be a *ſerach*.

BOÆ, in *Ancient Geography*, a town of Peloponneſus in Laconia, at the extremity of the Bœotian gulf. Diana was particularly worſhipped in this place; Apollo and Eſculapius had their reſpective chapels here. At ſome ſtadia from this city was a temple of Serapis and Iſis. Pauſanias.

BOAGRIUS, a river, or rather torrent, of Greece, in the country of the Epicnemidian Locrians, according to Ptolemy. Strabo ſays, that it watered the town of Thronium——Alſo, a town of the ſame country, ſituate to the weſt, on the confines of Phocis.

BOANERGES, i. e. *Sons of Thunder*, in *Scripture Hiſtory*, a name given by our Lord to the two apoſtles James and John (Mark, iii. 17.), which ſome have erroneouſly ſuppoſed to be an appellation of reproach, intimating a fierceneſs and furiouſneſs of temper; whereas it is much more reaſonable to conſider it, with others, as a title of honour, prophetically repreſenting the reſolution and courage with which they would openly and boldly declare the great truths of the goſpel, when they were made fully acquainted with them. How well they deſerved this title, ſufficiently appears in the ſequel of their hiſtory. See JAMES, and JOHN.

BOANS, in *Zoology*, a ſpecies of RANA, or frog, the body of which is ſmooth, marked with contiguous ſpots beneath; and the feet palmated. Gmelin. Two varieties of this kind are deſcribed; β, having the upper part of the body blueiſh lead colour, and γ, with the body inclining to orange. Laurent. Amph. &c.

This kind inhabits America, and differs from *rana arborea*, the tree-frog, to which it is nearly allied, according to Gmelin, in having all the feet webbed, and the body ſpotted with white. Much confuſion prevails reſpecting the Linnæan ſpecies, boans. Dr. Shaw ſuſpects it to be the ſame as the *rana maxima* of that author, probably in a younger ſtate. He mentions likewiſe another ſuppoſed variety, the *rana virginiana altera* of Seba.

BOAR, the *wild boar* or hog from whence the common hog derives its origin. See SCROFA SUS. The male of the tame hog is alſo called the boar.

The wild boar is a native of almoſt all the temperate parts of Europe and Aſia, and is alſo found in the upper parts of Africa. Formerly it was an inhabitant of this country, as appears from the laws of Howel Dda, who permitted his grand huntſman to chaſe that animal from the middle of November to the beginning of December. (Leges Wallicæ, 41.) There are alſo many places in Wales that retain the name Pennarth, or the Boar's Head, to this day. William the Conqueror puniſhed with the loſs of their eyes any that were convicted of killing the wild boar, the ſtag, or the roe-buck. (Leges Saxon. 292.) And Fitz-Stephen tells us, that the vaſt foreſt, which in his time grew on the north ſide of London, was the retreat of ſtags, fallow-deer, wild boars, and bulls. Charles I. turned out wild boars in the New Foreſt, Hampſhire; but theſe were deſtroyed in the civil wars. (Pennant.) In France, Germany, Poland, and other countries on the European continent, they are ſtill common, and the hunting of them is a principal amuſement among parties of the gentry. Boar-hunting is a favourite diverſion alſo in other more diſtant parts of the world.

Theſe animals are found in the ſteppes of the Samara and the Volga, in Ruſſia, on the confines of the river Ural in Daouria, and about the Irtyſh. Between the Ural and the Yamba they are very numerous, and are hunted in winter by the Coſſacks, not without danger, with dogs, and ſometimes killed with carabines, and ſometimes with lances. Although they feed ſolely on the roots of ſea-weed and ſedge, they grow to ſuch an extraordinary ſize, that they are frequently found weighing upwards of ſix hundred pounds; their bacon is nearly four inches thick in fat, though their fleſh is in general dry and firm and well-flavoured.

Sonnini thinks it probable (ſee his Travels in Upper and Lower Egypt, p. 348.) that the wild boars of Egypt are not the ſame with thoſe in Europe. The great difference of climate, and the ſtill greater difference of ſituation, muſt have occaſioned at leaſt ſome varieties in the ſpecies of theſe animals. More multiplied in temperate or cold countries, which appear more ſuitable to their nature, they inhabit the thick receſſes of the foreſts, where they can find abundance of food. They never leave the woods but to paſs from one to another, or to ravage the growing crops, and theſe predatory excurſions are undertaken only by night. In general, they retire to the darkeſt and cloſeſt places at the riſing of the ſun, the brightneſs and heat of which they ſeem to dread. The wild boar of Egypt, on the contrary, has no ſhelter. Continually expoſed to the rays of a burning ſun, he roams over the hotteſt ſands, where he with difficulty finds a few ſcattered ſhrubs, which afford him a ſcanty ſubſiſtence, and ſcarcely any ſhade. He is alſo frequently ſeen in the deſerts of Nitria, which is the reſort of a greater number of animals than any other part of the deſerts, on account of the ſheets of water it contains, and of the plants that grow on their banks. Theſe boars are ſolitary, though a general want of food ſometimes drives them in herds to the environs of the lakes of Natron. As the Mahometans and Copts do not eat the fleſh of the wild boar more than that of the hog, and hold both theſe animals in equal abhorrence, it was impoſſible, ſays this writer, to procure a wild boar in Egypt, at leaſt without ſeeking it in the deſert. Upon the whole he concludes, that they are not the ſame as thoſe of Europe. It is perhaps, he adds, in this ſenſe only that we muſt underſtand the paſſages of Ariſtotle (Hiſt. Nat. l. viii. c. 24.), and Pliny (Hiſt. Nat. l. viii. c. 33.), who have aſſerted that there are no wild boars in Africa. Wild boars, ſays Buffon, are as common in Aſia and Africa as in Europe. But he has given an account and a drawing of an African wild boar, which is remarkable for ſeveral particular characters; and hence there is reaſon to believe, that the "hanzire" of Egypt is the ſame animal as the wild boar of Africa.

Among huntſmen, the wild boar has ſeveral names according to its different ages: the firſt year it is called a pig of the ſaunder; the ſecond, a hog; the third, a hog-ſteer; and the fourth, a boar. When leaving the ſaunder, he is called a ſingler, or ſangler. The wild boar inhabits woods, living on roots, maſts, acorns, and other vegetable food. Though gluttons, they do not attack other animals to devour them; but they eat fleſh when they meet with it. They have been ſeen to eat horſe-fleſh; and the ſkin of the deer,

deer, and the claws of birds have been found ſticking in their ſtomach, but this may be from neceſſity. Yet they are fond of blood, ſince they will eat their own young, or even children in the cradle, according to Buffon. "Wild boars (ſays this writer) do not ſeparate from their mothers until the third year, and till that age are called by the hunters ſtock beaſts, or beaſts of company. They never wander alone till they have acquired ſufficient ſtrength to reſiſt the attacks of the wolf. Theſe animals, when they have young, form a kind of flocks, and it is upon this alone their ſafety depends. When attacked, the largeſt and ſtrongeſt front the enemy, and by preſſing all round againſt the weaker, force them into the centre. Domeſtic hogs are alſo obſerved to defend themſelves in a ſimilar manner. The wild boar is hunted with dogs, or killed by ſurpriſe during the night when the moon ſhines. As he flies ſlowly, leaves a ſtrong odour behind him, and defends himſelf againſt the dogs, and often wounds them dangerouſly, fine hunting dogs are unneceſſary, and would have their noſe ſpoiled, and acquire a habit of moving ſlowly, by hunting him. Maſtiffs, with very little training, are ſufficient. The oldeſt boars, which are known by the track of their feet, ſhould alone be hunted: a young boar of three years is difficult to be attacked, becauſe he runs very far without ſtopping; but the old boars do not run far, allow the dogs to come near, and often ſtop to repel them. During the day, the boar commonly keeps in his ſoil, which is the moſt ſequeſtered part of the woods, and comes out by night in queſt of food; and in ſummer, when the grain is ripe, it is eaſy to ſurpriſe him among the cultivated fields, which he frequents every night.

The boar lives to twenty-five or thirty years, if he eſcapes accidents. The time of going to rut is in December, and laſts about three weeks. They feed on all ſorts of fruits, and on the roots of many plants; the root of fern, in particular, ſeems a great favourite with them; and when they frequent places near the ſea-coaſt, they will deſcend to the ſhores, and demoliſh ſhell-fiſh. Their general places of reſt are among the thickeſt buſhes that can be found, and they are not eaſily put out of them, but will ſtand the bay a long time. In April and May they ſleep more ſoundly than at any other time of the year, and this is therefore the ſucceſsful time for taking them in the toils. When a boar is roufed out of the thicket, he always goes from it, if poſſible, the ſame way by which he came to it; and when he is once up, he will never ſtop till he comes to ſome place of greater ſecurity. If it happens that a *ſaunder* of them are found together, when any one breaks away, the reſt will follow the ſame way. When the boar is hunted in the wood where he was bred, he will ſcarce ever be brought to quit it; he will ſometimes make towards the ſides, to liſten to the noiſe of the dogs, but retires into the middle again, and uſually dies or eſcapes there. When it happens that a boar runs a-head, he will not be ſtopped or put out of his way by man or beaſt, ſo long as he has ſtrength left. He makes no doubles or croſſings, when chaſed; and when killed, makes no noiſe, if an old boar; but the ſows and pigs will ſqueak when wounded.

The ſeaſon for hunting the boar begins in September, and ends in December, when they go to rut. If it be a large boar, and one that has lain long at reſt, he muſt be hunted with a great number of dogs, and thoſe ſuch as will keep cloſe to him; and the huntſman, with his ſpear, ſhould always be riding in among them, and charging the boar as often as he can, to diſcourage him. Such a boar as this, with five or ſix couple of dogs, will run to the firſt convenient place of ſhelter, and there ſtand at bay, and make at them as they attempt to come up with him. There ought always to be relays alſo ſet for the beſt and ſtaunchеſt hounds in the kennel; for if they are of young eager dogs, they will be apt to ſeize him, and be killed or ſpoiled, before the reſt come up. The putting of collars with bells about the dogs' necks is a great ſecurity for them; for the boar will not ſo ſoon ſtrike at them when they have theſe, but will rather run before them. The huntſmen generally kill the boar with their ſwords or ſpears; but great caution is neceſſary in making the blows, for he is very apt to catch them upon his ſnout, or tuſk, and, if wounded and not killed, he will attack the huntſman in the moſt furious manner. The places in which the wound is to be given with the ſpear, are either between the eyes in the middle of the forehead, or in the ſhoulders; both theſe places make the wound mortal. When this creature makes at the hunter, his ſafety conſiſts merely in courage and addreſs; if he flies for it, he is ſurely overtaken and killed; if the boar comes ſtraight up, he is to be received at the point of the ſpear; but if he makes doubles and windings, he is to be watched very cautiouſly, for he will attempt getting hold of the ſpear in his mouth, and if he does ſo, nothing can ſave the huntſman but another perſon's attacking him behind. He will, on this, attack the ſecond perſon, and the firſt muſt then attack him again. Two people will thus have enough to do with him; and were it not for the forks of the boar-ſpears, that make it impoſſible to preſs forward upon them, the huntſman, who gives the creature his death's wound, would ſeldom eſcape falling a ſacrifice to his revenge for it.

The modern way of boar-hunting is generally to diſpatch the creature by all the huntſmen ſtriking him at once; but the ancient Roman way was for a perſon on foot, armed with a ſpear, to keep the creature at bay; and in this caſe the boar would run of himſelf upon the ſpear to come at the huntſman, and puſh forward till the ſpear pierced him through.

The hinder claws of a boar are called *guards*. In the corn he is ſaid to *feed;* in the meadows or fallow-fields, to *rout*, *worm*, or *fern*; and in a cloſe, to *graze*. The boar is farrowed with as many teeth as he will ever have; his teeth increaſing only in bigneſs, not in number. Among theſe there are four called tuſhes, or tuſks, the two biggeſt of which are of no uſe to him when he ſtrikes, ſerving only to whet the two loweſt, which are his moſt formidable weapons of defence. As the boar advances in age, he becomes leſs dangerous, on account of the growth of thoſe tuſks, which turn up, or take ſuch a curvature, as rather to impede than aſſiſt him in wounding his adverſary. The Ethiopian boar, or hog, is a ſtill more fierce and dangerous animal than the kind found in Europe. In habits and manners they are pretty much the ſame, although ſpecifically different; and, like the common boar, is capable of inflicting the moſt tremendous wounds with its tuſks.

The fleſh of the boar was eſteemed a delicacy among the ancient Romans; a boar ſerved up whole was a diſh of ſtate. The boar was ſometimes alſo the military enſign borne by the Roman armies, in lieu of the eagle. Certain writers of modern date ſpeak of the fleſh being unwholeſome, except to thoſe of athletic conſtitutions.

A remarkable circumſtance concerning the wild boar is related by Sonnini. In the year 1787, an animal of this kind, of a moſt extraordinary ſize, was killed in the neighbourhood of Cognac, in Angoumois, which had many times eſcaped from the hunters, had received many gun-ſhot wounds, and had coſt the lives of ſeveral dogs and men each time of attacking him. When this animal was at length ſlain, ſeveral bullets are ſaid to have been found be-

tween his ſkin and fleſh. Had not the above account been given by hunters of diſtinguiſhed order, and too well acquainted with theſe animals to have made any miſtake, it might have been imagined, that this formidable creature, which had long continued its ravages in the park of Cognac, belonged to a different ſpecies. It was of an enormous ſize, with a very long head, a very ſharp or pointed ſnout, and its mouth was armed with teeth of a very ſingular form. The hairs of the body were white; thoſe of the head yelloviſh; the neck marked with a black band in form of a cravat; and the ears large and ſtraight; and what appears ſurpriſing, conſidering its ſize, it was of uncommon ſwiftneſs. For a further hiſtory of this animal, ſee SCROFA.

BOAR, in the *Manege*. A horſe is ſaid to *boar* when he ſhoots out his noſe as high as his ears, and toſſes in the wind.

BOARD, a piece of timber ſawed thin, for the purpoſes of building. See TIMBER.

We ſay, a deal-board, an oak-board, &c. Boards thicker than ordinary are called *planks*. Boards formed ready for the coopers uſe are called *clap-boards*. We have alſo mill-board, and ſcale-board, ſhaved very thin, for caſes, band-boxes, &c. Deal-boards are generally imported into England ready ſawed, becauſe they are prepared cheaper abroad, by means of ſaw-mills. Clap-boards are imported from Sweden and Dantzick. Oak-boards chiefly from Sweden and Holland; ſome from Dantzick. Pipe-boards are brought from Dantzick. We alſo import white boards for ſhoe-makers; mill and ſcale boards, paſte-boards, &c. for divers artificers. Scale-board is a thinner ſort, uſed for the covers of primers, thin boxes, and the like. It is ſawed with mills, and imported from Hamburgh.

BOARD, *feather-edged*, *graining*, *log*, *paſt*, *ſound*, *trail*, *waſte*, *weather*. See the ſeveral adjectives.

BOARD, is alſo uſed for a kind of table or bench, whereon ſeveral artificers perform their work.

In this ſenſe, we ſay a work-board, a ſhop-board, a taylor's-board, &c.

BOARD, is alſo uſed for a flat machine, or frame, uſed in certain games, and the like.

In this ſenſe, we ſay a draught-board, a cheſs-board, a ſhovel-board, and the like.

BOARDS, in *Book-binding*. See BOOK-BINDING.

BOARD, *bureau*, is alſo uſed for an office where accounts are taken, payments ordered, and the like.

In this ſenſe, we ſay the board of works, board of ordnance, board of treaſury, and the like.

BOARD *of green cloth*. See GREEN-CLOTH.

BOARD *of Controul*, was firſt inſtituted in 1784, by ſtat. 24 Geo. III. ſeſſ. 2. c. 25. with a view of directing and aiding the Eaſt India company, in the executive government of India, and eſtabliſhing a power of controul in this kingdom. This board was further eſtabliſhed and regulated by the ſtat. 33 Geo. III. c. 52. the operation of which commenced in India on the 1ſt of February 1794. By the former act ſix perſons were to be nominated by the king, as commiſſioners for the affairs of India; but by the latter, the number, inſtead of being limited to ſix privy-counſellors, is indefinite, depending upon the king's pleaſure; of which number the two principal ſecretaries of ſtate, and the chancellor of the exchequer, are to be three; and his majeſty, if he pleaſes, may add to the liſt two commiſſioners, not of the privy-council; and the perſon firſt named in the king's commiſſion is to be preſident. The king may give 5000l. a year among ſuch of the commiſſioners as he pleaſes; which, together with the ſalary of the ſecretary and officers, and other expences of the board, are to be paid by the India company; the whole not to exceed 16,000l. per annum. The members of this board and their officers are ſworn to execute the ſeveral powers and truſts repoſed in them, without favour or affection, prejudice or malice. The office of a commiſſioner, or chief ſecretary, is not to be deemed a new office, to diſable them from ſitting in parliament; nor is the appointment of a commiſſioner, not having a ſalary, or of a chief ſecretary, to vacate a ſeat. Three commiſſioners muſt be preſent to form a board. The powers of the board are to ſuperintend, direct, and control all acts, operations, and concerns, which relate to the civil and military government and revenues of the Britiſh territorial poſſeſſions in India, ſubject to certain reſtrictions. They and their officers are to have acceſs to the papers and records of the company, and to be furniſhed with copies or extracts of ſuch of them as ſhall be required. They are alſo to be furniſhed with copies of all proceedings of general courts, and courts of directors, within eight days, and with copies of all diſpatches from abroad, relating to matters of government or revenue, immediately after their arrival. No orders on thoſe ſubjects are to be ſent by the company to India, until approved by the board; and when the commiſſioners vary or expunge any part of the diſpatches propoſed by the directors, they are to give their reaſons; and all diſpatches are to be returned to the court of directors in 14 days. The directors may ſtate their objections to any alterations, and the commiſſioners are to re-conſider them; and if they interfere with what the directors deem matter of commerce, the directors may apply to the king in council to determine betwixt them. But the board is reſtricted from the appointment of any of the company's ſervants. If the directors, on being called upon to propoſe diſpatches on any ſubject relating to government or revenue, ſhall fail to do ſo within 14 days, the board may originate their own diſpatches on that ſubject. The board is not to authoriſe any increaſe of ſalaries, or any allowance or gratuity to be granted to perſons employed in the company's ſervice, except the ſame ſhall be firſt propoſed by the company; and their intention and reaſons for ſuch grant are to be certified to both houſes of parliament, 30 days before the ſalary can commence. The directors are to appoint three of their members to be a committee of ſecrecy, through whom diſpatches, relating to government, war, peace, or treaties, may be ſent to or received from India. This committee, and their clerks, are to be ſworn to ſecrecy. Orders of directors, concerning the government or revenues of India, once approved by the board, are not ſubject to revocation by the general court of proprietors. For the further proviſions of the acts, appointing the board of controul, ſee *Eaſt India* COMPANY.

BOARD *of Ordnance*. See ORDNANCE.

BOARD *of trade and plantation*, was eſtabliſhed by king William, in the year 1696. Commercial matters had before this time been generally referred to a fluctuating committee of the privy-council: the obvious inconveniences attending this mode of management, induced king Charles II. to erect a ſpecial council of trade in the year 1668, which was ſoon after laid aſide: it was renewed again in 1672, but ſoon diſcontinued, and the former method of reference to committees of the privy-council revived. In 1696, a regular and permanent board was eſtabliſhed, for ſettling all diſputes and regulations relating to commerce and colonies. This board, beſide ſuch of our miniſters of ſtate, who only attended on extraordinary occaſions, conſiſted of a firſt lord commiſſioner, and of ſeven other commiſſioners, with an annual ſalary of one thouſand pounds each. This board was aboliſhed in 1780.

BOARD *of trade, bureau de commerce*, an office in the French polity,

polity, eſtabliſhed in 1723, compoſed of eight perſons of experience in commerce and navigation, where all papers and propoſals relating to the improvement of trade are examined, and all difficulties which occur in affairs of navigation and commerce, either within or without the realm, are diſcuſſed.

Board-*wages*, denotes a certain annual ſum allowed to houſhold ſervants for maintenance. Board-wages, granted to the menial officers and ſervants of the crown, commenced in 1629, when the neceſſities of king Charles obliged him to retrench the expence of his houſhold, by aboliſhing the greateſt part of the daily tables in his palace, which were eighty in number, and ſubſtituting this annual allowance in their room.

Board, or Aboard, in the *Sea Language*, is uſed in ſpeaking of things within a ſhip, or other veſſel.

Hence, to go *aboard* ſignifies to go into the ſhip; to heave *over board*, is to throw a thing out of the veſſel into the ſea; to ſlip by the *board*, is to ſlip down by the ſhip's ſide; to fall *a-board* of, is to ſtrike or encounter another ſhip, when one or both are in motion; to keep the land *a-board*, or to keep hold of the land, is to ſteer near to, or in ſight of the land; *board* and *board*, is when two ſhips come ſo near as to touch one another, or when they lie ſide by ſide. *Weather-board*, is that ſide of a ſhip which is to windward. To *board a ſhip*, is to enter an enemy's ſhip in an engagement. See Boarding. *infra*.

Board denotes the diſtance run by a ſhip at one tack; and hence to *make a board*, or, as it is otherwiſe expreſſed, to *board it up* to a place, is to turn to windward; and to beat ſometimes upon one tack, and ſometimes upon another; in which it is to be noted, that the farther you ſtand off to one point of the compaſs, the better board you will make; and that it is better making *long boards* than ſhort ones, if you have ſea-room. A *long board* is when you ſtand a great way off before you tack or turn; a *ſhort board* is when you ſtand off a little; a *good board* is when a ſhip does not go to leeward of her courſe, or advances much at one tack, and ſails upon a ſtraight line. To leave a land on *back-board*, is to leave it a ſtern, or behind; the *back-board* being that which, in boats or ſhips, we lean our backs againſt. *A-board* main-tack, the order to draw the main-tack; i. e. the lower corner of the main-ſail, down to the cheſs-tree. See Cheſs-*tree*.

Board-*Lar*, and *Starboard*. See Larboard, and Starboard.

BOARDED *Floor*. See Floor.

BOARDING, in *Naval Tactics*, denotes the art of approaching the ſhip of an enemy ſo near as to admit of the graplings, which are fixed on the lower yard-arms, at the forecaſtle, gang-ways, &c. being thrown into it, for the purpoſe of ſecuring the veſſels together, and of entering her decks with a detachment of armed men. The method of conducting or of avoiding this kind of attack depends upon the relative ſituation of the contending ſhips; and varies, as it is to be performed to windward, to leeward, with the wind at large, or when the ſhip propoſed to be boarded is at anchor.

In the firſt caſe, when the enemy's ſhip keeps her wind under an eaſy ſail, and is overtaken in a chaſe by thoſe who intend to board her, the veſſel of the latter muſt get on the weather-quarter of the former, within half a piſtol ſhot. She ſhould then begin and continue a briſk action, ſo that the ſmoke of the cannon and muſquetry of both ſhips may conceal her manœuvres; and, under the cover of this cloud, ſhe ſhould increaſe her ſail, if ſhe has not way enough, in order to augment her velocity and the rapidity of her movements, that ſhe may more readily lay on board the enemy, on the weather-ſide, either exactly abreaſt or a little abaft. This may be eaſily done, by edging down ſuddenly upon her, but avoiding being raked by the enemy's fire. By this manœuvre the grapnels will be on board of the adverſe ſhip, before or very ſoon after ſhe ſuſpects the deſign of the boarders. In this ſituation, the veſſel propoſed to be boarded can recur only to one precarious expedient, which, duly obſerved by the boarder, will be of little or no avail. For when ſhe braces ſharp a-back her head ſails, to cauſe the ſhip's falling off, and ſquares thoſe aft, to give her ſtern-way, the boarder, by performing briſkly the ſame manœuvre, will be as well ſituated for boarding as before; provided the boarding ſhip feels the impulſe of her ſails and helm, which ought to be put a-weather, and kept ſo till the ſhip's head-way ceaſes, when it is to be put a-lee, to aſſiſt her in falling off, in order to board the enemy to lee-ward; for the boarder ought to be on the quarter of the other, ſince at the moment the two ſhips were right before the wind, ſhe who was directly to windward, and wiſhed to board, had only to continue her movement of rotation, and render her velocity equal to that of her adverſary, by ſhortening ſail in order not to paſs her. If, therefore, the circular motion is kept up by the boarder, which at firſt cauſed him to fall off, and now brings him to the wind on the other tack, he will join the enemy to lee-ward; for it is evident that, if this motion of turning be more rapid than that of the ſhip which wiſhes to avoid boarding, the boarder will cloſe with her before ſhe can range to the wind on the other tack, ſince the boarder comes round with greater celerity. However, if the ſhip which fears boarding was preſſed thus cloſely, ſhe could make no other attempt than to throw once more all her ſails to the maſt, by bracing them only perpendicular to the keel to give her ſtern-way, and putting the helm a-weather, to keep her to the wind, as ſoon as her head-way ceaſes; obſerving that, as ſhe is to windward, ſhe may be thus driven on the boarder, who watches for her under her lee. But neceſſity obliges her to adopt this only expedient; becauſe, if ſhe could go a-ſtern with ſufficient velocity, ſhe might let the boarder paſs a-head, veer under his ſtern, and rake him, if he does not anticipate this manœuvre, and as quickly manœuvre in the ſame manner; the great velocity with which he comes to the wind, and goes a-head, his ſails being ſtill full, reducing him to this ſtate, which may prevent his perſiſting in the deſign of boarding. Nevertheleſs the boarder may attain his purpoſe, if he throws all his ſails a-back at the ſame time as the ſhip to windward; becauſe, the attacked ſhip dropping to leeward, and having ſtern-way firſt, approaches the boarder, who has preſerved his poſition on the quarter, and longer kept his luff, by having gone a-ſtern ſomewhat later than the weather ſhip. It ſhould alſo be obſerved, that when the two ſhips are right before the wind, if the veſſel which fears boarding moves more quickly to the wind than the one which attacks, ſhe will avoid it, as the retreating ſhip will be cloſe to the wind before the other, and able to get a-head of her, by making all ſail to keep her wind, or to heave in ſtays, and get upon the other tack. This laſt movement, however, is diſadvantageous; becauſe it will preſent the ſtern to a ſhip, which will avail itſelf of that ſituation, and rake her, and this may be more deſtructive than a well oppoſed attack by boarding. After all, if the ſhip that is inclined to board ſails better than the other, ſhe will always have it in her power to execute her purpoſe, if ſhe is as well manœuvred as the ſhip which endeavours to eſcape.

In the ſecond caſe of boarding to leeward, when cloſe to the wind, the boarder ſhould arrive within piſtol ſhot, cloſe in

the wake, or, at moſt, to the weather-quarter of the ſhip againſt which the attack is meditated; taking care to continue ſteering, ſo as not to be raked by any of the guns that belong to the quarter on which he ſtands. In order to come up with his adverſary, he muſt edge away a little, and range round aft, ſo cloſe upon the enemy's lee-quarter, that his cat-head may almoſt touch her quarter-gallery. When the ſhip has ſhot ſufficiently a-head, and is parallel to that of the adverſary, the fore-caſtle being a-breaſt of the enemy's main-maſt, the mizen and mizen ſtay-ſail ſheets are to be well hauled aft, the helm put hard a-lee, and the head-ſheets let fly; then the ſhip, coming rapidly to the wind, ſhivers her ſails, and cloſes with the oppoſing veſſel ſide to ſide. In executing this manœuvre, which cannot fail to ſucceed with the advantage of ſailing, great attention is neceſſary; becauſe, if at this moment the weather-ſhip, which wiſhes to avoid being boarded, either ſets her courſes, or lays all thoſe flat a-back which ſhe had ſet, ſhe may chance to break the grapnels, if the ſails of the boarding veſſel have not been trimmed like thoſe of the other; for, by making more ſail, if the wind be a little freſh, ſhe will ſhoot a-head through the water, and drag the boarder with ſuch force as to break the chains or hawſers by which the two ſhips are confined together. By laying all flat to the maſt the boarded veſſel is ſtill more likely to ſucceed, ſince the ſails of one ſhip will be full, while thoſe of the other are a-back.

This mode of boarding may be avoided, if the boarder does not pay ſtrict attention to his own manœuvres, as well as to thoſe of his adverſary; and it may be more readily avoided, if the adverſary's veſſel braces her head-ſails ſharp a-back, ſetting only, if neceſſary, the fore-ſail, at the ſame inſtant laying to the maſt or ſhivering, according to the neceſſity for more or leſs ſtern-way, all thoſe which are abaft, and putting the helm hard a-lee. This is to be executed, when the boarder is about a ſhip's length a-ſtern of the other veſſel. The quickneſs of this evolution, and the rapid veering of the weather-ſhip, may bring the boarding veſſel, which is a little to leeward or a-ſtern of the other, into the moſt dangerous ſituation, if ſhe does not manœuvre in the ſame manner, and with equal celerity; as the boarder's ſails being full, keep up his velocity, and may, before he can veer, engage his bowſprit in the main ſhrouds of the enemy, who pays ſhort round on her head. Thoſe who wiſh to board a ſhip, and to engage the enemy's bowſprit in their main ſhrouds, need only to get a little to windward of her, and about one or two ſhip's lengths a-head, according to the eſtimated celerity of their movements; then brace ſharp a-back the head-ſails, ſhiver the after-ones, or lay them flat to the maſt, with the helm a-lee. This manœuvre, well performed, and covered by a briſk fire, will commonly ſucceed; but care muſt be taken not to come round too ſoon, but to range very cloſe to the adverſary; becauſe, if the boarding veſſel be not ſufficiently a-head of him, it might fail in boarding, by paying too ſhort round, and its bowſprit get foul of his fore-ſhrouds, which would be very diſadvantageous. The deſign will be fruſtrated, if the boarding ſhip, being too far a-head, paſſes under the bowſprit of the enemy, who will thus, however, be expoſed to be raked at his head, if he does not manœuvre in the ſame manner and equal quickneſs as the boarding veſſel, which has the great advantage of priority. In order to engage the bowſprit of the enemy's ſhip in the rigging of the boarding veſſel, this ſhould be ranged very cloſe to the other; becauſe, if this were attempted at only a ſhip's length large, and to windward of the enemy, he need merely, upon perceiving the deſign, to put the helm hard a-lee, and heave in ſtays. If this laſt method be properly executed, the two ſhips can only range very near each other, and exchange their broadſides, and the lee-ſhip will immediately gain the wind of her adverſary. Conſequently to execute this manœuvre well, the veſſels muſt be nearly yard-arm and yard-arm.

If the boarder be at a certain diſtance aft on the weather-quarter, the ſhip wiſhing to avoid boarding muſt heave in ſtays, as ſoon as the other veſſel is in the act of veering, in order to cloſe with her to leeward. By this manœuvre they will come head to head, ſo that they may reciprocally fire their broadſides, in paſſing on oppoſite directions, and the lee-ſhip will get to windward.

In the third caſe, when two ſhips engage with the wind large, the boarding veſſel ſhould keep as cloſe as poſſible on the lee-quarter of the ſhip ſhe means to attack by boarding, that ſhe may execute her purpoſe by coming rapidly to the wind, and being careful not to paſs a-head of her opponent. The weather-ſhip, in order to avoid being boarded, muſt act according to circumſtances, in the manner directed in the laſt caſe. A ſhip may be boarded on the weather-ſide, by conforming to the inſtructions relating to boarding to windward. When two veſſels are engaged with the wind right aft, the boarder ought to drop a-ſtern of the enemy, in order to run up cloſe along-ſide of him, if the boarder has the advantage of ſailing; for, as ſhe then advances towards her adverſary, the adverſary can only endeavour to range rapidly to the wind on the other tack, as ſoon as the bowſprit of the boarder is a-breaſt of her ſtern, and thus gain the wind, in order to be in a ſituation to extricate herſelf more eaſily by a good manœuvre. The boarding veſſel ſhould be allowed to come a-breaſt of the ſtern of her adverſary, before ſhe hauls her wind; becauſe, if this were done ſooner, the ſhip a-ſtern, at a ſmall diſtance, would board her perfectly well, even if ſhe ſailed with equal celerity, ſince the boarder would be to windward, would run large longer than the other, would range more ſlowly to the wind, and continue to ſtem a-head of the flying ſhip. This will appear more evident by conſidering, that the boarder coming from windward preſerves his velocity longer, trimming his ſails only as the ſhip comes to the wind, and cuts the courſe of his adverſary with a line leſs curved than that deſcribed by the retreating ſhip. If, by coming too ſoon or too faſt to the wind, the boarder choſe to abandon his deſign, he might do ſo by veering a few points on the other tack, and ſhortening ſail; ſo that the retreating ſhip will ſhew her ſtern, and the boarder can then rake her by paſſing under her ſtern.

In attacking a ſhip cloſely to leeward, the boarder ſhould keep away a little when abreaſt of her, and ſeem to yield under her fire. If the enemy's ſhip ſhould thus be induced to veer, in order to bring the boarder more under her guns, the latter ſhould heave rapidly to the wind, by putting the helm a-lee, trimming all ſharp abaft, and ſuppreſſing the effect of the head-ſails; which ſhould be done at the inſtant when the enemy is perceived to be bearing down. The two ſhips will, by the quickneſs of this manœuvre, and the priority of the movement thus gained on the enemy, ſoon cloſe, and, with proper attention, the enemy's bowſprit may be entangled in the fore or main rigging of the boarding veſſel, which would be a favourable circumſtance in the attempt to board. However, it may happen that no attempt can be made to board, if the weather-ſhip, inſtead of bearing away, plies more and more to windward: for this faint manœuvre may take the boarder too far off to leeward of the adverſary. If the boarder ſhould chance to be a ſhip's length to leeward, and about the ſame diſtance a-head of the enemy's veſſel, it may, under cover of a heavy fire, heave in ſtays; and thus come right athwart the enemy's hawſe, rake him fore and aft, and board him, his bowſprit being

right over the enemy's gang-way; nor can he poſſibly avoid a broadſide; for if he heave all a-back and make a-ſtern board, which is his only reſource, he may avoid being boarded, but his ſituation will be very perilous.

In the laſt caſe of boarding a ſhip, which is at anchor, riding head to wind, it muſt be executed under ſail; for if the boarder cannot approach the enemy except by towing a-head, he will never be able to board the latter againſt his will; becauſe he will be always able to annoy the boats which are laying out the tow-lines. It ſhould not therefore be attempted, unleſs the boarder be under way. In order to perform it with ſucceſs, the boarder muſt be ſufficiently to windward to approach the enemy by a little falling off, without expoſing his ſtern to the fire of the latter, which in this ſituation might be played on with great advantage. If the boarder, then, ſhould be thus to windward, ſo as to be able to approach the enemy at anchor, he ought to ſtop his head-way, by taking a-back his mizen top-ſail and fore ſtay-ſail; and when about a ſhip's length from the veſſel propoſed to be boarded, let go an anchor, and then work, ſo that, as ſoon as the mizen top-ſail is taken a-back, the mizen cloſe aft, the top ſails clued up, and the fore-topmaſt ſtay-ſail hauled down, he may come head to wind, and veer away cable, till, by falling off, he comes board and board with his opponent, who is ſtill riding at his moorings, and who at that inſtant ought to be alſo raked by the boarder. This is the only method of manœuvring to which the boarding ſhip can recur; becauſe, as ſoon as the anchor is gone, the ſhip acquires ſtern-way, and when the cable is checked, ſhe runs head to wind, in which ſhe is much aſſiſted by the mizen and mizen top-ſail, which impel her ſtern to leeward, till the wind is right in the direction of the keel; and, as the cable is veered away, till exactly along-ſide the ſhip at anchor, her own anchor being right a-head of the veſſel ſhe means to board, it follows that, as ſoon as the boarding ſhip comes head to wind, ſhe is in a proper ſituation to throw her grapnels, and ſend her crew on board of the other, if they are the ſtrongeſt.

The ſhip at anchor ſhould never wait for the enemy in that ſituation, which is always diſadvantageous, and as there is much greater probability of eſcape when under way. But if it be neceſſary for the enemy to continue at anchor, he ſhould take advantage of the boarder's ſhip letting go her anchor, to cut the cable by which he rides; and by this manœuvre fall athwart, rake the boarder, avoid being boarded, and bring up with the lee-anchor. If time allow, two ſprings ſhould be caſt out, one on each ſide of the cable by which the ſhip rides, if there have been no previous opportunity for laying out two anchors, and thus guard againſt ſurpriſe, in caſe the ſhip which attacks has it in her power to paſs on either ſide of the other; and when the ſide for which ſhe is determined is perceived, the aſſailed ſhould heave on the ſpring which is on the ſame ſide ſhe has let go her anchor, if ſhe be a-head, and on the oppoſite, if ſhe be a-ſtern, veering out at the ſame time the other ſpring and cable, till the aſſailant be brought right a-breaſt. Then he may be raked at pleaſure, as he has no way of eſcape. His only courſe to prevent danger would be having alſo a ſpring; and, under cover of a briſk fire, veering upon that ſpring and cable, to lay his enemy handſomely on board. But if this precaution ſhould have been neglected, he muſt cut his cable, and drop on board of the ſhip to leeward; who, on the other hand, has no mode of avoiding being boarded, but by cutting, to get under way, or to run on ſhore.

It is always eaſy to board a ſhip at anchor, when the wind will allow approaching to her under ſail; in which caſe it is moſt adviſeable to run her along-ſide, or to bring-to to windward of the ſhip intended to be attacked, keeping her exactly to leeward; then to drift on board of her, by trimming the ſails in ſuch a manner as to keep as nearly as poſſible the broadſide of the attacking veſſel oppoſite to that of the adverſe ſhip. In this ſituation the boarder ſhould annoy the enemy with his guns till he can cloſe with him; and by conſtantly cannonading, his fire may not be ſo well ſerved as it otherwiſe might be. If, whilſt a veſſel is underway, it be propoſed to board a veſſel that is moored, an anchor ſhould be let go at the time of boarding; for if the attacked ſhip ſhould at this moment cut her cables to drive on ſhore, this would prevent the aſſailant and the aſſailed running a-ground together. Elements and Practice of Rigging and Seamanſhip, vol. ii. Bourdé's Manœuverer, or Skilful Seaman, &c. tranſlated from the French by Sauſeuil, 4to. 1788.

Boarding-*netting*, in *Ship Rigging*. See Netting.

BOARI, in *Geography*, a village of Africa, on the Gold Coaſt, ſituated between Sukonda and Sama, where the Dutch had formerly a ſmall factory, which was afterwards removed to Sama.

BOARIA Lappa, a name given by the ancient Romans to the fruit or rough balls of the common aparine or cleavers. Pliny calls this plant ſometimes *lappa*, ſometimes *lappago*; and the fruit by the names of *lappæ boariæ*, or *lappæ caninæ*, and ſometimes *canariæ*.

BOARINA, Boarola, in *Ornithology*, the name of a ſmall bird, deſcribed by Aldrovandus and others. This is the fig-eater of Albin and Latham; and *Motacilla Nævia* of Gmelin.

BOARULA, a ſpecies of Motacilla, called in England the grey wagtail. The colour of this bird is cinereous above, beneath yellow; tail-feathers dark, and pale at the edges. This is an European bird, about ſeven inches and a half in length, and, like the reſt of the wagtail tribe, frequents watery places. They are lively, active birds, perpetually flirt the tail, and ſeldom perch, but reſt upon the ground. They feed chiefly upon inſects. The neſt of this ſpecies is made on the ground, and is compoſed of dried fibres and moſs, lined with wool or feather, and uſually contains from ſix to eight eggs, which are of a dirty white, marked with yellow ſpots. They breed in the north of England, ſeldom approaching nearer to the ſouthward than Cumberland, till after the month of October. Linn. Donov. Brit. Birds, pl. 40, &c. *Le Bergette*, of Belon; and *la Bergoronette jaune*, of Briſon, is of this ſpecies.

Obſ. A variety of *Motacilla Boarula* inhabits Java. The colour is an olive brown, beneath yellow; lower part of the neck grey; firſt tail-feather entirely white; innerſide and tip of the ſecond and third white.

BOAS, in *Entomology*, a ſpecies of Scarabæus, that inhabits Sierra Leona. The thorax is retuſe, excavated, bidentated; horn of the head recurved and ſimple. Fabricius.

BOAT, a ſmall veſſel, generally without a deck, managed by ſails or oars, or drawn by horſes upon canals, rivers, or lakes, for the purpoſe of conveying paſſengers, goods, &c. from one place to another. The form, equipment, and names of boats are different according to the purpoſe for which they are intended, or to the country where they are built. Hence, boats are made ſlight or ſtrong, ſharp or flat-bottomed, open or decked, plain or ornamented, as they may be deſigned for ſwiftneſs or burden, for deep or ſhallow water, for ſailing in a harbour or at ſea, and for convenience or pleaſure.

As boats make always a neceſſary appendage to ſhips, it will,

will, therefore, be proper to give a brief account of thoſe belonging to the different claſſes of ſhipping.

Ships of war, particularly of the line, have uſually ſix boats, and the number decreaſes with the rate of the ſhip. The largeſt is called the *long-boat*, and ſometimes the *launch*; and its principal employment is to convey heavy ſtores to the ſhip. This boat is generally furniſhed with a maſt and ſails, and is occaſionally decked, armed, and equipped, for cruiſing ſhort diſtances againſt merchant ſhips of the enemy, or ſmugglers, or for impreſſing ſeamen, &c. The *barge* is the next leſs boat, and is particularly appropriated to carry the principal ſea officers, as the admiral, captain, &c. to or from the ſhip; and in conſequence of its ſlender conſtruction, combined with its ſmall breadth, is very unfit for ſea. This boat never rows leſs than ten oars. The *pinnace* is ſimilar to the barge, but ſmaller, never rows above eight oars, and is uſed by lieutenants in going aſhore, or coming off to the ſhip. *Cutters* are broader, deeper, and ſhorter than the former; they are employed on almoſt all occaſions, as for going aſhore, carrying ſtores, proviſions, boarding ſhips at ſea, &c. *Jolly-boat* is the ſmalleſt boat uſed in any of the ſhips in his majeſty's ſervice. In *Plate* VI. of *Ships* are perſpective views of a man of war's long boat, of a barge, and flat-bottomed boat.

In an Eaſt Indiaman there are four boats, the *long boat*, *cutter*, *jolly-boat*, and *yawl*. The firſt of theſe is for conveying ſtores and goods to and from the ſhip; the ſecond for going aſhore; and the others are employed occaſionally.

Ships in the Weſt India trade uſe boats in number and ſize according to the iſlands at which they intend to take in their cargo. Four boats generally belong to a ſhip in the Jamaica trade. The largeſt, called a *ſhallop*, will carry from eighteen to twenty hogſheads of ſugar. The next leſs in ſize is uſually called a *ten hogſhead boat*, from the number of hogſheads it carries; theſe two are left in the country. The next leſs boat, called a *double moſes*, or *pinnace*, carries two hogſheads a ſhort diſtance; and the ſmalleſt boat is called the *jolly boat*, and is generally ſuſpended from the taffrail.

Ships in the Windward Iſland trade, loading at Barbadoes, Martinico, Dominica, &c. generally uſe a flat launch with ſkeeds, each about thirty-ſix feet long, one end being upon the boat's ſtern, and the other upon the beach, upon which the ſugar hogſheads are rolled from the beach into the launch. At St. Vincent's, Grenada, and Tobago, a one hogſhead moſes is uſed. At Trinidad a launch as flat as can be built is uſed. At Demerara, Berbice, and Surinam, they generally uſe ſailing craft that will carry from twelve to twenty hogſheads.

Ships employed in the whale-fiſhery have ſix or more boats. Theſe are very narrow in reſpect to their length, for the purpoſe of pulling faſt; they are ſtrong built, and ſharp at both ends.

Smaller veſſels of one hundred tons and under, have in general one boat.

Bachot, a fiſhing boat on the rivers in France; it is provided with a maſt, oars, fiſhing lines, a ſtaff, a pole to faſten their boat on the river when they are fiſhing, &c.

Balza, or *balſa*, a boat, or rather raft, compoſed of five, ſeven, or nine logs or trunks of trees, uſed in South America. This boat is ſo called from balza or balſa, the name of the wood of which it is conſtructed, but which is called puero by the Darien Indians. The balza is a whitiſh ſpungy wood, and ſo very light that a boy can eaſily carry a log four yards long and a foot in diameter. The following account of this boat is extracted from the Relacion Hiſtorica del Viage a la America Meridional, necho de Orden, de S. Mag, &c. Impreſſa de Orden de Rey en Madrid, 1748.

The balzas are not only adapted to this river (Guayaquil), but venture to ſea, and carry on the trade as far as Payta. Their dimenſions are proportionate to their uſe, or the voyage for which they are intended; ſome being only for fiſhing, others for the river trade, bringing fruits, and all ſorts of merchandize from Bodega to Guayaquil, and from thence exporting them to Puna, Salto de Tumbez, and Payta; others are yet more commodiouſly contrived for carrying families, with all their furniture and neceſſaries, to their plantations or country houſes. The puero trees, of which they are built, are twelve or thirteen toiſes long, reckoning five feet to the toiſe, and two feet, or two and a half diameter; ſo that the whole breadth of nine logs, of which ſome of them conſiſt, is between twenty and twenty-four feet; and thoſe of ſeven or fewer logs are proportionate.

Theſe logs are faſtened to each other only by the bejucos or withies, with which the croſs logs are alſo laſhed to them, yet ſo ſecurely as never to give way, if not worn out by long uſe, though in their voyage to the coaſt of Tumbez and Payta the ſea runs very high; but the negroes neglecting to examine if the bejucos are not too much worn to ſuſtain another voyage, before they put to ſea, it too often happens that the laſhing breaks, the logs ſeparate, and both cargo and paſſengers periſh: indeed the Indians, being more active, get upon a log and ſafely work it to the neareſt harbour. One of theſe melancholy inſtances happened while we were in the juriſdiction of Quito, and are wholly to be imputed to the ſordid negligence of the Indians, who ſeem to have no ſenſibility of danger.

The thickeſt log of the balza is placed ſo as to reach farther than the others; at the ſtern, another log is laſhed to this, on each ſide, and others to theſe, till the intended number be completed, which is always odd; the large one in the middle being, as it were, the ſtay and foundation of the others. The larger ſort of theſe veſſels uſually carry about twenty-five tons, without damaging the cargo in conſequence of its being too near the water's edge, for the ſea never breaks over them, nor does the water ſwell between the logs, or ever riſe above them, becauſe the whole body of the vehicle accommodates itſelf to the motion of the water in all weathers.

Theſe rafts work and ply to windward like a keeled veſſel, and keep their courſe before the wind almoſt as exactly, which is the effect of another contrivance beſides the rudder; ſome large planks, three or four yards long, and half a yard broad, called guares, are ſet up vertically at the ſtern, and alſo forward between the main logs. By puſhing ſome of theſe under the water, and taking others a little up, the float fails large, bears up, tacks, or lies to, according as the machine is worked; an invention which has hitherto eſcaped the acuteneſs of the moſt ingenious Europeans; and though the Indians have indeed contrived the inſtrument, yet they are utter ſtrangers to the principles of mechanics, and the cauſes of its operations.

Had it been known before in Europe, the loſs of many lives in ſhipwreck might have been prevented, as appears by the following, among many other inſtances: in the year 1730, the Genoueſa ſhip of war, being loſt in the Vivora, the mariners made a jangada, or raft, to ſave their lives, but miſcarried by committing themſelves to the winds and currents, without any ſteerage; and the frequency of ſuch melancholy events induces me to give a minute explanation of this inſtrument, from a memoir of Don Jorge Juan, relating to it.

The direction in which a ſhip moves, when under ſail, is in a line perpendicular to the ſail, according to the demonſtrations of Renau, in his Theory of Manual Arts, cap. ii. art. 2. Bernouilli, cap. i. art. 4; and Pitot, ſect. ii. art. 13. The

re-action being equal, and oppoſite to the action, the oppoſition of the water to the motion of the veſſel will alſo be in a direction perpendicular to the ſail, from leeward to windward, and the impulſe of a longer body exceeding that of a ſmaller, ſuppoſing the motion of both to be equal, it follows that, upon one of the fore guares being thruſt under water, the veſſel will lie to, and bear up again, if it be taken out; and by a parity of reaſoning, an after one being thruſt under water will cauſe the ſhip to bear up and to lie to, on its being taken out. The way uſed by the Indians, in managing the balza, is to increaſe the number of guares to four, five, or ſix, to keep her to windward; for it is evident that the more there are under water the greater will be the lateral reſiſtance, which is thus increaſed by the lee-boards uſed in ſmaller veſſels, and for the ſame purpoſe. Theſe guares ſo effectually anſwer the end for which they are intended, that, when once the balza is underway, only one need be worked; and by thruſting it down or raiſing it up a foot or two, the veſſel is kept in a right courſe. *Plate* I. of *boats*, contains a perſpective view of a Balza.

Barge, the ſecond boat in a ſhip of war, as mentioned above; a veſſel employed in carrying merchandize in the river Thames, with one maſt. See alſo the article BARGE.

Bum boat, a ſmall boat employed in ſelling vegetables, &c. to veſſels lying at a diſtance from the ſhore.

Bunder boat, a boat at Bombay for carrying off pilots to a ſhip, and taking paſſengers aſhore.

Chalaud, a boat navigated on the river Loire in France; theſe boats are narrow and low, for the purpoſe of more eaſily paſſing through the locks of canals; they are principally uſed in carrying wines, and other productions, and merchandizes of the provinces, which lie near the Loire and Allier.

Coolie, a boat employed as a wherry at Bombay; it has one maſt, with a conſiderable rake forward, and ſails very faſt.

Felucca, is a ſtrong paſſage-boat uſed in the Mediterranean, having from 10 to 16 banks of oars. The natives of Barbary often employ boats of this ſort as cruiſers.

Ferry boats, are uſed for conveying paſſengers, goods, horſes, cattle, &c. acroſs a river or branch of the ſea; and, therefore, are of different dimenſions and forms of conſtruction accordingly.

Fiſhing boats, are of various kinds; thoſe employed in the ſalmon fiſhing, which is generally in rivers, or at the ſea ſhore, and commonly called *cobles*, are narrow at one end, and broad at the other, for the purpoſe of making up the net upon it, and from which the net is let into the river or ſea. Boats employed in the white fiſhery, that is, in taking ling, cod, haddocks, &c. are pretty large; ſome carrying ten tons and upwards, with two maſts, with ſquare or lug-ſails, and ſtrong built ſo as to endure a rough ſea; they are uſually and unequally ſharp at both ends, the ſharpeſt end being the bow. Decked veſſels called *ſmacks* having one maſt, or *luggers* with three maſts, are employed in this fiſhery.

Flat-bottomed boat, is ſo conſtructed for taking the beach eaſily, for the greater convenience of landing troops with their baggage, accoutrements, &c.

Flottes, boats of the maſter ferrymen at Paris. The ordnance of that city, made in the year 1672, enjoins them to keep their boats always provided with ſlaves and oars; and to have a ſufficient number of boats ready at the places and ſervices appointed by the provoſt of the merchants and echevins.

Foncets, boats which navigate on the river Seine; they are large, long, and ſtrong; they come from Roan, and from the river Oiſe, and are commonly uſed to carry great loads of wood for fuel, alſo goods, &c.

Gig, a ſmall light boat, uſually ſuſpended from the taffrail of a ſhip.

Holland, Boats of. In almoſt all the Seven United Provinces there are boats which ſerve for public carriages, which ſet out from every city at all hours of the day, and carry paſſengers very conveniently from one place to another, at a very ſmall expence. They are long, narrow, and covered, and can contain about ſixty perſons; each boat is drawn by one horſe, and has only two men to manage it, the one attends the helm, and the other takes care of the rope; the horſe is generally rode by a boy. In theſe boats there is a room which can eaſily contain ſix perſons; this room, which is called a *roef*, has glaſs windows, whereas the other openings in the boat are ſhut with oil cloth in bad weather. A paſſenger may take a place in this room, or the whole room. Thoſe boats which carry goods from Amſterdam to the Hague, and which leave Amſterdam at eight at night, arrive at the Hague next morning. In thoſe boats, however, deſigned for paſſengers only, a perſon is obliged to change boats ſeveral times. From Amſterdam to Haerlem he muſt change boats half way, becauſe the canal there is cut by a dyke. At Haerlem, the paſſengers muſt croſs the town to get to the boat that is to carry them to Leyden. At Leyden, he muſt again croſs the town to meet the boat in which he is to go to the Hague. All this can be performed in ten hours and a half; for, at eight o'clock preciſely, a boat ſets out from Amſterdam to Haerlem, where it arrives about half an hour after ten; at eleven a boat ſets out from Haerlem for Leyden, and arrives there at three in the morning; half an hour after three a boat ſets out from Leyden, and arrives at the Hague half an hour after ſix. There is ſuch good order kept, that at the ringing of a bell the boat muſt ſet out immediately, without waiting for any paſſenger. There are few countries where people can travel ſo conveniently as in Holland.

Ivahah, a boat or canoe of the Society Iſlands, of which captain Cooke gives the following deſcription. The ivahah is uſed for ſhort excurſions at ſea. Theſe boats are all of the ſame figure, but of different ſizes, and uſed for different purpoſes; their length is from ten to ſeventy-two feet, but the breadth is by no means in proportion; for thoſe of ten feet are about a foot wide, and thoſe of more than ſeventy are ſcarcely two feet. They have the fighting ivahah, the fiſhing ivahah, and the travelling ivahah, for ſome of theſe go from one iſland to another. The fighting ivahah is by far the longeſt; and the head and ſtern are conſiderably raiſed above the body, in a ſemicircular form, particularly the ſtern, which is ſometimes ſeventeen or eighteen feet high, though the boat itſelf is ſcarcely three feet. Theſe never go to ſea ſingly, but are faſtened together ſide by ſide at the diſtance of about three feet, by ſtrong poles of wood, which are laid acroſs them, and laſhed to the gunwales. Upon theſe in the fore part, a ſtage or platform is raiſed about ten or twelve feet high, and ſomewhat wider than the boats, which is ſupported by pillars about ſix feet long; upon this ſtage ſtand the fighting men, whoſe miſſile weapons are ſlings and ſpears; for, among other ſingularities in the manners of theſe people, their bows and arrows are uſed only for diverſion, as we throw quoits; below theſe ſtages ſit the rowers, who receive from them thoſe that are wounded, and furniſh freſh men to aſcend in their room. Some of theſe have a platform of bamboos, or other light wood, through their whole length, and conſiderably broader, by means of which they can carry a great number of men. The fiſhing ivahahs vary in length from about forty feet to the ſmalleſt ſize, which is about ten feet; all that are of the length of twenty-five feet and upwards, of whatever ſort, occaſionally carry ſail. The travelling ivahah is always double, and furniſhed with a ſmall neat houſe, about five or

ſix

ſix feet broad, and ſix or ſeven feet long, which is faſtened upon the fore part, for the convenience of the principal people, who ſit in them by day, and ſleep in them at night. The fiſhing ivahahs are ſometimes joined together, and have a houſe on board, but this is not common. Thoſe which are ſhorter than twenty-five feet, ſeldom or never carry ſail; and though the ſtern riſes about four or five feet, they have a flat head, and a board that projects forward about four feet. The ivahahs are the only boats uſed by the inhabitants of Otaheite.

Life-boat, a boat invented by Mr. Henry Greathead of South Shields, for the purpoſe of preſerving the lives of ſhipwrecked perſons. The following circumſtance gave riſe to this invention:

In September 1789, the ſhip Adventure of Newcaſtle, was ſtranded on the Herd ſand, on the ſouth ſide of Tynemouth haven, in the midſt of tremendous breakers; and all the crew dropped from the rigging one by one, in the preſence of thouſands of ſpectators, not one of whom could be prevailed upon, by any reward, to venture out to her aſſiſtance, in any boat or coble of the common conſtruction.

On this occaſion, the gentlemen of South Shields called a meeting of the inhabitants, at which a committee was appointed, and premiums were offered for plans of a boat which ſhould be the beſt calculated to brave the dangers of the ſea, particularly of broken water.

Many propoſals were offered; but the preference was unanimouſly given to that of Mr. Greathead, who was immediately directed to build a boat at the expence of the committee.

This boat went off on the 30th of January 1790; and ſo well has it anſwered, and indeed exceeded, every expectation, in the moſt tremendous broken ſea, that ſince that time, not fewer than two hundred lives have been ſaved at the entrance of the Tyne alone, which otherwiſe muſt have been loſt; and in no inſtance has it ever failed.

The principle of this boat appears to have been ſuggeſted to Mr. Greathead by the following ſimple fact.—Take a ſpheroid, and divide it into quarters; each quarter is elliptical, and nearly reſembles the half of a wooden bowl, having a curvature with projecting ends; this, thrown into the ſea or broken water, cannot be upſet, or lie with the bottom upwards.

The length of the boat is thirty feet; the breadth, ten feet; the depth, from the top of the gunwale to the lower part of the keel in midſhips, three feet three inches; from the gunwale to the platform (within), two feet four inches; from the top of the ſtems (both ends being ſimilar) to the horizontal line of the bottom of the keel, five feet nine inches. The keel is a plank of three inches thick, of a proportionate breadth in midſhips, narrowing gradually towards the ends, to the breadth of the ſtems at the bottom, and forming a great convexity downwards. The ſtems are ſegments of a circle, with conſiderable *rakes*. The bottom ſection, to the floor-heads, is a curve fore and aft, with the ſweep of the keel. The floor timber has a ſmall riſe curving from the keel to the floor-heads. A bilge plank is wrought in on each ſide, next the floor-heads, with a double rabbit or groove, of a ſimilar thickneſs with the keel; and, on the outſide of this, are fixed two bilge-trees, correſponding nearly with the level of the keel. The ends of the bottom ſection form that fine kind of entrance obſervable in the lower part of the bow of the fiſhing boat, called a *coble*, much uſed in the north. From this part to the top of the ſtem it is more elliptical, forming a conſiderable projection. The ſides, from the floor-heads to the top of the gunwale, flaunch off on each ſide, in proportion to above half the breadth of the floor. The breadth is continued far forwards towards the ends, leaving a ſufficient length of ſtraight ſide at the top. The ſheer is regular along the ſtraight ſide, and more elevated towards the ends. The gunwale fixed to the outſide is three inches thick. The ſides, from the underpart of the gunwale, along the whole length of the regular ſheer, extending twenty-one feet ſix inches, are caſed with layers of cork, to the depth of ſixteen inches downwards; and the thickneſs of this caſing of cork being four inches, it projects at the top a little without the gunwale. The cork, on the outſide, is ſecured with thin plates or ſlips of copper, and the boat is faſtened with copper nails. The thwarts, or ſeats, are five in number, *double-banked*; conſequently the boat may be rowed with ten oars. The thwarts are firmly ſtanchioned. The ſide oars are ſhort, with iron tholes and rope grommets, ſo that the rower can pull either way. The boat is ſteered with an oar at each end; and the ſteering oar is one third longer than the rowing oar. The platform placed at the bottom, within the boat, is horizontal, the length of the midſhips, and elevated at the ends, for the convenience of the ſteerſman, to give him a greater power with the oar. The internal part of the boat next the ſides, from the under part of the thwarts down to the platform, is caſed with cork; the whole quantity of which, affixed to the life-boat, is nearly ſeven hundred weight. The cork indiſputably contributes much to the buoyancy of the boat, is a good defence in going along-ſide a veſſel, and is of principal uſe in keeping the boat in an erect poſition in the ſea, or rather for giving her a very lively and quick diſpoſition to recover from any ſudden *cant* or *lurch*, which ſhe may receive from the ſtroke of a heavy wave. But, excluſively of the cork, the admirable conſtruction of this boat gives it a decided pre-eminence. The ends being ſimilar, the boat can be rowed either way; and this peculiarity of form alleviates her in riſing over the waves. The curvature of the keel and bottom facilitates her movement in turning, and contributes to the eaſe of the ſteerage, as a ſingle ſtroke of the ſteering oar has an immediate effect, the boat moving as it were upon a centre. The fine entrance below is of uſe in dividing the waves, when rowing againſt them; and, combined with the convexity of the bottom, and the elliptical form of the ſtem, admits her to riſe with wonderful buoyancy in a high ſea, and to launch forward with rapidity, without ſhipping any water, when a common boat would be in danger of being filled. The flaunching or ſpreading form of the boat, from her floor-heads to the gunwale, gives her a conſiderable bearing; and the continuation of the breadth, well forward, is a great ſupport to her in the ſea; and it has been found by experience, that boats of this conſtruction are the beſt ſea boats for rowing againſt turbulent waves. The internal ſhallowneſs of the boat from the gunwale down to the platform, the convexity of the form, and the bulk of cork within, leave a very diminiſhed ſpace for the water to occupy; ſo that the life-boat, when filled with water, contains a conſiderable leſs quantity than the common boat, and is in no danger either of ſinking or overturning. It may be preſumed by ſome, that in caſes of high wind, agitated ſea, and broken waves, a boat of ſuch a bulk could not prevail againſt them by the force of oars; but the life-boat, from her peculiar form, may be rowed a-head, when the attempt in other boats would fail. Boats of the common form, adapted for ſpeed, are of courſe put in motion with a ſmall power; but, for want of buoyancy and bearing, are over-run by the waves, and ſunk, when impelled againſt them; and boats conſtructed for burthen meet with too much reſiſtance from the wind and ſea, when oppoſed

to

to them, and cannot in ſuch caſes be rowed from the ſhore to a ſhip in diſtreſs.

Mr. Greathead gives the following inſtructions for the management of the life-boat.

The boats, in general, of this deſcription are painted white on the outſide; this colour more immediately engaging the eye of the ſpectator when riſing from the hollow of the ſea, than any other. The bottom of the boat is at firſt varnished (which will take paint afterwards) for the more minute inſpection of purchaſers. The oars ſhe is equipped with are made of fir, of the beſt quality; having found by experience, that a rove aſh oar, that will dreſs clean and light, is too pliant among the breakers; and when made ſtrong and heavy, from rowing double-banked, the purchaſe being ſhort, ſooner exhauſts the rower, which makes the fir oar, when made ſtiff, more preferable.

In the management of the boat ſhe requires twelve men to work her; that is, five men on each ſide rowing double-banked, with an oar ſlung over an iron thole, with a grommet (as provided), ſo as to enable the rower to pull either way, and one man at each end to ſteer her, and to be ready at the oppoſite end to take the ſteer-oar, when wanted. As, from the conſtruction of the boat, ſhe is always in a poſition to be rowed either way, without turning the boat; when manned, the perſon who ſteers her ſhould be well acquainted with the courſe of the tides, in order to take every poſſible advantage: the beſt method, if the direction will admit of it, is to head the ſea. The ſteerſman ſhould keep his eye fixed upon the wave or breaker, and encourage the rowers to give way, as the boat riſes to it; being then aided by the force of the oars, ſhe launches over it with vaſt rapidity, without ſhipping any water. It is neceſſary to obſerve, that there is often a ſtrong reflux of ſea occaſioned by the ſtranded wrecks, which requires both diſpatch and care in the people employed, that the boat be not damaged. When the wreck is reached, if the wind blows to the land, the boat will come in ſhore without any other effort than ſteering.

The following additional obſervations and inſtructions are given by Mr. Hinderwell of Scarborough.

The life-boat at Scarborough is under the direction of a committee. Twenty-four fiſhermen, compoſing two crews, are alternately employed to navigate her. A reward, in caſes of ſhipwreck, is paid by the committee to each man actually engaged in the aſſiſtance; and it is expected the veſſel receiving aſſiſtance ſhould contribute to defray this expence. None have hitherto refuſed.

It is of importance that the command of the boat ſhould be entruſted to ſome ſteady experienced perſon, who is acquainted with the direction of the tides or currents, as much ſkill may be required in riſing them to the moſt advantage, in going to a ſhip in diſtreſs. It ſhould alſo be recommended, to keep the head of the boat to the ſea, as much as circumſtances will admit; and to give her an accelerated velocity to meet the wave, much exertion is neceſſary in approaching a wreck, on account of the ſtrong reflux of the waves, which is ſometimes attended with great danger. In a general way, it is ſafeſt to go on the lee quarter; but this depends on the poſition of the veſſel; and the maſter of the boat ſhould exercise his ſkill in placing her in the moſt convenient ſituation. The boatmen ſhould practiſe themſelves in the uſe of the boat, that they may be the better acquainted with her movements; and they ſhould at all times be ſtrictly obedient to the directions of the perſon who is appointed to the command.

Plate II. of *Boats* contains a perſpective view of the life-boat riſing over a heavy ſurge, and going out to the aſſiſtance of a ſhip, which appears in the horizon in diſtreſs. In the life-boat are ten rowers pulling to get to the ſhip. At the lower end of the boat, a man is ſteering her with a long oar towards the ſhip; and another perſon is ſtationed with an oar at the higher end, to ſteer the boat on her return; both ends of the boat being formed alike, in order to uſe either at pleaſure in going to or coming from the ſhip. The ſheer, or curve of the boat, riſing conſiderably from the middle to the ſtems, or ends, is clearly diſtinguiſhed; alſo the coating of cork, ſecured by ſlips of copper along the outſide of the boat, near the part where the rowers are ſeated.

As every thing relating to this important invention muſt be intereſting to the public, it is, therefore, preſumed the following additional information will not be unacceptable, eſpecially as it contains the ſtrongeſt evidence of the great utility of this boat.

The life-boat having been ſubmitted to a teſt of twelve years' experience, during which period Mr. Greathead ſacrificed a very conſiderable portion of his time in furniſhing plans, and otherwiſe rendering the invention as extenſively uſeful as he could; on the 25th of February 1802, he preſented a petition to the houſe of commons, the prayer of which was as follows:

"Your petitioner having been inſtrumental in ſaving the lives of ſo many perſons; the utility of the boat being now eſtabliſhed; and your petitioner having derived little or no pecuniary advantage whatever from the invention, his models having been made public; humbly hopes, that this honourable houſe will take his caſe into their conſideration, and grant your petitioner ſuch reward as to this honourable houſe ſhall ſeem meet, &c."

The petition, having been recommended by his majeſty, was referred to the conſideration of a committee; from whoſe report the following is a brief abſtract.

"It appeared to your committee to be neceſſary to direct their inquiries particularly to the three following ſubjects.

"1ſt. The utility of the life-boat.

"2dly. The originality of the invention claimed by Mr. Greathead.

"3dly. Whether he had received any, and what remuneration.

"And in order to aſcertain theſe facts, your committee proceeded to examine,

"Ralph Hillery, a ſeaman, who ſtated, that he had been forty-five years at ſea, in the Greenland and coal trade, and has reſided always at Shields. About three years ago, he was in the Northumberland life-boat, which was preſented to North Shields by the duke of Northumberland, the firſt time ſhe went off, which was to the relief of the ſloop Edinburgh. This veſſel was ſeen to go upon the Herd ſands, about a mile and a half from ſhore; ſhe was brought to an anchor before the life-boat got to her, and ſhe continued ſtriking the ground ſo heavily, that ſhe would not have held together ten minutes longer, had they not got to her; they made her cut her cable, and then took ſeven men out of her, and brought them on ſhore. The ſea at that time was monſtrouſly high, ſo high that no other boat whatever could have lived in it.

"He was then aſked, whether he had been out in the life-boat on any other occaſion? to which he replied, that he had been five times out in her to the relief of different ſhips; from one ſhip they ſaved fifteen men; and in every inſtance when he, the witneſs, was in the boat, they ſaved the whole of the crews of the wrecked ſhips. Beſides the times he has been himſelf in the boat, he has ſeen her go off ſcores of times, and never ſaw her fail in bringing off ſuch of the crews as ſtayed by the ſhips. But many times part of the crews of the veſſels wrecked have taken to their own boats,

and have been drowned by the boats' upſetting; whilſt the remainder of the crews that continued on board have been ſaved by the life-boat. And the witneſs declared his conviction, that no other boat that ever he ſaw could have gone from the ſhore, and ſaved the crews, at the times the life-boat went.

"He ſtated, that in the event of the life-boat filling with water, ſhe would continue ſtill upright, and would not founder, as boats of a common conſtruction do. That about two months ago, he ſaw her come on ſhore with a ſhip's crew, beſides her own crew, ſo full of water, that it ran over each ſide; the ſea had broken ſeveral of her oars; and he believes, that no boat of any other conſtruction could have brought the crew on ſhore ſo filled with water.

"Captain William Carter, of the ſhip Providence, of Newcaſtle, ſtated, that he had reſided at South Shields twenty-five years, and been fifteen years in the coal and Baltic trades; that on the 28th of November 1797, he commanded the Velocity of 59 tons, riding at anchor on Tynemouth bar, amongſt the broken water, when the ſhip Planter was driven on ſhore by the violence of the gale, about one hundred yards from the Velocity; the life-boat came off and took fifteen perſons out of the Planter; and they had ſcarcely quitted the ſhip, when ſhe went to pieces; they muſt all otherwiſe have inevitably periſhed, as the wreck came on ſhore almoſt as ſoon as the life-boat. He conceived, that no boat of a common conſtruction could have given relief at that time. There were ſeveral other veſſels in the ſame ſituation with the Planter, namely, the Gateſhead, the Mary, and the Beaver, beſides a ſloop, whoſe name the witneſs does not know. The crew of the Gateſhead, being nine in number, took to their own boat, which ſunk, and ſeven of them were loſt; the other two ſaved themſelves by ropes thrown from the Mary. After the life-boat had landed the crew of the Planter, ſhe went off ſucceſſively to the other veſſels, and brought the whole of their crews ſafe on ſhore, together with the two perſons who had eſcaped from the boat of the Gateſhead. He has ſeen the life-boat go to the aſſiſtance of other veſſels at different times, and ſhe always ſucceeded in bringing the crews on ſhore.

"The witneſs has ſeveral times obſerved her to come on ſhore full of water, and always ſafe.

"Captain Gilfred Lawſon Reed, an elder brother of the Trinity-houſe, ſtated, that he had been bred to the ſea, and had been a member of the Trinity-houſe ſeventeen years. He had the management of the life-boat at Loweſtoffe, particularly laſt year, where he was requeſted by the ſubſcribers to make any improvement he thought neceſſary. She was built exactly upon Mr. Greathead's plan, correſponding with the model before the committee. Having fitted her for ſervice as far as he thought proper, he was requeſted by a number of the ſubſcribers to launch this life-boat; he took an opportunity, when the ſea fell very heavy on the beach, and launched her in the preſence of at leaſt two hundred ſpectators. Twenty-four men jumped into her; and when ſhe firſt mounted the waves, the ſpectators with one voice expreſſed their aſtoniſhment. He had given the men orders to croſs a ſhoal, that lay about a mile and a half from the ſhore, upon which the ſea broke very heavily; by ſome miſtake one of the plugs was left out of the bottom, and ſhe filled with water before ſhe got to the ſhoal, which obliged the men to return immediately, and ſhe brought the twenty-four men ſafe to ſhore, though when ſhe gained the ſhore, ſhe was full of water to the gun-wale and midſhips; yet by her ſheer one-third of her at each end was out of the water.

"Being aſked, wherein he conſidered the ſuperiority of the life-boat conſiſts over any other boat that has hitherto been invented? he anſwered, the curvature of the keel, and the flaunching ſides, which render it almoſt impoſſible to be upſet. When this boat was afloat and full of water, the men all went to one ſide of the boat, in order to try the poſſibility of upſetting her, which they could not effect.

"Mr. Thomas Henderwell, of Scarborough, ſhip-owner, ſtated, that the peculiar nature of the curvature of the keel of this boat is the foundation and baſis of its excellence. It regulates, in a great meaſure, the ſheer with elevation towards the ends. This conſtruction ſpreads and repels the water in every direction, and enables her to aſcend and deſcend with great facility over the breakers. The ends being reduced regularly from the centre to leſs than one-third proportion of the midſhips, both ends are lighter than the body ſection. By means of the curved keel, and the centre of gravity being placed in the centre of the boat, ſhe preſerves equilibrium in the midſt of the breakers. The internal ſhallowneſs of the boat in the body ſection, occaſioned by the convexity of the keel and the ſheer at the top, leaves ſo ſmall a ſpace for the water to occupy, that the boat, though filled with water, is in no danger of ſinking or upſetting. The buoyancy of the boat, when filled with water, is alſo aſſiſted by the cork being placed above the water-line.

"Mr. Samuel Plumb, of Lower Shadwell, deſcribed himſelf to have been bred to the ſea, and to have acted in the capacity of maſter of a ſhip from 1777 until within theſe eighteen months; that he had been chiefly employed in the coal and Baltic trades, and had reſided at Shields the whole of his life till within the laſt five years. He is acquainted with the Shields' life-boats; and from every information he had received, Mr. Greathead has been univerſally conſidered as the inventor of them.

"He went out in one of them to the relief of a ſhip, which was wrecked on the coaſt near the mouth of the Tyne. The firſt time they reached the wreck, the rope, which they threw from the wreck to the life-boat, broke, and the boat was drifted to the northward by the violence of the wind and ſtrong current of the tide; they then landed, and by two horſes dragged the boat along the ſand to the ſouthward, and then launched her again through the breakers to the veſſel. In the ſecond attempt they ſucceeded in bringing the crew on ſhore. The witneſs never ſaw any other boat in which he would have ventured to the relief of the crew, or which he thinks could have executed the purpoſe of ſaving them.

"Mr. William Maſterman, of South Shields, ſhip-owner, was one of the original committee that ordered the life-boat at South Shields in 1789. He corroborated the evidence given by captain William Carter; and ſtated, that from the ſituation of his reſidence, he has ſeen the performance of the life-boat more frequently than probably any other of the committee at South Shields, and has frequently ſeen and aſſiſted in the launching of the life-boat from the beach into the ſea during a ſtorm. That this is done with the aſſiſtance of low wheels, or what may be called rollers, upon which ſhe is dragged to the water's edge, and by means of hands proportioned to the weight of the boat, ſhe can be launched with as much eaſe as any other boat. He remembers the inſtance ſtated by Mr. Samuel Plumb, in which the life-boat, being drifted to the northward by a ſtrong tide, was landed, and again launched to the ſouthward, oppoſite to the wreck, and in the face of a very heavy ſea. When the Gateſhead, Planter, and other ſhips were wrecked, it was firſt diſcovered that the life-boat could act with perfect ſafety *athwart the ſea*; and ſince that time, the boat has been rowed *athwart ſea*, or otherwiſe, indifferently,

as the object to be relieved required it; and that ſhe goes with the ſame ſafety from one object to another, in a broken ſea, as an ordinary boat would paſs from one ſhip to another in a ſmooth ſea. He is confident, ſince the eſtabliſhment of the life-boat, that there have been at leaſt 300 perſons brought on ſhore from ſhips in diſtreſs, and wrecks off Shields, the greateſt part of whom muſt otherwiſe have periſhed. And the witneſs added, that it was his opinion, founded upon experience and the obſervations he had been enabled to make, that no ſea, however high, could overſet or ſink the life-boat."

The *originality* of Mr. Greathead's invention is there proved by proper certificates and atteſtations; and the remuneration that he had received, over and above a profit of from ten to fifteen pounds each, upon building a few boats, are ſtated to be,

From the Literary and Philoſophical Society of Newcaſtle, five guineas.

Royal Humane Society, a medallion.

Corporation of the Trinity Houſe, 100 guineas.

Society of Arts, a gold medallion and 50 guineas.

The vote of parliament, on the 3d of June, in conſequence of the foregoing report, was, "That a ſum not exceeding 1200 pounds be granted to his majeſty, to be paid to Henry Greathead, of South Shields, in the county of Durham, boat-builder, as a reward for his invention of the life-boat, whereby many lives have already been ſaved, and great ſecurity is afforded to ſeamen and property in caſes of ſhipwreck."

The ſubſcribers at Lloyd's, on the 20th of May, voted to Mr. Greathead the ſum of 100 guineas, "as an acknowledgment of his talents and exertions in inventing and building a life-boat," and 2000 pounds "for the purpoſe of encouraging the building of life-boats on different parts of the coaſts of theſe kingdoms."

At the beginning of 1804, Mr. Greathead received a very valuable diamond ring from the emperor of Ruſſia, whoſe munificence to ingenious men of all countries is well known.

The following extract from the Tyne Mercury of the 29th November 1803, is another proof of the great utility of the life-boat.

The Bee of Shields, John Houſton maſter, having put to ſea (21ſt Nov.) in an eaſterly wind, had not proceeded far, when it began to blow ſtrong from the ſouth-eaſt, which obliged him a few hours after to put back. In taking Tynemouth bar at the laſt quarter ebb, in a very heavy ſea, ſhe ſtruck the ground, and unſhipped her rudder. Being now completely unmanageable, ſhe drifted towards the north ſide of the bar, and at length drove on the Black Middens. They who have witneſſed the tremendous ſea which breaks on the north-eaſt part of this harbour, in a ſouth-eaſterly wind, may form a conception of the dreadful ſituation in which the crew of the veſſel were ſituated. In the midſt of rocks, where the ſea runs mountains high, ſo as frequently to obſcure the ſhip, and where any veſſel might be expected immediately to go to pieces; their only refuge from being ſwept into the gulf, was to climb up into the ſhrouds, which the captain, with ſix men and boys, being the whole crew, inſtantly effected. The dangerous ſituation in which they were placed, immediately attracted an immenſe number of ſpectators from both North and South Shields. The ſhores in every direction were lined with people, who expreſſed, by their anxious looks, the moſt ſympathetic apprehenſions for their ſafety. The making uſe of the life-boat was by moſt people thought impoſſible; and at all events, the attempt was attended with extreme danger, owing to the tremendous ſea, and the immenſe rocks which lay where the veſſel was ſtranded. So confident, however, was Mr. Greathead, the inventor, of the life-boat being able to live in any ſea, if properly navigated, that he, without heſitation, and with the greateſt alertneſs, volunteered his ſervices to bring off the men from the brig. This intrepid offer operated like electricity among the ſailors; and immediately the Northumberland life-boat was launched, and manned with Mr. Greathead and South Shields pilots. In the courſe of a few minutes they reached the veſſel, without much difficulty, and picked off the men from the ſhrouds ſhivering with cold, and almoſt periſhed by fatigue. One man, in making too much haſte to enter the boat, fell into the breakers, but was immediately recovered. When the whole crew was in the boat, they rowed towards the ſhore, and in leſs than an hour from the time the boat was launched, did they return in ſafety to South Shields, without a ſingle accident!

Upon the 1ſt of Auguſt 1777, ſome trials were made on a boat, or ſloop fit for inland navigation, coaſting voyages, and ſhort paſſages by ſea, which is not, like ordinary veſſels, liable to be overſet or ſunk by winds, waves, water-ſpouts, or too heavy a load, contrived and conſtructed by Monſieur Bernieres, director of the bridges and cauſeways in France, &c. at the gate of the invalids in Paris, in the preſence of the provoſt of the merchants, of the body of the town, and of a numerous concourſe of ſpectators of all conditions.

Theſe experiments were made in the way of compariſon with another common boat of the ſame place, and of equal ſize. Both boats had been built ten years, and their exterior forms appeared to be exactly ſimilar. The common boat contained only eight men, who rocked it and made it incline ſo much to one ſide, that it preſently filled with water, and ſunk; ſo that the men were obliged to ſave themſelves by ſwimming; a thing common in all veſſels of the ſame kind, either from the imprudence of thoſe who are in them, the ſtrength of the waves or wind, a violent or unexpected ſhock, their being overloaded, or overpowered any other way.

The ſame men who had juſt eſcaped the boat which ſunk, got into the boat of M. Bernieres; rocked and filled it, as they had done the other, with water. But, inſtead of ſinking to the bottom, though brim-full, it bore being rowed about the river, loaded as it was with men and water, without any danger to the people in it.

M. Bernieres carried the trial ſtill farther. He ordered a maſt to be erected in this ſame boat, when filled with water; and to the top of the maſt had a rope faſtened, and drawn till the end of the maſt touched the ſurface of the river, ſo that the boat was entirely on one ſide, a poſition into which neither winds nor waves could bring her; yet, as ſoon as the men, who had hauled her into this ſituation, let go the rope, the boat and maſt recovered themſelves perfectly in leſs than the quarter of a ſecond; a convincing proof that the boat could neither be ſunk nor overturned, and that it afforded the greateſt poſſible ſecurity in every way. Theſe experiments appeared to give the greater pleaſure to the public, as the advantages of the diſcovery are not only ſo ſenſible, but of the firſt importance to mankind.

Marnois boats, ſo called from being employed on the river Marne in France. They are flat, and carry wine, corn, timber, &c. from the province of Champaigne.

Norway boat, or yawl, is ſharp at both ends, and of various dimenſions. This boat, from its conſtruction, is admirably adapted for enduring a high ſea, and will often ven-

ture out to a great diſtance from the land, when ſome ſhips can ſcarcely carry any ſail.

Pahie, a boat of the Society iſlands; it is bow-ſided. and ſharp-bottomed. The pahie, according to captain Cook, is of different ſizes, from thirty to ſixty feet long, but like the ivahah, is very narrow. One that was meaſured was fifty-one feet long, and only one foot and an half wide at the top; in the wideſt part it was about three feet, and this is the general proportion. It does not, however, widen by a gradual ſwell, but the ſides being ſtraight and parallel for a little way below the gunwale, it ſwells abruptly, and draws to a ridge in the bottom; ſo that a tranſverſe ſection of it has ſomewhat the appearance of the mark upon cards, called a ſpade, the whole being much wider in proportion to its length. Theſe, like the largeſt ivahahs, are uſed for fighting, but principally for long voyages. The fighting pahie, which is the largeſt, is fitted with the ſtage or platform, which is proportionably larger than thoſe of the ivahah, as their form enables them to ſuſtain a much greater weight. Thoſe that are uſed for ſailing are double, and thoſe of the middle ſize are ſaid to be the beſt ſea-boats. They are ſometimes out a month together, going from iſland to iſland, and ſometimes, as is credibly reported, they are not unfrequently a fortnight, or twenty days at ſea, and could keep it longer, if they had more ſtowage for proviſions, and conveniences to hold freſh water.

When any of theſe boats carry ſail ſingle, they make uſe of a log of wood which is faſtened to the end of two poles that lie acroſs the veſſel, and project from ſix to ten feet, according to the ſize of the veſſel, beyond its ſide; ſomewhat like what is uſed by the flying proa of the Ladrone iſlands, and called, in the account of lord Anſon's voyage, an *Outrigger*; to which the ſhrouds are faſtened.

Some of them have one maſt, and others two; they are made of a ſingle ſtick; and when the length of the canoe is 30 feet, that of the maſt is ſomewhat leſs than 25 feet; it is fixed to the frame that is above the canoe, and receives a ſail of matting about one-third longer than itſelf; the ſail is pointed at the top, ſquare at the bottom, and curved at the ſide, ſomewhat reſembling what is called a ſhoulder of mutton ſail, and uſed for boats belonging to men of war; it is placed in a frame of wood, which ſurrounds it on every ſide, and has no contrivance either for reefing or furling, ſo that if either ſhould become neceſſary, it muſt be cut away, which, however, in theſe climates, can ſeldom happen. To the top of the maſt are faſtened ornaments of feathers, which are placed inclining obliquely forwards, the ſhape and poſition of which will be conceived at once from the figure in the *plate* of *Boats*.

The oars or paddles that are uſed with theſe boats, have a long handle and flat blade, not unlike a baker's peel. Of theſe, every perſon in the boat has one, except thoſe that ſit under the awning, and they puſh her forward with them at a good rate. Theſe boats, however, admit ſo much water at the ſeams, that one perſon at leaſt is continually employed in throwing it out. The only thing in which they excel is landing and putting off from the ſhore in a ſurf; by their great length, and high ſterns, they could land every day, where the Engliſh boats could ſcarcely land at all: they have alſo the ſame advantages in putting off by the height of the head.

The exact dimenſions of a pahie, given from a careful admeaſurement, will ſo very materially contribute to the elucidation of the deſcription ſubſequently given, as to the manner and particular form in which this claſs of canoes is built, that they might perhaps enable an European draughtſman, to conſtruct one ſo nearly reſembling them as to create ſome difficulty in pointing out the true from that which was fictitious:

	Feet.	Inches.
Extreme length from ſtem to ſtern, not reckoning the bending up of either -	51	0
Breadth in the clear of the top forward -	1	2
Breadth in the midſhips - - -	1	6
Breadth aft - - - -	1	2
—In the bilge forward - - -	2	8
—In the midſhips - - - -	2	11
—Aft - - - - -	2	9
Depth in the midſhips - - -	3	4
Height from the ground on which ſhe ſtood	3	6
Height of the head from the ground without, including that of the figure -	4	4
Height of the figure - - -	0	11
Height of the ſtern from the ground -	8	9
Height of the figure - - -	2	0

To illuſtrate the deſcription of the manner in which theſe veſſels are built, it will be neceſſary to refer to *fig.* 2. *Plate* II.

The firſt ſtage or keel under *a a*, is formed of a tree hollowed out like a trough, for which the longeſt trees are choſen that can be procured, ſo that there are never more than three in the whole length; the next ſtage under *b b*, is formed of ſtraight planks, about four feet long, fifteen inches broad, and two inches thick; the third ſtage under *c c*, is like the bottom, made of the trunks hollowed into its bilging form; the laſt is alſo cut out of trunks, ſo that the moulding is of one piece with the upright. To form theſe parts ſeparately without ſaw, plane, chiſſel, or any other iron tool, may well be thought no eaſy taſk; but the great difficulty is to join them together.

When all the parts are prepared, the keel is laid upon the blocks; and the planks, being ſupported by ſtanchions, are ſewed or clamped together with ſtrong thongs of plaiting. Theſe are paſſed ſeveral times through holes that are bored with a gauge or auger of bone, which performs its office with tolerable exactneſs; and the nicety with which this is done, may be inferred from their being ſufficiently water-tight for uſe without caulking. As the plaiting ſoon rots in the water, it is renewed, at leaſt, once a year, in order to which the veſſel is taken entirely to pieces; the head and ſtern are rude, with reſpect to the deſign, but very neatly finiſhed, and poliſhed to the higheſt degree.

Theſe pahies are kept with great care in a kind of houſe, built on purpoſe for their reception; the houſes are formed of poles ſet upright in the ground, the tops of which are drawn towards each other, and faſtened together with their ſtrongeſt cord, ſo as to form a kind of Gothic arch, which is completely thatched quite to the ground, being open only at the ends: they are ſometimes fifty or ſixty paces long.

Peter-boat, a boat employed in the river Thames in fiſhing. They in general ſail well, and are good ſea boats.

Pleaſure-boat, a veſſel employed by gentlemen in excurſions upon the water, for their amuſement. Their ſize and manner of equipment are very various, being from a few tons burthen, to upwards of two or three hundred tons, and having one or more maſts.

Poſt-boats, are boats eſtabliſhed on the river Loire in France, for the convenience of the public. They are long in reſpect to their breadth, and go very faſt. There are alſo ſome on the Rhone, which go from Lyons to Avignon in 24 hours.

Proa; ſee that article.

Punt, a ſort of flat-bottomed boat, whoſe floor reſembles the platform of a floating ſtage. It is uſed by the naval artificers,

artificers, either in caulking, breaming, or repairing the bottom of a ſhip.

Sampan, a Chineſe boat without a keel, appearing almoſt like a trough; they are made of different dimenſions, but are moſtly covered. There are paſſenger ſampans, to carry people backward and forward, between the town and ſhips. Theſe boats are as long as ſloops, but broader, almoſt like a baking trough, and have, at the end, one or more decks, made of bamboo-ſticks; the cover, or roof, is alſo made of bamboo-ſticks, arched over in the ſhape of a grater, and may be raiſed or lowered at pleaſure; the ſides are made of boards, with little holes, and ſhutters inſtead of windows; the boards are faſtened on both ſides to poſts, which have notches like ſteps on the inſide, that the roof may be let down, and reſt on them; on both ends of the deck are commonly two little doors, at leaſt there is one at the ſtern. A fine, white, ſmooth carpet, ſpread up as far as the boards, makes the floor, which, in the middle, conſiſts of looſe boards; but this carpet is only made uſe of to ſleep on. As theſe boats differ from thoſe of Europeans in ſhape, they are likewiſe rowed in a different manner; for two rowers, poſting themſelves at the back end of the ſampan, work it forwards very readily by the motion of two oars, and can almoſt turn the veſſel juſt as they pleaſe; the oars, which are covered with a little hollow quadrangular iron, are laid on iron ſwivels, which are faſtened in the ſide of the ſampan. At the iron the oars are pieced, which makes them look a little bent. In common, a rower ſits before with a ſhort oar, but this he is forced to lay aſide when he comes near the city, on account of the great throng of ſampans; and this inconvenience has confirmed the Chineſe in their old way of rowing.

Sampans of *burden* are the largeſt boats, by which all porcelain, ſilk, and other commodities, are conveyed from Canton to the European ſhips. But theſe boats do not ſerve for the above-mentioned purpoſes only, but are uſed, beſides, as houſes for whole families, which are born, marry, and die in them. They commonly have, beſides, hogs, ſome chickens and dogs, and ſome flower-pots, containing Guinea pepper, or ſome other plants, in theſe boats.

Duck ſampans, are boats in which they feed four or five hundred ducks. They have on both ſides a bridge, which may be let down. In the day-time the ducks feed in the river upon herbs and fiſh; at night their maſter calls them into his boat; they immediately obey him, and come on board as ſoon as he lets down his bridge.

Fiſhing ſampans, are the ſmalleſt of all, narrow, like ſome European fiſhing boats, and have either a very ſmall deck of ſtraw, or bamboo, or are even without that poor convenience. Bad as theſe boats are, yet parents, and their naked children, are ſeen to get their livelihood in them, both ſummer and winter, by fiſhing, and picking up what has been thrown overboard from other veſſels. For this purpoſe they tie ſeveral hooks to a cord, and throw them out in different places, almoſt in the ſame manner as fiſhermen lay their eel-hooks. They have better or worſe fortune, as it happens. There is nothing ſo filthy but what theſe people will uſe as food; and the hogs, which having died are thrown overboard, when they begin to putrefy, float in a few days, and often become the occaſion of quarrels, which end in battles. The reaſon why the Europeans ſink the hogs, which die on board their ſhips, is, that the inhabitants of this place may not fall upon them; for it is ſaid that the Chineſe, when they go on board any ſhips, will give pepper to the hogs, which they think is poiſon to them, that they may get them again if they ſhould die. It is certain, that numbers of hogs die in poſſeſſion of the Europeans whilſt they ſtay in China.

Mandarin's ſampans are greater or leſs red-painted boats, ornamented with dragons, and ſuch like figures, or with little flags.

The *Stage-boats*, called in French, bateaux coches, and more commonly coches-d'eau, water coaches, are large covered veſſels, which ſerve, particularly on the river Seine, for the convenience of travellers, and for carrying all ſorts of merchandizes. The names of them are the paſſage-boat, or water coach of Sens, of Auxerre, of Montereau, and of Fontainbleau, or Valvin.

Tilt-boat, one with a cover, to defend the paſſengers from rain, &c.

Tract-boat, a boat employed in a canal in conveying paſſengers, &c. from one place to another. This mode of travelling, though not expeditious, is indeed very pleaſant, and certainly much cheaper than by any land carriage. From Grangemouth to Port Dundas, a diſtance of nearly 30 miles, the fare is only one ſhilling, or eighteen pence.

Well-boat, a boat having a well in the bottom, to preſerve fiſh alive.

A *Wherry* is a light ſharp boat, uſed in a river or harbour, for carrying paſſengers from place to place.

The boats, or wherries, allowed to ply on the Thames about London, are either *ſkullers*, wrought by a ſingle perſon with two oars; or *oars*, wrought by two or more perſons, with each an oar.

The following are ſome of the terms uſed in the management of a boat.

Bale the boat, is to throw out the water which remains in her bottom, or the well-room. See BAILE.

Fend the boat, to ſave her from beating againſt the ſhip's ſides.

Man the boat, an order to thoſe appointed to manage her to go on board the boat immediately.

Moor the boat, the order to faſten a boat with two ropes, ſo as that the one ſhall counteract the other.

Trim the boat, the order to ſit in the boat in ſuch a manner as that ſhe ſhall float upright in the water, without leaning to either ſide.

Wind the boat, the order to bring her head the other way.

The *boat's gang*, includes thoſe who are employed for rowing in the boat; ſuch as the cockſwain and his gang, to whom the charge of the boat immediately belongs.

A *bold-boat* is that which will endure a rough ſea well.

To preſerve boats from foundering at ſea when ſhips founder. Take any maſt, yard, boom, &c. that may be found floating from the ſhip; the longer the better; make faſt to each end of the boom a rope about twice its length; and bend one end of another rope, about ten fathoms long, exactly in the middle of the ſpan, and the other end is to be made faſt to the forepart of the boat, ſo that ſhe may drive ſtern on to the ſea. When this misfortune happens far from land, and the ſtorm ceaſes, in moderate weather the driſt boom may be towed end on to the boat's ſtern, that they may either row or ſail towards land.

Mr. Hutchinſon, in his treatiſe on practical ſeamanſhip, gives an account of a boat being preſerved by this method, as follows. The Baſil, in her paſſage from the Weſt Indies, took up ten men in a ſmall boat, twelve feet long, which was preſerved from foundering after the veſſel had foundered, by having a rope faſt to a log of wood, as they called it, and tied to the boat's bow, which kept her to drive end on with the head to the waves, and broke their violence ſo much as to preſerve her from filling with water, when one half of them was obliged to lie down in the bottom of the boat, to prevent her being top-heavy. By particular inquiry of the

maſter

maſter and mate of the Baſil, Mr. Hutchinſon was informed, that thoſe people belonged to a ſchooner bound from Bermudas to the Weſt Indies; that it was after a hard gale of wind when they met with the boat, which had two oars for maſts, and two blankets ſet upon them for ſails, and was ſteering for Bermudas, when they were fortunately taken up; and that the log of wood, as it was called, they drove by, was their fore ſquare-ſail-yard, ſpanned with a rope to each yard-arm, and a rope about ten or twelve fathoms long bent to the middle of the ſpan, and made faſt to the boat's bow, to drive by. The mate of the ſchooner told the maſter of the Baſil, that they had been ſaved in this manner in a boat once before, by driving to leeward of a maſt, in a hurricane in the Weſt Indies.

In order to account for this wonderful effect of the drift-boom, in preventing the broken water from ſwamping the boat, it may be obſerved, ſays Mr. Hutchinſon, that waves never break till their tops are forced forwards by their great velocity beyond the perpendicular of their baſe; then that water falls down forward, and incloſes and compreſſes a quantity of air, which, by the power of its elaſticity, blows this fore-part of the waves to pieces, forwards and upwards, in an oblique direction, and makes it appear like froth. They then have no buoyant power to lift a boat; but when they are high, they fill and ſink her. And they break more in ſhoal water than in deep, in proportion as their bottoms or baſe are more obſtructed in their velocity by the ground than their tops; hence, in very ſhoal water, they are continually breaking, ſo that they make nothing but what is called broken water, by which ſhoals may be ſeen and known at a great diſtance in clear weather.

If we endeavour to account for the wonderful effect of ſo ſmall and ſimple a machine, to preſerve ſuch a ſmall boat, deeply laden as ſhe muſt be with ten men, from being filled with water in ſuch a ſtorm; in our opinion, it is owing to the boat driving end on by the drift boom, that keeps it always ſwimming on the ſurface, broadſide to the wind; and the waves that are running towards it, within the length of the drift boom, muſt certainly obſtruct the velocity of the upper part of theſe waves, ſo as to leſſen their increaſe in height, and prevent the top from running beyond the perpendicular of the baſe, or bottom of theſe waves, that occaſions their breaking, as has been deſcribed, but ſpend themſelves without breaking. Theſe reaſons, we hope, will be thought ſufficient to recommend this method to be tried and brought into practice on ſuch dreadful occaſions: and we cannot help thinking, that the ſame method ſhould be tried, when under the dreadful neceſſity of ſaving lives by boats landing on a lee ſhore in a ſtorm, where broken waves run high. The only difference we would recommend in the management, is to proceed with the boat's ſtern to the drift boom, and her head to the ſhore, to be ready to row and ſteer for the beſt apparent landing-place; and if it is a long flat ſhore, as ſoon as the boat ſtrikes the ground, cut or ſlip the drift boom rope, that it may not haul the boat off the ſhore again by the back ſweep of the waves.

Upon landing a boat in a ſurf. Before the boat comes near the ſhore, pour a little oil on the water, which will prevent its breaking, and greatly allay the ſwell, ſo that the boat may approach the ſhore without the dread of being ſwallowed up in the breakers.

M. Danzel has lately invented an hydraulic machine for making a ſhip or boat advance during a calm, and even againſt a current.

The mechaniſm of this machine is very ſimple; it conſiſts of a long pole, to the anterior extremity of which an apparatus, ſhaped like a drawer without back or front is attached in ſuch a manner, that when puſhed forwards it folds itſelf back under the pole, to which it (as it were) adheres, and preſents to the water the thin cutting ſurface of its three edges, viz. of the bottom and two ſides, which can neither oppoſe to the water a reſiſtance capable of preventing the pole from penetrating farther, or of making the ſhip recede. When the pole, which is puſhed forwards from the veſſel, has attained to its full reach, the drawer, as ſoon as the pole is pulled back, aſſumes a vertical poſition, and preſents to the water its whole cavity. By theſe means it embraces a column of water, which, without finding means to eſcape, preſſes on a ſurface much larger than that of a common oar, and keeps the drawer immoveable; ſo that thoſe who draw the pole towards them, inſtead of making the veſſel to recede, cauſe it to advance. This machine, which may be multiplied more conveniently than oars, has this viſible advantage over the latter, that it oppoſes to the water a reſiſtance infinitely ſuperior, while the paſſive re-action of this reſiſtance renders the labour of the mariners leſs laborious and more effectual.

De Chales propoſes the conſtruction of a boat, which, what burden ſoever it bear, ſhall not only move againſt the current, without either ſails or oars, but alſo advance ſo much the faſter, as the rapidity of the water is greater. Its make is the ſame with that of the others, excepting only a wheel added to its ſide, with a cord, which winds round a roller as faſt as the wheel turns.

Something of the like kind has alſo been ſince done by M. Pitot. Vide Mem. Acad. R. Scienc. an. 1729. p. 359, and p. 540.

M. de la Hire has given us an examination of the force neceſſary to move boats, both in ſtagnant and running water, either with ropes faſtened to them, or with oars, or with any other machine: wherein he ſhews, that the larger the ſurface of the oars plunged in the water, and the ſmaller that of the boat preſented to the water, is; and again, the longer that part of the oar between the hand and the places where the oar reſts on the boat, and the ſhorter that between this laſt point and the water; the freer will the boat move, and the greater effect will the oar have. See OAR.

Hence it is eaſy to calculate the force of any machine that ſhall be applied to rowing; v. gr. if we know the abſolute force of all the men who row, it muſt be changed into a relative force, according to the proportion of the two parts of the oar; i. e. if the part out of the veſſel be double the other, and all the men together can act with the force of 900 pounds, we compute firſt, that they will exert 300; which 300, multiplied by the ſurface which the veſſel preſents to the water, gives a ſolid water of a certain weight; which weight may be found, and of conſequence the velocity impreſſed on the veſſel by the oars. Or, the velocity of the oars may be found in the ſame manner, by multiplying the 300 pounds by the ſurface of all the parts of the oars plunged in the water. Nor would there be any difficulty in finding firſt the relative forces, then the abſolute ones; the velocities either of the oars, or of the veſſel, being given, or the proportion of the two parts of the oar.

Boats ſail more ſlowly and heavily over ſhallow than over deep waters. See an account of experiments for explaining this, in Dr. Franklin's Letter to St. John Pringle. Experiments, &c. 4to. 5th ed. p. 510.

BOATS, *Conſtruction of.* In order to illuſtrate this by an example, let it be required to lay down the ſeveral plans of a long boat, the extreme length being 31 feet, and breadth moulded 9 feet.

Draw

Draw the ſtraight line PO, *fig.* 1. *Plate* I. (*Ship-building*) equal to 31 feet, the extreme length of the boat, and alſo to repreſent the upper edge of the keel. Let ⊕ be the ſtation of the midſhip frame. From the points P, ⊕, and O, draw the lines PT, ⊕M, and OS, perpendicular to PO. Make ⊕M, ⊕N, equal to the upper and lower heights of breadth reſpectively at the main frame, PT, the height of breadth at the tranſom, and OS, the height at the ſtern. Deſcribe the curve TMS, to repreſent the ſheer, or extreme height of the ſide, which, in a ſhip, would be called either the upper height of breadth line, or the upper edge of the wale. Through the point N draw a curve parallel to TMS, to repreſent the breadth of the upper ſtrake of a boat, or lower edge of the wale, if in a ſhip. The dotted line TNS may alſo be drawn to repreſent the lower height of breadth.

Set off the rake of the poſt from P to *p*, and draw the line *pt*, to repreſent the aft ſide of the poſt; then *Tt* will repreſent the round up of the tranſom. Set off the breadth of the poſt from *p* to *r*, and from T to *s*, and draw the line *rs* to repreſent the foreſide of the poſt, which may either be a curve or a ſtraight line at pleaſure. Set up the height of the tuck from *p* to *k*. Let *lx* be the thickneſs of the tranſom, and draw the line Z *x* to repreſent the fore ſide of the tranſom.

There is given the point S the height of the ſheer on the foreſide of the ſtem; now that ſide of the ſtem is to be formed either by ſweeps, or ſome other contrivance. Set off the breadth of the ſtem, and form the aft ſide of it.

Set up the dead-riſing from ⊕ to *d*, and form the riſing line *ris*. Draw the line KL parallel to PO, to repreſent the lower edge of the keel, and another to repreſent the thickneſs of the plank or the rabbet. The rabbet on the poſt and ſtem may alſo be repreſented; and the ſtations of the timbers aſſigned, as ⊕, (1), 1, 2, 3, 4, 5, 6, 7, 8, 9; and ⊕, (A), A, B, C, D, E, F, G, H; and the ſheer plan will be completed.

The half-breadth plan is to be formed next; for this purpoſe the perpendiculars TP, 9, 8, &c. muſt be produced. Upon M⊕ produced ſet off the half-breadth from the line KL to R (*fig.* 2.); ſet off alſo the half-breadth at the tranſom from K to *b*, and deſcribe the extreme half-breadth line *b*RX, making the fore-part of the curve agreeable to the propoſed round of the harpin.

We may next proceed to form the timbers in the body plan. Let AB (*fig.* 3.) be the breadth moulded at ⊕. Erect the perpendicular CD in the middle of the line AB, draw the line *mn* diſtant therefrom the half thickneſs of the poſt, and *xy* the half thickneſs of the ſtem. Then take off the ſeveral portions of the perpendiculars ⊕, 1, 2, &c. intercepted between the upper edge of the keel and the riſing line in the ſheer plan, and ſet them up from C upon the line CD; through theſe points draw lines parallel to AC; take off alſo the ſeveral lower heights of the breadth at ⊕, 1, 2, &c. from the ſheer plan; and ſet them up from C upon the middle line in the body plan; and draw lines parallel to AC, through theſe points; then take off the ſeveral half-breadths correſponding to each from the floor plan; and ſet them off on their proper half-breadth lines, from the middle line in the body plan.

Conſtruct the midſhip frame according to the directions mentioned in that article, the form of which will in ſome meaſure determine the form of the reſt. For if a mould be made on any ſide of the middle line to fit the curve part of it, and the riſing line, or that marked *bend mould*, (*fig.* 4.) and laid in ſuch a manner that the lower part of it, which is ſtraight, may be upon the ſeveral riſing lines, and the upper part juſt touch the point of the half-breadth in the breadth line correſponding to that riſing upon which the mould is placed, a curve may then be drawn by the mould to the riſing line. In this manner we may proceed ſo far as the riſing line is parallel to the lower height of the breadth line. Then a hollow mould muſt be made, the upper end of which is left ſtraight, as that marked *hollow mould* (*fig.* 4.). This is applied in ſuch a manner, that ſome part of the hollow may touch the ſide of the keel, and the ſtraight part touch the back of the curve before deſcribed by the bend mould; and beginning abaft, the ſtraight part will always come lower on every timber, till we arrive at the midſhip timber, when it comes to the ſide of the keel. Having thus formed the timbers, as far as the whole mouldings will ſerve, the timbers abaft them are next formed. Their half-breadths are determined by the ſheer and floor plans, which are the only fixed points through which the curves of theſe timbers muſt paſs. Some form theſe after timbers before the whole is moulded, and then make the hollow mould, which will be ſtraighter than the hollow of either of theſe timbers. It is indifferent which are firſt formed, or what methods are uſed: for after the timbers are all formed, though every timber may appear very fair when conſidered by itſelf, it is uncertain what the form of the ſide will be. In order to find which, we muſt form ſeveral ribband and water lines; and if theſe do not make fair curves, they muſt be rectified, and the timbers formed from theſe ribband and water lines. In uſing the hollow mould, when it is applied to the curve of each timber, if the ſtraight part is produced to the middle line, we ſhall have as many points of interſection as there are timbers; and if the heights above the baſe be transferred to the correſponding timbers in the ſheer plan, a curve paſſing through theſe points is called a *riſing ſtrait*. This may be formed by fixing a point for the aftermoſt timber that is whole moulded, and transferring that height to the ſheer plan. The curve muſt paſs through this point, and fall in with the riſing line ſomewhere abaft dead-flat; and if the ſeveral heights of this line be transferred from the ſheer to the middle line in the body plan, theſe points will regulate what is called the *hauling down* of the hollow mould.

The timbers in the after-body being all formed, thoſe in the fore-body are formed in the ſame manner, by transferring the ſeveral heights of the riſing and breadth lines from the ſheer to the body plan; the half-breadths correſponding to each height muſt alſo be transferred from the floor to the body plan. The ſame hollow mould will ſerve both for the fore and after-body; and the level lines, by which the water lines to prove the after-body were formed, may be produced into the fore-body, and by theſe the water lines to prove the fore-body may be deſcribed.

Another method of proving the body is by ribband lines, which are formed by ſections of planes inclined to the ſheer plan, and interſecting the body plan diagonally, as before obſerved, of which there may be as many as may be judged neceſſary. In this, four ribband lines are laid down, marked *diag.* which are drawn in ſuch a manner as to be perpendicular to as many timbers as conveniently may be. After they are drawn in the body plan, the ſeveral portions of the diagonal, intercepted between the middle line and each timber, muſt be transferred to the floor plan. Thus, fix one foot of the compaſs in the point where the diagonal interſects the middle line in the body plan, extend the other foot to the point where the diagonal interſects the timber, for example, timber 9. Set off the ſame extent upon the perpendicular repreſenting the plane of timber 9, from the point where it interſects the line KL, on the floor plan; in like manner proceed with

with all the other timbers, both in the fore and after-body, and we ſhall have the points through which the curve muſt paſs. If this ſhould not prove a fair curve, it muſt be altered, obſerving to conform to the points, as nearly as the nature of the curve will admit; and, therefore, it may be carried within one point and without another, according as the timbers will allow. For after all the ribband lines are formed, the timbers muſt, if neceſſary, be altered by the ribband lines; this is only the reverſe of forming theſe lines; for taking the portions of the ſeveral perpendiculars intercepted between the line KL, and the curve of the ribband line in the floor plan, and ſetting them off upon the diagonal, from the point where it interſects the middle line, we ſhall have the points in the diagonal through which the curves of the timbers muſt paſs. Thus the diſtance between the line KL, and the ribband at timber 3, on the floor plan, when tranſferred to the body plan, will extend on the diagonal from the middle line to the point where the curve of timber 3 interſects that diagonal. The like may be ſaid of all the other timbers; and if ſeveral ribband lines be formed, they may be ſo contrived that their diagonals in the body plan ſhall be at ſuch diſtances, that a point for every timber being given in each diagonal, will be ſufficient to determine the form of all the timbers.

In ſtationing the timbers upon the keel, for a boat, there muſt be room for two futtocks in the ſpace before, or abaft ⊕; for which reaſon the diſtance between theſe two timbers will be as much more than that between the other, as the timber is broad. Here it is between ⊕ and (A), which contains the diſtances between ⊕ and (1), and the breadth of the timber beſides.

The timbers being now formed, and proved by ribband and water lines, proceed then to form the tranſom, faſhion-pieces, &c.; ſee theſe articles.

This method of whole moulding will not anſwer for the long timbers afore and abaft. They are generally canted in the ſame manner as thoſe for a ſhip. In order to render this method more complete, we ſhall here deſcribe the manner of moulding the timbers after they are laid down in the mould loft, by a *riſing ſquare*, *bend*, and *hollow mould*.

It was ſhewn before how to form the timbers by the bend and hollow moulds in the draught. The ſame method muſt be uſed in the loft; but the moulds muſt be made to their proper ſcantlings in real feet and inches. Now, when they are ſet, as before directed, for moulding each timber, let the middle line in the body plan be drawn acroſs the bend mould, and draw a line acroſs the hollow mould at the point where it touches the upper edge of the keel; and let them be marked with the proper name of the timber, as in *fig.* 4. The graduations of the bend mould will therefore be exactly the ſame as the narrowing of the breadth. Thus, the diſtance between ⊕ and 7 on the bend mould is equal to the difference between the half breadth of timber 7 and that of ⊕. The height of the head of each timber is likewiſe marked on the bend mould, and alſo the floor and breadth firmarks. The floor firmark is in that point where a ſtraight edged batten touches the back of the bend mould, the batten being ſo placed as to touch the lower edge of the keel at the ſame time. The ſeveral riſings of the floor, and heights of the cutting-down line are marked on the riſing ſquare; and the half-breadth of the keel ſet off from the ſide of it.

The moulds being thus prepared, we ſhall apply them to mould timber 7. The timber being firſt properly ſided to its breadth, lay the bend mould upon it, ſo as may beſt anſwer the round according to the grain of the wood; then lay the riſing ſquare to the bottom of the bend mould, ſo that the line drawn acroſs the bend mould at timber 7 may coincide with the line repreſenting the middle of the keel upon the riſing ſquare; and draw a line upon the timber by the ſide of the ſquare; or let the line be ſcored or cut by a tool made for that purpoſe, called a *raſeing knife;* this line ſo raſed will be the ſide of the keel. Then the ſquare muſt be moved till the ſide of it comes to 7 on the bend mould, and another line muſt be raſed in by the ſide of it, to repreſent the middle of the keel. The other ſide of the keel muſt likewiſe be raſed after the ſame manner, and the point 7 on the riſing ſquare be worked on each ſide of the keel, and a line raſed acroſs at theſe points to repreſent the upper edge of the keel. From this line the height of the cutting down line at 7 muſt be ſet up, and then the riſing ſquare may be taken away, and the timber may be raſed by the bend mould, both inſide and outſide, from the head to the floor firmark; or it may be carried lower if neceſſary. After the firmarks and heads of the timbers are marked, the bend mould may likewiſe be taken away; and then the hollow mould applied to the back of the ſweep in ſuch a manner, that the point 7 upon it may interſect the upper ſide of the keel, before ſet off by the riſing ſquare; and, when in this poſition, the timber may be raſed by it, which will complete the outſide of the timbers. The inſide of the timbers may likewiſe be formed by the hollow mould. The ſcantling at the keel is given by the cutting down before ſet off. The mould muſt be ſo placed as to touch the ſweep of the inſide of the timber formed before by the bend mould, and paſs through the cutting down point.

The uſe of the firmarks is to find the true places of the futtocks; for, as they are cut off three or four inches ſhort of the keel, they muſt be ſo placed that the futtock and floor firmarks may be compared and coincide. Notwithſtanding which, if the timbers are not very carefully trimm d, the head of the futtock may be either within or without its proper half breadth, to prevent which a half breadth ſtaff is made uſe of.

The half breadth ſtaff may be one inch ſquare, and of any convenient length. Upon one ſide of it are ſet off, from one end, the ſeveral half breadths of all the timbers in the after-body; and thoſe of the fore-body, upon the oppoſite ſide. On the other two ſides are ſet off the ſeveral heights of the ſheer; the after-body on one ſide, and the fore-body on its oppoſite. Two ſides of the ſtaff are marked *half-breadths*, and the other two ſides *heights of the ſheer*.

The ſtaff being thus prepared, and the floor timbers faſtened on the keel, and levelled acroſs, the futtocks muſt next be faſtened to the floor timbers; but they muſt be ſet firſt to their proper half breadth and height. The half breadth ſtaff, with the aſſiſtance of the ram-line, ſerves to ſet them to the half breadth; for as the keel of a boat is generally perpendicular to the horizon, therefore the line, at which the plummet is ſuſpended, and which is moveable on the ram-line, will be perpendicular to the keel, whence we may by it ſet the timbers perpendicular to the keel, and then ſet them to their proper half breadths by the ſtaff; and when the two firmarks coincide, the futtock will be at its proper height, and may be nailed to the floor timbers, and alſo to the breadth ribband; which may be ſet to the height of the ſheer, by a level laid acroſs, taking the height of the ſheer by the ſtaff, from the upper ſide of the keel; by which means we ſhall diſcover if the ribband is exactly the height of the ſheer; and if not, the true height may be ſet off by a pair of compaſſes from the level, and marked on the timbers.

Juvenal (ſat. xv. v. 126—128,) deſcribes the boats of the ancient Egyptians, as if they were earthen-ware; and it is alleged, that ſuch earthen-ware ſhips were uſed on the Nile, and that they were called "pictæ," painted, becauſe theſe

boats

boats of baked earth were marked with various colours. However, it is much more probable, that the Egyptians formerly, as they have done in more modern times, made uſe of raſts, which were made to float by empty veſſels of earthen-ware faſtened under them. The word "pictæ," it is ſuggeſted, does not denote their being beautified with a variety of colours, but means their being rubbed with ſome ſubſtance that might fill up the pores, ſo as to prevent the water's penetrating into the cavity of the pitchers, and cauſing them to ſink, for the Egyptian earthen-ware is ſaid to be very porous. Theſe floats, however, were not conſtructed to paſs up and down the Nile like boats, or properly deſigned for carrying goods upon them, but it is an eaſy mode of conveying their earthen-ware from Upper Egypt, where it is manufactured, to the lower parts of that country, where, when they reach the deſtined place, the float is taken to pieces, and ſold to the inhabitants. Harmer's Obſervations, vol. iii. p. 56.

Boat-*hook*, an iron hook with a ſharp point, having a ſocket in which a long pole is ſtuck. This is a very neceſſary appendage to a boat, as by means of it, any thing floating paſt may be hooked; the boat may be held on to the ſhip, or puſhed along, &c.

Boat-*ſteerer*. In the whale fiſhery a perſon is appointed to each boat, whoſe expreſs duty is to ſteer the boat towards the fiſh, &c.

Boats, *bridge of*. See the article Bridge.

Boat, *removed with ſteam*. An experiment was lately tried on the canal between Grangemouth and Glaſgow, to make a large boat or lighter move by the power of ſteam. As, it is preſumed, the ſeries of experiments is not yet completed, the reader is, therefore, referred to the article Steam.

Boat-*ſwain*, the officer who has the care of the boats, ſails, rigging, colours, anchors, and cables committed to him, which he receives by indenture from the ſurveyor of the navy, and is enjoined to uſe great care in the diſpoſition of them.

It is the duty of the boatſwain particularly to direct whatever relates to the rigging of a ſhip, after ſhe is equipped from a royal dock-yard. Thus, he is to obſerve that the maſts are properly ſupported by their ſhrouds, ſtays, and backſtays, ſo that each of thoſe ropes may ſuſtain a proportional effort when the maſt is ſtrained by the violence of the wind, or the agitation of the ſhip. He ought alſo to take care that the blocks and running-ropes are regularly placed, ſo as to anſwer the purpoſes for which they are intended; and that the ſails are properly fitted to their yards and ſtays, and well furled or reefed when occaſion requires. It is likewiſe his office to ſummon the crew to their duty, to aſſiſt with his mates in the neceſſary buſineſs of the ſhip; and to relieve the watch when it expires. He ought frequently to examine the condition of the maſts, ſails, and rigging, and remove whatever may be judged unfit for ſervice, or ſupply what is deficient; and he is ordered by his inſtructions to perform this duty with as little noiſe as poſſible.

The boatſwain is not to cut up any cordage or canvas without an order in writing from the captain, and under the inſpection of the maſter; and always to have by him a ſufficient quantity of ſmall plats for ſecurity of the cables.

He is not to ſign any accounts, books, lifts, or tickets, before he has thoroughly informed himſelf of the truth of every particular therein contained. His accounts are to be audited and vouched by the captain and maſter, and preſented to the ſurveyor of the navy; and until ſuch accounts are paſſed, he is not to receive any wages. If he has cauſe of complaint againſt any of the officers of the ſhip, with relation to the diſpoſition of the ſtores under his charge, he is to repreſent the ſame to the Navy-board before they pay off the ſhip. Fifteen years ſervitude intitles a boatſwain to ſuperannuation.

The *Boatſwain's Mate* has the charge of the long boat, anchors, cables, &c.; he muſt give an account of his ſtore; and he is appointed to execute the ſentence of a captain or court-martial.

Boats, *train of*, a number of ſmall veſſels faſtened to each other, aſcending up the Loir in France, by ſails when the wind ſerves, otherwiſe towed by men, ſometimes to the number of ſeventy or eighty to a ſingle rope.

Boat-*bill*, in *Ornithology*, the Engliſh name of a ſpecies of Cancroma, *cochlearia*. Brown's Illuſtrations. Or, more properly, at this time the Engliſh name of the *Cancroma* genus, *C. Cochlearia* being called by the modern writers the *creſted boat-bill*, and C. *Cancophraga*, the *white bellied boat-bill*. Theſe are the two only ſpecies known. See Cancroma.

Boat, *ſcapha*, in *Surgery*, a ſpecies of bandage, uſed when the crown of the head and the part between that and the forehead are to be bound. It is likewiſe called *tholus diocleus*.

Boat-*fly*, in *Entomology*. See Notonecta.

Boat *iſland*, in *Geography*, a ſmall iſland in the gulf of St. Lawrence, near the ſouth coaſt of Labrador. N. lat. 50° 2′. W. long. 60° 55′.

Boat *Paſſage*, a channel into Facile harbour, in Duſky bay, New Zealand.

BOATING, a kind of puniſhment in uſe among the ancient Perſians for capital offenders.

The manner of boating was thus: the perſon condemned to it being laid on his back in a boat, and having his hands ſtretched out, and tied faſt on each ſide of it, had another boat put over him, his head being let out through a place fit for it. In this poſture they fed him, forcing him to eat by thruſting ſharp iron inſtruments into his eyes, till the worms, which were bred in the excrements he voided as he thus lay, eat out his bowels, and ſo cauſed his death, which was uſually twenty days in effecting; the criminal lying all this while in moſt exquiſite torments. On his face, placed full in the ſun, they poured honey, enticing the flies and waſps to torment him. Plutarch tells us, that Mithridates, whom Artaxerxes condemned to this kind of puniſhment, for pretending to have killed his brother Cyrus, lived ſeventeen days in the utmoſt agony; and that, when the uppermoſt boat was taken off at his death, they found his fleſh wholly conſumed, and ſwarms of worms gnawing his bowels. Herodot. l. i. c. 133, 140. Plut. in vit. Artaxerxes.

BOATIUM Civitas, in *Ancient Geography*, a town of Gaul, and one of the twelve cities of Novempopulania.

BOATSKIDS, in *Naval Architecture*, are long ſquare pieces of fir, extending acroſs the ſhip from the gang-boards, on which the boats, ſpare maſts, &c. are ſtowed.

BOB, or Ball, in *Horology*, is the metallic weight which is attached to the lower extremity of a pendulum rod, by means of a tapped adjuſting nut, at ſuch a diſtance from the point of ſuſpenſion as the time of a given vibration requires. (See the articles Centre of Oscillation and Pendulum.) In fixing upon a proper bob for any pendulum, two things are particularly to be attended to: the ſhape which is beſt calculated for meeting with the leaſt reſiſtance from the air; and the weight which is beſt adapted for preſerving the iſochroniſm of the vibrations with a given maintaining power. Each of theſe conſiderations has been the ſubject of much inveſtigation. A ſphere is a ſolid, the ſurface of which bears the leaſt proportion to its ſolidity of any other, and a cube is one with great extent of ſurface compared to its ſolid contents; conſequently, the former ſhape has

has obtained in cannon balls, intended to paſs through the air with as little obſtruction as poſſible, and has ſometimes, for the ſame reaſon, been applied as a bob for a pendulum. Such a ſhape is better adapted for a large bob than a ſmall one; for the increaſe of the ſurface is in proportion to the ſquare of the diameter, whereas the increaſe of weight or quantity of matter is as the cube. Mr. B. Martin (Mathematical Inſtitutions, vol. ii. p. 417.) propoſed two equal fruſta of ſimilar cones, to be joined together at the baſes, as a figure approximating nearly to a ſolid of leaſt reſiſtance, and recommended it as that out of which the middle one of three ſegments, cut longitudinally, will conſtitute the beſt ſhape for an appended weight, to anſwer the purpoſe of avoiding reſiſtance. Such a ſection, he conceived, would diſplace but a ſmall quantity of air in one vibration, and the impulſes of that quantity, being made obliquely on the ſloping ſurfaces of the ends, would produce but a ſmall effect. The lenticular ſhape, however, compoſed of two ſegments of a large globe joined to the line of ſection, has been generally adopted by clock-makers, probably becauſe two plates of braſs of that ſhape can be eaſily ſoldered together, and left hollow, ſo as to be filled with lead, or other heavy metal, in order to obtain a due degree of weight without adding to the thickneſs, which is an advantage that braſs or copper cannot have of itſelf in any ſhape. M Ferdinand Berthoud (Eſſai ſur l'Horlorgerie, tome. ii. chap. xiii.) made ſome experiments with bobs of both a ſpherical and lenticular ſhape, of equal weight, attached ſucceſſively to the ſame free pendulum, from which it appeared, that, in the ſame temperature, the latter continued to vibrate ſeconds much longer than the former before they arrived at the quieſcent ſtate, which experiment was conſidered as a proof that the lenticular ſhape has the advantage in eſcaping the effect of reſiſtance; it was diſcovered, however, on a repetition of the experiment, with ſeconds and half-ſeconds pendulums, that the friction at the point of ſuſpenſion occaſioned by heavy weights, particularly when vibrating in long arcs, made conſiderable alterations in the reſults, and proved itſelf a ſecond ſource of reſiſtance to the free motion of the pendulum.

The ſecond conſideration to be attended to in making the bob, as has been ſaid, is the weight which a given pendulum requires, with a given maintaining power. No theory is adequate to determine this deſideratum of itſelf, becauſe the diminution of the maintaining power by the friction of the pivots and the ſtate of the oil, the duration of the impulſe on the pallets, the nature of the eſcapements in other reſpects, the reſiſtance of the air, and at the point of ſuſpenſion, and particularly the nature and quantity of momentum of the pendulum, muſt all enter into the calculation; and theſe are data, many of which are conſtantly varying. The momentum, or whole quantity of motion of any pendulum, is the weight multiplied into the ſquare of its velocity, ſo that a large arc with a ſmall weight, and a ſmall arc with a correſponding large weight, cæteris paribus, ought to have an equal effect upon the iſochroniſm of the ſame pendulum; but the theory is not perfect; for firſt, large circular arcs deviate conſiderably from cycloidal ones, which, it has been demonſtrated by Huygens and others ſince, are thoſe which have the iſochronal property in an uniformly denſe medium; and ſecondly, they require a greater maintaining power than calculation gives: for inſtance, where the arc is 10° from the point of reſt, the addition to be made to the maintaining power beyond calculation is 57 parts in 100, according to Berthoud's experiments, which conſideration induces him to conclude, that irregularities in the maintaining power will affect the momentum principally compoſed of velocity, more than the momentum principally compoſed of weight; each kind of momentum, however, has its peculiar diſadvantage; for great velocity is ſubject to great reſiſtance from the air, and great weight to much friction at the point of ſuſpenſion. Mr. Alexander Cummings was an advocate for a large arc with a ſmall bob; but modern practice is in favour of a large ball or bob with a ſhort arc of vibration. It ſeems to be generally allowed, that the momentum of a pendulum ought to be as great as poſſible for a given maintaining power, provided the latter be ſufficient to overcome all obſtacles to conſtant motion; but as the momentum is obtained in two different ways, it may be proper to ſubjoin here an illuſtration of them.

If a pendulum, moving in an arc of one degree from the quieſcent point, with a bob or ball of ſix pounds, have its momentum denominated by unity, then the ſquare of any given momentum will give its correſponding weight for another bob, moving in the ſame arc; or the ſquare root of the given momentum will give the arc of ſemivibration with the ſame weight; for inſtance, a momentum 4 will require $6 \times 4 = 24$ for the weight where the arc remains unaltered; but the root of $4 = 2$ will be the arc from the point of reſt with the ſame weight; again, if the momentum be required to be 9 for a given maintaining power, the weight muſt be 54, or the arc 3° from the point of reſt, and in the ſame proportion for any other momentum; but, in fact, both the weight and arc may be varied according to circumſtances, which latitude affords great variety in the adjuſtment of the bob, and matter for multiplied experiments to determine what weight and arc ſhall be moſt deſirable, taken conjointly under different circumſtances.

The moſt practicable method of adjuſtment of the momentum of a pendulum, where a weight is uſed as the maintaining power, ſeems to be, to vary this power inſtead of the weight of the bob or ball, which, when once finiſhed of the requiſite ſhape, is not ſo eaſily altered. In pendulum clocks, actuated by a ſpring as a maintaining power, ſuch adjuſtment cannot indeed be made in the power properly without changing the ſpring, or altering the fuſee after they are adjuſted to each other; but as theſe inſtruments are not intended to meaſure time with great nicety, the adjuſtment of the bob to the maintaining power is exactly done by gueſs. In Huygens's beſt clock, the maintaining power was equal to three pounds, falling about 90 inches in 24 hours, and the ball of its ſeconds pendulum, together with the pendulum itſelf, was alſo three pounds; but the nature of his eſcapement required the vibrations to be performed in long arcs. Cummings tried different weights for his pendulums from 6 to 16 pounds, and various arcs from 3° to 6° from the point of reſt; but it does not appear that any other ſtandard has been adopted by clock-makers than what accords with the individual opinion of each. See MAINTAINING POWER.

BOB, in *Ringing*, denotes a peal conſiſting of ſeveral courſes, or ſets of changes.

BOB-*ſtay*, in *Sea-Language*, a rope uſed to confine the bowſprit of a ſhip downward to the ſtem, or cut-water, and to counteract the force of the ſtays of the fore-maſt, which draw it upwards.

It is fixed by thruſting one of its ends through a hole bored in the fore-part of the cut-water, and then ſplicing both ends together, ſo as to make it two-fold, or like the link of a chain; a dead-eye is then ſeized into it, and a lanyard paſſing through this, and communicating with another dead-eye upon the bowſprit, is drawn extremely tight by help of mechanical powers. The bob-ſtay is the firſt part of a ſhip's rigging, which is drawn tight to ſupport the maſts. With this view, it is uſual to ſuſpend a boat, anchor, or other weighty body, at the bowſprit end, to preſs it downwards during the operation.

BOB-*ſtay-holes*, are thoſe holes in the ſtem, or fore-part of the knee of the head, to which the bob-ſtay is faſtened.

BOBAC, in *Zoology*. The bobak of the French and Engliſh writers is a ſort of MARMOT with ſmall, and ſomewhat oval ears; tail hairy; a claw upon the fore thumb; and the body grey above, and yellowiſh beneath. Gmelin calls this animal *arctomys bobac*.

There appear to be two varieties of this ſpecies, if not more. The bobac of Rzaczinſki (Nat. Hiſt. Pol. p. 235.) deſcribed by Briſſon, in his Hiſtory of Quadrupeds, under the name of *marmotta polonica*, is of yellowiſh colour, inclining to reddiſh upon the head; but the bobac deſcribed by Pallas is of a greyiſh brown colour, with only the under parts yellow. In every reſpect, except the colour of the hair, theſe two varieties agree.

This creature is rather larger than the rabbit, meaſuring about ſixteen inches from the noſe to the baſe of the tail, the latter of which is four inches and an half in length; ſo that the whole animal meaſures above twenty inches. Dr. Pallas, to whom we are chiefly indebted for an account of the bobac, tells us, that it is a native of the high, but milder and ſunny ſides of mountainous countries, which abound with fiſſile, or free-ſtone rocks, where it is found in dry ſituations, and ſuch as are full of ſprings, woods, or ſand. It abounds in Poland and Ruſſia, among the Carpathian hills: it ſwarms in the Ukraine, about the Boriſthenes, eſpecially between the Sula and Supoy; and then again between the Boriſthenes and the Don, and along the range of hills which extend to the Volga. It is found about the Yaik and the neighbouring rivers; and inhabits the ſouthern deſert in Great Tartary, and the Altaic mountains, eaſt of the Irtis. It ceaſes to appear in Siberia, on account of its northern ſituation, but is found again beyond the lake Baikal, and about the river Argun and the lake Dalay, in the ſunny mountains about the Lena, and very frequently in Kamtſchatka, but rarely reaches as high as latitude 55°.

The bobac is not conſidered as an article of food by the Mahometan tartars. The Coſſacks and the Calmucks, on the contrary, hunt and kill them for eating; the fleſh, however, is very fat, and not in much eſteem for the goodneſs of its flavour. In its manners of life the bobac reſembles thoſe of the Alpine marmot, with which it has been apparently ſometimes confounded. It inhabits deep burrows, in ſocieties of from twenty to twenty-four in each receptacle. Their habitation is lined with the fineſt hay; and it is ſaid, the quantity found in every ſuch receptacle is ſufficient for a night's provender for a horſe. In the morning, or the middle of the day, when the ſun ſhines, they go abroad in ſearch of food, always taking the precaution to ſtation one of the party at the entrance of their cell as a centinel, who announces the leaſt approach of danger with a whiſtle; and all, if within hearing, are thus enabled to provide for themſelves in the beſt manner circumſtances may require, either by returning for ſhelter to their cell, or remaining at a diſtance till the danger is over. The marmot, when attacked, rears itſelf upon the haunches, and defends itſelf with the fore paws. It eats with the fore paws, in the ſame poſture. The bobac is an animal of a mild and gentle diſpoſition, and may be eaſily domeſticated. They are torpid throughout the winter, unleſs kept in a warm room. They breed early in the ſpring, and are ſaid to produce ſix or eight young. The fat of this creature is uſed for dreſſing furs and leather.

BOBAN, in *Geography*, a town of Arabia, 32 miles S. of Saade.

BOBART, ROBERT, in *Biography*, curator of the botanical garden at Oxford, which had been lately inſtituted by lord Danby, publiſhed, in 1648, "Catalogus plantarum horti medici Oxonienſis," 8vo. The catalogue gives the names of about 1600 plants, many of them from Canada, firſt the Latin, then the Engliſh names, in alphabetical order. This was re-publiſhed in 1658, conſiderably improved and enlarged to more than double its bulk; Bobart being aſſiſted in the work, as he acknowledges, by Dr. Philip Stevens and Wm. Brown, M.A. Beſides the trivial names of the plants, there were now added thoſe from Gerard, Parkinſon, and Bauhine, which were not in the firſt edition. Bobart died in 1679, at the age of 81 years.

BOBART, JACOB, who ſucceeded his father, as curator of the garden, publiſhed, in 1699, the third volume of Morriſon's "Plantarum hiſtoria univerſalis Oxonienſis, ſeu herbarum diſtributio nova, per tabulas cognitionis, ex naturæ libro detecta," fol.; making up by his own induſtry and ſagacity what was deficient in the looſe and imperfect ſketches left by the author at his deceaſe. There is an ingenious paper by this writer in the Philoſophical Tranſactions for the year 1683, on the effects of the great froſt, which happened the preceding winter, on trees and other plants. Many oak, elm, aſh, walnut, and other trees, were found, he ſays, with large rents or cleſts in different parts of their trunks, in the large branches, and in ſuch parts of their roots as were not ſunk deep into the earth. Parts, he adds, that were ſo knotted, that they could not have been ſplit but with great difficulty with beetles and wedges, were rent aſunder by the force of the ice contained within them, making, at the time of burſting, a noiſe like the exploſion of gunpowder. It was ſuppoſed, that the trees which ſuffered were diſeaſed, that ſome of the veſſels were diſtended or burſt, and that the effect was produced by the freezing of the ſap or other juices contained in theſe cavities. Philoſ. Tranſ. abr. vol. iii. p. 89. Haller. Bib. Botan.

BOBARTIA, in *Botany*, (named in honour of James Bobart, formerly profeſſor of botany at Oxford), a genus formed by Linnæus for a plant ſaid to grow in the Eaſt Indies, with the following eſſential character:—*Glumes of the calyx* numerous; the exterior ones ſhort, univalved; the interior longer, bivalved; *glume of the corol.* ſingle, ſhorter than thoſe of the calyx, ſitting on the germ, ſhrivelling. This generic character was firſt publiſhed in the Amœnitates Academicæ, vol. i. p. 113. (Lugd. Bat. Ed.); and in the Species Plantarum a reference is given to Scheucher, Gram. 369. Reichard added another ſuppoſed ſynonym from Plukenet tab. 30. fig. 7. Schreber, Juſſieu, La Mark, and Boſc, have all taken it up from Linnæus; and La Mark, in his Illuſtrations, has copied Plukenet's figure. Willdenow, in his new edition of the Species Plantarum, has aboliſhed the genus; aſſerting, on the authority of Schumacher (Act. Soc. Nat. Hafn.), that Linnæus drew up the character of his bobartia from a mutilated ſpecimen of morœa ſpathacea, firſt completely deſcribed by Thunberg, and adopted by Linnæus the younger in the Supplementum Plantarum, p. 99.

The miſtaken ſynonyms of Scheucher and Plukenet are referred by Willdenow to cyperus arenaria of Retz, of which Plukenet's figure, copied by La Mark, is ſaid to be a good repreſentation. A figure of morœa ſpadicea is alſo given by La Mark under its proper genus.

BOBARTIA. See alſo RUDBECKIA *Purpurea*.

BOBBIN, in *Commerce*, a term denoting about $\frac{3}{4}$ of a hundred of undreſſed flax.

BOBBING, or BOBBIN, a little piece of wood turned into a cylindric form, whereon thread is wound, to be uſed in the weaving of bone-lace.

The French alſo give the denomination *bobine* to what among us is more properly called a *ſpool* or *quill*. In which they are alſo followed by ſeveral Engliſh.

In this general ſenſe, bobbins are uſed to wind thread, worſted, hair, cotton, ſilk, gold, and ſilver; and they are

ol different lengths and fizes, according to the materials which are fpun or wound.

Bobbing *for Eels*, among *Fifhermen*, is an amufing method of catching eels, generally practifed from the fide of a boat, the piers of bridges, wharfs, or other fituations, where deep water can be at once reached. The bait made ufe of may be either fcoured lob-worms, or garbage of any kind; which bait of whatever kind is ftrung lengthwife on worfted, fo as to completely cover it: fome yards are prepared in this way, which are then tied up in links, making fomething like a bundle of fringe. So prepared, the bait is fufpended from a ftrong rod or pole by two or three yards of packthread, leaded within a foot of the worms with more or lefs weight according to the ftrength of the current. The bait and lead muft be funk to the bottom, and fuffered to remain, when the fifh will foon be felt to nibble; but time muft be allowed for them to make their hold fecure, after which they may be gently pulled up to within a fmall diftance, when a flight jerk will fecure them. The mouths of rivers, muddy and deep places, where the tide reaches, are particularly favourable for this fport.

BOBBIO, or Bobio, *Bobium*, in *Geography*, a fmall town of Italy, and capital of a diftrict of the fame name, formerly belonging to the duchy of Milan, feated on the river Trebia, the fee of a bifhop, fuffragan of Genoa, 30 miles N.E. of Genoa. It is now a canton of the diftrict of Alexandria, in the department of Marengo.

Bobbio. See Biobio.

BOBENHAUSEN, a town of Germany, in the circle of the Upper Rhine, and principality of Upper Heffe; 17 miles eaft of Giefen.

BOBENNEUKIRCHEN, a town of Germany, in the circle of Upper Saxony, and the Vogtland; 6 miles S.W. of Oelfnitz.

BOBER, a river which runs into the Oder, at a fmall diftance to the weft of Croffen in Silefia.—Alfo, a town of Lithuania. N. lat. 55° 46'. E. long. 25° 46'.

BOBERG, a high promontory in the prefecture of Bofling, and diocefe of Ripen, in Denmark, near which the coaft is very dangerous, and has proved fatal to many fhips.

BOBERSBERG, a town of Silefia, 9 miles S.S.W. of Croffen, and 28 S. of Frankfort on the Oder.—Alfo, a town of Germany, in the circle of Upper Saxony, and duchy of Croffen, 6 miles S. of Croffen.

BOBI, in *Conchology*. Adanfon gives this name to the variety β of *voluta perfcula*.

BOBISATIO, or Bocedisatio, in *Mufic*, denotes the ufing of the feven fyllables, *bo*, *ce*, *di*, *ga*, *lo*, *ma*, *ni*, to expref the feven mufical notes in lieu of the fix ufual ones introduced by Aretine, *ut*, *re*, *mi*, *fa*, *fol*, *la*, as has been fometimes done by the Netherland and German muficians fince the beginning of the feventeenth century, to avoid the mutation neceffary in the ufe of thefe latter.

BOBLINGEN, in *Geography*, a fmall town and diftrict of the fame name, of Germany, in the duchy of Wurtemberg, fituate in a fertile country, and in the foreft of Schonbuch, which abounds with game, having a caftle feated on an eminence lying above the town. The diftrict contains 12 parifhes; and the vicinity produces fome wine.

BOBR, a river of Lithuania, which runs into the Dnieper; 5 miles S.S.E. of Rohaczow.

Bobr, in *Zoology*, a kind of marine otter, fo called by the Ruffians, who refide at Kamtfchatka, the precife fpecies of which is doubtful. Some have imagined it to be allied to the caftor.

BOBRITZSCH, in *Geography*, a town of Germany, in the circle of Upper Saxony, and country of Erzgeberg, 4 miles S.E. of Freyberg.

BOBROF, a diftrict of the government of Voronetz, in Ruffia, feated on the Biliuk, falling into the Don.

BOBROWNIK, a town of Poland, in the palatinate of Lublin, 24 miles W.N.W. of Lublin.

BOBRYSLE, a town of Lithuania, in the palatinate of Minfk, feated near the river Berezyna. N. lat. 53°. E. long. 29° 12'.

BOBTI, a town of Lithuania, in the palatinate of Troki. N. lat. 55°. E. long. 24° 15'.

BOCA. See Bocca.

Boca *Efcondida*, in *Geography*, a bay of North America, in the bay of Campechy, on the coaft of Yucatan. N. lat. 18° 50'. W. long. 91° 46'.

Boca *Grand*, a bay of North America, at the mouth of the river Zucar, on the S.E. coaft of Coita Rica. N. lat. 10° 50'. W. long. 83° 26'.

Boca *Tora*, a bay of North America, in the Caribbean fea, on the coaft of Veragua. N. lat. 8° 58'. W. long. 82° 1'.

BOCABRITO, a town of North America, in the country of New Navarre, 65 miles eaft of Cinaloa.

BOCA-CHICA, the ftrait or entrance into the harbour of Carthagena, in South America; which was filled up fince the attack of the Engliih in 1741, who, having made themfelves maflers of the forts which defended it, entered the bay with an intent of taking the city; but their attempt mifcarried, and they were obliged to retire with confiderable lofs. This event produced orders for opening the old entrance, by which all fhips now enter the bay.

BOCA-DEL-DRAGO, a ftrait between the ifland of Trinidad and Andalufia, in the province of Terra Firma, South America.

BOCAGE, a fmall territory of France, in Normandy, of which the principal place was Vire.

BOCALIEAU, a fmall ifland near the eaft coaft of Newfoundland. N. lat. 48° 15'. W. long. 52° 26'.

BOCAMELE, in *Zoology*, the provincial name of an animal of the Mustella tribe found in the ifland of Sardinia. This is believed to be the creature defcribed by Ariftotle by the name of *Ictis*.

BOCANA, in *Ancient Geography*, a town fituate in the eaftern part of the ifle of Taprobana. Ptolemy.

BOCARDO, in *Logic*, the fifth mode of the firft figure of fyllogifms, wherein the firft propofition is particular and negative; the fecond, univerfal and affirmative; and the third, or conclufion, particular and negative. Thus:

BOC Some animal is not man.
AR Every animal has a principle of fenfation.
DO Therefore fomething has a principle of fenfation, that is not man.

BOCAS, Las, in *Geography*, a town of North America, in New Bifcay, 120 miles E. of Parmal.

BOCAT, the name of a valley in Syria, in which are the ruins of Balbec, of which Mr. Wood fays, it might by a little care be made one of the richeft and moft beautiful fpots in Syria; for it is more fertile, he adds, than the celebrated vale of Damafcus, and better watered than the rich plains of Eldraelon and Rama. In its prefent neglected ftate, it produces corn, fome good grapes, but very little wood. Here, it is fuppofed, was fituated "Baal-hamon," which was the marriage portion of the bride of Solomon. Sol. Song. viii. 12. This eftate was leafed out to a variety of tenants, each of whom paid her a clear rental of a thoufand fhekels of filver, amounting to about 120l. 16s. 8d. fterling. Harmer's Outlines of a New Commentary on Solomon's Song, p. 35. Good's Song of Songs, Pref. p. 13.

Bocat was alſo called "Bekaa," which ſee. See alſo Balbec.

BOCAUD, John, in *Biography*, born at Montpellier, where he received his education. In 1540, he was made doctor; and in 1544, on the death of Denis Fontenon, profeſſor of medicine in the univerſity there; an office he is ſaid to have filled with diſtinguiſhed honour to the time of his death, which happened in 1558. We have only one work publiſhed by this writer; "Tabulæ curationum et indicationum ex prolixo Galeni methodo, in ſumma rerum capita contractæ," fol. Lyons. Haller. Bib. Med. Pract. Eloy. Dict. Hiſt. Med.

BOCCA, in *Geography*, a town of Italy, in the duchy of Mantua, in the Comeſfezza, 5 miles N.N.E. of Sabionetta.

Bocca *Tigris*, a name given by foreigners to the river Pe-kiang of China, near its diſcharge into the ſouthern ſea of China. See Pe kiang.

Bocca, in *Glaſs-making*, the round hole in the working furnace, by which the metal is taken out of the great pots, and by which the pots are put into the furnace. This is to be ſtopped with a cover made of earth and brick, and removeable at pleaſure, to preſerve the eyes of the workmen from the violence of the heat.

BOCCACCI, or Boccaccino, Camillo, in *Biography*, a painter of hiſtory and portrait, was born at Cremona in 1511; and, having received inſtructions in the art of painting from his father, removed to Rome, and aſſumed the Roman taſte. His application was indefatigable, and his improvement ſo obſervable, that he was immediately employed in ſeveral noble works for the churches and convents. He died young in 1546, when he was making rapid progreſs towards very high perfection. Pilkington.

BOCCACCINI, Anthony, a ſurgeon of Comachio, a town in Ferrara, flouriſhed in the early part of the laſt century. Reviving the practice of Magatus, in the cure of wounds and ulcers, which had fallen into diſuſe, he admitted no oily or greaſy applications in the treatment of them, nor made uſe of tents or injections in the cure of abſceſſes, which, by irritating the parts, prevented, he ſaid, their union, and frequently occaſioned the oriſices to become callous. His works, illuſtrating his practice, are "Cinque diſinganni Chirurgici, per la cura delle ferite," Venice, 1713, 8vo. treating of the cure of gun-ſhot wounds; "Cinque diſinganni Chirurgici, per la cura delle ulcere," Ven. 1714, 8vo. with obſervations explaining and defending the doctrine of Magatus. Haller. Bib. Chirurg. Eloy. Dict. Hiſt. Med.

BOCCACIO, or Boccace, John, an eminent Italian writer, and one of the reſtorers of literature in Europe, was born of parents in low condition at Certaldo in Tuſcany, in 1313. Declining that mercantile occupation for which he was originally deſigned, and in which he ſpent ſome of his earlier years, he devoted ſome time to the ſtudy of the canon law; but as ſoon as he had an opportunity of chooſing for himſelf, he purſued a courſe of literature; and with this view ſought inſtruction from the beſt maſters, and at Florence put himſelf under the tuition of Leonzio Pilato for the Greek language. Beſides the advantage he derived in furniſhing his mind with ſtores of literature, and in cultivating a good taſte, from converſation with the moſt learned men of his age, and from collecting and copying the moſt approved Greek and Latin writers of antiquity, he was particularly indebted for his progreſs in learning, and for his future reputation, to the inſtruction and patronage of Petrarch, who was eminently uſeful to him both by his advice and by ſupplying him with money for aiding the proſecution of his ſtudies, when his own patrimony was exhauſted. By a diligent improvement of theſe advantages, he acquired ſuch reputation, that the republic of Florence conferred upon him the honour of citizenſhip, and employed him in a variety of public tranſactions. Among other important commiſſions with which he was entruſted, that of negotiating the return of his friend Petrarch to Florence was particularly agreeable to him. But though his meſſage to this purpoſe did not ſucceed, it afforded him an opportunity of eſtabliſhing a more intimate and confidential correſpondence with this patron of his youth. In 1353, two years after his viſit to Petrarch, he was ſent to pope Innocent VI. at Avignon. At this time he lived freely, and devoted himſelf chiefly to poetry and compoſitions of a lighter kind. During his rambles in Italy, he viſited Naples, as ſome have ſaid, in the year 1341, where he was favourably received by king Robert, and where he reſided for ſome time. Here he fell in love with a young perſon whom he calls Fiametta, and who is commonly ſuppoſed to have been the natural daughter of Robert. In 1359, he had a conference with Petrarch at Milan, the reſult of which was his indulging more ſerious reflections than he had hitherto done; and, having received an admonition in 1361, that his life would not be of long continuance, and that he would ſoon abandon poetry, his mind was ſo impreſſed that he immediately determined to relinquiſh his poetical lucubrations, and even the peruſal of profane authors, and, againſt the counſel and remonſtrance of Petrarch, to part with his library. About this time he aſſumed the clerical habit, and adopted a plan of conduct more guarded and regular than that of his paſt life. In 1362 or 1363, he again viſited Naples; and, without making any long ſtay there, went to Venice, and paſſed three months with his friend Petrarch. He was again deputed by his countrymen as ambaſſador to pope Urban V. at Avignon; and in 1367 he attended the pontiff under the ſame character at Rome. A public lecture on the "Comedia" of Dante, having been inſtituted at Florence, he commenced his expoſitions of that author in October, 1373; but, preferring the retirement of Certaldo, his native place, towards the cloſe of his life, he died there in December 1375. Boccacio was a voluminous writer both in proſe and verſe. His works in Latin were, a mythological treatiſe in 15 books, "De Genealogiâ Deorum," Baſil, 1532, fol. eſteemed excellent at the time when it was written, but long ſince ſuperſeded by more valuable publications of a ſimilar kind; to this was annexed a "Treatiſe on Mountains, Rivers, Seas, Lakes, &c.;" with reſpect to both theſe he has been charged with plagiariſm; "An Abridgement of the Roman Hiſtory," from Romulus to the year of Rome 724, with a parallel of the ſeven kings of Rome and of the emperors to Nero inclufively, Cologn. 1534, 8vo.; an hiſtorical treatiſe, in nine books, entitled "De Caſibus virorum et fœminarum illuſtrium," beginning with Adam, and terminating with John king of France taken priſoner by the Engliſh at the battle of Poictiers, in 1356, which work was tranſlated into Italian, Spaniſh, French, and Engliſh, printed at Augſburgh, in 1544, and in French at Lyons, in 1483, and at Paris, in 1578, by Claudius Vitart, under the title of "Traité des Meſaventures des Perſonnages ſignalez," 8vo.; and another book "De claris mulieribus." He alſo wrote in Latin a number of eclogues. In Italian poetry, his compoſitions were the "Theſeide," in 12 books; the "Filoſtrato;" the "Ninfale Fiſolano," &c. &c. But though he was reckoned one of the three princes of the poets of that age, he is ranked only as the third of the triumvirate, precedency being aſſigned to Dante and Petrarch. It is ſaid, that he was duly ſenſible of his inferiority; and that, after having ſeen the ſonnets and ſongs of Petrarch, he determined to throw his own into the fire. His proſe works, which

which are more valuable, are his "Commentary on Dante," printed at Rome in 1544, 16to.; and at Florence, in 1576, 8vo.; ſome romances of an amorous kind, intermixed with verſe, as "Il Filocopo," "La Fiametta," "L'Ameto," "Il Laberinto d'Amore," &c. &c. But his moſt celebrated production of this kind is his "Decamerone," or collection of one hundred ſtories, or novels, feigned to have been recited in ten days by a company of ladies and gentlemen, who had retired into the country from the plague of Florence in 1348. Theſe ſtories are partly founded on fact, and partly the productions of the author's own imagination; and they preſent a curious exhibition of characters and manners in all the ranks of ſociety. They abound with ſatirical ſtrokes levelled againſt the vices and frauds of the prieſts, and even the myſteries of religion; and the language, in ſome parts, is ſo free and licentious, that we may well wonder at their being recited before females of character and condition. However trite and vulgar many of the reflections may now appear, the ſtyle in which they are delivered is conſidered as a model of elegance and purity for the age in which they were written, and places the Italian language far beyond that of any modern nation at ſo early a period. No work was ever more popular, or more generally tranſlated, than the Decamerone. The ſtories that occur in this work have furniſhed materials for ſome of the moſt popular pieces of La Fontaine and other ſimilar writers. Boccace aſſumes the credit of having firſt brought the writings of Homer and of ſeveral other Greek authors from Greece to Tuſcany; and he was, without doubt, a moſt induſtrious and indefatigable copyiſt of the remains of antiquity. His poetry is pronounced by his countrymen to be as feeble and languid in its character, as his proſe is exquiſite and admirable. His valuable library was bequeathed to a convent in Florence, where it was long preſerved. For a further account of his life and writings, ſee Fabricius's Bibl. Lat. medii ævi. tom. i. p. 248. &c.; and Tiraboſchi, tom. v. p. 83. 439—451. Gen. Dict.

BOCCALE, or Bocal, a liquid meaſure uſed at Rome, anſwering to what among us is called a bottle, being equivalent to about an Engliſh quart. Seven *boccales* and an half make the *rubbia*.

BOCCALINI, Trajan, in *Biography*, a ſatirical writer of the 16th century, was the ſon of an architect at Carpi, and born at Loretto in 1556. At Rome, where he principally reſided, he had acceſs, by the vivacity of his genius, to ſeveral perſons of rank, and among others to cardinal Bentivoglio, whom he inſtructed in geography. Protected from the danger to which his ſatirical turn expoſed him, by the influence of the cardinals Borgheſe and Gaetani, he alſo, by their recommendation, obtained ſeveral offices of truſt and honour in the eccleſiaſtical ſtate, and was appointed to the government of Benevento. But his public conduct occaſioned complaints, and he became obnoxious to the Spaniards, by expoſing with freedom and ſeverity their deſigns againſt the liberty of Italy, ſo that he was under a neceſſity of retiring to Venice in 1612. In the following year, it is ſaid that he was aſſaſſinated by four ruffians, who broke into his chamber at an early hour in the morning, and beat him ſo ſeverely with ſand-bags as to occaſion his death. Of his works, the moſt celebrated is his "Ragguagli di Parnaſo," or news from Parnaſſus, in which, under the fiction of a court in which Apollo preſides, he takes occaſion to ſatirize the actions and works of ſeveral perſons who paſs under review; but his reflections frequently betray the want of critical judgment and of a regard to truth. A ſecond part of this work, written with the ſame views, is entitled "The Secretary of Apollo." His "Political Touchſtone," levelled againſt the Spaniards, is of a ſimilar kind. He alſo wrote the "Political Balance," "Commentaries on Tacitus," and ſome other works. Tiraboſchi. Gen. Dict.

BOCCARELLA, in the *Glaſs-Manufacture*, a ſmall hole or aperture of the furnace, one of which is placed on each ſide of the bocca. almoſt horizontally with it. Out of them the ſervitors take coloured or finer metal from the piling pot.

BOCCAS, in *Ichthyology*, the Arabian name of a fiſh belonging to the Scomber genus, obſerved by Forſkal in the Red Sea. Vide Scomber sansun.

BOCCHERINI, Luigi, in *Biography*, who, we hope, is ſtill living at Madrid, and whoſe inſtrument is the violoncello, though he writes but little at preſent, has perhaps ſupplied the performers on bowed-inſtruments and lovers of muſic with more excellent compoſitions than any maſter of the preſent age, except Haydn. His ſtyle is at once bold, maſterly, and elegant. There are movements in his works, of every ſtyle, and in the true genius of the inſtruments for which he writes, that place him high in rank among the greateſt maſters who have ever written for the violin or violoncello. There is perhaps no inſtrumental muſic more ingenious, elegant, and pleaſing, than his quintets; in which invention, grace, modulation, and good taſte, conſpire to render them, when well executed, a treat for the moſt refined hearers and critical judges of muſical compoſition.

BOCCHETTA, in *Geography*, a chain of mountains, over which is the high road between Lombardy and Genoa; on the ſummit of the higheſt, which is very ſteep, is a way ſo narrow that three perſons can hardly go a-breaſt, called "The Paſs of Bocchetta," defended by forts, and conſidered as the key to the city of Genoa. In 1746, the imperialiſts, having made themſelves maſters of this paſs, found little difficulty in proceeding to that capital. In 1778, a magnificent road was made from the Bocchetta to the north of Genoa, through the Polzevera, which, for the ſpace of three years, employed from 5 to 800 men, by the patriotic munificence of one noble family, the Cambiaſi. The Polzevera in the Bocchetta yields a beautiful ſtone, which is ſerpentine, of various colours veined with marble.

BOCCHIANICO, a town of Italy, in the kingdom of Naples, and province of Abruzzo citra, 3 miles S. E. of Civita di Chieta.

BOCCIARDI, Clementi, called *Clementone*, in *Biography*, a painter of hiſtory and portrait, was born at Genoa in 1620, and after having been the diſciple of Bernardo Strozzi, went to Rome for improvement, by a judicious obſervation of the ancient ſculptures, and the works of the celebrated modern artiſts. By the efforts of his own excellent genius, and a diligent application to deſign, he diſcovered the art of blending the antique and modern guſts in a ſtyle both of gracefulneſs and ſtrength. Moſt of his works (his portraits excepted, which were lively, natural, and graceful,) are in the chapels of Genoa, Piſa, and other cities of Italy, where they are much eſteemed. Pilkington.

BOCCOLD, Bockholdt, or Beukels, John, commonly called *John of Leyden*, a journeyman-taylor of Leyden, who, in the earlier part of the 16th century, connected himſelf with John Matthias, a baker of Haerlem, and with his aſſiſtance diſplayed the aſtoniſhing effects of fanaticiſm and enthuſiaſm. Theſe two anabaptiſt prophets, for this was the appellation which they aſſumed, fixed their reſidence at Munſter, in Weſtphalia, and at length gained ſuch a number of proſelytes, that they became maſters of the city, and eſtabliſhed in it a new form of government, directed by Matthias, who iſſued his commands, with the ſtyle, and with

with the authority of a prophet. Matthias, having pillaged the city, amaſſed large hoards of wealth, and reduced all ranks to an equality, provided for its defence, by repairing and extending its fortifications, by forming all his followers, who were capable of bearing arms, into regular bodies, and by endeavouring to add the vigour of diſcipline to the impetuoſity of enthuſiaſm. After theſe preparations, he ſent out emiſſaries to the anabaptiſts in the Low Countries, inviting them to aſſemble at Munſter, which he dignified with the title of Mount Sion, and from thence he propoſed that they ſhould ſet out to reduce all the nations of the earth under their dominion. The biſhop of Munſter, juſtly alarmed by theſe hoſtile appearances, aſſembled an army, laid ſiege to the town, and ſlew Matthias, with 30 of his attendants, in their firſt frantic ſally. Matthias, in the ſame year 1534, was ſucceeded by Boccold, who, more cautious than his predeceſſor, ſatisfied himſelf with carrying on a defenſive war, whilſt he waited for the ſuccours from the Low Countries, which he encouraged his deluded followers to expect. But though leſs daring in action than Matthias, he was a wilder enthuſiaſt, and of more unbounded ambition. Accordingly he marched naked through the ſtreets, and proclaimed with a loud voice, "That the kingdom of Sion was at hand; that whatever was higheſt on earth ſhould be brought low, and whatever was loweſt ſhould be exalted." In order to verify his declaration, he commanded the churches, and the moſt lofty buildings in the city, to be levelled with the ground; and depriving Cnipperdorling, one of the moſt conſiderable of their proſelytes of the conſulſhip, the higheſt rank in the commonwealth, he degraded him to the humiliating office of common executioner. In place of the depoſed ſenators, he named 12 judges, according to the number of tribes in Iſrael, and reſerved to himſelf the authority poſſeſſed by Moſes as legiſlator of the people. He further declared to the aſſembled multitude, that it was the will of God, that John Boccold ſhould be king of Sion, and ſit on the throne of David. Accepting this heavenly calling, which he pretended to have received by a ſpecial revelation, he was immediately acknowledged as monarch by the deluded multitude, and aſſumed all the ſtate and pomp of royalty. He wore a crown of gold, and was clad in the moſt ſumptuous garments. A Bible was carried by him in one hand, and a ſword in the other; he appeared in public attended by a body of guards, coined money with his own image, and appointed the great officers of his houſhold and kingdom, among whom Cnipperdorling was nominated governor of the city, as a recompence for his former ſubmiſſion. As the exceſſes of enthuſiaſm have uſually led to ſenſual gratifications, Boccold inſtructed his prophets and teachers to inculcate the lawfulneſs of a plurality of wives, as one of the privileges granted by God to his ſaints; and he himſelf ſet the example of this Chriſtian liberty, as he called it, by marrying at once three wives, one of whom was the beautiful widow of Matthias. He proceeded with augmenting the number of his wives to fourteen, reſtricting, however, the title of queen to Matthias's widow, and allowing no other to ſhare with him the ſplendour and ornaments of royalty. The multitude availing themſelves of his example, indulged their deſires to the moſt licentious and extravagant exceſs; and polygamy and freedom of divorce univerſally prevailed. The biſhop of Munſter, in the mean while, aided by the German princes, preſſed cloſer the blockade of the town into which the ſiege had been converted; but its fortifications were ſo ſtrong, and ſo diligently guarded, that they durſt not attempt an aſſault. But no ſuccours arrived to the beſieged; and after a cloſe blockade of about fifteen months, they began to feel and lament the effects of ſcarcity. However, ſuch was the faſcinating influence of Boccold's promiſes and predictions, that no one ſeemed inclined, or at leaſt poſſeſſed reſolution enough, to propoſe a ſurrender. One of his wives, intimating a ſmall doubt of his divine miſſion, was ſummoned before him as a blaſphemer, and commanding her to kneel, he cut off her head with his own hands; his frantic followers at the ſame time dancing with joy round the bleeding body of their companion. Notwithſtanding all the horrors of famine, the people of Munſter ſtill refuſed to capitulate. At length, however, a deſerter made his eſcape to the enemy; and offered to head a party of the beſiegers, under cover of the night, to a weak part of the fortifications, and leſs vigilantly guarded than any other. The propoſal was accepted; and the party ſcaled the walls, ſeized one of the gates, and admitted the reſt of the army. A dreadful carnage enſued; the king and Cnipperdorling were taken priſoners. The former, loaded with chains, was carried about from city to city, as a ſpectacle to the people; but notwithſtanding all their inſults, he maintained a firm and unbroken ſpirit; and adhered inflexibly to the tenets of his ſect. He was afterwards brought back to Munſter, and ſuffered the moſt exquiſite as well as lingering tortures of death with aſtoniſhing fortitude; thus finiſhing an extraordinary courſe of deluſion, at the age of 26 years. Bayle, Art. *Anabaptiſts*. Robertſon's Hiſt. of Ch. V. vol. iii. p. 99, &c. Moſheim's Eccl. Hiſt. vol. iv. p. 452, &c.

BOCCONE, Paolo, or Paul, an ingenious naturaliſt, was born at Palermo, in Sicily, April 24th 1633. He was of a wealthy and reſpectable family, originally from Savona in Genoa. To improve himſelf in natural hiſtory, particularly in botany, to which he was early attached, he travelled over Sicily, Corſica, Malta, many parts of Germany, Holland, and England, converſing with the moſt eminent literary characters in the places he viſited, with whom he afterwards kept up a correſpondence. In the courſe of his travels, he was admitted doctor in medicine at Padua, was elected member of the Academ. Naturæ Curioſ. and made botaniſt to the grand duke of Tuſcany. In 1682, he entered among the Ciſtertian monks at Florence, and with the habit of the order, took the name of Sylvio, which he affixed to his latter works, but he was ſtill permitted to continue his reſearches in natural hiſtory. Returning at length to Sicily, he retired to one of the houſes of the Ciſtertians near Palermo, where he died, Dec. 22, 1704. As he had been indefatigable in his reſearches, his collection of plants and other natural productions was very conſiderable. Sherrard, who ſaw his hortus ſiccus, or ſpecimens of dried plants, in 1697, was ſo ſtruck with their number and beauty, that he engaged him to give a catalogue of them to the public, which he did in his "Muſæo piante rare," publiſhed at Venice in 4to. the ſame year. The catalogue was alſo publiſhed by itſelf. Several of his works appear to have been printed while he was on his travels. The firſt of them, "De abrotano mare monitum," in 1668; and in the ſame year, "Manifeſtum botanicum, de plantis Siculis," Cataneæ, 4to. By an advertiſement at the beginning of the work, he offers to botaniſts the ſeeds of many of the curious and rare plants he had collected, at moderate prices. Morriſon publiſhed an edition of this work at Oxford in 1674, 4to. under the title of "Icones et deſcriptiones rariorum plantarum Siciliæ, Melitæ, Galliæ, et Italiæ." Many of the plants, Haller ſays, were new. The figures are ſmall, and in general not well delineated or engraved. His next production was "Recherches et obſervations naturelles," publiſhed at Paris in 1671, 12mo. again at Amſterdam in 1674, and again in 1744, in 8vo. It conſiſts of letters to his correſpondents in France, Italy, England, &c. In 1684, in 16mo. "Oper-

vazioni

vazioni naturali ove ſi contengono materie medico fiſiche e di botanica," Bologna. The obſervations are 26 in number, and dedicated, or addreſſed to ſo many of the author's friends and patrons, among whom are many perſons of high rank. He is very profuſe in his elogia on the medical virtue of many of the plants, which he praiſes far beyond their real value. "Tenere oportet," Haller ſays, "credulum eſſe virum, et in viribus medicis plantarum liberalem." "Muſæo di fiſica e di eſperienze decorato di opervazioni naturali," Venet. 1697, 4to. The author here aſſumes the name of Sylvio. The obſervations are, as in the former work, dedicated to his noble patrons, and contain ample accounts of the medical virtues of various plants, much beyond what, from experience, they have been found to poſſeſs. Some ſmaller diſſertations were printed in Miſcel. Naturæ Curioſ. and in the Journal des Savans. On the whole, Boccone appears to have been an induſtrious and intelligent writer, and to be deſervedly reckoned one of the promoters and improvers of botany. Haller Bib. Botan. Eloy. Dict. Hiſt. Med.

BOCCONIA, in *Botany*, (named from Paolo Boccone, M. D.) a genus of the claſs *dodecandria monogynia*. Nat. Ord. *Rhoeadeæ. Papaveraccæ*, Juſſieu. Lin. gen. 591. Reich. 643. Willden. 927. Schreb. 803. La Mark, p. 394. Gært. 44. Juſſ. 236.

Eſſ. Char. *Cal.* two-leaved. *Cor.* none. *Style* biſid. *Pericarp.* two-valved. *Seed* one.

Gen. Char. *Perianth* two-leaved, ovate, obtuſe, concave, caducous. *Cor.* none. *Stamens*, before the opening of the flower, from 12 to 24, afterwards ſeldom more than 10; very ſhort. *Anthers* linear, very large, as long as the calyx. *Piſt.* germ roundiſh, contracted both ways, large, pedicelled. *Style* one, biſid. *Stigmas* ſimple, reflex. *Pericarp.* capſule ſubovate, attenuated to each end, compreſſed, one-celled, two-valved. *Valves* coriaceous, opening at the baſe; the annular future crowned with the permanent ſtyle. *Seed* one, globular, involved in pulp at its baſe, fixed to the bottom of the capſule. *Obſerv.* The capſule reſembles a ſilicule in its general ſhape, and in the permanent future terminated by the ſtyle.

Species, 1. *Bocconia frutescens*, ſhrubby bocconia tree, celandine, or parrot-weed. "Leaves oblong, ſinuated. Willd." An ornamental ſhrub, 10 or 12 feet high, with a ſtraight, hollow trunk filled with pith, covered with a ſmooth, white bark, and divided near its ſummit into ſeveral cylindric branches. It abounds in all its parts with a thick, yellowiſh juice, ſimilar to that of celandine. *Leaves* ſix or ſeven inches long, and about three broad; alternate, oblong, ſemipinnatifid; a little ſinuated, with oval, unequally toothed ſegments; green and ſmooth above, glaucous, and a little tomentoſe beneath; on ſhort petioles; flowers ſmall, greeniſh, numerous, in large pyramidal, terminating panicles; bractes lanceolate.

It is a native of Mexico and the Weſt Indies, where its acid juice is uſed to take off tetters and warts, and is alſo ſaid to be employed in dying yellow. It has an evident affinity with the celandines in its ſenſible qualities and two-leaved caducous calyx, but differs remarkably from them in its incomplete flowers and monoſpermous fruit. La Mark conjectures that its want of a corolla is owing to the change of its natural petals into ſtamens: for, he obſerves, after the fall of the true ſtamens, four are conſtantly left, which continue as long as the calyx. See La Mark. Encyc.

The ſhrubby *bocconia* was firſt cultivated in England by Mr. Miller in 1739, and has flowered and ripened its ſeeds in the phyſic garden at Chelſea. It is propagated by ſeeds, which ſhould be ſown in a pot filled with light freſh earth, early in the ſpring, and then plunged into a bed of tanner's bark, and occaſionally watered. When the plants are come up, they ſhould be tranſplanted into ſeparate pots filled with light ſandy earth, plunged again in the hot bed, and ſhaded from the ſun in the heat of the day, till they have taken root: at firſt they ſhould be ſparingly watered, but when their ſtems are become woody, they will require a larger ſupply. In about two months, they ſhou'd be tranſplanted into larger pots, and plunged again into the bark. In warm weather they ſhould have a good ſhare of freſh air, but ſhould never be taken out of the ſtove.

2. B. *cordata*. "Leaves cordate, a little lobed." A native of China. *Panicle* elongated, with ſingle, not divided, branches. *Calyx* white, as in the preceding ſpecies, but larger. *Stamens* about 24. *Style* none. *Stigma* bilamellated, ſeſſile. Willdenow, by whom it was firſt deſcribed, as it ſhould ſeem, from a dried ſpecimen.

BOCCORE, in *Natural Hiſtory*, בכירה, q. d. firſt and early fruit, a name given in the kingdoms of Algiers and Tunis, and alſo in Paleſtine, to the early fig, which was produced in June, in Paleſtine, though the kermez, or kermouſe, the fig properly ſo called, which they preſerved and made up into cakes, was rarely ripe before Auguſt, and ſometimes hung upon the trees all the winter. Theſe latter figs continued a long time upon the tree before they fell off; whereas the boccores dropped as ſoon as they were ripe, and, according to the appropriate and beautiful alluſion of the prophet Nahum, (iii. 12.) fell into the mouth of the eater, upon being ſhaken. We learn from Pliny (N. H. l. xvi. c. 26.) that the fig-tree was bifera, or bore two crops of figs, viz. the boccore, as we may imagine, and kermouſe: and it is well known, that the fruit of theſe prolific trees always precedes the leaves; conſequently, when our Saviour ſaw one of them, in full vigour, having leaves, (Mark xi. 13.) he might, according to the common courſe of nature, very juſtly look for fruit, and haply find ſome boccores, if not ſome winter-figs likewiſe upon it. The time of the year in which the event referred to in this paſſage occurred, was undoubtedly three or four days before the paſſover, at which our Saviour was crucified, and the paſſover in that year fell in the beginning of April. But it has been inquired, how Chriſt could expect to find ripe figs on the tree at the latter end of March? to which it is replied, becauſe figs were ripe ſo ſoon in Judæa. It has been ſatisfactorily proved, that the harveſt in Judæa began at the paſſover, and ended at pentecoſt; and as the barley in Judæa was ripe in March, and the wheat in April, we need not wonder, if there were ripe figs in the beginning of April too, or before the time of the paſſover. This, indeed, was the uſual time for the firſt ripe figs; and therefore it was natural to expect that there ſhould be figs at this ſeaſon, more eſpecially as the tree had leaves, before which the fruit came forth; and as the "time of figs" as biſhop Kidder has ſhewn, the time of gathering in ripe figs, was not yet come. When St. Mark ſays, "for the time of figs was not yet," he does not deſign to give a reaſon of what he ſaid in the immediately foregoing clauſe, viz. "he found nothing but leaves," but he gives a reaſon of what he ſaid in the clauſe before that, viz. "he came, if haply he might find any thing thereon." And it was a good reaſon for our Saviour's coming and ſeeking figs on the tree, becauſe the time of gathering them was not yet come. The tranſpoſition above ſuppoſed, is not uncommon. See Mark xvi. 3, 4. Gen. xiii. 10. Joſh. xxii. 22. See Hallett's Notes on Texts of Scripture, vol. ii. p. 115, &c. Harmer's Obſerv. vol. i.

BOCH, John, in *Biography*, a modern Latin poet and claſſical ſcholar, was born at Bruſſels in 1555; and having entered

entered into the ſervice of cardinal Radzevil, accompanied him to Rome, and there ſtudied theology under Bellarmin. He afterwards travelled into Poland, Livonia, and Ruſſia, and was in danger of loſing his feet by the froſt in his journey to Moſcow. Upon his return to the Low Countries, the duke of Parma appointed him ſecretary to the town-houſe of Antwerp. He died in 1609. His poetical works, conſiſting of epigrams, elegies, heroic poems, &c. were collected, and printed at Cologne in 1615. He has been highly eſteemed as a Latin poet by the critics of his country, and called the "Belgic Virgil." Gen. Dict.

Boch, in *Geography*, a river of the Netherlands, which runs into the Meuſe, 5 miles below Dinant.

BOCHARIA. See Bucharia.

BOCHART, Samuel, in *Biography*, a learned orientaliſt, was the ſon of a miniſter of the reformed church at Rouen, where he was born in 1599. Having ſtudied polite literature at Paris, philoſophy at Sedan, and divinity, with the oriental languages, at Saumur, and made a ſurpriſing progreſs at a very early age, he completed his courſe of oriental literature under Erpenius and Ludolf at Leyden. On his return to France, he ſettled as miniſter at Caen. In 1646, he publiſhed his "Phaleg" and "Canaan," the two parts of his "Geographia Sacra," a work of very extraordinary erudition and reſearch, in which he inveſtigates the hiſtory of the human race as recorded in the Bible, the diſperſion of mankind, and the origin of nations and languages, together with a variety of collateral ſubjects. Notwithſtanding the charge of fanciful interpretations and chimerical conjectures, which has been alleged againſt ſome parts of this work, it has long maintained a high degree of reputation, and furniſhed an ample ſupply of materials for modern writers. In the progreſs of this work, the author was led to purſue a variety of inquiries concerning the animals, vegetables, and minerals mentioned in the ſacred writings, on which he intended to have compoſed diſtinct treatiſes; but he only completed that relating to animals, which was printed at London in 1663, under the title of "Hierozoicon." In this work the errors are ſuch as muſt unavoidably occur at a period when the knowledge of natural hiſtory was very imperfect, compared with that of more modern times. In compliance with the invitation of queen Chriſtina, Bochart viſited Sweden in 1652, accompanied by the learned Huet, who wrote an humourous and elegant Latin poem on their journey. But finding that the capricious levity of the Swediſh queen was not ſuited to his own grave character, he returned to France in 1653, and reſumed his former ſtudies. He was a member of the academy at Caen, and by his moderation and candour, maintained the diſtinguiſhed reputation which he acquired by his profound erudition, together with the eſteem and reſpect of perſons of all parties, till the time of his death, which happened, in conſequence of an apoplectic ſtroke, during a diſputation with Huet in the academy, May 16, 1667. Beſides the learned works already mentioned, Bochart left ſeveral diſſertations, particularly one, in which he attempts to prove that Æneas never was in Italy. His works were collected and printed by M. de Villemandy at Leyden in 1712, in 3 vols. folio. Gen. Dict.

BOCHO, in *Geography*, a town of Germany, in the circle of Upper Saxony, and principality of Querfurt, 3 miles S. E. of Juterbock.

BOCHOLICZE, a town of Poland, in the palatinate of Sandomirz, 20 miles E.S.E. of Radom.

BOCHOLT, or Bockolt, a town of Germany, in a prefecturate of the ſame name, in the biſhopric of Munſter, and circle of Weſtphalia; ſeated on the Aa, and having iron mines in its vicinity; 36 miles W.S.W. of Munſter.

BOCHOULT, or Bochout, a town of Flanders, ſituate on a canal cut from the Scheldt; 4 miles N. W. of Sas-de-Gent.

BOCK, Blauer Bock, in *Zoology*, a ſynonymous name of the *blue antelope*, *antilope leucophæa*. Kolbe.—Bock alſo ſignifies the male of the common goat. Geſn. Thierb.

BOCKA, or Buckau, in *Geography*, a mine town of Germany, in the circle of Upper Saxony, and country of Erzgeberg, 3 miles W. of Schwartzenberg.

BOCKENBURG, a town of Germany, in the circle of Weſtphalia, and biſhopric of Minden, one mile from Minden.

BOCKENHEIM, a town of Germany, in the circle of the Upper Rhine, and county of Hanau-Munzenberg; 2 miles W. N. W. of Franckfort on the Mayne.

BOCK HORD, or Book-Hoard, in *Antiquity*, a place where books, evidences, or writings were kept.

BOCKHORST, John Van, in *Biography*, a painter of hiſtory and portrait of the Flemiſh ſchool, was born at Munſter, about the year 1610; and removing to Flanders, acquired the art of deſign and colouring in the ſchool of Jacques Jordaens. He deſigned well; the heads of his women are generally graceful, and thoſe of his men diſtinguiſhed by character: his tone of colouring ſometimes reſembled that of Rubens, but more frequently that of Vandyck. His pictures have great force and harmony, and his ſkilful management of the chiaro-ſcuro produces an agreeable effect. An altar piece at the church of St. James in Ghent, repreſenting the martyrdom of this ſaint, and a picture of the Annunciation in another church, painted in 1664, are diſtinguiſhed performances of this maſter. Deſcamps. Pilkington.

BOCKI, in *Geography*, a ſmall town of Poland, in Podalachia, in the palatinate of Bielſk.

BOCKING. See Braintree.

Bocking *herring*, in the *Dutch Trade*, ſignifies the ſame with bloated herring among us.

BOCK-KOGO, in *Geography*, a vaſt peak of the Brenner mountains in the Tyrol, riſing little inferior to Gefrorn, and in the ſame latitude, but towards the weſt.

BOCK-LAND, or Book-land, formerly denoted that which we now call freehold-*land*, or charter-*land*; and it was by that name diſtinguiſhed from folk-*land*, which was copyhold-*land*. In *Ancient Law-Writers*, it denotes a poſſeſſion or inheritance held by evidence in writing. The word was doubtleſs written *bock-land*, quaſi *book-land*, anſwering to free land, or land held by book or charter, which was regarded as free property, and deſcended to the heirs of the poſſeſſor. It ſtood oppoſed to folk-*land*, which was that held without writing.

BOCKUM, Bochum, or Bocheim, in *Geography*, a town and prefecturate of Germany, in the circle of Weſtphalia, and county of Mark; ſeated in a very fertile diſtrict, 24 miles N. E. of Duſſeldorp, and 35 N. of Cologn.

BOCNIA, a town of Poland, in the palatinate of Cracow, famous for its ſalt-mines, firſt diſcovered in 1251. The ſmall river called Raab, that falls into the Viſtula, runs near this town, which is ſurrounded with hills and eminences. The ſalt-mine of Bocnia is in a narrow ſlip of land, about 750 feet in breadth from north to ſouth, and about 10,000 feet in length from eaſt to weſt, and its greateſt depth below the ſurface is about 1200 feet. The ſalt lies in veins, and is ſomewhat finer, eſpecially at a certain depth, than that of Wieliczka. It is cut in ſmall pieces, and put up in caſks. Large pieces of black wood have been found in this mine, which are incruſted with ſalt; and likewiſe ala-

baſter. The mines, which are very dry, are under the direction of the magiſtrates of Wieliczka. The town is 20 miles E. of Cracow.

BOCZEYKOWO, a ſmall town of Lithuanian Ruſſia, in the palatine of Polock.

BODÆUS A. Stapel, John, in *Biography*, was born at Amſterdam the beginning of the 17th century, where, at a proper age, he was admitted doctor in medicine, but attached himſelf particularly to botany, in which he acquired conſiderable celebrity. He died in 1636, at an early age, leaving a work, on which he appeared to have beſtowed much labour, prepared for the preſs, which was publiſhed ſome years after, viz. Joannes Bodæus, a Stapel, in Theophraſti Hiſtoriam Plantarum, fol. Amſt. 1644. Eloy's Dict. Hiſt. Med.

BODAISKA, in *Geography*, a town of Hungary, 7 miles W. of Patak.

BODDAERTI, in *Ichthyology*, a name given to a ſpecies of Chætodon. This has the body variegated with brown and blue bands, and the ventral fins armed with two ſpines. Schr. der. berl. naturf. Gmel. The habitat of this fiſh is unknown.

Boddaerti, a ſpecies of Gobius, found in the Indian ocean. Pallas deſcribes it ſpecifically as having the rays of the anterior dorſal fin cirriform, and the third ray very long. This fiſh is ſix inches in length; the body blueiſh brown, pale and yelloviſh beneath, of a convex ſhape, tapering in a ſlight degree towards the tail, and covered with ſmall ſoft ſcales. The head is thick, blunt, ſomewhat convex, and ſpotted with brown and white. Jaws nearly equal. Lips thick and fleſhy: eyes vertical. Lateral line with ſcarcely perceptible papillæ, and a few ſnowy white ſpots. Each ſide of the back marked with ſeven black ſpots, and on the ſides below theſe as many dots of white. Vent nearer the head than the tail; ſurrounded by a black circle, with a conic peduncle behind. Dorſal fins blueiſh-black, the anterior ones ſpotted with white, the other with ſetaceous rays, and ſix tranſverſe white lines between each ray. Pectoral fin rounded. Tail blueiſh white. In the firſt dorſal fin five rays, in the ſecond twenty-five; pectoral twenty-one; ventral thirty-four; anal twenty-five; caudal eighteen. Pallas. Gmel. &c.

BODECKEN, in *Geography*, a town of Germany, in the circle of Weſtphalia, and biſhopric of Paderborn, 4 miles N. N. E. of Buren.

BODEGAS, a town of North America, in the province of Verapaz, on the north-eaſt coaſt of Dolce-bay. N. lat. 15° 40′. W. long. 75° 35′.

BODEGNE'E, a town of France, the principal place of a canton, in the diſtrict of Huy, and department of Ourte; the place contains 320, and the canton 7422 perſons; the territory comprehends 107½ kiliometres, and 17 communes.

BODEGON, a town of Spain, in Andaluſia, 4 leagues from Seville.

BODEKKER, in *Biography*, a painter of portraits, was born in the country of Cleves, in 1660, and abandoning the profeſſion of muſic for which his father had intended him, he was placed as a diſciple, in the art of painting, under John De Baan, at the Hague. He commenced the exerciſe of his profeſſion at Bois-le-Duc and Breda with great reputation; and having reſided ſome time at the Hague, he cloſed his life in 1727, at Amſterdam, where his performances were much eſteemed. Pilkington.

BODENBURG, in *Geography*, a town of Germany, in the circle of Lower Saxony, and biſhopric of Hildeſheim; 8 miles N. E. of Alfeld.

BODENETZ, a town of Bohemia, in the circle of Chrudim; 10 miles N. of Chrudim.

BODENFELDE, a town of Germany, in the circle of Lower Saxony, and principality of Calenberg, ſeated on the Weſer, in the quarter of Gottingen.

BODENHAUSEN, a town of Germany, in the circle of the Upper Rhine, and principality of Heſſe, 18 miles E. N. E. of Caſſel.

BODENI, in *Ancient Geography*, a people of European Sarmatia, according to Ptolemy.

BODENLEICH, in *Geography*, a town of Germany, in the circle of Lower Saxony, and principality of Luneburgh-Zell; 32 miles N. E. of Zell.

BODEN-SEA, a name ſometimes given to the gulf of Bothnia, which ſee.

BODENSTEIN, Adam, in *Biography*, a celebrated German phyſician, ſon of a famous theologian, called from the place of his reſidence, Carloſtadt, was born there in 1528. He was a pupil, and ſtrenuous defender of the doctrines of Paracelſus, in which he appears to have placed an entire confidence. For a malignant fever raging at Baſle, in 1577, he went there, armed with a Theriaca, compoſed on the principles of his maſter, with which he boaſted he ſhould be able to ſubdue the fever; but taking the infection, he fell a ſacrifice to his credulity and temerity. Beſides editing ſeveral of the works of Paracelſus, he left the following, which were collected and publiſhed in one volume folio, at Baſle, in 1581.

" Epiſtola ad Fuggeros, in qua Argumenta Alchymiam infirmantia, et confirmantia adducuntur; quibus et eam artem eſſe veriſſimam demonſtratur; lapiſque vere inventus oſtenditur." " De Podagra preſervatione, tractatus." " De herbis duodecim zodiaci ſignis, dicatis, &c." Adamus records his epitaph, placed on his monument, he ſays, at his own deſire, in which he is ſaid to have died, anno ſalutis, 1577, ætatis hebdomada ſeptima, for ſeven times ſeven, or 49 years. Alſo the following lines, in which Bodenſtein is ſuppoſed to ſay:

" Nec omnia, nec omnes mihi
Placuere: quinam ego omnibus?
Non omnibus cous ſenex,
Non eremita ſpagirus.
Nam tu viator omnibus?
Deo placere cura. Abi."

Adami Melch. Vitæ Germ. Med. Haller Bib. Med. Eloy Dict. Hiſt.

BODENWERDER, in *Geography*, a town of Germany, in the circle of Lower Saxony, and principality of Calenberg, ſeated on the Weſer; 16 miles S. of Hamelen. It has ſome trade with Bremen and Hamburg in coarſe linen.

BODEN-ZEE, a name given by the Germans to the ſuperior lake of Conſtance, which ſee.

BODERIA, or Bodotria, in *Ancient Geography*, an æſtuary mentioned by Ptolemy in his deſcription of Great Britain, which is the preſent Firth of Forth in Scotland.

BODGURVA, in *Geography*, a town of Aſiatic Turkey, in the province of Natolia, 28 miles N. N. W. of Kaſtamoni.

BODIANUS, or Bobianus, in *Ancient Geography*, a borough of Italy, which was repeopled by a decree of Julius Cæſar.

Bodianus, *Bodian*, in *Ichthyology*, a genus of *Thoracic* fiſhes, firſt eſtabliſhed by Dr. Bloch, for the reception of ſuch ſpecies of the two Linnæan genera Sparus and Perca, as have certain characters common to both, and are not therefore ſufficiently diſtinct to be divided into two genera. The character of this new genus, as laid down in the firſt inſtance, conſiſts in having the gill covers ſcaly, armed, and ſmooth, or even at the edges. Under this head Dr. Bloch deſcribes

deſcribes ten ſpecies only, namely, *Bodianus bodianus*, *bodianus guttatus*, *bodianus pentacanthus*, *bodianus bænac*, *bodianus aya*, *bodianus maculatus*, *bodianus apua*, *bodianus macrolepidotus*, *bodianus ſtellifer*, and *bodianus argenteus*. Lacepede, in adopting the genus *Bodianus*, conſiderably augments the number of its ſpecies by the addition of others not previouſly deſcribed under either of the Linnæan genera. In his "Hiſtoire Natureile des Poiſons," there are altogether no leſs than four and twenty ſpecies. The generic character is modified, and two ſections formed to admit them. Its eſſential character is thus expreſſed: one or more ſpines to the gill covers, the margins of which are neither denticulated, nor jagged; only a little beard, or ſometimes none to the jaws; and a ſingle dorſal fin.

The firſt ſection of the Bodians include thoſe which have the caudal fin furcated in the form of a creſcent, of which there are fourteen kinds; le bodian œilére (*bodianus palpebratus*), le bodian louti, le bodian jaguar (*bodianus pentacanthus*), le bodian macrolépidote, le bodian argente, le bodian Bloch (*bodianus bodianus*), le bodian aya, le bodian tacheté, le bodian vivanet, le bodian Fiſcher, le bodian décacanthe, le bodian lutjan, le bodian groſſe tête, and le bodian cycloſtome.

In the ſecond diviſion, the ſpecies of which have the tail fin entire, Lacepede deſcribes only ten, le bodian rogaa, le bodian lunaire, le bodian mélanoleuque, le bodian Jacob Evertſen, le bodian bœnac, le bodian hiatule, le bodian apua, le bodian etoilé, le bodian tétracanthe, and le bodian ſix raies.

The genus *Bodianus* is recogniſed, and admitted by Dr. Shaw into the general zoology. He includes in this tribe preciſely the ſame ſpecies as thoſe deſcribed by Dr. Bloch, with five additional ſpecies deſcribed by Lacepede as *Bodians*, namely, perca louti, Gmel. ſparus palpebratus, Gmel. perca rogaa, Gmel. perca lunaria, Gmel. and bodianus melanoleucus of Lacepede. But the generical definition of the *Bodianus*, as given by this author, is evidently at variance with that aſſigned to it by others. The great object of the Ichthyologiſt, in eſtabliſhing the new genus *bodianus*, muſt have been to ſeparate from the two genera *perca* and *ſparus*, ſuch ſpecies as do not ſtrictly belong to either; and unleſs this could be accompliſhed in a ſatisfactory manner, it were better to permit them to remain where Linnæus placed them. By ſome unuſual overſight Dr. Shaw appears to have failed in this reſpect; his bodiani are not ſufficiently diſtinguiſhed from the Linnæan percæ, as the following generic character will ſhew: "*Habit* of the genus perca. *Gill covers* ſcaly, ſerrated and aculeated. Scales (in moſt ſpecies) ſmooth." The *gill-covers* of the perca, according to this writer, are ſcaly and ſerrated, and the ſcales of the body (in moſt ſpecies) hard and rough. According to this definition; a perch with ſmooth ſcales, and the denticulations of the gill covers conſpicuouſly large, may be miſtaken for a bodian; and a hard ſcaled bodian, on the contrary, for a perch. If we are to allow an innovation on the Linnæan arrangement by the inſertion of the genus *bodianus*, its true character ſeems to be that the plates which conſtitute the gill-covers are ſmooth at the edges, and only armed with one or more diſtinct ſpines; while the ſerrated edges of thoſe plates as plainly point out the percæ: and if the plates be both ſerrated and aculeated, we conceive it highly proper to retain them under the old Linnæan genus *perca*.

BODIN, John, in *Biography*, a famous lawyer of France, was born at Angers in 1530, ſtudied the law at Toulouſe, and preferring the common to the civil law, quitted Toulouſe and entered at the bar in Paris; but not ſucceeding to his expectations, he devoted himſelf to literature. He commenced his career as a writer, with a tranſlation into elegant Latin verſe of "Oppian's Cynegeticon," or books of hunting, accompanied with learned notes, claimed as his own by Turnebus. His "Method of Hiſtory," was publiſhed in 1566, and his "Diſcourſe on Coins," with an anſwer to the paradoxes of Maleſtroit in 1568; but theſe were introductory to his great work in French, "Concerning a Republic," printed in 1576, in folio, and frequently reprinted in 8vo. To this work the preſident Thuanus bears very honourable teſtimony; it was alſo much commended by other perſons of learning; and obtained for the author a high degree of reputation throughout Europe. It became the text-book of private lectures both at London and Cambridge. His tables of law, entitled "Juris Univerſi Diſtributio," were printed in 1578, and in the following year his "Demonomanie des Sorciers," to which was annexed "A Refutation of the book, de Lamiis," of John Wier, phyſician to the duke of Cleves, who had undertaken to prove that the ſtories of witchcraft and ſorcery have chiefly ariſen from impoſture or deluſions of fancy. The literary character of Bodin, who defended this kind of ſuperſtition, incurred reproach, and he himſelf was ſuſpected of being a magician. Before this time he had been invited by Henry III. to his court, who was much delighted with his converſation and treated him with attention and reſpect. But the royal favour was of no long continuance; for Bodin, who held an office in the preſidial court of Laon, was ſent, in 1576, as a deputy of the third eſtate of Vermandois, to the aſſembly of the ſtates-general at Blois; where he remonſtrated againſt the project of alienating the royal demeſnes belonging to that province; and this he did with ſuch effect, that Thuanus principally aſcribed the defeat of the injurious ſcheme of alienation to his conduct on this occaſion. Bodin alſo reſolutely oppoſed the party of the Guiſes, who were endeavouring to procure a decree for compelling all the king's ſubjects to profeſs the catholic religion. By ſuch meaſures he became obnoxious at court; and he, therefore, accepted a propoſal made to him by the king's brother, the duke of Alençon and Anjou, to accompany him to his government of the United Provinces. He afterwards attended him to England, and, it is ſaid, that he adviſed the ſeizure of Antwerp, in conſequence of which the duke loſt both credit and influence. After the death of his patron, Bodin returned to Laon, and diſcharged the office of chief magiſtrate with great integrity. In this city he died of the plague in 1596. A work, written by him but never printed, and entitled "Heptaplomeron, ſive de abditis rerum ſublimium arcanis," is ſaid to have been an attack upon religion, and deſigned to invalidate the authority of revelation. By the ſeeming advantages which he gave in this work to the Jewiſh religion, he was ſuſpected of being a convert to it; but it is more probable, that he was a ſceptic with regard to religion, and alike indifferent to all modes of faith. A little while before his death he publiſhed a Latin treatiſe, entitled "Theatrum Univerſæ Naturæ," in which he purſues the cauſes and effects of things to their principles. Bodin was of an ardent and inquiſitive temper; and his erudition was ſuperior to his judgment. Gen. Dict.

BODLEY, Sir Thomas, was born at Exeter in 1544, and at 12 years of age removed with his father to Geneva, who took his family thither to avoid the perſecution of queen Mary's reign. In the univerſity of that city he commenced his ſtudies; and when his father returned to England, on the acceſſion of queen Elizabeth, he was ſent to Magdalen college, Oxford, where he remained for ſome years, and became fellow of Merton college. Here he read lectures in Greek and philoſophy, and officiated as proctor and public orator. In 1576 he went abroad for improvement, and

ſpent four years in his travels. In 1583 he was made gentleman-uſher to the queen; and having married, he entered into public life, and was employed in various foreign embaſſies. At the Hague, where he reſided ſeveral years, his chief buſineſs was the negotiation of money-concerns between the States and queen Elizabeth. After his final return to England, in 1597, he found that his further advancement was obſtructed by the intrigues and jealouſies of perſons in power, and he therefore formed a fixed purpoſe of retiring from all public affairs, devoting the remainder of his life to the laudable employment of refounding the univerſity library at Oxford, furniſhing it with books, and enlarging the building. See Library. At the acceſſion of king James, Mr. Bodley received the honour of knighthood. He died in 1612, and was buried in Merton college choir. An annual oration is ſtill ſpoken in his praiſe. Biog. Brit.

Bodley, John, who practiſed phyſic in London, in the beginning of the laſt century, publiſhed, in 1741, a critical eſſay on the works of various authors, particularly on thoſe treating on medicine, with the view of ſhewing that neither thoſe phyſicians who wrote the moſt correct and valuable treatiſes on medicine, nor thoſe who were the moſt intelligent practitioners, were uſually the moſt encouraged: fame and ſucceſs being more commonly the appendages of craft and policy, than of ſkill and judgment. A ſimilar opinion was held by the late Dr. Samuel Johnſon, who thought a judicious hiſtory of the fate of phyſicians might prove both an entertaining and uſeful work. Something of this kind was done by Pierius, in his book "De Literatorum Infelicitate," but on a larger ſcale, embracing the whole community of letters. Eloy. Dict. Hiſt.

BODINCOMACUM, in *Ancient Geography*, the name of a borough of Italy in Liguria, where, according to Pliny, the river Eridanus was at its greateſt depth; called in his time "Induſtria."

BODIONTICI, a people whom, according to Pliny, Galba annexed to Gallia Narbonnenſis; but before this time they formed a part of the Liguriana. M. D'Anville has placed them in the maritime Alps. Their capital was Dinia.

BODKIL, in *Geography*, one of the channels between Flanders and Walcheren iſland, in Zealand, by which great ſhips may ſail in.

BODMER, in *Biography*, a celebrated profeſſor and writer of Swiſſerland, was born at Zurich in 1698; and became profeſſor of Helvetic hiſtory and politics in his native place. In this office he taught his pupils to think for themſelves, and to make ſuch obſervations on hiſtorical facts as might render them intimately acquainted with the human heart. He wrote the hiſtory of his own country in the form of dramatic dialogues. Although he became one of the moſt voluminous of the German poets, and contributed in a great degree to reform the taſte of his contemporaries, and to familiarize them to the ſublime beauties of Homer and Milton, he had ſcarcely written a verſe in the German language before he was 50 years of age, when the firſt canto of Klopſtock's Meſſiah fell into his hands, and excited his emulation. His firſt eſſays were in epic poetry, the ſubjects of which he took from the Scriptures, but he afterwards devoted his muſe to other topics; and it is obſervable, that old age, which generally increaſes auſterity of manners, had the contrary effect on Bodmer; inſomuch that his laſt pieces were the moſt gay, and that when he was 80 years old, he frequently amuſed himſelf with Tibullus and Petronius, and alſo with Boccace and la Fontaine. At the age of 77, he began a tranſlation of Homer's Iliad and Odyſſey, which he finiſhed; he was 80, alſo, when he publiſhed his verſion of the Argonautics of Apollonius Rhodius. He died in 1783, at the age of 85 years. Bodmer has been deſervedly ſtyled by the unanimous voice of his contemporaries, "the father of German literature;" whoſe juſt criticiſms and correct judgment animated the poetical genius of Klopſtock, Haller, and Geſner. Bildniſſe, &c. or Portraits of celebrated German Literati, &c. Rome, 1793.

BODMIN, in *Geography*, an ancient borough and market town of Cornwall, England, is ſeated near the eaſtern borders of the county, on the confines of Devonſhire. This town appears to have been formerly the principal ſeat of religion in the weſtern diſtrict, and contained a priory, a collegiate church, and, according to Hals, thirteen other churches, or free-chapels. The remains and foundations of ſome of their religious ſtructures ſtill exiſt; and the ſites of others are remembered by the old inhabitants. Among theſe were the priory with its chapel, &c. St. Peter's church, St. Paul's church, on the northern ſide of the town, of which a ſolitary ſquare tower remains; St. Nicholas, or the friary. The preſent town-hall and ſeſſion houſe occupy the ſite, and are conſtructed with parts of the latter building. The firſt religious foundation of Bodmin was removed to it from Padſtow, a town on the northern coaſt of the county, which being much infeſted by the Saxons and Danes, was the reſort of the monks for greater protection and ſafety. Here they eſtabliſhed the priory, and its various dependent buildings; all of which gradually decayed after the removal of the ſee. The town occupies the northern face of a hill, and conſiſts principally of one long ſtreet ſtretching eaſt and weſt. Near the eaſtern end of it is the pariſh church, a large ancient ſtructure, conſiſting of three aiſles, and a tower which is attached to the north ſide. The chancel part is certainly the moſt ancient, and was formerly connected with the priory-building. An old chapel, now appropriated to a ſchool-room, ſtill remains near the eaſt end of the church, and a little farther eaſt is a neat modern manſion, occupying the ſite of the domeſtic part of the priory. A monument richly and curiouſly ſculptured, of one of the priors of this houſe, is carefully preſerved in the chancel. This was made to commemorate the name and official character of Thomas Vivian, who was biſhop of Megara, and died in 1533.

Bodmin is diſtinguiſhed among the numerous boroughs of Cornwall, as being the only one free from the controul of a patron. It was firſt made a borough in the time of Henry II. and its privileges were afterwards confirmed by king James I. who incorporated it in the 15th year of his reign. In 1799, a new charter was obtained, which veſted the government in a town clerk, twelve aldermen, and twenty-four common council-men, who hold the ſole privilege of electing two members for parliament. About half a mile N.W. of the town is a regular, commodious county gaol, which was begun building in 1779, from deſigns by Sir John Call, who planned it according to the ſyſtem recommended by the philanthropic Howard.

Bodmin gave birth to Dr. Richard Lower, an ingenious phyſician and anatomiſt, who made various experiments on the transfuſion of blood from one animal into another. This town has a market on Saturday, is 235 miles ſouth weſt from London, and contains 278 houſes, and 1951 inhabitants.

BODOBRICA, in *Ancient Geography*. See Baudobricum.

BODODO, in *Geography*, a town of Africa, in the kingdom of Benin, containing about 50 houſes, or little cabins, built of reeds and covered with leaves. Here a viceroy has his reſidence, attended by a council, whoſe juriſdiction extends over this canton in all civil affairs, levying taxes, and rating duties and impoſts on merchandize. In criminal caſes

of

of great importance, the viceroy and council are obliged to ſend to Benin, the capital, for the orders of the court.

BODOK, a diſtrict of Lower Hungary, in the province of Nitra, containing 101 large villages.

BODON. See WIDIN.

BODROG, a diſtrict of Hungary, near the Danube, 30 miles S. E. of Colocza, inhabited by Ruſſians and a few Hungarians.—Alſo, a river of Upper Hungary, which has its ſource in the Carpathian mountains, and diſcharges itſelf into the Theis near Tokay.

BODTY, in *Zoology*, the name of a certain kind of American ſnake, ſuppoſed to be of the *amphiſbæna* tribe, but of which this ſpecies is apparently doubtful. The ſame ſnake is likewiſe called Ibijara.

BODUNGEN, *Great*, in *Geography*, a market town of Germany in the circle of Upper Saxony, and county of Klettenberg, 5 miles north of Bleicherode. *Little Bodungen* lies in the bailiwick of Lora, 4 miles north of Bleicherode.

BODWELL's FALLS, lie in Merrimack river, between Andover and Methuen, in North America, about 5 miles below Patucket falls.

BODY, in *Phyſics*, a ſolid, extended, palpable ſubſtance; of itſelf merely paſſive, and indifferent either to motion or reſt: but capable of any ſort of motion, and of all figures and forms.

The word alludes to the Saxon *bodige*, *ſtature*; and to the Belgic *boode*, *a cover*, q. d. *the tabernacle of the ſoul*. Body is compoſed, according to the Peripatetics, of *matter*, *form*, and *privation*; according to the Epicureans and Corpuſcularians, of an aſſemblage of hooked, heavy *atoms*; according to the Carteſians, of a certain quantity of *extenſion*; according to the Newtonians, of a ſyſtem or aſſociation of ſolid, maſſy, hard, impenetrable, moveable *particles*, ranged or diſpoſed in this or that manner; whence reſult bodies of this or that form, diſtinguiſhed by this or that name. Theſe elementary or component particles of bodies muſt be infinitely hard; vaſtly harder than the bodies compounded of them; nay, ſo hard as never to wear, or break in pieces. "This," ſir Iſaac Newton obſerves, "is neceſſary in order to the world's perſiſting in the ſame ſtate, and bodies continuing of the ſame nature and texture in ſeveral ages."

BODY, *affections of*. See AFFECTION.

BODY, *colours of*. See COLOUR.

BODY, *elements of*. See ELEMENT.

BODY, *eſſence of*. See ESSENCE.

BODY, *exiſtence of*. See EXISTENCE.

BODY, *extenſion of*. See EXTENSION.

BODY, *modes of*. See MODE.

BODY, *motion of*. See MOTION.

BODY, *qualities of*. See QUALITY.

BODY, *ſolidity of*. See SOLIDITY.

BODY, *ſolid*, that whoſe particles cohere, or are ſome way connected with each other. See SOLID.

BODY, *fluid*, that whoſe particles eaſily ſlide over each other, and are of a fit ſize to be agitated by heat; or that whoſe particles do not cohere, but are eaſily put in motion by the ſmalleſt force. See FLUID.

BODY, *rough*, that whoſe ſurface is beſet alternately with eminences and cavities, in contradiſtinction from a ſmooth body.

BODIES, *ductile*, thoſe which being ſtretched do not break, but extend one way as much as they ſhrink another. Of theſe ſome are hard and malleable, as metals; others, ſoft or viſcid, as glues, gums, &c. Mem. Acad. Scien. an. 1713. p. 268.

BODIES, *flexible*, thoſe which admit of being bent without breaking: ſuch are thread, wire, fibres, and even glaſs, when ſpun very fine. Theſe are contradiſtinguiſhed from brittle bodies.

BODIES, *ſpecific gravity of*. See GRAVITY, and WEIGHT.

BODY, *denſe*. See DENSITY.

BODY, *rare*. See RARE.

BODY, *luminous*, or *lucid*, that which emits its own rays, or ſhines by its own light.

BODY, *illuminated*, that which diffuſes the light of another by reflection, or which ſhines by borrowed light.

BODY, *opake*, that which intercepts the rays of light, or prevents their paſſage through it.

BODY, *tranſparent*, *diaphanous*, or *pellucid*, that which tranſmits the rays of light. See TRANSPARENCY.

BODY, *the inertia of*. See VIS *inertiæ*.

BODIES, *homogeneous*. See HOMOGENEOUS.

BODIES, *congruous*, thoſe whoſe particles have the ſame magnitude and velocity, or at leaſt harmonical proportions of magnitude and velocity.

BODIES, *incongruous*, thoſe which have neither the ſame magnitude, nor the ſame degree of velocity, nor an harmonical proportion of magnitude and velocity.

BODY, *hard*. See HARD.

BODY, *volatile*, that which riſes by the force of heat. See VOLATILE.

BODIES are divided into *animate* and *inanimate*; i. e. into thoſe informed by a ſoul, and thoſe which are not; or thoſe that have life and thoſe that have none.

Some conſider bodies, either as *natural* and *ſenſible*; viz. as formed by phyſical cauſes, and clothed by phyſical qualities (in which ſenſe, body makes the object of phyſics); or, as *intellectual* or *quantitative*, in the general or abſtract; and according to three dimenſions: in which ſenſe, body makes the ſubject of geometry.

BODIES, *alkaline*, *conſiſtent*, *elaſtic*, *fixt*, *heterogeneous*, *atmoſphere of*, *deſcent of*, *mercury of*. See the ſeveral articles.

BODY, with regard to animals, is uſed in oppoſition to *ſoul*; viz. for that part of an animal, compoſed of bones, muſcles, canals, juices, nerves, &c. concerned in digeſtion, circulation, &c.

In which ſenſe, body makes the ſubject of comparative anatomy. See ANATOMY.

BODY, *faculties of the*. See FACULTY.

BODY is alſo applied by anatomiſts to ſeveral particular parts of the animal fabric.—As, the callous body of the brain, the cavernous or ſpongeous bodies of the penis, &c.

BODY, *reticular*. See RETICULAR.

BODY, in ſpeaking of a horſe, denotes the cheſt, but chiefly the flanks.

A horſe is ſaid to have a good body, when he is full in the flank; a light body, when he is thin or ſlender in the flank. If the laſt of the ſhort ribs be at a conſiderable diſtance from the haunch-bone, though ſuch a horſe may have a tolerable body for a time, if he be much laboured, he will loſe it. It is a general rule never to buy a horſe that is light bodied and fiery, becauſe he will preſently deſtroy himſelf.

BODY *of a plant*, in *Botany*. See BOTANY.

BODY *of a piece of ordnance*, in *Gunnery*, that part comprehended between the centre of the trunnions and the caſcabel. It ought always to be more fortified than the reſt. See CANNON.

BODY *of a pump*, in *Hydraulics*, the thickeſt part of the barrel or pipe of a pump, within which the piſton moves. See PUMP.

BODY, in *Geometry*, denotes the ſame with ſolid, which ſee.

BODIES, *regular*, or *Platonic*, are thoſe which have all their ſides, angles, and planes, ſimilar and equal.

Of

Of theſe there are only five; viz. the *tetrahedron*, conſiſting of four angles; the *octahedron*, of eight; the *icoſahedron*, of twenty; the *dodecahedron*, of twelve pentagons; and the cube of ſix ſquares. See REGULAR *bodies*; ſee alſo TETRAHEDRON, &c.

BODY, in *Law*.—A man is ſaid to be bound or held in *body and goods*; that is, he is liable to remain in priſon in default of payment.

A woman, though in other reſpects ſhe cannot engage her perſon but to her huſband, may *be taken by the body*, when ſhe carries on a ſeparate trade.

BODY *of the place*, in *Fortification*, denotes either the buildings incloſed, or more generally the incloſure itſelf. Thus, to conſtruct the body of the place, is to fortify or incloſe the place with baſtions and curtains.

BODY is alſo uſed for an aſſemblage of ſeveral different things collected into one; more particularly a number of perſons united into a company or college.

A ſtate or nation, under the adminiſtration of one ſovereign, is called a *body politic*. All large empires are unnatural, becauſe the relation between the head and limbs is here too remote. No body, either natural or politic, can long remain ſound without exerciſe. See CORPORATION.

BODY, *corps*, in *War*, is an aggregate or aſſemblage of forces, horſe and foot, united and marching under ſome chief.

An army, ranged in form of battle, is divided into three bodies: the van-guard, the rear-guard, and the main body; which laſt is ordinarily the general's poſt.

BODY *of reſerve*, in the *Military Art*, a draught or detachment of a number of forces out of an army, who are only to engage in caſe of neceſſity.

BODY, in matters of *Literature*, a name given to a collection of whatever relates to any particular ſcience; thus we ſay, the body of the canon law; the body of the Saxon law. King James I. had a deſign to compile a body of the Engliſh law.

The body of the civil law conſiſts chiefly of the Inſtitutes, Pandects, Code, and Novels. A *gloſſated* body, is that to which gloſſes are added in the margin, compoſed by ſeveral lawyers.

BODY is alſo uſed figuratively for conſiſtence, ſolidity, and ſtrength. In this ſenſe, we ſay the body of a cloth, wine, &c.

Vintners have divers arts of increaſing or diminiſhing the body of wine.

BODY, among *Painters*.—A colour is ſaid to *bear a body*, when it is capable of being ground ſo fine, and mixing with the oil ſo entirely, as to ſeem only a thick oil of that colour; as white-lead, lamp-black, vermillion, lake, indigo, &c. But verditers, ſmalts, &c. will not embody with the oil, but are ſtill apt to ſeparate from it in working.

BODY *plan*, or plane of projection, in *Ship-building*, is a ſection of the ſhip at the midſhip frame, or broadeſt place, perpendicular to the ſheer and half-breadth plans. The ſeveral breadths, and the particular form of every frame of timbers, are deſcribed on this plane. As the two ſides of a ſhip are ſimilar to each other, it is therefore unneceſſary to lay down both, hence the frames contained between the main frame and the ſtem are deſcribed on one ſide of the middle line, commonly on the right-hand ſide; and the after frames are deſcribed on the other ſide of that line.

BODZELIN, in *Geography*, a town of Poland, in the palatinate of Sandomirz, 24 miles ſouth of Radom.

BOE, in *Ancient Geography*. See BOÆ.

BOE, a ſmall iſland of Norway, 25 leagues north of Bergen.—Alſo, a town of Norway, 18 miles north of Bergen.—Alſo, a town of Norway, 12 leagues north of Romſdale.

BOEBE, in *Ancient Geography*, the name of a lake or marſh in the iſland of Crete. Steph. Byz.

BOEBIS, or BOEBIAS, a lake which ſome place in Bœotia, was ſituated near the confines of Magneſia, not far from mount Oſſa. It has been ſince called the lake of Eſero. North of this lake was a town called *Boebe*, whence the lake derived its name.

BOECE, or BOEIS, HECTOR, Lat. *Boethius*, in *Biography*, a celebrated Scottiſh hiſtorian, was born of an ancient family at Dundee, about the year 1470. After having ſtudied in his native place, and alſo at Aberdeen, where he was profeſſor in 1497, he went for further improvement to Paris, where he became a profeſſor of philoſophy, and where he had an opportunity of cultivating an acquaintance with ſeveral literary perſons of eminence, and particularly with Eraſmus. Upon the eſtabliſhment of the king's college at Aberdeen, by Dr. Elphinſton, the biſhop, about the year 1500, Boethius was ſent for by the founder, and appointed principal of that univerſity, and contributed, in concurrence with his colleague Mr. Hay, to furniſh the kingdom with ſeveral excellent ſcholars. After the death of Elphinſton, his patron, in 1515, he wrote his life, together with an account of his predeceſſors, under the title of "Vitæ Epiſcoporum Murthlacenſium et Aberdonenſium," Paris, 1522, 4to. He then engaged in his great undertaking of writing the hiſtory of Scotland, to which he prefixed a large geographical deſcription of the country. This hiſtory was publiſhed under the title of "Scotorum Hiſtoria ab illius gentis origine," Paris, 1526, fol.; and he continued to improve it till his death, which happened about the year 1550. The firſt edition of this work conſiſted of 17 books, and ended with the death of king James I. The next edition, printed at Lauſanne and Paris, in 1574, fol. was much enlarged by the addition of the 18th and part of the 19th books. It was afterwards carried down to the end of the reign of James III. by J. Ferrerius, a native of Piedmont. The whole hiſtory was tranſlated into the Scottiſh dialect by John Bellenden, archdeacon of Murray, by command of James V. and publiſhed in 1536. R. Holinſhed publiſhed it in Engliſh, with conſiderable additions, in the firſt volume of his Chronicles. This work has been differently appreciated by national partiality on the one hand, and national prejudice on the other. Whilſt it is allowed the merit of elegance and purity of ſtyle, it is charged with detailing marvellous tales and legends, and with introducing imaginary and fictitious circumſtances, in order to ornament and dignify the antiquity of the Scots nation. As to his general character, Boethius was a great maſter of claſſical and polite learning, well ſkilled in divinity, philoſophy, and hiſtory; but too credulous, and much addicted to the belief of legendary ſtories. With regard to his other accompliſhments, he was diſcreet, genteel, well-bred, attentive, generous, affable, and courteous. Biog. Brit.

BOECKEL, JOHN, born at Antwerp in November 1535, was admitted doctor in medicine at Bourges in 1564. At Hamburgh, where he went to reſide, he was ſoon diſtinguiſhed for his ſuperior ſkill, and appointed teacher of anatomy and medicine, an office he filled with ſufficient reputation, ſeveral years. He died there March 21ſt, 1605. His works are "De peſte quæ Hamburgum civitatem, anno 1565, graviſſimé afflixit," Henricopoli, 1577, 8vo.; "Synopſis novi morbi, quem plerique catarrhum febrilem vocant, qui non ſolum Germaniam, ſed pene univerſam Europam graviſſimé

viſſimé afflixit," Helmſ. 1580, 8vo. This may be conſidered as the carlieſt record of the contagious catarrhal fever, which has many times ſince viſited the world, and which has, in this country, been familiarly denominated the influenza. "Anatomia vel deſcriptio partium corporis humani," Helmſ. 1585, 8vo. The text book from which the author gave his lectures, "De philtris. Utrum animi hominum his commoveantur, necne?" a queſtion much agitated at that period of the world, but long ſince laid aſleep. Haller. Bib. Anat. Eloy Bib. Hiſt. Med.

BOECLER, John-Henry, an eminent German philologiſt, was born at Cronheim in Franconia, in 1610, and preferred, at the age of 21, on account of his great learning, to the office of profeſſor of eloquence at Straſburg. In 1648 he was invited to Sweden by queen Chriſtina, and appointed to the chair of eloquence at Upſal, and to the office of royal hiſtoriographer; but being obliged by ill health to quit the country, he became profeſſor of hiſtory at Straſburg. He was counſellor both to the elector of Mentz and to the emperor, and received a penſion from Louis XIV. He died in 1692. His principal works are "Commentationes Plinianæ;" "Timur, vulgo Tamerlanus," 4to. 1657; "Notitia Sti. Romani Imperii," 1681, 8vo.; "Hiſtoria, ſchola principum;" "Bibliographia critica," 1715, 8vo.; "Diſſertationes Academicæ," 3 vols. 4to. 1710; "Animadverſiones in Polybium," 4to. 1681; "Commentatio in Grotii librum de jure belli et pacis," 4to. 1712. He wrote, beſides, Latin commentaries on various ancient authors, and ſeveral tracts on German hiſtory. Nouv. Dict. Hiſt.

BOEDROMIA, in *Antiquity*, from βοηδρομος, *helper*, derived from βοαω, *I cry*, and δρεμω, *I run*, ſolemn feaſts held at Athens, in memory of the ſuccour brought by Ion, ſon of Xuthus, to the Athenians, when invaded by Eumolpus, ſon of Neptune, in the reign of Erectheus. Plutarch gives another account of the boedromia, which, according to him, were celebrated in memory of the victory obtained by Theſeus over the Amazons, in the month Boedromion, called by the Corinthians "Panemos;" which was, in the ancient chronology, the third month of the Athenian year. It conſiſted of thirty days, and anſwered to the latter part of our Auguſt and beginning of September.

BOEHM, in *Biography*. See Behmen.

BOEHMER, Philip Adolphus, ſon of Juſtus B. profeſſor of anatomy at Hall in Saxony, under whom he received his education; was admitted doctor in medicine in 1736. As he applied his mind particularly to the ſtudy of midwifery, he gave for his inagural theſis, "De precavenda polyporum generatione." His next diſſertation, which was publiſhed in 1741, in 4to. was "Situs uteri gravidi, ac fœtus, ac ſede placentæ in utero." In this he has given a critical examination of the midwifery forceps uſed in England, which he compares with, and prefers to Leuret's. Theſe pieces were added by the author to his edition of ſir Richard Manningham's "Compendium artis obſtetriciæ," publiſhed in 1746, 4to. Having acquired celebrity by theſe and other works, he was adopted member of the Acad. Nat.-Curios. and foreign aſſociate of the Royal Academy of Surgery at Paris. He was alſo appointed to ſucceed his father as profeſſor of anatomy and medicine in the univerſity at Hall. In 1749 he publiſhed "Inſtitutiones oſteologicæ, in uſum prelectionum," 8vo. Haller particularly commends in this work the engravings of the embryos, and ſome fœtal ſkeletons. His "Obſervationum anatomicarum, faſciculus primus," folio, was publiſhed in 1752. Among many rare and curious objects are, an engraving of a pregnant uterus, to ſhew the membrana decidua, and a fœtus in one of the Fallopian tubes, with the placenta. The ſecond collection, alſo in folio, publiſhed in 1756, contains a ſmaller fœtus in one of the tubes, and a child with two bodies and only one head. For the titles of the remainder of his diſſertations, ſee Haller. Bib. Anat. and his collection of medical theſes, in which the greater part of them is inſerted.

BOEHMERIA, in *Botany* (named by Jacquin in honour of George Randolph Boehmer, profeſſor of anatomy and botany at Wittenburg), a genus of the claſs *monœcia tetrandria*, formed by Swartz for three plants, not deſcribed by Linnæus, natives of the Weſt Indies, to which he added two others, the urtica cylindrica, and the caturus ramiflorus of Linnæus. It conſtitutes a connecting link between urtica and parietaria. Nat. Ord. *ſcabridæ. Urticæ* Juſſieu. Schreb. 1421. Jacq. Americ. 246. Swartz. prod. 34. Juſſieu. 403. Gen. Char. Male flowers on the ſame plant with the female, either diſtinct or mixed. *Cal.* perianth one-leafed, four-parted to the baſe; ſegments lanceolate, acute, ſomewhat erect, coloured. Schreb. (tubular, Juſſieu and Boſc). *Cor.* none. *Nect.* none. *Stam.* filaments four, longer than the calyx, awl-ſhaped, erect; anthers roundiſh, ovate. Female flowers, *Cor.* none. *Piſt.* germ ovate, compreſſed; ſtyle filiform, erect, permanent; ſtigma ſimple, pubeſcent. *Pericarp*, none. *Seed*, roundiſh, compreſſed, margined. Schreb. (ſingle, very ſmall, encloſed in the permanent calyx. Juſſ. Boſc). The flowers are ſeparated from each other by numerous, denſe, ovate-acuminate, bractes or ſcales.

Species, 1. B. *caudata*. Brown Jam. 238. "Leaves oppoſite, ovate, acute, ſerrate; racemes very long, pendulous; flowers diœcous; ſtem ſuffruticoſe." A ſhrub ten or twelve feet high. Brown calls it the nettle-tree. 2. B. *littoralis*. "Leaves oppoſite, ovate-lanceolate, ſerrate; flowers conglomerate, axillary, monœcous, mixed; ſtem herbaceous, four-cornered." Native of Hiſpaniola. 3. B. *cylindrica*. "Leaves oppoſite, ovate, acuminate, ſerrate; racemes ſpiked, axillary, erect, ſimple." An annual plant, with a lucid, herbaceous ſtalk, dividing into ſeveral branches; leaves with three longitudinal veins; on pretty long petioles. A native of North America and Jamaica. 4. B. *ramiflora*. "Leaves alternate, broad-lanceolate, acuminate, ſerrate, wrinkled; flowers aggregate, axillary and lateral, monœcous, diſtinct. Males three-ſtamened." A ſhrub, eight feet high, with long branches; leaves ſickle-ſhaped, rugged, on very ſhort petioles, placed towards the ends of the twigs; very different in ſize, ſome being two inches, and others a foot in length on the ſame twig. Male flowers ſmall, yelloviſh, numerous, aggregate, on the leafleſs old branches. Female flowers whitiſh on the younger twigs to the very end. Native of Jamaica and other iſlands of the Weſt Indies. 5. B. *hirta*. "Leaves alternate, ovate, acute, ſerrate, hirſute; flowers monœcous, heaped, axillary, mixed." A native of Jamaica.

La Mark has not inſerted this genus either in the alphabetic part of the Encyclopedie, or in the ſubſequent ſyſtematic ſeries of figures. He follows Linnæus in referring the cylindrica to urtica, and the ramiflora to caturus.

BOEL, Peter, in *Biography*, an excellent painter of fruit, flowers, and animals, was born at Antwerp in 1625, and having been a diſciple of Snyders, whoſe widow he married, he went to Italy, where his uncle Cornelius de Waal reſided, and in his return through France was much employed, particularly at Paris, where he continued for ſome time. He died in 1680. As an artiſt he copied after nature, with a free and bold pencil, and a tint of colour that was natural and beautiful. There are ſome few ſlight, but ſpirited, etchings by Boel, from his own compoſitions, repreſenting various animals, &c. Cornelius Boel, who flouriſhed in 1611, and Coryn or Quirin Boel, who flouriſhed in 1660, both engravers, were of the ſame family. Pilkington. Strutt.

BOELE-

BOELE-BOELE, in *Geography*, a diſtrict of the iſland of Celebes, ſituated in the bay of Boni, at and near a river of the ſame name. To the weſt it has Wauwo Woele; to the ſouth, the river Caſſa; to the north, the river Tanka; and to the eaſt, the ſhores of the bay. It is ſometimes called *Tellolimpoe*, and has three chief townſhips, viz. Boele boele, Lamant, and Radja, which are all independent of each other. The kings of Boni conſider it as an appendage of their crown.

BOELE-COMBA, a territory of Celebes, which was anciently a ſeparate kingdom, but in later times it was ſubjugated by the Macaſſers; and is become one of the provinces belonging to the Dutch Eaſt India company. It ſtretches from the river Kalenkongang, which divides it from Bontain, to Bera, or rather to the river Bampang, which runs between them; to the north of it lie the mountains of Kyndang, which ſeparate it from Boni, or rather from the highlanders of Touraayo; and to the ſouth, it is waſhed by the ſea. The land is fertile in rice, and abounds in game and extenſive foreſts; but the timber is not adapted to the conſtruction of houſes. When the weſt monſoon renders it dangerous for ſhips to lie in the road before Boele-Comba, they run into the river Kalckongang, near the mouth of which ſtands the paliſadoed fort Carolina, in which the reſident of the Dutch Eaſt India company, who is a junior merchant, has his abode. The province of Bera reaches from the river Bampang eaſtward, along the ſea-coaſt to the point of Laſſem or Laſſoa, and thence northward to the point of Cadjang; and on the land ſide, it borders upon Boele-Comba, Tourang, and Kadjang, belonging to Boelcboele. This country belongs to the Dutch company. It is barren and rocky, but has ſome woods which furniſh timber fit for building proas. The men are good warriors both by ſea and land; the richeſt are merchants; and others employ themſelves in building proas, and in manufacturing a ſort of coarſe white cloth from the cotton which the place ſupplies.

BOELON. See Bælon.

BOEN, in *Geography*, a town of France in the department of the Loire, and chief place of a canton in the diſtrict of Montbriſon, ſeated on an eminence near the river Lignon; 6 leagues ſouth of Roanne, and 3½ north of Montbriſon. The place contains 1220, and the canton 10,929 perſons; the territory comprehends 305 kiliometres, and 22 communes.

BOENAC, in *Ichthyology*, a ſpecies of Bodianus, deſcribed by Dr. Bloch. The body is of a clear olivaceous colour, marked with ſeven oblique brown bands; and the caudal fin is rounded. This fiſh is mentioned as a native of the ſeas about Japan, where it is called ycan boenac.

There are ſeven rays in the gill membrane of this ſpecies, fifteen in the pectoral fin, ſix in the ventral fin, eleven in the anal fin, fixteen in the caudal fin, and twenty-five in that on the back.

BOENASA, in *Ancient Geography*, a town of Cappadocia, in the interior of the Galatic Pontus. Ptolemy.

BOEON, a town placed by Ptolemy in the interior of the Taurie Cherſoneſus.

Boeon, or Bœlo, a town of Greece, in the Doric region, according to Thucydides, near mount Parnaſſus. This was one of the four cities which, according to Pliny, Strabo, and Steph. Byz. gave the name of "Tetrapolis" to the country poſſeſſed by the Dorians, near mount Oeta.

BOEONUS, *Diu*, an iſland of India, according to the Periplus of the Erythræan ſea, placed by M. d'Anville at the ſouth-weſt entrance of the "Barygazenus ſinus."

BŒOTIA, a name given to two ancient kingdoms of Greece; one founded, or rather reſtored, by Cadmus, and called by him Bœotia, from the ox (*bos*), which is ſaid to have directed him to the place where he built the capital of his kingdom, afterwards known by the name of Thebes; the other in Theſſaly, ſaid to have been founded by Bœotus, the ſon of Neptune, and brother of Œolus, by Arne, the daughter of Œolus king of Œlis. This Bœotus, according to Bryant (Anal. Anc. Myth. vol. ii. p. 326.), from whom the Bœotians are ſuppoſed to be deſcended, and from whom this country is ſaid, by ſome, to have derived its name, was an imaginary perſonage, and merely a variation of Boutus and Butus, the ark; which in ancient times was indifferently ſtyled Theba, Argus, Aren, Butus, and Bœotus. This Bœotus of Greece, according to the mythology of this writer, is the ſame with Boutus of Egypt, Battus of Cyrene, and Buto or Budde of the Indians. The hiſtory of the origin of this kingdom is intermixed with fables; but it is more certainly known, that the poſſeſſors of this ſettlement held it for more than 200 years; and that when they were expelled from it by the Theſſalians, they fought a new eſtabliſhment in that country, which till that time had been called Cadmeis, and which was then named Bœotia. We are informed by Diodorus and Homer, that theſe Bœotians ſignalized themſelves at the Trojan war; and the latter adds, that five of Bœotus's grandſons were the five chiefs who led their Bœotian troops thither. Whatever be the true etymology of the name Bœotia, given to this country, it was diſtinguiſhed by ſeveral other appellations, according to its ſuppoſed founders: thoſe, who aſcribed it to Ogyges, called it Ogygia; others called it Cadmeis, from Cadmus; and by others it was denominated Aonia, from Aon, the ſon of Neptune; and Hyanthis, from Hyas, the ſon of Atlas. It is now called Stramulippa; and Thebes, its ancient capital, Thive, and, corruptly by the Greeks, Stibes or Stives.

It bordered on the eaſt with Attica, and was in time joined to it, being parted from it by the mountain Cithæron; on the north, it was bounded by the ſtreight Euripus, now called the Negropont; on the weſt it had the kingdom of Phocis; and on the ſouth, the gulf of Corinth. Its utmoſt extent from eaſt to weſt was 1° 10′, and it was nearly of the ſame length from north to ſouth, but approaching to a point eaſtward. Ephorus, from Strabo, calls it μονη τριθαλαττος, *ſola trimaris*, becauſe it was contiguous to three ſeas; and by means of its commodious havens it could carry on a commerce on one ſide with Italy, Sicily, and Africa; and on the other, with Egypt, the iſle of Cyprus, Mauritania, and the Helleſpont. It had alſo the large lake Copais, and the two large rivers, the Aſopus and Iſmenus, beſides other ſtreams, by which it was watered and rendered fertile. This country is partly hilly, eſpecially Aonia, properly ſo called; the reſt is low and flat, and abounding with excellent paſturage and corn; but the air was ſo denſe and foggy, that Horace thought it influenced the genius of the inhabitants. The Bœotians, in general, were reckoned not to poſſeſs that penetration and vivacity, which characterized the Athenians, whoſe air was remarkably pure, though ſeparated from them only by mount Cithæron; but this, perhaps, might have been attributed more to education than to nature. As they employed their time more in bodily than in mental exerciſes, they were deficient with reſpect to that facility of expreſſion, thoſe graces of elocution, the knowledge derived from ſtudy, and thoſe pleaſing manners, which are more the work of art than nature. But it ſhould not be ſuppoſed, that Bœotia produced no men of genius. Several Thebans have done honour to the ſchool of Socrates. Epaminondas was not leſs diſtinguiſhed for his knowledge than

for his military talents. It ſhould alſo be remembered, that Bœotia was the birth-place of Heſiod, Corinna, and Pindar. Its moſt remarkable places were the Trophonian cave, Theſpia, Aulis, the ſtraits of Thermopylæ and Thebes, which ſee reſpectively.

The government of Bœotia was altogether monarchical, and peculiarly deſpotic, the will of the kings being the law; and of theſe ſome governed more like tyrants than moderate ſovereigns. Plutarch, in his "Morals," mentions an ancient cuſtom that prevailed among them; which was the manner of introducing their new-married women into their new habitations. They were brought home in a kind of chariot, or cart, the axle-tree of which was immediately burnt, thus intimating to the bride, that ſhe was fixed with her huſband for life, and muſt not expect to return to her parents.

The Bœotians, as to their general character, were courageous, inſolent, and vain; and with them the tranſition was very ſhort from paſſion to inſult, and from a contempt of law to a total diſregard of the dictates of humanity. The ſmalleſt expectation of advantage gave occaſion to the groſſeſt acts of injuſtice; and murders were frequently the conſequence of the moſt frivolous quarrels. The women were tall, well-formed, and generally of a fair complexion; and their voice was remarkably ſweet and tender; whereas that of the men was harſh and diſagreeable, and in ſome meaſure ſuited to their character. Of this character for inſolence and ferocity, which generally diſtinguiſhed the Bœotians, no traces were to be found in a body of young warriors, called the "Sacred Battalion," conſiſting of 300, who were brought up together, and maintained at the public expence in the citadel. Their exerciſes, and even their amuſements, were regulated by the melodious ſounds of the flute. To prevent their courage from degenerating into blind fury, care was taken to inſpire them with the nobleſt and the moſt animated ſentiments. From this band each warrior choſe a friend, to whom he remained inſeparably united, whom it was his ambition to pleaſe, and to ſhare his pleaſures and ſufferings in life, and his labours and dangers in battle. Theſe 300 warriors were at one time diſtributed in troops at the head of the different diviſions of the army. Pelopidas, who had frequently the honour of commanding them, having made them fight in a body, the Thebans were indebted to them for almoſt all the advantages they gained over the Lacedæmonians. Philip deſtroyed this cohort, that had been invincible, at Cheronæa; and the prince, when he ſaw theſe young Thebans ſtretched on the field of battle, covered with honourable wounds, and lying ſide by ſide on the ground on which they had been ſtationed, could not reſrain from tears, but bore a noble teſtimony to their virtue as well as to their valour. Plut. in Pelop. t. 1. p. 287.

For the ſucceſſion of the kings of Bœoti, after Cadmus, and the hiſtory of the kingdom as a monarchy, ſee THEBES. The Bœotians, after having expelled their kings, who had reigned in ſucceſſion from Cadmus to Xanthus, for about 300 years, formed themſelves into a republic, of which the chief magiſtrates were the prætor, or ſtrategos, the Bœotarchi, and the Polemarchi. The authority of the prætor, who was choſen from among the Bœotarchi, laſted only a year, and reſembled that which was veſted in the prætors of Achaia and Ætolia. The Bœotarchi aſſiſted him with their advice, principally in time of war, and commanded under him; and they conſtituted the ſupreme court in military affairs; ſo that the prætor could not act in a manner contrary to their determinations. They alſo bore a great ſway in the civil adminiſtration, and hence derived their title. Their number was uncertain, being 7, 9, or 11; they were choſen yearly, and obliged by law, as well as the prætor, to reſign their office, on pain of death, before the firſt month of the new year was expired. The Polemarchi were altogether civil magiſtrates; it being their province to maintain peace and concord at home, while the Bœotarchi were employed in the wars of the republic. Beſides theſe officers, there were four councils, in which the whole authority of the ſtate conſiſted. Theſe were compoſed of the deputies that were ſent by all the cities of Bœotia; and without their approbation, the Bœotarchi could not declare war, make peace, conclude alliances, or tranſact any buſineſs of importance. The Bœotians, and eſpecially the Thebans, were continually haraſſed by the princes of Macedon; nevertheleſs, they took part with Philip againſt the Romans, and could not be prevailed upon by the Athenians and Achæans to deſert him, and to join the other ſtates of Greece, till he was entirely defeated in the famous battle of Cynoccephalæ. They then, foreſeeing their danger, ſent deputies to Flaminius, imploring his protection. He received them with great humanity, and put them upon the ſame footing with the other allies of the republic in Greece. Flaminius, at their requeſt, obtained the releaſe of the Bœotians who ſerved in the Macedonian army; but, notwithſtanding this favour granted them by the interpoſition of the proconſul, they neglected to make the neceſſary acknowledgments, and filled up all vacant offices with perſons who were enemies to Rome, and attached to the intereſts of Macedon. Flaminius was exaſperated by this conduct; and Brachyllus, their prætor, was murdered by the friends of Rome. The murderers, however, were diſcovered, and one of them, Piſiſtratus, was put to death. For this murder of their prætor the Bœotians determined to be revenged; and they took occaſion to aſſaſſinate all the Romans whom they found wandering about in the fields. In conſequence of this outrage, Flaminius ravaged their territories; but, upon their conſenting to deliver up the offenders, he deſiſted from any further acts of ſeverity; and the Bœotians, duly apprized of his lenity, continued ever afterwards faithful to the Romans. But as ſome of their leading men joined Perſes, king of Macedon, in his wars againſt the Romans, the whole country was, on that account, treated with great ſeverity; Rome being at this time under no apprehenſion of an invaſion from Antiochus, as ſhe was when Flaminius was ſo eaſily appeaſed. At the diſſolution of the Achæan league, Bœotia, with the reſt of Greece, was reduced to a Roman province. See ACHÆANS.

BOER, in *Geography*, a town of Germany, in the circle of the Lower Rhine, and county of Reeklinghauſen, 6 miles W.S.W. of Reeklinghauſen, and 42 N. of Cologn.

BOERHAAVE, HERMAN, in *Biography*, a profeſſor of medicine and chemiſtry, of ſuch eminence as to form a new æra in theſe ſciences, was born at Voorhout, about two miles from Leyden, in Holland, the 31ſt of December 1668. His father, James Boerhaave, the paſtor of the village, having nine children, took on himſelf the care of their education; and, as he intended Herman for the church, he was careful to ground him well in Greek and Latin. In theſe languages he made ſuch rapid progreſs, that when he was only fourteen years of age, his father ſent him to complete his education to the public ſchool at Leyden; and, in 1684, he went from thence to the univerſity. His father dying ſoon after, and in ſlender circumſtances, the progreſs of our young ſtudent's attainments would have been interrupted but for the friendly aſſiſtance afforded him by Daniel Van Alphin, burgomaſter of Leyden, who furniſhed him with the means of continuing his ſtudies. The kindneſs of this worthy man was remembered by Boerhaave, with gratitude, to the end of his life. He now applied to the mathematics, and to acquire a knowledge of the Hebrew and Chaldee languages; propoſing, agreeably to the intentions

of his father, to qualify himſelf for the miniſtry: and that he might relieve his patron from a part of his expence, for his ſuſtenance, he gave private leſſons to the ſtudents in mathematics, and here probably laid the foundation of that excellence in the art of communicating knowledge by lectures, for which he in time became ſo celebrated. In 1690, he took his degree in philoſophy, and gave for his inaugural theſis, "De diſtinctione mentis a corpore," in which he refutes, in a ſolid and judicious manner, the errors of Hobbs and Spinoſa. This, however, did not prevent his being ſuſpected of Spinoſiſm, which made him quit his intention of entering into the ſervice of the church, and turn his mind to medicine, particularly to the ſtudy of chemiſtry, as more ſuited to the activity of his diſpoſition. To acquire a knowledge of anatomy, he read the works of Veſalius, Fallopius, and Bartholine, and attended diſſections under Nuck. In medicine, he ſtudied Hippocrates, and the reſt of the Greek and Latin writers in ſucceſſion, but returned to Hippocrates, whoſe works were always mentioned by him with veneration. Among the moderns, he gave the preference to our countryman Sydenham, whom he called the Divine Sydenham.

Thus qualified, in 1693, being 25 years of age, he was admitted by the univerſity of Harderwyck, in Guelderland, to the degree of doctor in medicine. His theſis on this occaſion was "De utilitate explorandorum excrementorum in ægris, ut ſignum." To the urine he paid the greateſt attention. He now applied to the practice of medicine, from which, however, he is ſaid to have derived but little profit. As his practice, therefore, employed but a ſmall portion of his time, he had leiſure for examining all the theories of medicine which had prevailed, in ſucceſſion, from the earlieſt time, and of forming from them a theory, if far from perfect, much leſs exceptionable than any that had preceded it; and which, when matured, ſuperſeded them, and became the reigning doctrine over all Europe for more than half a century. Drelincourt, who had long been profeſſor of the theory of medicine, dying in 1701, the univerſity of Leyden ſeized the opportunity this event afforded them of attaching him further to that place, by placing him in the vacant chair. This they were prompted to by gratitude as well as by prudence; Boerhaave having refuſed an advantageous offer of ſettling at the Hague, and, though in no public office or capacity, he had already acquired a conſiderable reputation, and drawn a great many foreigners to Leyden, to hear his lectures in chemiſtry. On the occaſion of this promotion he read his "Oratio de commendando ſtudio Hippocratico." In Hippocrates, he particularly admired the correctneſs of his deſcriptions and hiſtories of diſeaſes, his patience in attending to the indications of nature, or the conſtitution, to which, with little interference, he frequently committed the cure of the diſeaſe, and his honeſt and ſincere account of the termination of the diſeaſe, whether in health or death. In this he has not been always followed by writers of caſes. In 1703, he was invited to accept a profeſſor's chair at Groningen; but as he had refuſed, when much leſs known, an eſtabliſhment at the Hague, he had no difficulty, now that his fame was more extended, and pupils were flocking to him from all parts, in rejecting this offer. The univerſity at Leyden thought it neceſſary to reward this freſh proof of his attachment to the country, by augmenting his ſalary. About this time he delivered his "Oratio de uſu ratiocinii mechanici in medicina." Theſe compoſitions were all publiſhed; and as they were drawn up, and poliſhed with care, they doubtleſs contributed in extending the fame of our profeſſor over Europe. On the death of Peter Hotton, curator of the univerſity garden, in 1709, he was appointed his ſucceſſor, and made profeſſor of botany. He now read his "Oratio qua repurgatæ medicinæ facilis aſſeritur ſimplicitas;" ſhewing that the knowledge of medicine would be eaſieſt obtained by avoiding hypotheſes, and attending to facts and obſervations; and that diſeaſes would be more certainly cured by uſing only a few choice and ſimple medicines, than by the heterogeneous compoſitions then in vogue. He now, in addition to his other ſtudies, employed himſelf ſedulouſly in acquiring a more extended knowledge of plants; and this continued to be his amuſement and delight to the end of his life. "Often have I ſeen," Haller ſays, "the good old man, moving ſlowly along the garden, at a very early hour in the morning, attending to the culture of the numerous exotics he had introduced there, claſſing and arranging them for his lectures." One year only after being appointed profeſſor in botany, he publiſhed "Index plantarum quæ in horto Lugduno Batavo reperiuntur," 8vo. This work was re-publiſhed by him in 1720, much enlarged and improved, including a hiſtory of the garden, 2 vols. 8vo. In 1709, appeared his "Aphoriſmi de cognoſcendis et curandis morbis," 8vo.; "aureus in ſumma brevitate libellus," Haller ſays. A work univerſally read and admired, on which baron Van Swieten, his illuſtrious pupil, who had attended his inſtructions for near twenty years, publiſhed his Commentaries, in 1742, extending it to five volumes in 4to. About the ſame time he publiſhed his "Inſtitutiones rei medicæ in uſus annuæ exercitationis domeſticæ," 8vo. Theſe two works, the one treating of the hiſtory and cure of diſeaſes, the other of the phyſiology of the human body, improved and enlarged at different times by the author, have paſſed through numerous editions, and have been printed in every country, and tranſlated into every language in Europe. Schulten ſays, there is a verſion of them alſo in the Arabic. Boerhaave was now in the zenith of his reputation, and had ſuch a confluence of ſtudents from all parts of the world, as never probably before occurred to any one profeſſor. He gave lectures on the theory of medicine, in botany, and in chemiſtry, and delivered them with ſuch clearneſs and preciſion, as to fill his pupils with equal aſtoniſhment and delight. Haller, who was two years under his tuition, ſpeaks of him with enthuſiaſm. "Vix ſui parem habuit." We have hardly ſince ſeen, and perhaps may never again ſee his equal. In 1714, he was made rector of the univerſity. On laying down this office at the end of the year, he read his diſcourſe "De comparando certo in phyſicis." It is only to be acquired, he ſays, by experiment, and by a careful and minute examination of natural objects. Bidloo dying at this time, he was advanced to the chair of profeſſor in the practice of medicine; and, on the death of Le Mort, in 1718, he was made profeſſor of chemiſtry. He was now at the head of every branch of medicine; and his pupils were become ſo numerous, Dr. Matty ſays, that Leyden was ſcarcely ſufficiently capacious to contain them. In addition to theſe numerous vocations, he was frequently conſulted, in caſes of difficulty and danger, by phyſicians in all parts of the world.

With theſe advantages, it will not excite ſurpriſe, that his wealth ſhould accumulate and become extremely abundant. As his diet was frugal and ſparing, and he was plain in his apparel, he has been accuſed of being too parſimonious; but it ſhould be conſidered, that attached as he was to ſcience, and immured in buſineſs of ſuch variety and magnitude, he had no time for expence or luxury, except in what regarded the improvement of ſcience. In procuring rare and valuable books, and in collecting plants from diſtant countries for his garden, he ſpared, we are told, no expence.

In 1718, Boerhaave had publiſhed "De Chemia, ſuos errores expurgante," which was all he purpoſed giving on that ſubject; but ſome of his pupils having, at the inſtigation, he ſays, of the bookſellers, ventured to print, in his name,

name, tranſcripts of his lectures, ſo incorrectly taken as to materially injure his fame, to vindicate himſelf from the diſgrace this might bring upon him, he found himſelf under the neceſſity of preparing his lectures for the preſs; and, in 1732, he publiſhed them under the title of "Elementa Chemiæ, quæ anniverſario labore docuit, in publicis privatiſque ſcholis, Hermannus Boerhaave," 2 vols. 4to. The work is dedicated by a moſt affectionate addreſs to his brother James Boerhaave. The firſt volume contains the hiſtory and the theory of the art, and is furniſhed with numerous engravings and deſcriptions of furnaces, and other inſtruments of chemiſtry. The ſecond contains the proceſſes, or operationes chemicæ. In the firſt volume he gives a catalogue of all the works he had publiſhed, preceding it, with much modeſty, with this declaration; "Sciaſque, me nihil edidiſſe unquam, præter ſequentia, quæ non abſque verecundia recenſenda puto." At the back of the title-page he ſays, "Ut certus ſit lector, hunc librum a me editum prodire, propria manu adſcribendum putavi; nec pro meo agnoſco, ubi hæc adſcriptio abeſt, Hoerhaave;" uniting, as his cuſtom was, the H and the B.

The character of Boerhaave, as a chemiſt, is thus given by Macquer, in his Preliminary diſcourſe to his Dictionary of Chemiſtry. "Next to Stahl we place the immortal Boerhaave, though he excelled in a different way. This powerful genius, the honour of his country, of his profeſſion, and of his age, threw light upon every ſubject which he treated. To the view which he took of chemiſtry, we owe the fineſt and moſt methodical analyſis of the vegetable kingdom; his admirable treatiſes on air, on water, and on earth, and particularly on fire, which is an aſtoniſhing maſter-piece, is ſo complete, that the human underſtanding can ſcarcely make an addition to it." To his moral character his diſciple Haller bears the following honourable teſtimony: "Some, though few, will rival him in erudition; his divine temper, kind to all, beneficent to foes and adverſaries, detracting from no man's merits, and binding by favours his daily opponents, may, perhaps, never be paralleled." In his converſation he was eaſy and familiar, and in his demeanour grave and ſober, but at the ſame time diſpoſed to pleaſantry, and occaſionally indulging in good-humoured raillery; ſo that he was compared to the admirable Socrates, whoſe buſt he is alſo ſaid to have reſembled in features. By his pupils, whom he regarded with the kindneſs of a parent, he was beloved and reſpected in a very high degree. Piety formed a diſtinguiſhing feature of his character; and devotion was his daily exerciſe.

As Boerhaave was of an athletic make, had accuſtomed himſelf to exerciſe on horſeback, to ſpend much of his time in the open air, and to uſe a frugal and plain diet, he had been enabled thus far to endure the extreme fatigue of his profeſſional labours, with only ſome occaſional interruptions from illneſs; but being grown corpulent, and incapable of riding, his conſtitution began to be on the decline, ſo that, in 1729, he found it neceſſary to reſign his offices of profeſſor in chemiſtry and botany. The ſpeech he made on this occaſion, was publiſhed under the title of "Oratio cum cathedræ chemiæ et botanices valediceret," 4to. In this he recounts ſome of the moſt memorable occurrences of his life, and ſpeaks with gratitude of the patronage and favours he had received from individuals, in enabling him to chuſe his walk in life, as well as from the members of his own profeſſion, who had admitted his improvements in the theory and practice of the arts he taught, with more kindneſs and leſs oppoſition than is uſually given to innovators of any kind. This doubtleſs aroſe in part from the great learning and abilities he was known to poſſeſs, and from the high reputation he had thence acquired, demanding reſpect; and partly from his diſpoſition, averſe from contention, and thinking but modeſtly of his endowments. From whatever cauſe it might ariſe, there was never perhaps ſo great a revolution in any ſcience brought about with ſo little oppoſition as was made to that produced by Boerhaave. He had before, viz. in 1728, been admitted foreign aſſociate of the Royal Academy of Sciences in Paris; and in 1730, he was elected a fellow of the Royal Society in London. The ſame year he was again made rector of the univerſity at Leyden. On quitting that office, he read his "Oratio de honore medici ſervitute," which was alſo publiſhed in 4to. In this he again inſiſts on the neceſſity of attending to the method nature takes in curing diſeaſes, or the manner in which they terminate ſpontaneouſly, as practiſed by Hippocrates. Though this ſucceſſion from public employment procured him ſome reſpite from his labours, he ſtill continued reviſing and correcting his original works. He alſo ſpent much of his time in reviſing the works of other writers, and publiſhed more correct editions than were before extant; as the "Opera Anatomica et Chirurgica And. Veſalii," fol.; Albinus contributed to this work; of Bellinus, "De urinis et pulſibus," 4to. 1730; of Proſper Alpinus, "De præſagienda vita et morte," 4to. 1733; Aretæus, "De cauſis, ſigniſque morborum," fol. 1731; Luiſinus, "De lue venerea," fol. 1728, and ſome other works. Still, however, he enjoyed eaſe and relaxation from the more fatiguing part of his buſineſs, and he paſſed the principal part of his time, during the remainder of his life, at his manſion, a ſmall diſtance from Leyden, in domeſtic recreations, with his wife and daughter, to whom he was much attached. Here he had a garden well-ſtocked with every thing that could contribute to his pleaſure, and here he amuſed himſelf with his violin, in which he was a proficient. Towards the end of the year 1737, he became ſenſibly affected with difficulty of breathing, and a ſenſe of ſuffocation, which incommoded him, whether walking or lying down. This went on increaſing; and a ſmall time before his death, he perceived a ſtrong pulſation on the right ſide of his neck, which he attributed to a polypous concretion in the aorta. No remedy being competent to combat this dreadful diſeaſe, he expired calmly, in the midſt of his family, on the 23d of September 1738. He was buried in the church of St. Peter's at Leyden, where his fellow-citizens erected an elegant monument to his memory. The pedeſtal is of black marble, ſupporting an urn, decorated with emblematic figures, repreſenting the four ages of man's life, and the ſciences in which he excelled. On one face of the pedeſtal is a medallion with the head of Boerhaave, ſurrounded with ſuitable decorations, his ſeal hanging under it, on which is engraved his favourite motto, "Simplex ſigillum veri," ſimplicity the ſeal of truth; and underneath, "Salutifero Boerhavii genio ſacrum," ſacred to the health-reſtoring genius of Boerhaave.

In the courſe of this ſketch of the life of Boerhaave, his principal works have been noticed; for a more complete catalogue of them, ſee Haller's Bib. Med. Pract. Anatom. et Botan. and Eloy's Dict. Hiſt.

Boerhaave, Abraham Kaan, profeſſor of medicine in the univerſity of Peterſburgh, was born at the Hague in 1715. He was the ſon of James Kaan, and of Margaret the daughter of Herman Boerhaave. After receiving a good claſſical education, he went to Leyden, where applying to the ſtudy of medicine, under the celebrated Albinus Gaubius, and other maſters, he was admitted to the degree of doctor in 1738. He had before obtained an honorary medal from the univerſity, for his diſcourſe, "De gaudiis Alchemiſtarum;" though he was more particularly attached to anatomy, which he cultivated with great ſucceſs. The year following he took the name of his uncle Boerhaave. In

1740 he went to Peterſburgh, where his talents ſoon procured him the ſituation of profeſſor in medicine in the univerſity there, and of one of the members of the imperial academy. By Portal and Blumenbach, he is called archiater, or aulic counſellor, and firſt phyſician to the empreſs, confounding him with his brother, Herman Kaan B. who about the ſame time enjoyed that honour. In the courſe of a ſevere and tedious illneſs, from which he with difficulty recovered, he loſt his hearing. This happened in 1749. He died in 1753. His works are "Perſpiratio dicta Hippocrati, per univerſum corpus anatomicè illuſtrata," Lugd. B. 1738, 12mo; in which he ſhews there is a conſtant inhalation, or abſorption, and an exhalation, or perſpiration, carried on, not only on the ſurface of the body, but in all the principal cavities. "Impetum faciens dictum Hippocrati per corpus conſentiens, philologicè et phyſiologicè illuſtratum," Lugd. Bat. 1745, 12mo. In this he treats of the action of the mind upon the body, by the means of the nerves; of the fabric and motion of the muſcles; on the effects of opium, given to a dog, &c. He alſo gave the anatomy of an elephant, which he had an opportunity of diſſecting, and of two monſtrous infants, and a diſſertation on what have been called, improperly he ſays, hermaphrodites; no real hermaphrodite having ever been produced. Haller. Bib. Anat. Portal. Bib. Chir.

BOERHAVIA, in *Botany*, (named by Vaillant in honour of the celebrated Boerhaave.) Lin. gen. 9. Schreb. 13. Reich. v. i. p. 6. Willden. 20. Juſſieu 91.; a genus placed by moſt botaniſts in the claſs *monandria monogynia*, though in different ſpecies, there are from one to four ſtamens. Nat. Ord. *Aggregatæ.—Nyctagenes.* Juſſieu.

Gen. Char. *Cal.* oblong, tubular and angular, placed beneath the coroll, with a contracted, entire mouth, permanent. *Coroll.* monopetalous, bell-ſhaped, upright, obtuſely five-cleft, plaited, fixed on the calyx. *Nect.* fleſhy, ſubcylindric, with a mouth ſlightly toothed, ſurrounding the baſe of the germ. *Stam.* filaments one, two, three, or four, inſerted on the margin of the nectary, between its teeth; capillary, near the bottom (within the calyx) more ſlender, upright, about the length of the corolla; anthers twin-globular. *Piſt.* germ roundiſh, pedicelled, the pedicel ſurrounded by the nectary; ſtyle thread-ſhaped, twiſted, as long as the ſtamens; ſtigma capitate. *Pericarp.* none; calyx enlarged, cloſed, encruſting the ſeed. *Seed* one, oblong, obtuſe, angular. *Obſerv.* It is nearly allied to Mirabilis. The toothlets of the nectary are ſometimes triangular, very ſmall, and ſometimes obſolete.

Eſſ. Gen. Char. *Cal.* ſmall, entire. *Cor.* one-petalled, bell-ſhaped, plaited. *Seed* one, encruſted with the enlarged calyx.

Dahl has injudiciouſly aboliſhed this genus, and placed its ſpecies with the Valerians. In the opinion of Willdenow, it belongs properly to the claſs *triandria*, and may readily be diſtinguiſhed from valerian by its very entire calyx, ſo minute, as ſcarcely to be viſible, without the aſſiſtance of a lens, on which account it appears to have been overlooked by Linnæus and La Marck. Profeſſor Martyn, in his edition of Miller, has inadvertently given *Calyx* none, as part of its eſſential general character; though in the natural character tranſlated from Schreber, he had properly aſſigned it one.

Species, 1. B. *erecta*, upright hogweed. "Stem erect, ſmooth; *Stamens* two." Jacq. and Miller. "Stem tetragonal, ſmooth, with viſcous joints, and flowers in a corymboſe panicle." Willden. Stem two feet high, ſprinkled with very minute protuberances as fine as hairs. Leaves waved, ovate, acute, rough at the margin, growing by pairs on long petioles from the joints of the ſtem, which are placed at a conſiderable diſtance from each other. Corolls cylindric, white, with five reddiſh ſhades; ſegments acute, with ſmall teeth interpoſed. Stigma capitate. Diſcovered by Dr. Houſton at La Vera Cruz in 1731, and ſince found at the Society Iſles. 2. B. *adſcendens*. "Leaves oblong-ovate, ſomewhat fleſhy; flowers panicled; peduncles two-flowered; ſtem aſcending." Willden. Stem ſmooth, tetragonal; leaves petiolate, oppoſite, veined, entire, ſmooth; the young leaves and the margin and petioles of the older ones hairy; hairs jointed as in veronica aphylla; panicle terminal, ſpreading, naked; peduncles two-flowered, involved in membranaceous bractes; fruit club-ſhaped, rough, with ſmall tubercles. A native of Guinea. Willden. 3. B. *diffuſa*. "Stem ſmooth and even, ſpreading; leaves ovate." Linn. "Stem round, pubeſcent; flowers in corymboſe heads." Willden. Leaves white underneath; flowers purple, with one ſtamen. A native of the Eaſt and Weſt Indies. Cultivated in the royal garden at Hampton Court 1690. Mr. Miller received ſeeds from Jamaica by Dr. Houſton. 4. B. *hirſuta*. "Stem ſpreading, pubeſcent; leaves ovate, repand, or ſerpentine." Reich. "Stem roundiſh, hairy; flowers in heads." Willden. Stems a foot high; peduncles axillary, ſuſtaining ſmall cloſe heads of ſcarlet diandrous flowers, which generally fall off in about half a day. A native of Jamaica. 5. B. *plumbaginea*. "Leaves ſubcordate, orbiculate-acute, pubeſcent beneath; flowers in umbels." Willden. Umbels axillar, on long peduncles; coroll of a pale roſe colour; ſtamens three; fruit turbinate, ſtriated, crowned at the apex with pedicelled tubercles. Willden. A native of Spain. 6. B. *ſcandens*. La Marc, Tab. 4. "Stem erect; flowers two-ſtamened; leaves cordate, acute." Linn. "Stem erect, flowers two-ſtamened, in umbels; leaves cordate." Willden. Stem ſhrubby, very ſtiff, ſmooth, with alternate branches; leaves ſmooth; umbels of ſix green flowers; involucre of five leaves. A native of the rocky coaſts of Jamaica and other Weſt India iſlands. Cultivated in 1691, in the royal garden at Hampton court. 7. B. *excelſa*. "Stem erect; lower leaves cordate-ovate, upper ones ovate, flowers with three ſtamens in umbels." It reſembles the ſcandens, but differs from it in its taller ſtem, in its upper ovate leaves, in its doubly larger purple flowers, and in the number of its ſtamens. Native place unknown. Deſcribed by Willdenow from a living plant. 8. B. *repanda*. "Stem erect; leaves cordate, repando-ſinuate; flowers in umbels, with three ſtamens." Willden. Reſembles the ſcandens, but differs from it in its herbaceous ſtem and oppoſite branches and peduncles. A native of India and China. 9. B. *chærophilloides*. (Valeriana Chærophylloides. Smith Ic. ined. faſc. 3.) "Leaves bipinnatifid, toothed; flowers with three ſtamens in umbels." Willden. It has entirely the habit of a Boerhavia, and agrees in all the generic characters, excepting only the ſtyle which is trifid. 10. B. *repens*. "Stem creeping." Linn. Native of Nubia, between Mocho and Tangos. 11. B. *anguſtifolia*. "Leaves linear, acute." Linn. Native place unknown. 12. B. *tetrandra*. Stem creeping; flowers with four ſtamens. Forſt. Prod. 2. Native of the Society Iſles, found by Forſter in the iſland of Huaheine 1774.

Theſe are all the ſpecies in Willdenow's edition of the Sp. Pl. La Marck (Illuſt.) has made the hirſuta and the repens the ſame as the diffuſa, and appears to have been unacquainted with the adſcendens, plumbaginea, excelſa, repanda, chærophylloides, anguſtifolia, and tetrandra; but has inſerted two others, which, as far as can be determined from their ſpecific characters, ſeem to be diſtinct ſpecies. B. *paniculata*. "Stem erect; leaves ovate, acute; panicle naked, filiform, very viſcous." A native of South America. B. *tuberoſa*. "Stem erect, ſhrubby; root tuberoſe, eſculent." A native of Peru. The following may poſſibly be the hirſuta, though he unites that ſpecies with the diffuſa. B. *obtuſifolia*. "Stem procumbent, ſpreading, viſcidly pubeſcent;

cent; leaves ovate, obtuſe; umbels ſmall, ſomewhat in heads, lateral." A native of South America,

Propagation and Culture. None but the firſt, third, fourth, and ſixth, have been cultivated in England. They will not thrive in the open air, but muſt be raiſed from ſeeds, and treated like other tender exotic plants. The firſt three are annual, and when they grow too tall to remain under a common frame, may be planted in a warm border, where, if the ſeaſon prove favourable, they ripen their ſeeds; but a plant or two ſhould always be placed in the ſtove, to enſure a ſucceſſion of ſeeds. The fourth, which is perennial, may be preſerved in a warm ſtove two or three years. See Martyn's Miller.

BOERNÆR, Frederic, in *Biography*, profeſſor in medicine at the univerſity of Wittemburg, in Saxony, and an active member of the Acad. Nat. Curioſ. received his education at Leipſic, where he was born, June 17, 1723. He publiſhed ſeveral diſſertations on medical ſubjects, but his principal work is "Noctes gnelphicæ, five opuſcula medico-literaria," Roſtock, 1755, 8vo. He died June 1761. Eloy. Dict. Hiſt.

BOERNERIANUS *Codex*, in *Biblical Hiſtory*, a MS. of part of the N. T. noted G, in the ſecond part of Wetſkin's N. T. It belonged to Dr. C. F. Boerner, was collated by Kuſter, and deſcribed in the preface to his edition of Mill's Greek Teſtament. It contains the epiſtles of St. Paul, that to the Hebrews excepted, which was formerly rejected by the church of Rome; it is written in Greek and Latin, according to one of thoſe verſions, which were in uſe before the time of Jerom. The Latin is interlined between the Greek, written over the text, of which it is a tranſlation. Stemmler ſuppoſes that the Latin was written ſince the Greek; but profeſſor Matthäi, who publiſhed this MS. at Meiſſen in Saxony in 1791, ſuggeſts, that an uniformity in the hand-writing, and a ſimilarity in the colour of the ink evince, that both the Greek and Latin texts proceeded from the ſame tranſcriber. That it is an ancient MS. appears, ſays Michaelis, from the form of the characters, and the want of accents and marks of aſpiration. It ſeems to have been written in an age when the tranſition was making from the uncial to the ſmall characters; and from the correſpondence of the letters *r*, *s*, and *t*, in the Latin tranſlation, to that form which is found in the Anglo-Saxon alphabet it is inferred, that this MS. was written in the Weſt of Europe, and probably between the 8th and 12th centuries. This MS. is preſerved at preſent in the electoral library at Dreſden: and a copy of it is kept in the library of Trinity college, Cambridge, among the books and MSS. that were left by Dr. Bentley. Michaelis on the N. T. by Marſh, vol. ii. and iii.

BOERO, in *Geography*. See Burro.

BOESCHOT, a town of Brabant, on the river Nethe; 12 miles N. E. of Malines.

BOESEROENS, or Budgeroons, three ſmall uninhabited iſlets of the Eaſt Indies, ſituated in the ſtrait that lies between the iſland Saleyer and the point of Celebes, called Laſſem. Theſe three iſlands almoſt block up the paſſage between the ſouthern part of Celebes and the northern part of Saleyer, the whole ſpace between which is about a league and a half. The ſtrait is paſſed between the ſouthernmoſt and middlemoſt, or between the latter, and the northernmoſt of the Budgeroons. This is one of the moſt dangerous parts of the navigation for ſhips ſailing to or from the Moluccas, or ſpice iſlands; and it cannot be avoided without going round to the ſouth of Saleyer, which is a much more dangerous route, on account of the great number of ſhoals and ſunken rocks, which abound there, and are not accurately laid down in the charts.

BOESIPPO. See Bæsippo.

BOETHICUS, in *Entomology*, a ſpecies of Hesperia, (Pleb. Rur. Linn.) that inhabits India. The wings are tailed, bluciſh-brown, pale aſh colour beneath, and undulated with whitiſh; a double ocellar ſpot in the anal angle.

BOETHIUS, Anicius Manlius Torquatus Severinus, in *Biography*, deſcended from one of the moſt illuſtrious conſular families of Rome, lived in the time of the emperor Zeno, near the end of the 5th century. He was born at Rome about 470, the ſame year with Martianus Capella, another Roman writer on muſic. He is ſaid to have ſpent 18 years in the ſchools of Athens, purſuing the ſtudy of philoſophy under Proclus; others, however, have queſtioned this fact, and it has generally been allowed, that the term of 18 years is too long. Nevertheleſs, his viſit to Athens is juſtified by much internal evidence, adduced by Brucker, (Hiſt. Crit. Philoſ. t. iii. p. 524—527.) and by an expreſſion, though vague and ambiguous, of his friend Caſſiodorus, (Var. i 45.) "longé poſitas Athenas introiti." It is certain, that the erudition of the Latin language was inſufficient to ſatiate his curioſity, and that he devoted much of his time and attention to the ſtudy of Grecian ſcience and letters. From a letter of Caſſiodorus, written in the name of Theodoric, it appears that he had the honour of introducing to the Romans, in their own language, the muſic of Pythagoras, the aſtronomy of Ptolemy, the arithmetic of Nicomachus, the geometry of Euclid, the logic of Ariſtotle, and the mechanics of Archimedes. He alone was eſteemed capable of deſcribing the wonders of art, a ſun-dial, a water-clock, and a ſphere which repreſented the motions of the planets. He commented upon parts of Ariſtotle, Cicero, and Porphyry; and from the commendations which he beſtows upon the latter, as the beſt interpreter of the former, he ſeems to have united the Platonic with the Ariſtotelian doctrine. Boethius ſeems to have been the firſt who applied ſcholaſtic philoſophy to the ſervice of Chriſtian theology; and he employed himſelf in defending the orthodox creed againſt the Eutychian, Arian, and Neſtorian hereſies, in a treatiſe "De Unitate et Uno. In civil life he attained to peculiar honours; as he was conſul in 487, and alſo in 510; and he was alſo created patrician, and advanced to the poſt of maſter of the offices. He married the daughter of his friend, the patrician Symmachus, and he enjoyed the peculiar ſatisfaction of ſeeing his two ſons elevated to the conſulate together in 522. Few perſons paſſed through life with a greater ſhare of outward reſpect and honour; and few could be more diſtinguiſhed by the teſtimonies that were given to his benevolence and liberality, his virtue and patriotiſm, as well as to his ſingular talents and learning. His own aſſeveration claims our aſſent, that he had reluctantly obeyed the divine Plato, who enjoined every virtuous citizen to reſcue the ſtate from the uſurpation of ignorance and vice. For the integrity of his public conduct he appeals to the memory of his country. His authority had reſtrained the pride and oppreſſion of the royal officers; he had always pitied, and often relieved, the diſtreſs of the provincials, whoſe fortunes were exhauſted by public and private rapine; and he alone had the courage to oppoſe the tyrrany of the Barbarians, elated by conqueſt, excited by avarice, and, as he complains, encouraged by impunity. In theſe honourable conteſts, his ſpirit ſoared above the conſideration of perſonal danger, and perhaps of prudence. In addition to his other learned labours, he had formed a deſign of tranſlating all the works of Plato and Ariſtotle into Latin; but was prevented from executing his purpoſe by a premature death. Having for ſome years enjoyed the favour of Theodoric, the Gothic king of Italy, he was at length ſuſpected of being hoſtile to his

his government, and of concurring with others, and particularly with Albinus, who was accuſed and convicted on the preſumption of *hoping*, as it was ſaid, the liberty of Rome. "If Albinus be criminal," exclaimed Boethius in the preſence of the king, "the ſenate and myſelf are guilty of the ſame crime. If we are innocent, Albinus is equally entitled to the protection of the laws." The advocate of Albinus was ſoon involved in the danger and perhaps the guilt of his client; their ſignature, which they aſſerted to be a forgery, was affixed to the original addreſs, inviting the emperor Juſtin to deliver Italy from the Goths; and three witneſſes of honourable rank, but probably of infamous character, atteſted the treaſonable deſigns of the Roman patrician. Upon this kind of evidence, Boethius was committed to cuſtody, and rigorouſly confined in the tower of Pavia; and a ſervile ſenate, at the diſtance of 500 miles, pronounced a ſentence of confiſcation and death againſt the moſt illuſtrious of its members. During his confinement, he compoſed his treatiſe "De conſolatione philoſophiæ," mentioned in the ſequel of this article; and at length the executioners of Theodoric's mandate fulfilled the ſavage commiſſion with which they had been entruſted, or, perhaps, even exceeded it, by the mode of putting him to death. Some ſay that he was beheaded; but others relate, that a ſtrong cord was faſtened round his head, and forcibly tightened, till his eyes almoſt ſtarted from their ſockets; and he was then beaten with clubs till he expired. This event happened, according to ſome, in the year 526, but according to others in 524. Boethius, in his laſt hours, derived ſome comfort from the ſafety of his wife, of his two ſons, and of his father-in-law, the venerable Symmachus. But Symmachus, perhaps indiſcreet in the mode of teſtifying his grief, was ſometime after dragged in chains from Rome to the palace of Ravenna, and there put to death, A. D. 525. Theodoric, it is ſaid, experienced the bitterneſs of ſelf-reproach, and the anguiſh of an unavailing repentance for the murder of theſe two illuſtrious ſenators, Boethius and Symmachus. His daughter Amalaſuntha is ſaid to have reſtored to the ſons of Boethius the confiſcated eſtates of their father.

His celebrated tract on muſic, divided into five books, was firſt printed in black letter, with his treatiſes on arithmetic and geometry, at Venice, 1499. It is remarkable, that in this copy the Greek of the famous *ſenatus conſultum*, againſt Timotheus at Lacedæmon, is omitted; though it was afterwards found in a beautiful MS. of Boethius, *De muſica*, 15 B. IX. of the 11th century, in the Britiſh Muſeum, where the infamous chromatic (χρωμάτος) is ſaid to have been ſubſtituted by that muſician to their grave and ſimple enharmonic (ἐναρμονίου), in the ſame manner as it is printed in the Oxford edit. of Aratus. (See Diſſert. on the Muſ. of the Ancients, p. 27.)

It ſeems neceſſary here to give ſome account of this famous treatiſe on muſic by Boethius, which, to read, was long thought neceſſary to the obtaining a muſical degree in our univerſities; and which, with great parade, has been ſo frequently praiſed, quoted, and pronounced, by writers on that art, to be of the greateſt importance to every muſician, yet contains nothing but matters of mere ſpeculation and theory, tranſlated from Greek writers of higher antiquity; which, if neceſſary to be known at this time, would be more profitably ſtudied in the original; but the theory of every art being vain and uſeleſs, unleſs it guide and facilitate practice, the definitions, calculations, and reveries of Boethius, are no more uſeful or eſſential to a modern muſician than Newton's *Principia* to a dancer.

In the proemium, or introduction to his firſt book, "De Muſica," he treats of the *morality* of muſic, and gives us all the old ſtories concerning its miraculous powers of exciting virtue, repreſſing vice, curing diſeaſes, &c. And in this book we find whence Zarlino, and all the Italian writers on muſic, down to Padre Martini, drew their extenſive diviſions of muſic into *mundane*, *human*, and *inſtrumental*. For Boethius ſays, "Tres eſſe Muſicas," lib. i. cap. 2. So had Ariſt. Quintilianus informed us, long before the birth of Boethius. And as far as we are able to divine at preſent concerning theſe diſtinctions, the ancients meant by *mundane* muſic, the muſic of the ſpheres. By human, or humane muſic, the perfect organization of our frame, and the union of ſoul and body. By the laſt only, the inſtrumental, we are brought to real muſic, by the grateful production and union of tuneful ſounds.

Then we have definitions, ſuch as are given in Euclid and all the Greek writers, on harmonics and ſpeculative muſic in Meibomius. After which, we have the doctrines of proportion and ratios, inſtituted by Pythagoras, who would not truſt to the various and fallacious judgment of the ſenſes, but had recourſe to reaſon and calculation to ſettle his doubts. The account of the diſcoveries and harmonial laws eſtabliſhed by Pythagoras, not only inſerted in Boethius, but all ſubſequent writers, is taken from Nicomachus, one of the ſeven Greek writers on muſic in Meibomius. In the ſame book, we have a very ſuperficial and unſatisfactory account of the genera. But we are indulged with ſeveral chapters on the muſic of the ſpheres from "Cicero de Repub." lib. vi. where the ſuppoſed analogy between the planets and the ſeptenary, or ſeven ſounds in muſic, is aſſerted.

At the cloſe of this book, chap. xxxiv. Boethius eſtimates theory and ſpeculation far above practice in muſic. But what, we may aſk, is the uſe to the world of ſuch a theory as he deſcribes, without practice? Or, indeed, practice, without the ſupport of what is now underſtood by theory? The ſpeculative theoriſts, confined to meditation and experiments in harmonics, talk of muſic without hearing it; and the mere practician hears it, without underſtanding it. Boethius allows him only to be a muſician who can examine, judge, and give reaſons for what is done. Here we have the origin of the verſes aſcribed to Guido:

Muſicorum et cantorum,
Magna eſt diſtantia, &c.

The whole ſecond book is relative to the diſpute between the Pythagoreans and Ariſtoxenians, which is not yet ſettled, about dividing the ſcale, whether by the ear, or by numbers. All the muſicians in Europe are now diſputing whether we ſhould temper our ſcales on fixed inſtruments, or adopt the triple progreſſion of Pythagoras, and tune by perfect 5ths. See Triple Progression, and Temperament. We have here the tone-major and tone-minor to diſcuſs; which we talk about, but never feel or think of the diſtinction in our modulation or performance. The *apotome*, *comma*, and *limma*, are left for the amuſement of ſpeculative harmoniſts to talk about, and for muſicians to practiſe with their ears and fingers, *ſans y penſer*.

In the third book, Boethius continues his controverſy with the Ariſtoxenians, and proves what has been long ſettled, that there is no ſuch thing in muſic as a literal *half-note*. The octave is ſaid to contain five tones and two ſemitones; and in the temperament of equal participation, the twelve ſemitones of the octave muſt be nearly equal.

In book iv. the ſubject is purſued of ſplitting of tones; for the ancients could "divide and ſubdivide a tone from ſouth to ſouth-weſt ſide."

We were very much diſappointed formerly at the non-performance of a promiſe made book v. at chap. 3. the title of which is "Muſicarum per Græcas ac Latinas literas notarum nuncupatio." But Meibomius ſays the promiſe does not extend to the Roman notation in the Seldon MS. at Oxford; nor had the Romans any notation of their own

in

in the time of Boethius; and all the muſical terms he uſes are Greek, as were thoſe of Vitruvius.

Even the eulogiſts of Boethius confeſs, that his work is ſo purely theoretic, that in reading it we never think of practice. Let us leave it then to philoſophers who are content with imaginary ſounds. The mention of inſtruments, or of the voice as employed in ſinging, never occurs. No alluſions to the muſic of his time, but all is abſtract ſpeculation, tending doubtleſs to the perfection of the art, but ſeeming little connected with it. The harmony he talks of is more the *harmonia mundi* of Kepler, than that of Handel and Haydn. Guido ſaid, that Boethius's work was only fit for philoſophers. In the middle ages, ſo few underſtood Greek, that thoſe who were curious to know ſomething about the miraculous powers of that muſic, imagined that they ſhould find it in Boethius's tranſlation, who had been educated at Athens. Such ſpeculations are curious and amuſing, in moments of meditation, to ſcientific and inquiring minds; but practical muſicians, whether compoſers or performers, can afford little time for ſuch ſublime and ſpiritual amuſements. Nevertheleſs, he muſt be a dull and incurious profeſſor, who ſeeks not the reaſon of things, the principles of his art, and origin of ſounds. If he have a mathematical turn, let him read Galileo, Daniel Bartoli, D'Alembert, Holder, Rameau, Tartini, and Smith's harmonics. They are all intelligible, and lead to knowledge which he will be expected to poſſeſs; but for any thing uſeful that he can acquire from Boethius's ſpeculations, or from the Greek theoriſts, his prototypes, that will make him a better compoſer or performer, the caſe is hopeleſs. Yet there are, who, after allowing that "it was of ſo little uſe in practical muſic, that they never thought of it in reading Boethius;" yet returning afterwards to former prejudices, it is inſiſted on, that "he has communicated to the world ſuch a knowledge of the fundamental principles of the muſic of the ancients, as is abſolutely *neceſſary* to the right underſtanding of our own ſyſtem."

When we ſpeak of the inutility of Boethius's work on muſic to the muſical ſtudents of modern times, we preſume not to extend our cenſures further. The writings of this great and good man on other ſubjects have been too long held in reverence to be depreciated ſlightly. His moſt celebrated production was his ethic compoſition "De conſolatione philoſophiæ," and has always been admired both for the ſtyle and ſentiments. It is an imaginary conference between the author and philoſophy perſonified, who endeavours to conſole and ſoothe him in his afflictions. The topics of conſolation contained in this work, are deduced from the tenets of Plato, Zeno, and Ariſtotle, but without any notice of the ſources of conſolation which are peculiar to the Chriſtian ſyſtem. It is partly in proſe, and partly in verſe; and was tranſlated into Saxon by king Alfred, and illuſtrated with a commentary by Aſſer, biſhop of St. David's; and into Engliſh, by Chaucer and queen Elizabeth. It was alſo tranſlated into Engliſh verſe by John Walton, in 1410, of which tranſlation there is a correct manuſcript on parchment in the Britiſh muſeum. Few books have been more popular, eſpecially in the middle ages, or have paſſed through a greater number of editions in almoſt all languages. It has been obſerved by Mr. Harris, in his "Hermes," that "with Boethius the Latin tongue, and the laſt remains of Roman dignity, may be ſaid to have ſunk in the weſtern world." To the ſame purpoſe, Gibbon ſays, that "the ſenator Boethius is the laſt of the Romans, whom Cato or Tully would have acknowledged for their countryman." Fabr. Bib. Lat. tom. ii. p. 146, &c. Le Clerc, Bib. Choiſ. t. xvi. p. 168—275. Burney's Hiſt. Muſ. vol. ii. p. 31, &c. Gibbon's Hiſt. Rom. Emp. vol. vii. p. 43, &c. Brucker's Hiſt. Phil. by Enfield, vol. ii. p. 313.

BOETTICHER, Gottlieb, a phyſician of eminence, and in conſiderable practice at Berlin, during the early part of the laſt century, publiſhed various works on the theory and practice of medicine. The principal are, on the exiſtence of a nervous fluid, "De vera fluidi nervorum exiſtentia," Berlin, 1721, 4to.; "De morborum malignorum, imprimis peſtis et peſtilentiæ, explicatio," 4to. 1713; this has been ſeveral times reprinted. He contends, that the plague is contagious; and that the infecting effluvia may be retained, and conveyed in full vigour, in the clothes or bedding of the ſick, to diſtant countries; a doctrine that has been lately ſtrongly oppoſed. Pregnant women, affected with the plague, conſtantly part with the fruit of the womb before they die. Hypochondriac perſons, he thinks, are not ſuſceptible of the contagion. But in this he is probably miſtaken; as we know lunatics do not enjoy ſuch an exemption from contagious diſeaſes in this country. He recommends bleeding on the firſt attack of the fever, and then to have recourſe to ſudorifics. "De reſpiratione fœtus in utero," 4to. 1702. Haller. Bib. Med. et Anat.

BŒUF, Le, in *Geography*, a place in the north-weſtern corner of Penſylvania, at the head of the north branch of French creek, and 50 miles diſtant by water from fort Franklin, where this creek joins the Alleghany. The French fort of Le Bœuf, from whence the place has its name, lies about two miles eaſt from Small lake, which is on the north branch of French creek; and from Le Bœuf, is a portage of 14 miles northerly to Preſque iſle in lake Erie, where the French had another fort. N. lat. 42° 1'. W. long. 79° 53' 20".

Bœuf, in *Ornithology*, acording to Salerne, the common name of the bulfinch (*loxia pyrrhula*) in the canton of Sologne. The troglodyte, *ſylvia troglodytes* of Latham, is likewiſe called by the ſame name (*bœuf*) in Switzerland.

Bœuf *de Marais*. The French call the common bittern (*ardea ſtellaris*), becauſe it frequents marſhes, and has a loud cry, and emits a ſort of roaring noiſe that has been compared to that of an ox or bull, by this name. "Il n'y a," ſays Belon, "bœuf qui pût crier ſi haut."

Bœuf *d'Afrique*, in *Zoology*. By this name ſome French writers diſtinguiſh the buffalo; the epithet is miſapplied, becauſe that animal is equally common in India, whence indeed, it is ſuppoſed, the African buffalo firſt originated.

Bœuf *a Boſſe*, ſynonymous with *biſon*. By ſome it is likewiſe called *bœuf des Illinois*.

Bœuf *Guerrir*. Under this denomination the French deſcribe a race of African oxen, which the Hottentots call *backleys*; the word *backley* in their language ſignifying war, to the purpoſes of which they are trained up, in the ſame manner as elephants are by the Indians. War-oxen of this deſcription are inſtructed alſo to guard the herds of the common oxen.

Bœuf *de Mer*, in *Ichthyology*, is the name of the long-beaked ray, *raja oxyrinchus* of Linnæus.

Bœuf *de Mer*, in *Zoology*, the common French name for any of the Phocæ tribe of animals, correſponding with the general Engliſh name of *ſea-cow*.

BOFFRAND, Germain, in *Biography*, a celebrated French architect and engineer, was born at Nantes in 1667, and having been educated at Paris, he employed himſelf for ſome time in ſculpture, during the winter, and ſtudied architecture in the ſummer. His talents at length engaged the attention and patronage of Hardouin-Manſart, an eminent architect, who obtained for him a place in the commiſſion for the royal buildings. In 1709, he became a member of the Royal

Royal Academy of Architecture, and was much employed at Paris, and by ſeveral German princes, in furniſhing deſigns for various edifices. His ſtyle of building was grand and noble, and formed after the model of Palladio. He was likewiſe a ſkilful engineer, and conſtructed a great number of canals, ſluices, bridges, and ſimilar works. As architect to the general hoſpital of Paris, he gratuitouſly ſerved the inſtitution; and, as he was diſintereſted in his temper, he was lively and amuſing in converſation; and he indulged his taſte for literature by the compoſition of ſeveral pieces, adapted to the purpoſe of producing temporary gaiety and mirth, for the Italian comedy. His "Book of Architecture," with plates, was printed at Paris in 1745, folio; and contains an account of the general principles of the art, exemplified in his own works. In this work he has alſo introduced a curious memoir, deſcribing the method of caſting the bronze equeſtrian ſtatue of Lewis XIV. He retained his gaiety of diſpoſition to the age of 87 years, and died at Paris in 1755. Encycl. Hiſt. Gen. Biog.

BOFIN, Boffin, or Baffin *Lough*, in *Geography*, one of thoſe large lakes in Ireland into which the river Shannon expands, ſituated between the counties of Roſcommon and Leitrim.

BOG, derived from the Italian *buca*, a *hole*, or rather from the Belgic *boogen*, to *bend*, on account of its giving way when trod upon, in *Agriculture*, a quaggy ſort of earth, generally met with in low ſituations, covered with coarſe graſſes, but of ſo little ſolidity as to be incapable of ſupporting the tread of heavy animals; cauſed by the diſſolution, decay, and depoſition of different vegetable and other ſubſtances, from the ſtagnation and detention of the water that oozes along on the clayey or other thin tenacious ſtrata below, or which ſprings up through the fiſſures, or other openings of them. They are of different kinds, depths, and conſiſtencies, according to the different circumſtances of the caſe, and the nature of the ſituation of the ground on which they are formed, as well as that of the earthy material that enters into their compoſition. Dr. James Anderſon, in his treatiſe on draining bogs and ſwampy grounds, remarks, that clay is a ſubſtance that ſtrongly reſiſts the entrance of water into it; but, when it is long drenched with water, it is, in proceſs of time, in ſome meaſure, diſſolved thereby, loſing its original firmneſs of texture and conſiſtence, and becoming a ſort of ſemi-fluid maſs, which is called bog. And as theſe bogs are ſometimes covered with a ſurface of a particular kind of graſs, with very matted roots, which is ſtrong enough to bear a ſmall weight without breaking, although it yields very much; it is in theſe circumſtances denominated a *ſwaggle*.

But, whatever be the nature of the bog, it is invariably occaſioned by water being forced up through a bed of clay, as juſt deſcribed, and diſſolving or ſoftening a part thereof. A part is only mentioned, becauſe, whatever may be the depth of the bog or ſwaggle, it generally has a partition of ſolid clay between it and the reſervoir of water under it, whence it originally proceeds. For if this were not the caſe, and the quantity of water were conſiderable, it would meet with no ſufficient reſiſtance from the bog, and would of courſe, iſſue through it with violence, and carry the whole ſemi-fluid maſs along with it. This would more inevitably be the caſe, if there was at firſt a cruſt at the bottom of the bog, and if that cruſt ſhould ever be broken, eſpecially if the quantity of water under it was very conſiderable. And as it is probable that, in many caſes of this ſort, the water ſlowly dilutes more and more of this under-cruſt, no doubt is entertained but that in the revolution of many ages, a great many irruptions of this kind may have happened; although they may not have been deemed of importance enough to have the hiſtory of them tranſmitted to poſterity.

It has been remarked by Mr. King, in the Philoſophical Tranſactions, N° 170, that the ſprings, with which Ireland abounds, are generally dry, or nearly dry, in the ſummer time, and that graſs and weeds grow thick about the places where they burſt out. In the winter, he obſerves, they ſwell, run, ſoften, and looſen all the earth about them. The ſward or ſcurf of the earth, which conſiſts of the roots of graſs, being lifted up and made fuzzy by the water, at that ſeaſon (he has ſeen it lifted up a foot or two at the head of ſome ſprings), is dried in the ſpring, and does not fall together, but withers in a tuft, through which ariſes new graſs, which is alſo lifted up the next winter. By this means the ſpring is more and more ſtopped, and the ſcurf grows thicker and thicker, till at firſt it makes the appearance which we call a quaking bog; and as it grows higher and drier, and the roots of the graſs and other vegetables become more putrid, together with the mud and ſlime of the water, it acquires a blackneſs, and grows into that which we call a turf-bog.

It is, however, confeſſed, that there are quaking-bogs cauſed otherwiſe. When, it is obſerved, a ſtream or ſpring runs through a flat, the paſſage, if not kept open, fills with weeds in ſummer, trees fall acroſs it and dam it up; then in winter the water ſtagnates further every year, till the whole flat is covered. Afterwards a coarſer kind of graſs ſhoots up, peculiar to theſe bogs; this graſs grows in tufts, its roots conſolidate together, and its height increaſes every year, inſomuch that he has ſeen it as tall as a man. This graſs rots in winter, and falls on the tufts, and with it the ſeed, which ſprings up the next year; and ſo continues making an annual addition. Sometimes the tops of the flags and graſs are interwoven on the ſurface of the water, and this becomes by degrees thicker till it lies like a cover on it; then herbs take root in it, and by the matting of their roots, it becomes very ſtrong, ſo as to bear a man. He has gone on bogs which would riſe before and behind, and ſink where he ſtood to a conſiderable depth, under which was clear water.

It is further obſerved, that Ireland abounds in moſs more than any other country; this moſs is of divers kinds, and that which grows in bogs is very remarkable. The light ſpongy turf is nothing but a congeries of the threads of this moſs, before it be ſufficiently rotten; the turf then looks white, and is light. It has been ſeen in ſuch quantities, and ſo tough, that the turf-ſpades could not cut it. In the north of Ireland, they denominate it old-wives tow, being not much unlike flax. The turf-holes in time grow up with it again; and all the little gutters in bogs are generally filled with it. To this he chiefly imputes the red or turf bog; and from the ſame cauſe even the hardened turf, when broken, is ſtringy, though there plainly appear in it parts of other vegetables; and he is almoſt, from ſome obſervations, tempted to believe, that the ſeed of this bog-moſs begets heath, when it falls on dry and parched ground. However, the moſs is ſo fuzzy and quick-growing a vegetable, that it greatly ſtops the ſpring, and contributes to thicken the ſcurf, eſpecially in red bogs, where he remembers to have obſerved this moſt particularly. The ſituations of land may ſometimes contribute to the formation of bogs in it, as flat ſpots of ground lower than the level of an adjoining river or lake; for when that part is filled up by the ſlime and earth brought from the ſurrounding grounds, and the rotten plants and animals, which are buried in it, have choked it up, it will become a bog; and then the water will continue to flow into it from the river or lake, eſpecially when either of theſe is ſwelled by a fall of rain or melting of ſnow. Theſe waters may alſo ſometimes have

this

this effect, without a communication above ground, by ſoaking through a ſandy or gravelly ſoil. And another cauſe that may contribute to the production of bogs, may be the fall of a number of trees, which, by occaſioning a ſtagnation in the water brought down from higher grounds, may cauſe the depoſition of much earthy vegetable, and other materials, and conſequently the production of boggy appearances in the places where ſuch obſtructions are met with.

Bogs are diſcriminated by different titles, according to the nature of the circumſtances under which they occur; as *peat-bogs*, *quaking-bogs*, *ſpring-bogs*, and *turf-bogs*. The firſt being that ſort of bog which is principally compoſed of peat-earth. The ſecond ſuch a kind of bog as, when trodden upon, affords an elaſtic kind of motion, or ſhaking under the foot. The third is ſuch a bog as ariſes from the oozing or ſpringing up of water through the ſtiff ſtrata of materials on which it is formed. Mr. Elkington, the celebrated drainer, makes two claſſes of this ſort of bog; the firſt of which is diſtinguiſhed by the ſprings riſing out of the adjoining higher grounds, in a regular line, along the upper ſide of the wet ſurface; while, in the latter, the number of ſprings that appear are not confined to one regular direction along the upper ſide, but burſt out promiſcuouſly over the whole ſurface, eſpecially towards the lower ſide, forming quagmires all round, that ſhake and bend under the feet like a ſuſpended cloth, over which it is dangerous for the lighteſt cattle to paſs, and which ſhew themſelves at a diſtance by the verdure of the graſs, which the quags or ſpots immediately round the ſprings produce. The laſt is a ſort of bog conſtituted of materials which partake of the nature of turf.

Wherever bogs are met with, draining is unqueſtionably the firſt ſtep to be taken towards their improvement. For the full accompliſhment of this purpoſe, Mr. Elkington's mode may in many caſes be ſucceſsfully reſorted to, and with great and ſudden effect; though the improver ſhould not be too ſanguine in his expectations, or imagine that it is in every caſe an eaſy operation to free this ſort of land from an exceſs of moiſture. There are probably ſome bogs which cannot, without great difficulty, be drained at all; and others that would coſt the value of the land, in drains and machinery, to effect ſuch improvements in them. But notwithſtanding unſucceſsful trials may ſometimes be made, the drainer ought not to be totally diſcouraged from further attempts, where there is a tolerable proſpect of ſucceeding in the buſineſs at laſt; as the caſes are no doubt very numerous, in which this ſort of land may be effectually drained at an eaſy expence, and thereby brought from a ſtate of inutility to yield conſiderable profit to the owners and the public. See DRAINING *of Boggy Lands*.

It is obſerved in the appendix to Mr. Johnſton's account of Mr. Elkington's mode of draining, that in the improving of bogs, after their being drained, as the great object is to get the ground brought to ſuch a ſtate, as to be fit for being laid down with graſs ſeeds, when it may be conſidered in ſuch a ſtate of improvement, that any ſubſequent crops will require no more than ordinary management to cultivate them; the firſt thing to be done, where they are extenſive, is to have them divided into proper incloſures by open ditches, by which means much ſurface water may be carried off, as well as by properly attending to the formation of the ridges and furrows in ploughing, and giving them a direction towards the open ditches, by which the rain or ſurface water may be diſcharged as it falls; and after this has been effected, to have the ſurface well levelled by means of the ſpade, as being in moſt caſes more effectual than by the plough. The better ſorts of the materials thus removed may be mixed up with lime or other ſubſtances, and ſet upon the land; while thoſe of the coarſer kinds are made uſe of to fill up the inequalities on the ſurface. Paring and burning, where there is much coarſe vegetable matter, may be practiſed with advantage. In order to this, whatever earth remains unemployed, in filling up hollows, ſhould be burnt, together with that taken out of the ditches, unleſs the latter has been already carried off for fuel. The greater quantity of aſhes there is, the greater will be the improvement of the ſoil itſelf, and the more will the earth be benefited. The aſhes, after being well incorporated with the ſoil by means of light or ſuperficial ploughing, frequently ſo enrich it, as to produce excellent crops for two years or more. The effects of the aſhes and burnt materials have been ſaid, in ſome caſes, to be increaſed by the addition of a little lime. When the turfs have been reduced to aſhes, ſpread over the ſurface of the ground, and turned in with a little furrow, turnips or potatoes ought to be the firſt crop. If the former, they may be ſown broad-caſt, and fed off by ſheep, by the dung and urine of which the ſoil will be greatly benefited, as well as by the refuſe of the plants, and the conſolidation produced by their treading upon it. It will then be in a ſtate for a crop of oats or barley, which ſhould be ſown with graſs-ſeeds, and well rolled down. The ploughing after the turnip crop, thus eaten off, ſhould be very ſlight, in order not to bury the enriching materials too deep; in which view oats ought to be preferred to barley. If the ſoil be full of the roots of ruſhes, weeds, and coarſe plants, a ſummer fallow may be neceſſary before any crop be taken; and when the aſhes have been made in a particular part of the field, they may be ſpread over the ſurface before the ſeed furrow is given, and the roots and tough clods, after being collected and burnt, may be ſpread along with them.

If the bog be very ſoft and deep of peat, ſo as not to admit horſes for ploughing the firſt year, a crop of turnips broad-caſt may be got by ſowing the ſeed among the ſpread aſhes, harrowing it in with a light harrow and roller drawn by men. This crop, being eat off as above, will leave the land the enſuing year ſo much conſolidated as to admit the plough.

When the ſurface has not been pared and burnt, fallowing for two years may be neceſſary to reduce the ſoil to a proper mould, in the laſt ſtage of which the lime or other manure muſt be applied. In this caſe two white crops, with an intervening one of turnips, potatoes, &c. may be taken before the graſs-ſeeds are ſown.

Boggy ſoil, of whatever kind, after being once broken up and pulveriſed by tillage and a courſe of fallow, ſhould not be over-cropped before being laid down in graſs; and, when brought into a good ſward of graſs, ſhould not be too ſoon broken up again, but continue ſo, buſh-harrowing and top-dreſſing it when the herbage begins to moſs. Repeated rolling is alſo neceſſary in ſuch ſoils.

It is probably a better practice to feed ſheep the firſt and ſecond years of the graſs than to cut it for hay, as it cauſes the roots of the graſs to ſtrike more horizontally through the ſoil, and more cloſely to cover the ſurface. With this view a greater proportion of white and yellow clover, and other ſhort graſs ſeeds, ſhould be ſown.

In the manuring of ſoft boggy lands ſome caution is neceſſary; for, though the ploughings, previouſly to the application of the dung, may be made deep with advantage, the ſubſequent furrows ſhould be very ſuperficial, and the dung regularly and uniformly blended with the ſoil; for, when this is not the caſe, it is apt to ſink down too much, and be of little utility. The ſame thing takes place with reſpect to lime; and even when marle is buried too deep it is ſaid to loſe its power as a manure.

On ſoft boggy ground, merely intended for paſture, nothing will produce a more rapid improvement than the application of a thin covering of marle. In order to this, the directions already given, with reſpect to paring and burning, ſhould be obſerved.

Marle, which is often found under a gravel or clay, may alſo be of great ſervice; but if a loamy earth be near at hand, it will, perhaps, be leſs expenſive to the farmer to bring ſuch earth to cover the bog, than it will be to dig up the clay. But of whatever kind the earth be which is laid upon the bog, the quantity ſhould always be ſufficient to cover its whole ſurface four, five, or ſix inches deep, according to the ſtiffneſs of the ſoil ſo brought.

Sea-ſand, as being frequently mixed with ſhells, is well ſuited to this purpoſe, if the boggy ground be ſituated near the ſea, ſo that it can be eaſily procured. The great weight of theſe materials tends equally to conſolidate the bog, and preſs out the moiſture from the ſpongy peaty earth; therefore the thicker they are applied the better. A ſlight ſprinkling of lime over it will add to the effect, and bring up much white clover and other ſweet graſſes.

The moſt barren earths or ſoils, when uſed in this way, may have good effects; but lime-ſtone gravel, where it can be procured, is to be preferred to all others. After the land has been treated in this manner, and lain ſome years in paſture, it may be broken up for tillage, and crops of grain taken before being laid down with graſs-ſeeds. By ploughing, part of the natural ſoil will be turned up, and intimately mixed with the earth, &c. that has been laid upon it, and, if lime or dung be added, will together form a very fertile mould. When boggy grounds are much over run with ruſhes, and other coarſe, ſour, aquatic plants, ſcarcely any thing tends more to the firſt part of its improvement than that of over-ſtocking it with different ſorts of cattle, as ſoon as ever it is ſufficiently ſolid to bear them with ſafety; care muſt, however, be taken not to put them on till it is quite firm, as if that be done they will not only poach the ſurface, but the coarſe herbage will remain without being eaten cloſely down. The practice of cutting the ruſhes frequently in their young and tender ſtate, is alſo of conſiderable utility. By theſe means alone a better kind of herbage is ſpeedily brought up, and much improvement produced.

Another conſiderable means of improving this ſort of land, where the ſituation is ſuch as to admit of it, or when it lies near the ſide of a large river or ſtream, of which, by means of proper dams and cuts, a command can be obtained, is that of floating it with water, a proceſs that, when judiciouſly managed, never fails to produce abundant crops of graſs. And that it is a mode of improvement well ſuited to this ſort of land, is evident from the effects that have been produced in different inſtances; and from the obſervations of Mr. Boſwell, that it requires more and longer watering than any ſandy or gravelly ſoil: the larger the body of water that can be brought upon it the better; its weight and ſtrength will greatly aſſiſt in compreſſing the ſoil, and deſtroying the roots of the weeds that grow upon it; neither can the water be kept too long upon it, eſpecially in the winter ſeaſon, immediately after the after-math is eaten; and the cloſer it is eaten the better. The manner of conducting the buſineſs of watering muſt be ſuited to the circumſtances of the particular caſes.

After being thus improved, it muſt next be determined to what laſting purpoſe it may be beſt applied. The too great moiſture of theſe ſoils, which always lie flat, renders them unfit for continued tillage, and their mould becomes ſo looſe by frequent ploughing, that it frequently does not afford ſufficient ſtability to the roots of corn. For this reaſon barley, oats, and rye do better here than wheat, which requires a firmer footing; but neither of them ſhould be ſowed thick, becauſe the fruitfulneſs of the ſoil will always make up in the ſize of the plants, what ſome might think wanting in their number. The moſt beneficial method of employing this ſort of land is, undoubtedly, that of converting it into meadow, becauſe, when thus prepared, and not injudiciouſly exhauſted by crops of corn, it will yield great quantities of excellent graſs. It is, however, uſual to begin with ſowing ſome kind of grain on this prepared ſurface, to indemnify the farmer by the plentiful crop which it generally yields; ſuch, indeed, as ſometimes defrays at once the whole expence of the improvement. In ſome caſes the moſt profitable method may be to ſow it in the autumn with rape, the leaves of which ſhading the ſurface in hot weather, and rotting in the winter, contribute greatly to mellow the earth: the ſtrong roots of this plant open the ſoil too, and its ſeed brings a great return when ſold for making oil. One or two ploughings after this will prepare it for a crop of wheat. After this is taken off, and the ſtubble turned down, white clover and graſs-ſeed ſhould be ſown, and the ground laid down for a laſting meadow; or if turnips be ſown, or cabbages planted in the autumn, theſe in the ſpring may be ſucceeded by barley, with which the graſs-ſeeds may be ſown.

In crude moory or black peat boggy improved lands, Mr. Marſhall remarks, that what is moſt deſirable is a crop that is ſown and reaped during the ſummer months, and which demands neither labour nor attendance in the humid ſeaſons of autumn, winter, or ſpring; and ſuch a crop is found in rape, which is luckily natural to the climate, and at the ſame time highly profitable. Trials with this may be made at but a trifling expence on a ſmall portion of the ground, the proof of which anſwering, it is obſerved, "is not whether the plant will thrive as herbage, but whether it will mature its ſeed on the given ſoil in the given ſituation."

After a recompence has been obtained by crops of this ſort, which may be repeated, as there is no danger of exhauſting ſuch deep ſoils, the foundation of more laſting profits is to be laid; which may be effected by ſowing graſs-ſeeds, with or over the rape crops, or after the ſtems have been drawn, according to ſeaſons and the circumſtances of the land, ſtocking, as directed above, till ſuch time as the ſurface becomes ſufficiently firm, and the ſoil has attained a ſuitable texture for mixed cultivation, which time may be much ſhortened by the application of foſſile ſubſtances of the calcareous kind in any period of the improvement.

When either through neceſſity, for want of other arable land, or out of choice, the farmer intends to continue ploughing his improved bogs, the ſurface muſt be raiſed in ridges, and the further management of it may be like that of moſt other ploughed grounds.

If a ſoil of this kind happens to be ſituated near a town, a greater profit may accrue from planting it with garden ſtuffs than from any ſort of grain, as beans, peaſe, cabbages, potatoes, turnips, carrots, &c. are found to thrive exceedingly well in earth of this kind.

Bog, *moving* or *migrating*. Theſe ſoft maſſes of earth have been ſometimes known to move out of their place. An inſtance of this there was in Ireland, in the year 1697, about Charleville in the county of Limerick. There was heard for ſome time a noiſe under ground like that of thunder at a great diſtance, or almoſt ſpent; and ſoon after this the earth of a large bog in the neighbourhood began to move, and a hill or riſing ſituated in the middle of it ſtood no longer above the level of the reſt, but ſunk flat. The bog not only moved itſelf, but carried with it the neighbouring paſture-lands,

lands, though ſeparated by a large and deep ditch; the motion continued a conſiderable time, and the ſurface of the moving earth roſe into a ſort of waves, but without breaking up or burſting any where. The paſture-land roſe very high, and was carried on with the ſame motion till it reſted upon a neighbouring meadow, the whole ſurface of which it covered, remaining ſixteen feet deep upon its ſurface. The whole quantity of the bog was torn from its former ſeat, and left great gaps in the earth where it had joined, which threw up foul water, and very ſtinking vapours. Phil. Tranſ. N° 233. The whole country came in to ſee ſo ſtrange a ſight as this, for it continued moving a long time; but few gueſſed the true cauſe of it, which was this: a more than ordinary wet ſpring occaſioned the riſing of the bog to a great height in one part, and thence propagated itſelf through the whole bog; ſo that the hill in the midſt was undermined, and naturally ſunk flat; this and the more than ordinary weight of this large bog preſſing upon the adjoining paſture-land, forced up its foundations, which were only a looſe ſand. This was puſhed on ſideways, where there was a deſcent from the bog, and at length having given the bog more room, all was quiet and remained in that ſtate. The bog was more than forty acres of ground.

Another inſtance of this kind occurred, in March 1745, at the bog of Addergoole, about a mile and a half from the town of Dunmore, in the county of Galway. In conſequence of a violent ſtorm, attended with a fall of rain, reſembling a water-ſpout, the turbary, which the turf-cutters had juſt left, containing about twelve acres, was put into motion, and floated till at laſt it ſubſided upon a piece of low paſture of near thirty acres, by the ſide of the river, where it ſpread and ſettled. The moving-bog choaked up the river, which conſequently overflowed the back grounds, and in a little time a lough or lake of near 55 acres covered the adjacent fields. A paſſage for the river was formed as ſpeedily as poſſible; but before it could be finiſhed, and the lake diſcharged, it was ſuppoſed to have covered 300 acres; however, in ſeven or eight days it gradually decreaſed to 50 or 60 acres, of which extent it continued. Iriſh Tranſactions, vol. ii. p. 4.

Bog, ancient *Hypanis*, in *Geography*, a river of Poland, which riſes in Podolia and joins the eſtuary of the Dnieper or Nieper, a little above Oczakow, about N. lat. 46° 32′. E. long. 32° 32′. This river ſeparates Poland and a portion of European Turkey from Ruſſia. By taking up the Ingul, the Sinucha, and the Guiloi, beſides other ſtreams in its courſe, it becomes a very conſiderable river.

Bog *bean*, in *Botany*. See Menyanthes.

Bog *berry*. See Vaccinium.

Bog *moſs*. See Splachnum.

Bog *buſh*. See Schoenus.

Bog *wood*. See Wood *ſubterraneous*.

Bog *ore*. See Iron.

BOGA, in *Ichthyology*, ſynonymous with *Bogue*, and *Sparus boops*.

BOGAERT, Martin Vanden, ſurnamed *Desjardins*, in *Biography*, an eminent ſculptor, was born at Breda, in Holland, in 1640, and ſettling in early life at Paris, he became a member of the Royal Academy, at the age of 31 years. The firſt of his moſt conſiderable works was an equeſtrian ſtatue of Louis XIV. erected at Lyons in the place Bellecour. He alſo adorned the gate of the church of the Mazarin college with ſix groups of ſtone, repreſenting the evangeliſts and the Greek and Latin fathers of the church; and beſides many other works, the moſt diſtinguiſhed was the monument erected in the place of Victory, at the expence of marechal du Feuillade, on which the king, crowned by victory, is exhibited in a ſtanding poſture, inveſted with the regal ornaments, and having under his feet a cerberus, to denote his triumph on occaſion of the triple alliance. This group is 30 feet high, and was formed by a ſingle caſt, under the particular direction of Desjardins. This artiſt died rich in 1694. Encycl.

BOGAHA, in *Botany* and *Mythology*, a tree held ſacred in Ceylon, on account of the imagined preference given by the deity Buddou to the ſhade of this tree above all others. Wherever it is found throughout the iſland, perſons are appointed to watch over it, and preſerve it from dirt or injury. It is held in the ſame eſtimation among the followers of Buddou, as the banyan tree is among the Brahmins. The Candians hold their great feſtival under the ſhade of a tree of this kind, which ſtands at Annarodgburro, an ancient city in the northern part of the king of Candy's dominions; and none but his own ſubjects are permitted to approach this ſanctuary. Tradition ſays, that the bogaha tree ſuddenly flew over from ſome diſtant country and planted itſelf in the ſpot where it now ſtands. It was intended as a ſhelter for the god Buddou, and under its branches he was wont to repoſe, while he ſojourned on earth. Near this hallowed ſpot 90 kings are interred, who all merited admiſſion into the regions of bliſs by the temples and images they conſtructed for Buddou. They are now ſent as good ſpirits to preſide over the ſafety of his followers, and protect them from being brought into ſubjection to Europeans; a calamity againſt which they continually pray. Around the tree are a number of huts, erected for the uſe of the devotees, who repair hither: and as every ſort of filth and dirt muſt be removed from the ſacred ſpot, people are retained for the purpoſe of continually ſweeping the approaches before the worſhippers, and to attend the prieſts during the performance of the ceremonies. Percival's Ceylon.

BOGANEU, in *Geography*, a town of Bohemia, in the circle of Chrudim; 6 miles S. of Chrudim.

BOGAR. See Bokhara.

BOGAROVSKOI, a town of Siberia, 136 miles N. of Tobolſk.

BOGAS, or Boghas, a ſmall town of Egypt, at the mouth of the Nile, 3 miles N. of Damietta. See Boghass.

BOGATOI, a town and diſtrict of Ruſſia, in the government of Kurſk, ſeated on the rivulet Penna, falling into the Pſol; 48 miles S. S. W. of Kurſk.

BOGAZI, a town of Aſiatic Turkey, in the country of Diarbekir, 50 miles W. of Diarbek.

Bogazi, ſignifying in the Turkiſh language a "canal," or "ſtrait," a name given by the Turks to two ſtraits, adjoining to the iſland of Samos; one, called Little Bogazi, and ſcarcely half a league broad, ſeparates Samos from the continent of Aſia; the other, called the Great Bogazi, and nearly two leagues broad, lies to the weſt and ſeparates this iſland from the ſmall Fournis iſlands, ſo denominated, becauſe, at a diſtance, they appear like the roofs of ovens; they were anciently called "Corſeæ inſulæ." This is a paſſage much frequented by ſhips failing from Conſtantinople to Syria and Egypt, and they find here good anchorages

BOGDANA, a town of European Turkey, in Moldavia, on the borders of Tranſylvania; 60 miles S. of Niemecz.

BOGDEN, Martin, in *Biography*, a favoured pupil of T. Bartholine, and ſtrenuous defender of his name and opinions, was born at Dreſden, about the year 1630. After viſiting France, England, and other parts of Europe, to im-

prove himſelf in knowledge, he took the degree of Doctor in Medicine, at Baſle in Switzerland, in 1652, and at the end of four or five years, paſſed principally with Bartholine, to whom he was ſtrongly attached, he ſettled at Bern. His works are principally controverſial, defending the priority of the diſcovery of the lymphatics by Bartholine, againſt Rudbeck the Swede, who claimed it; and who, if he did not diſcover them, Haller ſays, has the merit of having more fully and accurately deſcribed them, than Bartholine had done. Bogdan, in this conteſt, diſplayed much learning, but equal roughneſs and ill-humour. The titles of his works are; "Rudbekii inſidiæ ſtructæ vaſis lymphaticis Thomæ Bartholini," 4to. and "Apologia pro vaſis lymphaticis Bartholini, adverſus inſidias ſecundo ſtructas ab Olao Rudbeck." Haſſniæ, 1654, 12mo. "Simeonis Seth, de alimentorum facultatibus," Gr. & Lat. 8vo. 1658. "Obſervationes Medicæ ad Thomam Barth." The obſervations, 12 in number, are publiſhed in the "Culter Anatomicus," of Lyſer; Copenh. 1665. Haller Bib. Anat. Eloy Dict. Hiſt.

BOGDIKOTZ, in *Geography*, a town of Ruſſian Siberia, on the Tchulim; 6 miles N. W. of Atchinſk.

BOGDINSKOI, or Bogdom Dabassu, an inexhauſtible ſalt-lake of Siberia, in the ſteppe towards Tzaritzin; the ſalt of which, according to Pallas, is better than that of the Elton.

BOGDO, Great, the higheſt mountain of central Aſia, according to the reports of the Monguls and Tartars, is properly a central ſummit of the Altaian chain of mountains, which gives ſource to the Upper Irtyſh, and ſeems to be delineated in Arrowſmith's map of Aſia at longitude 94°, and latitude 47°. See Altai and Belur.

Bogdo, *Little*, is a mountain of Aſiatic Ruſſia, lying to the north of the Caſpian ſea, near which is a ſalt-lake of the ſame name.

BOGDOMANTIS, in *Ancient Geography*, a country of Aſia Minor. Ptolemy.

BOGDOY, in *Geography*, a name given by the Ruſſians to the Manchews, or Mandſhurs, who inhabit the eaſtern part of Chineſe Tartary, an extenſive and populous diſtrict N. N. E. of China, and who are ſubject to the Chineſe empire. See Mandshurs and Chinese Tartary.

BOGENSEE, a town of Denmark, in the iſland of Funen; 12 miles N. W. of Odenſee.

BOGESUND, a ſmall town of Sweden, in weſt Gothland, 4 leagues S. of Falkioping.

BOGGILCUND, a diſtrict or circar of Allahabad, in Hindoſtan, ſituate weſt of Benares.

BOGHASS, a canal or ſtrait, ſo called in the language of the country, at the mouth of the weſtern or Bolbitic branch of the Nile, now called the branch of Roſetta. This paſſage is not navigable through its whole width; there being only a narrow channel, which, owing to the inſtability of the bottom, and the agitation of the ſea, is continually ſhifting. A pilot or maſter of the Boghaſs is continually employed in ſounding this changeable paſſage, and giving directions to thoſe who navigate it. The increaſing danger of this paſſage led to the operation of cleanſing the canal of Alexandria, and thus to facilitate the communication between Alexandria and the reſt of Egypt. See Bogaz.

BOGIA. See Boujeiah.

BOGILLANA. See Baglana.

BOGLIASCO, a town of Italy, in the ſtate of Genoa, near the ſea coaſt; 6 miles E. of Genoa.

BOGLIO, or Beuil, a mountainous territory of Italy, in the principality of Piedmont, and county of Nice, ſeated near the Alps; its chief place has alſo the ſame name. This country was ſurrendered to France in May 1796.

BOGLIPOUR, a town of Hindoſtan, and capital of a province, in the country of Bahar, near the Ganges; 35 miles S. E. of Monghir, and 115 N. W. of Moorſhedabad.

BOGLORAY, a town of Poland, in the palatinate of Sandomirz; 24 miles E. S. E. of Sandomirz.

BOGMUTTY, a river of Hindoſtan, which runs into the Ganges near Monghir, in the country of Bahar.

BOGNOR, or Hothampton, (as it is ſometimes called in honour of its founder,) is a pleaſant retired hamlet, on the ſouthern coaſt of England, in the county of Suſſex. This place has only riſen into notice within a few years, being, previous to 1790, merely inhabited by a few fiſhermen. About this period ſir Richard Hotham purchaſed ſome ground here, where he built a houſe for himſelf, and had others erected for the accommodation of bathers. His plan of making this a faſhionable bathing place has ſucceeded, but it was not much frequented till after his death, which happened in 1709. Soon after this event, the ground and houſes were ſold in different lots. Some of the purchaſers have built additional dwellings, and Bognor is now become a place of great reſort during the ſummer months. The adjacent villages of Berſted, Felpham, &c. alſo receive a number of ſummer viſitors, who reſort to this coaſt for the purpoſe of its fine beach and mild air. Bognor is 7 miles S. of Chicheſter, and 67 S. W. from London. It has a good hotel, an aſſembly-room, a library, and ſome other eſtabliſhments for the accommodation and amuſement of its viſitors.

BOGODUKHOF, a town and diſtrict of Ruſſia, in the government of Kharkof, ſeated on the Merlo, falling into the Vorſkla; 84 miles N. N. W. of Kharkof.

BOGOE. See Boog.

BOGOGNANO, a town of the iſland of Corſica, 5 leagues N. E. of Ajaccio.

BOGOIAVLENSKIO, a town of Ruſſia, in the government of Ufa, 48 miles S. of Ufa.

Bogoiavlenskoi, a town of Ruſſia, in the government of Archangel, near the coaſt of the White Sea; 72 miles S.W. of Archangel.—Alſo, a town of Ruſſia, in the ſame government, near the river Onega, 100 miles S. of Archangel.—Alſo, a town in the ſame government, on the Pinega; 70 miles E. of Archangel.—Alſo, a town of Ruſſia, in the province of Uſting; 51 miles E. N. E. of Uſting.—Alſo, a town of Siberia, on the Tchulim; 80 miles E. N. E. of Tomſk.

BOGOMILI, or Bugarmitæ, in *Eccleſiaſtical Hiſtory*, a ſect ſprung from the Manichees, or rather from the Maſſalians, towards the cloſe of the eleventh century; whoſe chief, Baſil, was burnt alive by order of the emperor Alexius Comnenus. Being condemned to be burnt, he declared that the fire would not hurt him; upon which the Greeks who carried him to execution, firſt took off his cloak, and flung it into the fire, to try whether it would prove incombuſtible; whilſt it was burning, the poor fanatic cried out, "Do you not ſee that my cloak is untouched, and carried away in the air?" upon which they caſt him alſo into the fire, where he was ſoon conſumed to aſhes. Du-Cange derives the name from two words in the Bulgarian language; *Bog*, *Deus*, and *milvi*, *miſerere*, *have mercy*. The Bogomili denied the Trinity; maintaining that God had a human form; that the world and all animal bodies were created by evil angels; and hence they concluded, that the body was the priſon of the immortal ſpirit, and that it ought to be enervated by faſting, contemplation, and other exerciſes, ſo that the ſoul might be gradually reſtored to its primitive liberty; and that wedlock

was

was to be avoided; and they alſo maintained that it was the archangel Michael that became incarnate. They rejected the books of Moſes, and only admitted ſeven books of ſcripture; they maintained the Lord's prayer to be the only euchariſt; that the baptiſm of the Catholics was only that of St. John, and their's that of Jeſus Chriſt; and that all thoſe of their ſect conceived the Word, or *Logos*, as much as the Virgin, denying the reality of Chriſt's body, which they conſidered only as a phantom. They alſo held, that the body, upon its ſeparation by death, returned to the malignant maſs of matter, without either the proſpect or the poſſibility of a future reſurrection to life and felicity. Moſh. Eccl. Hiſt. vol. iii. p. 110. Jortin's Rom. on Eccl. Hiſt. vol. v. p. 46.

BOGORDSKOI, in *Geography*, a town of Ruſſia, in the government of Archangel; 8 miles S. W. of Mezen.

BOGORODITZK, a town of Ruſſia, in the government of Archangel, on the Dwina; 44 miles S. S. E. of Archangel.

BOGORODSK, a town and diſtrict of Ruſſia, in the government of Moſcow, on the Kliaſma; 28 miles E. of Moſcow.

BOGORODSKOI, a town of Ruſſian Siberia, in the province of Tomſk, ſeated on the Oby. The church belonging to this town is famous for a celebrated picture of the Virgin Mary, called "Oediitria," which is brought every year, on the 21ſt of May, in proceſſion to Tomſk. There are irons works in this place.

BOGOROSTAN, a town and diſtrict of Ruſſia, in the province of Ufa, ſeated on a river falling into the Samara.

BOGOTA, a town and province of New Granada, in Spaniſh South America, ſeated near the river Magdalena. The town is called *Santa Fé de Bagota*, and is the capital of the kingdom of New Granada; it is ſituate on the banks of the ſmall river Pati, which runs into the Magdalena. It was made an archbiſhop's ſee by pope Julius III. in 1554, and an univerſity was erected here in 1610. It has a ſovereign court of judicature, the preſident of which is governor of the whole province or kingdom of New Granada. Near it are ſome gold mines, and the chief modern mines of Peruvian emeralds, juſtly preferred to all others, ſince thoſe of Egypt have been neglected. Among the numerous cataracts of this country Bouguer mentions that of the river Bogota, which paſſes the city of the ſame name, about 8 leagues before it joins the Magdalena, ſaid to be a vertical fall of more than 1200 feet. N. lat. 4° 20'. W. long. 75° 40'. When the Spaniards took poſſeſſion of this part of South America, they found in Bogota a nation more conſiderable in number, and more improved in the various arts of life, than any in America, except the Mexicans and Peruvians. The people of Bogota ſubſiſted chiefly by agriculture. The idea of property was introduced among them, and its rights ſecured by laws, handed down by tradition, and obſerved with great care. They lived in large towns; they were decently clothed, and their houſes, compared with thoſe of ſurrounding tribes, might be termed commodious. Government had aſſumed, in this ſtate of civilization, a regular form, and a juriſdiction was eſtabliſhed, which took notice of different crimes, and puniſhed them with rigour. They were acquainted with the diſtinction of ranks, and their chief reigned with abſolute authority. He was attended by various officers and guards, carried with much pomp in a ſort of palanquin, and the road was ſwept before him and ſtrewed with flowers. For the ſupport of this expence taxes were levied on the people, who regarded their prince with veneration, and ſeldom approached him but with an averted countenance. One of the chief cauſes of that obſequious ſpirit, which prevailed among the people of Bogota, was the influence of ſuperſtition. The reſpect they paid to their monarchs was inſpired by religion; and the heir apparent of the kingdom was educated in the innermoſt receſs of their principal temple, under ſuch auſtere diſcipline, and with ſuch peculiar rites, as tended to fill his ſubjects with high ſentiments concerning the ſanctity of his character, and the dignity of his ſtation. This ſuperſtition, which, in the rudeſt period of ſociety, is either altogether unknown, or waſtes its force in childiſh unmeaning practices, had acquired ſuch an aſcendant over thoſe people of America, who had made ſome little progreſs towards refinement, that it became the chief inſtrument of bending their minds to an untimely ſervitude, and ſubjected them, in the beginning of their political career, to a deſpotiſm hardly leſs rigorous than that which awaits nations in the laſt ſtage of their corruption and decline.

The people of Bogota (as well as the tribe of the Natchez) had advanced beyond the other uncultivated nations of America, in their ideas of religion, as well as in their political inſtitutions. The ſun and moon were the chief objects of their veneration. They had temples, altars, prieſts, ſacrifices, and that long train of ceremonies, which ſuperſtition introduces wherever ſhe has fully eſtabliſhed her dominion over the minds of men. But the rights of their worſhip were cruel and bloody; they offered human victims to their deities, and many of their practices reſembled the barbarous inſtitutions of the Mexicans. Robertſon's Hiſt. America, vol. ii.

BOGRA, an uncultivated mountainous tract on the north of the barony of Muſkery, in the county of Cork and province of Munſter, Ireland. It is upwards of ten miles long, and in ſome parts ſix miles in breadth; and is a common to the adjacent eſtates. In winter it is for the moſt part deep, marſhy, and impaſſable; but in ſummer hard and firm, producing graſs and heath, and is then grazed by vaſt herds of cattle, which are removed to the lower lands when this ſeaſon is over. Large quantities of turf are alſo procured from it. Dr. Smith has applied to it theſe lines of Thomſon:

"The brown burnt earth
Of fruits and flowers, and every verdure ſpoiled,
Barren and bare, a joyleſs dreary waſte
Thin cottaged; and in time of trying need
Abandoned."

Many conſiderable ſtreams flow from this high and wild tract, which diſcharge themſelves into the Lee or Blackwater, as their direction is ſouth or north. Smith's Cork.

BOGRUSH, in *Ornithology*. The *Motacilla Schœnobanus*, Linn. and *Red Warbler* of Latham, is deſcribed under this name in the Arctic Zoology.

BOGUE, in *Ichthyology*, the French name of a fiſh of the Sparus genus, *Sparus boops* of Linnæus.

Bogue, Bell, in *Mythology*, the white god to whom the Slavonians paid their adorations. His ſtatue, ſmeared with blood, was covered with flies. His rites conſiſted in diverſions, games, and feaſts. He was a beneficent deity, correſponding to the good principle, the "Oromazes," of the Perſians. The black god, "Toherry Bogue," correſponded on the contrary to the evil principle, the maleficent being Arimanes. He was worſhipped by bloody ſacrifices, and the prayers of his votaries were addreſſed to him in a mournful and plaintive voice.

BOGUSLAW, in *Geography*, a town of Poland, in the palatinate of Kiovia; 32 miles S. E. of Bialacerkiew. N. lat. 49° 36'. E. long. 31° 12'.

BOGUTCHAR, a town and diſtrict of Ruſſia, in the govern-

government of Voronetz, on a rivulet of the ſame name, falling into the Don.

BOGWANGOLD, a town of Hindoſtan, near the Ganges; 11 miles N. of Moorſhedabad.

BOHABOL, in *Ancient Geography*, a town of Aſia in Syria.

BOHADSCHIA, in *Botany*. See PELTARIA.

BOHAIN, in *Geography*, a town of France, in the department of the Aiſne, and chief place of a canton, in the diſtrict of St. Quentin; 10 miles N. N. E. of St. Quentin. The place contains 2152, and the canton 13181 inhabitants. The territory comprehends 172½ kiliometres, and 14 communes.

BOHAR, in *Ichthyology*, a ſpecies of SCIÆNA, deſcribed by Forſkal, as a native of Arabia. The colour is red, lineated, and clouded with white. Forſk. Fn. Arab.

This bears a ſtrong affinity to another fiſh deſcribed by the ſame writer, as an inhabitant of the ſame country, Kaſmira. Gmelin expreſſes a doubt whether it does belong to the SCIÆNA genus. The body is of an oblong form, and covered with ſmooth ſcales. When alive there are two large ſpots on the back, which diſappear after the fiſh is dead. There are two ſhort cirri, or beards before the noſtrils: in the upper jaw two ſubulate teeth, which project beyond the lower, the two middlemoſt of which are placed remote. The lateral line runs nearer to the back. Dorſal and anal fins rounded behind, and the unarmed part of both ſcaled, the ſpines of the latter growing gradually larger: ventral connected by an intermediate membrane. Tail bifid. Gmelin.

BOHAROWCZE, in *Geography*, a town of Poland, in the palatinate of Kaminiec; 60 miles N.W. of Kaminiec.

BOHDANICE, a town of Bohemia, in the circle of Chrudim, which has the privilege of holding fairs.

BOHEA, in *Botany*. See THEA.

BOHEMIA, in *Geography*, called in German *Boierheim*, *Beikeim*, *Boheim*, and corruptly *Boehmen*, that is, the habitation of the Boii (ſee BOII); a kingdom of Europe, in the Auſtrian dominions; bounded on the north by Miſnia, Luſatia, and Sileſia; on the weſt, by the circle of the Erzgeberg, the Voghtland, the margraviate of Culmbach, and the Upper Palatinate; or, in general, by Franconia; on the ſouth, by Bavaria and Auſtria; and on the eaſt, by Moravia, Sileſia, and the county of Glatz. Bohemia is environed on all ſides with high mountains and large foreſts; towards the ſouth it is ſeparated from Auſtria by a ridge of conſiderable elevation, which paſſes to the north-eaſt of Bavaria; and on the north-weſt, it is parted from Saxony by a chain of metallic mountains, called the Erzgeberg, a word denoting hills that contain mines. On the weſt of the river Eger, near its junction with the Elbe, ſtands the mountainous group of Mileſſou, near which is Donneberg, ſuppoſed to be the higheſt in the province; and on the north-eaſt is the Sudetic chain, which branches from the Carpathian, and divides Bohemia and Moravia from Sileſia and the Pruſſian dominions. This country was formerly remarkable for an extenſive foreſt, a remain of the ancient Hercynia Sylva, which extended from the Rhine to Sarmatia, and from Cologne to Poland. The Gabreta Sylva lay on the ſouth-weſt of the ſame country, where a chain of hills now divides it from Bavaria.

Bohemia, as we have already obſerved, derived its name from the Boii, who, under their leader Segoveſus, ſettled in that country about 590 years before the Chriſtian æra. The Boii were ſoon after expelled by the Marcomanni; and theſe, being weakened by their wars with the Romans under the conduct of Tiberius, were ſubdued by the Sclavi (ſee SCLAVONIANS), who, like the other Scythians, wandered from place to place with their families and cattle; and, as Strabo informs us, even in the time of Auguſtus Cæſar, lived promiſcuouſly with the Thracians. Afterwards, ſpreading themſelves weſtward, in a few centuries they poſſeſſed Illyricum, Poland, Moravia, and Bohemia. But retaining their ancient manners, they neglected to build cities; and inhabiting the country in detached hordes, they regarded only paſturage and the care of their flocks. The firſt ruler, or chief, mentioned by hiſtorians, was one Czechius, from whom the natives derived the appellation of Czechs, or Zechs, who, quitting Croatia, migrated firſt to Moravia, and from thence to Bohemia, about the middle of the ſixth century, which he found covered with wood, and poſſeſſed rather by herds of wild cattle than by men. Here he ſettled his ſmall colony, and taught the few inhabitants of the country to cultivate the lands, and to ſow corn. After his death, the Bohemians remained for ſeveral years without a ruler or judge; but being now aſſembled in villages, they were anxious to obtain a more ſettled form of government than that which they had found effectual during their paſtoral life. With this view they choſe for their governor a young man, whoſe name was Croc, diſtinguiſhed by his prudence, who reſtored peace and order, and maintained the authority of the laws. He was ſucceeded by the youngeſt of his three daughters, Lybuſſa, who was reſpected for her ſkill in the art of divination; and who, about the cloſe of the ſeventh century, married a country labourer of the name of Premiſlaus, who, being called from the plough to the dignity of governor, carried his cloak and ſhoes along with him, as memorials for his poſterity, to prevent their being elated with the proſperity of their condition. This Premiſlaus is ſaid to have founded the city of Prague, to have diſtributed the people into different ranks, and, after quelling ſome temporary inſurrections, to have reigned peaceably till his death. He is ſaid to have been the firſt duke, though others trace the origin of the duchy to an earlier period, and ſay that Czechius was the firſt who bore this title. The government ſeems afterwards to have continued hereditary in his family, though with ſome form of election; and a deſcendant, whoſe name was Borivorius, or Borzivori, embraced Chriſtianity about the cloſe of the ninth century, and, after ſome oppoſition, introduced it into his dominions. On this occaſion ſeveral churches were built, and ſchools erected; but upon the death of his ſon Wratiſlaus I. in the beginning of the tenth century, his wife Drahomira, who aſſumed the government during the minority of her ſons, manifeſted her hatred againſt the Chriſtians, maſſacred about 300 of them in one night, burnt their temples, and ordered them to deliver up their arms. However, upon the acceſſion of her ſon Wenceſlaus II. A. D 916. the Chriſtian religion was again encouraged; and, in order to prevent diſputes with his brother Boleſlaus, who had been educated under his mother, he ceded to him that part of Bohemia, which lay beyond the Elbe. Wenceſlaus, having obtained a victory in a duel, a challenge to which he accepted for the purpoſe of ſparing the lives of his rebellious ſubjects, was invited by Otho the Great to the diet at Worms, where he offered him the title of king, which Wenceſlaus declined accepting. In the year 932, Wenceſlaus was murdered by his brother Boleſlaus I. ſurnamed the Cruel, who, ſucceeding him, conducted his adminiſtration with great cruelty, perſecuting the Chriſtians, and expelling them the kingdom. His ſon and ſucceſſor, Boleſlaus II. ſurnamed the Pious, founded and endowed 20 churches, and obtained leave from pope John IX. to create a biſhop at Prague. His ſubjects formed a conſpiracy againſt him, on account of ſome reforms which he attempted to introduce;

troduce; and encamping on a mountain in the vicinity of Prague, they were expelled thence by the Chriſtians, with the aſſiſtance of the Jews, and obliged to remain in peace. In recompence of this ſervice, the Jews were allowed to build a ſynagogue at Prague. In the eleventh century, Bretiſlaus, the ſon of Udalricus, having obtained the government of Moravia, kept poſſeſſion of it by repulſing the Poles who invaded it; and, ſucceeding to the government of Bohemia, on the death of his father, A. D. 1043, he again defended it againſt Hungarian robbers, by whom it was ravaged; and having concluded a perpetual peace with Caſimir, king of Poland, he died, leaving five ſons, of whom the eldeſt inherited Bohemia; and Moravia was divided among the four youngeſt. Wratiſlaus II. ſucceeded his brother, A. D. 1061; and, in 1086, was honoured with the regal title by the emperor Henry IV. who alſo inveſted him with the domains of Luſatia, Moravia, and Sileſia. This dignity, however, was merely perſonal; and the conſtant title of king only commences with Premiſlaus II. in 1199. He, and his immediate ſucceſſors, were ſtyled Ottocari, or Othogari, on account of their attachment to the intereſt of the emperor Otho. Upon the death of Wenceſlaus IV. A.D 1255, his ſon Premiſlaus Othogar ſucceeded him; and having ſettled his affairs in Bohemia, took poſſeſſion of Auſtria, Stiria, part of Carinthia, and other provinces to the ſouth, and carried his arms into Pruſſia for the defence of the Chriſtians; and having defeated his oppoſers in ſeveral engagements, he prevailed on many of the people to abandon Paganiſm. After his return to Bohemia, in 1271, he is ſaid diſdainfully to have rejected the imperial crown, which was afterwards given to Rodolphus, count of Hapſburg; but Othogar refuſing to do him homage, and to take from him the inveſtiture of his ſtates, alleging that he owed him nothing, and that he had paid him his wages, Rodolph having been great marſhal of his court, was at length obliged to comply, and to deliver five ſtandards to the emperor for the five fiefs which he poſſeſſed. A reconciliation, however, afterwards took place, and Othogar received the inveſtiture of Bohemia and Moravia, on condition of renouncing Auſtria, Carinthia, and Stiria. Wenceſlaus V. ſucceeded his father in 1278, and was elected king of Poland; but refuſed the ſceptre of Hungary, that was offered him, in favour of his ſon. In 1310, the ancient lineage failed; and John, the ſon of the emperor Henry VII. of the family of Luxembourg, who had married the youngeſt ſiſter of Wenceſlaus VI., obtained poſſeſſion of the kingdom of Bohemia. John, having reſigned Bohemia to his ſon Charles, and procured for him the imperial dignity, proceeded with him to France, to the aſſiſtance of Philip againſt the Engliſh, and was ſlain in the famous battle of Crecy, in 1346. Charles IV. emperor, having ſucceeded his father, created his brother John marquis of Moravia, erected an univerſity at Prague upon the plan of that at Paris, and engaged pope Clement VI. to erect the ſee of Prague into an archbiſhopric, with this privilege annexed to it, that the archbiſhop ſhould have the honour of crowning the king of Bohemia. He enlarged and beautified his capital, by adding what is called the New City, in which he founded the college of Carlſtein. With the aſſiſtance of ſeveral learned perſons, he reduced the laws of the kingdom to writing, which are ſtill extant, under the name of "Caroline Conſtitutions." He greatly extended the boundaries of his hereditary dominions, and cauſed his ſon Wenceſlaus to be crowned king, in the ſecond year of his age. He alſo prevailed with the electors to chuſe him king of the Romans, in the ſixteenth year of his age; and having commenced the junction of the Moldaw with the Danube, he died before he had executed his deſign; and in 1378, was ſucceeded by his ſon Wenceſlaus VII. In the reign of this prince, who was notoriouſly diſſolute, profligate, and ſavage, and who, by his licentiouſneſs and cruelty, incurred the hatred of his ſubjects, John Huſs and Jerome of Prague introduced the doctrines of the reformation into Bohemia. See Huss, and Jerome. Wenceſlaus died ſuddenly in 1419; and before his brother Sigiſmund, who ſucceeded him as king of Bohemia and emperor of Germany, could come from Hungary to take poſſeſſion of the crown, the Huſſites, under John Ziſca, had acquired great ſtrength, and, upon his approach to the kingdom, they ſent deputies to him, deſiring liberty of conſcience; but, inſtead of granting their requeſt, he only declared, that he intended to govern the kingdom as his father had done. A civil war enſued, in which the troops of Sigiſmund ſuſtained ſeveral defeats; and which, after a continuance of ſixteen years, occaſioned by his breach of faith to Huſs and Jerome, terminated in ſeveral conceſſions, and in his admiſſion into Prague with great ſolemnity and rejoicing. Upon the death of Sigiſmund, in 1438, Albert of Auſtria, who had married his daughter, received the crowns of Bohemia and Hungary. The ſucceſſion was, however, afterwards diſputed and infringed by George Podiebrad, a Huſſite chief; by Uladiſlaus, ſon of Caſimir, king of Poland; and by Matthias, king of Hungary. Uladiſlaus ultimately ſucceeded, being elected, in 1471, by the majority of the ſtates, and ſoon after receiving the inveſtiture from the emperor. Upon the death of Uladiſlaus, in the 45th year of his reign over the Bohemians, and the 23d over the Hungarians, he was ſucceeded by his ſon Lewis in both the kingdoms of Bohemia and Hungary, A.D. 1516; but, in 1526, he engaged the Turks at Mohatz, and being utterly defeated, was drowned in the Danube, in his flight. After the death of Lewis, his dominions fell to Ferdinand, archduke of Auſtria, infant of Spain, and afterwards emperor, who had married Anne, the only daughter of Uladiſlaus: and both the empire, and the kingdom of Bohemia, have ever ſince continued in the houſe of Auſtria. Ferdinand, at a diet of the ſtates held in 1547, declared the kingdom hereditary and abſolute; and when Ferdinand II., in 1620, had routed the army of his rival Frederick at the White Mountain near Prague, Bohemia was reduced fully to the condition of an hereditary kingdom; ſo that from that time the ſtates had no concern with the right of ſucceſſion. The crown, however, is conferred with ſome appearance of election, which right the ſtates of that kingdom pretend to claim; although, by the treaty of Weſtphalia, Bohemia is declared hereditary in the houſe of Auſtria. The king of Bohemia is the firſt ſecular elector, and as ſuch pays homage to the emperor and the empire for his ſtates; and with this exception, he has a right to exerciſe, through all his dominions, the royal authority agreeably to the laws of the kingdom, which prohibit his raiſing contributions or taxes otherwiſe than at the time when the ſtates are aſſembled, the appointment of which is entirely in their own power. He gives his opinion, as elector, after the elector of Cologne, and formerly aſſiſted at the aſſembly of the electors only at the election of an emperor, nor did he appear always at the diets of the empire. He is arch-butler, or arch-cup-bearer, of the holy Roman empire; and on this office his right to chuſe a king of the Romans is ſaid to depend. It has been alleged, that Bohemia has been of old time a genuine ſtate of the German empire, without contributing to its taxes, which was a privilege conferred upon it by Frederick II. in 1212, who at the ſame time exempted it from the juriſdiction of the ſupreme judicatory of the empire. In 1708, it was acknowledged by the three colleges of the empire, at an act of the diet called "the admiſſion," that the king and elector of Bohemia has an undoubted right of ſeat and voice in all its aſſemblies; in conſequence of which the emperor promiſed,

miſed, that, on account of his hereditary kingdom of Bohemia, and of the countries belonging to it, he will pay an electoral proportion of all taxes and impoſts of the empire and circle, and alſo 300 florins yearly to the chamber-judicatory; the collective body of the empire engaging at the ſame time to take the kingdom of Bohemia, and the countries united with it, under its protection and defence.

Bohemia, ever ſince the time of Charles IV., has been divided into twelve circles, beſides Prague, which is conſidered as a diſtinct territory. Theſe are Kaurzimer (comprehending Great Prague), Pilſner, Leutmeritzer, Konigingratzer, Rakowitzer (including Beraun), Chrudimer, Prachiner, Slaner (comprehending Little Prague), Bunzlauer, Saatzer, Czaſlauer, and Bechiner. Each circle has two head-men, or captains, appointed annually, for the adminiſtration of the government, one from the ſtate of lords, and the other from that of knights. The duchy of Silefia, the marquiſate of Moravia, and that of Luſatia, formerly held of this crown, but at preſent only Moravia, which is incorporated with the kingdom of Bohemia, and is in poſſeſſion of the houſe of Auſtria. In 1742, the county of Glatz was ceded to the king of Pruſſia, and by him added to Silefia. The government of Bohemia is managed by ſix different courts; viz. the council of the regency, or great royal council, in which preſides the great judge or burgrave of Bohemia, who has under him 18 lieutenants of the king, and other aſſeſſors; the council, or ſuperior chamber of juſtice, at which the great maſter of the kingdom is preſident; the chamber of fiefs; the new tribunal, to judge the appeals of the German vaſſals, with its preſident, vice-preſident, and aſſeſſors; the royal chamber of finances, with a preſident and vice-preſident; and the chancery, which always follows the court. The ſtates, conſiſting of the clergy, nobility, and gentry, and repreſentatives of the towns, meet at Prague, where a commiſſioner from the ſovereign points out the neceſſity of granting ſuch ſupplies as the court demands, which, however exorbitant, are granted without heſitation or examination, though not ſometimes without ſubſequent complaint. The clergy are compoſed of the archbiſhop of Prague, ſeveral biſhops, provoſts, and abbots, beſides the inferior clergy. The nobility conſiſt of princes, counts, barons, and knights; the others are burghers, huſbandmen, and peaſants.

The eſtabliſhed religion of Bohemia is popery; but there are many proteſtants among the inhabitants, who are now tolerated by the wiſe regulations of Joſeph II. in the free exerciſe of their religion. The Jews at Prague are indulged alſo with a toleration. The archbiſhop of this city is born legate of the holy apoſtolic ſee of Rome, and crowns the king of Bohemia; he is alſo a prince of the holy Roman empire, primate of the kingdom, and perpetual chancellor of the univerſity of Prague. His ſuffragans are the biſhops of Leutmeritz and Konigingratz. The government of the church and clergy is veſted in the archiepiſcopal conſiſtory, from which an appeal lies to the king or the pope.

The extent of Bohemia, and alſo its population, have been variouſly eſtimated. Its length is about 162 miles, and its breadth 142. Some centuries ago, the inhabitants were eſtimated at three millions; but in later times they have been very much diminiſhed. It is ſaid, that in the year 1622, and the three or four following years, no fewer than 30,000 families, and many other individuals quitted the country, among whom were many of the nobility, on account of the inteſtine religious wars, and the ſucceeding irruptions of the Swedes. In M. Hoeck's "Statiſtical View of the States of Germany, &c." 1801, the kingdom of Bohemia is ſtated to contain 962½ ſquare miles, 250 cities, 308 market towns, 11,455 villages, 430,000 houſes, 1,340,510 men, 1,466,433 women, and the total of the population 2,806,943. The number of Lutherans has been eſtimated at 9050, of the reformed at 25,110, and of Jews at 36,000. Some writers have ſtated the number of Proteſtants at 36,000, and that of the Jews at 40,000, of whom 8000 are ſettled at Prague. In their diſpoſitions, habits, and manners, the Bohemians reſemble the Germans; being indeed a mixture of Sclavonians and Germans, the former of whom live in villages and are ſlaves. They have no middle rank of people; for every lord is a petty ſovereign, and every tenant a ſlave. The Bohemian peaſants, on the imperial demeſnes, have been lately relieved from the ſtate of villainage, in which they had been ſo long and ſo unjuſtly retained; and it is hoped, that the example of the emperor will be followed by that of the Bohemian nobility in general, ſo that their vaſſals may recover thoſe rights of which they have been long deprived. The natives of this country are ſingularly robuſt and ſtrong-built, handſome, except that their heads are ſomewhat too large, and active, ſhrewd, courageous, and ſincere. The gentry are ingenuous, brave, and more inclined to arms than arts. Learning in Bohemia is in a low ſtate; though the kingdom poſſeſſes one univerſity, 12 gymnaſia, 2,219 German ſchools, 200 ſchools of induſtry, and 33 ladies' ſchools.

The Bohemian language is a dialect of the Sclavonic, but ſomewhat harſher than that of their neighbours, who ſpeak the ſame language, and who change the conſonants, and particularly the *l*, more into vowels. The Bohemians formerly uſed the ſame letters with the Ruſſians; but in the time of Boleſlaus the Pious, the Latin was introduced among them. Upon the firſt introduction of Chriſtianity in this reign, the religious ſervice was performed in the Latin tongue, a language unknown to the people; but in conſequence of the repreſentation of Methodius to pope Nicholas the Great, he allowed the prayers to be rehearſed in the vulgar tongue. But ſome years after, when a biſhop was ſent into Bohemia, the Latin tongue was again ordered to be introduced in all their churches. Perſons of a ſuperior claſs, from their intercourſe with the court of Vienna, ſpeak high Dutch or German, with which the language of the common people is alſo intermixed.

Bohemia is, upon the whole, one of the higheſt countries in Europe, and forms a large extended plain, ſurrounded, as we have obſerved, by high hills covered with wood. The vale in the middle, which is watered by the Elbe, the Moldaw, and the Egra, is protected from the wind, and it has neither lakes nor moraſſes which taint the air, which is dry and clear, with unwholeſome vapours. The climate is therefore ſalubrious, and not liable to thoſe ſudden changes, which are ſo fatal to health in other places. The heat of ſummer, and the cold of winter, are alike moderate. The ſoil is in general rich, though in ſome places it is ſandy. It is fertile in corn, wine, fruits, paſture, ſaffron, ginger, hops, wool, flax, and timber. The Bohemian hops, which are much valued, are carried as far as the Rhine in great quantities. Bohemia produces a ſtrong large breed of horſes, many of which are purchaſed for the uſe of the French cavalry. Its mountains are the richeſt in Europe, in gold, ſilver, precious ſtones, copper, quickſilver, iron, lead, tin, ſulphur, and ſaltpetre. The Bohemian tin is reckoned the beſt of any except the Engliſh. All kinds of marble are alſo found in this country, together with pit-coal, alum, muſcovy-glaſs, excellent mineral waters, and hot baths. It alſo furniſhes numerous herds of cattle, and abundance of game and wild fowl, and alſo bears, lynxes, wolves, foxes, badgers, martens, beavers, and otters. Its rivers and ponds afford a plentiful ſupply of fiſh, and ſuch as are of the beſt quality and flavour.

Accord-

According to the ſtatement of M. Hoeck (ubi ſupra), Bohemia had, in 1787,

	Acres.	Sq. Toiſes.
1. Of ploughed land, -	3,609,360 -	776
2. Ponds, - -	6,,115 -	1373
3. Fields, - - -	220,136 -	1393
4. Meadows, - -	798,393 -	1076
5. Gardens, - -	85,712 -	722
6. Marſhy ground, -	65,515 -	970
7. Paſtures and heaths, -	613,131 -	1209
8. Vineyards, - -	4,482 -	672
9. Woods, - -	2,319,811 -	557
Total	7,785,655	8738

The territorial produce of grain, forage, vines, woods, and rivers, amounted, in 1789, to 30,057,939 florins. Of cattle there were, in 1771, 9789 oxen, 2338 bulls, 9688 cows, 2723 calves, 8452 ſheep, 16,738 hogs, 564 he-goats, 2758 ſhe-goats, and 533 aſſes. The produce of grain amounted to two millions of minots (a minot being equal to three buſhels) of wheat, ten millions of minots of grain, four millions of minots of barley, and eight millions of minots of oats. In the liſt of natural productions are alſo to be reckoned fruit-trees, hops, principally in the circle of Saaz, flax, tobacco, ſaffron, poultry, bees (of which, in 1791, there were 20,257 hives), tin (chiefly at Schlackenwalde, and there are ten mines of tin in the circle of Saaz, and two in that of Leutmeritz), cobalt, 10,000 quintals in the circle of Saaz, ſilver, alum, at Commothau, in 1788, 1,539 quintals. This author alſo ſtates, that Bohemia had, in 1782, 95 manufactures, which employed 139,613 workmen. Theſe manufactures are of linen, wool, cotton, ſilk, paper, glaſs, leather, &c. amounting in the whole to 35,645,447 florins, of which ſtrangers take to the value of 11,840,737 florins. The articles of export, according to his enumeration, are alum, Epſom-ſalt, butter and greaſe, fiſh, flax, poultry, grain, mineral waters, hare-ſkins, wood, hops, cobalt, hides and ſkins, fruit, horſes, pork, brimſtone, vitriol, game, flax, tin, dimity, articles in iron, articles in glaſs, garnets, hats, linens, braſs, paper, pot-aſh, aqua fortis, lace, cloth, and thread. The articles of import are cotton, lead, white lead, books, iron, and iron articles, colours, flax, jewellery, ſpicery, horned cattle from Hungary, coffee, cotton, ſtuffs, galls, merchandiſe of Lyons, liqueurs, ſilks, Hungarian cattle to the value of 800,000 florins, and wine to the value of 500,000 florins. The balance of trade is ſaid to be in favour of the country. M. Hoeck alſo informs us, that the revenues of the ſtate are fifteen or ſixteen millions; but that the expences are ſo high, that out of this ſum the ſurplus amounts only to 636,000 florins; that the contribution in 1789 was 3,646,017 florins, and the tax on the Jews 216,006 florins; and that the annual revenue from the domains of the crown was, during the life of Maria Tereſa, 332,720 florins; theſe domains are now eſtimated at 177,774 acres. The number of ſoldiers to be furniſhed by Bohemia, in time of peace, is 54,964; and, in time of war, 76,896. The capital city of Bohemia is Prague; which ſee.

Bohemia, a broad navigable river of North America, 10 miles long, which runs W.N.W. into Elk river, in Maryland, 11 miles below Elkton.

BOHEMIAN, or Moravian, Brethren, in *Eccleſiaſtical Hiſtory*, is an appellation anciently given to the Proteſtants in Bohemia. By their adverſaries they were called *Picards*, i.e. *Beghards*. They were deſcended from the better ſort of Huſſites, and were diſtinguiſhed by ſeveral religious inſtitutions of a ſingular nature, and well adapted to guard their community againſt the reigning vices and corruptions of the times; and as ſoon as they heard of Luther's deſign of reforming the church, they ſent deputies, in the year 1522, to recommend themſelves to his friendſhip and good offices. In ſucceeding times, they continued to manifeſt the ſame zealous attachment to the Lutheran churches in Saxony, and alſo to thoſe that were founded in other countries. Upon this their religious principles were examined, and nothing was found, either by Luther or his diſciples, in their doctrine or diſcipline, that was liable to cenſure. Their confeſſion of faith, though not altogether approved by this reformer, was regarded as an object of toleration and indulgence. Nevertheleſs, the death of Luther, and the expulſion of theſe brethren from their country, in 1547, changed their religious connections; and many of them, more eſpecially of thoſe who retired into Poland, embraced the religious ſentiments and diſcipline of the reformed. Their attachment to the Lutherans ſeemed, however, to be revived by the convention of Sendomir in 1570; but as the articles of union, that were drawn up in that aſſembly, ſoon loſt their authority, the Bohemians by degrees entered univerſally into the communion of the Swiſs church. This union was at firſt formed on the expreſs condition, that the two churches ſhould continue to be governed by their reſpective laws and inſtitutions, and ſhould have ſeparate places of public worſhip; but, in the following century, all remains of diſſenſion were removed in the ſynods held at Aſtrog, in 1620 and 1627, and the two congregations were formed into one, under the title of "The Church of the United Brethren." In this coalition the reconciled parties ſhewed to each other reciprocal marks of toleration and indulgence: for the external form of the church was modelled after the diſcipline of the Bohemian Brethren, and the articles of faith were taken from the creed of the Calviniſts. See Unitas *Fratrum*.

Laſitius has a treatiſe De Geſtis Fratrum Bohemicorum. Camerarius has alſo given the hiſtory of the Bohemian brethren, from whom eccleſiaſtical hiſtorians have derived a large train of ſects, as the Huſſites, Adamites, Taborites, Calixtins, &c. which ſee reſpectively.

Bohemian *chatterer*, in *Ornithology*, a bird of the *Paſſerine* order, common in many parts of Europe, in Northern Aſia, and America. It ſometimes viſits the ſouthern parts of Britain in the winter. The common Engliſh name of Bohemian chatterer was impoſed upon this bird by old writers, under the idea that it was peculiar to Bohemia. Later authors call it the *Waxen chatterer*, from the horny appendages at the extremity of the ſecondary quill-feathers, which are of a ſcarlet colour, and in appearance bear ſome reſemblance to ſealing-wax. This is called *Ampelis garrulus* by Linnæus. Donov. Brit. Birds, &c.

BOHEMICUS, the name of a ſpecies of Falcon that inhabits the mountains of Bohemia. The legs of this kind are yellowiſh; body above cinereous, beneath hoary white; five exterior quill-feathers black on the outſide; orbits of the eyes white. Gmel. *Falco Bohemicus*. *Maeuſe-habicht, miſſy-lauce*, Mayer.

This bird is ſcarcely a foot in length; bill near the angles of the mouth yellowiſh; irides yellow; tail acute and long; legs thickiſh, and feathered below the knees; claws black and roundiſh. Feeds on mice.

BOHKAT, in *Ichthyology*, is the Arabic name of a ſort of Ray that inhabits the Red ſea, and is deſcribed by Forſkal under the appellation of *Raja djiddenſis*.

BOHME, in *Geography*, a river of Germany, which runs into the Aller, 4 miles S. E. of Bethem, in the principality of Luneburg-zell.

BOHMISCHKRUTT, a town of Germany, in the archduchy of Auſtria, 5 miles S.S.W. of Feldſburg.

BOHN, John, in *Biography*, was born at Leipſic the 20th of July 1640, where he received the rudiments of his education. At a proper age his father ſent him to Jena, to be initiated into the ſtudy of medicine. In 1659, he returned to Leipſic, continuing his ſtudies there, until 1663, when deſirous of participating in the knowledge of the improvements making in his profeſſion, in different parts of Europe, he went to Copenhagen, Holland, England, France, and Switzerland, every where attending the lectures of the moſt celebrated maſters, but particularly attaching himſelf to Malpighi. Returning, at the end of two years, to Leipſic, he took his degree of doctor in medicine, and was in ſucceſſion advanced to the rank of profeſſor in anatomy, and in therapeutics. In 1691 he was appointed public phyſician to the city of Leipſic; and, in 1700, dean of the faculty of medicine, which offices he continued to hold with credit to the time of his death, in 1718.

Beſides numerous diſſertations on the different branches of medicine, which had great merit, he publiſhed, in 1688, "Exercitationes phyſiologicæ xxvi," 4to. This work was afterwards conſiderably enlarged, and republiſhed in 1680, under the title of "Circulus anatomico-phyſiologicus, ſive œconomia corporis animalis," 4to. In this he examines, with accuracy and judgment, the different hypotheſes then prevailing in medicine. He here firſt ſhewed the difference between the cyſtic and the hepatic bile. Finding the liquor amnii coagulable, he ſuppoſed it contributed to the nouriſhment of the fœtus; which, however, later experience contradicts, as fœtuſes born without heads, or where the paſſage through the œſophagus into the ſtomach has been cloſed, are found to attain, in utero, equal bulk and firmneſs, as thoſe that are perfect. He ſuppoſed the heart to be excited to contraction by the ſtimulus of the blood; and ſhews the oſſa pubis are not ſeparated in parturition, to allow a free paſſage to the fœtus; which was in his time the prevailing doctrine. In his "De variolis, hactenus in patria graſſatis," publiſhed in 1679, he adviſes giving purgatives with calomel, on the firſt attack of the complaint, with the view of rendering the diſeaſe more mild; a practice of which later experience has proved the utility. In his "De Renunciatione vulnerum," 1689, 4to. Amſterdam, he ſhews what wounds are neceſſarily fatal. His treatiſe "De Officio medici duplici, clinico, et forenſi," 4to. 1704, gives rules for the conduct of phyſicians, in attending their patients, and in giving evidence before a court of judicature. This is a work of great merit, and has ſcarcely been exceeded by any later production on the ſubject. Theſe have all been frequently reprinted. Haller. Bib. Med. Eloy. Blumenbach.

BOHOL, in *Geography*, one of the Philippine iſlands between Manila and Mindanao, about 16 leagues long from north to ſouth, and 8 or 10 broad. The ſouth coaſt towards Mindanao is the moſt populous; that is, from Lobag, the metropolis, to the little iſland or peninſula of Pangloo. The ſoil does not produce rice, but is ſaid to be rich in gold mines, and to yield, in great abundance, cocoas, batatas, and ſeveral ſorts of roots which ſerve inſtead of rice. In the mountains there are multitudes of cattle, and fiſh in the ſea, which the natives exchange with thoſe of the neighbouring iſlands for cotton. N. lat. 10°. E. long. 122° 5′.

BOHONIZ, a town of Bohemia, in the circle of Bechin, 2 miles S.S.W. of Teia.

BOHRAN, a town of Sileſia, in the principality of Breſlaw, 16 mimes ſouth of Breſlaw.

BOHRLITZ, a town of Moravia, in the circle of Brunn, 9 miles W.N.W. of Auſpitz.

BOHUS, or Bahus, a fortified iſland of Sweden, in Gothland, encircled by two branches of the Gotha, about 9 miles north of Gotheborg. The fort ſtands on a rocky eminence, and was formerly celebrated in the hiſtory of Norway, as a place of conſiderable ſtrength, and forming the frontier fortreſs during the conſtant wars between the Danes and Swedes. It was erected in 1309 by Hacquin IV. king of Norway, and, before the invention of gun-powder, it was a wooden fortreſs; but in 1448 was built with ſtone by Chriſtian I. The ſituation is ſtrong, and it is garriſoned by 100 men. The ſummit affords a pleaſing view of the Gotha, winding at the feet of barren rocks. Bohus gives name to a juriſdiction of which it is the capital. It formerly belonged to Denmark, but by the treaty of Roſchild, in 1658, it was ceded to Sweden.

BOHUSLAW, a town of Poland, in the palatinate of Kiov, near the river Ros. N. lat. 49° 37′. E. long. 31° 11′.

BOJA, in *Antiquity*, a collar or chain faſtened about the necks of criminals to prevent their eſcape.

The word is alſo written *boga*, *bodia*, and *baga*.

BOIA, in *Ancient Geography*, an iſland in the Ægean ſea. Anton. Itin.

BOJADOR, Cape, or Bajadore (which ſee), in *Geography*, lies on the weſtern coaſt of North Africa, placed in the Tables of the Commiſſioners of Longitude, in N. lat. 26° 12′ 30″, W. long. 14° 27′, and, in Rennell's map, in N. lat. 26° 20′, W. long. 14° 17′.—W. long. 14° 49′, by M. Fleurieu, and 14° 28′ Conn.-de-Temps. This cape was doubled by Gilianez and the Portugueſe navigators, under the direction of prince Henry, and emboldened by their voyages to Madeira, which required their quitting the coaſt and venturing into the open ſea, in the year 1433. For 20 years before this time, this cape had been the boundary of their navigation, and it had been deemed impaſſable. But this ſucceſsful voyage, placed by the ignorance of the age on a level with the moſt famous exploits recorded in hiſtory, opened a new ſphere to navigation, as it diſcovered the vaſt continent of Africa, ſtill waſhed by the Atlantic ocean, and ſtretching towards the ſouth. Of ſuch conſequence was the doubling of this cape, that the Portugueſe ſoon after advanced within the tropics, and in the ſpace of a few years diſcovered the river Senegal, and the whole coaſt extending from cape Blanco to cape de Verd.

BOIANO, a town of Naples, in the county of Moliſe, the ſee of a biſhop, ſuffragan of Benevento, who reſides at Campo Baſſo; 9 miles ſouth of Moliſe. See Bovianum.

BOIARDO, Matteo-Maria, in *Biography*, count of Scandiano, a perſon eminent for literature, was born at Fratta near Ferrara, about the year 1430, and educated at the univerſity of that city, where he principally reſided. Being highly eſteemed by the dukes Borſo and Hercules I., he was appointed by the latter governor of Reggio in the Modeneſe, where he died in 1494. He was well acquainted with the Greek and Latin languages; and tranſlated into Italian, from the former, the hiſtory of Herodotus, and from the latter, the golden age of Apuleius, and the chronicle of Ricobaldo. His eclogues in Latin verſe are reckoned among the moſt elegant productions of that age. He alſo wrote in Italian verſe a comedy, entitled "Timon," taken from a dialogue in Lucian, and other pieces. But his greateſt fame was derived from his "Orlando Inammorato," which combines with the ancient epic the extravagance of modern romance. His ſtyle was rude, and his verſification ſtiff and harſh; but the fervour of his fancy and the livelineſs of his imagery rendered this work, which he left unfiniſhed, captivating and popular. It was continued by Niccolo Agoſtino, and

and recompoſed and poliſhed, about half a century afterwards, by Lud. Domenico and Fr. Berni. The work of the latter is ſo well executed, that it has almoſt ſuperſeded the original. The beſt edition of Boiardo's own performance is that of Venice in 1544. This work ſerved as the model and groundwork of Arioſto's "Orlando Furioſo;" which is properly a continuation of it, with new adventures. Boiardo's ſonnets bear the character of a much purer ſtyle than his Orlando. Moreri.

BOIARKI, in *Geography*, a town of Poland, in the palatinate of Kiov, 38 miles S.S.E. of Bialacerkiew.

BOICININGA, or, more properly, Boicininɢua, in *Zoology*, the Braſilian name of the moſt common kind of rattle-ſnake that is found in South America:—*Crotale boiguira* of Boſc.

BOICUAIBA, a kind of Peruvian ſerpent, ſuppoſed to belong to the *Boa* genus. It is deſcribed as being twenty feet long black on the anterior part, the reſt yellow.

BOIGA, the name of an American ſnake, called by Linnæus *Coluber abaetulla*.

BOIGUACU, the name of a ſort of ſerpent, called alſo *iiboia*, and by the Portugueſe *Cobra de veado*. The relations of thoſe writers who ſpeak of this extraordinary creature partake rather of the marvellous, inſomuch that we cannot but entertain conſiderable doubt as to the identity of the ſpecies; that it is of the boa tribe there can be no diſpute. Perhaps it is no other than the *ibiboboca* and *boiguacu* of Seba, which Dr. Shaw deſcribes under the name of *Boa regia;* a ſpecies ſomewhat allied to conſtrictor, and of which the hiſtory has probably been confounded with that of the latter kind. The boiguacu is repreſented as the largeſt of all the ſerpent tribe, in which it agrees with conſtrictor. It grows, we are told, to the length of four and twenty feet, and more. The middle of the body very thick, but becoming ſmaller at the head and tail. Down the middle of the back runs a chain of black ſpots, a hand's breadth diſtant from one another, each having a ſpot of white in its middle; and below theſe are two other rows of ſmaller black ſpots, towards the belly. Each jaw is ſaid to be furniſhed with two rows of ſharp teeth white as pearl. The head very broad, with two protuberances over the eyes, and, in ſome of this ſpecies, two claws, like thoſe of birds, behind the anus, towards the tail. The laſt particular of which muſt evidently be an abſurd miſtake, ariſing from the inattention of the deſcriber.

We are further told, that the boiguacu is a terrible creature, one that preys upon the larger animals, and will ſeize upon a man. That it either lies in ambuſh in the thickets, or on the branches of large trees, from which it throws itſelf upon its prey. It has no venom in its bite; and its fleſh is eaten, and eſteemed a delicacy. This ſort is common in the Braſils. The ſize to which it attains ſometimes is aſtoniſhing. Borritus preſerved the ſkin of one (ſuppoſed to be the ſame) which had been killed by himſelf, that was twelve yards long; and he relates, that there was a ſerpent of this kind deſtroyed in Java, that meaſured thirteen yards and a half in length, and had, when killed, a boar in its belly. And de Laet relates, that in Rio de le Plata there are ſome of this kind of ſerpents ſo large, that they will ſwallow a whole ſtag, the horns not excepted. This is probably exaggerated. It is affirmed of the boa conſtrictor, by others, that when the enormous creature has gorged an animal of this kind, the horns remain ſticking out of the mouth of the ſerpent, till the digeſtion of the fleſh takes place, and the horns drop off. The boiguacu is eaten by the natives of Braſil.

BOII, in *Ancient Geography*, a people, who, according to Cæſar (lib. vi. c. 24.), were a Gauliſh nation, but from Gaul paſſed into Germany, and, ſettling in the preſent Bohemia, continued there till they were expelled by the Marcomanni. Strabo calls them at different times Celtes and Gauls; and M. Pelloutier is of opinion, that they were a tribe of the Celtæ, who inhabited Thrace and Illyria. Some of theſe, he ſays, occupied the Hernician foreſt on the other ſide of the Danube, and migrated into Bohemia; others were mixed among the inhabitants of Thrace; and others remained in Illyria, between the Danube and the Drave. Of theſe Boii there were, therefore, ſeveral diſtinct tribes. After Bellovеſus had made an irruption into Italy through the country of the Taurini, the Boii and Lingones entered it by the Pennine Alps. Theſe Boii occupied the more ſouthern part of Gallia Ciſpadana, or Ciſalpine Gaul, and were ſeparated from Etruria by the Apennines, and from the Senones by the Rubico. Their principal city was Bononia. In the year of Rome 395, they advanced in Italy as far as the plain of Prænelle, and were defeated there by the dictator C. Sulpicius. Purſued by the Romans, they retired over the Danube, and inhabited the confines of Pannonia and Illyria, along with the Tauriſci and Scordiſci. In this country they contended with Boerebiſtas, king of the Getæ, and were deſtroyed by his troops. Their country afterwards remained deſert and uncultivated, and was called the "deſert of the Boii." The Romans in proceſs of time built here the towns of Scarabantia and Sabaria. Cæſar is ſuppoſed to have referred to theſe Boii, when he ſays, that the Boii who had remained on the other ſide of the Rhine, and who had deſcended from Noricia, where they laid ſiege to the town of Norcia, were ſummoned by the Helvetii to unite with them in an irruption into Gaul. Another body of the Boii having entered into Germany, ſettled on the north of the Danube, in an extenſive country, almoſt wholly ſurrounded by mountains, and having on the weſtern part the Hereynian mountains. This country was afterwards occupied by the Marcomanni, and is now called Bohemia. Theſe Boii were blended by degrees with other nations; but retaining ſome kind of importance, they preſerved an imperfect trace of their name in that of Boioarii, whence proceeded Bavaria. The Boii, who joined the Helvetii on their attack of the Gauls, were overpowered by Cæſar; but after their defeat, the Ædui prevailed with Cæſar to allow them a ſettlement, on account of their diſtinguiſhed valour, in a ſmall diſtrict of their territory. It is ſaid that he built for them a ſmall town called "Gergovica," of which no trace now remains. M. d'Anville places theſe Boii in a kind of peninſula, formed by the rivers Liger and Elaver, before their re-union. Another body of the Boii, denominated by Auſonius "Picci," occupied the weſtern part of Gaul, comprehended in Novem-Populana, ſouth-weſt of the Bituriges Viviſci, upon the ſea-coaſt.

BOIL, or Furuncle, in *Surgery*, is a painful, circumſcribed, and inflammatory tumor, ſeldom larger than a pigeon's egg, generally of a conical figure, ſeated in the ſubcutaneous adipoſoſe membrane, and proceeding from an internal cauſe. Its apex or central point is but ſlightly raiſed above the ſkin, and commonly tends to ſuppuration. No part of the ſurface of the body is exempt from the attacks of this diſorder, but thoſe parts are more liable to boils which abound with cellular ſubſtance. The purulent fluid they contain is uſually incloſed in one or more cyſts or facculi, and is very ſlow in coming to a ſtate of full maturation; ſo that it is requiſite to aid the formation of matter by warm ſtimulating applications, and at the ſame time to ſupport the conſtitution by ſtrengthening remedies, nutritious diet, and ſalubrious air.

Several boils will often appear at the ſame time, and after they have healed, new ones may ariſe; in which caſe, we may ſuſpect the patient to be of an ill habit of body, and re-

quire particular medical attention. But it is a very bad practice, though by no means uncommon, to adminiſter frequent purges in ſuch caſes, which tend ſtill more to diminiſh the tone of the patient, already too much exhauſted. The ſtate of the ſyſtem muſt be remedied by ſuch means as are indicated by the peculiar circumſtances of the patient; for no general plan can be preſcribed, which is proper in all caſes.

Before a conſiderable boil appears, the patient ſometimes feels himſelf indiſpoſed, rather feveriſh, and is troubled with a number of ſlight complaints, which all diſappear as ſoon as the tumor is formed; ſo that in this caſe it ſeems to have ſome ſimilarity with a critical metaſtaſis. Otherwiſe, boils, on account of the ſenſe of tenſion and pain which they occaſion, are more troubleſome than dangerous.

The beſt common method of treating theſe tumors locally, is to bring them as ſoon as poſſible to ſuppuration, as this ſeems to be their natural tendency; and as the attempt to diſcuſs them generally ſucceeds either very imperfectly or not at all, ſome few caſes excepted. For diſcuſſing them are recommended the external applications of ſpirit of vitriol mixed with honey, ſtrong wine-vinegar, camphorated oil, &c. In moſt caſes, however, it is neceſſary that we ſhould immediately endeavour to promote ſuppuration, which may be done by means of ſimple emollients; ſuch as bread and milk poultices, linſeed cataplaſms, or a mixture of oatmeal and honey. If the pain be extremely great, we may add a ſmall quantity of the extract of hemlock or poppies, and give a grain or two of opium internally. When the inflammation is moderate, but the hardneſs conſiderable, ſtimulant and calefacient remedies, ſuch as roaſted onions, white-lilly roots, gum ammoniac, &c. muſt be combined with the emollients. Mr. Fielitz affirms that no remedy brings boils ſo eaſily and quickly to ſuppuration, as the leaves of the *ricinus communis* boiled in milk, and applied in the form of a poultice.

When the tumor does not burſt ſpontaneouſly, which it generally does at its point, it is to be opened with a lancet. Beſides the general rules, according to which ſuch an abſceſs muſt be treated, it is neceſſary alſo that the core or membranous part of the boil ſhould be extracted in due time, and that all the remaining hardneſs about the circumference of the ſore ſhould be diſcuſſed. For as long as this core remains in the cavity, the ſore will not heal perfectly, neither can it be brought to heal unleſs the hardneſs be diſcuſſed, but either an ulcer or a fiſtula is produced, or the ſore ſkins over, whilſt an induration ſtill remains behind, which gives riſe, according to the part in which it is ſituated, to various troubleſome ſymptoms, and after ſome time becomes again inflamed, nor does it diſappear entirely till it is diſcuſſed by a complete ſuppuration.

We may indeed attempt to diſcuſs ſuch indurations by means of the uſual deobſtruents, ſuch as the external applications of mercury, hemlock, ſoap, belladonna, &c. but they will generally fail of their effect, and we ſhall be obliged to wait till a new inflammation is produced. It is therefore beſt to ſupport and promote the ſuppuration from the very commencement, and not to ſuffer the abſceſs to heal up till all remains of induration have diſappeared; and when the ſuppuration does not proceed with ſufficient vigour, it ought to be promoted by means of warm turpentine, and digeſtive ointment. If this do not produce the requiſite effect, it ſhould be mixed with red precipitate; and to the indurated parts we ought to apply externally hot fomentations, with other emollient and ſtimulant remedies, according to the general rules laid down under the article Abscess.

Boils, *gum.* See Gum.

BOILEAU, Nicholas, named *Deſpreaux*, in *Biography*, an eminent ſatirical poet and critic, was born either at Paris, or at Crone near that city, in 1636. Boileau himſelf, after having been truly ennobled by his writings, had the ſilly vanity to pique himſelf on the high antiquity of his lineage. He pretended that John Boileau, the anceſtor of his family, was ennobled in 1371 by Charles V. king of France: and he boaſted, in conſequence of a ſuit inſtituted againſt his family, and occaſioned by a ſevere ſcrutiny into the validity of titles aſſumed by the nobleſſe of the kingdom, under a commiſſion of inquiry eſtabliſhed by Lewis XIV. in 1695, that he had gained his cauſe with flying colours, and that he had a patent in his poſſeſſion which allowed him a nobility of 400 years' antiquity. It is ſaid, however, that the ſentence paſſed in favour of Boileau's nobility was the reſult of his reputation as a poet, honoured with the protection of the king; that the titles produced had been fabricated; and that a writ had been found among the papers of the poet for 20 louis d'ors, paid by him for his ſhare in the titles which had been forged by an obſcure perſon of the name of Haudiquer. However this be, his own writings were unqueſtionably his beſt "lettres de nobleſſe." As a younger brother, he was harſhly treated in his youth, more eſpecially becauſe his father regarded him as a heavy and ſtupid lad, deſtitute of that vivacity of temper and underſtanding for which his elder brothers were diſtinguiſhed. We are informed alſo, that he underwent an operation for the ſtone at eight years of age. Theſe circumſtances probably induced him to declare, that if he could be reſtored to infancy, on the hard conditions he had experienced, he would not have accepted the grant; and hence he always diſputed the common opinion, that infancy is the happieſt period of our lives. Deſpreaux, indeed, ſeems not to have thought the other parts of his life more happy than his infancy; to him all appeared equally miſerable; youth, tormented with paſſions, maturity with cares, and old age with infirmities; and he ſeemed to have adopted in ſome meaſure that philoſopher's opinion, who, when he was aſked "what was the happieſt period of a man's life?" anſwered, "that which is paſt." "It would be difficult," ſays Deſpreaux, "to determine this queſtion; we are ſure, however, that it is hardly ever the preſent time." Boileau was intended by his father for the profeſſion of an advocate; but his taſte for polite literature, to the culture and gratification of which he devoted his leiſure hours, diſqualified him for this mode of life; and his repugnance to it was ſtrongly indicated by his dropping aſleep, while his brother-in-law, M. Dongois, a clerk of parliament, was reading an arret, which he had taken great pains to compoſe. Upon this, he was ſent home to his father as an invincible dunce, who would be nothing elſe but a ſimpleton during his life. Relieved from the embarraſſment of purſuing a profeſſion which he deteſted, his attention was next directed to ſcholaſtic divinity, from which he was equally averſe. When his father found, that his views reſpecting him were altogether fruſtrated, he allowed him to indulge his own inclination, and to devote himſelf wholly to literature. At the age of 30 years, Boileau's true character, which had long been unknown to any but his intimate and confidential friends, was developed; and he appeared before the public as "a writer of ſatires." He began with ridiculing the numerous tribe of bad writers, and he thus excited a hoſt of enemies. Among others the duke de Montauſſier reproached him on account of the ſeverity of his perſonal ſatires as injurious to ſociety; but he contrived to diſarm his enmity by a ſingle ſtroke of flattery, which verified, ſays D'Alembert, the lines of La Fontaine:

"Amuſe the great with adulation,
Your praiſe to all their faults extend,

Whate'er

Whate'er their former indignation,
The bait goes down, and you're their friend."

Twelve of his ſatires were publiſhed; one of theſe was his ſatire againſt women, the moſt bitter and outrageous of all, which is ſaid to have been occaſioned by his having been in early life jilted by a young perſon to whom he was going to be married, and who ran away with a moſquetaire. Racine the younger, one of his particular friends, however, ſays, that he never had a miſtreſs, nor ever thought of marrying. On the publication of this ſatire he was attacked from all quarters; but his friend Racine conſoled him as well as he could: "Courage," ſays he, "you have attacked a numerous corps, which is all tongue; but the ſtorm will blow over." The beſt of his ſatires was that entitled "A ſon Eſprit;" a piece of irony, abounding with the moſt keen and poliſhed ridicule. Whatever reproach Boileau incurred for the perſonality of his ſatires, it is mentioned to his honour, that he always diſtinguiſhed between folly and vice; and that he never attacked bad taſte and dunces with any other arms than ridicule, while vice and profligacy were treated by him with juſt indignation.

The ſatires of Boileau were followed by his "Art of Poetry," which is reckoned the beſt of all the poetical works of criticiſm exiſting, equally admirable for the good ſenſe of its maxims, and the appropriate beauties of language by which his precepts are exemplified. This was ſucceeded by his "Epiſtles," formed after the model of Horace, and rendered peculiarly pleaſing by the union of morality with criticiſm, and deſcription with ſentiment; interſperſed with characteriſtic traits and anecdotes of himſelf. In one of theſe, addreſſed to the king, he artfully, at the inſtigation of Colbert, endeavoured to divert the ſovereign's mind from the ſchemes of conqueſt to the glory of promoting the welfare of his ſubjects by plans of utility and beneficence. Lewis was gratified by the delicate praiſe with which this advice was accompanied, and applauded the epiſtles; but went to war with Holland. In 1674, he publiſhed his "Lutrin," a mock-heroic kind of compoſition, founded on a trifling diſpute between the treaſurer and chanter of the holy chapel, and ranking among the firſt productions of this claſs. Boileau had now acquired a degree of reputation which recommended him to favour and patronage at court; and the king honoured him with a penſion, an excluſive privilege for printing his own works, and the office, conjointly with his friend Racine, of royal hiſtoriographer. In this latter capacity neither he nor his aſſociate had an oportunity of appearing before the public. Boileau, indeed, publiſhed his "Ode on the taking of Namur," which is more an hiſtorical than a poetical effort. At this time he attended frequently at court; and yet he maintained a freedom and frankneſs of ſpeech, more eſpecially on topics of literature, which are not common among courtiers. When Lewis aſked his opinion of ſome verſes which he had written, he replied; "Nothing, ſire, is impoſſible to your majeſty; you wiſhed to make bad verſes, and you have ſucceeded." He alſo took part with the perſecuted members of the Port-royal; and when one of the courtiers declared, that the king was making diligent ſearch after the celebrated Arnauld, in order to put him in the Baſtile, Boileau obſerved, "His majeſty is too fortunate; he will not find him:" and when the king aſked him, what was the reaſon why the whole world was running after a preacher, named le Tourneux, a diſciple of Arnauld, "Your majeſty," he replied, "knows how fond people are of novelty: —this is a miniſter who preaches the goſpel." Boileau appears, from various circumſtances, to have been no great friend to the Jeſuits, whom he offended by his "Epiſtle on the Love of God," and by many free ſpeeches. By royal favour, he was admitted unanimouſly, in 1684, into the French academy, with which he had made very free in his epigrams; and he was alſo aſſociated to the new Academy of Inſcriptions and Belles Lettres, of which he appeared to be a fit member by his "Tranſlation of Longinus on the Sublime." To ſcience, with which he had little acquaintance, he rendered, however, important ſervice by his burleſque "Arret in favour of the Univerſity, againſt an unknown perſonage called Reaſon," which was the means of preventing the eſtabliſhment of a plan of intolerance in matters of philoſophy. His attachment to the ancients, as the true models of literary taſte and excellence, occaſioned a controverſy between him and Perrault concerning the comparative merit of the ancients and moderns, which was proſecuted for ſome time by epigrams and mutual reproaches, till at length the public began to be tired with their diſputes, and a reconciliation was effected by the good offices of their common friends. This controverſy laid the foundation of a laſting enmity between Boileau and Fontenelle, who inclined to the party of Perrault. Boileau, however, did not maintain his opinion with the pedantic extravagance of the Daciers; but he happily exerciſed his wit on the miſrepreſentations of the noted characters of antiquity, by the faſhionable romances of the time, in his dialogue entitled "The Heroes of Romance," compoſed in the manner of Lucian. In oppoſition to the abſurd opinion of father Hardouin, that moſt of the claſſical productions of ancient Rome had been written by the monks of the 13th century, Boileau pleaſantly remarks, "I know nothing of all that; but though I am not very partial to the monks, I ſhould not have been ſorry to have lived with friar Tibullus, friar Juvenal, Dom Virgil, Dom Cicero, and ſuch kind of folk." After the death of Racine, Boileau very much retired from court; induced partly by his love of liberty and independence, and partly by his diſlike of that adulation which was expected, and for which the cloſe of Lewis's reign afforded more ſcanty materials than its commencement. Separated in a great degree from ſociety, he indulged that auſtere and miſanthropical diſpoſition, from which he was never wholly exempt. His converſation, however, was more mild and gentle than his writings; and, as he uſed to ſay of himſelf, without "nails or claws," it was enlivened by occaſional ſallies of pleaſantry, and rendered inſtructive by judicious opinions of authors and their works. He was religious without bigotry; and he abhorred fanaticiſm and hypocriſy. His circumſtances were eaſy; and his prudent economy has been charged by ſome with degenerating into avarice. Inſtances, however, occur of his liberality and beneficence. At the death of Colbert, the penſion which he had given to the poet Corneille was ſuppreſſed, though he was poor, old, infirm, and dying. Boileau interceded with the king for the reſtoration of it, and offered to transfer his own to Corneille, telling the monarch, that he ſhould be aſhamed to receive his bounty while ſuch a man was in want of it. He alſo bought, at an advanced price, the library of Patru, reduced in his circumſtances, and left him in the poſſeſſion of it till his death. He gave to the poor all the revenues he had received for eight years from a benefice he had enjoyed, without performing the duties of it. To indigent men of letters his purſe was always open; and at his death he bequeathed almoſt all his poſſeſſions to the poor. Upon the whole, his temper, though naturally auſtere, was, on many occaſions, kind and benevolent, ſo that it has been ſaid of him, that he was "cruel only in verſe;" and his general character was diſtinguiſhed by worth and integrity, with ſome alloys of literary jealouſy and injuſtice.

juſtice. He died of a dropſy in the breaſt in 1711, at the age of 75, and bequeathed the greater part of his property to charitable uſes. His funeral was attended by a very conſiderable number of perſons of rank and literature. How came this man (exclaimed a woman in the ſtreet) to have ſo many friends? They ſay he never ſpoke well of any body in his life.

As a poetical writer, he has been denominated the "poet of good ſenſe," correct in his verſification, choice and pure in his language, juſt and rational in his ſentiments, always guided by judgment and taſte, obſerving the limits of decorum, and never betrayed by wit or fancy into extravagancies. Few, if any writer, ever compoſed ſo much, with ſo little occaſion for eraſement or alteration, Voltaire, who often denied the equity of his deciſions in matters of criticiſm, ſays of him, in a letter to Helvetius; "I agree with you that Boileau is not a ſublime poet; but he executed admirably whatever he undertook. He is clear, eaſy, happy in his expreſſion; he ſeldom riſes very high, but he never ſinks. Beſides, the ſubjects of which he treats are not of a kind to require great elevation. —— I ſhall, therefore, always warmly recommend that kind of writing which he has ſo well taught, that reſpect for language, that quick ſucceſſion of ideas, the art and facility with which he conducts his reader from one ſubject to another; and above all, his ſimplicity, which is the true fruit of genius." Boileau was the firſt writer who formed the national taſte of France, and by his tranſlations and imitations gave his countrymen a true reliſh for the epiſtles and ſatires of Horace, which before his time uſed to be much leſs eſteemed than his odes. The great defect of Boileau, according to D'Alembert, is want of ſenſibility; and if enthuſiaſm, which is incompatible with that coldneſs of heart that diſtinguiſhed his character, is eſſential to a true poet, his claim to this honourable appellation muſt be diſallowed. Nevertheleſs, his works may be juſtly regarded as maſter-pieces of their kind, and can never die, as long as the language in which they are written exiſts. Having taken great pains in the compoſition of them, he was not inſenſible of their peculiar and characteriſtic excellence; accordingly, in ſome lines written by himſelf, and intended to be placed under his portrait, he makes no heſitation in affirming that he had united the merits of Perſius, Juvenal, and Horace. Boileau and Pope have been thought much to reſemble one another, as to both the kind and diſcriminating character of their writings; but, ſays a very competent judge, "Boileau, with a nearly equal portion of wit, has much more delicacy and correctneſs; while Pope as much ſurpaſſes him in force and fancy. Both abound in good ſenſe, and each has enriched his language with nervous lines that have paſſed into proverbial ſentences." In another place the ſame writer obſerves, that after we have rendered to Boileau Deſpreaux all due homage as a great poet, and as the legiſlator of taſte, his faults as a ſatiriſt indicate an acrimonious and unfeeling character, a high conceit of his own powers and conſequence, and an unpardonable diſregard of the happineſs and reputation of others. "If the Engliſh poet had as much cauſticity as the French, and more peeviſh irritability, he ſeems to have had a more feeling heart, and a nicer ſenſe of juſtice." We may remark, that perſonal ſatire ſoon loſes its ſalt and poignancy; and that the ſatires of Boileau, as well as the Dunciad of Pope, are leſs read now than any of their other works.

Beſides the works of Boileau, already mentioned, there are ſeveral ſmaller pieces both in proſe and verſe. Of the whole there have been various editions, with explanatory notes; and of theſe the principal are that of Geneva, 2 vols. 4to. 1716, with illuſtrations, by Broſette; that of the Hague, with Picart's figures and notes, 2 vols. fol. 1718, and 4 vols. 12mo. 1722; that by Allix, with Cochin's figures, 2 vols. 4to. 1740; and that of Durand with illuſtrations, by St. Marc, 5 vols. 8vo. 1747.

Boileau had ſeveral brothers of very ſingular characters. *James*, a doctor of the Sorbonne, was born in 1635, ſtudied in the univerſity of Paris, took his degree of doctor in theology in 1662, was appointed dean of Sens, and vicar of the archbiſhop Gondoin, in 1667; and in 1694, was preſented by the king with a canonry in the holy chapel of Paris. He died dean of the faculty of theology in 1716. He is well known by a number of works in a peculiar ſtyle, ſome of which were not remarkable for decency; but theſe he wrote in Latin, "leſt the biſhops," he ſaid "ſhould condemn them." He was not more a friend to the Jeſuits than his brother; and he deſcribed them as "Men who lengthened the creed, and ſhortened the commandments." As dean of the chapter of Sens, he was appointed to harangue the celebrated prince of Condé, when he paſſed through the city. This great commander took particular pleaſure on theſe occaſions in diſconcerting his panegyriſts; but the doctor, perceiving his intention, counterfeited great confuſion, and addreſſed him in the following manner: "Your highneſs will not be ſurpriſed, I truſt, at ſeeing me tremble in your preſence, at the head of a company of peaceful prieſts; I ſhould tremble ſtill more, if I was at the head of 30,000 ſoldiers." He manifeſted a contempt of fanaticiſm, as well as of decorum, by his "Hiſtoria Flagellantium, &c." or, an account of the extravagant, and often indecent, practice of diſcipline by flagellation, in the Chriſtian church. It was tranſlated into French; and not many years ago (viz. 1777, 4to. and again in 1782, 8vo.) by M. de Lolme, into Engliſh. In his treatiſe "De antiquo jure preſbyterorum in regimine eccleſiaſtico," he diſcovers the greateſt freedom of ſentiment, endeavouring to ſhew, that in the primitive times the prieſts participated with the biſhops in the government of the church. He was alſo the author of ſeveral other publications, diſplaying much curious learning and a ſatirical turn, which are now conſigned to oblivion.

Gilles, the eldeſt brother of Boileau Deſpreaux, was born in 1631, and had a place in the king's houſhold. He was a man of wit and learning, and publiſhed a tranſlation of Arrian's Epictetus, with a life of the philoſopher, Paris, 1655, 8vo. He alſo publiſhed a tranſlation of Diogenes Laertius, in 2 vols. 12mo. 1668; and two diſſertations againſt Menage and Coſtar. His "Poſthumous Works" were publiſhed in 1670. He alſo wrote verſes, in no high eſtimation; and his poetical pretenſions exited a jealouſy of his brother's riſing fame, which produced an open variance between them. He was a member of the French academy; and died in 1669. Gen. Dict. Nouv. Dict. Hiſt. D'Alembert's Hiſt. des Membres de l'Acad. Franc. 1787, and Eloges, &c. 1779,—tranſlated by Aikin in 2 vols. 8vo. 1799.

BOILED, or Boyled *ſilks*, thoſe which have been put, while in the balls, into hot water, to make them wind the better.

In which ſenſe, boiled ſilk ſtands oppoſed to raw.

BOILER, or Boyler, a large copper veſſel, wherein things are expoſed over the fire to be boiled.

The boiler in the alum-works is a veſſel, in which the liquor is evaporated to a conſiſtence, and is made of lead. The general ſize is about eight feet ſquare, and they contain about twelve tons each.

They make them in this manner: firſt, they lay long pieces of caſt-iron, twelve inches ſquare, as long as the breadth

breadth of the boiler, and at about twelve inches diſtance from one another. Theſe are placed twenty-four inches above the ſurface of the fire. On theſe maſſy bars of iron they lay, croſs-wiſe, the common flat bars of iron, as cloſe as they can lie together, and then make up the ſides with brick-work. In the middle of the bottom of this boiler is laid a trough of lead, wherein they put at firſt about a hundred pound weight of the rock. They uſe Newcaſtle coals in the boiling; and if they find the liquor not ſtrong enough, they add more of the rock at times, as it boils. Phil. Tranſ. N° 142.

The boiler for making colours, &c. muſt be made of pewter; becauſe iron and copper will be corroded by the ſaline ſubſtances uſed in the manufacture of them.

Count Rumford (See his Eſſays, vol. i. p. 220.) recommends double bottoms to boilers, and alſo to ſaucepans and kettles of all kinds, uſed for culinary purpoſes; which contrivance, he ſays, will, in all caſes, moſt effectually prevent what is called by the cooks, "burning-to." The heat is ſo much obſtructed in its paſſage through the thin ſheet of air which, notwithſtanding all the care that is taken to bring the two bottoms into actual contact, will ſtill remain between them, that the ſecond has time to give its heat as faſt as it receives it to the fluid in the boiler; and conſequently it never requires a degree of heat ſufficient for burning any thing that may be upon it. He ſuggeſts that it will probably be beſt to double copper ſaucepans and ſmall kettles throughout; and as this may and ought to be done with a very thin ſheet of metal, it would not coſt much, even if the lining were to be made of ſilver. When the two ſheets of metal that form the double bottoms of boilers are made to touch each other throughout, by hammering them together after the falſe bottom has been fixed in its place, they may be tacked together by a few ſmall rivets placed here and there, at conſiderable diſtances from each other; and when this is done, the boiler may be tinned. In this operation, if proper care be taken, the edge of the falſe bottom may be ſoldered by the tin to the ſides of the boiler, and thus the water or other liquids, put into the boiler, will be prevented from getting between the two bottoms. The Count adds, that this invention of double bottoms might be uſed with great ſucceſs by diſtillers, to prevent their liquor, when it is thick, from burning to the bottom of their ſtills. (See Still.) Having found in the courſe of his experiments, (See Phil. Tranſ. 1792, Part I.) that confined air is the beſt barrier that can be oppoſed to heat for the purpoſe of confining it, he propoſed to confine the heat in the boilers of his conſtruction, and to prevent its eſcape into the atmoſphere, by means of double covers. Theſe covers were made of tin, or rather of thin iron-plates tinned, in the form of a hollow-cone; the height of the cone being equal to about one-third of its diameter; and thus the air which it contained was entirely ſhut up, the bottom of the cone being cloſed by a circular plate or thin ſheet of tinned iron. The bottom of the cone was accurately fitted to the top of the boiler, which it completely cloſed by means of a rim about two inches wide, which entered the boiler; which rim was ſoldered to the flat ſheet of tinned iron that formed the bottom of the cover. The ſteam, generated by the boiling liquid, was carried off by a tube about half an inch in diameter, which paſſed through the hollow conical cover, and which was attached to the cover, both above and below, with ſolder, in ſuch a manner that the air with which the hollow cone was filled remained completely confined, and cut off from all communication with the external air of the atmoſphere, as well as with the ſteam it generated in the boiler. For his various contrivances in the moſt advantageous conſtruction of boilers for the ſaving of fuel, and for producing the deſired effect, we refer to his Eſſays, vol. ii. p. 18, &c.

BOILERY, or Boilary, in the *Salt Works*, denotes a ſalt-houſe, pit, or other place, where ſalt is made.

BOILING of Meat, in *Cookery*, is the expoſing of meat to the heat of boiling water, while it is immerſed in it for a certain time. By this joint application of heat and moiſture, the texture is rendered more tender and more ſoluble in the ſtomach; and it is only in this way, that the firmer parts, as the tendinous, ligamentous, and membranous parts can be duly ſoftened, and their gelatinous ſubſtance duly extracted. A moderate boiling renders the texture of animal fleſh more tender, without much diminution of its nutritious quality; but if the boiling is extended to extract every thing ſoluble, the ſubſtance remaining becomes leſs ſoluble in the ſtomach, and at the ſame time much leſs nutritious. But as boiling extracts in the firſt place the more ſoluble, and therefore the ſaline parts; ſo the remainder, after boiling, is in proportion to the continuance of the operation leſs alkaleſcent, and leſs heating to the ſyſtem.

Boiling is commonly practiſed in open veſſels, or in veſſels not cloſely covered; but it may be performed in digeſters, or veſſels accurately and tightly cloſed; and in ſuch veſſels the effects are very different from thoſe that take place in open veſſels. As we can hardly employ any other degree of heat than that of boiling water, the water in the digeſter is never made to boil, ſo there is no exhalation of volatile parts; and, although the ſolution is made with great ſucceſs, and may be to any degree required, yet if it be not carried very far, the meat may be rendered very tender, while it ſtill retains its moſt ſapid parts; and this kind of cookery will always give the moſt deſirable ſtate of boiled meat. Boiling, in the ordinary way, is different, according to the proportion of water that is applied. If a ſmall quantity be applied, and the heat in a moderate degree is continued for a long time, this is called "ſtewing," and has the effect of rendering the texture more tender, without extracting much of the ſoluble parts; and of courſe it leaves the meat more ſapid, and ſufficiently nouriſhing. Cullen's Mat. Med. vol. i. p. 400, &c.

Boiling, *ebullition*, in *Phyſics*, is the internal commotion excited in a maſs of water or other liquefied ſubſtance, by the ſucceſſive converſion of the lower portions of the fluid into vapour, and their violent effort under this expanſive and elaſtic form to make their eſcape. It is uſually, though not neceſſarily, produced by the application of heat. The circumſtances which precede or accompany the phenomenon of boiling, are beſt obſerved in a thin tranſparent flaſk nearly filled with water, and ſuſpended over a lamp or a charcoal fire. Numerous minute globules are ſeen collecting from all points towards the ſides and riſing in a ſtream to the ſurface; occaſioned evidently by the diſcharge of air, which is always in ſome proportion combined with water. As the heat increaſes, the liquid particles near the bottom of the flaſk ſuddenly burſt into ſteam, and ſhoot upwards; but in aſcending through the colder maſs, they again collapſe, ſtop their progreſs, and ſeem loſt. Such alternate expanſions and contractions, by throwing the fluid into a gentle tremor, frequently cauſes a peculiar ſort of ſinging noiſe, which is rightly ſuppoſed to betoken the approach of actual boiling. This ſinging is more likely to happen in the caſe where heat is applied partially; for inſtance, if a tea-kettle be placed at the ſide of the fire, ſince the heat is then more ſlowly and unequally diffuſed through the body of the water. But after the whole contents being fully penetrated, are warmed up to the requiſite degree of intenſity, the ſteam, as faſt as it is

formed, aſcends continually and eſcapes unimpaired through the fluid, which it therefore heaves with violent agitation.

The ſame appearance almoſt is produced by removing or even diminiſhing the atmoſpheric preſſure. Thus, if a tumbler holding warm water be introduced under the receiver of an air-pump, as the exhauſtion proceeds, or the incumbent weight is gradually withdrawn, the latent portion of air is diſcharged in a rapid flow of expanded bubbles. But this proceſs, at ſome certain point of rarefaction, is ſucceeded by the vehement commotion which conſtitutes boiling; and the water, aſſuming its inviſible form, fills the imperfect void with vapour, which betrays its exiſtence by condenſing againſt the ſides of the receiver in copious dew. Nor is heat poſitively neceſſary towards vaporization, for it only conſpires in accompliſhing that effect, and ſupplies the want or the imperfection of our means of producing exhauſtion. By help of an air-pump of the beſt conſtruction, the coldeſt water may be made to boil, nay, ice itſelf could be changed into inviſible ſteam. Hence the utter impoſſibility of ever obtaining a perfect *vacuum*, becauſe the reſtraining influence of preſſure being entirely removed, the liquid matter unavoidably preſented would always diffuſe a thin vapour.

The oppoſite influence of heat and preſſure on the conſtitution of fluids is well exhibited by a very ſimple yet ſtriking experiment. Take a large thin phial, and having warmed it gradually to avoid the riſk of cracking the glaſs, fill it completely with boiling water, cork it tight, and expoſe it to a current of cold air. As the water cools, it neceſſarily contracts its volume, and leaving an imperfect vacuity below the neck of the phial, it hence becomes to a conſiderable degree relieved from the load of atmoſpheric preſſure. It therefore ſoon begins again to boil, nay, it will boil more briſkly the faſter it cools; and this ſingular appearance, ſo contrary to our uſual notions, may continue perhaps for the ſpace of half an hour, till the water has grown as cold almoſt as the temperature of the human body. On the ſame principle depends the conſtruction of what is called the *pulſe glaſs*: this conſiſts of two balls connected by a pretty long tube; one of theſe balls is filled with coloured water or ſpirits of wine, which having been made to boil and expel the air by its vapour, at the ſame inſtant the point projecting from the other ball is hermetically ſealed. As that vapour condenſes with cold, it will leave the included liquid then in a ſort of vacuum, and the heat of the hand is then ſufficient to cauſe it to boil and to flow from one ball into the other.

If a veſſel containing water be placed over a ſteady fire, the water will grow continually hotter till it reaches the limit of boiling, after which the regular acceſſions of heat are wholly ſpent in converting it into ſteam. The water therefore remains at the ſame pitch of temperature, however fiercely it boils. The only difference is that, with a ſtrong fire, it ſooner comes to boil, and more quickly boils away. Hence the reaſon why a veſſel full of water, and plunged into the centre of a larger one, which is likewiſe filled with that fluid, barely acquires the boiling heat, but will never actually boil.

The formation of ſteam occaſions a prodigious conſumption of heat; for if the time be noted in which water, by the action of a ſtrong fire, is raiſed from the limit of freezing to that of boiling, it will be found to require more than five times longer a ſpace to boil entirely away. Thus, a portion of heat correſponding to above 900 degrees by Fahrenheit's ſcale, is always conſumed in the act of boiling, or rather it is transferred and enters into the compoſition of ſteam, the gaſeous product. This abſorbed heat is as conſtantly evolved when ſteam condenſes and returns to its liquid form. Hence in diſtillation a very large refrigeratory is required for condenſing a comparatively ſmall quantity of aqueous or ſpirituous vapour. Hence too the explication of the familiar remark that ſteam ſcalds more cruelly than boiling water.

The heat of boiling water, being ſubject to the influence of the atmoſpheric preſſure, is thus not abſolutely fixed. It varies with the variation of the barometer, and decreaſes as the mercury deſcends. The extent of this fluctuation may in our changeable climate amount to five degrees by Fahrenheit's ſcale, the ſucceſſive difference of a degree correſponding nearly to each twentieth part of the remaining incumbent weight. On the tops of lofty mountains water will boil much ſooner than in the plains below. This curious fact has been noticed by ſeveral travellers, and was particularly obſerved by Sauſſure on the ſummit of Mont Blanc. A ſtill greater variation would be experienced on the peak of Chimboraco, the higheſt point of the Andes, where water would boil with a heat ſcarcely ſuperior to that which is commonly aſſigned for the boiling of ſpirits of wine.

It is therefore evident that, under an augmented preſſure, all liquids will more ſlowly reach the criſis of ebullition and will then have acquired a more intenſe heat. Thus water may be heated up many degrees above the mean point of boiling, if it be ſubjected to the action either of condenſed air or of confined ſteam. Such is the principle of *Papin's Digeſter*; which, being nearly filled with water, is ſhut perfectly cloſe, and ſet on a good fire. As the ſteam ſo formed is prevented from eſcaping, it neceſſarily concentrates, and exerting accumulated energy, it by its prodigious compreſſion enables the water continually to receive additional heat. Nor would this progreſs at all ſtop, till the elaſticity of the impriſoned vapour comes to ſurmount every obſtacle, and burſts the veſſel with terrible exploſion. Accidents of that ſort are extremely dangerous, and the experiment has conſequently never been puſhed to its utmoſt practicable limits. When the fracture takes place, not only the confined ſteam is liberated, but the preſſure being now removed, the exceſs of heat inſtantaneouſly converts a part or the whole of the water likewiſe into ſteam, which augments the general effect. This we may perceive in the burſting of a glaſs cracker; for the little baſe is ſhivered into atoms, and the water which it contained is entirely diſperſed, beating down flat the wick of the candle by the violence of the ſudden expanſive blaſt.

Hence the boiling heat of a deep cauldron is always rather greater than that of a ſhallow pan. This exceſs we might eſtimate at nearly one degree of Fahrenheit, for each foot of depth. The heat of ebullition muſt alſo riſe ſomewhat higher, if the ſteam be not allowed to eſcape as faſt as it is generated; for which reaſon there may be a ſlight difference of energy between rapid and ſlow boiling. Hence by the combined operation of both theſe cauſes, water deeply lodged in the bowels of the earth or concealed under the dark bed of the ocean, is capable of acquiring the moſt intenſe heat from the action of ſubterranean fires; a principle of which Dr. Hutton has ingeniouſly availed himſelf in framing his Theory of the Earth.

But the poſition of the boiling point is likewiſe modified by the influence of chemical attraction. Thus ſugar, common ſalt, and other ſaline ſubſtances, have all of them a tendency to fix water and retard the criſis of its converſion into elaſtic vapour. Strong brine will not boil until it is heated up ſeveral degrees above the ordinary limit. Hence a veſſel containing freſh water, and immerſed in another which is filled with brine, will gently boil, while the ſurrounding fluid only ſimmers. On the other hand, the addi-

tion of alcohol renders water more volatile. In the diſtillation of ſpirits, the fermented liquor in the copper boils always at a lower temperature, or at ſome intermediate point between the ebullition of water and that of alcohol. The ſpirituous fumes which riſe carry along with them a portion of evaporated water. Hence the neceſſity of rectification, or repeated diſtillations, to procure alcohol in its pureſt ſtate; for the boiling heat is lowered, and conſequently the proportion of aqueous admixture is diminiſhed, at each ſucceſſive proceſs. See Digester, Ebullition, Fire, Fluid, Heat, Pressure, Steam, Vapour.

Boiling *of ſilk with ſoap*, is the firſt preparation in order to dyeing it. Thread is alſo *boiled* in a ſtrong *lixivium* of aſhes, to prepare it for dyeing.

Boiling is alſo a part of the proceſs for bleaching warp linen.

Boiling *to death*, *caldariis decoquere*, in the *Middle Age*, a kind of puniſhment inflicted on falſe coiners, thieves, and ſome other criminals.

This puniſhment was inflicted on thoſe who were guilty of murder by poiſon, 22 Hen. VIII. cap. 19. but this act was repealed by 1 Edw. VI. cap. 12.

Boiling is alſo a method of trying or aſſaying the goodneſs or falſeneſs of a colour of a dye, by boiling the ſtuff in water with certain drugs, different according to the kind or quality of the colour, to try whether or no it will diſcharge, and give a tincture to the water.

With this intention, red crimſon ſilks are boiled with alum, and ſcarlets with ſoap, in quantity equal to the weight of the ſilk.

Boiling *waters*, in *Natural Hiſtory*. See Spring, and Water.

BOINITZ, in *Geography*, a town of Hungary, eleven miles W. N. W. of Kremnitz.

BOJOBI, in *Zoology*, the Braſilian name of the Linnæan *boa canina*. See Canina.

BOIODURUM, in *Ancient Geography*, a town of Vindelicia, ſituate on the Danube, according to Ptolemy; the Itinerary of Antonine places it on the route from Ovilabis to Auguſta Vindelicium, between Stanacum and Quintianæ.

BOIOHEMUM, or Boimum, the country of the Boii, anſwering to the preſent *Bohemia*, which ſee. On the ſouth of it lay the "Gabreta Sylva," and to the ſouth, weſt, and north, the "Hercynii montes." The interior of it was penetrated with difficulty, and was little known.

BOJOWKA, in *Geography*, a town of Poland, in the palatinate of Braclaw, forty-eight miles eaſt of Braclaw.

BOIQUIRA, in *Zoology*, a name by which the natives, in ſome parts of America, call the *rattle ſnake*. Suppoſed to be the *Crotalus horridus*, of Naturaliſts.

BOIREL, Anthony, in *Biography*, born at Argentan, in Normandy, about the year 1625, applied himſelf to the practice of ſurgery, in which he acquired conſiderable reputation. In 1677 he publiſhed, "Traité de plaies de tete," 8vo. extracted principally from the works of Hippocrates, Galen, and of Ambroſe Parè, which he appears to have ſtudied diligently. He has added ſome improvements to their practice.

Nicholas Boirel his brother, phyſician at Argentan, publiſhed, in 1702, "Nouvelles obſervations ſur les maladies veneriennes," 12mo. Paris, which was reprinted 1711, but contains little new on the ſubject. Haller Bib. Eloy. Dict. Hiſt.

BOIS, Cardinal du. See Dubois.

Bois, Gerard du, a member of the congregation of the Oratory, and a Latin profeſſor in it, was born at Orleans, in 1620. Having ſucceeded father Le Comte, in his place of librarian to St. Honoré, and having poſſeſſion of his papers, he finiſhed for the preſs his eighth and laſt volume of the "Eccleſiaſtical Annals of France," which was printed in 1683; and in conſequence of it he obtained a perſion from the French clergy. He afterwards undertook to write the hiſtory of the Pariſian church; and, in 1690, publiſhed the firſt volume in folio. The ſecond, which he did not live to finiſh, appeared after his death, which happened in 1696. This work is written in pure elegant Latin, and contains a variety of intereſting facts relating to civil as well as eccleſiaſtical hiſtory. Nouv. Dict. Hiſt.

Bois, Boys, or Boyse, John, an eminent divine, and one of the tranſlators of the bible, in the reign of James I. was born at Nettleſtead in Suffolk, in 1560, and made ſuch early proficiency under the inſtructions of his father, that at the age of five years he read the bible in Hebrew; and at ſix, wrote that language in a fair and elegant character. At the age of 14 he was admitted into St. John's college, Cambridge, and by his great ſkill in the Greek language obtained a ſcholarſhip before he had been half a year at college, and afterwards a fellowſhip. Declining the profeſſion of phyſic, for which he was intended, he devoted himſelf to the ſtudy of divinity, and was ordained in 1583. He officiated for 10 years in his college as principal Greek lecturer; and as an inſtance of his aſſiduous application, and of the early hours of ſtudy at that period, it is mentioned, that he voluntarily read a Greek lecture at four in the morning, which was attended by moſt of the fellows. On the death of his father, he ſucceeded him in the rectory of Weſt-Stowe, near Bury, in Suffolk; but in 1596, he married the daughter of Mr. Holt, rector of Boxworth, in Cambridgeſhire, and having before reſigned Weſt-Stowe, took poſſeſſion of this living. In this ſituation the neglect of domeſtic economy involved him ſo much in debt, that he was under a neceſſity of ſelling his choice collection of books. Afterwards, however, he retrieved his affairs by keeping a boarding-ſchool; and was appointed one of the Cambridge tranſlators of the bible. (See Bible.) The part that fell to the lot of that claſs of divines, with whom he was connected, was the Apocrypha; and this he compleated in four years, without deriving any advantage from it beſides his commons. He was afterwards appointed one of the ſix delegates who met at Stationers'-hall in London, for the purpoſe of reviſing the tranſlation, and who were employed for nine months in this buſineſs, with an allowance from the Stationers' company of 30s. a-week each. For the aſſiſtance which he gave to ſir Henry Savile, in the publication of St. Chryſoſtom's works, to which he devoted the labour of many years, he received the very inadequate recompence of a ſingle copy of the work. However, ſuch was his reputation, that he obtained, without ſolicitation, from Dr. Andrews, biſhop of Ely, a prebend in his cathedral, in 1615; and he was thus enabled to ſpend the laſt 28 years of his life in tranquil retirement. Although he was always a hard ſtudent, he publiſhed nothing; but left behind him many MSS. particularly a commentary on the greateſt part of the N. T. A work of which few copies were printed, and, therefore, little known, appeared after his death, under the following title "Johannis Boiſii veteris Interpretis cum Beza aliiſque recentioribus collatio in IV Evangeliis, et Actis Apoſtolorum," London, 1655, 8vo. He ſuſtained the character of an excellent Latin writer, a profound ſcholar, a loyal ſubject, a ſtrict churchman, and a plain practical preacher. It was his practice to attend the public ſervice of the church twice, if not thrice a day; and his charity was as extenſive as his devotion was regular and conſtant. Although he devoted eight hours a day to ſtudy even in his old age, he preſerved his health by the exerciſe of walking,

to which he had accuſtomed himſelf from his youth, by confining himſelf to two meals a day, dinner and ſupper, by ſitting or walking an hour after dinner before he went into his ſtudy, by occaſional faſting, ſometimes twice in a week, and ſometimes once in three weeks, and by not ſtudying after ſupper, particularly towards the cloſe of life, but diverting himſelf with cheerful converſation for two hours among his friends. When he was a young ſtudent at Cambridge, he received from the learned Dr. Whitaker theſe three rules for avoiding thoſe diſtempers which uſually attend a ſedentary life, to which he adhered with equal conſtancy and ſucceſs. The firſt was to ſtudy always ſtanding; the ſecond never to ſtudy in a window; and the third never to go to bed with his feet cold. Accordingly he attained the age of 84 years, and died in 1643. Biog. Brit.

Bois, Du, *Lake*, in *Geography*, lies in North America, to the north-weſt of lake Superior, and receives the river de la Pluie, in N. lat. 49°. It was formerly famous for the richneſs of its banks and waters, which abounded with all the neceſſaries of a ſavage life. The French had formerly ſeveral ſettlements in and about it; but it has ſince declined, though it is now recovering its priſtine ſtate. The few Indians who inhabit it might live very comfortably, if they were not ſo immoderately fond of ſpirituous liquors. This lake is rendered remarkable by its having been named on the part of the Americans, as the ſpot from which a line of boundary between them and Britiſh America was to run weſt till it ſtruck the Miſſiſſippi, which, however, as Mr. Mackenzie obſerves, can never happen, becauſe the N. W. part of the lake du Bois is in N. lat. 49° 37′. and W. long. 94° 31′. and the northernmoſt branch of the ſource of the Miſſiſſippi is in N. lat. 47° 38′. and W. long. 95°6′. aſcertained by Mr. Thomſon, aſtronomer to the North-weſt Company, who was ſent expreſsly for that purpoſe in the ſpring of 1798. He, in the ſame year, determined the northern bend of the Miſſiſoury to be in N. lat. 47° 32′. and W. long. 101° 25′. and acording to the Indian accounts, it runs to the ſouth of weſt, ſo that if the Miſſiſoury were even to be conſidered as the Miſſiſſippi, no weſtern line could ſtrike it. It does not appear, ſays Mackenzie, to be clearly determined what courſe the line is to take, or from what part of lake Superior it ſtrikes through the country to the lake du Bois; if it were to follow the principal waters to their ſource, it ought to keep through lake Superior to the river St. Louis, and follow that river to its ſource; cloſe to which is the ſource of the waters falling into the river of lake la Pluie, which is a common route of the Indians to the lake du Bois; the St. Louis paſſes within a ſhort diſtance of a branch of the Miſſiſſippi, where it becomes navigable for canoes; and if the navigation of the Miſſiſſippi is conſidered as of any conſequence by this country, from that part of the globe, ſuch is the neareſt way to get at it. The lake du Bois is nearly round, and the canoe courſe lies through the centre of it among a cluſter of iſlands, ſome of which are ſo extenſive that they may be taken for the main land. The reduced courſe would be nearly north and ſouth. But, according to the navigating courſe, the diſtance is 75 miles, though in a direct line it would not be ſo long. At about two-thirds of it there is a ſmall carrying place where the water is low. The carrying place out of the lake is on an iſland, and named Portage du Rat, in N. lat. 49° 37′. and W. long 94° 25′. and is about 50 paces long. The lake diſcharges itſelf at both ends of this iſland, and forms the river Winipic, which ſee. Mackenzie's voyage, &c. through the Continent of North America. Introd. p. 59.

Bois-*belle*, or *Henrichemont*, a ſmall ſovereignty of France before the revolution, ſituate in Berry, between Bourges and Sancerre, about 10 leagues in circuit, containing about 6300 inhabitants; its principal towns are Bois-belle and Henrichemont, which ſee.

Bois-*belle*, a town of France, in the department of the Cher, 15 miles N. E. of Bourges.

Bois-*commun*, a town of France, and principal place of a diſtrict in the department of the Loiret, containing about 1600 inhabitants; 7 leagues N. E. of Orleans, and 5 W. of Montargis.

Bois, *Glacier des*, one of the lower Glaciers of the Alpine mountains adjoining to Mont Blanc, and the valley of Chamouny in Swiſſerland, from the thawed ice of which flows the river Arveron. This glacier is more than 15 miles long, and above three in its greateſt breadth. The general thickneſs of the ice was found by M. Sauſſure to be from 80 to 100 feet.

Bois-*le-duc*, or the *Duke's wood*, a city of Dutch Brabant, ſeated on the river Dommel, where it receives the waters of the Aa; ſo called from its ſituation in a woody country, to which the dukes of Brabant were accuſtomed to reſort for the purpoſe of hunting. The woods were cut down by order of Godfrey III. duke of Brabant; and he laid the foundation of a city in 1184, which was finiſhed in 1196, by his ſon duke Henry I. and much enlarged in 1352, 1453, and 1559. The city is encompaſſed by the Dommel and Aa, by the waters of which it may be eaſily inundated; and it is ſometimes inacceſſible except by boats. The principal forts that defend it are thoſe of Crevecœur, near the Meuſe; another called Iſabella; and a ſmall fort called St. Antoine, towards Brabant. It has alſo a caſtle, built by order of the States General, in the 17th century, as a check on the Roman catholics then more numerous than the reformed. It has four gates; and its walls are flanked with baſtions; the approach to it by land is on cauſeways, and by water at three gates or avenues. The cathedral, erected in 1366, and dedicated to St. John the Evangeliſt, is one of the moſt beautiful ſtructures in the Low Countries. Its wooden tower which was very lofty and ſupported by four ſtone pillars, was deſtroyed by lightning in 1584. It has had ſeveral other churches and monaſteries. This city ſuffered very much in the 16th century, during the religious wars; but at length the Dutch made themſelves maſters of it in 1629. Pope Paul IV. founded a biſhopric at Bois-le-duc in 1559, having juriſdiction over ten cities and 189 villages; the chief revenue of which aroſe from the abbey of Tongerlo. The diſtrict of Bois-le-duc, called "Mayerey," is ſituated between Holland and Guelderland, having Holland to the N., Upper Guelderland and the duchy of Cleves to the E., the quarter of Antwerp to the W., and the biſhopric of Liege to the S. It is divided into five ſmall diſtricts, and comprehends 102 villages, and three cities, Bois-le-duc, Helmont, and Eyndhoven. On the 14th of September 1794, an engagement took place near this town between the Britiſh army and the French, in which the latter were victorious; and on the 9th of October, in the ſame year, the town was taken by the French. It is 18 miles E. N. E. of Breda, and 42 S. S. E. of Amſterdam. N. lat. 51° 42′. E. long. 4° 59′.

Bois, *St. Marie, le*, a town of France, in the department of the Saone and Loire, and chief place of a canton, in the diſtrict of Charolles, 7 miles S. E. of Charolles.

Bois *d'Oignt*, a town of France, in the department of the Rhone, and chief place of a canton, in the diſtrict of Villefranche, 4½ leagues N. W. of Lyons. The place contains 900, and the canton 13,501 inhabitants; the territory comprehends 192½ kiliometres, and 18 communes.

BOISEAU, in *Commerce*, a meaſure of two buſhels and half of a peck at Bourdeaux in France.

BOISMONT, Nicholas Theinel de, in *Biography*, abbot of Greſtain, preacher in ordinary to the king, doctor in theology, and member of the French academy, was born in 1715, and obtained great reputation for eloquence, particularly in the compoſition of funeral orations. His principal works are, a panegyric of St. Lewis, and funeral orations on the Dauphin, on the queen of Lewis XV. and on that king himſelf. Theſe pieces are diſtinguiſhed by great fertility of ideas, a rapid and animated ſtyle, lively and noble imagery, and philoſophical reflection. On ſterile ſubjects, the orator exerciſes too much art in decoration, and is too fond of antitheſes. He is reckoned, however, the moſt eloquent of French orators in this department, and M. D'Alembert has alluded to him in a ſtrain of high applauſe in his eulogy of Flechier. Nouv. Dict. Hiſt.

BOISROBERT, Francis le Metel de, a man of wit and pleaſantry, much favoured by cardinal Richelieu, was born at Caen in 1592, and contributed much to the eſtabliſhment of the French academy, of which he was a member. He wrote poems, comedies, tragedies, tales, letters, romances, &c. which ſucceeded for a time, but are now almoſt forgotten. He was the amuſing companion of Richelieu, and gained by his buffooneries the abbacy of Chattillon-ſur-Seine, though his habits were far from being clerical. He was generous and beneficent, and took pleaſure in ſerving men of letters. He died in 1661. Nouv. Dict. Hiſt.

BOISSARD, John-James, an eminent antiquary, was born at Beſançon in 1528, and travelled, for the purpoſe of collecting antiquities, into Italy, the iſles of Corfu, Cephalonia, and Zante, and the Morea. After his return home, he was made governor to the ſons of the baron de Clervaut, and travelled with them into France, Germany, and Italy. Having loſt a great part of his valuable collection at Montbelliard, when the Lorrainers ravaged Franche-Comté, he took pains in repairing his loſs, and publiſhed his great work, much valued by antiquaries, and now ſcarce, entitled "De Romanæ urbis topographia et antiquitate," in 4 vols. fol. 1597—1602, enriched with many engravings by Theodore de Bry, and his ſons. He alſo publiſhed a work, entitled "Theatrum vitæ humanæ," 1597—1599, 4to. conſiſting of the lives of 198 illuſtrious perſons, with their portraits. His "Book of Emblems" was publiſhed, with figures, by Theodore de Bry, in 1593, 4to. His Latin verſes were inſerted by Gruter in the "Deliciæ Poetarum Gallorum;" and after his death was printed his work "De Divinatione et magicis præſtigiis," fol. He finally ſettled at Metz, and died there in 1602. Gen. Dict. Nouv. Dict. Hiſt.

BOISSEAUX, in *Geography*, a town of France, in the department of the Loiret, 4 leagues N. of Neuville.

BOISSEZON *d'Aumontel*, a town of France, in the department of the Tarn, and chief place of a canton, in the diſtrict of Caſtres, 2½ leagues E. S. E. of Caſtres.

BOISSIERE, La, a town of France, in the department of the Somme, and chief place of a canton, in the diſtrict of Montdidier, 2 leagues E.N.E. ofMontdidier.

BOISSIEU, Bartholomew, Camillus de, ſon of a phyſician at Lyons, was born in the year 1734. His father dying when he was only ſix years of age, his mother is ſaid to have taken on herſelf the care of his education, until he was ſufficiently advanced to be fit to be ſent to Montpellier. Paſſing through the uſual ſtages, in 1756 he was admitted doctor in medicine, and went thence to Paris, where he continued his ſtudies for twelve months longer. He here became acquainted with Sauvages, with whom he afterwards kept up an epiſtolary correſpondence. He now returned to Lyons, and was admitted of the college of phyſicians, and attained to conſiderable practice. His career was however ſhort, for he died in 1770, aged only 36 years. He was author of two diſſertations, the one on the power of antiſeptic medicines, the other containing a comparative view of the cordial or heating, and the cooling or antiphlogiſtic, mode of treating fevers, and gives the preference to the latter. He received for each of them a medal from the academy at Dijon. They were publiſhed in the years 1770, and 1772. Eloy. Dict. Hiſt.

BOISSY, Louis de, a dramatic writer of France, was born at Vic, in Auvergne, in 1694, and, though originally deſtined for the church, indulged his more prevalent inclination to the theatre. His firſt performance was a tragedy, which failed of ſucceſs; but he was more proſperous in comedy. His beſt pieces are "L'Impatient," "Le François a Londres," "Les Dehors Trompeurs," "Le Babillard," "La Surpriſe de la Haine," "Le Comte de Neuilli," and "La Pièce ſans Titre." Boiſſy's diſtinguiſhing merit conſiſted in availing himſelf of the ridicule of the day. His verſes are often ingenious, but his plots are defective. He became a member of the French academy in 1751; and had the honour of reviving the credit of a periodical publication, called the French Mercury. He died in 1758. His dramatic works have been collected in 9 volumes, 8vo. Nouv. Dict. Hiſt.

Boissy, *St. Leger*, in *Geography*, a town of France, in the department of the Seine-el-Oiſe, and principal place of a canton, in the diſtrict of Corbeil; the place contains 470, and the canton 14,224 inhabitants; the territory comprehends 177½ kiliometres, and 26 communes.

BOISZKY, a town of Poland, in the palatinate of Bielſk, 12 miles S.W. of Bielſk.

BOITIAPO, in *Zoology*, a ſort of ſerpent that inhabits Braſil, and is called by the Portugueſe *cobra de cipo*. This is an ambiguous ſpecies. It is deſcribed as being ſeven or eight feet long, as thick as a man's arm, round, and pointed towards the tail, like a ſhoe-maker's awl. The body covered with fine ſub-triangular ſcales, the colour olive and yellowiſh. It lives on frogs, and muſt be of the poiſonous kinds, ſince its bite is repreſented dangerous.

BOITMANZDORF, or Boesdorf, in *Geography*, a town of Sileſia, in the principality of Neyſz, 5 miles N.N.E. of Neyſz.

BOITZENBURG, a town of Germany, in the circle of Upper Saxony, and Ucker Marck of Brandenburg, 8 miles S. W. of Prenzlow.

Boitzenburg, or Botzenburg, a town of Germany, in the circle of Lower Saxony, and duchy of Mecklenburg, at the conflux of the Boitze and the Elbe. It was ſurrounded with walls in the 14th century; at this town, veſſels that paſs the river pay a toll, producing annually 40,000 dollars, of which the duke of Mecklenburg-Strelitz is entitled to 9000; 3 leagues E. of Lauenburg.

BOIVIN, Louis, in *Biography*, a diſtinguiſhed ſcholar and penſionary of the academy of belles letters, was born at Mentreuil l'Argilé in Upper Normandy, and educated, firſt under the Jeſuits at Rouen, and afterwards at Paris, where he ſettled. His acquirements in literature were various and extenſive; but his temper, according to his own account, was intractable and unſocial, enterpriſing, vain, and verſatile. He was employed by ſeveral eminent magiſtrates as the aſſociate and director of their private ſtudies; but the litigiouſneſs of his diſpoſition involved him in great trouble and expence. He publiſhed ſome learned diſſertations on hiſtorical ſubjects, in the "Memoirs of the Academy of Belles Letters;" and made great progreſs towards a new edition of Joſephus. He died in 1724, aged 75 years.

Boivin, John, a younger brother of the preceding, was born in 1662, and inſtructed by his brother, eſtabliſhed his reputation as a man of letters at Paris, at the age of 18 years. His diſpoſition was a counterpart to that of his brother, and he was much eſteemed for his amiable temper and manners. The abbé de Louvois aſſigned him a conſiderable penſion, and in 1714 procured for him the place of under-keeper of the king's library. In 1721, he was admitted member of the French academy, and became penſionary of that of belles lettres in 1724, on the death of his brother. He excelled in the Greek language, of which he was profeſſor in the royal college. His printed works are "An apology for Homer, and the ſhield of Achilles," 12mo; a French tranſlation of "Homer's Batrachomyomachia;" a French tranſlation of the "Oedipus of Sophocles, and the Birds of Ariſtophanes;" "Greek Poems," much admired for their anacreontic delicacy; an edition of the "Mathematici Veteres," 1693, fol.; a Latin "Life of Claude Pelletier;" a Latin tranſlation of the "Byzantine Hiſtory of Nicephorus Gregoras, with notes," 1702, which is eſteemed faithful, learned, and elegant. He alſo publiſhed ſeveral diſſertations on hiſtorical and literary topics in the "Memoirs of the Academy of Belles Lettres." He died in 1726. Nouv. Dict. Hiſt.

BOIUM, in *Ancient Geography*, one of the four principal cities of the Doride country in Greece. It was ſeated on the river Pindus, to the eaſt of Erineus.

BOKEA, in *Botany*, (Aubl. Guian. Sup. 38. t. 391.) fructification unknown.

Species. B. *pronacenſis*. A tree ſixty feet high, three feet and a half in diameter. *Trunk* with a greyiſh, ſmooth bark, throwing out at its ſummit a great number of branches, ſome upright, others inclining, and almoſt horizontal, which ſpread in all directions. *Leaves* alternate, oval-lanceolate, entire, terminated by a long, tender point, ſmooth, firm, green, on ſhort petioles; two caducous ſtipules at the baſe of each petiole; the exterior part of the wood is white, the interior brown, intermixed with yelloviſh green. The latter is very firm and compact. It is a native of Guiana. See La Marck, Encyc. Method.

BOKELMAN, John Frederic, in *Biography*, publiſhed the beginning of the laſt century at Leyden, "Medicus Romanus ſervus, ſexaginta ſolidis æſtimatus." On this ſubject, a moſt intereſting controverſy was carried on ſome years after, between Drs. Mead and Middleton, in which many of the literati took part; and this diſſertation, originally written to convey a cenſure on Drelincourt, was republiſhed. The ſubject will be noticed again in the life of Dr. Mead. Haller Bib. Med.

BOKENEM, in *Geography*, a town of Germany, in the circle of Lower Saxony, and biſhopric of Hildeſheim, 16 miles S.S.E. of Hildeſheim.

BOKET, a town of Germany, in the circle of Franconia, and biſhopric of Wurtzburg, 4 miles N. of Kiſſingen.

BOKHARA, Bucharia, or Bogar, a famous city of Great Bucharia (ſee Bucharia), ſeated on the river Sogd, in that diſtrict, lying N.E. of the river Jihon, or Oxus, called Sogdiana, or Al Sogd. It is ſituated very advantageouſly for trade, in a delightful and fertile country, and has repeatedly conteſted the metropolitan dignity with Samarcand. Beſides its own wall, which was very ſtrong, it had an outward incloſure, comprehending not only the ſuburbs, but a diſtrict about four leagues in extent on each ſide, which contained ſeveral villages and farms, watered by the river Sogd. The Sogd, which is the valley or plain of Sarmacand on the eaſt, and the mountain called Vorka on the north, were the boundaries of this territory; although its juriſdiction extended to ſeveral towns which were ſituated beyond its great wall. Mirkhond, in his hiſtory of the poſterity of Japhet, affirms, that Bokhara was the capital of Turqueſtan, in the time of Oguz Khan, one of the moſt ancient kings of the Moguls, or Tartars, and reckoned by the Mahomeddan Tartars the eighth in deſcent from Japhet; and enumerates ſeveral towns which were dependent upon it. Bokhara afterwards became the capital of the ſtate of the Samanides founded by Iſmael, the great grandſon of Saman, in the year of the Hegira 297, or of Chriſt 909, under the caliph Motadhed. After the fall of the empire of the Samanides, the Moguls of Cathai made themſelves maſters of this city; but it was retaken by Mohammed, king of Karaſm, in the year of the Hegira 594, or A. D. 1197. This conqueſt of the Karaſmians alarmed the nations of the north, and drew towards Jihon very powerful armies of Moguls and Tartars, who deſolated ſome of the fineſt provinces of Aſia. In the year of the Hegira 617, or A. D. 1220, Jenghiz Khan, after a ſiege of ſome continuance, took this city, and ordered it to be ſet on fire; ſo that nothing of it remained, except the ſultan's palace, called "Ark," conſtructed of ſtone, and ſome few private houſes built of ſtone, all the reſt having been wooden edifices. He then cauſed a ſearch to be made in the palace and houſes, and commanded all the ſoldiers, who had concealed themſelves, to be put to death. Bokhara continued for ſome years in this deſolate ſtate; but at length the Khan ordered it to be rebuilt, not long before his death. In the year of the Hegira 772, A. D. 1370, Tamerlane took this city from ſultan Haſſain, who was the laſt prince of the houſe of Jenghiz Khan; and the Timurides, or deſcendants of Tamerlane, retained poſſeſſion of it till about the year of the Hegira 904, A. D. 1498; when Babur was deſpoiled of all his territories in Tranſoxana and Khoraſan by Schaibek Khan, who obliged him to fly to India; and from that time Bokhara has always belonged to the Uſbeks, who have maintained it by frequent wars with the Perſians. Herbelot Bib. Or. p. 190.

Bokhara was eminently diſtinguiſhed in former times by the arts and ſciences which flouriſhed in it, and by its famous univerſity, to which ſtudents reſorted from all parts, and in which the celebrated Avicenna was educated. As an emporium of commerce, it was alſo no leſs famous. To this place merchants repaired from all parts of India, from the different countries inhabited by the Tartars, from Perſia, and even from the dominions of the grand ſignior on one ſide, and from Ruſſia and Poland on the other; ſo that in the warehouſes and markets of this city might be ſeen a great variety of oriental and European merchandiſe. About the middle of the 16th century it was viſited by Anthony Jenkins, an Engliſhman, whoſe curious and intereſting account of the mart of this city has been tranſlated into ſeveral languages, and copied by the beſt writers. See Hackluyt's Collection, p. 355. At that period, indeed, it ſuſtained ſome injury from the vicinity of Samarcand; but ſince it became the ſeat of the khan of the Uſbek Tartars, who is maſter alſo of Samarcand, which he viſits only in the ſummer ſeaſon, its commerce has revived, to which the convenience of its ſituation in no ſmall degree contributes. When it was viſited by the Engliſh agents in 1741, (ſee Hanway's Travels, i. 242.) it was large and populous, ſubject to its khan; ſtanding on a riſing ground, with a ſlender wall of earth; the houſes of clay, but the numerous moſques of brick. The citizens manufactured ſoap and callico; and the chief products were cotton, rice, and cattle. From the Kalmuks they received rhubarb and muſk; and from Badakſhan, they uſed to receive lapis lazuli, and other precious ſtones; that city being computed at 16 days' journey from

Bokhara. There was gold and copper coin; and after Nadir took this city, the Perſian and Indian ſilver became common. The inhabitants were civilized, but perfidious. In the 10th century it was diſtinguiſhed by the manufacture of fine linen. N. lat. 29° 24′. E. long. 62°.

BOKI, a river of Africa, which riſes in the country called Jallonkadov, between the heads of the Senegal and Joliba, and joins the Barchſing, or an arm of the Senegal, in the diſtrict of Brooko, in N. lat. 13° 11′. W. long. 8° 31′.

BOKIRA, a river of India, which runs into the ſea, 50 miles W. of Junagur.

BOKSAN, a town of Hungary, 10 miles ſouth of Lugos.

BOL, Ferdinand, in *Biography*, a painter of hiſtory and portrait, was born at Dort in 1611, educated at Amſterdam, and placed as a diſciple in the ſchool of Rembrandt. He was chiefly diſtinguiſhed by his portraits, which he painted in a free, bold manner, but not with that clearneſs of fleſh, and remarkable relievo, for which his maſter was famous. His colouring was too much tinged with brown in the carnations; but with this exception, his portraits had a great appearance of life and nature. As a painter of hiſtory, he manifeſted a good taſte of compoſition, as well as a tolerable expreſſion in ſome of his figures; but he was deficient in grace and elegance. His "Appointment of the 70 elders in the camp of the Iſraelites," and "Moſes breaking the tables of ſtone," in the council chamber of Dort, are well deſigned and executed. In the chamber of the burgomaſters there is an hiſtorical picture of "Fabricius in the camp of Pyrrhus," which is exceedingly admired. The etchings of this artiſt are bold and free. The following, from his own compoſitions, are generally much eſteemed; viz. "Abraham's Sacrifice," "St. Jerom, ſeated in a cavern, holding a crucifix," and a "Philoſopher, holding a book." Bol died in 1681. Pilkington and Strutt.

Bol, John, a painter of landſcapes, hiſtory, and animals, was born at Mechlin in 1534, and completed his ſtudies at Heidelberg. His ſubjects were views of ſeveral cities and towns in the Low Countries, and different proſpects of Amſterdam; and in his pictures the veſſels, with the reflections of them from the water, are admirably executed. His invention and compoſition were very pleaſing; his colouring poſſeſſes great harmony and union; and his manner of ſketching and pencilling is broad and free. Van Mander highly commends one of the paintings of Bol, in diſtemper, the ſtory of which is "Dædalus and Icarus." This artiſt etched a ſet of landſcapes, which are "views in Holland," in the ſtyle of a maſter. He died in 1593. Pilkington and Strutt.

BOLA, in *Ancient Geography*, a town of Italy, the capital of the country of the Æqui, ſituate, according to Plutarch, 30 miles from Rome. Pliny places it in Latium. See Æqui.

BOLABOLA, more uſually pronounced Borabora, in *Geography*, one of the Society iſlands in the ſouthern Paciſic ocean, ſituate four leagues N. W. of Otaha, and inferior to it in extent, being about ſeven leagues in circumference. The reef that ſurrounds it is nearly full of iſlets, much larger than thoſe that are ſcattered among the rocks, encloſing Otaha and Ulietea. It differs from thoſe iſlands, and from Huaheine, in having only one harbour on its coaſt; whereas the ſhores of the others, being ſtrongly indented, form, like the coaſts of Eimeo, numerous places of ſhelter for ſhipping. It is alſo diſtinguiſhed by a very lofty, double-peaked mountain in its centre, and is more rude and craggy than the other Society iſles. Its eaſtern ſide appears barren; the weſtern is more fertile; a low border, which ſurrounds the whole, and alſo the iſlands on the reef, are productive and populous. Its earlieſt inhabitants are ſaid to have been malefactors baniſhed from the neighbouring iſlands. As their number rapidly increaſed, and their military proweſs gained reputation, they eſtabliſhed their authority in Ulietea and Otaha, and alſo in Maurōva and Toobāe. Their conqueſts acquired ſo much reſpect, that the ſuppoſed tutelary divinity of Bolabola, named Oorā, or Orāā, had been adopted by the people of Teiarraboo, in preference to two imaginary deities whom they formerly worſhipped. The Bolabolan warriors are punctured in a different manner from thoſe of the more eaſtern iſlands. Bolabola was diſcovered by captain Cook, together with the group called by him the "Society Iſlands," in July 1769; but though he took poſſeſſion of it in the king's name, he did not land upon it either in his firſt or ſecond voyage. But in 1777, he landed on this iſland, notwithſtanding the account which he had received of its inhabitants, and was introduced to Opoone, who had been repreſented as a very formidable chief, but whom he found old and feeble, though ſtill much eſteemed and feared. Opoone was ſucceeded in his government of this and the neighbouring iſlands by his daughter, who, in 1774, at the age of 12 years, had been betrothed to a chief named Boba, who governed Otaha under Opoone, and was deſigned to ſucceed him in the ſovereignty. In 1791, when captain Edwards viſited Bolabola, a man named Tatahoo, had the chief authority. S. lat. 16° 32′ 30″. W. long. 151° 52′. Miſſionary Voyage, Introd. p. 41.

BOLACA, in *Ancient Geography*, a town of Pelopponeſus, in Triphylia, a country of Elis. Polybius.

BOLAVOSANSKA, in *Geography*, a town of Siberia, in the government of Irkutzk, 80 miles N. W. of Ilimſk.

BOLBACH, a river of Germany, in the duchy of Stiria, which riſes in a lake, 10 miles S. W. of Voitſberg, and runs into the Sulm, near Wippelſpach.

BOLBÆ, in *Ancient Geography*, a town of Aſia Minor, in Caria, called alſo Heracleæ.

BOLBE, a marſh of Macedonia, near the Ionian ſea, before Apollonia, according to Scylax.

BOLBEC, or Bollebec, in *Geography*, a town of France, in the department of the Lower Seine, and chief place of a canton, in the diſtrict of Havre; the place contains 4921, and the canton 14,171 inhabitants; the territory comprehends 105 kiliometres, and 18 communes.

BOLBENA, in *Ancient Geography*, the name of a country in Aſia, in the Greater Armenia. Ptolemy.

BOLBITINA, a town of Egypt, ſituate near the ſecond mouth of the Nile, adjoining to the ſpot where Roſetta now ſtands.

BOLBITINUM *Oſtium*, a name given by Ptolemy and Pliny to the ſecond mouth of the Nile, from that of the town, Bolbitina, ſeated near the canal called "Tuli." The Bolbitine branch is now called that of Roſetta, Roſſetta, or Raſchid, which ſee. Strabo informs us (l. 17. tom. ii. p. 1153.) that, under the reign of Pſammitichus, the Mileſians, with 30 veſſels, landed at the Bolbitine, or Bolbitic branch, and there fortified themſelves.

BOLBONACH, in *Botany*. See Lunaria.

BOLBULÆ, in *Ancient Geography*, a name given by Pliny to an iſland of Aſia Minor, ſituate on the coaſt of Ionia.

BOLCA, in *Geography*, a branch of the Tyroleſe Alps, ſituate 50 miles N. W. of Venice, and noted for foſſil fiſh, in argillaceous ſchiſtus.

BOLCHE-

BOLCHERETSKOI, a town of Kamſchatka. N. lat. 52° 54′ 30″. E. long. 156° 37′ 30″.

BOLCHOF, or Bolkof, a town and diſtrict of Ruſſia, in the government of Orel, ſeated on the river Nugra, falling into the Occa; 32 miles N. N. W. of Orel.

BOLD SHORE, in *Sea Language*, a ſteep coaſt or ſhore, ſo that ſhips may approach cloſe to it.

BOLDSON, an iſland of Sweden, in the province of Halſingland, having a good harbour.

BOLE, in *Mineralogy*, *Bol*, Germ. *Bol*, Fr. *Argilla bolus*, Werner. The colour of bole is generally an obſcure Iſabella yellow, or reddiſh, or whitiſh brown; it is alſo ſometimes, though rarely, met with of a greyiſh yellow, or fleſh-red; its ſurface is often marked with black ſpots and dendritic figures. It occurs generally maſſive, ſeldom diſſeminated. Internally it exhibits a ſlight glimmering luſtre. Its fracture is perfectly conchoidal. It flies, when broken, into irregular, ſharp-edged fragments. The dark coloured varieties are opaque, the lighter coloured are more or leſs tranſlucid. It has a greaſy feel; adheres ſtrongly to the tongue; gives a ſhining ſtreak; is very ſoft, and eaſily frangible. Sp. gr. 1.4 to 2.

When put into water it abſorbs a portion with great eagerneſs, and then breaks down into ſmall fragments, with a very ſenſible crackling noiſe; but is not reduced to an impalpable powder. When finely pulverized, and diffuſed through boiling water, it remains ſuſpended in this fluid a much leſs time than any of the plaſtic clays, and is entirely ſeparable by the filter.

Before the blow-pipe it turns black, and melts without addition, though with ſome difficulty, into a porous, greeniſh, grey ſlag.

According to a ſomewhat inaccurate analyſis of Bergman, the Lemnian bole contains

Siliceous powder	47.
Carbonated lime	5.4
Carbonated magneſia	6.2
Alumine	21.
Oxyd of iron	5.4
Moiſture and volatile matter	17.
	102.0

Bole occurs in beds of wakke at Strigau in Sileſia, and in baſalt at Scheibenberg in Saxony; it is found alſo in Tuſcany and Sienna in Italy, and in the iſland Lemnos in the Archipelago.

The only uſe of bole, at preſent, is as a coarſe red pigment; for which purpoſe it is calcined and levigated, and is vended in Germany under the names of Berlin and Engliſh red. Anciently, however, a very high rank was aſſigned to bole among the articles of the Materia Medica; it was conſidered as a powerful aſtringent, ſudorific, and alexipharmic, that from Armenia and Lemnos being particularly eſteemed. The Lemnian bole, in the time of Dioſcorides, was dug up in the preſence of the prieſts of Venus, and after being mixed by them with goats' blood, was moulded into cakes, which were impreſſed with the figure of a goat, in order to authenticate them; hence it was called Σφραγις αιγος, *ſigillum caprinum*. It ſtill continued to be a conſecrated remedy even in the 16th century; according to Belon, the vein was opened annually on the 6th of Auguſt, and, after prayers ſaid by the prieſts, as much of the earth was taken out as was thought ſufficient for the enſuing year; the entrance to the vein was then cloſed, and the ſevereſt puniſhments were denounced againſt any one who ſhould open it without permiſſion. Part of the earth was ſent to Conſtantinople, where it was made up into ſmall cakes, and received the ſeal of the emperor; the remainder was prepared in the iſland itſelf, and was impreſſed with the ſeal of the governor. The profits of this manufacture were too conſiderable not to be encroached upon, and the bolar earths, and even the clayey marls of Italy, France, and Germany, obtained a place in the Materia Medica, under the general name of *Terræ ſigillatæ*, from which, however, they, together with the Lemnian earth, have been at length deſervedly excluded.

Bole is alſo uſed for the body or trunk of a tree; and hence boling trees are thoſe whoſe heads and branches are cut off.

BOLEMOW, in *Geography*, a ſmall town of Poland, in the palatinate of Rawa.

BOLENA, a town of the Morea, in the duchy of Clarence, 5 leagues from the gulf of Lepanto; the ſee of a biſhop, ſuffragan of the archbiſhop of Patras.

BOLENBERG, a ſmall town of the duchy of Mecklenburg, on the Baltic.

BOLENE, or Bollene, a town of France, in the department of Vaucluſe, and chief place of a canton in the diſtrict of Orange, 3 leagues north of Orange. The town contains 4064, and the canton 10,852, inhabitants; the territory comprehends 132½ kiliometres, and 7 communes.

BOLENIÆ, or Bodæ, in *Natural Hiſtory*, a name given by ancient writers to a ſort of ſtone of a roundiſh figure, and marked with ſeveral ridges and lines. They are ſuppoſed to be the ſame with thoſe called *Brontiæ* and *Ombriæ*, both being imagined to fall from the clouds in time of thunder-ſtorms; but they are really no other than a common ſpecies of *Echinitæ*.

BOLERA, in *Geography*, a town of Spain in Arragon, 4 leagues from Hueſca.

BOLERAZ, a ſmall town of Lower Hungary, in the upper outward diſtrict of the county of Preſburg.

BOLESKO, a town of Hungary, 28 miles north of Topoltzan.

BOLESLAW, or Buntzlaw, a circle of Bohemia, on the confines of Luſatia and Sileſia, from which it is ſeparated by mountains. The capital is Buntzlaw.

BOLESLAWIEC, a town of Poland, in the palatinate of Siradia, 24 miles S.S.W. of Siradia.

BOLETUS, in *Botany* (Gr. βωλιτης, from its globular form), a genus of the claſs *cryptogamia*, and of the order *fungi*, formed by Linnæus, and diſtinguiſhed from the agarics by having what is generally the lower ſurface compoſed of tubes inſtead of gills. The name was given by the Romans to a ſpecies of eſculent fungus, eſteemed by them a great delicacy, and celebrated by their hiſtorians and poets for being the vehicle of the poiſon adminiſtered to Claudius Cæſar, by his wife the younger Agrippina. This has been generally ſuppoſed by modern botaniſts to be the *Agaricus xerampelinus*, thence called by Scheffer *Cæſareus*; but Withering thinks it was the *delicioſus* of Linnæus. See Agaric.

Among the moderns it was firſt adopted as a generic name by Tournefort, who applied it to the common morel, the fungus favaginoſus of ſome of the older botaniſts, afterwards referred by Linnæus to his genus phallus. La Marck, diſpleaſed with Linnæus for altering Tournefort's names, has reſtored the name boletus to the morel, and has ſeparated it from phallus on account of its not being perforated at its ſummit. He has, in conſequence, divided Linnæus's genus boletus into two; calling thoſe that are ſeſſile and woody, agaricus, and thoſe that are pedicelled and ſoft, ſuillus. The Linnæan agaricus he has named amanita, as Dillerius and Haller had done before him. Juſſieu and Poiret concur with him in theſe alterations. But this, as Boſc well obſerves (Nouveau Dictionnaire,

Dictionaire, ſub voce Boletus), is to increaſe a confuſion already too great, and to overturn a nomenclature which has been generally adopted in Europe ſince the publication of the ſexual ſyſtem. For, however Linnæus may in ſome caſes have capriciouſly changed ancient names, and however it may be wiſhed that, in the preſent inſtance, he had called his boletus, agaricus, which would have preſerved to the officinal agaric its cuſtomary generic denomination, it is better to let things remain as they are, than again to unſettle the language of the ſcience, and thereby to impede its farther advancement. We ſhall, therefore, go on as we have begun, in adhering ſtrictly to the Linnæan nomenclature, where we are not induced to depart from it by weighty ſcientific reaſons.

Linnæus has enumerated only fourteen ſpecies, and Reichard has made no addition to the number. Gmelin has extended them to a hundred and ſeven; but there is reaſon to ſuſpect, that he has ſometimes given the ſame ſpecies more than once under a different name. The ſettling of ſynonyms is in every part of botany an intricate and often unſatisfactory buſineſs, but peculiarly ſo in the claſs *cryptogamia*. Withering, in the third edition of his Arrangement of Britiſh plants, has deſcribed fifty-one ſpecies, many of which have ſeveral varieties. In this number are included eight of the Linnæan ſpecies. He diſpoſes them under three grand diviſions, as they have central, lateral, or no ſtems; and ſubdivides them according to the colour of their tubes. None of them being cultivated, we ſhall confine ourſelves to thoſe which are of Britiſh growth.

Stem Central.

* *Tubes white.* 1. B. *pellucidus.* "Tubes decurrent, very ſhort; pores minute, angular: pileus concave, rich brown, ſcaly; ſtem whitiſh, thick, ſhort." 2. B. *ſubfuſcus.* "Tubes very ſhort; pileus light brown, ſmooth, clothy to the touch, regularly convex; fleſh very white; ſtem pale brown, covered with a beautiful white net-work over its whole ſurface; root conical; reſembles the elephantinus in habit." 3. B. *cyaneſcens.* "Tubes browniſh with age, not decurrent; pileus brown, convex, very fleſhy; fleſh white, changing to a fine blue when expoſed to the air; ſtem brown, rounded at the baſe." 4. B. *polyporus.* "Tubes very ſhort; pores circular, extremely minute; pileus brown, irregular; fleſh very thin; ſtem brown, varying from perfectly central to perfectly lateral, tough, thickening upwards." 5. B. *leptocephalus.* "Tubes very ſhort; pileus tawny bay, flat, thin, leatherlike; ſtem browniſh, thick as a crow-quill." Firſt obſerved in Britain by Mr. Dickſon, growing on rotten ſticks. 6. B. *aurantiacus.* "Tubes not decurrent, readily parting from the pileus; pileus convex, full orange-red, viſcid, thin at the edge, and without tubes for about one-tenth of an inch; ſtem whitiſh, rough, with coloured pimples, ſpongy, ſilken." It is eaten in France when young.

* *Tubes brown.* 7. B. *bovinus*, Linn. "Tubes not touching the ſtem, unequal in length; pileus thin at the edge, brown or olive, clammy, large; fleſh ſpongy, white; ſtem dirty white, with reddiſh ſtains, from three to ſeven inches high, and about an inch in diameter." It varies in the colour of its tubes and pileus, and in the ſmoothneſs or roughneſs of its ſtem. 8. B. *ſubſquamoſus.* "Tubes decurrent, oblong; pileus yellowiſh brown, with red brown, ſcurfy, ſcales, the centre hollowed; fleſh ſolid, pure white; ſtem browniſh, tapering downwards." 9. B. *perennis*, Linn. "Tubes decurrent, not ſeparating from the pileus, very ſhort; pileus flattiſh, hollow in the centre, ſtriated with hairs, marked with alternate circles of brown and tawny, leathery; ſtem red brown, often excentric, ſhort, wiry, frequently coming up ſo thick that the piles run into one another." There is a variety of a cinnamon colour, within and without, the B. *cinnamomeus* of Jacquin, firſt found in this kingdom by Mr. Dickſon. 10. B. *ſubtomentoſus*, Linn. "Tubes rather angular, of different ſhapes; pileus yellow, convex, fleſhy, ſomewhat woolly; ſtem yellow." 11. B. *rubellarius.* "Tubes olive-colour, fixed to the ſtem; pores rich red brown, moſtly oval; pileus red cinnamon, convex, ſoft to the touch, rather clammy; fleſh thick, ſpongy, buff-colour, inſtantly turning blue when wounded; ſtem red cinnamon, ſpongy within, and rich yellow, but inſtantly changing to a blue." 12. B. *piperatus.* "Tubes decurrent, deep orange, or earthy red; pores browner, open, irregular; pileus yellow, ſmooth, nearly flat, thin at the edge; ſtem greeniſh yellow." Its pungency on the tongue and throat is like that of a capſicum. Firſt found in England by Mr. Sowerby, in Hainault foreſt, Eſſex. * *Tubes buff.* 13. B. *nummularius.* "Tubes looſe from the ſtem, very ſhort; pores angular; pileus colour of brown horn, with a black circle at the edge, convex, dimpled, leathery, ſmooth, very thin, about an inch in diameter; ſtem colour of brown horn, black at the baſe, ſmooth." Chiefly found on rotten branches of hazle. 14. B. *nigripes.* "Tubes decurrent, very ſhort; pileus whitiſh, the ſize of a ſixpence; ſtem black at the bottom." * *Tubes yellow.* 15. B. *elephantinus.* "Tubes ſhort, adhering firmly to the pileus; pileus dead white, convex, but very irregular; ſtem yellow, thick and ſhort." 16. B. *edulis.* "Tubes not fixed to the ſtem, readily parting from the pileus; pores circular, ſmall; pileus brown, with ruſt-coloured patches, nearly globular, ſeven or eight inches acroſs when fully expanded: fleſh white, greeniſh when wounded; ſtem light browniſh yellow, tapering upwards." Bulliard reckons it a variety of bovinus. 17. B. *gregarius.* "Tubes ſhort; pores oblong, unequal; pileus cheſnut, ſmooth, thin, flattiſh; fleſh white, about three inches over; ſtem pale cheſnut, pinky below, inſenſibly ſwelling into the pileus. 18. B. *luteus.* "Tubes readily ſeparating from the pileus; pores round, ſmall; pileus deep bay, rather conical, ſtriated, viſcid; fleſh white, not changing; ſtem dirty white, cylindrical, widening at top; ring permanent." 19. B. *olivaceus.* "Tubes inſtantly turning blue when wounded; pores bright yellow, round or oval; pileus olive-brown; fleſh bright yellow, turning blue when expoſed to the air; ſtem brown below, yellow or crimſon above." 20. B. *ſanguineus.* "Tubes a little decurrent, unequal in length, changing to deep blue; pores lemon-yellow, angular; pileus crimſon, changing to rich red brown, ſemiglobular; fleſh white, changing ſlowly to a bluiſh caſt when wounded; ſtem yellow, with broad crimſon ſtreaks, apparently twiſted." Found by Dr. Withering, near Birmingham, but only in one place. 21. B. *chryſenteron.* "Tubes decurrent; pileus gently convex, pinky-red; ſtem yellow below, pinky upwards, ſwelling in the middle." 22. B. *flavus.* "Tubes a little decurrent; pores irregular in ſhape and ſize; pileus convex, deep orange when young, ſhining with a viſcid varniſh; ſtem yellow, cylindrical; curtain white, leaving a ring." 23. B. *lactifluus.* "Tubes in contact with the ſtem; pores very minute; pileus reddiſh-buff, very convex, viſcid; ſtem bright yellow." The plant abounds with a mild milky juice. Its flavour is like that of the agaricus campeſtris. 24. B. *ſubſtrictus.* "Tubes ſhort; pores minute; pileus yellow, brown, olive, convex, thin, ſmooth, leathery; fleſh thin, white; ſtem dirty yellow, hard, tough, ſometimes excentric.

Stem lateral.

* *Tubes white.* 25. B. *albidus.* "Tubes decurrent, not perpendicular to the pileus; pores angular, very irregular in ſhape; pileus white, lobed; ſtem ſolid, ſometimes only a knob." The whole plant white, with a cottony ſubſtance, which

which is eaſily rubbed off. 26. B. *rugoſus* (*lucidus*, Curtis). "Pores very ſmall; pileus cheſnut coloured, ſhining, flat, marked with concentric grooves; edge thick, wrinkled; ſtem cheſnut coloured, hard, uneven, ſhining." 27. B. *frondoſus*. "Tubes decurrent; pores very ſmall, ſometimes confluent; pileus brown, lobed, tiled, leathery; ſtem black at the baſe, very irregular and miſhapen; ſometimes nearly two feet acroſs." 28. B. *betulinus*. "Tubes very ſhort; pileus pinky-brown, ſmooth, oblong, convex, thin, curled in at the edge; fleſh white; ſtem black; whole plant leathery." 29. B. *criſtatus*. "Tubes ſhort, not ſeparating; pores irregular; pileus golden yellow, variouſly ſhaped, jagged, curled: ſtem brown, woody, diſtorted, thick, porous." 30. B. *ſquamoſus*. "Tubes ſhort, ſlanting; pores large, angular; pileus pale buff, pencilled with feather-like ſcales; fleſh firm, white, claſtic; ſtem dark coloured, white within." * *Tubes yellowiſh*. 31. B. *rangiferinus*. "Tubes decurrent, ragged at the extremity; pileus an expanſion of the ſtem, dirty yellow; ſtem dark brown, with one or more lateral branches, ſplitting at the end into ſeveral hornſhaped branches, either expanding into the pileus, or barren with yellow tops." The whole plant reſembles the palmated branches of ſome of the larger ſpecies of deer. 32. B. *calceolus*. "Tubes decurrent; pores ſmall, unequal; pileus deep buff to cheſnut, of a ſubſtance like cork, hollowed in the middle, thin, and waved at the edge; ſtem tough, white, conical." 33. B. *lateralis*. "Tubes very ſhort; pores very minute; pileus yellow, ſmooth, flat, very thin, leathery; ſtem yellow, ſpreading out at the top to form the pileus."

Stemleſs.

* *Tubes white*. 34. B. *ſuberoſus*. "Tubes pointed; pores irregular; pileus white, convex, thin, downy when young, ſmooth when old, perfectly reſembling cork." 35. B. *medullapanis*. "Wholly white, cruſtaceous, ſpreading; pores ſmall, on the upper ſurface only." On decayed wood and branches of trees. 36. B. *falcinus*. "Tubes very ſhort; pileus ſemi-circular, whitiſh, ſmooth, thin, ſoft, leathery." 37. B. *ſuaveolens* (*diſcoideus*, Dickſon). "Tubes very long, changing firſt to ſtraw-colour, then to tawny; pores irregular; pileus ſmooth, ſemi-circular, white or tawny; fleſh yellow brown." 38. B. *ſpongioſus*. "Pores fringed, angular; pileus often very large, brown, woolly, turning quite black when old." 39. B. *lachrymans*. "Pileus orange-coloured, wrinkled, reticulated, with a broad, white, arched border; pores chiefly on the upper ſurface of the white border." Frequent in damp cellars. 40. B. *verſicolor*. "Tubes ſhort, minute; pileus thin, velvety, ſtriped with concentric circles of various colours." * *Tubes brown*. 41. B. *cuticularis*. "Tubes long; pores minute, rich yellow brown: pileus rich dark red brown, ſemicircular, very uneven, with concentric ridges." 42. B. *cryptarum*. "Tubes very long; pores minute; pileus leathery, thin, ſupine, becoming woody when old." 43. B. *labyrinthiformis*. "Tubes long; pores ſinuous; pileus rugged, zoned, woody; lobes many from one root." 44. B. *unicolor*. "Tubes ſhort; pores labyrinth-formed; pileus leathery, woolly, with different ſhades of the ſame colour. * *Tubes red*. 45. B. *laciniatus*. "Tubes very ſhort; pileus browniſh, arched, warty, thin, fringed at the edge." 46. B. *abietinus*. "Pores angular; pileus thin, gently convex, wrinkled, woolly, greyiſh, whiter at the edge." 47. B. *hiſpidus*. "Tubes fringed; pileus bright red brown, in old age black, rough with briſtly hairs." Poſſibly a variety of the *velutinus*. * *Tubes yellow*. 48. B. *ſulphureus*. "Tubes ſhort; pores minute, irregular; pileus bright aurora, ſtreaked." 49. B. *velutinus*. "Pores angular, irregular; pileus large, very irregular in ſhape, covered with a denſe pile of a ſilvery grey colour." * *Tubes green*. 50. B. *igniarius*. "Tubes very ſlender; pores very fine, yellowiſh, changing to red brown; pileus ſhaped like a horſe's hoof, ſmooth, red brown to blackiſh." It is the officinal agaric, the *agaric amadouvier* of La Marck. For the domeſtic and ſurgical uſes to which it is applied, in different parts of the continent of Europe, and the manner in which it is prepared, ſee the article AGARIC, in *Pharmacy*. 51. B. *fomentarius*. "Pores circular, equal; pileus white, convex, thick at the edge, uneven."

To theſe La Marck adds the *agaricus quercinus* of Linnæus, and obſerves, that it properly belongs to this ſpecies; for though it has the appearance of gills, they are really tubes with large miſhapen pores, which near the edge of the pileus have a more regular form. Bulliard and Woodward incline to the ſame opinion; and we ourſelves have already ſuggeſted that it ſeems to connect the agarici with the boleti. See AGARICUS.

BOLETUS (Haller). See HELVELLA MITRA.

BOLETUS (Tournefort). See CLATHRUS CANCELLATUS.

BOLETUS (Tourn. Michel. and Haller). See PHALLUS ESCULENTUS.

BOLETUS (Gled.). See HYDNUM REPANDUM and AURISCALPIUM.

BOLI, or BOLLI, in *Geography*, a town of Aſiatic Turkey, in the province of Natolia, 140 miles eaſt of Conſtantinople, and 74 N.W. of Angora. This town is ſituated on a ſmall river, which diſcharges itſelf into the Black ſea. It is the capital of a maritime canton, called by the Turks "Boli vialicti," and in the interior part of its extent very mountainous. N. lat. 40° 45'. E. long. 31° 26'.

BOLIDES, in *Meteorology*. See *Fire*-BALLS.

BOLINA, in *Ancient Geography*, a ſea-port town of the Peloponneſus, in Achaia, near Argyra.

BOLINÆUS, a river of the Peloponneſus, which watered the towns of Argyra and Bolina, according to Pauſanias. It diſcharged itſelf into the ſmall gulf of Panormus.

BOLINAO, in *Geography*, a ſea-port town on the iſland of Luçon, or Manilla.

BOLINBROKE, a town of America, in Talbot county, on the eaſtern ſhore of Maryland, 5 miles E. of Oxford. It lies on the N. W. point of Choptank river.

BOLINGÆ, in *Ancient Geography*, a people of India, near the Indus, mentioned by Pliny, Ptolemy, and Steph. Byz.

BOLINGBROKE, in *Geography*, a ſmall town of Lincolnſhire, England, is ſeated in a valley between the river Witham and the ſea-coaſt. Here was formerly a very conſiderable caſtle, which was nearly demoliſhed by Oliver Cromwell and his partizans, who alſo laid other parts of the town, with the church, in ruins. In the times of feudal vaſſalage, the caſtle at Bolingbroke was diſtinguiſhed among the pompous manſions of the nobles. Here the celebrated John of Gaunt, duke of Lancaſter, occaſionally held his court, and it was the birth-place of his fourth ſon, who was afterwards crowned king of England. He was the fourth Henry who ſat on the Engliſh throne, and from the place of his birth was known by the name of Henry of Bolingbroke. The St. John family alſo derive the title of viſcount from this town. The only manufacture of the place is earthen-ware, and that is very inconſiderable. In the pariſh are 72 houſes, and 283 inhabitants.

BOLINTHOS, in *Natural Hiſtory*, a name given by Ariſtotle, and ſome of the other ancient Greeks, to the *monops* of Ælian, that is, the BONASUS.

BOLIPLEIKA, in *Geography*, a town of Ruſſia, in the government of Saratof, on the weſt ſide of the Volga; 124 miles ſouth of Saratof.

BOLISSUS, in *Ancient Geography*, a town of Aſia, in Æolia, near Chio, according to Herodotus. Thucydides (l. 8.) mentions a victory gained by the Athenians over the inhabitants of Chio near this town.

BOLKOF, in *Geography*. See Bolchof.

BOLKOWITZ, a town of Sileſia, 20 miles ſouth of Glogaw.

BOLLANDISTS, in *Literary Hiſtory*, a denomination given to certain Jeſuits of Antwerp, who were a conſiderable time employed in collecting the lives and acts of the ſaints.—Thus called from J. Bollandus, one of the firſt and chief of the aſſociation.

BOLLANDUS, John, in *Biography*, a famous eccleſiaſtical hiſtorian, was born at Tillemont in the Low Countries, in 1596, and educated among the Jeſuits, by whom he was employed in collecting memorials of the church-ſaints, under the title of "Acta Sanctorum." The plan of the work was formed by father Roſweide, and it was to be arranged according to the order of celebrating their memories in the calendar. Bollandus, in 1643, publiſhed "The Lives of the Saints of the Month of January," in 2 vols. fol.; followed in 1658, by thoſe of February, in 3 vols. fol. He had begun thoſe of March, when he died in 1665. This work was continued by Henſchenius, Papebroch, and others, on a ſcale of ſuch extent, that the commencement of October reaches the 47th volume folio. Nouv. Dict. Hiſt.

BOLLARDS, large poſts ſet in the ground on each ſide of a dock. On docking or undocking ſhips, large blocks are laſhed to them; and through theſe blocks are reeved the tranſporting haulers to be brought to the capſtans.

BOLLEN, in *Geography*, a town of Germany, in the circle of Auſtria, and duchy of Carinthia, 7 miles eaſt of Mellſtat.

BOLLENZ. See Bregno.

BOLLIN, a river of England, which runs into the Merſey, 4 miles E.N.E. of Warrington.

BOLLITO, in the *Glaſs Works*, a name by which the Italians called a ſea-green colour, or artificial cryſtal.

To prepare this colour you muſt have in the furnace a pot filled with forty pounds of good cryſtal, firſt carefully ſkimmed, boiled, and purified, without any manganeſe; you muſt then have twelve ounces of the powder of ſmall leaves of copper, thrice calcined, and half an ounce of zaffer in powder; mix them together, and put them at four times into the pot, that they may the better mix with the glaſs; ſtirring them well at each time of putting in the powder, leſt they ſhould ſwell too much and run over.

BOLLOS, in the mines of Peru, a denomination given to the ingots or bars of ſilver procured there from the ore by the operation of the fire, and the uſe of aqua fortis.

BOLM, in *Geography*. See Bulam.

BOLNEST, Edward, in *Biography*, practiſed medicine in London the beginning of the 17th century. He publiſhed, in 1605, "Chemia Medicina illuſtrata," or the true grounds and principles of the art of phyſic, 8vo. London, and the following year a tranſlation of it into Latin "Delineatio fundamenti et princip. art. med.;" alſo "Aurora chemica ſen naturalis methodus preparandi animalia, vegetabilia, et mineralia," 1675, 8vo. An edition of this work was publiſhed in Engliſh, in 1672. "A rational way of preparing animals, vegetables, and minerals, for phyſical uſes." Haller. Bib. Med.

BOLNKI, in *Geography*, a town of Lithuania, in the province of Wilna, 14 miles E.S.E. of Wilcomirz.

BOLOGNA, or Bononia, a city of Italy, the capital of the Bologneſe duchy, is, next to Rome, the largeſt, fineſt, and richeſt city in the Eccleſiaſtical State. Its ancient name was *Felſina*, derived from Felſinus, a Tuſcan king, who is ſuppoſed to have built it 25 years before the foundation of Rome. The name of Bononia is traced by ſome to a ſucceſſor of Felſinus, called Bonus; but others deduce it from the Boii. Its circuit is between five and ſix Italian miles, and the number of its inhabitants is eſtimated at 80,000; but the whole diſtrict, which includes 308 cities, towns, and villages, is ſaid to contain 308,000 perſons. Its figure is oblong, the length of it much exceeding the breadth; and viewed at a diſtance, it bears ſome reſemblance of a ſhip, the tower of Aſinelli, which is 371 feet high, being the maſt. It is ſurrounded by a ſolid and lofty brick wall, well built, and adorned with piazzas, which extend through the ſtreets, and under which paſſengers may walk without being incommoded by the ſun or rain. The houſes in general have lofty porticoes, which would have a better effect if the ſtreets were not ſo narrow; but in this particular, magnificence is ſacrificed to convenience, for, in Italy, ſhade is conſidered as a luxury. This city is ſeated at the foot of the Apennines, in an extenſive, fertile plain, which liberally ſupplies the inhabitants with its rich produce. The river Savona waſhes its walls, and the rivulet Reno paſſes through it, parting into ſeveral ſmall ſtreams; and the latter, by means of a canal, communicates with the Po, and affords great advantage to the city.

The public edifices of various kinds are numerous and magnificent. In the centre of the city ſtands a high tower, called Degli Aſinelli, from Gerardo Aſinelli, who built it at his own charge in 1109; near it is the leaning tower, called Gariſenda, which by a fall of part of it is now reduced to the height of 130 feet, and which inclines, ſo that a plumb-line let down from the top deviates ſeven feet from the wall at the bottom. Of the palaces in Bologna, that which is denominated the Public Palace is much the moſt ſpacious, though not the moſt elegant. In this the cardinal legate is lodged; and it has alſo apartments for the Gonfalonier, as well as halls, or chambers, for ſome of the courts of juſtice. This edifice contains ſome very magnificent apartments, and a few good pictures, of which the moſt eſteemed are, a large one, by Guido, of the Virgin, and the infant Jeſus, ſeated on a rainbow; a Sampſon, alſo by Guido, refreſhing himſelf with the water which iſſues from the jaw-bone, with which he has juſt defeated the Philiſtines; and a St. John the Baptiſt, by Raphael. The firſt object which ſtrikes the eye of a ſtranger on his arrival at this town, is a noble marble fountain in the area before the Palazzo Publico. The principal figure is a ſtatue of Neptune, 11 feet high, with one hand ſtretched out, and the other holding the trident. The body and limbs are finely proportioned, the anatomy perfect, and the character of the countenance ſevere and majeſtic. This figure of Neptune, as well as all the others of boys, dolphins, and ſyrens, which ſurround it, are in bronze. The whole is the workmanſhip of Giovanni di Bologna, and is highly eſteemed; and yet there ſeems to be an impropriety in making water flow from the breaſts of the ſea-nymphs or ſyrens. Over the entrance of this palace is a bronze ſtatue of pope Gregory XIII., weighing 11,300 pounds, and executed by Minganti. Near it is another ſtatue of pope Boniface VIII. The interview between the emperor Charles V. and pope Clement VII. in 1529, when that prince ſubmitted to be crowned by the pope, is recorded by an inſcription on a copper-plate. In the Sampieri palace are

are ſeveral pieces by the three Caraccis; one of the beſt ever done by Albano, repreſenting Cupid kiſſing his mother Venus, and, with an air of triumph, pointing at the rape of Proſerpine by Pluto; and another, more admired than all the reſt, and conſidered by the judges as the maſter-piece of Guido, the ſubject of which is the "Repentance of St. Peter," and conſiſting of two figures, that of the ſaint who weeps, and a young apoſtle who endeavours to comfort him. Although the nobility of Bologna are not now very rich, many of their palaces are furniſhed in a magnificent taſte, and contain paintings, particularly thoſe of the celebrated maſters which this city had the honour of producing, that are their chief ornaments, and are held in high eſtimation. The palaces were built, and ornamented, when the proprietors were richer, and when the fineſt works of architecture, ſculpture, and painting, could be procured on eaſier terms than at preſent. The galleries and apartments are ſpacious and magnificent; and yet there are circumſtances in the moſt ſplendid, that muſt hurt the eyes of thoſe who are accuſtomed to that perfect exactneſs in finiſhing, which prevails in Engliſh houſes. The glaſs of the windows of ſome palaces is divided into little ſquare panes, which are joined together by lead; and the floors of all are ſo indifferently laid, that you often feel a looſe brick ſhaking under your feet, as you walk through the fineſt apartments.

Bologna is alſo embelliſhed with a great number of churches and convents, which are enriched with a variety of paintings, ſculptures, &c. Of the churches, of which there are ſaid to be 200, that of St. Petronius is the largeſt. In this church the emperor Charles V. was crowned in 1530; and on the pavement of it, Caſſini drew his meridian line, conſiſting of pieces of red and white marble inlaid, of a hand's breadth; thoſe in which the ſigns of the zodiac are cut, are a foot ſquare. This line is half the length of the church, which is 360 feet; and at its commencement is a Latin inſcription, expreſſing that "the whole length of this meridian line, diſtinguiſhed by the ſigns, &c. is the ſix hundred thouſandth part of the circumference of the terraqueous globe." On the pavement, at the end of the line, is an inſcription in white marble, denoting "the meridian line from the zenith to the tropic of Capricorn." Oppoſite to the vertical point, is the date MDCLII. A ſmall round aperture has been made in the roof of the church, towards the ſouth, through which the rays of the ſun form a circular luminous ſpot, about eight inches in diameter, on the pavement, which ſhews the proper meridional point on the line every day. The church of the Dominicans is one of the moſt magnificent in Bologna. The chapel, dedicated to the honour of St. Dominico, who is ſaid to have died at Bologna in 1221, is much admired. It conſiſts of a curious dome, in which the glittering of gold appears throughout, adorned with the moſt capital paintings, repreſenting the hiſtory of his life. His monument is of white marble, ornamented with beautiful baſſo-relievos, by Michael Angelo; and the altar, together with the large candleſticks that ſtand upon it, are of ſilver. The pavement and the walls are inlaid with marble of different colours. In the veſtry is depoſited, amidſt jewels and various treaſures, a manuſcript of the Old Teſtament, or at leaſt of the Pentateuch, pretended to have been written by Ezra himſelf. See BIBLE. It is a large folio, carefully preſerved in a glaſs caſe, and was preſented to the convent by the Jews, when they removed hither from Rome, and were allowed to erect a noble ſynagogue about the cloſe of the 14th century. The other principal churches are the Franciſcan, in which are paintings by Facini, Luigi, Caracci, Brizio, Guido, and Tiarini; that of St. Agnes, containing, over the high altar, the martyrdom of the ſaint, by Domenichino; St. Bartholomew, before which ſtands a marble ſtatue of St. Petronius, by Brunelli, and in which are an annunciation, the nativity, and the flight into Egypt, by Albano; the church of the Capuchins, in the veſtry of which is a crucifixion, by Guido; that of S. Giovanni in Monte, famous for an admirable picture of St. Cecilia, by Raphael, which is much extolled by Addiſon, and reckoned one of Raphael's capital pieces, &c. &c. The convents alſo are enriched with valuable paintings and other ornaments, as well as the palaces and churches. A Dominican convent, ſeated on the top of a hill, about three miles from the city, is in poſſeſſion of a portrait of the virgin Mary, ſaid to have been painted by St. Luke. Sigoni ſays, that it was brought from the church of Sancta Sophia at Conſtantinople in 1160; and it is thought to have wrought many miracles in favour of the inhabitants of Bologna. A curious gallery, open to the ſouth, and cloſed by a wall to the north, is built all the way from the city to the convent; on the open ſide it is ſupported by a long row of pillars; and was erected by voluntary contribution, in honour of the virgin, and for the convenience of pilgrims. This long colonade is about twelve feet in breadth, from the pillars to the wall, and about ſixteen feet high; all the communities of the town walk, once a year, in ſolemn proceſſion, to the convent, and bring the holy picture to viſit the city. It is carried through the principal ſtreets, attended by every inhabitant who can afford to purchaſe a wax taper. During this proceſſion, the bells continue ringing, the cannon are fired, and the troops under arms practiſe the ſame ceremonies when the picture paſſes, as if it were commander in chief of the forces. In the library of the convent, belonging to the church di S. Salvatore, are many curious MSS.; particularly one of the hiſtory of queen Eſther, written on yellow coarſe leather in large Hebrew characters, and done up in a roll or volume, according to the original ſignification of the word. The canons pretend that this was written by Ezra. Here is alſo ſhewn a Hebrew MS. of the O. T. written on vellum, in 3 vols. fol ſaid to have been written in 953; it has, however, points or vowels. Among other MSS. amounting to about 300 in number, are the N. T. called the "Codex Bononienſis," ſaid to be of the 11th century, containing the whole N. T. except the apocalypſe, abounding with abbreviations; and a Greek verſion of the minor prophets and Daniel, ſuppoſed to be of the 10th century; and among the printed books are Manutius's edition of Cicero's works, 4 vols. fol. publiſhed at Milan in 1498, and a Latin bible in folio, which, by a printed advertiſement annexed to it, appears to have been completed at Mentz by John Fuſt and Peter Schoiffer in 1462.

The univerſity of Bologna is one of the moſt ancient and moſt celebrated ſeats of literature in Europe; it was founded, as ſome ſay, by the emperor Theodoſius in 433, but others, with greater probability, attribute it to Charles the Great. For an account of the academy of ſciences, ſee ACADEMY. Over the gate of the magnificent edifice appropriated to that academy, is the following liberal inſcription: "Bononienſe Scientiarum atque artium inſtitutum ad publicum totius orbis uſum." Here are an obſervatory, with the neceſſary inſtruments for aſtronomical obſervations; a very valuable library, in three ſpacious rooms, where any perſon may ſtudy and have the uſe of the books four hours every day; alſo, apartments for the ſtudents of ſculpture, painting, architecture, chemiſtry, anatomy, aſtronomy, and every branch of natural philoſophy. They are all ornamented with deſigns, models, inſtruments, and every kind of apparatus requiſite for illuſtrating thoſe ſciences. There are alſo profeſſors who regularly read lectures. There is a hall full of models

models in architecture and fortification, a valuable collection of medals, and another of natural curiosities, as animals, earths, ores, minerals; and a complete collection, to assist the study of the materia medica, and every part of natural history. There is also a gallery of statues, consisting of a few originals, and very fine casts of the best statues in Italy. Honorary premiums are distributed every year among the artists, for the best designs in painting, sculpture, and architecture.

The anatomical theatre is adorned with statues of celebrated physicians; and the museum belonging to it supplies an abundance of anatomical preparations, and a complete suite of anatomical figures in wax: a man and woman are exhibited in the natural state; the same with the skin and cellular membrane removed, so that the external muscles of the whole body and limbs appear. In the subsequent figures the more external muscles are gradually removed, till nothing but the simple skeleton remains. These figures are very well formed, preserving the natural appearance and situation of the muscles and blood-vessels with as great exactness as could be expected in a work of this nature. There are also models in wax, of particular parts, and of several of the viscera of the human body separately.

The inhabitants of Bologna carry on a very considerable trade in silks and velvets, and leather bottles, which are manufactured here in great perfection. The country produces immense quantities of oil, wine, honey, wax, flax, and hemp; and furnishes all Europe with hams, dried tongues, sausages, macaroni, sweetmeat, olive, perfumes, wash-balls, liqueurs, and essences. The people are industrious, and allowed to enjoy the fruits of their labour; the nuns are very ingenious in making artificial flowers, and imitating fruits of various kinds; and very beautiful works are also made of walnut-tree and rock-crystal. The markets are plentifully supplied with provisions; fruit is had in great variety, and of excellent quality; and the common wine of the country is a light white wine of an agreeable taste, which is preferred by strangers to any of the French or German wines that may be had there. The inhabitants, in general, are facetious and polite to strangers, who may receive at Bologna every kind of accommodation that may suit their taste.

Bologna long retained the name of a republic, sent an ambassador to the pope's court, and the word "Libertas" was inscribed on the arms and coin of the state, with the flattering capitals S. P. Q. R. The civil government and police of the town were allowed to remain in the hands of the magistrates, who were chosen by the senate, which formerly consisted of 40 members; but since this republic came under the protection, as it is called, of the pope, he thought proper to add ten more; but the whole 50 still retain the name of the "Quaranta." One of the senators presided in the senate, and was called the "Gonfalonier," from his carrying the standard (Gonfalone) of the republic. He was the chief magistrate, was attended by guards, and was constantly at the palace, or near it, to be ready on any emergency; but he remained only two months in office, and the senators took it by turns. In the midst of all this appearance of independence, a cardinal legate from Rome governed this republic; he was appointed by the pope, with a vice-legate, and other assistants. The orders which the legate issued, were supposed to be with the approbation of the senate; or at least, they never disputed the office, which was of higher dignity than any other in the gift of the court of Rome, and continued for three years; at the expiration of that time, his holiness either appointed a new legate, or confirmed the old one in the office for three years longer. This ecclesiastical viceroy lived in great magnificence, and had a numerous suite of pages, equerries, and halberdiers, who attended him in the city. When he went into the country, he was accompanied by guards on horseback. The gonfalonier and magistrates regulated all the usual matters which regarded the police, and decided, in common causes, according to the laws and ancient forms of the republic; but in affairs of great importance, and, indeed, as often as he chose to interfere, the cardinal legate without doubt influenced all decisions. This must be mortifying to the senators and noble families; but was less felt by the people in general, who exhibited every appearance of living under a mild and beneficent government. Bologna was the see of an archbishop; who had for his suffragans the bishops of Crema, Borgo, St. Domino, Modena, Parma, Piacenza, and Reggio. Bologna is 23 miles S.W. of Modena, and 145 N.W. of Rome. N. lat. 44° 29′ 36″. E. long. 11° 21′ 15″. Keysler's Travels, vol. iii. p. 247. Moore's View of Society, &c. in Italy, vol. i. p. 252. See Bolognese.

Bologna *Bottles*. See Unannealed *Bottles*.

Bologna *Stone*. See Bononian *Stone*, and Phosphorus.

BOLOGNE, in *Geography*, a town of France, in the department of the Upper Marne, and chief place of a canton in the district of Chaumont, 6 miles north of Chaumont.

BOLOGNESE, Francisco, in *Biography*, an eminent painter of landscape and history, whose original name was *Francisco Grimaldi*, was born at Bologna, in 1606, and educated in the school of Annibal Caracci. He completed his studies at Rome; and his improvement was such, as to attract the attention of pope Innocent X. by whom he was employed both in the gallery of his palace at Monte Cavallo, and in the Vatican. Among his numerous admirers and friends were the prince Pamfili, the pope's nephew, and many of the principal nobility at Rome; Lewis XIV. and cardinal Mazarin at Paris, who procured for him a large pension, and employed him in decorating the Louvre; and after his return to Italy, the popes Alexander VII. and Clement IX. He was peculiarly happy in his execution of landscape: and was distinguished by his fresh and bold colouring, light and fine touch, and an elegant mode of composition. His landscapes in the manner of Caracci are models of the style of that school, though the colouring of them is thought to be somewhat too green. He understood architecture, and also etched, with great freedom, taste, and spirit, a great number of landscapes, partly from his own designs, and five after Titian. His agreeable manners and amiable disposition attached universal esteem. His benevolence was singularly manifested towards a Sicilian gentleman and his daughter, who had retired to Rome from the troubles of his country. They lodged near him, and were known to be so poor as to want bread. As soon as Bolognese was apprized of their situation, he repeatedly knocked at their door in the morning, threw in some money, and withdrew undiscovered. The Sicilian at length detected him in one of his acts of beneficence, and in token of gratitude fell at his feet. The painter raised and embraced him, and they continued mutual friends through life. Bolognese died at Rome in 1680, and bequeathed considerable property to his six children. His principal works are at Rome, and consist of large landscapes, and historical pieces in fresco. The pictures of his best time are very rare, and afford large prices. His son *Alexander* was a good painter in the style and taste of his father, though much inferior. Among his engravings are the "Brazen Serpent," from a composition of his own, which, though slight, is a spirited, free etching, in the style of a painter. Pilkington and Strutt.

Bolognese, or the *duchy of Bologna*, in *Geography*, a ter-

ritory of Italy, in the eccleſiaſtical ſtate, bounded on the north by the Ferrareſe, on the eaſt by Romagna, on the ſouth by Tuſcany, and on the weſt by Modena; anciently inhabited by the Boii and Ligures. It was formerly a republic, under the protection of the emperor of Germany; but in 1278, it became ſubject to pope Nicholas III. After many viciſſitudes, pope Julius II. in 1513, annexed the city of Bologna, and all its dependencies, to the papal dominions; and in conſequence of its voluntary ſubmiſſion to the ſee of Rome, it was indulged in ſeveral privileges, which it continued long to enjoy without moleſtation. But after the city of Bologna was taken by the French in the campaign of 1796, the legations of Bologna, Ferrara, Modena, and Reggio, entered into a treaty to form a republic, under the name of the "Republica Ciſpadana," or "Ciſalpine Republic;" which was confirmed by the eighth article of the treaty of Campo Formio, October 17, 1797.

The ſoil of this territory is rich and fertile, and in the vicinity of Bologna it is ſo much improved by cultivation, that it appears like one continued garden. The vineyards are not divided by hedges, but by rows of elms and mulberry-trees; and the vines hang in a very beautiful pictureſque manner, in feſtoons from one tree to another. The country is not only fertile in vines, but likewiſe in corn, olives, and paſturage, and has, not without reaſon, acquired the name of "Bologna la Graſſa." The Bologneſe affirm, that their cheeſe is not inferior to that of Parma, and they ſell a great quantity of it under the name of Parmeſan cheeſe. See BOLOGNA.

BOLOGNETTI, POMPEY, in *Biography*, was born at Bologna in Italy, about the year 1616, where he received his education, and attaching himſelf to the practice of phyſic, was admitted doctor, and then profeſſor in medicine, at the univerſity there, in which capacity he was much admired, his lectures being numerouſly attended. His works are "Conſilium de precautione occaſione mercium, ab infultibus imminentis contagii," Bono. 1630, folio; which perhaps gave birth to Dr. Mead's work on that ſubject, or ſuggeſted the idea of it. "Remora fenectutis," 1650, 4to. Haller. Bib. Med. Eloy. Dict. Hiſt.

BOLOGNINI, ANGELUS, a celebrated profeſſor of medicine and ſurgery, who flouriſhed the beginning of the 16th century, was born in the neighbourhood of Padua, but practiſed and taught medicine at Bologna. At the earneſt intreaty of his pupils, he ſays, he publiſhed, in 1508, "De cura ulcerum interiorum, et de unguentis communibus in ſolutione continui," 4to. which has been frequently re-printed. He was of the ſchool of Avicenna, on whoſe works he commented in his lectures. He gives forms for preparing ointments with mercury, which he highly extols, and ſays, they cure the lues, though the ſalivary glands ſhould not be affected, which, however, he admits to be deſirable. The latter part of his life was ſpent in retirement at Padua. Aſtruc. de Morb. Gal. Hall. Bib. Med.

BOLOTOVA, in *Geography*, a town of Siberia, 24 miles N.E. of Nertſchink.

BOLSCHAIA, a town of Siberia, on the Irtiſh, 240 miles E.S.E. of Tobolſk.

BOLSCHAKINA, a town of Siberia, 68 miles ſouth of Orlenga.

BOLSEC, JEROM, in *Biography*, a carmelite of Paris in the 16th century, who deſerted his order on account of ſome free opinions, and became a refugee at Ferrara. There he commenced the profeſſion of phyſic, and being acquainted with Calvin, removed to Geneva. In this city he divulged ſome opinions concerning predeſtination, which excited the reſentment of the Genevan reformer, and which induced the magiſtrates of Geneva, probably at his inſtigation, firſt to impriſon him, and finally to baniſh him, as one convicted of ſedition and Pelagianiſm. He was afterwards expelled from the canton of Bern, whither he had retired; and failing in his endeavours to ingratiate himſelf with the Proteſtants of Paris and Orleans, he returned to the boſom of the Catholic church. He then revenged himſelf by writing a very ſlanderous account of the life of Calvin in 1577, and another of that of Beza in 1582, the falſities of which ſober Catholics are aſhamed to quote. He alſo wrote againſt Calvin's inſtitution, and his arguments were afterwards made uſe of by Cardinal de Richelieu. Bolſec practiſed phyſic at Autun, and at Lyons, in which latter city he died, a few years after he had written Beza's life. Gen. Dict.

BOLSENA, in *Geography*, a town of Italy, in the Eccleſiaſtical ſtate, and patrimony of St. Peter, delightfully ſituated on a lake that is of the ſame name, which is about 35 Italian miles in circumference. In this lake are two iſlands, namely, Biſentina and Martana, with a church in each iſland; in the former the unfortunate Amalaſunta, daughter of Theodoric, king of the Oſtrogoths, is ſaid to have been put to death in 534, by order of the ungrateful Theodatus, her couſin, whom ſhe had admitted to a ſhare in the government. We learn from Pliny, Hiſt. Nat. l. ii. c. 95, that in his time theſe two iſlands were floating. He calls this lake Tarquinian, a name which it derived from Tarquinium, one of the principal 12 Etrurian cities, whoſe territories anciently extended to this lake; but it has been doubted, whether Pliny refers to the iſlands of this lake. Bolſena is environed with mountains, covered with trees, forming a kind of auguſt amphitheatre. On an eminence near it may be ſeen the ruins of the ancient "Volſinium." It is 7 miles S. of Orvieto.

BOLSOVER, a conſiderable market town of Derbyſhire, England, has been noted for its manufactories of buckles, ſpurs, bridle-bits, ſtirrup-irons, and other ſimilar articles; but the greater part of them is now made in Birmingham, and its vicinity. The town is governed by a conſtable, and two head-boroughs; and a copyhold court is held here every three weeks. Here was formerly a caſtle, which, according to the Doomſday-book, was poſſeſſed, at the Norman conqueſt of England, by William Peverel. It was of conſiderable extent, and from its remaining fortifications was evidently of great ſtrength. Its fortreſs is mentioned by Leland, as being in ruins when he viſited this part of England, in the time of Henry the Eighth. A modern manſion, ſtill called the caſtle, occupies the ſite of the ancient buildings, and was erected by Sir Charles Cavendiſh in 1613. It is of ſquare ſhape, and aſſumes the caſtellated character by towers at the four corners, and an embattled parapet. In this manſion, a ſuperb entertainment was given by William Duke of Newcaſtle, to Charles the Firſt and his queen in the year 1633. Upon this occaſion, all the neighbouring gentry were invited to partake of the feſtival, which was conducted upon ſo magnificent a ſcale, that the expences were eſtimated as amounting to 15,000l. Grand pageants, &c. were repreſented before the royal gueſts, and the fancy and taſte of Ben Jonſon were employed in preparing ſpeeches and ſcenery upon the occaſion. It now belongs to the Duke of Portland, whoſe family obtained it by marriage with a daughter of the Earl of Oxford. In the pariſh church is a magnificent monument to the memory of the above-named Sir Charles Cavendiſh, many of whoſe family are alſo interred here. Bolſover has a weekly market on Fridays, one annual fair, and a ſtatute fair for hiring ſervants, &c. It is 8 miles from Mansfield, and 145 N. W. from London. In the pariſh are 435 houſes, and 1091 inhabitants.

At *Elmton*, a ſmall village three miles N. E. of Bolſover, was born *Jedediah Buxton*, a man who, though only a poor labourer, acquired extraordinary celebrity, for his retentive memory, and recondite powers of calculation.

Three miles north of Bolſover are the great coal works, called Norbrig's Colliery. Theſe belong to the Duke of Portland, and are let out to a company of perſons who ſend great quantities by the canal to Workſop, Redford, Stockwith, &c. Bibliotheca Topographica, No. 32.

BOLSTER, among *Surgeons*, a ſoft yielding ſubſtance either laid under the head or a broken limb.

Bolster is alſo uſed for a ſtuffing, intending to fill out or raiſe a flat, ſinking, or hollow part. In which ſenſe bolſters are contrived for crooked, bunched, and other diſtorted backs, ſhoulders, &c.

Bolsters *of a ſaddle*, in the *Manege*, thoſe parts which are raiſed on the bows, both before and behind, to reſt the rider's thighs, and keep him in a poſture of withſtanding the diſorders which the horſe may occaſion. Common ſaddles have no bolſters behind, or even before.

Bolsters, in *Sea Language*, ſmall cuſhions or bags, filled with tarred canvas or rope yarn, &c. and placed under the ſhrouds and ſtays, to prevent their chafing againſt the treſtle-trees, by the motion of the maſt, when the ſhip rocks at ſea.

Bolsters are alſo pieces of fir fayed upon the upper ſide of the treſtle-trees, and againſt the thwart-ſhip ſides of the maſt-head. They muſt be ſufficiently long to clear the ſid-hole and after croſs-tree, and broad enough to project one inch and a half, or more, without the treſtle-trees, and the ſame in depth, and rounded from the upper to the lower edge on the outſide, and nailed to the treſtle-trees at each end. Their uſe is to prevent the ſhrouds chafing by the motion of the maſts.

Bolsters of an anchor are cylindrical pieces of iron, with a hole through the middle, uſed when holes are to be punched, or opened with pins.

BOLSWAERT, Bolswerd, or Bolswert, in *Geography*, a town of Frieſland, in the United Netherlands, ſaid to have been built in 713 by Bolſwine, ſon of Radbode, king of Frieſland, from whom it took its name. It was almoſt burnt down in 1475, and again in 1515, when it was rebuilt and encompaſſed with a rampart of earth. About a league from this town is a port, which, though much obſtructed by ſand, is very uſeful to the inhabitants. Bolſwaert is about two miles in circumference, and was formerly one of the Hanſe towns; and a great part of the Frieſland baize, which formed a conſiderable article of exportation, was wove in this place. It is diſtant 13 miles S. W. of Leewarden, and 7 S. S. E. of Harlingen. N. lat. 53° 2′. E. long. 5° 24′.

BOLSWERT, or Bolsuerd, Boetius Adam A, in *Biography*, an engraver and printſeller of Antwerp, derived his name from Bolſwert in Frieſland, where his family reſided, and flouriſhed about the year 1620. He worked only with the graver, and ſucceſsfully imitated the free, open ſtyle of the Bloemarts, in whoſe ſchool he probably perfected himſelf in his art. When he worked from Rubens, he altered that ſtile, and his plates are neater, fuller of colour, and more highly finiſhed. His plates from Bloemart are a ſet of "Twenty landſcapes," "The foreſt of the hermits and hermiteſſes of Egypt and Paleſtine," and "The Nativity of Chriſt:" and thoſe from Rubens, in a more finiſhed ſtile, are the "Reſurrection of Lazarus," and its companion "The Laſt Supper," which is a very beautiful engraving. Strutt.

Bolswert, or Bolsuerd, Scheltius A, brother of the preceding, flouriſhed about 1626, and worked entirely with the graver. His general character, as an artiſt, is thus deſcribed by Baſan: "We have a large number of prints, which are held in great eſteem, by this artiſt, from various maſters, but eſpecially from Rubens, whoſe pictures he has copied with all poſſible knowledge, taſte, and great effect. The freedom with which this excellent artiſt handled the graver, the picturesque roughneſs of etching, which he could imitate without any other aſſiſting inſtrument, and the ability he poſſeſſed of diſtinguiſhing the different maſſes of colours, have always been admired by the connoiſſeurs, and give him a place in the number of thoſe celebrated engravers, who are deſirous of rendering their works as uſeful as they are agreeable, and of acquiring a reputation, as laſting as it is juſtly merited." His prints are the exact tranſcripts of the pictures from which he engraved them; and his laſt works, though not equally neat or finiſhed, are always beautiful and indicate the hand of a maſter. His boldeſt engravings are from Rubens; and his neateſt from Vandyck and Jordans. Some of this maſter's works have been carefully copied, ſo as eaſily to deceive the unſkilful. Amongſt the eſtimable engravings of this artiſt the following are mentioned: viz. the "Brazen Serpent," from Rubens; "Abraham offering his ſon Iſaac," from Theodore Rombout; the "Education of the Virgin, by St. Anne," the "Marriage of the Virgin," the "Nativity of Chriſt," the "Adoration of the Wiſe Men," the "Feaſt of Herod," in which the daughter of Herodias is exhibited, preſenting the head of John the Baptiſt to his mother, and the "Miraculous Draught of Fiſhes," all from Rubens; "Chriſt crowned with thorns," from Vandyck, and a "Crucifixion," from the ſame, in which a figure appears preſenting the ſponge to Chriſt; St. John and the Virgin are ſeen ſtanding at the foot of the croſs, and Mary Magdalene reclining towards it. This is one of his moſt beautiful engravings. The firſt impreſſions, in which the left hand of St. John is not ſeen, are very ſcarce; in the ſecond, the hand appears upon the ſhoulder of the Virgin; but in ſubſequent impreſſions, the hand was again eraſed. Strutt.

BOLT, in *Building*, an iron faſtening for a door, moved with the hand, and catching in a ſtaple or notch made to receive it. Bolts are chiefly of three kinds: *plate*, *round*, and *ſpring-bolts*.

Bolt *of a lock* is the piece of iron which, entering the ſtaple, faſtens the door; being the part which is moved backwards and forwards by turning the key.

Of theſe there are two ſorts; one ſhuts of itſelf by only putting-to the door, and is called a *ſpring-bolt*; the other, which only moves when the key opens or ſhuts it, is called a *dormant-bolt*.

Bolt is alſo uſed for a large iron pin, having a round head at one end, and at the other a key-hole or ſlit, wherein to put a pin or faſtening, ſerving to make faſt the bar of a door, window-ſhutter, or the like.

This is more particularly called a *round-bolt*, or *window-bolt*.

Bolts, in the *Artillery*, are of ſeveral ſorts; thoſe which go betwixt the cheeks of a carriage to ſtrengthen the tranſoms are called *tranſom-bolts*. The large iron bolts or knobs on the cheeks of a carriage, keep the handſpike from ſliding, when it is poiſing up the breech of the piece. The two ſhort bolts that being put one in each end of an Engliſh mortar-carriage, ſerve to traverſe her, are called *traverſe-bolts*. The bolts that go through the cheeks of a mortar, and, by the help of quoins, keep her fixed at the elevation given her, are called *bracket-bolts*. And the four bolts that faſten the bracket or cheeks of a mortar to the bed, are called

called *bed-bolts*. Beſides theſe there are bolſter, eye, breeching, garniſh, joint, ſtool-bed, and axle-tree bolts. See CARRIAGE.

BOLTS, in *Carpentry*, denote pieces of wood cleft with wedges, in order to be ſplit into laths.

BOLTS, or iron pins, in a *Ship*, are of ſeveral ſorts, of which the moſt common have ſmall round heads, and are uſed to unite two or more pieces together. Some have round flat heads, called faucer-heads, with a mortiſe in the other end, or point, and are uſed to faſten moveable pieces to thoſe that are fixed; others have an eye at one end, for laſhing or hooking blocks, &c. and are driven in maſt-heads, yards, caps, &c. Some have a ſquare part left at the back of the eye, that they may not be driven on the eye, and endanger ſplitting. Bolts are frequently diſtinguiſhed according to the places where they are uſed; as, *chain-bolts*, *bolts for carriages*, &c.; *ring-bolts*, ſerving for the bringing-to of the planks, &c. *drive-bolts*, uſed to drive out others; *fet-bolts*, employed for forcing the planks, and other works, and bringing them cloſe to one another; *rag-bolts*, on each ſide full of jags or barbs, to keep them from flying out of their holes; *clench-bolts*, thoſe which are clenched or faſtened at the ends where they come through; *fore-lock-bolts*, made like locks with an eye at each end, whereunto a fore-lock of iron is driven to prevent ſtarting out; *fend, or fender-bolts*, made with long and thick heads, ſtruck into the outermoſt bends or wales of a ſhip, to ſave her ſides from bruiſes and hurts. The following machine for drawing bolts in and out of ſhips was invented by Captain Bolton of the Navy, and obtained from the Society of Arts their prize of the gold medal. A model of it is preſerved in the repoſitory of the ſociety for the uſe of the public. The deſcription of it (See Tranſactions of the Society, vol. xvi.) is as follows:

AAAAAA (*Plate of Ships*) is the frame of the machine. B, a cylindrical tube, having a female ſcrew in the inſide. C, a wheel with teeth attached to the cylinder B. D, an endleſs ſcrew adapted to the wheel C. E, handle of the winch. F, the bolt drawing out. G G, blocks to ſupport the frame. H, a hollow piece of ſteel, having on its outſide a male ſcrew, whoſe threads work within the female ſcrew in the cylinder B. To this piece of ſteel the bolt is to be rivetted. I, a ſemicircular piece of ſteel, which is to be introduced into the notches on H, when a ſimilar notch has been cut in the head of the copper bolt, which by this means is prevented from turning in H, while drawing. K, the bolt, as prepared to receive the machine. L, a ſteel bar, ſomewhat ſmaller than the bolt to be drawn, having at one end a male ſcrew, A, and at the other end another male ſcrew that fits into the female ſcrew in B. M, a ſection of a male ſcrew, having a ſquare hole larger than the bolt. N. a bolt with a male ſcrew at one end ready to be drawn in.

The machine, of which a plate is annexed, conſiſts of a frame ſupporting a cylindrical female ſcrew tube. On this tube is mounted a wheel with teeth adapted to an endleſs ſcrew fitted to the frame, and worked by a handle.

To draw the bolt out.

The head of the bolt muſt be cut off, and a hole made in the timber big enough to receive the male ſcrew H, which is put over the bolt: a ſlit is then to be made, either by a ſaw or cold chiſſel, in the head of the bolt, to receive the key I, and which correſponds to the ſlit in H; the bolt head is then to be rivetted as firmly as poſſible upon H: the cylindrical tube, B, is then to be ſcrewed on, turning the whole machine round till it can be done no longer, when the endleſs ſcrew is to be uſed. If the machine is of a proper ſtrength, and the rivetting well done, the power is ſuch as to extract the bolt or break it, but generally it will be drawn out uninjured.

To draw bolts into ſhips.

It will be neceſſary to have a bar, L, which is recommended to be made of ſteel, long enough to paſs from the inſide to the outſide of the ſhip, and ſomewhat ſmaller than the copper bolt intended to be drawn in. This may be called a conductor. On one end ſhould be a male ſcrew, *a*; the bolt to be drawn in ſhould be tapped at one end to receive the male ſcrew, *a*, on the conductor, and at the other end ſhould be another male ſcrew that fits into the female ſcrew in B; after which the operation is the ſame as drawing a bolt out, and the machine ſhould be applied accordingly. When the bolt arrives at its deſtined place, it may be ſecured on the inſide by a nut, which is as good a way of faſtening as clinching, and much more expeditious.

This machine, though only of the height of eighteen inches, will draw bolts in or out of any length; for, after the bolt has riſen to the top of the tube, it will only be neceſſary to ſcrew the machine back, and follow up the work with blocks of timber, as repreſented in the drawing.

Note. If the upper part of the hole in H be made ſquare, larger than the round hole as ſhewn at M, and the head of the bolt rivetted into it, it will do away the neceſſity of the key, I, render the machine leſs complicated, and ſave much time and trouble.

BOLTS of *an Anchor*, are cylindrical iron pins for faſtening the two parts of the ſtock together.

BOLTS for *whirls*, in *Rope-making*, are large iron pins with round heads, driven in the board over the crank-wheel for the whirls to run on.

BOLT is alſo uſed for a meaſure or certain quantity of canvas, amounting to twenty-eight ells.

BOLT of ſilk or ſtuff denotes a long narrow piece, of indefinite meaſure.

BOLT, *peaſe*, in Eſſex, denotes the peaſe-ſtraw, when the grain is threſhed out of it.

BOLT, *thunder*. See THUNDER-*bolt*.

BOLT-*rope*, in *Sea Language*, is a rope ſewed to the edges of a ſail, to prevent it from rending by the force of the wind, or any other cauſe.

A bolt rope ſhould be made of fine yarn ſpun from the beſt hemp, and ſewed neatly on with good twine. To avoid ſtretching, the rope muſt be kept well twiſted while ſewing on, and care taken that neither too much nor too little ſlack is taken in: that part of the rope at the leech of the ſail is to be croſs ſtitched at every foot in length, at every ſeam, and in the middle of every cloth at the foot, with three croſs ſtitches: four croſs ſtitches ſhould be taken at all the beginnings and faſtenings off; the firſt ſtitch given twice, and the laſt three times. Small ſails have two croſs ſtitches at every ſeam, and three at every faſtening off.

BOLTED *flour*, that which has paſſed through the BOLTER.

BOLTEL, in *Building*, any prominence or jutting out, as of a piece of timber, end of a beam, or the like, advancing beyond the naked of the wall.

BOLTERS, or BOULTERS, a kind of ſieves for meal, having the buttons made of woollen, hair, or even wire. The word ſeems derived from the German, *beutal, a ſieve*; whence alſo *beutelen, to bolt*. The bakers uſe bolters, which are worked by the hand; millers have a large ſort, wrought by the motion of the mill.

BOLT-HEAD, a veſſel uſed by the chemiſts, the ſame as matraſs; which ſee.

BOLT-HEAD, in *Geography*, a promontory of England, on the

the ſouth-coaſt of the county of Devon, 19 miles S. E. of Plymouth. N. lat. 50° 9′. W. long. 30° 47′. The promontory 4½ miles W. N. W. of this is called *Bolt-tail*.

BOLT and Tun, in *Heraldry*, is a bird bolt in pale piercing through a ton.

BOLTING, or Boulting, the act of ſeparating the flour from the bran, by means of a ſieve or bolter.

Bolting-*cloth*, or Bolter-*cloth*, ſometimes alſo called *bulting-cloth*, denotes a linen or hair-cloth for ſifting of meal or flour.

That kind of bolting-cloth which is uſed for ſifting of meal, and alſo for a variety of needle-work, for young ladies' ſamplers, and for filling up the frames of window-ſcreens, &c. is wove after the manner of gauze of fine-ſpun woollen yarn. The wool neceſſary for making this cloth muſt be long, well-waſhed, and ſpun to a fine equal thread, which, before it is ſcowered, muſt be ſcalded in hot water, to prevent it from ſhrinking. The web muſt be ſtiffened; and in the manufacture of it the Engliſh have the advantage of the Germans, whoſe cloth of this kind is much cheaper, but much inferior in value to that of England. The bolting-cloth of this country is ſtiffer, as well as ſmoother, and the flour paſſes through it much better than through that of the Germans, which is either very little or not at all ſtiffened. A manufactory of this cloth was eſtabliſhed at Oſtra, near Dreſden, by one Daniel Kraft, about the end of the 17th century; and at Hartau near Zittau, it was introduced by one Pleſsky, who learned the art of making it in Hungary. The cloth, which is ſent from hence for ſale, not only every where round the country, but alſo to Bohemia, Moravia, and Sileſia, is wove in pieces, containing each from 64 to 65 Leipſick ells; the narroweſt being 10, and the wideſt 14 inches in breadth. Large quantities of it are alſo made by a company in the duchy of Wurtemberg. Bolting-cloth is alſo made at Gera, as well as at Potſdam and Berlin; at the latter of which places there is a manufactory of it carried on by the Jews.

Bolting-*mill*, a verſatile engine for ſifting with more eaſe and expedition. The cloth round this is called the bolter.

The method of applying a ſieve in the form of an extended bag to the works of the mill, that the meal might fall into it as it came from the ſtones, and of cauſing it to be turned and ſhaken by the machinery, was firſt made known in the beginning of the 16th century, as we are expreſsly told in ſeveral ancient chronicles.

Bolting, or Boulting, among *Sportſmen*, ſignifies rouſing or diſlodging a fox, rabbit, or badger, from its reſting place.

Bolting, in *Law*, a method of pleading, or arguing, formerly in uſe in the inns of court; inferior to mooting. The caſe is argued firſt by three ſtudents, then by two barriſters; an ancient, and two barriſters ſitting as judges.

The word comes from the Saxon *bolt*, a *houſe*; becauſe done privately within doors, for inſtruction.

BOLTON, Edmund, in *Biography*, an Engliſh antiquarian writer of the 17th century. By religious profeſſion he was a Roman Catholic, and probably enjoyed ſome office under Villiers duke of Buckingham. He was diligent in his reſearches into ſubjects of hiſtory and antiquities, and was the author of ſeveral works, of which the principal are the following; viz. "A Life of Henry II.;" "Elements of Armories," Lond. 4to, 1610; "A tranſlation of Florus;" "Nero Cæſar, or Monarchy depraved," Lond. fol. 1624, in which he attempts to eſtabliſh the improbable opinion, that Stonehenge was a monument to the memory of queen Boadicea. His "Vindiciæ Britannicæ," left in MS., was deſigned to prove the great antiquity and early importance of London. From all his performances, Bolton appears to have poſſeſſed the credulity, nationality, and love of trifles, often attendant on antiquarian ſtudies, when they are not directed by taſte and judgment. The time of his death is not known. Biog. Brit.

Bolton, in *Geography*, a village of Yorkſhire, in England, had a very conſiderable monaſtery of canons regular, of the order of St. Auſtin, founded in 1120 by Robert de Romeli, and this had afterwards other benefactors, and at the diſſolution its annual revenues were valued at 212 l. Part of the religious houſe ſtill remains, and one room is appropriated to a free ſchool, which was founded by Robert Boyle, eſq. This village is rendered remarkable from being the birth-place and reſidence of Henry Jenkins, who was born in the year 1500, and lived to the great age of 169 years. He enjoyed a conſtant ſtate of good health, and poſſeſſed his faculties to the laſt year of his life. See Longevity.

Bolton-*le-Moors*, is an ancient manufacturing town of conſiderable conſequence in Lancaſhire, in England. It may be conſidered as the original ſeat of the cotton trade in this country, and for the manufacture of ornamental and fancy goods is ſtill particularly celebrated. Leland, in his Itinerary, notices the cottons (then a ſpecies of woollen) and coarſe yarns which were brought to this town in his time, and obſerves, that many villages in the vicinity were engaged in this manufacture. Coal-pits were alſo worked at that time, and coals are ſtill obtained in abundance from pits in the neighbourhood. The making of fuſtians was introduced into this town, at a very early period, and ſtill continues a prominent object of trade. During the civil wars in the reign of Charles I., Bolton was beſieged by prince Rupert in 1644, and many of the inhabitants were killed. The town is well built, and has rapidly encreaſed in ſize and population. It is ſeated in a flat diſtrict, as its name partly implies. The advantage of canal conveyance to Mancheſter and Bury, has proved highly important to the town, whoſe manufactories are thereby greatly promoted. Bolton has a free ſchool, of which Ainſworth, the author of the Latin dictionary, was once a maſter. The proſperity of Bolton may be partly eſtimated from the following comparative ſtate of its population. In the year 1773, there were 5339 inhabitants in this town and Little Bolton. Theſe were augmented to 11,739 perſons in 1789; and in 1821, when the population of the country was eſtimated by order of the houſe of Commons, there were found to be 3476 houſes, and 17,413 inhabitants in the townſhip and chapelry of Great and Little Bolton. The principal mart for the ſale of goods made at this place is Mancheſter, where the manufacturers reſort on Tueſdays, Thurſdays, and Saturdays. "The neighbourhood of Bolton," obſerves the judicious Dr. Aikin, "has been diſtinguiſhed for producing men of great talents in mechanical invention, who have generally been wholly uneducated, and indebted only to native powers, and the habit of obſervation. The moſt celebrated of theſe was ſir Richard Arkwright, of whom falſe pride and prejudice alone can think it derogatory to ſay, that he paſſed a great part of his life in the humble ſtation of a barber in the town of Bolton. His mind was ſo ardently engaged in the improvement of the mechaniſm uſed in the manufactures, that he could ſcarcely keep above want by the exerciſe of his proper profeſſion; but his perſeverance and ingenuity were at length rewarded with a meaſure of opulence, which nothing but the tide of proſperity in a commercial nation could beſtow." See Arkwright.

At *Smithels*, an old hall, or manſion, north of Bolton, formerly belonging to the Fauconberg family, is a curious old

old wainſcotted room, the pannels of which are adorned with upwards of 50 heads, cut in wood. This hall is ſhewn and viſited as a curioſity, from a ſuperſtitious prevalent opinion that an impreſſion of a foot may be ſeen in the ſtone floor made by one Marſh a martyr, in the reign of queen Mary.

Rivington, in the pariſh of Bolton, is a conſpicuous hill, crowned with a building called Rivingtonpike. Some veins of lead and calamine have been worked in this neighbourhood, but have not hitherto proved very fortunate to the adventurers.

Bolton is 11 miles from Manchester, and 197 miles N. W. of London. It has a market on Mondays, and two fairs annually. Aikin's Deſcription of the Country round Manchester, 4to. 1795.

BOLTON, a townſhip of America, in Chittenden county, Vermont, ſeated on Onion river, about 104 miles N. N. E. from Bennington, containing 88 inhabitants.—Alſo, a townſhip in Tolland county, Connecticut, incorporated in 1720, and ſettled from Weathersfield, Hartford, and Windſor, 14 miles E. from Hartford.—Alſo, a townſhip in Worceſter county, Maſſachuſetts, 18 miles N. E. from Worceſter, and 34 W. from Boſton; containing 861 inhabitants, and a good bed of limeſtone.

BOLTONIA, in *Botany*, (named by L'Heretier, in honour of James Bolton, late of Halifax, in Yorkſhire, a ſelf-taught naturaliſt and artiſt in a humble ſphere of life, author of the "Hiſtory of Britiſh Singing Birds," 2 vols. 4to. of "Britiſh Ferns," 4to. and of "Funguſes growing about Halifax," 4 vols. 4to. with figures of the ſpecies, all drawn, etched, and coloured by himſelf.) L'Heret. Sert. Angl. p. 35, 36. Schreb. 1309. Juſſieu 450. Boſc. Nov. Dict. Claſs, *ſyngeneſia polygamia ſuperflua*. Nat. Ord. *Compoſitæ radiatæ.—Corymbiferæ*. Juſſ.

Gen. Char. *Cal.* common; imbricate, with nearly equal linear, acute ſcales. *Cor.* compound, radiate; florets of the diſk tubular, funnel-ſhaped, five-cleft, numerous; of the ray many, linear, entire, piſtiliferous. (Schreb.) three-toothed. (Boſc.) *Piſt.* germ oblong; ſtyle filiform; ſtigmas two, thoſe of the ray revolute. *Pericarp.* none; calyx unchanged. *Seed* ſolitary, compreſſed, ſlightly toothed, two-horned; receptacle naked, honey-combed, hemiſpheric.

Eſſ. Char. *Cal.* common, imbricate, with linear ſcales. *Cor.* radiate. *Germs* compreſſed, vertical. *Seed* obſcurely toothed, two-horned. *Recept.* honey-combed.

Species, 1. B. *aſteroides*, (matricaria aſt. Linn. Mant. 116). "Leaves quite entire." Stem upright, two feet high, even, ſcarcely angular, ſlightly ſtreaked; leaves alternate, remote, ſeſſile, lanceolate, even, bent down at the baſe, ragged about the edge; panicle thin, ſtiffiſh, with one-flowered peduncles; diſk yellow; ray pale fleſh-colour. 2. B. *glaſtifolia*. "Lower leaves ſerrate." Five or ſix feet high. Both ſpecies are natives of South America, flower late in the autumn, and were cultivated by Mr. Miller in 1758.

BOLTSACKEN, or BOLTSACK, in *Geography*, rocks at the N. entrance of the Great Belt, 5 miles S. E. from the iſland of Samſoe. N. lat. 55° 48'. E. long. 10° 40'.

BOLTY, in *Ichthyology*, a fiſh of the LABRUS genus, (*Labrus niloticus* of Linnæus), that is found in the Nile. It is figured and deſcribed by Sonnini, in his "Voyage en Egypte." This, it is obſerved, is one among the ſmall number of fiſhes that inhabit the river Nile, the fleſh of which is delicate, and of a good flavour. Daubenton, in the French Encyclopædia, calls the ſpecies *Nébuleux*, on account of the obſcure ſpots with which the fins are marked.

BOLTZNITZ, in *Geography*, a river of Germany, which runs into the Elſter near Elſterwerda, in the margraviate of Meiſſen.

BOLU, a mountain of Aſia, in Armenia, 144 miles S. E. of Erivan.

BOLUADIN, a town of Aſiatic Turkey, in the province of Natolia, 28 miles N. of Kara-hiſſar.

BOLUC *baſſi*, in the *Turkiſh Affairs*, denotes the chief of a company, or a captain who has the command of an hundred janizaries.

BOLURUS, in *Ancient Geography*, a town of Greece, in Theſprotia.—Alſo, a town of Illyria, which belonged to the Trallians. Steph. Byz.

BOLUS, in *Pharmacy*, is a very uſeful form of extemporaneous preſcription adapted to a variety of caſes in which a more ſolid or a more liquid form would not anſwer the purpoſe. The conſiſtence of a bolus is the ſame as that of an electuary, that is, about as ſoft as dough, ſo as eaſily to ſlip down the throat without falling to pieces. As it muſt in ſome degree be taſted while ſwallowed, it generally conſiſts of the medicine in powder, worked up to the proper tenacity by means of ſome grateful ſyrup, ſoft extract of liquorice, or a palatable conſerve; or, if the medicine be an oil, balſam, or other liquid, dry ſugar, with flour, almond-paſte, and the like, are added to bring it to the due conſiſtence. It is intended to be only a ſingle doſe.

The ſubſtances moſt proper to be exhibited in this form are thoſe that are very heavy, and ſcarcely to be ſuſpended in any liquid ſo as to be drank off, ſuch as calomel, tin-powder, ſteel-filings, æthiops mineral, or thoſe that are too bulky to be made into a convenient number of pills, and are nauſeated by the patient in a liquid form, ſuch as cinchona, chamomile, burnt-ſponge, Dover's powder, valerian root; or ſome of the ſtronger acrids and aromatics, as guaiacum, camphor, muſk, caſtor, ammonia: or thoſe that are little ſoluble in the ſtomach, unleſs previouſly mixed with ſome eaſily ſoluble matter, and yet do not readily combine with liquid ſufficient to be drank off, as oil of turpentine, the balſams and the like, mixed with ſugar and flour. Boluſſes differ from troches in this, that the latter are made firmer, though equally ſoluble, and being intended for ſlow ſolution in the mouth; they conſiſt only of inſipid, or not unpalatable ingredients. Subſtances that readily become very moiſt, ſuch as the kali preparatum, ſhould not be uſed in this form, unleſs the bolus is intended to be taken immediately; but on this head leſs caution is required than in compounding electuaries.

This form of medicine ſhould be avoided where the patient is in a ſtate in which the power of ſwallowing is with difficulty exerciſed, as in apoplexy, and other comatoſe diſorders; in ſome ſpaſmodic and painful affections of the throat; or where the œſophagus is naturally very narrow. Alarming accidents have ſometimes ariſen from a neglect of theſe precautions. It is likewiſe difficult to get very young children to ſwallow them, unleſs made extremely thin. Theſe minutiæ will not appear trifling to thoſe who are in the habit of perſonally witneſſing the trouble and difficulty which daily attend the exhibition of medicines, and are ſo liable to defeat the moſt judicious plans of the preſcriber.

In hoſpitals and diſpenſaries this form is very commonly adopted, as it is prepared with little trouble, and is economical in the more expenſive drugs, no more of them being employed than the immediate wants of the patient require.

BOLUS-*Head*, in *Geography*, a cape of Ireland, on the ſouth-weſt coaſt of the county of Kerry, 38 miles S. W. of Killarney. N. lat. 51° 44'. W. long. 10° 12'.

BOLWICK,

BOLWYCK, a town of Norway, 40 miles W. of Tonſberg.

BOLZANI, Urbano Valeriano, in *Biography*, one of the revivers of literature in the 15th century, was born at Belluno about the year 1440. Having entered, when young, into the order of the Minorites, he travelled through Egypt, Paleſtine, Syria, Arabia, Greece, and Thrace, obſerving whatever was curious either in nature or art. In the courſe of his perambulations, he twice aſcended the ſummit of Ætna, and ſurveyed its crater. As a ſtrict obſerver of his vows, he declined accepting the honours and dignities which were offered him. His fixed abode was at Venice, where he taught the Greek language, and, among other ſcholars, inſtructed the learned Gean-Antonio Flaminio, and John d'Medici, afterwards pope Leo X. He was the firſt who facilitated the attainment of the Greek, by compoſing a grammar in that language; of which the firſt edition was printed in 1497, and a ſecond, much enlarged, in 1512. He died in 1524.

BOLZANO, or Bolzen, in *Geography*, a town of Germany, in the Tyrol, ſeated on the river Eyſac, near its confluence with the Adige, famous for its four annual fairs, each of which continues a fornight, which are much reſorted to by Italian and German merchants; 6 leagues S. W. of Brixen, and 9 N. of Trent. It was taken by the French in March, 1797. N. lat. 46° 28′. E. long. 11° 14′.

Bolzano, a town of Italy, in the Vicentin, belonging to the ſtate of Venice, 2 leagues E. of Vicenza.

BOM, in *Zoology*, the name of an American ſerpent of the Boa genus, called likewiſe bome, and boma. It is ſaid to grow to a vaſt ſize, and to be perfectly harmleſs; but the latter aſſertion is improbable; it is not certainly of the poiſonous race of ſerpents. This is called the bom, becauſe it emits a remarkable noiſe reſembling the ſound of that word, when pronounced with a deep hollow voice.

BOMAL, or Bohemal, in *Geography*, a town of Germany, in the duchy of Luxemberg, ſeated on the Ourte, 7 miles S. W. of Spa, and 53 N. W. of Luxemberg.

BOMANGOY, a town of Africa, in the kingdom of Angoy, or Goy (which ſee), ſituate on the north bank of the river Zaire. S. lat. 5° 36′. W. long. 13°.

BOMARZO, a town of Italy, in the eccleſiaſtical ſtate, and patrimony of St. Peter, once epiſcopal; 14 miles from Civita Caſtellana.

BOMB, in the *Military Art*, a hollow iron-ball, or ſhell, furniſhed with a vent, by which it is filled with gun-powder, and which is fitted with a fuſee, or hollow plug, by which it gives fire, when thrown out of a mortar.

In the Engliſh artillery, bombs are now commonly called ſhells.

The word bomb comes from the Latin *bombus*, *crepitus*, or *ſibilus ani*: by reaſon of the noiſe it makes.

The method of preparing a bomb is as follows: a hollow iron globe A B (*Plate Gunnery*), is caſt pretty thick, having a round aperture A, by which it may be filled and lighted; and circular *anſæ* C, D, of hammered iron fixed in the mould when they are caſt, for the commodious putting it into the mortar, as well as for carrying it from one place to another. In France, the handles are caſt iron: but they are thus rendered more clumſy, and liable to break ſooner than the others.

It has been uſual to make the lower part of the bomb the thickeſt, that it may fall on that ſide, and never on the fuſee, and that it may alſo better reſiſt the ſhock, or impreſſion of the powder by which it is diſcharged from the mortar; but Mr. Muller thinks that neither of theſe conſiderations is of any great importance, and recommends rather to make them every where equally thick, becauſe they would thus burſt into a greater number of pieces. Artillery, p. 151. in his Syſtem, &c. vol. v.

After the ſhells have been gauged and examined as to their dimenſions and weight, they muſt be well ſearched within and without by means of a copper grater, to aſcertain whether there be any holes or cavities in them; and the iron pin or ſpike at the bottom of the inſide, which ſupports the corp when they are caſt, ſhould be beat down or broken off. They are then to be hammered all over, to knock off the ſcales, and diſcover flaws; and no hole, in the large ſhells, is allowed, of more than ¼ of an inch deep. An empty fuſee is then driven into the fuſee hole; and the ſhell is ſuſpended in a tub of water, ſo that the water may cover it, without running into the fuſee; in this ſituation the noſe of a pair of bellows is introduced into the fuſee hole, and ſeveral ſtrong puffs given with the bellows; and if no bubbles riſe in the water, it is concluded that there are no holes in the ſhell, but that it is ſound and fit for ſervice.

When the ſhell has been thus proved, and is found to be dry within, gun-powder is introduced into its cavity, by means of a funnel; but it is not quite filled. Artilleriſts, though they agree that ſhells ſhould not be quite full, have not aſcertained the preciſe quantity which would ſerve for their burſting into the greateſt number of pieces. Captain Deſaguilliers, after having made ſeveral experiments, apprehends, that the moſt proper quantity of powder is two thirds of the weight which would fill the cavity. A little ſpace or liberty is left, that when a fuſee or wooden tube *a*, *e*, of the figure of a truncated cone, is driven through the aperture, the powder may not be bruiſed. This fuſee is preſſed in at firſt by the hand as far as it will go, and then drove with a mallet as hard as poſſible, taking care, however, not to ſplit it; for if the leaſt crack were in it, the compoſition would give fire to the powder, and the ſhell would burſt either in the mortar, or in the air, and thus do no execution. For the method of preparing and filling the fuſee, ſee Fusee.

This fuſee is ſet on fire, and burns ſlowly till it reaches the gun-powder, which goes off at once, burſting the ſhell to pieces with incredible violence; whence the uſe of bombs in beſieging towns. Special care, however, muſt be taken, that the fuſee be ſo proportioned, as that the gun-powder do not take fire before the ſhell arrives at the deſtined place; to prevent which, the fuſee is frequently wound round with a wet clammy thread.

The fuſees are driven into the ſhell, ſo as that only about an inch and a half come out beyond the fuſee-hole; and then the ſhell is ſaid to be fixed. They are charged long before there is occaſion to uſe them; and in order to ſecure the compoſition with which they are filled, the two ends are covered with a mixture of two parts of pitch, one of roſin, and three of bees-wax, which will guard the compoſition within from the acceſs of air; and it will thus keep as long as you pleaſe. When the fuſee is to be put into the ſhell, the little end is opened or cut off; but the great end is never opened till the mortar is to be fired.

Bombs or ſhells are made of different magnitudes, from that of 17 or 18 inches diameter downwards; the very large ones are not uſed by the Engliſh, that of 13 inches diameter being the largeſt ſize now employed by them. The following table ſhews the weight, dimenſions, &c. of Engliſh and French ſhells.

SHELLS.—Their Dimenſions, Weight, &c.

Nature.	Weight.	Diameter.	Powder contained in Shells.	Powder for Burſting.	Diameter of Fuſee Hole.		Thickneſs of Metal.
					Outſide.	Inſide.	
	Ct. Qr. lbs. oz.	Inches.	lbs. oz.	lbs. oz.	Inches.	Inches.	Inches.
13 Inch	1 3 2	$12\frac{5}{4}$	10 4	6 12	1.837	1.696	2.05
10 ——	0 3 9	$9\frac{1}{4}$	4 5	2 10	1.57	1.45	1.575
8 ——	0 1 $11\frac{1}{2}$	$7\frac{1}{4}$	2 12	1 14	1.219	1.127	1.2
$5\frac{1}{2}$ ——	0 0 $15\frac{1}{4}$	$5\frac{3}{4}$	1 0	0 12	.894	.826	0.822
$4\frac{2}{5}$ ——	0 0 8	$4\frac{1}{5}$	0 7	0 5	.832	.769	0.653
H. Gren.	0 0 3 11	3.49					
	0 0 1 13	2.77		0 $1\frac{1}{2}$			

French Shells, in French Weights and Meaſures.

Inches.	lbs.				Lines Po.	Lines Po.	Lines.
12-Inch	150	12	17 0	5 0	15 9	15 0	16
10 ——	100	10	10 0	3 0	15 9	15 0	16
8 ——	43	8	4 1	1 0	12 0	11 0	10
6 ——	23	6	2 8	0 12	11 0	10 6	10

Mr. Muller gives the following proportions, from the 13 inch bombs, now commonly uſed, and obſerves that they may be eaſily adjuſted to any other calibre, by making the diameter of the ſhell to 30, as any part expreſſed in inches, to the ſame part expreſſed in parts of the diameter divided into 30 equal parts.

Diameter of the bore - -	30
Diameter of the ſhell - - -	29.5
Diameter of the hollow ſphere - -	21
Thickneſs of the metal at the fuſee hole -	3.5
Thickneſs at the oppoſite part - -	5
Diameter of the fuſee-hole - -	4
Weight of the ſhell unloaded,	$\frac{d}{11.7}$
Weight of the powder contained in the ſhell	$\frac{d}{236.5}$

N.B. The letter *d* denotes the cube of the diameter of the bore.

But ſhells have alſo been lately made with the metal every where of the ſame thickneſs, and are found to burſt into a greater number of pieces by this conſtruction. The Germans do not name their ſhells from the diameter of the bore which receives them, but from the weight of a ſtone-ball that fits the ſame bore as the ſhell. Thus a 7lb. howitzer admits a ſtone-ball of that weight: the ſhell for this weighs 15lbs. and correſponds to the Engliſh $5\frac{1}{2}$ inch. The 30lbs. howitzer ſhell weighs 60lbs., and is rather more than 8 inches in diameter. At the ſiege of Gibraltar, ſmall ſhells, as $4\frac{2}{5}$ inches, and hand-granades, were quilted into grape for 13-inch mortars. The fuſees were turned inwards next the iron-tampion, and leaders of quick-match for communicating fire to the fuſees were introduced through holes made in the wood-bottom, and placed as near the fuſees as poſſible in the centre of the grape. Theſe anſwered very well for ſhort ranges. In general, the windage, or difference between the diameter of the ſhell and mortar, is $\frac{1}{10}$th of the latter; and the diameter of the hollow part of the ſhell is $\frac{7}{10}$ths of the ſame. For finding the weight of an iron-ſhell, the following rule has been given. Take $\frac{6}{9\,4}$ of the difference of the cubes of the external and internal diameters, and this will be its weight. In order to find how much powder will fill a ſhell; divide the cube of the internal diameter of the ſhell in inches by 57.3, which will be the number of pounds of powder. To find the ſize of a ſhell for containing a given weight of powder; multiply the number of pounds of powder by 57.3, and the cube root of the product will be the diameter in inches.

Bombs only differ from granades, in that the latter are much leſs; and inſtead of mortars are thrown out of the hand. Bombs are thrown not only out of mortars and howitzers, but out of cannon. The following ſhells may be fired from guns; viz. hand-granades from 6-pounders; $4\frac{2}{5}$ ſhells from 12-pounders; $5\frac{1}{2}$ ſhells from 24-pounders; and 8-inch ſhells from 68-pr-carronades. Shells may be alſo thrown from guns to ſhort diſtances, in caſe of neceſſity, though the bore be not of a diameter ſufficient to admit the ſhell. For this purpoſe the gun may be elevated to any degree that will retain the ſhell upon its muzzle, which may be aſſiſted by a ſmall line paſſing from the lugs of the ſhell round the neck of the gun. To produce a greater effect, the ſpace between the ſhell and the charge may be filled with wads, or ſome other ſubſtance.

Bombs may be uſed without mortar-pieces, in the manner practiſed by the Venetians at Candia, when the Turks had poſſeſſed themſelves of the ditch, rolling down bombs upon them, along a plank ſet ſloping towards their works, with ledges on the ſides to keep the bomb right forwards. They are ſometimes alſo buried under ground to blow up. See CAISSON.

M. Blondel, who has written on the art of throwing bombs, obſerves that the firſt bombs were thoſe thrown into the city of Watchtendonch, in Guelderland, in 1588, though others pretend they were in uſe a century before, viz. at the ſiege of Naples by Charles VIII. in 1495. Stowe ſays (p. 584), that mortars and bombs were invented in 1544 by foreigners, whom Henry VIII. employed. But they came not into common uſe before the year 1634, and then only in the Dutch and Spaniſh armies. One Malthus, an Engliſh engineer, is ſaid to have firſt carried them into France, where they were put in uſe at the ſiege of Collioure, in 1642.

The art of throwing bombs makes a branch of gunnery, founded on the theory of projectiles, and the laws and quantities of gun-powder.

Meſſ.

Meſſ. Blondel, Guiſnée, de Reſſons, de la Hire, and others, have written expreſsly on the art of throwing bombs.

Bomb-*battery*. See Battery.

Bomb-*cheſt*, is a kind of cheſt filled uſually with bombs, ſometimes only with gun-powder, placed under ground, to tear and blow it up in the air, with thoſe who ſtand on it.

Bomb-cheſts were formerly much uſed to drive enemies from a poſt they had ſeized, or were about to take poſſeſſion of: they were ſet on fire by means of a *faucifſee* faſtened at one end, but they are now much diſuſed.

Bomb, *water*. See Water-*bomb*.

Bomb-*veſſels*, which are ſmall ſhips formed for throwing bombs into a fortreſs, are ſaid to be the invention of M. Reyneau, or Renard, and to have been firſt uſed at the bombardment of Algiers, in 1681. Till then, it had been judged impracticable to bombard a place from the ſea.

The bomb-ketches on the old eſtabliſhment carry one 13-inch, and one 10-inch mortar; with eight 6-pounders, beſides ſwivels, for their own immediate defence. The modern bomb-veſſels carry two 10-inch mortars, four 68-pounders, and ſix 18-pounders carronades; and the mortars may be fired at as low an angle as 20 degrees; though theſe mortars are not intended to be uſed at ſea, but on very particular occaſions, their principal uſe, at theſe low angles, being to cover the landing of troops, and to protect our coaſts and harbours. A bomb ketch is generally from 60 to 70 feet long from ſtem to ſtern, and draws eight or nine feet water. The tender is generally a brig, on board of which the party of artillery remain, till their ſervices are required on board the bomb-veſſel. The following inſtructions ſerve for their management and ſecurity in action.

1. A Dutch pump, filled with water, muſt be placed in each round-top, one upon the fore-caſtle, one on the main-deck, and one on the quarter-deck; and furniſhed with leather buckets, for a freſh ſupply of water.

2. The booms muſt be wetted by the pumps before the tarpaulins and mortar-hatches are taken off; and a wooden ſkreen, 5 feet ſquare, is to be hung under the booms, over each mortar, to receive the fire from the vents.

3. The embrazures being fixed and properly ſecured, the port muſt be let down low enough to be covered by the ſole of the embrazure. Previous to its being let down, a ſpar muſt be laſhed acroſs it, to which the tackles for raiſing it again muſt be fixed: this ſpar ſerves to project the tackles clear of the exploſion.

4. The mortars muſt not be fired through the embrazure at a lower angle than 20 degrees, nor with a greater charge than 5lbs. of powder.

5. Previous to firing, the doors of the bulk-head, under the quarter-deck, muſt be ſhut, to prevent the cabin being injured by the exploſion.

6. The bed muſt be wedged in the circular curb, as ſoon as the mortar is pointed, to prevent re-action; the firſt wedge being driven tight before the rear ones are fixed, in order to give the full bearing on the table, as well as the rear of the bed.— The holes for dog-bolts muſt be corked up, to prevent the ſparks falling into them.

7. When any ſhells are to be uſed on board the bomb, they muſt be fixed on board the tender, and brought from thence, in boxes in her long-boat; and kept along-ſide the bomb-ſhip till wanted, carefully covered up.

8. In the old conſtructed bomb-veſſels it is neceſſary to hoiſt out the booms; and raſt them along-ſide previous to firing; but in theſe new ones, with embrazures, only the boats need be hoiſted out; after which the mortars may be prepared for action in 10 minutes. See Kitch.

BOMBA, in *Zoology*, a ſpecies of Trichoda, one of the genera of Animalcule or Vermes infuſoria. This kind is briefly deſcribed as being of a changeable form, with a few hairs on the anterior part. This is found abundant in ſtagnant water: the body is thick, ſomewhat pellucid, of a yellowiſh colour, and filled with paler molecules. Müll. Gmel. &c.

BOMBARD, Bombarda, a piece of artillery anciently in uſe, exceedingly ſhort and thick, and with a very large mouth, by ſome alſo called *baſiliſk*, by the Dutch *donderbuſs*. Some derive the word, by corruption, from *Lombard*, as ſuppoſing this piece firſt uſed in Lombardy. Du-Cange, after Voſſius, derives it from *bombus* and *ardeo*; Menage, from the German *bombarden*, the plural of *bomber*, *baliſta*. But we doubt whether the Germans knew any ſuch word. It is no unuſual thing with Menage, and many other etymologiſts, to give derivations from words of their own making.

There were ſome of theſe pieces ſaid to have carried balls of 300 pounds weight; Froiſſart mentions one of fifty feet long. To load them, they made uſe of cranes, &c. The bombard is ſuppoſed to have been in uſe before the invention of cannon.

Bombards can hardly be ſuppoſed to have been of metal, nor charged with gun-powder. They were rather a ſort of baliſtæ for throwing ſtones, and were played with ropes.

BOMBARDIER, an engineer, or perſon, whoſe buſineſs is to take care of the firing and throwing bombs out of mortars.—He firſt drives the fuſee, then fixes the ſhell, points, loads, and fires.

Bombardier, in *Entomology*. See Carabus.

BOMBARDING, the art or act of attacking a city or fortreſs, by throwing bombs into it, in order to ruin or ſet on fire the houſes and magazines, and do other miſchiefs.

Bombarding is not reckoned the moſt honourable method of making war, as it rather tends to do miſchief to the inhabitants than to the works.

BOMBARIN, in *Zoology*, the name uſed by ſome old writers for the Hippopotamus.

BOMBASINE, in *Commerce*, a kind of ſilk ſtuff manufactured at Milan, and thence ſent into France and other countries. The French alſo uſe the word bombaſine for ſtuff made of cotton, more properly called dimity.

BOMBAST, in *Rhetoric*, denotes a *ſtyle* too high and pompous for the ſubject and occaſion; or a certain manner of elocution and action, which is grand when ſupported by dignity in the ſentiment, and force in the expreſſion, but never fails to appear ridiculous where the ſentiment is mean, and the expreſſion flat. See Style.

BOMBAX, in *Botany*, (a name given to the common cotton tree by Serapion an Arabian phyſician in the beginning of the ninth century; Pliny had before called cotton Bombyx. Gr. βομβαξ. Suid.) ſilk cotton. Lin. Gen. 835. Reich. 901. Schreb. 1127. Juſſieu. 275. Willden. 1284. La Marck. *Fromager*. Claſs, *monadelphia polyandria*. Nat. Ord. *Columniferæ—Malvaceæ*. Juſs.

Gen. Char. *Cal.* permanent, either of one leaf, tubular-campanulate, three, four, or five cleft; or of five unequal leaves. *Cor.* either five petals, or one petal five-cleft. *Stam.* filaments five or more, connate at the baſe, ſometimes ſlightly, ſometimes tubular. *Piſt.* germ ſuperior, turbinate-oblong. Stigma capitate, with five teeth more or leſs developed. *Pericarp.* large ovate-oblong, membranous and almoſt woody, five-celled, five-valved. *Seeds* numerous, round, woolly. *Recept.* columnar five cornered, forming the partitions.

Eſſ. Char. *Cal.* ſimple. *Capſule* ſomewhat woody, five-celled, five-valved. *Seeds* woolly. *Recept.* five-cornered.

Species, 1. B. *pentandrum.* (La Marck Tab. 587.) "Flowers pentandrous." Linn. "Anthers bent; leaves in ſevens." Willden. A tree ſixty or eighty feet high. Bark greeniſh, ſmooth, eaſily ſeparated from the wood; often ſprinkled, eſpecially when young, with large, conic, ſpinous tubercles; branches, near the ſummit, pendant; leaves on long petioles, digitate, folioles from five to nine, either entire or ſerrate, lanceolate, ending in a point; flowers in a ſimple umbel; partial peduncles about an inch long, with ſeveral alternate bractes; petals five, white and velvety without, ſmooth, concave, and of a purple or delicate roſe colour within; anthers two or three, on a filament, twiſted together; fruit half a foot long, ſhaped like a cucumber, very ſlender at its baſe; ſeeds oval with a ſharpiſh point, enveloped with a great quantity of ſhort dark cotton which is not ſpun, but uſed for ſtuffing pillows, mattraſſes, &c. Rumphius ſays that the valves open at the baſe. Plumier aſſerts the contrary. Jacquin, who ſaw the living plant in fruit, gives no information on the ſubject. A native of both Indies. Cultivated by Mr. Miller in 1739. 2. B. *erianthos.* (Cavan. Tab. 152.) "Flowers pentandrous; anthers ſimple, erect; leaves in ſevens." Willd. Trunk very ſpinous; leaves terminated by a filament, very ſmooth; calyx ſhort and very large; petals three inches long, whitiſh, covered without with a ſhort thick down, ſmooth within, concave, and rounded at their extremity; tube formed by the lower part of the filaments, bottle ſhaped; anther linear, longitudinally fixed to the upper part of the filament. Found by Commerſon in Brazil. 3. B. *pyramidale.* "Stem without thorns; leaves cordate, angular; flower pentandrous; anthers united; fruit very long, pyramidal." Cavan. A large tree with very ſpreading branches; wood white and ſo light that fiſhers uſe it inſtead of cork; bark thick, fibrous, cinereous, marked with whitiſh ſpots, and reddiſh wrinkles; leaves a foot in diameter, ſtrongly nerved, green on the upper, yellowiſh and downy on the lower ſurface, on long and thick petioles; flowers numerous on long peduncles; coroll large, monopetalous, campanulate, deeply divided into five ſegments; calyx large, reddiſh, green, campanulate, with five blunt diviſions; filaments five, thick, ſupporting as many large nearly arrow-ſhaped anthers which are ſpirally united and encloſe the ſummit of the ſtyle; ſtyle reddiſh, club-ſhaped, marked at the end with five ſpiral furrows; capſule furrowed, from eight to ten inches long; ſeeds very ſmall, ſomewhat egg-ſhaped, enveloped with fine, ſhort, reddiſh cotton. A native of the Antilles. 4. B. *grandiflora.* "Leaves in ſevens; flowers pentapetalous, large, polyandrous; ſtamens united into a tube at the baſe." Cavan. Calyx large, expanding with four blunt diviſions; coroll ſuperb, of five petals, each five inches long, but narrow in proportion to their length, whitiſh, fleſhy at their baſe, velvety without, ſmooth within, and rounded at their extremities, inſerted at the baſe of the tube of the filaments, which is naked, entire in its whole length, and terminated by a prodigious number of red filaments a little ſhorter than the coroll; anthers kidney-ſhaped, ſmall and looſely attached to the filaments; ſtyle filiform, thick, longer than the ſtamens, with five ſmall teeth; fruit unknown. Deſcribed by Cavanilles from a ſpecimen in the Herbarium of Thouin. It grows about Rio-Janeiro. 5. B. *Ceiba.* "Flowers polyandrous; leaves in fives." Linn. Trunk cloſely armed with ſhort, ſtrong ſpines, ſo large as to be hollowed out into canoes of twenty-five tons burden; calyx ſmall, campanulate, with five ſmall teeth; coroll monopetalous; tube ſtraight, twice as long as the calyx; border divided into five long, concave obtuſe ſegments; filaments numerous, proceeding from five diſtinct bodies, which are united at the baſe and form a conic tube adhering to the baſe of the coroll; anthers oblong, looſe; germ ſomewhat ovate, with five angles; capſule oblong, ſmall at the baſe; ſeeds nearly round, covered with down, which is uſed by the lower ranks to ſtuff pillows and chairs. A native of South America, near Carthagena. Cultivated at Hampton Court in 1692. 6. B. *heptaphyllum.* "Flowers polyandrous; leaves in ſevens." Linn. "Stamens in five bodies." Cavan. A tree fifty feet high, ſix feet diameter at its baſe; wood ſoft, light, and brittle; bark thick, cinereous, ſpinous when young; leaves digitate; calyx four cleft; flowers numerous, large, odorous; coroll of five petals, downy without, attached by its baſe to the bottom of the tube of the filaments; filaments very numerous, kidney-ſhaped, ſhorter than the coroll, looſely attached; fruit elongated. 7. B. *globoſum.* "Leaves in fives or ſevens, obovate, emarginate; fruit globular." Willd. (Aub. Guian. Tab. 281.) A tree thirty feet high; trunk a foot and a half in diameter; leaves palmate, green, ſmooth, oval, obtuſe, ſlightly crenulated at the ſummit, the middle one the largeſt, on long petioles, with two long, pointed, caducous ſtipules at their baſe; flowers unknown; fruit in axillary and terminating racemes. A native of Cayenne. 8. B. *goſſypium.* "Leaves five-lobed, acuminate, tomentoſe beneath." Linn. A large tree with green, nearly ſmooth bark; leaves alternate on long, ſlender, pubeſcent petioles; flowers large, in ſimple panicles on downy peduncles; calyx of five unequal leaves; petals five, as long again as the calyx, expanding, yellow; filaments numerous, ſlightly united at their baſe; anthers oblong, curved; capſule oval-obtuſe; ſeeds kidney-ſhaped. A native of the coaſt of Coromandel.

The ſpecies known to Linnæus were at firſt placed by him with the common cotton and its congeners, under the old Greek name Xylon; but afterwards ſeparated on account of the ſimple calyx. Thoſe with the double calyx he then called goſſypium; thoſe with the ſimple one bombax. The ſpecies of the genus bombax, as it now ſtands, differ ſo much from each other in moſt of the parts of fructification, as almoſt to juſtify the diviſion of them into diſtinct genera. The calyx, the coroll, the number and ſupport of the ſtamens, the form and inſertion of the anthers, all vary: nothing is conſtant but the ſimple calyx; the five-celled, five-valved capſule, and the woolly ſeeds. We have altered the natural and eſſential generic characters, and ſo formed them as not to exclude any of the ſpecies.

Propagation and Culture. Silk cotton is propagated by ſeeds ſown in a hot-bed in the ſpring. In about two months it ſhould be tranſplanted into a ſmall pot filled with freſh loamy earth, and plunged into a moderate hot-bed of tanners' bark. At firſt it ſhould be ſhaded from the ſun; but afterwards, when the weather is warm, ſhould be allowed freſh air, and frequent ſupplies of water in ſmall quantities, with a uniform degree of heat. In autumn it muſt be removed into the bark-ſtove and ſparingly ſupplied with moiſture. It makes a pleaſing variety in a large ſtove, but is not likely to produce flowers in England. See Miller, Gardener's Dictionary.

BOMBAY, in *Geography*, a ſmall iſland in the Indian Sea, near the weſtern coaſt of Hindoſtan, about 7 miles in length and very narrow, containing a very ſtrong and capacious fortreſs, a large city, a dock-yard, and marine arſenal. It is ſeparated on the N.E. by a narrow ſtrait from Salſette, another iſland, and theſe two, together with the neighbouring ſhores of the continent, form a large ſound, in which are ſeveral other iſlands, particularly Caranjah and Elephanta;

Elephanta; the latter (which fee) being famous for its ſubterraneous temple, and both of them acquiſitions from the Mahrattas. It was firſt taken poſſeſſion of by the Portugueſe, ſoon after their arrival in India, and called by them *Buon Bahia*, or Good Bay, from the excellence of its harbour, which is ſo ſpacious as to accommodate, as it is affirmed, a thouſand ſhips at anchor, and well ſheltered from all winds. The Portugueſe ceded it to the Engliſh in 1662, as part of the dower of the Infanta, queen of Charles II. After the king's marriage, a fleet under the command of lord Marlborough was ſent to take poſſeſſion of it; and Sir Abraham Shipman was appointed Governor. But upon their arrival in September 1663, the Viceroy, actuated by the Popiſh clergy, who objected to the ceſſion of the iſland to hereties, refuſed to ſurrender it. At length, however, in 1664, he was terrified into compliance, and a treaty was eſtabliſhed, by which Mr. Cook, upon the death of Shipman, was inveſted with the poſſeſſion of the iſland, in quality of Governor. By this treaty the inhabitants were to be continued in the free exerciſe of their religion, and in the undiſturbed poſſeſſion of their eſtates under the crown of England. Although the trade of Bombay was at this time very proſperous, it was ſoon found, that the royal revenues were not ſufficient for defraying the charge of the eſtabliſhment, and that the trade itſelf was ſubject to very conſiderable obſtructions; ſo that the king found it expedient to make a full grant in fee-tail of the port and territory to our Eaſt India Company, which was done by charter, dated 26th March 1668, and thus they have continued to hold it to the preſent time.

The city of Bombay, the principal port and ſettlement of the Engliſh in this part of India, is ſituated in the northern part of the iſland, N. lat. 18° 58′, E. long. 72° 38′. It is about a mile in length, but narrow; and defended both towards the ſea and land with various fortifications, which have been conſtructed at a great expence, and which have rendered it the moſt conſiderable fortreſs in India. On the iſland alſo there are ſmall forts ſufficient for protecting it from any irruption of the Indians; and in the harbour there are baſons hewn out in the rock, for the purpoſe of careening ſhips. The houſes of Bombay are in general neither ſplendid nor commodious; but there are ſeveral handſome buildings, among which are the governor's palace, and a large, elegant church near it; the houſes are not flat-roofed, as they are in other parts of the Eaſt, but they are covered with tiles in the European faſhion. The Engliſh have glaſs windows. The other inhabitants of the iſland have their windows of ſmall pieces of tranſparent ſhells framed in wood, which render the apartments very dark. The ſoil of the iſland is ſterile, and incapable of any great improvement; its chief produce conſiſts of cocoas and rice, beſides mangoes and ſome Indian fruits. It draws a conſiderable ſupply of proviſions from the continent, and from the fertile iſland of Salſette. Large quantities of ſalt are manufactured on the ſhore, from the ſea-water that flows into pits adapted to this purpoſe. The ſea-breezes and frequent rains cool the atmoſphere, and render the climate of this iſland temperate; and though the air is not ſo pure as at Madras, yet it is much more wholeſome than at Bengal; the coaſt of Malabar being pretty healthy, though leſs ſo than the coaſt of Coromandel. The iſland of Bombay has been rendered much more healthy than it was formerly, by a wall, which has been built to prevent the encroachment of the ſea, where it formed a ſalt marſh, by draining the marſhes in its environs, and by an order that none of the natives ſhould manure their cocoa-nut trees with putrid fiſh. Nevertheleſs, many Europeans, eſpecially on their firſt arrival, are ſeized with fevers, fluxes, and other diſorders, which prove fatal; and others ſhorten their days by not adhering to a mode of life ſuitable to the climate. The natives, however, and others, who abſtain from exceſs of animal food and ſtrong liquors, enjoy a good ſhare of health, and live to a conſiderable age. The want of freſh water is an inconvenience to which the inhabitants are ſubject; the beſt being that which they preſerve in ciſterns after rain; whereas that which is ſupplied by their wells has a brackiſh taſte.

This iſland is become very populous, in conſequence of the toleration which is granted by the Engliſh to perſons of every religious profeſſion. The number of inhabitants is eſtimated by Niebuhr at 140,000, and of theſe the Europeans form the moſt inconſiderable claſs. The other inhabitants are Portugueſe, or Indian Catholics; Hindoos, the original poſſeſſors of the country; Perſians from Kerman; Mahometans of different ſects; and ſome Oriental Chriſtians. The Engliſh have a handſome church at Bombay, but they are diſadvantageouſly circumſtanced with regard to officiating clergy. The Catholics are much more numerous than the Proteſtants, and have many prieſts, as well Europeans as Indians, who attend their ſtudies at Goa. The pope, many years ago, appointed for their ſuperintendance a biſhop of Bombay, but he was diſmiſſed by the governor of the iſland. The Catholic churches are decent buildings, and are within ſumptuouſly ornamented. The Jews had once a college and a ſynagogue in the middle of this iſland; but the college was converted into a country-houſe for the Engliſh governor, and the ſynagogue into a ſuite of aſſembly rooms.

Bombay is the ſeat of the Engliſh government for the coaſt of Malabar; as Madras is for the Coromandel coaſt, Calcutta for Bengal, and as Bencoolen was for Sumatra. Theſe four governments, of which that of Bengal has the ſuperiority and control, are obliged, by an act of the Britiſh parliament paſſed in 1773, (13 Geo. III. c. 63.) to afford mutual aſſiſtance in caſes of extraordinary exigence. The different eſtabliſhments are under ſimilar adminiſtration, and all proceſſes between ſubjects of the company are determined by the law of England. The council or regency of Bombay (as well as that of Bengal) conſiſts of a governor and three members of council. The other ſervants of the company are factors and writers of different ranks, and are ſometimes transferred from one department to another. The governor and members of council of the other preſidencies are to be under the control of the government-general of Bengal, with reſpect to treaties with the native powers of India, levying war, making peace, collecting and applying revenues, levying and employing forces, or other matters of civil and military government; and they are required in all caſes to obey the orders of the ſaid government-general, unleſs the directors of the company ſhall have ſent to theſe ſettlements any contrary orders not known to the government-general, of which, in that caſe, they are to give this government immediate advice. The Court of Directors are to appoint to theſe ſeveral governments, and likewiſe the commander in chief of all the forces, and the three provincial commanders in chief. All governors and counſellors are prohibited from trading, except from the company, 24 Geo. III. ſeſſ. 2. c. 25. 33 Geo. III. c. 52. See BOARD of *Controul* and *Eaſt India* COMPANY.

BOMBAY *Hook*, an iſland of America at the mouth of Delaware river, about 8 miles long and 2 broad, formed by the Delaware on the eaſtern ſide, and Duck Creek and Little Duck Creek on the Maryland ſide; theſe are united together by a natural canal. The N. W. end of Bombay Hook is about 47 miles from Capes Henlopen and May; from the Hook to Reedy Iſland is 9 miles.

BOMBAZINE,

BOMBAZINE Rapids, lie on a river in Lincoln county, and district of Maine in America, and are navigable for boats with some lading, at a middling pitch of water. They took their name from Bombazine, an Indian warrior, who was slain by the English in attempting to cross them.

Bombazine, a lake, seven or eight miles long, in the township of Castleton, county of Rutland, and state of Vermont.

BOMBELLA, in *Entomology*, a species of Bombyx, of a middle size, that inhabits Austria, the wings of which are cinereous, sprinkled with fuscous. Fabr. Mant. This is *Tinea Bombycella* of the Vienna catalogue. (Wien. Schmetterl.

BOMBERG, Daniel, in *Biography*, one of the early printers, was a native of Antwerp, and settled at Venice, where, in 1518, he printed a folio edition of the Hebrew Bible. See Bible. He also began an edition of the Talmud, in 1520, and completed it some years afterwards in eleven volumes folio. Each of the three impressions of this immense work is said to have cost him 100,000 crowns. His whole property was devoted to the impressions of valuable editions of Hebrew Bibles and rabbinical works, for which purpose he employed a great number, as some say, more than 100 of learned Jews. Bomberg was himself a Hebrew scholar. He died about the middle of the 16th century.

BOMBIC Acid. The silk worm has a small reservoir near the anus, from which, when full grown, or especially when in the chrysalis state, a minute quantity of an acid liquor is seen to ooze out. If the entire animal is bruised, it gives a liquor containing the usual soft animal matters, together with a native acid. Alcohol separates the former, and leaves the latter in solution, which, by evaporation, furnishes a very sour pungent yellow fluid, which shews all the marks of an acid by reddening blue vegetables, and uniting with alkalies and some earths. The discoverer, Chaussier, considers it as peculiar, and hence it has obtained a separate place in the list of animal acids; but from analogy with the experiments on the *formic* acid, and other circumstances, the separate existence of the bombic acid is very questionable. No other chemist has yet undertaken to confirm or dispute the original statement. Mem. de l'Acad. de Dijon. 1783.

BOMBICHIE, in *Geography*, a town of Asia in Syria, 44 miles E. N. E. of Aleppo.

BOMBINA, in *Entomology*, a large species of Curculio, described by Fabricius, as a native of Cayenne. The colour of this insect is ferruginous brown, and the wing-cases striated, with black elevated tubercles.

Bombina, in *Zoology*, a species of Rana, or frog, the belly of which is orange, spotted with sky-blue, and the pupil of the eye triangular. Blumenb. This kind appears to be extremely variable in point of colour and markings. In the tenth edition of the Linn. Syst. Nat. it is described as the *Rana variegata*. Roesel, in his "History of Frogs and Toads," calls it *Bufo igneus*, (bufo vulgo igneus dictus). It is likewise *La sonnante*, and *le couleur de feu*, of Lacepede, and *Rana ignea*, or fire-frog, of Dr. Shaw.

The permanent varieties, if they may be so expressed, of this particular species, do not seem to be very correctly ascertained. Gmelin, upon the authority of preceding writers, constitutes the following varieties: β has the belly black, with clear white spots and speckles; γ is of a fuscous colour; and δ is distinguished by its loud sonorous voice.

This is the smallest of the European kinds of either the frog or toad. The general habit resembles that of a toad, but it is said to leap and swim with as much or even greater facility than the common frog. Dr. Shaw observes, that he places it among the frogs instead of toads, on account of its depositing its ova in clustered heaps; not in strings like the latter animals. In Germany, Italy, and other European countries, which this creature inhabits, it is known to delight in marshy places. The sound of the male, which alone is vocal, is clear and sharp, and is thought by some to resemble, in a very peculiar manner, that of a man giggling with laughter. This, indeed, is not the universal opinion; some authors compare it to the tone of a bell, or the note of a cuckow, for which reason it has obtained the name of bombycina.

This animal, according to Dr. Shaw, may be considered rather as an aquatic than terrestrial species; being rarely found on land, but chiefly inhabiting turbid stagnant waters, in which, in the month of June, it deposits its spawn, the ova being much larger in proportion than in most others of the genus. The tadpoles are hatched towards the end of June, and are of a pale yellowish brown colour; and, when young, are often observed to hang from the surface of leaves, &c. by a glutinous thread proceeding from the small tube or sucker beneath the lower lip. They arrive at their full size towards the close of September, and at that period are remarkable for the fleshy or muscular appearance of the tail, which is stronger in proportion than in most other tadpoles. About the beginning of October they assume their complete or ultimate form; and when the tail has so far decreased as to be still a quarter of an inch in length, that remaining portion becomes entirely obliterated in the space of about twelve hours. The fire-frog is a lively active animal; leaping and swimming admirably well. When surprised on land, or unable to escape, it squats close to the ground; at the same time turning back its head and limbs in a singular manner, and if farther teized and irritated, evacuates from the hinder part of the thighs, a kind of saponaceous frothy fluid, of no bad scent, but which, in some circumstances, has been found to excite a slight sensation of acrimony in the eyes and nostrils. This species is observed to breed at the age of three years, and may be supposed to live about ten; but this is not entirely ascertained.

It ought not to escape remark, that the triangular form of the pupil of the eye, which Gmelin and others consider as the most striking criterion of this species, can only be observed in a full light, for when examined in the shade its shape is circular.

BOMBOESKJE, in *Zoology*, the Sciurus Asiaticus in Le Bruyn's it. p. 434, t. 254.

BOMBUS, in *Medicine*. See Flatulency.

Bombus, in *Music*, an artificial motion with the hands, imitating, in cadence and harmony, the buzzing of bees. The word is originally Greek, and signifies the buz or noise of bees, gnats, and the like. In this sense, *bombus* made one of the species of applause used by the ancient auditories.

BOMBYCILLA Bohemica, in *Ornithology*, the name under which Brisson describes the Bohemian chatterer, *Ampelis Garrulus*. The same author likewise calls an American variety of this bird *Bombycilla Carolinensis*.

BOMBYCINUM, in *Ancient Writers*, properly denoted a species of silk, brought from Assyria and the island of Cos. In which sense it stood distinguished from *Sericum*, another sort of silk brought from the Indies.

Bombycinum *velamentum*. See Velamentum.

BOMBYLIUS, in *Entomology*, a genus of Dipterous insects, distinguished by the following character: beak or sucker very long, setaceous, straight, and consisting of two unequal valves, within which three setaceous bristles are contained: feelers two, short and hairy: antennæ subulate, and connected at the base. Linn. Gmel. &c.

The antennæ of the insects in this genus are short, and contain three articulations, the first of which is long, the second short, and the third or last conical, and terminating

in a kind of appendage, almoſt forming a fourth joint, as is to be obſerved with the aſſiſtance of glaſſes. Thoſe who have carefully examined the ſtructure of the trunk with the microſcope affirm, that the number of valves or briſtles concealed within the external bivalve ſheath are four inſtead of three, as Gmelin deſcribes them. The antennæ are inſerted at the baſe of the trunk.

Inſects of this genus have the head comparatively of a ſmall ſize, of a form ſomewhat rotund, and almoſt wholly occupied by the eyes. The thorax large, the abdomen bulky, and rounded at the extremity as in the bee. Both the thorax and abdomen are hairy, or covered with down. The wings longer than the body, and extended horizontally. Legs long and ſlender.

The ſize and rotundity of the body afford an excellent natural character, by which this tribe of inſects may be diſtinguiſhed from thoſe of the genera empis and aſilus, with which ſome naturaliſts have confounded them. The Fabrician ſpecies of volucella, cytherea, and anthrax, have been referred to the bombylius genus with very little propriety.

The true bombylius is a lively active tribe of inſects, that ſubſiſt entirely on the nectareous juices they extract from flowers, with the aſſiſtance of their long proboſcis or trunk. They fly with much rapidity, making all the time a ſoft humming noiſe ſimilar to that of the bee. In England the largeſt ſpecies (major) has acquired the name of the humble bee fly. The inſects of this tribe are found in the winged ſtate in the ſummer, but their metamorphoſe is utterly unknown.

Only a ſmall number of ſpecies in this genus are at preſent known, namely major, medius, minor, minimus, ater, fuſcus, griſeus, vireſcens, and albifrons: theſe are natives of Europe. The extra-European kinds are æqualis, capenſis, cupreus, maculatus, pygmæus, and verſicolor.

BOMBYX, a genus of LEPIDOPTEROUS inſects, or rather one of the ſubdiviſions of the PHALÆNA, an extenſive genus, in which all the inſects of the moth tribe are compriſed by Linnæus. Fabricius, in his "Entomologia ſyſtematica," admits the bombyx as a genus, applying the term phalæna, which Linnæus gave indiſcriminately to all the ſpecies of the moth tribe, as a generical name to that particular deſcription of moths which have the palpi cylindrical, the tongue advanced and membranaceous, and the antennæ filiform.

The true definition of the bombyces, whether conſidered as a ſubdiviſion of the phalæna, or as conſtituting a genus of themſelves, is not ſufficiently explicit. A great number of the ſpecies may be readily referred to their proper ſtation in the genus, by obſerving with attention the characters laid down by Linnæus; but there are others which cannot be ſo accurately diſtinguiſhed from the noctua as we could wiſh, by the aſſiſtance of thoſe characters. If, for inſtance, we advert to the earlier editions of the Linnæan Syſtema naturæ, we ſhall find even in the ſmall number of ſpecies which that naturaliſt deſcribes, that the greateſt confuſion prevails in this reſpect. Had Linnæus been himſelf correct in his ideas of the natural character of the bombyces, we are almoſt perſuaded he would not have conſidered phalæna bucephala as a noctua, any more than dominula, fuliginoſa, jacobææ, and ſome others, which he includes as ſuch in his arrangement of the lepidoptera.

Linnæus thought at firſt the pectinated antennæ of the lepidoptera a ſufficient criterion of the bombyces, provided the wings were incumbent and depreſſed, while the inſect remained in a reſting poſition, becauſe the geometræ, though often furniſhed with pectinated antennæ, have the wings expanded horizontally when at reſt. But later obſervations of other naturaliſts have determined this character of the bombyx to be inſufficient to diſtinguiſh it.

In the Syſtema naturæ, Linnæus divides the bombyces into ſections in the following order; the *elingues*, or thoſe without a manifeſt ſpiral tongue, and the *ſpirilingues*, having an involuted ſpiral tongue. Theſe two principal ſections are ſubdivided again; the *elingues*, into thoſe with the back ſmooth or not creſted,—with expanded wings,—with reverſed wings,—with deflected wings,—with erect creſts, or tufts on the back; and the *ſpirilingues*, thoſe ſmooth, with expanded wings,—with deflected wings,—and with the back creſted.

This mode of arrangement is entirely ſuperſeded by the Entomologia Syſtematica of Fabricius. The latter writer takes his characters, as uſual, chiefly from the tongue and palpi. His bombyx is thus generically deſcribed; feelers two, compreſſed, reflected; tongue ſhort, and membranaceous; antennæ filiform. By this many of the Linnæan bombyces are excluded, for the reception of which he eſtabliſhes two other genera, thoſe of Coſſus and Hepialus, both of which moſt ſtrictly appertain to the Linnæan bombyces. The bombyx coſſus gave Fabricius the idea of forming a diſtinct genus of the ſpecies analogous to this inſect. The characters he lays down for the coſſus are theſe; the palpi or feelers two, compreſſed, cylindrical; with no tongue; and the antennæ ſhort and filiform. His hepialus has two hairy feelers, between which is the rudiment of a biſid tongue; and the antennæ are moniliform.

Gmelin, in the laſt edition of the Syſt. nat. endeavours to reconcile the Fabrician genera as ſubdiviſions to the principal Linnæan genus *phalæna*. His bombyces conſiſt of the attaci, which have the wings expanded, and the bombyces (ſtrictly ſo) which have not the wings expanded, and theſe latter are again arranged in ſubdiviſions in the following order: firſt, thoſe with reverſed wings, as in *quercifolia;* ſecond, thoſe with deflected wings, as in *bucephala* and *bele;* third, thoſe with incumbent wings, as in *antiqua;* and fourth, thoſe with convoluted wings, as in *bella*. The four families, into which Olivier ſeparates the bombyces, ſcarcely differ from the preceding; they conſiſt of thoſe with expanded wings, with wings reverſed, with wings bent down (deflected), and with wings recovered (incumbent).

The bombyces are to be conſidered as a true natural family of the moth tribe, which for the moſt part may be diſtinguiſhed by the caſual obſerver, who will attend to the ſtructure of the antennæ, the form of the body, the poſition of the wings, and ſome few other particulars to be mentioned hereafter. The antennæ, which are filiform, and either pectinated or ciliated, differ greatly in the two ſexes of the ſame ſpecies; the male being generally diſtinguiſhed by having the antennæ much broader, or larger, than in the other ſex. The thorax of the bombyx is rather more bulky, and the body thicker than in the noctuæ, eſpecially in the females. Thus far conſiſtent with the Linnæan character; but a ſtrict attention to the feelers and ſtructure of the tongue, as Fabricius obſerves, will be alſo neceſſary to determine many of the bombyces, which approach ſo cloſely to the noctuæ as not to be accurately diſtinguiſhed by any other means. For this reaſon Fabricius is commendable in having endeavoured to define the preciſe limits between the bombyces and their analogous tribes: his character is more definite than that which Linnæus had previouſly aſſigned to this family. The diſcrimination of Fabricius is obvious in ſeparating the two tribes or genera of coſſus and hepialus from the bombyces, under which head Linnæus comprehends them; for thoſe inſects certainly form diſtinct natural families, both in their general appearance, their metamorphoſes, their habits of life, and other peculiarities, from that

which

which ought to be conſidered as the natural family of bombyces.

The inſects of the bombyx tribe never fly except in the evening. During the day time they ſecrete themſelves under the leaves, or beneath the branches, in the clefts of trees, where they may remain ſecure till about ſun-ſet, at which time they appear to be on the alert, at firſt crawling about the branches, then fluttering their wings, and becoming briſker in all their motions as the evening comes on. The larger ſort of moths, which we ſee firſt ſtarting from the woods or hedges after ſome of the geometræ, are the *ſwifts*, the Fabrician hepiali, which fly ſwiftly as their trivial name implies, but low or near the ſurface of the ground; theſe at twilight are ſucceeded by the bombyces and noctuæ, whoſe flight is more elevated. They continue to ſport about till it becomes quite dark. The males of the bombyces are commonly firſt upon the wing in ſearch of the females, which latter are in ſome few ſpecies entirely deſtitute of wings, or at leaſt have only the rudiments of them cloſe to the thorax; in which caſe the female waits upon the trees or herbage for the arrival of the male; the female of bombyx antiqua, the vapourer moth, is a ſtriking proof of this, for it has ſo little the appearance of a moth that any one, except an entomologiſt, would miſtake it for an apterous or wingleſs inſect. Thoſe females which have wings are commonly larger even than the males.

The bombyces are produced from a larva, or as it is more uſually termed by common obſervers, a caterpillar. This is of a long cylindrical form, having in ſome ſpecies a ſmooth ſkin, or in others more or leſs tuberculated; ſometimes the ſkin is covered with a fine ſilky down, or with hairs; and ſome of the larger kinds are armed with ſpines and briſtles. All the larvæ of the bombyces ſubſiſt on vegetables. Their jaws are ſtrong, and of a horny texture, and below them is a ſmall opening, through which the creature draws the ſilky thread of ſo much utility in its general economy. Moſt of theſe larvæ have ſixteen feet, ſome have only fourteen feet, and others no more than twelve, ſix of which are hooked, and ſituated on the three firſt annulations near the head, the others towards the lower extremity of the body are ſhort, broad, and very different in ſtructure.

The greater number of ſpecies in the bombyx tribe, when in the larva ſtate, lead a ſolitary life, in which caſe they ſeparate as ſoon as they are hatched from the eggs, and crawl about to provide for themſelves, the ſmalleſt of theſe even being able to obtain its own ſubſiſtence; they can eat as readily, and ſpin, or throw out the ſilky thread with as much facility as when grown bigger. The latter is of conſiderable utility to the larva, for when it wiſhes to deſcend from one branch of the tree or buſh to another, inſtead of being obliged to purſue a circuitous courſe, by crawling or walking, it need only faſten one end of the ſilken thread to any particular ſpot and lower itſelf by its aſſiſtance to the branch deſired; or when ſuſpended mid-way between the branches, it can paſs aſide with a ſwing to any other point within a convenient diſtance. In like manner, when obſerved by birds or other enemies, it can drop in an inſtant and elude the enemy, waiting concealed below among the leaves or on the ground till the danger is over, and then remounting to the former ſpot by the aid of this thread. This is a proviſion of nature for the ſecurity of the larvæ of the bombyces, in common with that of other lepidopterous inſects.

Some ſpecies of the bombyces live in ſocieties, as may be obſerved, for inſtance, in *bombyx neuſtria* of entomologiſts, (the *lackey-moth* of Engliſh collectors). The larvæ of this ſpecies, by their united labours, ſpin a capacious habitation, in which the infant brood is hatched from the egg, and after undergoing their ſeveral transformations finally become moths.

Like other larvæ of the moth tribe, thoſe of the bombyces caſt their ſkin ſeveral times. When full grown, and approaching the pupa ſtate, thoſe of the bombyx kind ſpin a ſort of web, in which we find the moſt valuable ſilk produced by theſe creatures at any time of their lives. The ſilk ſpun by the hairy larvæ is obſerved to be of little value, becauſe the creature interweaves it with the hairs it plucks off its ſkin for this purpoſe. The common ſilk worm (*bombyx mori*), whoſe cocoon conſiſts of the moſt valuable kind of ſilk, as is well known, has the ſkin perfectly ſmooth, or free from hair. There are certain ſpecies of the larger bombyces, the larvæ of which have ſmooth ſkins, but ſtill beſet with annular ſeries of ſpines or briſtles, that produce very ſtrong ſilk, and are reared with the view of obtaining the cocoons for the manufacture of ſilk in the Eaſt Indies. The breed of theſe uſeful inſects has long been cultivated in India, although the ſilk produced from them is very little, if at all, known in Europe. See SILK. The bombyces remain in the pupa ſtate for a certain time, varying according to the ſpecies, ſome only a few days or weeks, others ſix or twelve months, two years, or even three. The ſame day that the creatures emerge from the pupa ſtate they are in a condition to perpetuate their race. Almoſt immediately after coupling the males die; the females live long enough to depoſit the eggs in a proper place for their ſecurity, and where the infant brood may find ſubſiſtence, after which they periſh likewiſe.

The ſpecies of the bombyx tribe are numerous. Thoſe already deſcribed by naturaliſts amount to a large number; and there are, in the cabinets of the curious, many more, eſpecially of the extra-European ſpecies, that have never been deſcribed; even in the collections of this country, thoſe of the latter deſcription are numerous. The following are deſcribed by Linnæus and Fabricius, and enumerated by Gmelin: atlas, heſperus, aurotus, cecropia, paphia, polyphemus, cypria, cytherea, mulitta, promothea, erythrinæ, janus, megaera, hippodamia, nictitans, ſemiramis, boreas, luna, epimethea, argus, pavonia, minor, media, major, achelous, angulata, liberia, tau, jo, abas, ſalmonea, proſerpina, feneſtra, penelope, tyrrhea, perſpicua, armida, militaris, caſtalia, populifolia, quercifolia, illicifolia, promula, caſſandra, capenſis, aluco, auſtralaſiæ, quadricincta, rubi, pruni, amphione, potatoria, ocularia, hibiſci, cynira, ceraſi, pini, trifolii, quercus, ſtigma, luſca, dumeti, catax, laneſtris, vinula, fagi, verſicolor, mori, populi, eueria neuſtria, tricolor, caſtrenſis, franconica, taraxaconis, cinerea, mali, avellanae, proceſſionea, pityocampa, rurea, atra, rufa, lagopus, imperialis, craſſicornis, hyphinoë, cyane, bucephala, helops, oleagina, caja, pudica, caſta, maculoſa, virgo, menete, deflorata, tarquinia, tarquinius, hebe, villica, plantaginis, vittata, monacha, flava, lutea, diſpar, amaſis, chryſorrhœa, auriflua, bicolor, ſalicis, caſſinia, centrolinea mendica, advena, rutila, lentifera, crataegi, eridanus, tibialis nitidula, plumigera, obſoleta, corones feſtiva, dryas, coryli, flavomaculata, nuda, furcula, curtula, recluſa anachoreta, anaſtomoſis, teſtudo, aſella, bufo, cippus, pudibundus, ſcopularia, faſcelina, tremula, cæruleocephala, argentina, decora, rufa, dictæa, elegans tritophus, ziczac, dromedarius, terebra, coſſus, palpina trepida, querna, gnoma, arenacea, morio, rubea, alphæa, purpurea, ceraria, murina, nebuloſa, ſtrigoſa, albida, aulica, helvola, undulata, lubricipes, lota, læta, communimacula, compreſſa, milhauſeri, ſpreta, lineus, ſtrigula, begga, vnigrum, ruſſula, ruſina, grammica, ſtriata, matronula, parthenias, leporina, celſia, dione, capucina, camelina, oo, aeſculi, antiqua gonoſtigma, paradoxa, zona, pylotis,

pylotis, graminis, popularis, fulminea, glorioſæ, crini, roſea, luſoria, cribrum, libatrix, lectrix, credula, dominula, hera, ſanguinolenta, ricini, crotalariæ, colon, populeti, ancilla, conſperſa, fuliginoſa, ornatrix, priverna, franciſca, jeſuita, viciella, veſtita, muſcella, bombella, pectinella, annulata, griſea, jacobææ, rubricollis, pulchella, bella, hiſtrio, and umber. To which are to be added bombyx figura Donov. Ind. Inſ.; hepialus mappa Donov. Brit. Inſ.; coſſus labyrinthicus, argenteus, lituratus, and nebuloſus, Donov. Inſ. New Holland.

In adhering to the Fabrician ſyſtem, in preference to that of Linnæus, we are to exclude from the foregoing liſt of bombyces the following ſpecies: lagopus, roſtrata, fagitta, gemina, deflorata, and faga, all of which are to be referred to the Fabrician genus *hyblæa*: humuli, jodutta, lupulina, hecta, obliqua, carna, crux teſtudo, aſella, bufo, and mappa, ſpecies of the *hepialus* genus of Fabricius: and coſſus, unguiculatæ, terebra, aeſculi, ſcalaris, pyrina, labyrinthicus, argenteus, lituratus, and nebuloſus, which ſtrictly belong to the Fabrician genus *coſſus*.

Bombyx is alſo a name given to the Silk-*worm*.

Bombyx, in the *Ancient Muſic*, a kind of inſtrument, which, in Ariſtotle's time, was made of a reed, calamus, and, by reaſon of its length, was difficult to play on.

The word ſeems alſo to have been uſed for a key, or contrivance for ſhutting and opening the holes of wind inſtruments.

Bombyx, in the *Ancient Naturaliſts*, ſignifies indifferently either ſilk or cotton.

BOMENE, in *Geography*, a port town of Zealand, one of the provinces of Holland, on the north ſhore of Schouwin iſland, one league eaſt of Brouwerſhaven.

BOMING, an iſland of Aſia, in the mouth of the Ganges. N. lat. 22° 45′. E. long. 91° 25′.

BOMIO, in *Ancient Geography*, a ſtation near Axbridge, according to Antonine's Itinerary; but placed by Camden and Gale at Boverton, in Glamorganſhire.

BOMMEL, in *Geography*, a town of Holland, in the iſland of Over-Flahee, 7 miles W. of Willemſtadt.

Bommel, a ſtrong town of the duchy of Gueldres, ſeated on the Wahal, in the iſland of Bommel-Waert, firſt ſurrounded with a wall by Otho III. count of Gueldres, in 1229; 60 miles N.E. of Antwerp, and 7 N. of Bois-le-Duc. Bommel was taken by the republican troops of France, October 4, 1794.

Bommel-*Waert*, a kind of iſland, in the province of Gueldres, about five leagues in length from Louveſtein N.W. to Fort St. Andrew S.E., and two in its greateſt breadth, formed by the rivers Maes and Wahal. It is defended by three forts, viz. St. Andrew, Voorn, and Crevecœur. The firſt has five baſtions, and was built in 1599 by the admiral of Arragon, and the cardinal Andrew of Auſtria, lieutenant general of the Spaniſh forces; the ſecond is ſituated at a ſmall iſland, called Voorn, at the eaſt end of Bommel-Waert, and was conſtructed by the prince of Orange, and on that account is ſometimes called Fort Naſſau; and the third is at the ſouth ſide of the iſland towards Bois-le-Duc. Theſe three forts were conſtrained to ſurrender to prince Maurice in the year 1600. In 1672, the French took the iſland under marſhal Turenne, who, after deſtroying the fortifications, abandoned it in the following year. At the commencement of the religious diſputes, count Charles de Manſvelt, paſſing this iſland with ſome Spaniſh troops, was encompaſſed by ſeveral Dutch ſhips under the command of count Hohenlo, who ordered the dykes to be opened, and thus totally inundated the iſland, ſo that the Spaniards were obliged to retire to the citadel, and would have miſerably periſhed, if a ſudden froſt had not conſtrained the count to abandon the ſiege, and to allow them liberty to retire. In commemoration of this deliverance a chapel was built at Bruſſels, in honour of the immaculate conception of the Virgin, next the Dominican church, which, being deſtroyed in 1695, was afterwards re-built with greater magnificence. In 1794, the republican troops of France, having compelled the Dutch to abandon Bommel, overtook them in their retreat, and compelled a great part of them to ſurrender. They afterwards availed themſelves of the frozen ſtate of the Wahal, and were making progreſs towards Gorcum and Calenberg; but they were attacked by the Britiſh troops in conjunction with the Heſſians, and driven acroſs the river, with the loſs of a conſiderable number of men and four pieces of artillery. But this temporary ſucceſs was of no permanent avail for reſtraining the progreſs of the French army.

This iſland belonged to the province of Guelderland, except the town of Louveſtein, which, with a very ſmall diſtrict at the weſtern end of the iſland, belonged to Holland.

BOMO, in *Ancient Geography*, a name given to the iſland of Eubœa, from the cattle with which it was ſtored; the ancient Arabian word *bomo*, or *bohmo*, ſignifying, according to Heſychius, cattle, or herds of cattle. This is, probably, the moſt ancient appellation; the iſland having been firſt peopled, as Strabo informs us, by the inhabitants of Arabia and Phœnice.

BOMOA, in *Geography*, a town of North America, in New Navarre, 10 miles S. of Cinaloa.

BOMONICA, in *Antiquity*, an appellation given at Sparta to the children, who, in the ſacrifices of Diana, ſtrove who ſhould receive the greateſt number of ſtripes with rods, which they ſometimes continued to do the whole day, and even, as Plutarch relates, to death itſelf.

The word is formed from βωμος, *altar*, and νικη, *victory*; importing as much as *victor ad aras*, or *conqueror at the altars*.

BOMPART, Marcellus, in *Biography*, practiſed medicine at Clermont Ferrand the early part of the ſeventeenth century, and was aulic counſellor to the king. No memorials of his life are known; but his work "Miſer Homo," in which he gives a ſuccinct account of all the principal diſeaſes afflicting the human frame, was much eſteemed. It was dedicated to Pietre, Riolan, and Guy Patin; and to be patroniſed by them was highly creditable: alſo "Nouveau Chaſſé Peſté," Paris, 1630, 8vo.; and "Lettres d'Hippocrates traduites et commentées," 1632, 8vo. Haller. Bib. Med. Eloy. Dict. Hiſt.

BOMPEL, in *Geography*, a town of Hindoſtan, in the Panjab, 15 coſſes eaſt of Seba, and 3 miles S.E. of Nadone, a town on the Beyah. N. lat. 31° 55′. E. long. 75° 57′.

BOMRAUZE, a town of Hindoſtan, in the Carnatic, 58 miles W.N.W. of Madras, and 36 N. of Arcot. N. lat. 13° 24′. E. long. 79° 38′.

BOMY, a town of France, in the department of the ſtraits of Calais, and chief place of a canton in the diſtrict of St. Omer, 8 miles S.W. of Aire.

BON, John, Le, in *Biography*, a native of Anterville, in Champagne, and eminent in his time for his knowledge in medicine, phyſician to the king of France, and to the cardinal de Guiſe, publiſhed, in 1571, "Therapeia Puerorum," 16to. Paris, "induced to it," he ſays, "by the ignorance of the ſurgeons, midwives, and tonſors, who attended women in child-birth. By their blunders and inexpertneſs in their art, many women loſt their lives, and many children

children were deſtroyed." His work is very full on the ſubject, giving rules for the management of women before, during, and after parturition. He has left formulæ for a variety of ointments, with which he directs the pudenda of the women to be anointed, and which he thought conduced much to accelerate the birth of the child. When theſe failed, lapis ætites was to be tied to one of the thighs of the woman, and polipody of the oak to the feet. But theſe, he gravely admoniſhes, are to be taken away as ſoon as the child is born, leſt they ſhould draw away the womb alſo. Such mighty power was attributed to theſe trifles! It is probable, however, that the author only meant by theſe proceſſes to gain time, and to prevent the too haſty interference of the midwives, ſurgeons, &c.; and as there was nothing in the remedies that could injure the woman, who would frequently be delivered by the natural pains, during their uſe, he might not be ſorry to find the attendants attributing the ſafety of the woman and child, and the happy termination of the labour, to them. Whatever his real opinion might be, it is certain, that, among the people, theſe kinds of remedies acquired great credit, and the uſe of them was continued for near a century after his time. Among other objects that engroſſed the attention of this writer, we find him giving formulæ for ointments for ſmoothing the wrinkles of the abdomen, and for preventing the breaſts of women who had borne children from becoming large and pendulous. "Ne venter rugis indecoru," he ſays, "et ſtatens, eas viris ſuis ingratas, parum amabiles, et abominandas reddat; ne mammæ in majorem molem extendantur." His book appears to have been in great requeſt, as it paſſed through many editions, and is inſerted in the "Collection of Treatiſes on diſorders attending pregnancy and child-birth," by Caſpar Wolfius, publiſhed in 1586, re-edited by If. Spachius, fol. 1597, under the title of "Gynecia, ſive de mulierum morbis," from which the above quotations have been taken. Haller. Bib. Med.

Bon, John Philip, probably of the ſame family with John le Bon, publiſhed, at Padua, "De Concordantiis Philoſophiæ et Medicinæ," 4to. 1573; he was alſo author of ſeveral poetical works, which were much eſteemed in their time. Eloy. Dict. Hiſt.

Bon, in *Botany*, (*Alpinus*). See Coffea.

Bon, *Cape*, in *Geography*, called by the Moors *Ras-Addar*, and the promontory of Mercury, or Hermes, of the ancients, is a cape of Africa, in the kingdom of Tunis, in the Mediterranean ſea, diſtant 11 leagues E.S.E. from that of Zibeeb, and forming the eaſtern point, as Zibeeb does the weſtern, of the gulf of Tunis. It is ſo high, that from its ſummit the mountains of Sicily, diſtant more than 20 leagues, may be diſcovered in fair weather. See Ægimurus, and Dakhul. Cape Bon is ſituated about N.N.E. from Tunis. N. lat. 36° 50'. E. long. 11° 15'.

Bon, in *Modern Hiſtory*, the name of a feaſt celebrated annually by the Japaneſe in honour of the dead. On this occaſion they uſe a great number of lights, and run with eagerneſs to the tombs of their departed relations with ſuch choice meats as they conceive to be ſuited to the taſte and nouriſhment of the dead.

Bon, Fr.; *Buono*, Ital.; as *tems bon*, and *tempo buono*, uſed, in *Muſic*, to expreſs the accented parts of a bar. It is the firſt note of binary meaſure of two minims or two crotchets in a bar; the firſt note of the ternary meaſure of $\frac{3}{2}$ or $\frac{3}{4}$, and the firſt and third notes of common time. It is oppoſed to *tems mauvais* and *tempo cattivo*, the unaccented part of a bar. The French, at preſent, diſtinguiſh theſe portions of a bar by the terms *tems fort* and *tems foible*, ſtrong and weak, and almoſt loud and ſoft parts of a bar. It is on the accented part of a bar that a diſcord regularly prepared is ſtruck, and reſolved on the unaccented part.

BONA, John, *Cardinal*, in *Biography*, was born at Mondovi, in Piedmont, in 1609, and entered at an early age into a reformed congregation of Ciſtertians. After having ſtudied philoſophy and theology at Rome, he returned to his own country, and became, in 1651, general of the congregation; and he was, at length, viz. in 1669, nominated a cardinal by pope Clement IX. Upon the death of this pontiff, he was thought of as a fit perſon to ſucceed him; but another was elected. The cardinal ſpent the remainder of his days in ſtudy and pious exerciſes, and died at Rome in 1674. He was the author of ſeveral works, chiefly of a devotional kind; ſuch as, "De Divina Pſalmodia, deque variis ritibus omnium eccleſiarum in pſallendis divinis officiis," 4to. containing an hiſtorical account of the practice of pſalmody in the Chriſtian church; and "Rerum Liturgicarum libri duo," 4to. giving a ſimilar account of the celebration of the maſs. Both theſe works have been often reprinted; and of the latter an edition much enlarged was publiſhed at Turin, in 1747, by father Salas, in 4 vols. fol. Gen. Dict.

Bona, John de, profeſſor of medicine at Padua, publiſhed, 1758, "Hiſtoriæ aliquot curationum, mercurio ſublimato corrodente, perfectarum," Veronæ, 4to. This medicine was much commended by baron Van Swieten, and forms probably the baſis of moſt of our noſtrums celebrated for their power of removing pimples, bloteches, &c. from the face and other parts of the ſkin. It was intended by the author to ſuperſede ſalivation in the cure of lues venerea, and in ſome caſes it has been uſed with complete ſucceſs; but it too often diſappoints the expectation of the preſcriber, to be entirely depended on. "Tractatus de Scorbuto," 4to. 1761. The author ſhews that this diſeaſe, though moſt frequent in cold marſhy places, is not unfrequent in warm countries. "Dell uſo e dell abuſo dell caffé," Venet. 1761. Coffee, which is hot and drying, ſhould only be uſed, he ſays, by perſons of cold phlegmatic conſtitutions. In the quantity it is uſually taken in this country, it will ſcarce be hurtful to any habit or conſtitution. "Obſervationes medicæ ad praxim in noſocomio anno," 1765, 8vo. Patav. 1766. Haller Bib. Anat.

Bona, in *Botany*, (*Dodoens*). See Vicia *Narbonenſis*, and Faba.

Bona *Nox*. See Smilax.

Bona, in *Geography*, a ſea-port town of Africa, in the eaſtern or Levantine government of the kingdom of Algiers, and province of Conſtantina; known to the Moors by the name of Blaid el Aneb, or the town of jujebs, from the plenty of fruit which is gathered in the neighbourhood. Bona, ſays Dr. Shaw (Travels, p. 46.), is, without doubt, a corruption of Hippo, or Hippona, though the rivers of the ancient Hippo-regius are ſituated ſomewhat more than a mile to the ſouth, and furniſhed materials for the erection of Bona, which is the Aphrodiſium of Ptolemy, and placed by him 15' to the north of Hippo. Bona was formerly rich and populous, but is now poorly built and thinly inhabited. Bona, beſides its capacious harbour to the eaſt, had formerly a convenient little port under its walls towards the ſouth; but by the conſtant diſcharge of ballaſt into the one, and a neglect of cleanſing the other, both are rendered unſafe and incommodious. However, a great quantity of corn, wool, hides, and wax, are every year permitted to be ſhipped off from this place; and, by proper management, it might be rendered the moſt flouriſhing city in Barbary; and, by introducing a ſupply of freſh water, it would alſo become one of the moſt convenient and delightful. The

adjacent

adjacent country produces corn and fruit, and great numbers of ſmall and large cattle, but is much expoſed to the incurſions of the plundering Arabs. The French have a factory at Bona, where they purchaſe corn, oil, leather, wax, and wool, and conſtantly keep a reſident agent, who has charge of the correſpondence between Bona, Algiers, La Calle, and Marſeilles. N. lat. 37°. W. long. 7° 50′.

Bona *Fortuna, Cape*, is a cape of Ruſſia, in the White Sea. N. lat. 65° 35′. E. long. 38° 25′

Bona *Shoals*. See Bassaws.

Bona *Dea*, the *good goddeſs*, in *Mythology*, a myſterious kind of divinity, whoſe name was unknown to men, and whoſe ſacred rites, performed by the Veſtal virgins for the ſafety of the Roman people, were attended only by women. Some have ſuppoſed that this name belonged to Cybele, or the earth, as the ſource of all good things. Plutarch confounds her with Flora. Varro pretends that ſhe was the wife of Faunus; and that ſhe maintained her character for chaſtity to ſuch a degree, as never to allow herſelf to look upon any man beſides her huſband. Lactantius, on the contrary, ſays, that this wife of Faunus, having drank wine in violation of the prevailing cuſtom of the period in which ſhe lived, was whipped to death by her huſband with rods of myrtle; and that he, afterwards repenting of the deed, and lamenting the loſs of his wife, placed her in the rank of divinities. The feaſts of the Bona Dea were annually celebrated, with peculiar ſolemnity, on the firſt day of May. The houſe, in which the rites of the feſtival were performed, was adorned at a great expence; and as the night was the ſeaſon appropriated to this purpoſe, the apartments were illuminated with a great number of lights. The veſtals were conveyed into the houſe of the ſovereign pontiff, or one of the chief magiſtrates; and care was taken to exclude all males, and all animals of this ſpecies; and every thing maſculine was ſo ſcrupulouſly excluded, that even pictures of that ſort were covered during the ceremony. To this purpoſe, Juvenal (vi. 339.) ſays:

" ——————— ubi velari pictura jubetur
Quæcunque alterius ſexus imitata figuram eſt."

It was ſuppoſed, that if a man by chance, and without any deliberate intention, became the witneſs of theſe myſteries, he would be ſtruck blind. Clodius, however, was guilty of polluting theſe myſteries. Whilſt Pompeia, the wife of Cæſar, with whom he had an intrigue, was, according to annual cuſtom, celebrating in her houſe the awful and myſtic ſacrifices of the " Bona Dea," Clodius determined to gain acceſs to his miſtreſs, even in the ſeaſon of her holy miniſtry. Accordingly, he dreſſed himſelf in a woman's habit, and by the benefit of his ſmooth face, and the introduction of one of the female ſervants who was in the ſecret, hoped to paſs without diſcovery. But by ſome miſtake between him and his guide, he loſt his way when he came into the houſe, and unluckily fell in among the other female ſervants, who, detecting him by his voice, alarmed the whole company by their ſhrieks, to the great amazement of the matrons, who preſently threw a veil over the ſacred myſteries, while Clodius found an opportunity of making his eſcape by the favour of ſome of the damſels. This ſtory was preſently ſpread abroad, and raiſed a general ſcandal and horror through the whole city. Cæſar put away his wife upon it; and perſons of all ranks were deſirous of availing themſelves of this circumſtance to get rid of a citizen, who, by this, as well as other ſpecimens of his audaciouſneſs, ſeemed born to create much diſturbance to the ſtate. It had been the conſtant belief of the populace, that if a man ſhould ever pry into theſe myſteries, he would be inſtantly deprived of ſight; but it was not poſſible, as Cicero ſays, to know the truth of it before, till Clodius ventured upon the experiment; though it was now found, as he tells him, that the blindneſs of the eye was converted to that of the mind. The affair was ſoon brought before the ſenate, and by them referred to the college of prieſts, who declared it to be an abominable impiety: upon which the conſuls were ordered to provide a law for bringing Clodius to a trial for it before the people. Clodius's faction, however, ultimately prevailed; and when the trial came to the iſſue, 25 condemned, and 31 abſolved him. When Cæſar, on this occaſion, was ſummoned to give evidence, he declared, that he knew nothing at all of the matter, though his mother Aurelia, and ſiſter Julia, who were examined before him, had given a punctual relation of the whole fact; and being interrogated, how he came then to part with his wife? he replied, " that all who belonged to him ought to be free from ſuſpicion as well as guilt." Cicero, in his oration for Milo againſt Clodius, often refers to this ſacrilege, with a view of rendering his adverſary odious to the people. Many Roman writers have exclaimed againſt the licentiouſneſs and infamy of theſe myſteries, called by way of eminence the Roman myſteries, and celebrated on the 4th of December, though thoſe of the goddeſs Cybele were celebrated on the firſt of May. Nevertheleſs, this goddeſs is called *holy* in an inſcription recorded by Gruter, " Bonæ Deæ *Sanctæ* ſacrum, &c." Lucretius (ii. 598.) depicts the good goddeſs as bearing a mural crown, and drawn in a chariot by lions. She is alſo thus repreſented on the medals of the emperor Philip. The Greeks alſo had their good goddeſs, whom they denominated the goddeſs of women; and the Carthaginians paid divine honours to a goddeſs under this appellation, whom they believed to be Juno.

Bona *Fides*, or *Bona Fide*, is uſed in ſpeaking of things done with an honeſt intention, in oppoſition to thoſe done with a deſign of fraud and deceit, ſaid to be *mala fide*. In this ſenſe, we ſay, a grant, a conveyance, *bona fide*.

In many caſes, in the civil law, the *bona fide* of an action excuſes the want of ſome of the cuſtomary forms.

Contracts *bonæ fidei*, among *Civilians*, ſtand contradiſtinguiſhed from thoſe *ſtricti juris*; the former being gained by plain honeſty and conſcience, which ſometimes include ſeveral things not expreſsly mentioned; whereas the latter are reſtrained to the expreſs terms of the deed. A buyer *bonæ fidei*, is he who really believed the thing to belong to the ſeller at the time when he purchaſed it. A poſſeſſor *bonæ fidei*, is he who is in poſſeſſion of a thing belonging to another, but which he truly believes his own. To be entitled to the benefits of next acceſſion, it is requiſite the perſons have poſſeſſed the thing *bona fide*, or really thought themſelves the proprietors.

Preſcription cannot ariſe from acts done *mala fide*; ſince what was unjuſt in its origin, can never be made juſt by time and continuance. See Prescription.

Bonæ *Fidei Actions*, thoſe wherein for farther light, the judge might take cognizance of things not mentioned between the parties.

Bona *Fide Judgment*, that wherein the parties are obliged to pay each other what is due *bona fide*, i. e. juſtly and equitably; and the judge has a power of eſtimating what is thus due to the actor or plaintiff; a power given him by the formula of the prætor, viz. *ex fide bona, vel quantum æquius melius*.

Bona *Geſtura*. See Good *A-bearing*.

Bona *Gratia*, a phraſe anciently uſed in ſpeaking of divorces, which were brought amicably about for ſome juſt reaſon, with the conſent of both parties, and without any

crime on the part of either, as in caſe of old age, diſeaſe, barrenneſs, monachiſm, captivity, or the like.

Bona *defuncti ad colligendum.* See Colligendum.

Bona *Mobilia.* See Mobilia.

Bona *Notabilia*, in *Law.* Where a perſon dying has goods, or good debts, in another dioceſe, but within the ſame province, beſides his goods in the dioceſe where he dies, amounting to the value of five pounds at leaſt, he is ſaid to have *bona notabilia:* in which caſe, the probate of his will, &c. belongs not to the biſhop of the dioceſe where he dies, whoſe juriſdiction cannot extend beyond the bounds of his own dioceſe, but to the archbiſhop of the province.

Though if a perſon happens to die in another dioceſe than that wherein he lives, on a journey; what he hath about him above the value of five pounds, &c. ſhall not be *bona notabilia.*

Bona *Patria*, a jury or aſſiſe of countrymen, or good neighbours. See Assise and Jury.

Bona *peritura*, periſhable goods. By ſtat. 13 Ed. I. cap. 4. the cargo of a ſhip that hath been caſt away ſhall be kept for a year and a day, and reſtored to the rightful owner; but if the goods be ſuch as will not endure ſo long, they are *bona peritura*, which the ſheriff is allowed to ſell, and to account in money for the value.

Bona *vacantia*, goods, ſuch as royal fiſh, ſhipwrecks, treaſure-trove, waifs, and eſtrays, in which no one can claim a property. Theſe goods, by the law of nature, and by the imperial law, belonged to the firſt occupant or finder; but in the modern conſtitutions of European governments, they are annexed to the ſupreme power by the poſitive laws of the ſtate.

BONACCIOLUS, Lewis, in *Biography*, a phyſician of great eminence and authority, practiſed medicine at Ferrara, in the early part of the 16th century. His great work "Æneas muliebris, ſive de fœtus formatione," was firſt publiſhed in 1503, in fol. "qua, præter alia, plurima quoque ad coitum, et ad rem veneream facientia, dictione liberrima deſcribuntur." It was nevertheleſs dedicated to Lucretia, daughter to pope Alexander VI. But the dedication, Blomenbach obſerves, is only to be found to the folio edition, princip. which is extremely rare. A copy of this edition was ſold by Paterſon, in 1791, with the ſplendid Paris library. This writer, Douglas ſays, was the firſt who diſtinguiſhed the clitoris from the nymphæ, and ſhewed them to be diſtinct parts. The Æneas was again printed in 1587. It was alſo inſerted by Caſpar Wolfius in his Collection of Treatiſes, called "Gynecia, ſive de mulierum morbis," 4to. 1586, re-edited by If. Spachius, fol. 1597; and with Pinæus's phyſiological treatiſes. Though of little value now, the work was for a long time held in great eſteem; the author having given in it a more accurate anatomy of the fœtus, and of the partes generationi ſubſervientes, than any preceding writer. Douglas Bib. Hal. Bib. Anat.

BONACHI, in *Geography*, a town of North America, in New Navarre, 180 miles S. of Caſa-grand.

BONACOPUS, Hercules, in *Biography*, of Ferrara, and for ſome years profeſſor in medicine at Bologna, publiſhed, in 1552, "De affectu quem Latini tormina appellant, 4to.; "De humorum exuperantium ſignis ac ſerapiis, de compoſitione Theriacæ, de modo preparandi aquam ligni ſancti, &c." 4to. 1553; the latter medicine was now in the zenith of its reputation for its powers in curing the lues venerea; "De curatione pleuritidis, ab Hippocratis, Galeni, &c. monumentis deprompta," 4to. 1553. He died in 1558. Bonacopus had much learning, and contributed by his works to revive among his compatriots a taſte for literature, particularly for the works of the ancient Greek fathers in medicine. His brother, or near relative, James Bonacopus, was alſo in much eſteem. He was phyſician to pope Paul III. He died in 1553, aged 69 years. Aſtruc. de Morb. Gall. Haller. Bib. Med.

BONAFIDES, Francis, profeſſor in the practice of medicine at Padua, publiſhed, in 1533, "Quæſtio de cura pleuritidis per venæſectionem, adverſus Curtium," 4to. Venet. He defends the practice of the Arabian phyſicians, who recommended bleeding by the vena faphæna, on the ſide oppoſite to the part affected, in plethoric habits; in debilitated conſtitutions, by the baſilica in the arm, of the ſide where the pain was felt; a diſtinction not attended to in modern practice. Haller. Bib. Med.

BONAIRE, in *Geography*, an iſland almoſt uninhabited, near the coaſt of South America, about 20 leagues from the continent, and 14 S.E. of Curaçoa, belonging to the Dutch. It is about 50 miles in compaſs, and has on the S.W. ſide, near the middle of the iſland, a good bay and road. Here were formerly a few houſes, with a fort guarded by a ſmall number of ſoldiers; and five or ſix Indian families reſided here, and cultivated maize, yams, potatoes, &c. The iſland has plenty of cattle and goats, which are annually ſalted and ſent to Curaçoa. On the ſouth ſide is a good ſalt pond, from whence the Dutch procure ſalt. N. lat. 12° 16′. W. long. 68° 18′.

BONAMES, a town of Germany, in the circle of the Upper Rhine, 3 miles N.N.W. of Frankfort on the Mayne.

BONAMY, Peter-Nicholas, in *Biography*, was born at Louvres, in the diſtrict of Paris, in 1694, and educated for the eccleſiaſtical profeſſion. But, devoting himſelf entirely to literature, he became under-librarian of St. Victor, and diſtinguiſhed both by the politeneſs of his manners, and the variety as well as aſſiduity of his ſtudies. In 1727, he was admitted a member of the Academy of Inſcriptions and Belles Lettres, and made many valuable contributions to its Memoirs. His papers are characteriſed by ſimple but correct language, variety of erudition, clearneſs of argument, and ſolidity of criticiſm. At the inſtigation of M. Turgot, a place was created of hiſtoriographer of Paris, and Bonamy was appointed to occupy it. He was thus led to write various memoirs relative to the hiſtory and antiquities of the city; and on occaſion of a bequeſt of a curious library to the city, he was made librarian. From the year 1747, he conducted the "Journal of Verdun" with the ſtricteſt propriety and decorum. In univerſal eſteem for candour and probity, as well as learning, he died at Paris, in 1770, aged 76. Gen. Biog.

Bonamy's *Point*, in *Geography*, lies on the ſouthern ſide of Chaleur bay, at the N.W. extremity of Eel river cove, and forms the S. limit of Riſtigouche river.

BONANA, in *Ornithology*, a ſpecies of Oriolus, of a fulvous colour, with the head and breaſt cheſnut; back, quill, and tail feathers black. Gmel.

This is called by Briſſon *xanthormus*, and *le carouge.* It is ſuppoſed to *xochitototl* of Hern. Mex. and *xochitotl altera* of Ray. Brown names it the bonana bird.

The length of this bird is ſeven inches: bill black; baſe of the lower mandible grey; head, neck, and breaſt cheſnut; upper part of the back velvet black; lower part, with the rump, belly, thighs, and under the wings, a deep orange red; vent the ſame, tipped with cheſnut; greater wing coverts, quills and tail, black; legs and claws grey. The female differs in having the colours leſs vivid than in the male.

The bonana bird is a native of Martinico, Jamaica, and the other iſlands in the Weſt Indies, where it chiefly inha-

bits woods. The neſt of this ſpecies is of a curious ſtructure, being compoſed of leaves and fibres of vegetable, ſewed with the greateſt ingenuity to the leaf of a banana plant, in ſuch a manner that the leaf itſelf forms one of the ſides to the neſt; when completed, it is ſaid to be exactly in ſhape of the fourth part of a globe.

Another bird, of a ſpecies very analogous to the above, is deſcribed by Ray and Sloane under the names of *watchy picket*, *Spaniſh nightingale*, *American hang-neſt*, and *icterus minor nidum ſuſpendens*. This appears to have been confounded with the former kind. Briſſon, deeming them both the ſame, included the ſynonyms of the two ſpecies together, which led later obſervers into an error. Dr. Latham ſeparates them; and, upon the authority of this able ornithologiſt, Gmelin gives the *watchy picket* as a diſtinct ſpecies under the name of *oriolus nidipendulus*. This ſpecific name is choſen, in alluſion to the manner in which the neſt is faſtened to the extremity of the further twigs of the trees in which it lives. The neſt of the bonana bird is before deſcribed; that of the watchy picket is very different, being of a long cylindrical form, compoſed of ſtalks, fibres, and the inward hairs of the "*old man's beard*," which latter bears a ſtrong reſemblance to horſe-hair. The two oppoſite methods of conſtructing, as well as placing the neſt, as Dr. Latham judiciouſly obſerves, cannot ſurely belong to one bird. See Nidipendulus.

Obſ. Gmelin places the watchy picket, with a note of ſcepticiſm, as a ſynonym to *motacilla calidris*. This might poſſibly miſlead, without obſerving that Sloane, Ray, &c. deſcribe more than one bird under that name; the latter is the *American nightingale* of Edwards, and the *hang-neſt warbler* of Latham, the bird called the *watchy picket* by Sloane, Hiſt. Jam. 2. p. 299.

BONANNI, Padre Filippo, in *Biography*, a Jeſuit, who publiſhed at Rome, in 1722, in 4to. drawings of a curious collection of muſical inſtruments, repreſented in the hands of the performers; entitled "Gabinetto Armonico Pieno d'Iſtromenti Sonori indicati e ſpiegati—ed offerto al ſanto Re David." The collection is curious, and the inſtruments are not ill executed; but we are not ſure that the drawings are always correct.

BONARATTE, in *Geography*, a ſmall iſland of the Indian ocean, ſouth-eaſt of Saleyer, ceded by the Macaſſers to a raja of Boni, in Celebes, who uſed it as a place of education for his dancing girls, and appropriated to the ſame purpoſe by the kings of Boni. It is chiefly inhabited by Bougeneſe.

BONARELLI, Guidubaldo, *Count*, in *Biography*, an Italian poet, was born in 1563, in the palace of the duke of Urbino, to whom his father was favourite miniſter; and, after previous inſtruction at home, was ſent to ſtudy theology at Pont à Mouſſon, in France, where he made ſuch proficiency, that he was invited, at the age of 19, to take the chair of philoſophy at the Sorbonne. He returned, however, into Italy, and was employed by Cæſar, duke of Modena, in ſome important negotiations at the courts of Rome and France; but incurring diſgrace by his marriage, he withdrew to Ferrara, and, in 1607, publiſhed the paſtoral drama by which he acquired celebrity. This drama was acted by the academy of "Intrepidi" at this place, of which Bonarelli had been one of the founders. In his way to Rome, for the purpoſe of aſſuming the office of major-domo to cardinal Eſte, he was ſeized at Fano with a diſorder, which terminated his life, Jan. 8, 1608. The drama of Bonarelli, entitled "Filli di Sciro," was much applauded both in Italy and other countries at its firſt appearance, and was ranked by common opinion next to the Aminto of Taſſo, and the Paſtor Fido of Guarini. Although this paſtoral has many poetical beauties, it ſtrongly indicates the corrupt taſte which then prevailed: nevertheleſs it maintains its place among Italian paſtorals. Many editions of it have been printed; and it has been tranſlated into the French and Engliſh languages. Gen. Biog.

BONARES, in *Geography*, a town of Spain, in Andaluſia; one league from Lucena.

BONARIENSIS, in *Ornithology*, that ſpecies of Loxia, or groſbeak, deſcribed by Buffon under the name of *noir-fouci*. The head and back of the neck are blue; body above blackiſh, beneath yellow; belly and vent ſulphur colour; wings and tail blackiſh, edged with blue.

This bird is about ſeven inches long, and is obſerved generally to fly in pairs; they haunt gardens, where they do much miſchief, as they feed on ſeeds. The bill is blackiſh; legs reddiſh; claws acute, curved, and grooved; the hind claw largeſt. This is the *marigold groſbeak* of Latham.

Bonariensis, a ſpecies of Tanagra, that inhabits Bonaria. This is eight inches long; the colour black, gloſſed with violet, and with greeniſh on the wings and tail. Gmel. &c. Buffon calls this bird *tangavio*. The beak is black, the legs blackiſh, with large claws. The female is of a brown colour, with the head black, and gloſſed with blue.

Bonariensis, a ſpecies of Motacilla, of a black colour; throat and ſides ferruginous; face, chin, middle of the belly, and exterior tail feathers, white. This bird is of the ſize of a linnet; bill blackiſh; hind-claw large. Buffon calls this *demi-fin noir et roux*. It is the *white-chinned warbler* of Latham.

BONAROTA, in *Botany*, Michel. and Scopol. See Pæderota.

BONASCOLA, in *Geography*, a town of Italy, in the ſtate of Genoa, near the ſea-coaſt, $4\frac{1}{2}$ miles S.S.W. of Brugnetto.

BONASIA, in *Entomology*, a ſpecies of Cicada (*membracis*, *cruciata*) found in America. Fabricius deſcribes it as having the thorax bicornuted, produced behind, and edged with white; at the baſe of the wings is a white ſpot.

Bonasia, is alſo the name of a ſpecies of Papilio (*Heliconius*), the wings of which are fuſcous, with a common fulvous band; the lower pair ſpotted at the baſe with black.

Bonasia, in *Ornithology*. Under this name Briſſon deſcribes ſeveral ſpecies of the Tetrao genus; as for inſtance, *tetrao Canadenſis* he calls *bonaſia freti Hudſonis*; *tetrao Canace*, *bonaſia Canadenſis*; *tetrao lagopus*, *bonaſia ſcotica*; and *tetrao togatus*, *bonaſia major Canadenſis*.

BONASUS, in *Zoology*, one of the ſynonyms of the wild ox. See Bos Taurus.

By ſome the bonaſus is underſtood to be that particular kind of wild ox which has the horns bent back, and the mane very long. Bonaſus of Pliny, &c. bos cornibus in ſe flexis, juba longiſſima. Linn. Syſt. Nat. The biſon is thought by Geſner to be the bonaſus of Ariſtotle.

BONAT, in *Geography*, a town of France, in the department of the Creuſe, and chief place of a canton, in the diſtrict of Gueret, $3\frac{1}{2}$ leagues N. of Gueret.

BONAVENTURA, St., in *Biography*, a cardinal of Rome, and entitled the "Seraphic doctor," was born at Bagnarea, in Tuſcany, in 1221; and having entered into the order of Minorites, in 1243, ſtudied at Paris under Alexander de Hales, and there taught theology with great applauſe. He received his doctor's degree in 1255, and in the following year was made general of his order. He declined accepting the archbiſhoprick of York, to which he

was

was nominated by pope Clement IV. in 1265; and, after his death, the choice of a ſucceſſor was referred by the cardinals to Bonaventura, who fixed on Gregory X. by whom he was made cardinal, and whom he attended to the ſecond council of Lyons, in 1274, where he died in the ſame year. He was canonized by Sixtus IV. in 1482, and declared a doctor of the church by Sixtus V. in 1588. His works have been collected in 8 vols. fol. and were printed at Rome in 1588; and an edition of them in 14 vols. 4to. has alſo been publiſhed. Among theſe are his "Life of St. Francis," the founder of his order, and "A Commentary on the Maſter of the Sentences," in which he appears to be a complete maſter of the theology of the 13th century. To him has been inſcribed the inſtitution of religious confraternities; and though his private character, and literary talents, are commended both by proteſtants and catholics, he has incurred ſome reproach for the zeal with which he promoted the worſhip of the virgin Mary, as the mother of God. Moreri. Encycl. Moſheim. vol. iii.

Bonaventura, Frederic, an eminent ſcholar and phyſician of Urbino, in Italy, who flouriſhed in the early part of the 17th century, publiſhed, in 1601, "De natura partus octomeſtris, adverſus vulgarem opinionem, libri decem," Francof. folio; an enormous volume, containing upwards of one thouſand pages, on this unintereſting ſubject, in which he has introduced the opinions of different writers, and accounts of all the controverſies that have been held on the legitimate period of utero-geſtation in women. The author had publiſhed a diſſertation on the ſubject, in the preceding year, which he incorporated in the great work, but with which a modern reader would probably have been fully contented. Haller. Bib. Med.

Bonaventura, *Cape*, in *Geography*, is ſituate on the coaſt of New Guinea, in S. lat. 6° 15′, and about 65 leagues N.E. from port St. Auguſtine. The land is low and luxuriant, and produces the cocoa-nut, bread-fruit, plantain, &c.

Bonaventura, the name of an iſland, north-eaſt of the bay of Chaleur, off the coaſt of New Brunſwick, in the gulf of St. Lawrence, and a little to the ſouth-weſt of the point which forms the ſouth-eaſt entrance into that river; about a league from Gaſpé bay.—Alſo, an iſland on the ſtarboard ſide of the entrance into Porto-Bello harbour, oppoſite to the mouth of Guanches river. See Porto-Bello.

BONAVENTURE, or Bueneventura, a river, bay, harbour, and fort, on the coaſt of Papayan, in South America, nearly ſouth from Panama bay. N. lat. 4° 20′. W. long. 77°. Barks and ſloops of 40 or 50 tons may go up to a village a league beyond the fort. Bonaventure is the ſtaple port of Cali, Papayan, Sta. Fé, &c.

Bonaventure, *Cape* and *Port*, are ſituated on the eaſt coaſt of Newfoundland, about ſouth-weſt of Bonaviſta cape, and form the north entrance into Smith's ſound, from whence the coaſt runs S. by W. into Trinity bay.—Alſo, a bay on the eaſt ſide of the iſland of St. Vincent. N. lat. 13° 9′. W. long. 61° 18′.

BONAVISTA, ſo called in reference to its beautiful appearance at ſea, the moſt eaſterly of the Cape de Verde iſlands, about 20 miles long, and 12 broad, and diſtant about 70 leagues weſt from the coaſt of Africa. Its ſurface is low towards the ſea, but within hilly, particularly towards the north-eaſt extremity, where is a hill, which, from its conical and truncated ſhape, appears to have been a volcano; and there is another hill, much higher, towards the ſouth-weſt end, with high land to the weſtward of it. The ſoil is ſandy, barren, and uncultivated; milk, goats, fiſh, and turtle, are the principal food of the inhabitants. It affords ſome ſalt; and if the culture of it were not neglected, it would yield cotton and indigo. It is known at a diſtance by ſeveral white banks on its north ſide, where the ſhore is bold, and where a rapid river diſcharges itſelf into the ſea. This iſland has a good harbour on its weſt ſide, where veſſels may lie in 15 or 16 fathoms water. At the diſtance of a league or a league and a half from the ſouth-eaſt point of the iſland is a reef of rocks; and over this point, ſays Capt. Cook, there is a pretty high round mountain, riſing not far from the ſhore. This point, by his obſervations, is in N. lat. 16° 0′, and longitude from London, by account, 21° 51′ W. The latitude of the north end of the iſland is 16° 12′ N. and of the ſouth end 15° 57′ N. but that at the eaſt end was not aſcertained. Mr. Wales, in the ſecond voyage, determined the latitudes of theſe three points as follows: north point 16° 13¾′ N. eaſt point 16° 3⅔′ N. and latitude of the ſouth point 15° 58′ N. Stavorinus ſays, that this iſland has two eminences of a middling height, that appear diſtinctly upon it; and that there are two reefs, one at the north ſide, and one at the ſouth ſide, which ſtretch out to the eaſtward, and which are both very dangerous. According to the account in lord Macartney's embaſſy to China, the ſea-coaſt on the ſouth-eaſt ſide was guarded by rocks; but towards the ſouth-eaſt end the ſhore was much covered with white ſand. On that ſide there ſeemed to be neither cultivation nor inhabitants. The latitude of Bonaviſta was 16° 6′ N. and the longitude 22° 47′ W. The variation 12° 36′ to the weſtward of the pole. This iſland belongs to the Portugueſe.

Bonavista, *Cape*, the extreme N.W. point of the iſland of Cuba in the Weſt Indies, opening into the gulf of Mexico, from whence the land falls off ſoutherly to cape St. Antonio.

Bonavista, *Cape and Bay of*, lie on the eaſt ſide of Newfoundland iſland, the cape lies in N. lat. 48° 54′, and W. long. 52° 33′, and was diſcovered by John Cabot and his ſon Sebaſtian, in 1497, under a commiſſion for exploring unknown lands, obtained from Henry VII. The bay is formed by this cape and cape Freels, 15 leagues apart.

BONAYE, a town of France, in the department of the Lower Loire, and chief place of a canton, in the diſtrict of Nantes. The place contains 834, and the canton 9,530, inhabitants; its territory comprehends 135 kiliometres and 7 communes.

BONCAT, a town of France, in the department of the Lower Pyrenées, 6 leagues N. of Bayonne.

BONCHAMPS, a town of France, in the department of the Mayenne, 2 miles S.W. of Craon.

BONCONICA, Oppenheim, in *Ancient Geography*, a town of Gaul, placed between Mogontia to the north, and Borbatomagus to the ſouth, ſeated on the river Rhenus, in Germania prima.

BONCONVENTO, or Buon-convento, in *Geography*, a town of Italy, in the territory of Sienna, where the emperor Henry VII. died; 12 miles S. of Sienna.

BONCORE, Thomas, doctor in philoſophy, medicine, and law, in *Biography*, has left a memorial of a deſtructive peſtilence, which raged at Naples, where he was in high credit, as a practitioner in medicine, in the year 1622. "De populi, horribili, ac peſtilenti gutturis affectione, nobiliſſimam urbem Neapolim vexante, conſilium," 4to. 1622, Neap. An early account of the ſcarlatina anginoſa, or malignant ſore throat, which has of late years made ſuch frequent appearance, and proved ſo deſtructive, among children particularly, in this country. Eloy. Bib. Hiſt.

BOND, John, an Engliſh grammarian of the 16th century, was a native of Somerſetſhire, and after finiſhing

his grammatical education at Wincheſter ſchool, was entered, in 1569, at the age of 19 years, a ſtudent in the univerſity of Oxford, where he was diſtinguiſhed by his proficiency in academical learning. Having taken his degrees of bachelor and maſter of arts, the former in 1573, and the latter in 1579, he was promoted by the maſter and wardens of New College to the maſterſhip of the free-ſchool at Taunton, in Somerſetſhire, which office he occupied with reputation for ſeveral years. At length he quitted the laborious ſtation of ſchool-maſter, and directed his attention to phyſic, which he practiſed more for amuſement than profit. He died in 1612, and was buried in the chancel of the church at Taunton. He wrote "Commentaries on Horace and on Perſius."

Bond, or *Obligation*, in *Law*, is a deed whereby the *obligor*, or perſon bound, obliges himſelf, his heirs, executors, and adminiſtrators, to pay a certain ſum of money to another called the *obligee*, at a day appointed. If this be all, the bond is called a ſingle one, "Simplex obligatio;" but there is generally a condition added, that if the obligor does ſome particular act, the obligation ſhall be void, or elſe ſhall remain in full force; as payment of rent, performances of covenants in a deed, or repayment of a principal ſum of money borrowed of the obligee, with intereſt, which principal ſum is uſually one half of the penal ſum ſpecified in the bond. In caſe this condition is not performed, the bond becomes forfeited, or abſolute at law, and charges the obligor while living; and after his death the obligation deſcends upon his heir, who, on defect of perſonal aſſets, is bound to diſcharge it, provided he has real aſſets by deſcent as a recompenſe. So that it may be called, though not a *direct*, yet a *collateral*, charge upon the lands.

This ſecurity is called a "ſpecialty;" the debt being therein particularly ſpecified in writing, and the party's ſeal, acknowledging the debt or duty, and confirming the contract, rendering it a ſecurity of a higher nature than thoſe entered into without the ſolemnity of a ſeal. In order to make a good obligation, it has been held that three things are neceſſary, viz. writing in paper or parchment, ſealing, and delivery: but it hath been adjudged not to be neceſſary, that the obligor ſhould ſign or ſubſcribe his name, ſealing being deemed ſufficient, and ſubſcribing being no eſſential part of the deed. And though the ſeal be neceſſary, yet if the word ſealed be wanting, it is remedied by verdict and pleading over, for all neceſſary circumſtances ſhall be intended; and if it were not ſealed, it could not be the deed or obligation of the party. Moreover, though ſealing and delivery be eſſential in an obligation, it is not neceſſary to mention in the bond, that it was ſealed and delivered, becauſe, according to lord Coke, (2 Co. 5 *a*.) theſe are things which are done afterwards. The name of the obligor ſubſcribed is ſufficient, though there is a blank for his Chriſtian name in the bond; and where the obligor's name is omitted to be inſerted in the bond, if he ſigns and ſeals it, the court of chancery may make good ſuch an accident. An obligation is good, though it has no date, or a falſe or impoſſible date; the date not being of the ſubſtance of the deed; but the day of the delivery is the day of date, though no day be ſet forth. Every deed is ſuppoſed to be delivered and made on the day of its date; and if the plaintiff declare on a date, he cannot afterwards reply, that it was firſt delivered at another day. A plaintiff may ſuggeſt a date in a bond which has none, or one that is impoſſible, &c. provided that the parties and ſum are ſufficiently expreſſed. A perſon ſhall not be charged by a bond, though ſigned and ſealed, without delivery, or words, or other act, amounting to a delivery. But it may be delivered by mere words; and an actual delivery, without ſpeaking any word, is ſufficient. If a bond be altered by interlineation in a material part, it becomes void; and it may be made void by raſure, &c. or by raſing the date, &c. after delivery. If the words at the end of the condition, "that then this obligation to be void," are omitted, the condition will be void, but not the obligation. If the condition of a bond be impoſſible at the time of making it, or be to do a thing contrary to ſome rule of law that is merely poſitive, or be uncertain or inſenſible, the condition alone is void, and the bond ſhall ſtand ſingle and unconditional; for it is the folly of the obligor to enter into ſuch an obligation, from which he can never be releaſed. If it be to do a thing that is *malum in ſe*, the obligation itſelf is void; for the whole is an unlawful contract, and the obligee ſhall take no advantage from ſuch a tranſaction. And if the condition be poſſible at the time of making it, and afterwards becomes impoſſible by the act of God, the act of law, or the act of the obligee himſelf, there the penalty of the obligation is ſaved; for no prudence or foreſight of the obligor could guard againſt ſuch a contingency. Co. Litt. 206. When a condition is doubtful, it is always taken moſt favourably for the obligor, and againſt the obligee; but ſo that a reaſonable conſtruction may be made as nearly as poſſible according to the intention of the parties. If no time be limited in a bond for payment of the money, it is due preſently and payable on demand. 1 Brownl. 53.; and if a condition be impoſſible in reſpect of time, it ſhall be paid preſently. Jones 140. 1 Leon. 101. If the party, who is bound to perform the condition, diſables himſelf, this is a breach. A bond made with condition not to give evidence againſt a felon, &c. is void; but the defendant muſt plead the ſpecial matter. 2 Wilſ. 341, &c. Condition of a bond to indemnify a perſon from any legal proſecution is againſt law, and void. 1 Lutw. 667. And if a ſheriff takes a bond as a reward for doing of a thing, it is void. 3 Salk. 75. See Condition.

On the forfeiture of a bond, or its becoming ſingle, the whole penalty was formerly recoverable at law; but here the courts of equity interpoſed, and would not permit a man to take more than in conſcience he ought, viz. his principal, intereſt, and expences, in caſe the forfeiture accrued by non-payment of money borrowed; the damages ſuſtained, upon non-performance of covenants; and the like. And a ſimilar practice having gained ſome footing in the courts of law, (ſee 2 Keb. 553. 555. Salk. 596, 597. 6 Mod. 11. 60. 101.), the ſtatute 4 and 5 Ann. c. 16. at length enacted, in the ſame ſpirit of equity, that, in caſe of a bond, conditioned for the payment of money, the payment or tender of the principal ſum due, with intereſt and coſts, even though the bond be forfeited, and a ſuit commenced thereon, ſhall be a full ſatisfaction and diſcharge. The court of Chancery will not generally carry the debt beyond the penalty of a bond; yet in a caſe, where a plaintiff ſought relief againſt ſuch penalty, though it was decreed, it was on the payment of the principal money, intereſt, and coſts; and notwithſtanding they exceeded the penalty, this was affirmed, 1 Vern. 350. 1 Eq. Ab. 92. 6 Vin. tit. *Penalty*. 3 Comm. 435. And where the condition of a bond is to perform a collateral act, damages may be recovered beyond the penalty, and the court of K. B. will not ſtay the proceedings on payment of the money into court. 2 Term Rep. 388.

All perſons who are enabled to contract, and who are ſuppoſed in law to have ſufficient freedom and underſtanding for that purpoſe, may bind themſelves by bonds and obligations. 5 Co. 119. 4 Co. 124. 1 Roll. Abr. 340. If a perſon, illegally impriſoned, enters into a bond, during ſuch reſtraint, to the perſon who cauſes it, the ſame may be avoided

avoided for dureſs of impriſonment. Co. Litt. 253. 2 Inſt. 482. The bond of a feme covert is *ipſo facto* void, and ſhall bind neither her nor her huſband. The bond of an infant, even for neceſſaries, with a penalty for payment, is void. But if an infant, feme covert, &c. enter with a ſtranger, who is not ſubject to their diſabilities, into an obligation, the ſtranger ſhall be bound by it. However, infants, idiots, feme coverts, and aliens, may be obligees. Sole corporations, ſuch as biſhops, prebends, parſons, vicars, &c. cannot be obligees; but a corporation aggregate may take any chattel, as bonds, leaſes, &c. in its political capacity, which ſhall paſs in ſucceſſion, becauſe it is always in being. Cro. Eliz. 464. Dyer. 48 *a*. Co. Litt. 9 *a*. 46 *a*. Hob. 64. 1 Rol. Abr. 515. If a drunken man gives his bond, it binds him; and a bond without conſideration is obligatory, and no relief ſhall be had againſt it, for it is voluntary, and as a gift. Jenk. Cent. 109. But on the general iſſue, the defendant may give in evidence that they made him ſign the bond when he was ſo drunk that he knew not what he did; and though a voluntary bond cannot be relieved againſt in equity, it may not be paid in a courſe of adminiſtration, ſo as to take place of real debts, even by ſimple contract; yet it ſhall be paid before legacies. 1 Chan. Caſ. 157. An heir is not bound, unleſs he be expreſsly named in the bond, though the executors and adminiſtrators are. Dyer 13. Two or more perſons may bind themſelves jointly in an obligation, or they may bind themſelves jointly and ſeverally; in which laſt caſe, the obligee may free them jointly, or he may free any one of them at his election; but if they are jointly and not ſeparately bound, they muſt be freed jointly; and in ſuch caſe, if one of them dies, his executor is totally diſcharged, and the ſurvivor or ſurvivors only chargeable. 2 Rol. Abr. 148. Dyer. 19. 310. 5 Co. 19. 1 Salk. 393. 1 Lutw. 696.

With regard to diſcharge of bonds, if a leſſer ſum be paid before it is due, and the payment is accepted, it ſhall be good in ſatisfaction of a greater ſum; but after the money is due, a leſſer ſum, though accepted, ſhall not be a ſatisfaction for a greater ſum. Moor. 677. 3 Bulſt. 301. 1 Lutw. 464. It has been adjudged, that the acceptance of one bond cannot be pleaded in ſatisfaction of another bond. Cro. Car. 85. Moore, 872. Cro. Eliz. 716. 727. 2 Cro. 579. A bond, on which neither principal nor intereſt has been demanded for 20 years, will be preſumed in equity to be ſatisfied, and be decreed to be cancelled; and a perpetual injunction granted to ſtay proceedings thereon. 1 Ch. Rep. 79. Finch. Rep. 78. Satisfaction, moreover, may be preſumed within a leſs period, if any evidence can be adduced in aid of the preſumption, ſuch as the ſettlement of an account in the intermediate time, without any demand. Yet length of time is no *legal* bar; and is only a ground for the jury to preſume ſatisfaction. 1 Term. Rep. 270. As to the pleading of performance of a condition, the defendant muſt ſet forth in what manner he has performed it. By ſtat. 8 and 9 Will. III. c. 11. § 8. in actions on bonds for performance of covenants, the plaintiff may aſſign as many breaches as he pleaſes, and the jury may aſſeſs damages. In debt on a bond, the defendant may have ſeveral pleas in bar. 1 Salk. 180. But a defendant in an action on a bond cannot plead, "Non eſt factum," and a tender as to part. 5 Term Rep. 97. In debt on an obligation the defendant cannot plead, "Nil debet," but muſt deny the deed by pleading "Non eſt factum;" for the ſeal of the party continuing, it muſt be diſſolved, "Eo ligamine quo ligatur." Hard. 332. Hob. 218. In bonds to ſave harmleſs, the defendant being proſecuted, is to plead "Non damnificatus, &c." The ſtealing of any bond, bill, &c. for money, being the property of any one, is made felony, as if offenders had taken other goods of like value. Stat. 2 Geo. II. c. 25.

Form of a bond or obligation, with condition for the payment of money. "Know all men by theſe preſents, that I David Edwards, of Lincoln's Inn, in the county of Middleſex, eſquire, am held and firmly bound to Abraham Barker, of Dale-hall, in the county of Norfolk, eſquire, in ten thouſand pounds of lawful money of Great Britain, to be paid to the ſaid Abraham Barker, or his certain attorney, executors, adminiſtrators, or aſſigns; for which payment well and truly to be made, I bind myſelf, my heirs, executors, and adminiſtrators, firmly by theſe preſents, ſealed with my ſeal. Dated the fourth day of September, in the twenty-firſt year of the reign of our ſovereign lord George the third, by the grace of God king of Great Britain, France, and Ireland, defender of the faith, and ſo forth, and in the year of our Lord one thouſand ſeven hundred and ——."

The condition of this obligation is ſuch, that if the above bounden David Edwards, his heirs, executors, or adminiſtrators, do and ſhall, well and truly pay, or cauſe to be paid, unto the above named Abraham Barker, his executors, adminiſtrators, or aſſigns, the full ſum of five thouſand pounds of lawful money of Great Britain, with lawful intereſt for the ſame, on the fourth day of March next enſuing the date of the above written obligation, then this obligation ſhall be void and of none effect, or elſe ſhall be and remain in full force and virtue.

DAVID EDWARDS, (*L. S.*)

Sealed and delivered, being firſt duly
ſtamped, in the preſence of
GEORGE CARTER,
WILLIAM BROWNE.

Blackſtone's Com. ii. 340. Jacob's Law Dict. by Tomlins, vol. i. tit. *Bond.*

BOND of *Arbitration*. See ARBITRATION.

BOND, *Aſſignment* of. See ASSIGNMENT.

BOND, *bail*. See BAIL.

BOND, *counter*. See COUNTER-*bond*.

BOND of *reſignation*. See RESIGNATION.

BOND-*tenants*, are the ſame, in reſpect to the nature of their tenure, with copy-holders, and cuſtomary-tenants. Blackſtone's Com. vol. ii. p. 148.

BOND, in *Maſonry* and *Brick-laying*, is when bricks or ſtones are, as it were, knit and interwoven; and when they ſay, make good bond, they mean that the joints are not made over, or upon other joints; but reach at leaſt ſix inches, both within the wall and on the ſurface, as the art of building requires.

BONDAGE properly denotes a ſtate of ſervitude or ſlavery.

BONDAGE, *bondagium*, in *Engliſh Law Writers*, the ſame with VILLENAGE.

Tenants in bondage paid heriots, and did fealty; they were not to fell trees in their own garden, without licence of the lord.

The widow of a tenant in bondage held her huſband's eſtate, *quamdiu vixerit ſine marito.*

BONDAGE, *by the forelock*, or *bondagium per anteriores crines capitis*, was when a freeman renounced his liberty, and became ſlave to ſome great man; which was done by the ceremony of cutting off a lock of hair on the forehead, and delivering it to his lord; denoting, that he was to be maintained for the future.

Such a bondman, if he reclaimed his liberty, or were fugitive from his maſter, might be drawn again to his ſervitude by

by the nose; whence the origin of the popular menace, *to pull a man by the nose*.

BONDELIA, in *Ancient Geography*, a town of Italy, in Etruria. Ptolemy.

BONDENO, or Buondeno, in *Geography*, a town of Italy, in the duchy of Ferrara, at the conflux of the Panaro and Po, 9 miles W. of Ferrara.

BONDMAN, Bondus, formed from the Saxon *bond*, signifying a *fetter*, in the *English Law*, is used for a villain, or tenant in villenage. See Villain.

The Romans had two kinds of bondmen; one called *servi*, who were those either bought for money, taken in war, left by succession, or purchased by some other lawful acquisition; or else born of their bondwomen, and called *vernæ*. Both are called in our law villains in gross, as being immediately bound to the person and his heirs. We may add a third kind of bondmen mentioned by Justinian, called *adscriptitii glebæ*, or *agricensiti*; who were not bound to the person, but to the ground or place, and followed him who had the land. These, in our law, are called *villains regardants*, as belonging to the manor or place.

In the English as well as Scottish laws, those called by the Romans *vernæ*, are sometimes also denominated *nativi*, as being born on the land. See Nativus.

BONDORF, in *Geography*, a country of Germany, in the circle of Swabia, about five leagues long, and between one and three broad, lying between the Brisgaw and the landgraviates of Baar and Stuhlingen. It had formerly lords of its own, but in 1613 was purchased by the abbey of St. Blaise. It is assessed in the imperial matricula, at 25 florins, 30 kruitzers; and its contingency to the chamber, at Wetzlar, is 12 rixdollars, 15½ kruitzers. This territory comprehends the town of Bondorf, 28 miles N. N. W. of Zuric, and several villages.

BONDOU, a kingdom of Western Africa (formerly a part of the kingdom of Bambouk), the capital of which is Fatteconda, near the eastern bank of the river Faleme. This kingdom is bounded on the north by Kajaaga, on the east by Bambouk, on the south-east and south by Tenda and the Simbani wilderness, on the south-west by Woolli, and on the west by Foota Torra. It lies between N. lat. 13° 32′ and 14° 32′, and between W. long. 10° 8′ and 11° 18′. Mr. Park, in his journey through this kingdom towards the east, found that the country, though covered with woods, like that of Woolli, rose into hills, especially towards the Faleme river, and that the soil varied to a considerable degree; but wherever the land was cleared, great natural fertility was observable. Bondou, in particular, may literally be pronounced "a land flowing with milk and honey." Both these articles, together with rice, and Indian corn of two or three species, were to be obtained at a small expence. Of their honey, the unconverted or pagan natives make an intoxicating liquor, much the same as the mead, or metheglin, of Europe; and this, and the wine of the palm-tree, constitute their principal liquors. The price of a fowl in Bondou was a button, or a small bit of amber; goat's flesh and mutton were proportionably cheap; and for six or eight amber beads Mr. Park might at any time have purchased a bullock. The domestic animals are nearly the same as in Europe. Swine are found in the woods, but their flesh is not esteemed. Probably the marked abhorrence with which this animal is held by the votaries of Mahomet has spread itself among the Pagans. Poultry of all kinds, the turkey excepted, may be had every where. The Guinea fowl and red partridge abound in the fields; and the woods furnish a small species of antelope, of which the venison is highly and deservedly prized. Of the other wild animals in the Mandingo countries, the most common are the hyæna, the panther, and the elephant. But of the method of taming the latter animal, and applying his services to the use of man, the natives of Africa are totally ignorant; and when they were told by Mr. Park, that this was done in the east, they treated the information with contempt, and exclaimed "Tobaubio fonnio," i. e. the white man's lie. They find means, however, to destroy the wild elephants by fire-arms for the sake of their teeth, which they transfer in barter to those who sell them again to the Europeans. They eat the flesh, and deem it a great delicacy. The pastures of Bondou furnish an excellent breed of horses; but the usual beast of burthen in all the negro territories is the ass. The application of animal labour to the purposes of agriculture is no where adopted, and the plough is an instrument altogether unknown. The chief implement used in husbandry is the hoe, which in different districts is of various forms; and labour is universally performed by slaves. The Mandingoes cultivate, besides the grains proper to tropical climates, ground-nuts, yams, and pompions. They likewise raise cotton and indigo, and they produce of these materials a tolerably fine cloth, of a rich blue colour; and they make good soap from a mixture of ground-nuts and a ley of wood-ashes. Their trade with the whites is composed of slaves, gold-dust, ivory, and bees-wax. Their inland traffic consists chiefly of salt, which is procured from the Moors, in barter for corn and blue cloth, and of warlike stores, which are obtained from the European traders on the Gambia river. These are sold again to itinerant merchants, called "Slattees," who come down annually from distant countries, with slaves, and a commodity called "Shea-toulou," which is an excellent sort of butter, produced from the kernel of a nut boiled in water. They also bring down small quantities of iron, which is manufactured in the interior districts; but those articles of this metal which are in use among the natives of the coast, are made of iron from Europe. The natives of the Gambia countries are also supplied, in considerable quantities, with sweet smelling gums and frankincense, which are the produce of Bondou.

Bondou is chiefly inhabited by Foulahs, a race of negroes, who lead a wandering life, and employ themselves chiefly in the pasturage of cattle, and the cultivation of corn. Among these, however, are a great number of Mandingoes, by whom the trade of the country is chiefly conducted. The government in Bondou, and in all the adjacent petty states, is monarchical, but no where absolute. The persons, who are called chief-men, constitute a sort of aristocracy, which serves much to restrain the powers of the sovereign. The king cannot declare war, nor conclude a peace, without their advice. When Mr. Park visited Bondou, the king was a "Soninkee," or Pagan, like the king of Woolli; but he had adopted the Mooriſh name of Almami, and with the name he seemed to have imbibed somewhat of the Mooriſh disposition; for although the traveller had presented to him his umbrella, and some other articles, he compelled him, as he had before compelled major Houghton, to strip in his presence, and surrender his coat, which, he said, he should reserve for his own wearing, on great and public festivals. In return, however, he gave Mr. Park five minkallies (drams) of gold-dust, and loaded him with provisions. Every considerable town is under the immediate government of a magistrate, called the "Alkaid;" by whom the duties and customs on itinerant traders, which are paid in kind (the only system of taxation), are levied. The office is hereditary. The people of the lower classes are in a state of slavery, or vassalage, to individual proprietors; but the power of the master is far from being unlimited. He may punish his

ſlave corporally; but cannot deprive him of life for any offence, nor even ſell him to a ſtranger, without firſt bringing him to a public trial, called a "Palaver," before the chiefmen of the town; and on ſuch occaſions the cauſe of the ſlaves is pleaded by the native Mahometans, who are a ſort of profeſſional advocates. Theſe indulgences indeed extend only to native or domeſtic ſlaves; for captives taken in war, and thoſe who are obtained in traffic, may be ſold at pleaſure, and treated as the owner thinks proper. Park's Travels into Africa. Rennell's Proceedings of the African aſſociation.

BONDOUR, a town of Aſiatic Turkey, in the province of Natolia, 24 miles weſt of Iſbarteh.

BONDRE'E, in *Ornithology*, the honey buzzard (*falco apivorus*), ſtands under this name in Buffon's Hiſtory of Birds. The French writers of the preſent day alſo call it bondrée.

BONDUC, and Bonducella, in *Botany* (Plumier). See Guillandina.

BONDUCH, in the *Materia Medica*, a name by which many authors have called the Molucca, Marſao, or Bezoar nuts.

BONE, in *Anatomy*. The bones are the moſt ſolid parts of animals, and may be regarded as the walls of a building ſupporting and containing the other parts. The human body is compoſed of a pile of bones, the extremities of which are variouſly ſhaped, and adapted to each other, and calculated to admit of a variety of motions. Bones appear to be compoſed of a vaſcular ſubſtance, not differing materially in ſtructure from that of the reſt of the body, except that there is depoſited in its interſtices phoſphat of lime, which gives to the whole maſs rigidity, ſtrength, and a permanent figure. That ſtate of the veſſels in which they ſecrete, and depoſit, earthy matter, occurs in diſeaſes of other parts of the body. The nutrient veſſels of arteries, membranes, and ligaments, occaſionally depoſit lime, and cauſe the oſſification of thoſe parts. The earth of bone is alſo depoſited in ſome ſpecies of tumours, and often in conſiderable quantity, and in an irregular manner in the cellular ſubſtance of a limb, when the bone of it is diſeaſed. After this general view of the ſubject, we proceed to give an account of the ſtructure of a bone, both with reſpect to the arrangement of its earthy particles, and with relation to its vaſcular texture.

It is cuſtomary, however, in giving an account of the ſtructure of bones, firſt to deſcribe their original formation in the fœtus; and this is uſeful, becauſe it demonſtrates the ſimplicity of the proceſs, and tends to refute old and erroneous ideas reſpecting it. The parts of the young fœtus which are afterwards to become bones, are merely a vaſcular, gelatinous ſubſtance, ſcarcely diſtinguiſhable from the other parts; afterwards the outline of the bone becomes evident, and its ſubſtance is rendered white and firm, in proportion to the quantity of lime depoſited in it. The quantity depoſited in it, even at the time of birth, is only ſufficient to give firmneſs to the whole maſs, but not to prevent its flexibility. The extremities of all the long bones conſiſt of large portions of cartilage, and theſe, by degrees, become bony. This change is effected by an alteration, firſt, in the organization of the part; the cartilage is abſorbed, the veſſels enlarge, ſo as to admit of injection, and then they appear to have the power of depoſiting earthy matter, or forming bone. The formation of bone begins in the centre of a cartilage, and gradually extends from thence to the remote parts, ſo that the ſeparate piece of bone, formed at the extremity, remains to nearly the period of puberty, conjoined to the body of the bone, by a cruſt of cartilage. In this ſtate it is technically termed an epiphyſis. The obſervation of theſe facts led formerly to the erroneous notion, that it was neceſſary that cartilage ſhould exiſt, prior to the formation of bone; and that it was converted by preſſure, or in ſome inexplicable manner, into bone. It were a waſte of argument to refute this opinion. We can perceive a ſtriking advantage that reſults from the bones of the fœtus being formed as they are. Their flexibility admits of the form of limbs becoming adapted to the varying figure of the pelvis, through which they muſt paſs, and their elaſticity, which is powerful, reſtores them afterwards to their natural ſhape.

The ſubject which firſt engages our attention, in examining the ſtructure of bone, is the arrangement of the earthy parts. The phoſphat of lime is depoſited by the arteries in minute points or particles, and theſe being placed lengthwiſe, with reſpect to each other, form fibres; again theſe fibres being placed parallel to one another, form bony plates, ſcales, or laminæ. That bones are fibrous and laminous, is evident from a mere inſpection of them in the fœtal ſtate; that they are ſo in the adult ſubject may be demonſtrated by calcination, or long expoſure to weather: in which caſes the connecting vaſcular ſubſtance is more ſuddenly or ſlowly diſſipated, and thus the arrangement of the earthy matter is rendered viſible. The earthy fibres of long bones extend themſelves in a direction parallel to the axis of the bone; in broad bones they ſhoot out in every direction, like rays from a centre. In long bones the earthy matter is conſolidated in the circumference and ſides, ſo as to form thick and ſtrong walls; whilſt a tube or more ſpongy bony ſtructure is found in their centre. In broad bones a ſimilar ſtructure is obſerved; the earthy matter is conſolidated exteriorly, ſo as to form denſe plates or tables; whilſt interiorly the fabric of the bones is ſpongy or cancellous. In the internal ſpongy part of bones the marrow is depoſited. In the middle part of long bones the walls are very thick, being compoſed of a great number of bony lamellæ, and theſe walls gradually become extenuated as they approach to the extremities of the bone, where they are proportionally very thin. Long bones are alſo ſlender in the middle, but at the ſame time ſtrong, on account of the great quantity of earthy matter thus conſolidated to form their walls; whilſt there is but little cavity or medullary ſtructure. Theſe bones expand greatly at their extremities, in order to afford an extent of ſurface for the formation of joints, and for the ſupport of the weight of the body. In the extremities of long bones, though the walls are thin, there yet exiſts a great deal of bony matter, which is depoſited ſo as to leave interſpaces between its fibres, forming what is termed the cancellous ſtructure, or lattice-work of bones. It has been therefore concluded, that the quantity of earthy matter may be nearly equal in each part of a bone, and give to it an equal degree of ſtrength; but that it has this difference of arrangement, that in the middle it is compacted ſo as to form very thick and denſe walls, occupying but little ſpace, and leaving but little internal cavity, whilſt in the extremities it occupies a greater ſpace, and forms a leſs ſolid kind of fabric. It would be deſirable to aſcertain, with ſome preciſion, where ſimilar circumſtances are to be met with in broad bones; and though no preciſe rules can be given, yet this may be admitted as a general truth, that where a broad bone ſwells out into a protuberance, there we ſhall find the walls or tables thin, and the cancellous ſtructure abundant; and, on the contrary, where a broad bone is condenſed ſo as to occupy but little ſpace, there we ſhall find the tables proportionately thicker, and the cancellous ſtructure leſs in quantity.

Having thus deſcribed the arrangement of the earth of bones, we may next enquire into the advantages which reſult from this ſtructure. The long bones are made ſlender

in the middle, to allow of the convenient arrangement of large muſcles round them; they become expanded at their extremities to afford an extent of ſurface for the formation of joints, and the ſupport of the weight of the body. A cavity is left in the middle; for if all the earthy matter had been compacted into the ſmalleſt poſſible ſpace, the bones would have been ſuch ſlender ſtems, as to be very unſuitable to their offices; and if they had been of their preſent dimenſions and ſolid throughout, they would have been unneceſſarily ſtrong and weighty. Beſides, it can be proved by mathematical demonſtration, that the ſtrength of the bone becomes augmented, in proportion as its fibres are placed at a greater diſtance from its centre.

With regard to the vaſcular ſtructure of bones, there can be no doubt but that it exactly reſembles that of the reſt of the body. That bones poſſeſs numerous arteries, is proved by the injection of young bones from the general arterious ſyſtem of the ſubject; for they are made very red by the injection conveyed into them by numerous, though minute arteries, which enter them by pores evident on their ſurface. The effect of feeding animals with madder is an additional and ſtriking proof of the ſame fact; for the bone becomes deeply tinged with the red colour of the madder. The cauſe of this phenomenon has of late been explained by Dr. Rutherford: he has ſhewn that it ariſes from a chemical attraction that exiſts between earths and certain colouring materials, which cauſes them to combine ſo intimately as to form pigments which are called lakes by painters. Dr. Rutherford diſſolved madder in diſtilled water, and added to it muriate of lime, which produced no change of appearance in the ſolution; on the further addition of phoſphat of ſoda, a double decompoſition took place; the muriatic acid combined with the ſoda, and the phoſphoric acid with the lime. The phoſphat of lime alſo combined with the madder, and they were together precipitated, forming a beautiful red powder. If blood be conſtantly conveyed into bones by numerous arteries, it muſt be returned from them again by veins, or otherwiſe it muſt accumulate in them in conſiderable quantities. That bones poſſeſs abſorbents in common with other parts is equally clear, and is proved by their mode of growth, and alſo by their diſeaſes. The growth of the tube of a bone is a proof of the mutation of its parts by abſorption; for if bones grew merely by new matter depoſited on the ſurface, the tube of the bone ſhould be of the ſame dimenſions in the adult as in the fœtus: on the contrary, however, the tube enlarges, and bears the ſame proportion to the whole bone in either ſtate. If any number of laminæ of the ſides of a bone, or if a portion of its whole ſubſtance periſh, the mortified part is detached in the ſame manner that it is in ſoft parts; and this detachment is manifeſtly the effect, in the firſt inſtance, of the agency of the abſorbing veſſels. Though a portion of animal ſubſtance has periſhed, it ſtill poſſeſſes the ſame powers of coheſive attraction that it did while living; it ſtill tenaciouſly adheres to the living parts; but a ſpace takes place all round the dead portion, and the production of that ſpace can only rationally be attributed to the removal of parts by the abſorbents. In diſeaſes of bones their form becomes entirely altered, if an increaſed depoſition of matter takes place in their internal parts; and this alteration of form could not happen unleſs the walls were removed by abſorption, and depoſited anew in conformity to the augmented bulk and figure, which the diſeaſed depoſition had occaſioned. Not to cite leſſer inſtances, one may be mentioned, which Mr. Hunter uſed to ſhew in his lectures, of a very large and globular bony tumour, which had formed in the extremity of one of the bones of the leg in an ox. The tumour was ſo ſolid, that the ſection of it admitted of being poliſhed, and the walls of the bone had become thin, and of a ſpherical form, ſo as to make a neat kind of caſe containing this bony tumour. That bones poſſeſs nerves as well as arteries, veins, and abſorbents, cannot be doubted; for though they have naturally but little ſenſibility, they become extremely painful when diſeaſed; and again a fungus ſometimes grows out of a bone, which is ſenſible, though it may have no connection whatever with the ſurrounding ſoft parts; of courſe it muſt have derived its nerves, by means of which it poſſeſſes its ſenſation, from the bone out of which it aroſe. That the veſſels and nerves of a bone are connected together by common cellular ſubſtances, as in other parts of the body, is demonſtrated by ſoaking a bone in dilute muriatic acid, which diſſolves all the lime, and leaves the vaſcular matter a little thickened, but perfectly flexible. We then ſee that this vaſcular and cellular matter has a laminated arrangement correſponding to that of the earthy, which has been deſcribed, ſo that between each layer of earthy matter, there is a layer of ſoft ſubſtance, and of courſe the different layers of ſoft ſubſtance are connected by veſſels and cellular membrane, which intervene between the bony fibres, and connect the different ſtrata together. Bones are covered by a ſtrong, firm, fibrous ſubſtance, termed perioſteum, on which the veſſels are firſt diſtributed; from this they deſcend, connected by cellular ſubſtance, between the fibres of the bone. The veſſels and nerves of the bone enter it through holes which are evident on the ſurface, and which are larger and more numerous in the extremities of the long bones than in the middle. The veſſels do not penetrate the bone in a tranſverſe direction, but obliquely, running tranſverſely through a certain number of lamellæ, and then taking a perpendicular courſe between others, which prevents the bone from being weakened, particularly at any one part, by that want of earthy matter which is neceſſary to leave room for the admiſſion and diſtribution of veſſels.

The marrow that is contained in bones is of an unctuous nature, and in herbaceous animals, hardens when it becomes cold; but it remains fluid in thoſe which are carnivorous. Some of the red parts of the blood are depoſited with it in young animals, but in thoſe that are adult it is no longer tinged with blood. The marrow is contained in fine cells, which do not communicate with one another, like thoſe of the common cellular ſubſtance. This is proved by ſawing a bone through, and keeping it in a temperature which will preſerve the marrow fluid, with the part which is ſawn downwards. Under theſe circumſtances, if the cells communicated, the gravitation of the liquid marrow would cauſe it quickly to drop out, and leave the cells empty; but this does not happen. The cells which contain the marrow are lodged in the cancelli of the bone, at the extremities of the long bones; but in the middle they are unſupported by this kind of oſſeous ſtructure. The cellular ſubſtance which contains the marrow, being condenſed upon the inſide of the walls of the bone, and adhering to them, has been termed the perioſteum internum. In the principal bones we perceive arteries, much larger than thoſe for the nutrition of the bone, which penetrate the walls obliquely, and ſpread their branches upon the medullary cells, for the nouriſhment of theſe parts. That theſe are the chief nutrient arteries of the marrow cannot be doubted; and it has been contended, that they have excluſively this power, and that they do not anaſtomoſe with the nutrient arteries of the bone. This opinion has been formed, becauſe in ſome caſes of accidental injury, in which the medullary artery has been deſtroyed, the marrow has, as it were, periſhed. This opinion, however, ſtands in direct oppoſition to all analogy; and it muſt indeed be conſidered

ſidered as a very ſtrange peculiarity, were not the minute contiguous nutrient arteries to inoſculate with one another. The writer of this article is of opinion, that they do in this, as in other inſtances, for it is common in amputation to cut off the trunks of the medullary arteries, and yet the marrow of the remaining bone does not periſh; and, again, the bone may be injected from the medullary artery alone. We may next inquire into the uſes of the marrow. Havers thought that it tranſuded through the bone, and by this means prevented it from becoming brittle; nay, he even deſcribed the pores through which ſuch tranſudation was ſuppoſed to take place. The cells, however, which contain the marrow are perfect veſicles; and we know that no tranſudation of contained fluids takes place through the membranes which contain them during life, though in conſequence of putrefaction it does after death. If a bone be deprived of its perioſteum in a living body, no tranſudation of oil from its ſurface takes place; and even after death a recent bone may be deprived of its perioſteum, and put in warm water for a conſiderable time, and yet no ſudden tranſudation of oil from the ſurface will take place, as might be expected if there were natural channels for this purpoſe. The canals which Havers deſcribed, are probably the paſſages through which the veſſels are tranſmitted. If then this opinion of the uſe of the marrow be unfounded, we have ſtill to inquire, for what purpoſe is it deſigned? The utility of the bones being formed as they are, ſmall and tubular in their middle, expanded and ſpongy at their extremities, has been already explained. If then ſpaces are neceſſarily left in their interior parts, thoſe ſpaces muſt be filled with ſomething, for they cannot be left void, or the immenſe preſſure of the atmoſphere would cruſh their parietes, and aboliſh the vacuum. There is no matter in the animal body more ſuitable to fill their ſpaces than the marrow; and it is to be regarded as a part of the adipoſe ſyſtem of the animal. In corroboration of this remark, it has been obſerved, that in impoveriſhed and dropſical ſubjects, where there is no fat in other parts, there is likewiſe none even in the bones: and if a bone be ſawn, and the medullary cells broken down, ſo that the fluid which they contain may drop out upon paper, that it will not penetrate it, and render it tranſparent like oil; but, on the contrary, that it will encruſt upon it, from its being of a gelatinous nature, like that fluid which is found in the interſtices of the common reticular or cellular ſubſtance. From the circumſtances which have been detailed in the foregoing account, viz. the great and general vaſcularity of bones;—the quantity of ſoft ſubſtance exiſting in every part of them;—their growth and mutation of form in diſeaſe, &c.;—it is natural to conclude, that there exiſt in the compoſition of every bony fibre, arteries for its formation, abſorbents for its removal, cellular ſubſtance for the connection of its parts, and nerves to give animation to the whole. In this view of the ſubject, we perceive no eſſential difference of ſtructure between bones and other parts of the body; nor do we expect any eſſential difference in the functions of their nutrient, and other veſſels. We naturally conclude that bony fibres are formed and repaired, and that they undergo mutation or removal in the ſame manner, and from the ſame cauſes, that ſoft parts do. Mr. Hunter, however, from obſerving the ſtriated appearance of the bones of animals, who have been at one time fed with madder, and at another with common food, and obſerving that the exterior ſtria was red if the animal was killed after having been for ſome time fed with madder, and white if it had only taken its ordinary food, concluded that bones grew by a depoſition on their ſurface, and a correſpondent removal of the internal part of the walls of the bone. Mr. Hunter alſo, to inveſtigate the truth of Du Hamel's opinion reſpecting the growth of bones, bored two holes in the tibia of a pig, one near the upper end, and the other near the lower; the ſpace between the holes was exactly two inches; a ſmall leaden ſhot was inſerted into each hole: when the bone had been increaſed in its length by the growth of the animal the pig was killed, and the ſpace between the two ſhots was exactly two inches. Mr. Hunter's experiments and opinions are publiſhed by Mr. Home in the ſecond volume of Tranſactions of a Society for the improvement of Medical and Chirurgical Knowledge. We forbear to give a more detailed account of them, or enter into any diſcuſſion of the ſubject, but refer the reader to the original paper, becauſe we believe that no theory will be found, on conſideration, to be adequate to account for the phenomena of the growth and diſeaſes of bones, except that which admits the bony fibres to be of the ſame ſtructure as the ſoft fibres of the body, and conſequently concludes that both are formed, removed, and renovated in the ſame manner. We ſubjoin ſome references to the inſtructive works on the ſtructure of the bones. Albini icones oſſium fœtus, cui accedit oſteogen. brevis hiſtoria.—Annot. Acad. J. G. Bone, in *Chemiſtry and the Arts*. The analyſis of bone, and the products obtained from it by various chemical proceſſes, deſerve conſiderable attention, as this great claſs of animal ſubſtances ranks among the moſt important to the chemiſt.

So great a ſimilarity is found in the compoſition of the bones of different animals, that their properties may firſt be deſcribed generally.

Bone, when firſt taken from the animal, is moiſt and greaſy on its ſurface; and if cylindrical, it contains a quantity of the peculiar fat called *marrow*. When this is ſeparated, and the bone expoſed to the air, it gradually dries, becomes brittle and whiter; but the articulating heads long remain moiſt, greaſy, and yellow. When once dry, and kept in a dry and airy place, they are ſcarcely ſuſceptible of further ſpontaneous alteration.

The effect of mere heat on bone has long been known to chemiſtry and the arts, as furniſhing ſome very important articles of chemical manufacture. Heated in the open air, bone firſt becomes oily and yellow, gives out a watery vapour, to which ſucceeds a thick, denſe, fetid ſmoke, which readily takes fire, and when once kindled, affords heat enough, when the bones are in ſufficient quantity, to complete the entire calcination, which laſts for many hours, during which they become ſucceſſively black and carbonaceous, brittle, and at laſt, when every thing combuſtible is conſumed, they remain nearly white, friable, light, and extremely porous or cellular in texture, and retaining their original ſhape and bulk. This proceſs of burning bones in the open air, in large heaps, is performed near great towns for the ſake of the earthy ſalt *bone-aſh*, which is left behind, and forms on an average about half the weight of the freſh bone. It is compoſed chiefly of phoſphat of lime, and is uſed by the aſſayers as the material for cupels, and for a few other purpoſes.

But the volatile products which are waſted in the above proceſs, are highly valuable when the bones are diſtilled in cloſe veſſels, without addition as before, but with a proper apparatus to receive and condenſe the volatile products. In theſe circumſtances, with a heat at firſt gentle, but gradually increaſing,

increaſing, bone yields, at firſt, a limpid water, with a peculiar animal oily ſmell, which ſoon becomes impregnated with carbonated ammonia, together with an oil, at firſt of a clear yellow, pungent, and not ungrateful to the ſmell, but afterwards rendered brown, and even black, by the increaſing heat, ſtrongly fetid and ammoniacal. With the empyreumatic oil, a large quantity of ſulphurated hydrogen, of carbonated hydrogen, and of carbonic acid gas eſcapes. The products of this diſtillation, when condenſed, are the ammoniacal water, and the empyreumatic oil; the former contains, beſides carbonat of ammonia, a portion of ſebacic and pruſſic acid united with the alkali; the oil may be ſeparated into the leſs and more empyreumatic, by changing the receiver occaſionally, and keeping apart the firſt portions of the oil as the pureſt. If this oil is again repeatedly diſtilled by itſelf from clean veſſels with gentle heat, it becomes at laſt as colourleſs as water, pungent, and not very unpleaſant to the ſmell, ſo volatile at a common temperature as only to be kept by inverting under water the mouths of the veſſels that contain it, and acting in medicine as a powerful ſudorific. It is called from the name of the inventor, DIPPEL'*s oil*, which ſee.

The only valuable part of the products of the diſtillation of bone is the ammonia, or volatile alkali, which is mixed with every part of the diſtilled liquid, and is afterwards purified by ſubſequent proceſſes, aſſiſting in the formation of the MURIAT *of ammonia*, or forming the pure CARBONAT *of ammonia* of the ſhops, the *ſal volatile, ſpirit of hartſhorn*, &c. When the diſtillation is diſcontinued, the bones remain in the retort of a brown colour, and ſwimming in a black, thick, extremely fetid, tenacious oil. If they are then gradually heated to redneſs in cloſe iron veſſels, every thing volatile is diſſipated, and the earthy part remains dry and friable, ſtill retaining the original form of the bones, but thoroughly impregnated with the charcoal of the oil, ſo as to become a fine gloſſy black. This is afterwards ground to a fine powder, mixed with ſize into cakes of a convenient weight, and forms one of the ſpecies of *lamp-black*, uſed very largely as a pigment. The harder and compacter bones, ſuch as ivory, furniſh a ſimilar and more valuable black pigment, ſimply by heating to redneſs in cloſe veſſels.

But the analyſis by heat, though it furniſhes ſome valuable articles of commerce, is not well calculated to exhibit the conſtituent parts of bone in their proper characters.

In fact, the ammonia, probably much of the oil, and all the gaſſes, are formed by the action of heat out of the real conſtituents of bone, as they exiſt in the animal.

Water and acids are the chief re-agents to be uſed by the chemiſt.

Cold water has ſcarcely any action on bone, but by long maceration its texture becomes more looſe and open, and the gelatinous part becomes gradually changed, as by ſlow animal putreſaction.

Hot water acts with great eaſe upon bone, when reduced to ſmall pieces by raſping or bruiſing; the firſt effect is to ſeparate moſt of the *natural* oil of bone which riſes to the top, and when cool concretes to a ſuety fat. The water then diſſolves the *gelatin*, which is found to compoſe a very conſiderable part of the ſubſtance, even of the drieſt and moſt compact bone; and in this method a clear inſipid pure jelly is extracted, rendering the water, even when in large proportion, of a ſtiff, tremulous conſiſtence when cooled, which, by evaporation, leaves at laſt a ſtrong, hard *glue*.

The experiments of M. Pelletier on this ſubject are important. This accurate practical chemiſt took ſix pounds of dry bone ſhavings, procured from the button-mould makers, macerated them for two days in cold water, and then boiled them for nine hours with 24 quarts of water. The product was a very ſtrong clear jelly, and at the bottom of the veſſel the *marc*, or earthy reſidue, which was preſſed in order to ſeparate the portion of ſomewhat turbid jelly, with which it was entangled. By ſubſequent boiling down, the jelly became ſo ſtiff when cold, as to bear to be cut into firm ſlices, which were hung up on ſtrings in a place under cover from the weather (as in the common manufacture of glue), and in a fortnight became hard, brittle glue of good quality. The produce was 15½ ounces of clear glue, half an ounce more from the marc, and ſomewhat foul, and the marc itſelf weighed 4 lb. 3 oz. The loſs in the operation amounted to 13 oz. In like manner 50 lb. of ivory ſhavings, exhauſted by repeated boiling, gave 9½ lb. of clear glue, and 30 lb. of the marc remained.

Theſe facts are important to the manufacturer; nor is the uſe of bone leſs intereſting as an article capable of ſupplying much good and wholeſome nutriment to man and other animals. In the making of ſoups it is a matter of common obſervation, that bones contribute, when boiled with the meat, to the richneſs of the liquor; but it is not commonly known how much they may be made to add to the nutritious quality; nor is it generally known that the hardeſt and drieſt bones, even thoſe that have been kept for years, retain their gelatinous part unchanged.

The exact proportion of jelly cannot eaſily be aſcertained by extraction with water, for even when converted into the hardeſt glue, it has become intimately united with a portion of this fluid; and it is by no means certain that the utmoſt deſiccation of glue equals the degree of dryneſs of natural gelatin, as it exiſts in the more ſolid bones.

The quantity of jelly is alſo much increaſed, either by giving the water by which it is extracted a higher heat than the boiling point, or by reducing the bones to a fine powder, and uſing repeated coction and pulverization.

The former method was uſed by Papin, who, in his valuable experiments on the ſolubility of animal ſubſtances, when confined with highly heated water in his *Digeſter*, found that he was able to extract every thing from powdered bone, but the mere earthy part. The latter mode has been brought into notice by M. Prouſt, in an important economico-chemical memoir on the "Method of ameliorating the ſubſiſtence of the Soldier," publiſhed at Madrid, in 1791.

Though there is a great general ſimilarity between the bones taken from different parts of the body, they differ much in the relative portion of fat, of gelatin, and of earth. The younger the animal is, the leſs earthy ſalt, *cæteris paribus*, is contained in its bones. The large, round, joint-heads of the thigh, and other large bones, contain much more oil than the rib or blade bones, as is ſeen when they are expoſed to the air; the latter ſoon becoming dry and clean, but the former remaining long foul and greaſy.

No method of extracting all the ſoluble part of bone anſwers the purpoſe ſo completely, as long boiling in Papin's digeſter with a very great heat; the earthy reſidue then remains quite friable in the fingers, and gives little, if any, volatile, oily, or ammoniacal product on burning. But the jelly which remains in the water, and the oil which ſwims at the top, are found to have acquired a burnt unpleaſant taſte; and in the proceſs, a conſiderable quantity of gas is generated, doubtleſs from partial decompoſition of the ſoluble part. On the other hand, even after repeated boiling and laborious pulverization, unaſſiſted by a higher heat than that of boiling water, the earthy reſidue ſtill feels clammy and cohesive between the fingers, and retains ſome of the oil.

M. Prouſt aſſerts, that the knuckle and joint bones ſimply chopped into ſmall pieces, and boiled for a quarter of an hour in a common copper, yielded no leſs than one fourth of their weight of fine inſipid fat, which roſe to the top of

the water, and on cooling concreted into the conſiſtence of ſuet. The haunch bones yielded about one eighth of fat. The utmoſt economy of bones, therefore, when uſed as human food, may be obtained in the following method. Firſt chop the freſh bones into ſmall pieces, and extract the fat in the way juſt mentioned; then dry the bones, and powder, or reduce them to a fine paſte, by ſome pretty ſtrong mechanical power; and boil them with about ten times their weight of water, for ſome hours, till half the water is waſted, more or leſs according to the kind of bone; the joint and thick bones making a richer jelly than the thin bones, and therefore requiring ſomewhat leſs boiling down to make a jelly of a determinate conſiſtence.

M. Proult finds that this proportion of water is ſufficient to leave a jelly of about the ſame richneſs as would be produced by diſſolving one ounce of bone jelly, dried to the conſiſtence of portable ſoup, in thirty-one ounces of water, and makes a jelly of a very agreeable degree of richneſs. The extraction is much aſſiſted by uſing an iron veſſel with a cloſe lid, to give a heat ſomewhat greater than that of boiling water, though not to the degree of a Papin's digeſter.

In all the above experiments on the extraction of jelly and fat from bones, the uncooked bone is underſtood to be uſed. The bones of *boiled* meat, though deprived of ſome of their extractive matter, are ſtill rich in nutriment; but *roaſting* renders them entirely unfit for this purpoſe.

The earthy part, which compoſes on an average about half the weight of the larger bones of animals, was diſcovered firſt by Gahn, a Swediſh chemiſt, to conſiſt of the phoſphoric acid united with a large proportion of lime. It will be more minutely deſcribed under the article PHOSPHAT *of Lime*; and it is the moſt convenient ſubſtance from which PHOSPHORUS is prepared. It may here be mentioned, that the ſtronger acids, ſuch as the ſulphuric or nitric ſeparate a part of the lime from this earthy ſalt, but only a part, for when ſulphuric acid is added to bone aſh, ſulphat of lime is formed in great quantity, moſt of which remains at the bottom of a ſupernatant liquor, conſiſting of a great exceſs of phoſphoric acid united with a ſmall portion of lime, and alſo ſome ſulphat of lime diſſolved therein. It ſhould be remarked in the analyſis of this ſalt, that this acid phoſphat of lime, is not decompoſed by any ſingle acid, nor even by the pure or carbonated alkalies; for, on adding the latter, the precipitate is not carbonated lime, but ſtill the phoſphat.

This earthy ſalt, when in ſolution, is, however, entirely decompoſed by the nitrat or acetite of lead; the lime remaining diſſolved in the liquor by the nitric or acetic acid, and the phoſphat of lead forming an inſoluble precipitate. Phoſphat of lead is diſtinguiſhable from ſulphat of the ſame metal by being readily ſoluble in nitric acid. If the phoſphat is ſprinkled on hot charcoal, the lead is reduced, and the luminouſneſs and peculiar ſmell of phoſphorus are perceivable. The phoſphat of lime is equally diſtinguiſhable from the ſulphat of lime by being very ſoluble in moſt acids, even when dilute.

Much light has been thrown on the analyſis, and with it the phyſical ſtructure of bone, and of moſt other of the hard ſupporting or protecting parts of the body, by the accurate and numerous experiments of Mr. Hatchett, whoſe reſearches into theſe ſubjects are admirably calculated to ſhew the extreme advantage which phyſiology derives from the labours of the chemiſt, when aſſiſted by accurate knowledge, and guided by a philoſophical ſpirit.

When bones, boiled or freſh, are ſteeped in any acid, a ſlight efferveſcence is perceived, and they preſently are rendered ſoft and flexible by the gradual abſtraction of the earthy baſis (chiefly phoſphat of lime), which becomes diſſolved in the acid. If the bone be previouſly boiled for a long time in water, its gelatin is removed by this liquid; but if the bone is in its natural ſtate, the gelatin alſo is gradually diſſolved in the acid, rendering it yellow and ſomewhat tenacious. The inſoluble reſidue (except in a few kinds of bone, ſuch as the enamel of the teeth) is either a membrane or a ſpongy cartilage, retaining the form of the original bone; for, in the proceſs of oſſification, membrane or cartilage forms the firſt baſis or rudiments of bone, which is afterwards completed by the gradual depoſition of the earthy ſalts. Though phoſphat of lime forms the chief ingredient in the earth of bones of all animals, a ſmall portion of ſulphat of lime is mixed with it; and Mr. Hatchett has detected alſo a little carbonate of lime. The carbonic acid of this is that which occaſions the ſlight efferveſcence during the action of the acid; the lime remains diſſolved in the acid after the precipitation of the phoſphat of lime by pure ammonia. A carbonated alkali then precipitates it together with the now decompoſed earth of the calcareous ſulphat.

We have thus ſhewn the great conſtituent parts of bone to be *gelatin*, ſoluble by boiling in water, and giving a fine clear jelly; *oil*, ſeparable, during the boiling, by riſing to the top of the water, and when cold concreting into a ſuet; *phoſphat of lime*, ſoluble in dilute nitrous muriatic or acetous acid, and precipitable thence by pure ammonia; ſome *ſulphat of lime*; a little *carbonate of lime*; and a *membranous* or *cartilaginous* ſubſtance, retaining the form of the bone after every thing elſe has been extracted by water and an acid.

For a highly probable opinion on the nature and origin of this membrane or cartilage, we are indebted to Mr. Hatchett, who has ſhewn a number of characteriſtic marks, in which it moſt ſtrongly reſembles inſpiſſated albumen, and by which it differs from gelatin. The chief of theſe are the following:

When dry, it is ſemi-tranſparent, like horn, and more or leſs brittle. In this ſtate it reſiſts the action of water very powerfully; for when boiled for many days with this fluid, a ſcarcely perceptible precipitate is given by nitro-muriat of tin; a teſt of diſſolved albumen. In this it ſtrikingly reſembles coagulated albumen, and as pointedly differs from gelatin, which, as we have ſeen, is readily extracted by water even from the dryeſt and hardeſt bones.

This bony membrane, as well as albumen, is ſcarcely acted on by cold muriatic and ſulphuric and dilute nitric acids, which laſt readily extracts gelatin from bone. However, after an immerſion in theſe acids of ſome weeks, the bony cartilage, when taken out and ſteeped in ammonia, gradually diſſolves into a blood-red liquor. But if the nitric acid is heated, the albuminous membrane is rapidly diſſolved with the copious diſcharge of nitrous gas.

With cauſtic fixed alkali, the bony membrane or cartilage is readily diſſolved into a perfect animal ſoap (a ſtrong mark of reſemblance to albumen, and difference from gelatin), and during the proceſs much ammonia is given out. Acids again ſeparate the albumen from the ſoap, unaltered in chemical properties.

Laſtly, the bony cartilage is extremely ſlow to enter into a ſtate of putrefaction, though kept moiſt and warm for many weeks; and in this too it reſembles coagulated albumen.

Therefore, in addition to the above-mentioned conſtituent parts of bone, we may add *albumen*, in a condenſed ſtate, forming the ſubſtance of the original cartilaginous or membranous ſtructure, both of all the organized bones, and, as Mr. Hatchett has alſo ſhewn, of moſt of the hard parts, which ſerve for the covering, protection, and arming of almoſt

almoſt every part of the animal creation. See the articles Shell, Horn, &c.

The enamel of the tooth is a ſingular variety of the bone, being entirely deſtitute of the albuminous membrane. When an entire tooth is immerſed in dilute nitrous acid, the enamel totally diſſolves without reſidue; but the core of the tooth is acted on like other bone, leaving a cartilage of the ſame ſhape. The ſolution of enamel is found to be almoſt entirely phoſphat of lime, by the teſts already mentioned, being precipitable by pure ammonia, giving phoſphat of lead, by adding the acetite of this metal, &c.

Fiſh-bones Mr. Hatchett found to contain rather a larger quantity of cartilage, in proportion to the phoſphat of lime, than the bones of quadrupeds. Of the different kinds of horn and defenſive weapons, the ſtag's-horn, elephant's-tuſks, and the other hard and heavy defences, entirely reſemble bone; but the horns of cattle, rams, and the ſofter ſpecies, contain ſo little earthy reſidue, that they owe their ſolidity entirely to the extreme condenſation of the other conſtituents, the gelatin and albumen.

Bones may be ſoftened by a ſhort immerſion in a weak acid. This ariſes from the partial abſtraction of the earthy baſis; and advantage may be taken of this property in the working of bone, for the various purpoſes of manufacture to which this article is applied by the turner, comb-maker, cutler, &c. Bone, thus ſoftened, is again made hard, by being ſteeped in alum-water. Alkalies alſo ſoften bone, as they do every other animal matter, by beginning to act upon the ſofter parts. See Ivory.

Bones readily take various colours, which, if diſſolved in an acid, ſink deep into the ſubſtance of the bone, and produce a pleaſing effect. The metallic ſolutions are generally preferred for this purpoſe. To give a green, diſſolve verdegris in diſtilled vinegar, immerſe the bones in the ſolution, put the whole in a veſſel, very well cloſed, and bury it in a dunghill, or give it a ſlow and uniform warmth in any other way for about ten or twelve days. The bones are then found very deeply and permanently dyed green, and capable of a good poliſh. The once prized *Turquoiſe* ſtone is foſſile bone of various animals, accidentally impregnated with ſulphat of copper whilſt buried in the earth. To give the artificially dyed bones a finer colour, boil them in nut-oil, and they will then take a very high poliſh.

A permanent black is given to bone, either by nitrated ſilver, or in the following manner: boil equal parts of litharge and quick-lime in water, and the bones along with them for ſome hours, ſtirring them frequently. Other metallic ſolutions may be uſed for different colours.

Or the dye may be given by preparing the vegetable coloured lakes, or concentrated dyes; and by rubbing the bone, firſt with dilute nitrous acid to open its texture, and then rubbing in the dye for ſome time. This may be applied in various ways, firſt ſoftening the bone by a weak acid, whereby it is made fit to receive the colour.

Bones are whitened by ſimple expoſure to ſun, wind, and weather, being firſt thoroughly cleaned, and particularly by occaſional immerſion in brine: thus the bones of ſea-birds and fiſh, left for ſome time on the ſhore, are found beautifully white and clean. The ſame effect is produced much more ſpeedily, but perhaps leſs permanently, by the oxymuriatic acid, the bone being expoſed for ſome hours to this acid gas in cloſe veſſels, as Mr. Smith of Briſtol has obſerved. The acid firſt makes the bone yellow, which, by expoſure to air, goes off, and leaves the bone beautifully white. This colour a little fades, when the bone is kept in cloſe caſes excluded from the light. See Skeleton.

From all that has preceded, it will appear obvious that, to the chemiſt and manufacturer, bone is one of the moſt curious and valuable of the animal ſubſtances, though conſidered vulgarly as little better than refuſe, and ſcattered about without care. Beſides its uſe as a hard and good material for turnery and workmanſhip of various kinds, it gives, by chemical decompoſition, a large quantity of uſeful, nutritive jelly, fit for human food, or the ſame, in the form of glue, for the arts. When ſubjected to fire, it yields a vaſt quantity of ammonia, and is actually the material uſed in very many manufactures of the ammoniacal ſalts; and the reſidue, ſtrongly calcined in cloſe veſſels, (and therefore retaining its carbonaceous ingredient,) produces uſeful and fine black pigments; or, burned with acceſs of air, leaves an earthy ſalt, neceſſary to ſome important chemical proceſſes.

Some of the preparations from bone are only uſed in medicine. Of theſe, are Dippel's oil, and the leſs rectified *oleum cornu cervi*, (oil of hartſhorn,) both powerful ſudorifics, and ſuppoſed antiſpaſmodics; the *ſpiritus cornu cervi*, (ſpirits of hartſhorn), ſo univerſally known as a ſtimulant and cordial; and the carbonat of ammonia, often called ſalt of hartſhorn. The white calcined earth of bones, *cornu cervi calcinatum*, enters into the compoſition of one or two pharmaceutical preparations, but without exhibiting any obvious properties. In diſeaſes of the bones, where the ſoftening and ſpontaneous deformity ſhews an evident want of their earthy baſis, this calcareous phoſphat has been given with apparent advantage. Of the unprepared bones, the elk's tooth, rhinoceros's horn, and ſhavings of the dried human ſkull, &c. are medicines entirely exploded only within a few years from the European pharmacopœias, and ſtill maintaining high credit in the countries whoſe characteriſtic credulity and ſuperſtition in medicine firſt brought them into repute. The only real utility of unprepared bone in medicines is found in furniſhing, when boiled in water, a light and nutritive jelly for the invalid; and for this purpoſe, hartſhorn ſhavings are employed with advantage. Memoires de Pelletier, tom. ii. Prouſt in the Journal de Phyſique, tom. liii. Hatchett in the Phil. Tranſ. for 1799 and 1800. Smith in Beddoes's Weſt of England Contributions. Johnſon's Animal Chemiſtry. Encycl. Method. Arts and Metiers, (Article *Ecaille*), &c. &c.

Bones, *Diſeaſes of the*, in *Surgery*. As bones are organized parts of the animal body, they are liable to moſt of the diſeaſes with which the ſofter organs are affected. Theſe are either ſpontaneous, or accidental; but, from the hardneſs of their compoſition, and the ſmall degree of vaſcularity and ſenſibility they poſſeſs, there muſt neceſſarily be a conſiderable difference between the phenomena and ſymptoms of diſeaſed bones, compared with thoſe of the ſoft parts. They are naturally endowed with little or no ſenſation; but are extremely painful in an inflamed ſtate, when the blood-veſſels, which enter their ſubſtance, are diſtended, and the nervous filaments are kept upon the ſtretch, as in the caſe of venereal nodes, &c.

Bones may be wounded with a ſharp inſtrument or contuſed with a blunt one, in the ſame manner as the muſcles, or integuments; and they will re-unite again, if the injury they ſuffer be not ſo extenſive as to intercept the circulation, or deſtroy their vitality. But, if a bone be ſo injured as to periſh, its ſubſtance will either be gradually comminuted and diſſolved, or caſt off in a larger portion, by the proceſs we denominate *exfoliation*. If any two ulcerated ſurfaces of fleſh (ſuppoſe two contiguous fingers) be applied together, and allowed to heal, they will coaleſce, and the veſſels from one part will ſhoot into the other: in like manner, if the articulating ſurfaces of two contiguous bones (ſuppoſe

(ſuppoſe of the tibia and femur), be diveſted of their cartilage by ulceration, their extremities may coaleſce, and form one continuous bone, which is named *anchyloſis*. A ſtiff joint, from this cauſe, is irremediable, and in general it may be conſidered as the moſt favourable termination of diſeaſed joints; for they too commonly are attended with ſuch diſtreſſing ſymptoms as to require amputation, in order to preſerve the patient's life. See White Swelling, and *Diſeaſes of the* Joints.

The conſideration of *Fractures* and *Diſlocations* is reſerved for their proper places in the Cyclopædia, where will be likewiſe deſcribed the manner of reducing bones, vulgarly called *bone-ſetting*. This art, (which requires a very correct acquaintance with the anatomy of the joints and muſcles), has, moſt unaccountably, been often left to ignorant farriers and mechanics, who are totally deſtitute of knowledge on theſe ſubjects! We might, with as much reaſon, entruſt the repairing of a watch, or a mill, to perſons who never had an opportunity of examining their mechaniſm! By accident, it is barely poſſible, ſome good might be done; but the greater chance is, that the inſtrument would be damaged rather than rectified, in the hands of ſuch unſkilful operators.

Bones will, in ricketty and ſcrofulous conſtitutions, paſs into a ſtate of ſpontaneous enlargement, or decay, or flexibility, &c. The ſpongy parts of bones, e. g. the extremities of cylindrical bones, are moſt liable to become diſeaſed in ſuch ſubjects, eſpecially during the early period of life; but in venereal patients, who are alſo very ſuſceptible of morbid changes in the bones, they are their hard parts chiefly which become affected, as in the middle of the tibia, or ulna, or upon the central portions of the frontal and parietal bones. See Rickets, Scrofula, and Lues Venerea. Some obſervations on the ſurgical treatment of diſeaſed bones will be alſo made under the heads of Caries, Necrosis, Spina Bifida, Distortion, Curvature, Mollities, and Exostosis.

The ſtructure of bones may be altered from ſeveral cauſes; but principally, from either a deficiency, or a redundancy of the phoſphat of lime, which enters into their compoſition, and gives them ſolidity. When there is too little phoſphat of lime, the gelatinous part of the bones being unable to ſuſtain much weight or reſiſtance, they will become preternaturally flexible; and, on the contrary, when there is too much phoſphat of lime, in proportion to the gelatinous part, the bones will be very fragile, and perhaps, may even break from the mere action of the muſcles. The flexible ſtate is moſt common in young perſons, and the ſuperabundance of oſſeous matter is chiefly predominant in old age; but either condition of the bones may occur at any period of life, from peculiar morbid diſpoſitions. The popular notion of our bones being more frangible in cold weather than in hot, is erroneous, and without foundation; ſince the difference of ſeaſon make no difference in the texture of the living bones: and the only natural cauſe to be aſſigned for the fracture of our limbs more frequently in the winter than in the ſummer, is that of an increaſed ſlipperineſs and hardneſs in the ground from froſt, &c. which muſt neceſſarily occaſion more phyſical violence and frequency in our falls.

Bones, *in the funeral ſolemnities of the ancients*.—Divers uſages and ceremonies relating to the bones of the dead, have obtained in different ages; as gathering them from the funeral pile, waſhing, anointing, and depoſiting them in urns, and thence into tombs; tranſlating them, which was not to be done without the authority of the pontiffs; not to ſay worſhipping them, ſtill practiſed to the bones of the ſaints in the Romiſh church. Among the ancients, the bones of travellers and ſoldiers, dying in foreign countries, were brought home to be buried, till, by an expreſs S. C. made during the Italic war it was forbid, and the ſoldiers bones ordered to be buried where they died; the reaſon was, leſt the melancholy ſight ſhould diſcourage the people from venturing their lives. Antiquaries are divided as to the manner of diſtinguiſhing the bones of the deceaſed, from thoſe of the beaſts and ſlaves, who were ſacrificed at his funeral, and thrown into the ſame fire: probably it was done by diſpoſing the body of the dead in the middle of the pile, and the others towards the ſides. Potter's Archæol. tom. ii. lib. iv. cap. 6.

The Romans had a peculiar deity, under the denomination of *Oſſilago*, to whom the care of the induration and knitting of the human bones was committed: and who, on that account, was the object of the adoration of all breeding women. Pitiſc. Ant. tom. ii. p. 341.

Bones, *foſſile*, or *petrified*, are thoſe found in the earth, frequently at great depths in all the ſtrata, even in the bodies of ſtones and rocks.

There are divers ſorts of foſſile bone; ſome of a huge ſize, uſually ſuppoſed to be the bones of giants, but more truly of elephants, or hippopotami; others ſmaller, as vertebræ, teeth, and the like.

It has been diſputed whether theſe be really animal ſubſtances, or mineral, that is, ſtones thus figured. Modern naturaliſts generally allow them to be animal, not merely on account of their figure and reſemblance, but of their chemical principles, which are found to be wholly of the animal kind. It is ſuppoſed they were repoſited in thoſe ſtrata at a time when all things were in a ſtate of ſolution, and that they incorporated and petrified with the bodies where they happened to be lodged.

In the Philoſophical Tranſactions (vol. lxxxiv. p. 407, &c.) we have ſome obſervations on foſſil bones by the late Mr. John Hunter. They were occaſioned by an examination of bones of this kind, found in the caves of Gailenreauth and Klaufſtein, two ſmall villages in the principality of Bayreuth, (or Bareith,) and preſented to the Royal Society by the margrave of Anſpach. Theſe bones are conſidered more as incruſted bodies than extraneous foſſils, ſince their external ſurface has only acquired a covering of cryſtallized earth, with little or no change in their internal ſtructure. The principal earth with which bones are moſt commonly incruſted is the calcareous; and this happens either by the bones being immerſed in water, in which this earth is ſuſpended, or by water's paſſing through maſſes of this earth, which it diſſolves, and afterwards depoſits upon bones which lie underneath. Bones which are incruſted ſeem never to undergo this change in the earth, or under the water, where the ſoft parts were deſtroyed: while bones that are foſſilized become ſo in the medium, in which they were depoſited at the animal's death. The incruſted bones have been previouſly expoſed to the air; which is evidently the caſe with theſe bones, and alſo with thoſe of the rock at Gibraltar, thoſe found in Dalmatia, and thoſe of the iſland of Cerigo. They are thus diſtinguiſhed from foſſilized bones: but as they are found in different ſituations, it is more difficult to account for their preſent ſtate. Thoſe in Germany are found in caves; the coaſt of Dalmatia is ſaid to be wholly formed of them; and this is the caſe with a large portion of the rock of Gibraltar. With reſpect to the firſt claſs of bones, as they are thoſe of carnivorous animals, reſembling, in ſome reſpects, thoſe of the white bear, and yet differing, in ſome circumſtances, from the preſent animal of that ſpecies, Mr. Hunter ſuggeſts, that the animals to which they

they belong reſorted at different periods to theſe caves, as places of retreat, and periſhed in them. In Gibraltar, they are moſtly the bones of animals of the ruminating tribe, of the hare kind, and of birds, with ſome of a ſmall dog, or fox, and likewiſe ſhells. Thoſe in Dalmatia appear to be moſtly of the ruminating tribe. From theſe facts, it may be preſumed, that their accumulation did not ariſe from any inſtinctive mode of living, as the ſame mode could not ſuit both carnivorous and herbivorous animals. As to the local diſtribution of theſe bones, it is neceſſary to recur to ſucceſſive ſhiftings of the ſituation of the ſea, in conſequence of which we may have a ſtratum of marine extraneous foſſils, one of earth, mixed probably with vegetables and bones of land animals, a ſtratum of terreſtrial extraneous foſſils, then one of marine productions; but as the ſea carries its inhabitants along with it, wherever there are thoſe of land animals, there will alſo be a mixture of marine ones; and from the ſea commonly remaining thouſands of years nearly in the ſame ſituation, we have marine foſſils unmixed with any others. As all operations reſpecting the decompoſition, as well as the growth, of animal and vegetable ſubſtances, proceed more rapidly on the ſurface of the earth, to which the air has acceſs, than within it, we ſhall find fewer changes as we deſcend into the earth, and at laſt probably arrive at a certain depth, where no change takes place. Subſtances, therefore, that are foſſilized at a great depth, and depoſited in ſtone, clay, &c. are preſerved for a very long time from putrefaction; as much ſo as if they were in a vacuum; the heat alſo in ſuch ſituations being uniform, commonly about 52° or 53°; and in the colder regions they are ſtill longer preſerved. It has been generally underſtood, that in extraneous foſſils the animal part is deſtroyed; but Mr. Hunter has not found this to be the caſe. Shells, and bones of fiſh, muſt probably have the leaſt in quantity, having been longeſt in that ſtate, otherwiſe they ſhould have the moſt; for the harder and the more compact the earth, the better is the animal part preſerved; and this is an argument in proof of their having been longeſt in a foſſil ſtate. In the foſſil bones of ſea-animals, as the vertebræ of the whale, the animal part is in large quantity, and exiſts in two ſtates; the one having ſome tenacity, but the other like wet duſt; in ſome of the harder bones it is more firm. In the foſſil bones of land animals, and thoſe which inhabit the waters, as the ſea-horſe, otter, crocodile, and turtle, the animal part is in great quantity. In the horns of ſtags dug up in Great Britain and Ireland, when the earth is diſſolved, the animal part is in conſiderable quantity, and very firm. The ſame obſervations apply to the foſſil bones of the elephant found in England, Siberia, and other parts of the globe; alſo thoſe of the ox kind; and more particularly to their teeth, eſpecially thoſe from the lakes in America, in which the animal part has ſuffered very little: the inhabitants finding little difference in the ivory of ſuch tuſks from the recent, except its having a yellow ſtain; the cold may probably aſſiſt in their preſervation. In incruſted bones, the quantity of animal ſubſtance is very different in different bones: in thoſe of Gibraltar, there is very little; it partly retains its tenacity, and is tranſparent, but the ſuperficial part diſſolves into mucus. Thoſe from Dalmatia furniſh ſimilar reſults. Thoſe from Germany, eſpecially the harder bones and teeth, ſeem to contain all the animal ſubſtance natural to them, though in this reſpect they differ among themſelves. The bones of land animals have their calcareous earth united with the phoſphoric acid of the aerial, and retain it, when foſſilized, as Mr. Hunter thinks, in proportion to the quantity of animal matter they contain. This he infers from the quantity of efferveſcence. In ſome bones of the whale, put into the muriatic acid, the efferveſcence is very great; in the Dalmatia and Gibraltar bones it is leſs; and in thoſe of the German caves, it is very little, ſince they contain by much the largeſt proportion of animal ſubſtance. From the experiments and obſervations of the ingenious Mr. Hatchett, (ſee Phil. Tranſ. vol. lxxxix. p. 333.) we learn that the bones of the Gibraltar rock conſiſt principally of phoſphat of lime; and that the cavities have been partly filled by the carbonate of lime, which cements them together. Foſſil bones, he ſays, reſemble bones which, by combuſtion, have been deprived of their cartilaginous part; for they retain the figure of the original bone, without being bone in reality, as one of the moſt eſſential parts has been taken away. Such foſſil, or burned bones, can no more be regarded as bone, than charcoal can be conſidered as the vegetable of which it retains the figure and fibrous texture. Bones which keep their figure after combuſtion, reſemble charcoal made from vegetables replete with fibre; and cartilaginous bones, which loſe their ſhape by the ſame cauſe, may be compared to ſucculent plants which are reduced in bulk and ſhape in a ſimilar manner. Hence he is led to queſtion if bodies, conſiſting of phoſphat of lime, like bones, have concurred materially to form ſtrata of limeſtone, or chalk; as it appears to be improbable, that phoſphat is converted into carbonat of lime, after theſe bodies have become extraneous foſſils. The deſtruction, or decompoſition of the cartilaginous parts of teeth and bones in a foſſil ſtate, muſt have been the work of a very long period of time, unleſs accelerated by the action of ſome mineral principle; for, after having, in the uſual manner, ſteeped in muriatic acid the os humeri of a man, brought from Hythe in Kent, and ſaid to have been taken from a Saxon tomb, Mr. Hatchett found the remaining cartilage nearly as complete as that of a recent bone.

M. Cuvier communicated to the Societé d'Hiſtoire Naturelle at Paris, a curious memoir upon the foſſil bones of animals. The following abridgment has been taken from the Societé Philomatique, N° 18, Year VI. In order to determine the relations and differences that ſubſiſt between the ſeveral ſpecies of animals that do exiſt, or have exiſted on the ſurface of the globe, he directed his attention to the following. 1. The animal which afforded the bones and teeth, called the bones and horns of the mammouth, by the Ruſſians and Siberians, and of which remains are found in Europe, is a ſpecies of elephant, reſembling the elephant of Aſia; but differing from it in the alveolæ of its teeth, its tuſks being longer, the angle of its lower jaw more obtuſe, and the laminæ of which its grinders are compoſed thinner. The true analogous living animal is not known, though it has been hitherto conſidered as the ordinary elephant. 2. The animal, of which the remains are found on the banks of the Ohio in North America, which the Americans and Engliſh have alſo named mammouth, though it differs much from the former. Remains of it are found in Europe and Aſia. It muſt have been nearly as high as the elephant, but more bulky; its tuſks are ſmaller; its grinders are armed with large cutting points, of which the ſection by wear preſents double tranſverſal lozenges. There are three molar teeth on each ſide, one of four, one having ſix, and one eight points. 3. The animal of which the teeth tinged by copper afford the turquois ſtone, and of which there was a mine at Simore, in Languedoc. The remains of this ſpecies are found in the department of Ain, in Peru, and elſewhere. It muſt have conſiderably reſembled the former; but the points of its molar teeth are round, and when worn, their ſection preſents firſt, a circle, then a ſemioval, and afterwards a figure of a trefoil, which has cauſed them to be confounded with the teeth of the rhinoceros; ſome

ſome of theſe teeth have 12 points, others 6, others 4. 4. The rhinoceros. The feet and fragments of the jaws of this animal are found in France, and elſewhere, in which the author has hitherto obſerved nothing which differs from the common rhinoceros; but, as he has not yet ſeen an entire bone, he cannot poſitively affirm that they are identical. 5. The ſpecies of rhinoceros, with an oblong cranium, which is found in Siberia, Germany, and other countries. The author has ſeen teeth, and parts of the jaw-bones, found in France, which appeared to him likewiſe to belong to this animal; the principal character of this ſpecies conſiſts in the long cloſure of the noſe: the living analogous animal is unknown. 6. A molar tooth with two tranſverſal eminences, which is in the poſſeſſion of Citizen Gillet; and of which the National Muſeum poſſeſſes a young tooth that reſembles neither the teeth nor the germs of any animal yet known, whether living or foſſil: the only tooth which this ſlightly reſembles is the laſt molar tooth of the rhinoceros. This tooth, therefore, indicates the exiſtence of a ſixth foſſil ſpecies, of which the living analogous animal is unknown. 7. The animal, twelve feet in length, and ſix in height, of which the ſkeleton was found under ground at Paraguay, and is preſerved in the royal cabinet of Spain, at Madrid. The author proves by a detailed compariſon of the bones, with thoſe of all the known quadrupeds, that it is a proper and diſtinct ſpecies, more nearly approaching the ſloth than any other genus, and that it may be called the giant ſloth. Citizen Cuvier, in this place, communicates the intereſting diſcovery he has made, that the ſloth (*bradypus tridactylus*, Lin.) has naturally and conſtantly nine cervical vertebræ. It is the firſt known exception, eſtabliſhed by Citizen Daubenton, that all quadrupeds have neither more nor leſs than ſeven cervical vertebræ. 8. The animal, of which the remains are found in the caverns near Gaylenreuth and Muggendorf, in the margraviate of Bayreuth, in Franconia.

Various authors have conſidered it as a white bear; but it differs from this animal, as well as from all the known bears, in the form of its head, which is particularly characteriſed by the projection of the front, by the abſence of the ſmall tooth, which all the known bears have behind each canine tooth, by the oſſeous channel of the humerus, in which the brachial artery paſſes, and by ſeveral other circumſtances in the figure and proportion of the bones. This animal, however, reſembles the bear more particularly than any other kind. 9. The carnivorous animal of which the bones are found in the plaiſter-ſtone of Montemartre: the form of its jaws, the number of its molar teeth, and the points with which they are armed, indicate that this ſpecies is referable to the genus canis; but it does not completely reſemble any ſpecies of this genus. The moſt ſtriking diſtinctive mark is, that the ſeventh molar tooth is the greateſt in the animal of Montemartre, whereas the fifth is the largeſt in dogs, wolves, foxes, &c. 10. The animal of which the lower jaw was found near Verona, has been conſidered by Joſeph Monti as a portion of the cranium of the ſea-cow; a notion which all the geologiſts have adopted, though it be the contrary to the moſt ſimple notions of comparative anatomy. This jaw, according to Cuvier, has belonged to an animal reſembling, though ſpecifically different from, the mammouth, the animal of the Ohio, and that of Simore. Its moſt particular character conſiſts in the curve which forms its ſymphyſis. 11. The animal of the ſtag kind of which the bones and the antlers are found in Ireland, in England, at Maeſtricht, &c. It is ſufficiently different from all the ſtags, and even the elk, to which it has been referred, by the enormous magnitude of its antlers, the flattening of their ſuperior part, and the branches which ſpring from their baſe. Several figures of theſe are given in the Philoſophical Tranſactions. 12. The genus of the ox or beeve alone affords ſeveral foſſil ſpecies: the craniums of two were found in Siberia, which have been deſcribed by Pallas, who referred one of them to the ordinary buffalo; but he has ſince attributed them to a peculiar ſpecies, natives of Thibet, named arni. Citizen Cuvier proves, by oſteologic compariſon, that thoſe craniums have not belonged to the buffalo. The other appeared to Pallas to have belonged to the buffalo of the Cape, or the muſk ox of Canada. Citizen Cuvier ſhews that they cannot have belonged to the former; but not being in poſſeſſion of the cranium of the arni, nor the muſk ox, he makes no deciſion reſpecting their identity with the foſſil craniums.

The author likewiſe deſcribes two kinds of craniums which have been found in the turf-pits of the department of La Somme, which greatly reſemble our common ox, and that of L'Aurouchs, but are more than one fourth longer.

From this inquiry the Citizen Cuvier concludes, 1. That it is not true to affirm that the animals of the ſouth have formerly lived in the north, their ſpecies not being perfectly identical. 2. That in every country there have lived animals which do not at preſent exiſt, either on the ſame ſpot, or elſewhere in any known country. Hence he leaves to geologiſts, the taſk of making, in their ſyſtems, ſuch changes or additions as they may think beſt ſuited to explain the facts which he has thus eſtabliſhed.

Bone is alſo applied abuſively in ſpeaking of other matters which bear ſome analogy, either in reſpect of ſtructure or office, to the bones of animals.

In this ſenſe rocks are ſometimes called the bones of the earth. Divers ſpecies of figured ſtones, as the *cephalites*, *cardites*, *&c.* are denominated mineral bones, enoſta, oſteocolla, &c. Some naturaliſts conſider ſhells as a ſpecies of bones. The lobſter, according to Fontenelle, is an animal which carries its bones on its outſide.

Bones, *Mammouth*. See Mammouth.

Bone-*fire*. See *Bon*-Fire.

Bone-*lace*. See Lace.

Bone, *hurle*, *Neper's*, *quitter*, *ring*, *whale*. See the ſeveral articles.

BONEF, in *Geography*, a town and abbey of the Netherlands, in the county of Namur, 3 leagues north of Namur.

BONENCONTRE, a town of France in the department of the Cotê d'Or, and chief place of a canton, 5 miles S. W. of St. Jean.

BONETTA *Shoal*, lies about N. E. by E. from Bonaviſta iſland, one of the Cape de Verd iſlands, diſtant from it about 12 or 14 leagues.

BONEZIDA, a town of Tranſilvania, on the Samos, 12 miles N. of Clauſenburg.

BONFADIO, James, in *Biography*, an eminent Italian ſcholar of the 16th century, was born at Gorzano, in the Breſcian territory, and ſtudied in the univerſity of Padua. From thence he went to Rome, where, for ſome time, he ſerved the cardinals Merino and Ghinucci, as ſecretary; and after wandering from place to place, he reſumed his ſtudies at Padua, where he was probably employed in the inſtruction of youth. Deriving from none of his employments more than a precarious ſubſiſtence, he was, in 1545, invited to the chair of philoſophy, in the city of Genoa, to which was united the office of hiſtoriographer, with a conſiderable penſion. Whilſt he was buſily proſecuting his ſtudies, he was charged and convicted of an unnatural crime; beheaded in priſon; and his body was publicly burnt in July 1550. As a writer in the Latin and Italian languages, both in proſe and verſe,

he excelled; and his tranſlation of Cicero's oration for Milo, is reckoned one of the moſt elegant pieces of Italian proſe which the century affords. His capital work is the "Annals of the republic of Genoa," written in Latin, and compriſing the hiſtory from 1528, where Giuſtiniani left off, to February 1550. It was firſt publiſhed at Padua, in 1586, 4to. and tranſlated into Italian by Paſchetti. The ſtyle is elegantly ſimple, the narrative lively, and the ſentiments elevated. His Italian letters and poems were printed at Breſcia in 1746—47. Gen. Dict. Nouv. Dict. Hiſt.

BONFATTI, in *Geography*, a town of Italy, in the kingdom of Naples, and province of Calabria citra, 3 leagues W. of St. Marco.

BONFINI, Anthony, in *Biography*, was born at Aſcoli, and after being ſome years profeſſor of belles-lettres, at Recanati, was invited by Matthias Corvinus king of Hungary, in 1484, to his court, where he was employed in writing the hiſtory of the Huns. Here he enjoyed the office of tutor to the queen, Beatrice of Arragon, and received many honours from Matthias, and his ſucceſſor Ladiſlaus. He died in 1502, aged 75. Of the hiſtory of Hungary he left 4½ decads, brought down to 1495; of which 3, or 30 books were printed, by Martin Brenner, in 1543, and the remaining 15 books were added to a new edition by Sambucus, in 1568. This work is written with elegance, and is claſſed among the beſt modern hiſtories in Latin. He alſo wrote an account of the capture of Belgrade by Mahomet II.; and a work entitled "Sympoſion Beatricis, ſeu dialogorum de fide conjugali et virginitate, lib. iii." He likewiſe tranſlated, from the Greek into Latin, the works of Philoſtratus, Hermogenes, and Herodian. Gen. Dict.

BONGARS, James, a polite ſcholar and able negotiator, was born of proteſtant parents at Orleans in 1554. Having ſtudied firſt at Straſburg, and attended a courſe of law under Cujacius, he entered into the ſervice of the king of Navarre, afterwards Henry IV. by whom he was employed for 30 years in various negotiations, particularly with the German princes. Being at Rome in 1585, he wrote a ſevere reply to the violent bull fulminated by pope Sixtus V. againſt Henry IV.; and he alſo publiſhed a ſpirited anſwer to a German piece, imputing the bad ſucceſs of the joint expedition in 1587, to the miſconduct of the French. He was diſtinguiſhed by his knowledge of books, and had collected a large library, a great part of which was at length annexed to the public library of Bern. As a critic he became known by a valuable edition of "Juſtin," Paris, 1581, 8vo. He alſo edited a collection of the Hungarian writers, and the "Geſta Dei per Francos." But his reputation was principally owing to his Latin letters, written during his negotiations, and publiſhed after his death, at Leyden, in 1647, and afterwards tranſlated into French. The ſtyle is clear, eaſy, and poliſhed, and they ſeem to have been dictated by an honeſt heart. A collection of his French letters, "Le Secretaire ſans fard," has alſo been publiſhed. Although a Calviniſt, Bongars, diſapproved of the religious wars of that party. He died at Paris in 1612. Gen. Dict.

BONGO, or Bungo, in *Geography*, one of the iſlands of Japan. The principal town, ſeated on the eaſt ſide of the iſland, is called by the ſame name. This is a port oppoſite to Tonſa, and ſeparated from it only by a narrow channel. N. lat. 32° 41′. E. long. 131° 57′.

Bongo Pala, in *Botany*, Piſo. See Myristica *aromatica*.

BONGUATRORA, *Serpens ornatiſſima amboinenſis bonguatrora* of Seba, in *Zoology*, the name the *coluber ahætulla* bears among the natives in the iſland of Amboyna. See Ahætulla.

BONHAMPTON, in *Geography*, a town of America, in Middleſex county, and ſtate of New Jerſey; about 6 miles N. E. from New Brunſwick.

BONI, a kingdom of the iſland of Celebes, which lies on the weſtern ſide of a bay, called on that account the bay of Boni, is the ſecond kingdom, in point of importance, in the iſland. Its extent from the river Chinrana to the river Salenico is about 20 leagues; and within land it is bordered upon Soping, Lamoere, Macaſſes, and Boeleboele. In ancient times this kingdom was independent of, and unconnected with any other. It is ſtill in cloſe alliance with the two ſmall kingdoms of Soping and Loeboe, or Lochoe. The natives of Boni, that they may not appear inferior to the Macaſſers, deduce their origin in like manner from the gods. The firſt king, they ſay, deſcended from heaven, and was known by the name "Matta Salompo," that is, the all-ſeeing. This ſovereign, their firſt monarch, inſtituted the laws of the country, which are ſtill obſerved; made the royal ſtandard, called "Worong Porong;" and appointed ſeven electors, under the denomination of "Matoua petoes." The prince or ſovereign is called "pajong;" and he is elected for life by ſeven nobles, which number is kept up by the pajong, and they are appointed by him from certain freeholders. The pajong is often reſtrained by a ſort of parliament, elected by the freeholders; it conſiſts of 400 members, 200 of which are called "mattoua," 100 are called "pabicharro," and 100 are called "galarang." The firſt ſovereign, after reigning 40 years, reſigned the kingdom to his ſon, and, with his wife, aſcended again to heaven; and from him all the ſucceeding kings of Boni are deſcended; none others, beſides his poſterity, born of marriages with royal princeſſes, being entitled to the crown. Notwithſtanding the common deſcent of the rulers of Boni and Macaſſer from the gods, theſe two nations are avowed enemies. About the beginning of the 17th century the Bougineſe, or people of Boni, and their queen, were compelled to conform to the mahometan religion; and the condition is poſed upon them was, that the enemies of Macaſſer ſhould likewiſe be the enemies of Boni, but not the enemies of Boni thoſe of Macaſſer. At this time Boni was able to bring 70,000 fighting men into the field. The hatred which was thus excited among the Bougineſe againſt the Macaſſers, and their inceſſant quarrels, enabled the Dutch, who, as their intereſt required, favoured ſometimes the one party, and ſometimes the other, to make themſelves maſters of the iſland. The princes of Boni, Soping, &c. united themſelves to the Dutch by the Boni contract, which was concluded November 18th, 1667; and to this the Macaſſers were afterwards compelled to accede. At preſent the Bougineſe are the moſt powerful, as the Macaſſers were about a century ago.

The Bougineſe, or Buggeſſes as they are uſually called by the Engliſh, are of a middle ſize, and have a brown, but not dark, complexion. Among the female ſex in particular, ſome are found almoſt entirely fair. Their features in general are agreeable, only that their noſe is a little flattened. They are leſs open and more treacherous in their diſpoſitions than the Macaſſers; and never attack their enemies openly, but endeavour to fall upon them by ſurpriſe. Thoſe who never did them an injury are not ſecure from being murdered by them, when they can do it with privacy; and they often commit ſuch actions for no other reaſon, as they ſay, than to try the goodneſs of their kriſſes, or daggers. Many Macaſſers, as well as Europeans, have fallen ſacrifices to this thirſt for blood. Their daggers and aſſagays are commonly poiſoned, as well as their ſmall darts, which they can ſhoot at their enemies to a conſiderable diſtance by blowing them through a tube. Their clothing conſiſts of a piece of red or blue cotton cloth wrapped round the body, and drawn

between the legs. The upper part of the body is quite naked. On the head they wear a piece of cotton cloth in the form of an handkerchief, with which they cover their hair, which is as black as pitch, and very long. On the other parts of the body, neither the men nor women ſuffer any hair to grow; they pull it out by the roots, in the ſame manner as the Mahometans and Indians do, as ſoon as it appears. Their food is chiefly rice, fiſh, and piſangs; and their beverage is water, though they are not deſtitute of "ſaqueer," or palm wine. The Bougineſe women are in general much handſomer than thoſe of the other Indian tribes; ſome of them, if their complexion had the ſame mixture of red and white as our females, would be accounted beauties in Europe. They are naturally of an amorous diſpoſition, and are capable of undertaking any thing to gratify their inclinations. The Bougineſe, who have in general adopted the mahometan religion, may have four wives, provided the huſband can maintain them; but if they are not ſatisfied with each other, they may ſeparate with as little trouble as they were united. They are a high ſpirited people, fond of adventures and emigration, and capable of undertaking the moſt dangerous enterpriſes. The appellation "Buggueſe," has become, among Europeans in the eaſt of India, ſynonymous with ſoldier, juſt as ſeapoy is in the weſt. The people of Celebes are very induſtrious, and they are very adventurous merchants; and the Bugguefe, in particular, often find their way to the ſpice iſlands, in ſpite of the vigilance of the Dutch. They write their language from left to right, in a character peculiar to themſelves; on the ſea-coaſt they univerſally ſpeak the Malay tongue, and have many Malay phraſes in their own language. Their funerals are attended with very little ceremony. The body is wrapped up in a piece of white cotton cloth, and depoſited in the grave, over which ſome ſweet ſcented flowers are ſtrewed, and two ſtones are erected, one at the head and another at the feet. Stavorinus's Voyage to the Eaſt Indies, vol. ii.

Boni, *bay of*, a bay in the kingdom of Boni, in the ſouthern part of the iſland of Celebes. It is called Sewa by the natives, and Bugguefs, or long bay, by the Engliſh. Of this bay we have the following account by captain Foreſt. Having paſſed the ſtrait between Celebes and Saleyer, called the "Budgeroons," keep on in a direction N. E. by N. about 130 miles, and you will find, near the weſt coaſt of the Sewa, a ſmall iſland called "Baloonroo," viſible 8 or 10 leagues off, and having ſome rocky iſlets at its eaſt end. Farther on, about a day's ſail, or about 60 miles, is the mouth of the river Chinrana, which takes its riſe in the Warjoo country, the capital of which is Toſſoro, lying a day's journey by water from the mouth of the river; it afterwards paſſes through Boni; it has a good muddy bar, paſſable by large ſhips, and is navigable a good way up; it has ſeveral mouths, and on its banks are many towns, which carry on a great trade in gold, rice, ſago, caſſia, tortoiſe-ſhell, pearls, &c. The anchorage is good off the river's mouth. Half a day's ſail farther north, along the weſt coaſt of the Sewa, is the river Peeneekee, which is not very conſiderable. Farther on are two places called Akolingan and Telludopin, which are pretty well inhabited. Continuing ſtill north, you come to the river Sewa, not very conſiderable; then to the river Loo, famous for boat-building; then you come to Mankakoo, where are gold and plenty of ſago, very cheap, and alſo caſſia and ſeed-pearl. Being now come to the bottom of "Buggeſs-bay," the ſago-tree abounds very much; and in many parts of the Sewa, there are ſpots of foul ground, on which they fiſh for ſwallow, which they generally carry to Macaſſer, to ſell to the China junk. On the eaſt ſide of the Sewa the country is not ſo well inhabited as on the weſt ſide. The ſouth-eaſt point of the Sewa is called "Pajungan;" where is a cluſter of iſlands, rather ſmall, among which is good anchorage. Stavorinus's Voyage, vol. ii. p. 213.

BONIEUX, a town of France, in the department of the Vaucluſe, and chief place of a canton, in the diſtrict of the Apt. The place contains 2450, and the canton 6178 inhabitants; the territory comprehends 130 kiliometres, and 6 communes; 8 leagues E. of Avignon.

BONIFACE, in *Biography*. There are nine popes of this name. *Boniface* I. ſucceeded Zoſimus in the year 418; and when the ſchiſm, occaſioned by a party that favoured Eulalius, was terminated, he was fully eſtabliſhed in poſſeſſion of the papal ſee in 419. Before his election he was a preſbyter of irreproachable character, and after his advancement he was a lover of peace; and though he maintained what he called the juſt rights of the Roman ſee, in the juriſdiction which his predeceſſors had exerciſed over the biſhops of Illyricum, he made no attempt to extend his authority and claims. He revoked the privileges granted by Zoſimus to the ſee of Arles, and reſtored them to the ſees of Narbonne and Vienne, which had been unjuſtly deprived of them; and with a moderation that redounds much to his honour, he refuſed to interfere in a diſpute which took place between the clergy of Valence and Maximus, their biſhop. He died at a very advanced age, November 4, 422; was canonized as a ſaint in the church of Rome; and his feſtival was kept on the 25th of October. Bede gives credit to the relation of miracles wrought by this pope, and Baronius (ad ann. 423,) ſays, that he relieved Rome in the time of a famine.

Boniface II., a Roman by birth, and a Goth by deſcent, ſupplied the vacancy occaſioned by the death of Felix III. in 520; and upon the death of a competitor, named Dioſcorus, obtained quiet poſſeſſion of the papal chair. This pope confirmed the decrees of ſome Gallican biſhops, who condemned the ſemipelagian doctrine; and in 531 he propoſed to alter the mode of electing a pope, and to aſſume the prerogative of appointing his ſucceſſor. He obtained a decree for this purpoſe, and actually nominated a deacon, whoſe name was Vigilius. But at a ſecond council the Roman ſenate, in concurrence with the biſhops and clergy, obliged the pope to revoke his former decree, and to acknowledge himſelf guilty of high treaſon. Boniface died in October, 532.

Boniface III., a native of Rome, ſucceeded Sabinian, after a vacancy of almoſt a year, in 607; and having ingratiated himſelf with the emperor Phocas, to whom he was deputed as a nuncio by pope Gregory, in 603, he obtained from this tyrant the title of "univerſal biſhop," and "head of the church," which was taken from the biſhop of Conſtantinople, and transferred to Boniface and his ſucceſſors in the ſee of Rome. Thus, ſays Bower, was the power of the pope, as univerſal biſhop and head of the church, or in other words, the papal "ſupremacy," firſt introduced. It owed its original to the worſt of men; it was procured by the baſeſt means, or by flattering a tyrant in his wickedneſs and tyranny; and according to the previouſly declared judgment of Gregory the great, it was in itſelf "anti-chriſtian, heretical, blaſphemous, and diabolical." Boniface afterwards aſſembled a council for ſettling the election of biſhops, in which they were forbidden to nominate their own ſucceſſors, and the conſent of the people, clergy, and ſovereign, and the confirmation of the pope, were made neceſſary. Boniface died in November, 607.

Boniface IV., a native of Valeria, in the country of the Marſi,

Marſi, was elected to the papal ſee in Auguſt 608; and having obtained from Phocas the grant of the pantheon, converted it into a church, dedicating it to the Mother of God and the Chriſtian Martyrs. He held a council at Rome to ſettle ſome affairs of the Engliſh church, at which Mellitus, the firſt biſhop of London, is ſaid, by Bede, to have attended; but the acts of this council, and ſome pieces aſcribed to Boniface, are thought to be ſpurious. He died in 615, and was ſainted.

Boniface V., a native of Campania, and a preſbyter of the Roman church, ſucceeded Deuſdedit in December 619. In 624 he ſent the pall to Juſtus, the ſucceſſor of Mellitus in the ſee of Canterbury, and intereſted himſelf in the propagation of Chriſtianity in Britain, by ſending letters and preſents to Edwin the king of Northumberland, and alſo to his queen Edelberg, ſiſter of Eadbald king of Kent, who, having aſſumed the Chriſtian profeſſion, was allowed by her marriage articles the free exerciſe of it. He died in October 625. Some decretal epiſtles, relating to matters of ſmall importance, are aſcribed to him. According to Moſheim (Eec. Hiſt. vol. ii. p. 185), this Boniface enacted that infamous law, by which the churches became places of refuge to all who fled thither for protection; a law which procured a ſort of impunity to the moſt enormous crimes, and gave a looſe rein to the licentiouſneſs of the moſt abandoned profligates.

Boniface VI., was a Roman of infamous character, and ſucceeded Formoſus in 896. Baronius (ad Ann. 897.) will not allow him a place among the popes. He died ſoon after his election.

Boniface VII., denominated "Anti-pope," was a deacon of the Roman church, of the name of Franco, and advanced to the papal chair in 975, upon the death of Benedict VI. to whoſe murder he is ſaid to have contributed. Soon after his election he was conſtrained by an adverſe party to leave Rome, and to fly to Conſtantinople; but he carried with him the treaſures of St. Peter. Gerbert ſtyles him "of all monſters of wickedneſs the moſt wicked." Upon the death of the emperor Otho II. in 984, he returned to Rome, and occupied the ſee in the room of John XIV. whom he diſplaced, impriſoned, and put to death. Franco died in 985; and he had rendered himſelf ſo odious by his tyrannical conduct, that his corpſe was treated with the utmoſt indignity, and dragged naked through the ſtreets.

Boniface VIII., a native of Anagni, and a deſcendant of the noble family of Cajetani, was employed by popes Martin IV. and Nicholas IV. in ſeveral important legations, and ſucceeded pope Celeſtine V. whom he artfully perſuaded to reſign, in December 1294. The beginning of the following year he was enthroned at Rome with great ſolemnity and parade; in the proceſſion from St. Peter's, where he was conſecrated and crowned, to the Lateran, for the purpoſe of being inthroned, he was mounted on a white horſe, richly capariſoned, with the crown on his head, whilſt the king of Apulia held the bridle in his right hand, and the king of Hungary in the left, both on foot. His ſubſequent conduct correſponded to the haughty grandeur of his inſtallation. In order to ſecure himſelf againſt any future trouble from Celeſtine, he confined him in priſon at Anagni, where he died. Failing to mediate a peace between James king of Arragon, and Charles II. king of Sicily, he formed an alliance againſt Frederic of Arragon, whom the Sicilians had made their king, and proceeded to excommunicate him and all his adherents; but he was at length obliged to confirm him in his dominions. His next meaſure was that of humbling the family of Colonna, two cardinals of which had oppoſed his election; for this purpoſe, after having declared the whole family infamous by a public decree, confiſcating their eſtates, and excommunicating all who countenanced or protected them, he ordered a cruſade to be preached againſt them and their friends, demoliſhed their houſes and caſtles, and obliged them to ſeek ſhelter in foreign countries; and he moreover puniſhed with utter demolition the city of Præneſte, for its attachment to them. To Boniface is commonly aſcribed the inſtitution of the jubilee in 1300. See Jubilee. In his attempt to mediate a peace between Philip the Fair king of France, and Edward I. king of England, he was charged with partiality to the latter, ſo that Philip could be prevailed on merely to agree upon a truce; and his enmity againſt Boniface, which was ſmothered for ſome time, at length broke out into a flame. Philip, with a view of ſupporting the war againſt England, prohibited the exportation of any gold or ſilver from the kingdom without his permiſſion; and Boniface, apprized that this order was levelled againſt the ſee of Rome, iſſued a bull, forbidding ſecular princes to exact, and the clergy to pay, any ſums from the eccleſiaſtical revenues, without his approbation. The animoſity between the pope and the French potentate was increaſed by the arrogance with which a legate from Rome delivered the pope's meſſage, enjoining the king of France, in common with other Chriſtian princes, to aid the king of Tartary in a war againſt the Saracens, and by the ſubſequent arreſt of the legate. Boniface, much enraged, diſpatched a nuncio to demand his releaſe; and in caſe of refuſal, threatened to declare the kingdom devolved to the holy ſee, to abſolve his ſubjects from their allegiance, and to ſummon all the Gallican biſhops to Rome. The king reſented this violent proceeding, renewed the prohibition againſt carrying money out of the kingdom, and forbade his eccleſiaſtics on any pretence to viſit Rome. In theſe hoſtile meaſures the king was ſupported by the ſtates of the nation, which appealed to a general council, and Boniface prepared to fulminate a decree of excommunication and forfeiture of his crown againſt Philip. Nogaret and Sciarra Colonna were ſent, on this occaſion, into Italy to excite the perſecuted Ghibellines againſt the pope, who was then at his palace in Anagni. They ſecretly approached it with a body of troops, and made themſelves maſters of the perſon of Boniface and all his treaſures. During the three days of his confinement the pope was treated with great indignity, particularly by Colonna. At length the people of Anagni, recovering from their conſternation, reſcued the pope from his captivity; who returned to Rome, where he was ſeized with a fever, which terminated his life in October 1303. He was buried at St. Peter's in a grand mauſoleum, which he had erected for himſelf. Although Boniface has been juſtly extolled for his learning, intrepidity, and experience in public affairs, and for his patronage of literature; he was arrogant and overbearing, ambitious, crafty, and violent, and avaricious to ſuch a degree, that he was intent upon accumulating riches to exalt the church and aggrandize his own relations. He was the author of ſeveral works, ſuch as epiſtles and decrees, two diſcourſes on the canonization of Lewis IX. of France, called St. Lewis; two famous prayers, one to our Saviour, and the other to the Virgin. He alſo cauſed to be publiſhed the ſixth book of the decretals, and wrote a treatiſe entitled "De regulis juris."

Boniface IX., a native of Naples, deſcended from a noble family in reduced circumſtances, whoſe name was Peter Thomacelli, was more diſtinguiſhed by his prudence and addreſs than for his profound and extenſive learning, and was elected pope at Rome upon the death of Urban VI. in 1389. The greateſt part of his pontificate was devoted to negotiations with his rivals at Avignon, Clement VII. and Benedict XIII.

in

in which were diſplayed on both ſides much cunning and artifice, and at the ſame time an inflexible reſolution of retaining the tiara. Boniface was arbitrary in the exerciſe of power, and towards the end of the year 1394 he would have been maſſacred by the people, if he had not been ſeaſonably reſcued from the enraged multitude by the interpoſition of Ladiſlaus, king of Naples, who happened to be then at Rome. He afterwards retired to Perugia, and from thence he removed to Aſſiſi; but on the approach of the jubilee year, 1400, the Roman people, apprehending, that in the abſence of the pope it would not be celebrated with the uſual ſolemnity, and the pecuniary intereſts affected, deputed an embaſſy to invite his holineſs to Rome. Upon his arrival he was received with joy and inveſted with extraordinary powers, in the exerciſe of which he repaired and fortified the walls and towers of the city, and the caſtle of Angelo, and alſo placed garriſons in them, ſo that he made himſelf abſolute maſter of the city. Some aſcribe to Boniface the inſtitution of Annates (See Annates); but though the origin of theſe is of more ancient date, he is allowed to have been in a very high degree avaricious and rapacious, to have ſold church preferments to the beſt bidder, without regard to merit or learning, and to have made it his conſtant ſtudy to enrich his family and relations. He died of a paroxyſm of the ſtone in 1404. Bower's Hiſtory of the Popes.

Boniface, called the "Apoſtle of the Germans," was a native of England, whoſe original name was "Winifrid," born in Devonſhire, A.D. 670, and was educated in a Benedictine monaſtery at Exeter. This famous eccleſiaſtic, who was ordained a prieſt A.D. 700, with two companions, paſſed over into Frieſland in 703, in order to preach the goſpel among the heathens; but failing in his firſt attempt, on account of a war which broke out between Radbod the king of that country, and Charles Martel, he returned to England. However, he reſumed his pious undertaking in 718; and at Rome he was ſolemnly empowered by the Roman pontiff, Gregory II. to preach the goſpel not only in Frieſland, but throughout Germany; which commiſſion he executed with conſiderable ſucceſs. In the year 723, he was conſecrated biſhop by Gregory II., who changed his name of Winifrid into that of Boniface; and he is ſaid to have been the firſt who took a ſolemn oath of obedience to the pope, which he did at this time. Upon his return to Germany, with the inſtructions of the pope, and the peculiar protection of Charles Martel, he preached in Thuringia, Heſſia, and Bavaria, and erected a great number of Chriſtian churches. As theſe were too numerous to be governed by one biſhop, this prelate was advanced to the dignity of archbiſhop, in 732, by Gregory III., under whoſe authority, and the auſpicious protection of Carloman and Pepin, the ſons of Charles Martel, he founded in Germany the biſhopries of Wurtzbourg, Burabourg, Erfurt, and Aichſtadt; to which he added, in 744, the famous monaſtery of Fulda. His laſt promotion, and the laſt recompence of his aſſiduous labours in the propagation of the truth, was his advancement to the archiepiſcopal ſee of Mentz, A.D. 746, by pope Zachary, by whom he was at the ſame time created primate of Germany and Belgium. In his old age he returned again to Frieſland, that he might finiſh his miniſtry in the ſcene of its commencement; but his piety and zeal were ill rewarded by that barbarous people, by whom he was murdered in 754, together with fifty eccleſiaſtics, who accompanied him, and who ſhared the ſame fate. He was interred in the abbey of Fulda, and canonized by the church of Rome, to which he was ardently devoted. His zeal for the glory and authority of the Roman pontiff equalled, if it did not ſurpaſs, his ſolicitude for the ſervice of Chriſt, and the propagation of his religion; and in combating the heathen ſuperſtitions, he recurred to other weapons than thoſe which Chriſtianity recommended, employing violence and terror, and ſometimes artifice and fraud, in order to multiply the number of Chriſtians. His epiſtles, and thoſe of his coadjutors, firſt publiſhed with notes by Serrarius, in 1605, and re-publiſhed in 1629, are written in a barbarous ſtyle, and diſcover an imperious arrogant temper, a cunning and inſidious turn of mind, an exceſſive zeal for increaſing the honours and pretenſions of the ſacerdotal order, and a profound ignorance of many things, the knowledge of which was indiſpenſably neceſſary in an apoſtle, and particularly of the true nature and genius of the Chriſtian religion. The Benedictines have publiſhed his ſtatutes, and ſome of his ſermons. Bower's Hiſt. of the Popes, vol. iii. Moſheim's Eccl. Hiſt. vol. ii. p. 205, &c. Cave's Hiſt. Lit. t. i. p. 622. Dupin, Eccl. Hiſt. cent. 8.

Boniface, count of the Roman empire, one of the two generals of Placidia, the mother of Valentinian III., Aetius being the other (ſee Aetius), who have been deſervedly named as the laſt of the Romans; was the intimate friend of St. Auguſtine, biſhop of Hippo, but incurred his diſpleaſure by marrying a wife of the Arian ſect, after a ſolemn vow of chaſtity, and a reſolution of retiring from the world, and by ſome other inſtances of licentious conduct with which he was charged. However, the people applauded his ſpotleſs integrity, and the army dreaded his impartial and inexorable juſtice. Of his juſtice, the following ſingular fact is recorded. A peaſant, who complained of the criminal intimacy between his wife and a Gothic ſoldier, was directed to attend his tribunal the following day: in the evening, the count, who had diligently informed himſelf of the time and place of the aſſignation, mounted his horſe, rode ten miles into the country, ſurpriſed the guilty couple, puniſhed the ſoldier with inſtant death, and ſilenced the complaints of the huſband by preſenting him, next morning, with the head of the adulterer. Boniface, having defended Marſeilles, when attacked by Ataulphus, was rewarded by the emperor Honorius with the command of the troops in Africa, which province he reſcued from the repeated attempts of John, who uſurped the empire. Placidia, who aſſumed the government of the empire during the minority of her ſon, highly pleaſed with his bravery and loyalty, called him to court upon the death of that uſurper, preferred him to the poſt of "comes domeſticorum," and ſent him into Africa with unlimited power. Theſe marks of favour excited the jealouſy of Aetius (ſee Aetius), who artfully contrived, under the maſk of friendſhip, to engage Boniface in a revolt, which took place in 427. Accordingly, Placidia declared him a public enemy, and ſent troops againſt him. Having defended himſelf for ſome time, he found at length that he was likely to be overpowered; and therefore, after ſome heſitation, the laſt ſtruggle of prudence and loyalty, he diſpatched a truſty friend to the camp of Gonderic, king of the Vandals, with the propoſal of a ſtrict alliance, and the offer of an advantageous and perpetual ſettlement. The Vandals accepted the propoſal, and Genſeric, who ſucceeded his brother, and whoſe ambition had neither bounds nor ſcruples, tranſported his troops from Spain into Africa in 429, and obtained, by the concurrence of ſeveral favourable circumſtances, an eaſy conqueſt. Placidia diſcovered, when it was too late, the artifice that had been practiſed by Aetius; and Boniface, who alſo perceived and lamented his error, returned to his allegiance. But his efforts to recover Africa were unavailing; and he was under a neceſſity of abandoning the country, and of returning to Ravenna, where

where he was kindly received by Placidia, and advanced to the rank of patrician, and the dignity of maſter-general of the Roman armies. The haughty and perfidious ſoul of Aetius was exaſperated by the honourable mode of his reception, and he haſtened to return from Gaul to Italy, with an army of Barbarian followers, and to decide his quarrel with Boniface in a bloody battle. Boniface was ſucceſsful; but in the conflict he received a wound from the ſpear of his adverſary, of which he expired within a few days, A.D. 432. Before his death he is ſaid to have teſtified his forgiveneſs of Aetius's treacherous conduct, to ſuch a degree, as to exhort his wife, a rich heireſs of Spain, to accept him for her ſecond huſband. Anc. Un. Hiſt. vol. xiv. Gibbon's Hiſt. &c. vol. vi.

Boniface, Natalis, an engraver of great merit, who flouriſhed in Italy, towards the concluſion of the 16th century. His works are chiefly etchings, performed in a ſlight, fine ſtyle; and his ſmall figures he executed with great ſpirit. His chief work was the plates compoſed by D. Fontana, architect to pope Sixtus V. concerning the removal of the Vatican obeliſks. Strutt.

BONIFACIA, in *Botany* (J. Bauhin). See Ruscus *racemoſus*.

BONIFACIO, or Bonfacio, in *Geography*, a ſea-port town of the iſland of Corſica, department of Liamone, and chief place of a canton, in the diſtrict of Sartene, on the ſouth coaſt, and in the ſtrait between the iſlands of Sardinia and Corſica. The town is ſmall and fortified, and the canton contains 3172 inhabitants; 28 leagues ſouth of Baſtia. N. lat. 41° 24′. E. long. 9° 20′.

Bonifacio *Point*. See Baldivia.

Bonifacio *Strait*, commences near the town of the ſame name, on the S.E. of the iſland of Corſica; and its length to point Tico, the moſt northerly point of Sardinia, is 2½ leagues.

BONING, in *Surveying* and *Levelling*, &c. is the placing of three or more rods or poles, all of the ſame length, in or upon the ground, in ſuch a manner, that the tops of them all may be in one continued ſtraight line, whether it be horizontal or inclined, ſo that the eye may look along the tops of them all, from one end of the line to the other.

BONJOUR, William, in *Biography*, a learned Auguſtin, was born at Toulouſe in 1670; and at Rome, whither he was ſent for by cardinal Norris in 1695, he became diſtinguiſhed by his learning and piety. He was employed by pope Clement XI. in ſeveral matters of importance, and particularly in the examination of the Gregorian calendar. Bonjour had alſo the ſuperintendence of the ſeminary eſtabliſhed by cardinal Barbarigo at Monteſiaſcone, and denominated the Academy of Sacred Letters. He was acquainted with almoſt all the oriental tongues, and more eſpecially with the Coptic, or ancient Egyptian. Actuated by a zeal for acquiring knowledge, and for propagating the goſpel, he viſited China, where he died in 1714, whilſt he was employed in forming a map of that empire. His works are, "Select Diſſertations on the Scriptures;" "An Account of the Coptic MSS. in the Vatican;" "A Coptic Grammar;" and "A Roman Calendar." Moreri.

BONIS arrestandis ne dissipentur. See Arrestandis.

Bonis *non amovendis*, a writ directed to the ſheriffs of London, &c. where a writ of error is brought, to charge them that the perſon againſt whom judgment is obtained be not ſuffered to remove his goods, till the error is tried and determined.

Bonis, *terris, et catallis rehabendis poſt purgationem*. See Terris.

Arreſto facto ſuper Bonis *mercatorum*. See Arresto.

BONITO, in *Ichthyology*, ſynonymous with the French *bonite*. This appears to be a name aſſigned indiſcriminately to more than one or two kinds of fiſhes, although it ſeems to be confined in ſome degree to thoſe of the Scomber genus. The *ſcomber pelamis* of Loefl. is the fiſh mentioned under the name of *bonito* by Oſbeck, who alſo calls it *ſcomber pulcher*. The *bonito* is vaguely deſcribed as a large ſea-fiſh, with a long, broad, and thick body; eyes, and likewiſe the gills, large; and the greater part of the body free from ſcales. It is obſerved ſtill further to be a fiſh of great beauty, and very common in ſome ſeas; our Eaſt India ſhips uſually falling in with immenſe ſhoals of them. It is impoſſible to ſay whether this may be the *ſcomber pelamis*, or not: but as a matter of opinion, we think it to be the ſame, becauſe the latter is found in immenſe ſhoals between the tropics, and in the Atlantic ocean. The bonito of Bloch (*le bonite de Bloch*) bears the Latin name of *ſcomber ſarda*.

BONITON, the common French name of Scomber *amia* of Linnæus.

BONIZO, in *Geography*, a town of Italy, in the duchy of Mantua, on the ſouth ſide of the Po, oppoſite to Oſtiglia.

BONKOSE, in *Ichthyology*, the Sciena *nebuloſa*, a fiſh diſcovered by Forſkal in the Red ſea. Bonkoſe is the name it bears in Arabia.

BONLIEU, in *Geography*, a town of France, in the department of the Ardeche; 5 leagues N. N. W. of Tournon.

BONN, in Latin *Bonna*, a ſmall but populous and fortified city of Germany, in the circle of the Lower Rhine, and electorate of Cologne, or, according to the French arrangement, the chief place of a diſtrict, in the department of the Rhine and Moſelle; the place contains 8837, and the canton 18,951 inhabitants; and its number of communes is 31. The number of houſes is ſaid not to exceed a thouſand; and as it has little foreign trade, moſt of the inhabitants are attracted thither by its being the reſidence of the elector of Cologne. The ſtreets are narrow, crooked, dirty, and badly paved, and in winter badly lighted. The public walks are few, and not very agreeable. The churches are ſtately; and the town-houſe is adorned with fine paintings. The Jews at Bonn have a ſtreet to themſelves, conſiſting of 21 houſes; and their number is eſtimated at 250. Bonn was taken from Louis XIV. into whoſe hands it was ſurrendered by the elector, in 1673, by William prince of Orange; in 1689, by the marquis of Brandenburgh; in 1703, by a detachment of the duke of Marlborough's army, after a ſiege of three weeks, and the loſs on both ſides of 2000 men; and on the 6th of October, 1794, by the troops of the French republic. It is ſituated 14 miles S.S.E. of Cologne, 30 E. of Aix-la-Chapelle, and 28 N.N.W. of Coblentz. N. lat. 50° 40′. E. long. 7°.

BONNA, in *Zoology*, ſynonymous with Bonasus; which ſee.

BONNAGHT, or Bonnagh, an old term, which occurs frequently in *Iriſh hiſtory*, and was the ſame with *coin and livery*; being a certain proportion of meat, drink, and money for the maintenance of a ſoldier, and ſometimes free quarter. Hollingſhead ſpeaks of it as an Iriſh impoſition, which beggared the farmers; and ſir John Davis, the eminent attorney general of Ireland in the reign of James I. in his juſtly admired tract, entitled "A Diſcovery of the Cauſes, why Ireland was never ſubdued," has theſe words: "But the moſt wicked and miſchievous cuſtom of all others, was that of *coin and livery*, which conſiſted in taking of man's meat, horſe meat, and money, of all the inhabitants of

of the country, at the will and pleaſure of the ſoldier, who, as the phraſe of the Scripture is, *did eat up the people, as it were bread*, for that he had no other entertainment. This extortion was originally Iriſh, for they uſed to lay *bonnaght* upon their people, and never gave their ſoldiers any other pay. But when the Engliſh had learned it, they uſed it with more inſolence, and made it more intolerable; for this oppreſſion was not temporary, nor limited either to place or time, but becauſe there was every where a continual war, either offenſive or defenſive, and every lord of a country, and every marcher, made war and peace at his pleaſure, it became univerſal and perpetual, and was indeed the moſt heavy oppreſſion that ever was uſed in any Chriſtian or Heathen kingdom." The curious reader will do well to conſult the whole paſſage in ſir J. Davis's Hiſtorical Tracts, p. 132, et ſeq. of the edition printed in 8vo. Dublin, 1787. This practice was forbidden by the ſtatute of Kilkenny paſſed in 1450, and by ſeveral ſucceeding acts, in one of which (under Henry VII.) it is called a *damnable cuſtom*. Spenſer, in his "View of the ſtate of Ireland," ſeems, however, to think the ſtatute unneceſſarily ſevere in making it treaſon. Hollingſhead. Iriſh Statutes. Spenſer's State of Ireland.

BONNART, John, in *Biography*, barber ſurgeon, and maſter of the college of ſurgeons at Paris, publiſhed, in 1629, "La Semain des medicamens obſervée, et chefs d'œuvres des maitres barbiers chirurgiens de Paris," 8vo. It contains a courſe of ſtudy neceſſary for young men previous to their being elected into the college, with obſervations on the method of treating ſuch complaints as come under their care. The author ſtrongly recommends opening the jugular vein in caſes of quinſey. "Methode pour bien feigner les accidens qui arrive pour etre mal fait," 8vo. 1628. Haller Bib. Med. Eloy.

BONNAT, in *Geography*, a town of France, and chief place of a canton, in the department of the Creuſe, and diſtrict of Gueret; the place contains 2032, and the canton 10,804 inhabitants; the territory comprehends 257½ kiliometres, and 12 communes.

BONNAUD, in *Biography*, publiſhed, in 1770, "Degradation de l'eſpece humaine par l'uſage des corps de baleine," 12mo. Paris. In this very ſenſible and ingenious little work, the author forcibly repreſents the various evils conſequent on uſing ſtays ſtiffened with whale-bone: theſe are indigeſtion, and other diſorders of the ſtomach, ruptures, and difficult reſpiration, often terminating in conſumptions; beſides, they not unfrequently occaſion deformity of the body, which they are ſuppoſed by their admirers to contribute in preventing. Haller. Bib. Med.

BONNAY, in *Geography*, a town of France, in the department of the Doubs, and chief place of a canton, in the diſtrict of Beſançon, 2 leagues N. of Beſançon.

BONNE, a town of Savoy, in the Lower Faucigny, 10 miles E. S. E. of Geneva. N. lat. 46° 11'. E. long. 6° 7'.

Bonne, a bay on the weſt coaſt of Newfoundland. N. lat. 49° 35'. W. long. 53°.—Alſo, a bay on the coaſt of Spain in the Mediterranean, nearly eaſt from Malaga. N. lat. 36° 42'. W. long. 2° 40'.

BONNEBOSQ, a town of France, in the department of the Calvados, and chief place of a canton, in the diſtrict of Pont l'Eveque, 2 leagues S.W. of Pont l'Eveque.

BONNEFONS, John, or Bonnefonius, in *Biography*, was born, in 1554, at Clermont in Auvergne, became an advocate in Paris, and, in 1584, lieutenant-general at Barſur-Seine, and died in 1614. He was diſtinguiſhed as a Latin poet, and particularly by that kind of poetry, which is the ſhort verſe of Catullus, abounding with diminutives and tender expreſſions. Of this kind is the piece entitled "Pancharis," which is reckoned the moſt elegant performance of any modern writer. It ſeems to have been the aim of Bonnefonius to imitate Joannes Secundus, the celebrated author of the Baſia; and his reſemblance, with regard to ſoftneſs and ſweetneſs, has approached the extreme of laſciviouſneſs and effeminacy. His poems in heroic verſe have alſo been eſteemed. The Pancharis was publiſhed at Paris in 1588, and tranſlated into French by La Bergerie; and all the poems of Bonnefonius are printed after thoſe of Beza, in Barbou's edition of the latter, Paris, 1757. There are London editions in 1720 and 1727. A ſon of Bonnefonius diſtinguiſhed himſelf by Latin poetry, chiefly written on public characters and events. Nouv. Dict. Hiſt.

BONNER, Edmund, an Engliſh prelate of deteſtable memory as a perſecutor of Proteſtants, was born, as it is generally believed, of poor parents at Hanley, in Worceſterſhire; but ſome have affirmed that he was the natural ſon of George Savage, rector of Davenham, in Cheſhire. About the year 1512, he was admitted a ſtudent of Broadgate hall (now Pembroke college) in the univerſity of Oxford, famous at that time for the education of civilians and canoniſts. In 1519, he took his degrees of bachelor of the canon, and bachelor of the civil law; and about the ſame time entered into holy orders. In 1525, he was created doctor of the canon law. More diſtinguiſhed by his talents for buſineſs than for his learning, he was appointed commiſſary of the faculties by cardinal Wolſey, who conferred upon him a plurality of eccleſiaſtical benefices. After the cardinal's death, he contrived to inſinuate himſelf into the favour of king Henry VIII., and became a zealous promoter of the reformation, as well as an advocate for the king's divorce from queen Catharine, and a ſtrenuous ſupporter of the meaſures that were adopted for aboliſhing the pope's ſupremacy in this kingdom. He was alſo patronized by Cromwell, ſecretary of ſtate, and employed as ambaſſador at ſeveral courts. In 1532, he was deputed on an embaſſy to Rome, to excuſe the king's appearance to a citation at that court; and in 1533, he was ſent to pope Clement VII. then at Marſeilles, to deliver the king's appeal from the pope to the next general council againſt his excommunication; and on this occaſion he expoſed himſelf by his boldneſs and indecent warmth to perſonal danger. He was likewiſe employed in other embaſſies to the kings of Denmark and France, and to the emperor of Germany. Being recalled from France in 1538, on account of the boldneſs with which he remonſtrated againſt the protection afforded to an Engliſh traitor, he was nominated to the biſhopric of Hereford, and, before his conſecration, tranſlated to the ſee of London in 1539. At the time of the king's death in 1547, he was ambaſſador at the court of Charles V. Till this time he appears to have concurred in promoting the reformation; and by the ſubſerviency of his principles to his intereſt, as well as by his capacity for public buſineſs, he ſecured the favour and confidence of his tyrannical maſter. But from his ſubſequent conduct it is evident that he was ſecretly attached to the Romiſh religion; for ſoon after the acceſſion of Edward VI., he ſcrupled to take the oath that was required for renouncing the pope's authority, and he proteſted againſt the king's injunctions and homilies, which, however, he had never read. But being committed to priſon for diſobedience, he afterwards recanted, and was releaſed. Whilſt he outwardly profeſſed zeal for the reformation, he privately uſed all the means in his power for obſtructing its progreſs and eſtabliſhment. His conduct warranted the ſuſpicions that were entertained of his ſincerity; and in order to bring it to a teſt, he

he was ordered by the privy council to preach at St. Paul's croſs on certain articles, connected with the principles of the reformation, and given to him in writing. But he performed this ſervice in a manner ſo unſatisfactory, that, upon the complaints of Hooper and Latimer, commiſſioners were appointed to proceed ſummarily againſt him; the reſult of which was, that he was committed to priſon, and deprived of his biſhopric. Theſe proceedings, allowed even by his enemies to be arbitrary and ſevere, rouſed his reſentment; nor was he long obliged to wait for an opportunity of ample retaliation. Upon the acceſſion of Mary to the throne, he was reſtored to his biſhopric, by a commiſſion dated Auguſt 1553; and in the convocation of the following year, he was appointed preſident in the room of Cranmer, who was committed to the tower. In this year he viſited his dioceſe, and induſtriouſly rooted up all the ſeeds of the reformation. In the four ſucceeding years he was an active and ſavage perſecutor; and he is ſaid to have committed to the flames 200 perſons, who avowed their firm adherence to the proteſtant religion, and who refuſed to embrace the groſs errors of popery, beſides impriſoning and torturing many more. Bonner's diſpoſition was in the higheſt degree cruel and ferocious; and religious bigotry, grafted on a temper naturally ſavage, rendered him a fit inſtrument to be employed by the artful Gardiner in the condemnation and execution of heretics. But though his nature did not ſeem to recoil at this ſavage employment, he dreaded the increaſed odium that attended it, and refuſed any longer to be the executioner of the laws. However, in 1556, he concurred in the degradation of Cranmer, and enjoyed the malignant pleaſure of triumphing over him with his uſual inſolence. In the following year his name was inſerted in a kind of inquiſitorial commiſſion for ſearching after, and puniſhing all heretics, as all perſons who were of the proteſtant religion were then denominated. Upon the acceſſion of Elizabeth, he had the effrontery to accompany the other biſhops in their progreſs for meeting her at Highgate; but ſhe looked upon him with feelings of juſt indignation and horror, as a man polluted with blood. He remained for ſome months unmoleſted; but in May 1559, he was ſummoned before the privy council; and refuſing to take the oaths of allegiance and ſupremacy that were tendered to him, he was deprived of his biſhopric, and committed to priſon. In this ſtate of confinement he remained for ſome years, bearing his reverſe of condition with a degree of cheerfulneſs which might have become a better man, and occaſionally warding off, by keen and humorous repartees, the popular inſults that were offered him. He died in priſon, September 5, 1569; and was buried at midnight in St. George's church-yard, Southwark, leſt any indignities ſhould be offered to his remains by the incenſed populace. Bonner was ſingularly ſavage in his natural temper, bluſtering and prophane in his converſation and manners, furious and violent in his conduct, groſs and corpulent in his perſon, and in every reſpect fitted for the part he acted, as an unrelenting and brutal perſecutor. He was generally regarded as deſtitute of any fixed principles; and he has been charged even with Atheiſm. As a canoniſt and politician he was allowed to excel; but his knowledge of divinity was very imperfect, and he had no reputation for learning. However, ſeveral pieces, theological, controverſial, and paſtoral, were publiſhed under his name. By his intereſt with queen Mary, he obtained ſeveral advantages for the ſee of London, which his ſucceſſors have enjoyed. Biog. Brit.

BONNET, Charles, an eminent natural philoſopher, was born at Geneva in 1720, and educated under a domeſtic tutor, whom his father provided for him, as affording ſuperior advantages to thoſe which he enjoyed in any of the public ſchools. At the early age of 16, he diſcovered that peculiar inclination of his mind, which led him to thoſe ſtudies that laid the foundation of his future fame and excellence. From the peruſal of the Spectacle de la Nature, he was induced to direct his particular attention to the ſtructure and manners of the ant-lion, and added many curious obſervations relating to it, to the facts that had been previouſly collected by Meſſ. Poupart and Reaumur; and he was further led by the Memoirs on Inſects, publiſhed by the latter, to repeat many of his experiments, and to diſcover new facts, which indicated in a youth of 18 a degree of ſagacity and reſearch that ſurpriſed and gratified this eminent naturaliſt, by whom he was encouraged to proceed. The intereſting obſervations which he made on different ſpecies of caterpillars, and other inſects, in the years 1738 and 1739, were communicated by him to Reaumur. His father had deſtined him to the profeſſion of the law; but the ſtudy of natural hiſtory was his choſen and favourite employment. Having, in 1740, decided a queſtion that had been left unſettled by Reaumur, reſpecting the multiplication of tree-lice, or aphides, without actual conjunction, he communicated a paper on this ſubject to the Academy of Sciences at Paris, and in conſequence of it, had the honour of becoming a correſpondent of that illuſtrious body. His eye-ſight was irreparably injured by the minuteneſs of his reſearches on the generation of theſe animals. In 1741, he found that many ſpecies of worms poſſeſs, in a degree, the reproductive power of the polype: and in 1742, he diſcovered that the reſpiration of caterpillars and butterflies, was effected by means of their pores called "Stigmata." The tænia, or tape-worm, was alſo a ſubject of his ſucceſsful inveſtigation. In 1743, he was advanced to the rank of doctor of laws, and on this occaſion he totally abandoned the profeſſion of the law. A paper on inſects, which was this year communicated to the Royal Society of London, obtained for him the honour of being elected a member. His obſervations on aphides and worms, under the title of "Inſectology," were publiſhed in 1744; and this work was introduced with a preface, in which he gave a brief ſketch of his ideas concerning the developement of germs, and the ſcale of organized beings. This work was very favourably received by the public; but ſuch had been the nature of his reſearches and the aſſiduity of his application, that his eyes and his health failed him; and he was reduced to the diſtreſſing neceſſity of laying aſide his microſcope, and of deſiſting from reading and writing. This ſelf-denial, peculiarly afflictive to his ardent mind, he bore, however, with philoſophical reſignation; and by a total intermiſſion of his ſtudies he had the ſatisfaction of regaining a conſiderable degree of health and eaſe, though he was never able to employ his eyes as he had been accuſtomed to do. In 1746, he commenced a courſe of experiments on the vegetation of plants in moſs and other ſingular ſubſtances: and in the following year he examined with minute attention the leaves of plants, with a view of aſcertaining the appropriate action of their upper and under ſurfaces. He alſo employed coloured injections for the purpoſe of determining whether the ſap aſcends by the bark or wood; and he made various obſervations on vegetable monſters, and other circumſtances of vegetation, which were communicated to the public in one of the moſt curious and original of his works, entitled, "Inquiries into the uſe of the leaves of plants," firſt publiſhed at Leyden, in 1754, 4to.; to which ſupplements have been added as late as the year 1779.

Bonnet, probably conſtrained to remit his attention to experiments by the circumſtances already mentioned, directed

his ſpeculative reſearches to the faculties of the human mind; and having collected a maſs of materials on this ſubject, he publiſhed a kind of abridgment of them, under the title of an "Eſſay on Phyſiology," in 1755, at London. This work, which appeared without his name, and which he did not acknowledge for 30 years, contains a conciſe ſtatement of the fundamental principles of his philoſophy. "It traces the origin and progreſs of the human mind, from the firſt germ of life, to the developement of all its faculties, the mutual dependence of which it points out, as deduced from actual obſervation. It enters into the difficult ſubject of human liberty, and endeavours to reconcile it with the divine preſcience, and with the philoſophical principle, that every effect muſt have an adequate cauſe. From the eſſential properties of the activity of the ſoul, and the effects of habit upon it, the whole art of education and government is deduced; and a ſyſtem of the former is laid down, materially different from the uſually eſtabliſhed methods." Our author's metaphyſical ideas were evidently founded on the principles of Malebranche and Leibnitz; but as he had freely diſcuſſed ſome points of a delicate nature, and which were likely to involve him in perſonal controverſy, he choſe to conceal his name. His next work, the fruit of five years' labour, was an "Analytical Eſſay on the faculties of the Soul," firſt printed at Copenhagen in 1760, 4to. at the expence of the king of Denmark. In this work he aſſumes the hypotheſis of a ſtatue organized like the human body, which he animates by degrees, and ſhews how its ideas would ariſe from impreſſions on the organs of ſenſe. Although this performance was well received by ſome philoſophers, it ſoon ſubjected the author to the charge of materialiſm and fataliſm; but to this charge he made no reply. Accuſtomed to retirement, to which mode of life he was obliged to recur, on account of his deafneſs and other bodily infirmities, he ſought the comforts of a domeſtic life; and in 1759, he married a lady of reſpectable family, the aunt of the celebrated Sauſſure, with whom he paſſed 37 years of connubial felicity. In the proſecution of his phyſical ſyſtem, Bonnet publiſhed at Amſterdam in 1762, his "Conſiderations on organized bodies," 2 vols. 8vo. The principal objects of this work were, to detail, in an abridged form, all the moſt intereſting and well aſcertained facts, reſpecting the origin, developement, and reproduction of organized bodies; to refute the different ſyſtems founded upon "epigeneſis;" and to explain and defend the ſyſtem of germs. His "Contemplation of Nature," which appeared in 1764, Amſt. 2 vols. 8vo., was a popular work, diſplaying the principal facts relating to the different orders of created beings, in an inſtructive and entertaining manner, and recommended by the charms of an eloquent ſtyle, with a conſtant reference to final cauſes, and the proofs of wiſdom and benevolence in the creator. This was tranſlated into ſeveral European languages, and enriched with notes by the author himſelf, and alſo by others, in a new edition. His concluding work was his "Palingénéſie Philoſophique," printed at Geneva in 1769, 2 vols. 8vo. This treats on the paſt and future ſtate of living beings, and ſupports the idea of the revival of all animals, and the perfecting of their faculties in a future ſtate. To this work he annexed "An inquiry into the evidences of the Chriſtian revelation, and the doctrines of Chriſtianity, which, with a piece "On the exiſtence of God," was publiſhed ſeparately at Geneva in 1770.

Towards the year 1773 he reſumed his attention to natural hiſtory, and publiſhed, in Rozier's journal, a memoir on the method of preſerving inſects and fiſh in cabinets. In the following year he ſent to the ſame journal a memoir on the loves of plants, originating in the diſcovery of a kind of cleft or mouth in the piſtil of a lily. Other memoirs contained a detail of his experiments on the reproduction of the heads of ſnails, and of the limbs and organs of the water ſalamander. He alſo made obſervations on the pipa or Surinam toad, on bees, on the blue colour acquired by muſhrooms from expoſure to the air, and on various other ſubjects in natural hiſtory. His reputation introduced him as an aſſociate into moſt of the literary ſocieties of Europe; and in 1783 he was elected into the ſelect number of foreign aſſociates of the academy of ſciences in Paris. His correſpondence was extenſive, and his attention to public duties exemplary. In the great council of the republic into which he entered in 1752, and in which he had a ſeat till 1768, he diſtinguiſhed himſelf by his manly eloquence in the ſupport of wiſe and moderate meaſures, and his conſtant zeal in the cauſe of morals and religion, with which, in his opinion, the proſperity of the ſtate was eſſentially connected. The laſt 25 years of his life were ſpent altogether in the country, where he enjoyed, with a competence, the intercourſe of choſen friends. Some part of his time was employed in the education of youth, for which office he was admirably qualified. The reviſal of his works occupied near eight years of his life, and required a degree of application which was injurious to his health. This collection appeared at Neuchatel, in 9 vols. 4to. or 18 vols. 8vo. and contains, beſides the works already mentioned, ſeveral ſmaller pieces in natural hiſtory and metaphyſics. They are all written in French. Towards the year 1788 he manifeſted alarming ſymptoms of a dropſy in the breaſt; and theſe became more aggravated in proceſs of time, and occaſioned a variety of ſufferings which he endured with patience and ſerenity, till at length he was releaſed by death, May 20, 1793, at the age of 73 years. Public honours were rendered to his remains by his fellow citizens; and his funeral eulogy was pronounced by his illuſtrious friend and kinſman, M. de Sauſſure. Mem. pour ſervir a l'Hiſt. de la Vie et des ouvrages de M. Charles Bonnet; Berne 1794. Gen. Biog.

Bonnet, Jaques, publiſhed, in 1726, at Amſterdam, "Hiſtoire de la muſic," the hiſtory of muſic and of its effects from its origin to the preſent time, explaining, in what its beauty conſiſts, 4 vols. 12mo. This hiſtory was at firſt undertaken by the abbé Bourdelot, uncle to the editor of this work, and diſtinguiſhed by his erudition. Bonnet Bourdelot, brother of Bonnet, the firſt phyſician to the ducheſs of Burgundy, continued it after the death of his uncle, and at length arranged and digeſted the materials which he found among the MS. papers of his uncle and his brother. Indeed the firſt volume only was written by Bonnet; the three laſt were compiled in a patriotic fury by Frencuſe, a phyſician, in 1705, who died in 1707, in the flower of his age, having only arrived at his 33d year. He ſeems to have been wholly ſtimulated to this undertaking by the abbé Raguenet's parallel between the muſic of the Italians and the French; which, though written with the utmoſt circumſpection and civility to France, M. Frencuſe thought too favourable to Italy; and inſtead of a continuation of the hiſtory of muſic, has given us nothing but a violent philippic againſt the abbé Raguenet, for daring to draw a parallel between the muſic of France and Italy, and a cenſure of all the moſt illuſtrious Italians of the 17th century, ſuch as Cariſſimi, Luigi Roſſi, Scarlatti, and Corelli; and ſetting up Lulli againſt them all, has formed his refutation of the abbé into three dialogues; in which two of the interlocutors are champions for Lulli, and only one, and that a lady, neither a deep logician, nor a powerful advocate for the Italians, is the heroine that undertakes their defence. But the poor Italians have no quarter

ter given them; not only their muſic and ſinging, but even their language is cenſured for its eliſions, its metaphors, its ſimilies, conſtruction, and inverted phraſes.

The execution of the Italians he compares to the dexterity of the ſoldier who was brought to Alexander, to exhibit a trick which he had acquired by infinite pains and practice, of chucking a pea into a diſtant hole which juſt fitted it. When all the reward which the great conqueror beſtowed upon the ſoldier for his uſeleſs application of time was, to order him a peck of peas.

Indeed all the praiſe that is due to Bonnet for the firſt part of what he calls a hiſtory of muſic, is, the having collected materials towards a hiſtory of the art; but he was no muſician, and equally unable to explain the theory of the ancients as the practice of the moderns: ſo that his work is totally devoid of taſte, order, and uſeful information.

Bonnet, or Bonet, Theophilus, an eminent and reſpectable practiſing phyſician, and voluminous writer in medicine, of Geneva, where he was born, March 5th, 1620. Following in the ſteps of his father and grandfather, he early attached himſelf to the practice of phyſic. After viſiting ſeveral foreign academies, he was admitted doctor in medicine at Bologna, in 1643, and was ſoon after made phyſician to the duke de Longueville. Though he ſoon attained to high credit in his profeſſion, and had a large ſhare of practice, he dedicated a conſiderable portion of his time to reading, and to diſſecting ſuch ſubjects as the hoſpital afforded him, with a view of diſcovering the ſeats of the diſeaſes, under which the patient had laboured; minuting every deviation he obſerved from the natural ſtructure of the viſcera, or other parts of the body, and thus opening a new road for improving the ſcience he cultivated. He alſo appears to have made extracts of every thing he deemed worthy of notice, from the various works he read. His hearing from ſome accident becoming defective, he withdrew from practice, and employed the laſt ten or twelve years of his life in arranging the materials he had collected. The firſt fruit of his labour, which he gave to the public, in 1668, was "Pharos medicorum," 2 vols. 12mo. This was printed again, much improved and enlarged, in 1679, in 4to. under the title of "Labyrinthi medici, extricati," &c. compiled principally from Bellonius and Septalius. In 1675, "Prodromus anatomiæ practicæ, ſive de abditis morborum cauſis," fol.; the precurſor of his principal work, "Sepulchretum, ſeu anatome practica, ex cadaveribus morbo denatis proponens hiſtorias et obſervationes," &c. 2 vols. fol. Genev. 1679, which far exceeded the expectation raiſed by the prodromus. It was enlarged by nearly a third part, and republiſhed by Manget, 2 vols. fol. 1700, and was afterwards taken by Morgagni, as the baſis of his work, "De ſedibus, et cauſis morborum," by which the ſepulchretum is in a great meaſure ſuperſeded. The author begins with obſervations on the appearances of the brain and other parts of the head; then of the contents of the thorax, abdomen, and pelvis; and laſtly, of the extremities; forming an immenſe body of diſſections, which he has illuſtrated by many pertinent and ingenious obſervations. "Cours de medicine, et de la chirurgie," 2 vols. 4to. 1679. An epitome of the art of ſurgery, with ſome ſections relating to the practice of medicine, ſelected from the moſt accredited authors of the age. "Medicina ſeptentrionalis, collectitia," 2 vols. fol. 1684. ſhewing how largely the practitioners of the northern parts of Europe, Sweden, Denmark, Germany, Holland, and England, have contributed to the improvement of anatomy, ſurgery, and medicine, by extracts and accounts of the works of the principal writers of thoſe countries. "Mercurius compilatitius, ſeu index medico-practicus, deciſiones, cautiones, obſervationes in ſingulis affectibus, &c. oſtendens tutam medendi viam," fol. 1682. A moſt uſeful work, ſhewing under the name of every diſeaſe or affection where caſes or obſervations may be found, and what authors have written upon them. Such an index continued to the preſent time, though very voluminous, would be highly uſeful. Bonet alſo publiſhed "Epitome operum Sennerti," fol. 1685, and "J. D. Turqueti de Mayerne, de Arthritide," 1671, 12mo. and "Rohaulti tractatus phyſicus, e Gallico in Latinam verſus," 1675, 8vo. He died of a dropſy, March 3, 1689. Hall. Bib. Med.

Bonnet, in a general ſenſe. See Cap, Hat, Mitre, &c.

Bonnet, in *Fortification*, a kind of little ravelin, without a ditch, having a parapet three feet high; anciently placed before the points of the ſaliant angles of the *glacis;* being paliſadoed round; of late alſo uſed before the angles of baſtions, and the points of ravelins, and fauſſebrayes. See *Plate Fortif.*

The bonnet has two faces, from ten to fifteen, or more rods long: the parapet is made of earth, from thirty to thirty-ſix feet thick, and from nine to twelve feet high: it is environed with a double row of paliſadoes ten or twelve paces diſtant from each other; hath a parapet three feet high, and is like a little advanced *corps du guard.*

Bonnet *à prêtre*, or *prieſt's cap*, is an outwork, having at the head three ſaliant angles, and two inwards.

It differs from the *double tenaille* only in this, that its ſides, inſtead of being parallel, grow narrower, or cloſer at the gorge, and open wider at the front; on which account it is alſo denominated *queue d'aronde*, or ſwallow's tail.

Bonnet, in *Geography*, a river of the county of Leitrim, in Ireland, which paſſes within four miles of Lough Clean, from which the Shannon iſſues, and carries boats into Lough Gilly, and thence into Sligo bay. Dr. Beaufort obſerves, that the day may come, when the ſpirit of enterpriſe and commerce will open itſelf a paſſage by this channel alſo. Beaufort.

Bonnet, *St.* a town of France, in the department of the Higher Alps, and chief place of a canton, in the diſtrict of Gap, 2½ leagues N. of Gap. The place contains 1508, and the canton 10,284 inhabitants; the territory comprehends 245 kiliometres, and 20 communes.

Bonnet *le Chateau*, *St.* a town of France, in the department of the Loire, and chief place of a canton, in the diſtrict of Montbriſon, 4 leagues S. of Montbriſon. The town contains 1506, and the canton 12,945 inhabitants. The extent of the territory includes 192½ kiliometres, and 10 communes.

Bonnet *le Caſtel*, *St.* a town of France, in the department of the Puy de Dôme; 5 leagues N. E. of Brioude.

Bonnet *de Bruyères*, *St.* a town of France, in the department of the Rhone and Loire, and chief place of a canton, in the diſtrict of Villefranche, 6 leagues N. of Villefranche.

Bonnet *de Chavagne*, *St.* a town of France, in the department of the Iſere, and chief place of a canton, in the diſtrict of St. Marcellin, 1½ league S. W. of St. Marcellin.

Bonnet *de Joux*, *St.* a town of France, in the department of the Sâone and Loire, and chief place of a canton, in the diſtrict of Charolles, 2¼ leagues N. E. of Charolles. The town contains 1321, and the canton 6140 inhabitants; the territory comprehends 160 kiliometres, and 7 communes.

Bonnet, in *Heraldry*, a cap of velvet worn within a coronet.

Bonnet *pepper*, in *Botany*. See Capsicum annuum.

Bonnet, in *Sea-Language*, an additional part of a ſail,

laced at the bottom or foot of the fore-ſail, try-ſail, and ſtorm main-ſails, of ſome veſſels with one maſt, in moderate winds. It is made like the foot of the ſail for which it is intended, and has latchings in the upper part, to correſpond with and fall through holes in the foot of the ſail, by which it is faſtened.

The words in reference to it are, *lace on the bonnet*, that is, faſten it to the courſe; *ſhake off the bonnet*, that is, take it off the courſe.

Bonnet *chinois*, in *Conchology*, is the common or trivial name applied by French collectors to the Patella Chinensis, in the ſame manner as we ſhould call it in Engliſh the *Chineſe bonnet*, or limpet ſhell; thus alſo the French *Bonnet de Pologne*, for the Linnæan *Buccinum teſticulus*, &c.

Bonnet *chinois*, in *Zoology*, the French name of Simia Sinica, Gmel. or Chineſe ape of Pennant's ſynopſis, a ſpecies that inhabits the country of Bengal. See Sinica. Obſ. The ſame animal is called *Guenon couronée*, by late French writers.

BONNETABLE, in *Geography*, a town of France, in the department of the Sarthe, and chief place of a canton, in the diſtrict of Mamers. The place contains 4587, and the canton 11051 inhabitants; the territory comprehends 105 kiliometres, and 10 communes.

BONNETELLA, in *Entomology*, an European ſpecies of Tinea, deſcribed by Linnæus, in *Fn. Suec.* Fabricius and others. The wings are white, with two little ſilvery lines, the poſterior one of which is waved.

BONNETIA, in *Botany*. (in honour of Charles Bonnet of Geneva,) Schreb. 915. Willden 1050. Mahuria Aublet 222. Juſſ. 434. Encyc. method. Claſs, *polyandria monogynia*. Nat. Ord. uncertain. Juſſ. Gen. Char. *Cal.* of one leaf deeply divided into five ovate, acute, concave ſegments, two larger than the others. *Cor.* petals five, ovate, ſomewhat obtuſe, concave, longer than the calyx, the three ſuperior ſmaller, upright; two lower larger, inclined, at a diſtance from each other. *Stam.* filaments very numerous, inſerted into the receptacle, ſhorter than the coroll, dilated at the top. Anthers yellow, oblong, tetragonal. *Piſt.* germ ſuperior ſmall, oblong. Style incurved. Stigma hollow, three-lobed. *Pericarp.* capſule dry, membranous, oblong, three-celled, three-valved, valves ſharp pointed. *Seeds* many, ſmall, black, oblong, involved in a coloured membrane, affixed to the three-ſided receptacle.

Eſſ. Char. *Cal.* five-parted, two parts larger. *Cor.* five-petalled, three ſmaller upright, two larger inclining. *Capſ.* oblong, three-celled, three-valved, many ſeeded.

Species. B. *paluſtris*. Lamark. Illuſt. tab. 464. A tree fifteen feet high, ſeven or eight inches in diameter; branches upright, chiefly towards the top of the trunk; leaves alternate, petioled, ovate, entire, ſmooth; petioles chanelled, with two ſmall ſtipules at their baſe; flowers purple, ſpiked, one, two, or three together, furniſhed with three ſcaly bractes, one larger at the baſe of the peduncle, the two others lateral. A native of Cayenne and Guiana.

BONNEVAL, Claude-Alexander, *Count of*, in *Biography*, a deſcendant of an ancient family of Limouſin, was born in 1672, and having entered betimes into the army, ſerved with diſtinction in Italy under Catinat and Vendome. Abandoning his country in 1706, and entering into the ſervice of the emperor, a ſentence was procured againſt him by the miniſter Chamillart, which ſubjected him to decapitation. Notwithſtanding this proſcription, he ventured to Paris, and publicly married a lady of the family of Biron. In 1716 he ſerved againſt the Turks under prince Eugene, and was a major at the battle of Peter-Waradin, where he behaved with ſingular valour; but in 1720 he had a diſpute with prince Eugene, and challenged him, for which offence he was deprived of his employment, and condemned to a year's impriſonment. Upon regaining his liberty he meditated revenge, went over into Turkey, became a muſſulman, and was created a haſhaw of three tails, general of artillery, and at laſt, maſter of the ordnance. In this ſituation he introduced European improvements among the Turks, and lived much eſteemed to the age of 75 years. He left a ſon, who ſucceeded him in the office. He was a man of quick parts, courage, and ability; but ſingular in his conduct, quarrelſome in his diſpoſition, and addicted to ſatire. Upon changing his religion, he ſaid, "It was only changing his night-cap for a turban." With all his eccentricities he preſerved a calm temper; and ſaid, "In all my perſecutions I never loſt my appetite or good humour. Happy thoſe who have philoſophy in their blood!" His "True Memoirs," and his "New Romantic Memoirs," were publiſhed in London, in 1755. Nouv. Dict. Hiſt.

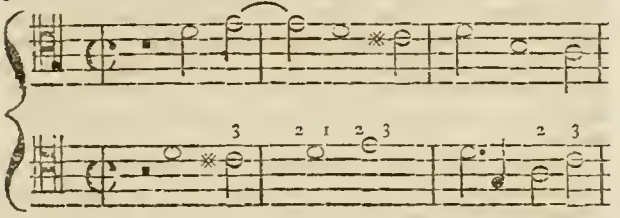
Bonneval, in *Geography*, a town of France, in the department of the Eure and Loire, and chief place of a canton, in the diſtrict of Chateaudun, ſeated on the Loire. The place contains 1551, and the canton 10,638 inhabitants; the territory comprehends 337½ kiliometres, and 27 communes.

BONNEVILLE, a town of Savoy, the chief place of a diſtrict in the department of Leman, and before the French revolution, the capital of Faucigny, ſeated on the banks of the Arve, at the bottom of a chain of rocks, which from this place diminiſh into hills. The adjacent country is a rich plain, producing plenty of wine and corn, but neither populous nor well cultivated. The place contains 590, and the canton 9286 inhabitants; the territory comprehends 165 kiliometres, and 15 communes. N. lat. 46° 11'. E. long. 6° 15'.

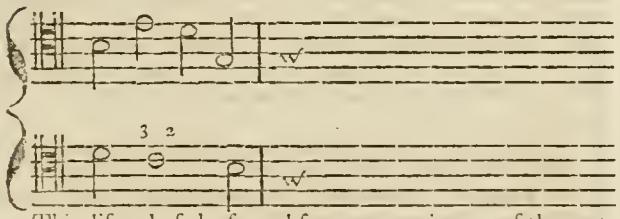
Bonneville-*des-Bouchoux*. See Bouchoux.

BONNIE'RES, a town of France, in the department of the Seine and Oiſe, and chief place of a canton in the diſtrict of Mantes; the place contains 769, and the canton 11.984 inhabitants; the territory comprehends 207½ kiliometres and 27 communes.

BONNY, a town of France, in the department of the Loiret, and chief place of a canton in the diſtrict of Gien; containing about 1300 inhabitants; 3 leagues S.S.E. of Gien.

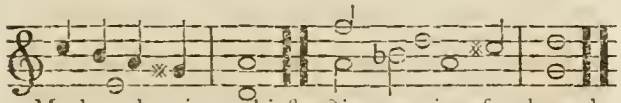


Bonny, a river of North Africa, which forms the æſtuary of New Calabar, in the kingdom of Benin, diſcharging itſelf into the bay of Biafra. N. lat. 4° 40'. E. long. 6° 30'.



Bonny, in *Mineralogy*, a name given by our miners to a bed of ore found in many places in hills, not forming a vein, nor communicating with any other vein, nor terminating in ſtrings, as the true veins do; it is a bed of ore of five or ſix fathoms deep, and two, or ſomewhat leſs than that, in thickneſs, in the larger ſort; but there are ſmaller, to thoſe of a foot long. They have their trains of ſhoad-ſtones from them, and often deceive the miners from the expectation of a rich lead vein. They differ from the ſquatts only in being round beds of ore, whereas thoſe are flat. Phil. Tranſ. N° 69. p. 2098.

BONO *et malo, Writ, de*, in *Law*, a ſpecial writ of gaol-delivery was anciently uſed for each particular priſoner under this title: but theſe being found inconvenient and oppreſſive, a general commiſſion for all the priſoners has long been eſtabliſhed in their ſtead. 2 Inſt. 43.



BONONCINI, Gio. Maria, in *Biography*, Modaneſe Accademico Filarmonico di Bologna, and father of the celebrated John and Anthony Bononcini, publiſhed in 1673, a work

work entitled "Il Muſico Practico," or the Practical Muſician, dedicated to the emperor Leopold, in thin quarto. This treatiſe contains many uſeful precepts, and examples of compoſition; but is neither ſo accurate as to be implicitly followed, nor ſo ample as to ſupply all the wants of a muſical ſtudent of the preſent times. Page 18, he ſpeaks of a canon, in his opera terza, for fifteen hundred and ninety-two voices, or ſix hundred and forty-eight choirs; which, on account of the difficulty of finding ſuch a number of ſingers aſſembled together, he has reduced to twenty-two. In the hiſtorical part of this tract, his knowledge is not very profound, or reading extenſive; and the authors he cites, in ſupport of his information, give it no additional weight. The examples he has given of the uſe of the ſecond, page 64, are, in many inſtances, erroneous, and ſuch as can be found in the works of no good contrapuntiſt of the laſt century. The ſecond is not only confounded with the ninth by this author, page 64, but improperly prepared and reſolved.

This diſcord of the ſecond ſeems to require one of the parts to remain ſtationary, till the ſuſpended harmony is completed; but Bononcini often puts both parts in motion. In his example of counterpoint upon a plain ſong, page 76, there are other diſallowances.

Much explanation and inſtruction are given for the eccleſiaſtical modes, but none of the keys, uſed in ſecular muſic, are defined or aſcertained.

Bononcini, John, the celebrated opera compoſer, and rival of Handel, was the ſon of Gio. Maria Bononcini, of Bologna, the ſubject of the preceding article. He firſt arrived in England in 1720, on the eſtabliſhment of our famous "Corporation of the Royal Academy of Muſic," under the auſpices of king George I. and the principal nobility and gentry in the kingdom; for the ſupport of which 50,000l. were ſubſcribed. We have now before us the original deed and covenant, with the ſeal and ſign manual of all the ſubſcribers, who became academicians, and bound themſelves and their reſpective executors, adminiſtrators, and aſſigns, to pay all ſuch reſpective ſum or ſums as ſhall from time to time be demanded out of their ſubſcription, &c. The king ſubſcribed 10000l. and the reſt, to the number of 73, in this original liſt, 200l. each.

It is a curious record to be in poſſeſſion of the autography of ſuch a number of the heads of our moſt ancient and illuſtrious families thus preſerved. It is not, indeed, equally important or honourable with the liſt of the barons who ſigned the Magna Charta; but it is ſuch a memorial of our proſperity, good-humour, patronage of a polite art, and happineſs, that we would give a ſac-ſimile of each ſignature on a copper-plate, if we had room.

In order to render this academy as complete as poſſible, it was determined by the directors not only to engage a lyric poet in their ſervice, but the beſt vocal performers that could be found in the ſeveral parts of Europe where there was a muſical theatre, and the three moſt eminent compoſers then living who could be prevailed upon to viſit this country. For this purpoſe Bononcini was invited from Rome, as he tells us himſelf, in the dedication of his Cantatas and Duets to George I. (Qui mi trovo, chiamata da Roma per ſervigio della real Accademia di Muſica). Attilio Arioſti, from Berlin, was likewiſe engaged as a compoſer on this occaſion; and Handel, who reſided at this time with the duke of Chandos, at Cannons, was not only included in the triumvirate, but commiſſioned to engage the ſingers.

During the firſt year of this eſtabliſhment, theſe three compoſers furniſhed new operas alternately, till January 1721, when, for diſpatch, an act of the opera of Muzio Scavola was aſſigned to each of theſe maſters; the firſt act to Attilio, probably from ſeniority, as he was far from young when he came hither; the ſecond act to Bononcini, at that time about 50; and the third to Handel, the youngeſt of the three.

As this diviſion of the drama ſeemed to imply a contention and trial of ſkill, the public took ſides, perhaps leſs from feeling than the ſpirit of party; for party whets our appetites for pleaſure as well as politics. Many of the nobility and gentry, who had been in Italy, and had witneſſed the applauſe which Bononcini had received there as a compoſer, were partial to him here. While others who had viſited the court of Hanover before the deceaſe of queen Anne, and knew the favour in which Handel had ſtood with the elector, as a great performer on the organ and harpſichord, before his compoſitions were much known, and afterwards had heard his productions performed in London, were unwilling to be pleaſed with the compoſitions of his principal rival. Attilio, though a good muſician, ſeems to have been out of the queſtion; neither his fame nor talents being equally ſplendid with thoſe of the other two, by whom, and for whom, the conflict continued with as great a rage as between the houſes of York and Lancaſter, till the year 1727; when Bononcini, after the run of the laſt and beſt opera which he had compoſed in England, "Aſſyanax," quitted the conteſt with Handel, and ceaſed to write for the ſtage. But the feuds among the friends of theſe great muſicians, which Swift's epigram had rendered ſo riſible, did not end here, but continued as long as Bononcini remained in this country.

Here, as his biographer, it ſeems our duty to give his real character as a compoſer. He was ſeldom heard on the violoncello in this country, though as a performer on that inſtrument he was extremely admired in Italy; and his melody was, perhaps, more poliſhed and vocal, though not ſo new as that of his powerful Saxon rival. Having been born and nurſed in Italy, where ſinging was ſo highly cultivated, he was reported by all his countrymen to ſing in a moſt exquiſite taſte. His recitative too, both in writing and utterance, was univerſally allowed to be the beſt of the time, and in the true genius of the Italian language; but as a correct, powerful, and inventive compoſer, he was an infant compared with Handel.

Of all the works which this celebrated compoſer publiſhed in England, his book of "Cantate e Duetti," dedicated to his

his majeſty George I. in 1721, the year after his arrival here, ſeems the beſt. In 1722, his "Divertimenti da Camera, tradotti (tranſpoſed or accommodated) pel Cembalo da quelli compoſiti pel Violino e Flauto," were publiſhed by himſelf, and ſold at his lodgings in Suffolk-ſtreet. In theſe we meet with pleaſing and maſterly paſſages, but they are ſo inferior in force, contrivance, and invention, to the leſſons of Handel, that even his admirers, on a comparative view, muſt have regarded them as frivolous and trivial. The *adagios* are the beſt movements in them, and have notes of taſte and paſſages of expreſſion, which muſt have been then new to Engliſh ears. Bononcini, however, like other compoſers of his time, is very ſparing of his paſſages, and indulges idleneſs and want of invention by frequent *reſalias*, or repetitions, which Handel ſeems always to avoid more than any compoſer of this period, except the Scarlatti's, father and ſon. In ſeveral of theſe leſſons the ſubject is heard in one part or other throughout a whole movement; as in the minuet, page 35, the firſt bar is perpetual.

His funeral anthem for the duke of Marlborough, was ſet and performed the ſame year, 1722. The ſhort ſymphony, and whole firſt movement are grand, and of a melancholy caſt. The ſecond movement has not much to recommend it. The third is more languid, than paſſionate or pathetic. The fourth is plaintive, but was not new at the time it was written. The fifth and laſt movement has muſical merit, but none of true feeling, or genius; no "heart-rending ſighs," or ſuch exclamations of ſorrow and affliction as would naturally be expected from a man of great abilities, who either felt the words or the loſs of his patron.

Bononcini was a celebrated and voluminous compoſer long before he arrived in England: his eighth work, conſiſting of "Duetti da Camera," was dedicated to the emperor Leopold, and publiſhed at Bologna in 1691. The ſeven operas he compoſed during his reſidence in England, make but a ſmall part of his dramatic productions. He produced two operas at Rome in 1694; after this he went to Vienna, where he compoſed many operas and oratorios for the imperial court and chapel. In 1720, he was again in high reputation as a dramatic compoſer at Rome, whence he was invited to London by the directors of the Royal Academy of Muſic. In 1732, he publiſhed "Twelve Sonatas for two Violins and a Baſe." It was about this time that he was accuſed of arrogating to himſelf a madrigal compoſed by Lotti of Venice, and publiſhed in that city in 1705, in a work entitled "Duetti, Terzetti, e Madrigali a più Voci," dedicated to the emperor Joſeph. The title of the madrigal is "La vita caduca" and has for initial line "In una ſiepe ombroſa." We are in poſſeſſion of the book in which this compoſition was printed, and, upon examination, are extremely aſtoniſhed that Bonocini would riſk the great reputation of which he was already in poſſeſſion, for a production which could increaſe it ſo little. The counterpoint of this madrigal is certainly correct, but it is dry, and all the ſubjects of fugue are ſuch as had been uſed by thouſands before Lotti was born. There are many madrigals by much older maſters, particularly Luca Marenzio, Stradella, and the elder Scarlatti that are learned and pleaſing in modulation, and more fanciful and agreeable in the traits of melody that are uſed as ſubjects of imitation. Indeed, Bononcini's plagiariſm was as weak as wicked. We uſed to doubt the truth of the charge, from an idea that his reputation was ſo well eſtabliſhed, and his genius ſo fertile, that he had not the leaſt occaſion to have recourſe to ſuch illicit means of extending it. The crime of theft is very much aggravated when the thief is not impelled to it by want. Rich men and miſers have, however, been often detected in illegal appropriation. Yet upon a careful and critical examination of the works of John Bononcini, we think his wealth did not conſiſt in rich and deep mines of ſcience, nor were his reſources in learned and elaborate compoſition, either in the eccleſiaſtical or madrigal ſtyle, very great. His performance on the violoncello, his cantatas, and his operas, had been admired in every part of Europe; but not content with partial fame, he aimed at univerſality. In his anthem for the funeral of the duke of Marlborough, he attempted to rival Handel in his grand church ſtyle; and finding in how much veneration well written madrigals were held at the Academy of Ancient Muſic in London, where Handel at this time was regarded as a modern, and an innovator, he was tempted to riſk the reputation he had fairly acquired, by trying to augment it in an illegal manner. Tradition had filled our minds with ideas of his abilities, which the examination of his works has diminiſhed; while a ſtrict ſcrutiny into the productions of Handel has greatly augmented our veneration for that compoſer. We have now before us, in a printed pamphlet, all the letters that paſſed between the ſecretary of the Academy of Ancient Muſic and ſignor Ant. Lotti on this occaſion, with ſuch teſtimonies and certificates, from the moſt reſpectable profeſſors at Venice and Vienna, in proof of the madrigal in diſpute having been compoſed by that maſter and not by Bononcini, that not the leaſt doubt remains of the fact.

Soon after the funeral of the duke of Marlborough, the counteſs of Godolphin, who, upon the death of her father, became ducheſs of Marlborough, as ſettled in his patent of creation, received Bononcini into her houſe, in the Stable-yard, St. James's, and ſettled on him a penſion of 500l. a year. Here he lived in eaſe and affluence, enjoying as an artiſt the *otium cum dignitate* in its full extent; the ducheſs having concerts twice a week, in which no other muſic was performed to the firſt people in the kingdom than the compoſitions of her favourite maſter, executed by the principal ſingers of the opera. It is ſuppoſed that he gained a 1000l. by the book of cantatas which he publiſhed by a two-guinea ſubſcription; many of the nobility ſubſcribing for five or ten copies; the duke and ducheſs of Queenſbury for twenty-five books each, and the counteſs of Sunderland alone for fifty. After the diſpute concerning this madrigal, his importance and reputation diminiſhed conſiderably; and about the year 1733, he quitted the kingdom. After which he reſided at Paris for ſeveral years, where he compoſed maſſes and motets for the chapel royal. At the concluſion of the peace of Aix la Chapelle in 1748, he was invited to Vienna by the emperor of Germany to compoſe the muſic for that occaſion, and is ſaid to have been preſented with eight hundred ducats for his trouble. After the celebration of the peace was over, quitting Vienna in company with Monticelli, he ſet off in the ſame poſt-chaiſe with this celebrated ſinger for Venice, where they were both engaged, Bononcini as compoſer, and Monticelli as firſt man, in the operas for the enſuing Carnaval in that city. Here we loſe ſight of this renowned compoſer, who if we ſuppoſe him to have been no more than thirty years of age in 1691, when his eighth work was printed at Bologna, and dedicated to the emperor Leopold, he muſt at this time have attained his eighty-ſeventh year; which will give weight to the general opinion, that his life was extended to near a century!

Bononcini, Antonio, brother of John, and an opera compoſer, little leſs renowned in Italy, than the author of *Griſelda* and *Aſtyanax*. It has always been imagined that the famous opera of *Camilla*, the ſecond attempt at that ſpecies of drama in England, in 1706, was ſet by John Bononcini; but we can find no proof of it in any one of the numerous volumes of operas in our poſſeſſion, or dramatic records

records that we have been able to conſult. "Camilla Regina de Volſci," written by Stampiglia, and ſet by Marc Antonio Bononcini, the brother of John, for the imperial court of Vienna, about the year 1697, was in ſuch favour all over Italy, that it was performed at Venice, 1698; Bologna, 1705; Ferrara, and Padua, 1707; Bologna again, 1709; Udine, 1715; and a third time at Bologna, 1719; and ſeems to have been the opera that was performed in England, during 1706, fifteen times; 1707, twenty; 1708, ten; and 1709, eighteen; in all ſixty-four times!

BONONIA, in *Ancient Geography*, a town of Gallia Ciſpadana, called Felſina, at the time when the Etruſcans were maſters of the northern part of Italy, and then their capital; ſuppoſed by ſome to have been founded by an Etruſcan prince, denominated Felſinus. But when theſe firſt poſſeſſors were driven away by the Boians, it acquired the name of Bononia. In the year of Rome 564, the Romans conducted a colony to this place, with a view of fortifying this ſide of the country. It afterwards became a municipal city; and owed much of its magnificence to Auguſtus. See Bologna.—Alſo, a town of Upper Pannonia, placed by Ptolemy on the Drave.—Alſo, a town of Dacia Ripenſis. Not. Imp.—Alſo, a town of Upper Mœſia, in the route from Viminiacum to Nicomedia, between Dorticon and Ratiaria. It. Antonin.—Alſo, a town of Lower Pannonia, in the route along the Danube, between Cuſi and Cucci, 19 miles from Sirmium, according to Ammianus Marcellinus.

BONONIAN Stone, a ſmall, grey, ſoft, gloſſy, fibrous, ponderous, ſulphureous ſtone, about the bigneſs of a large walnut, or even of an orange; when broken, having a kind of cryſtal, or ſparry talc within; found in the neighbourhood of Bologna, or Bononia, in Italy; and, when duly prepared, making a ſpecies of phoſphorus. It is of no certain figure; but is ſometimes round, ſometimes oblong and cylindric, and ſometimes denticular, which laſt kind is ſaid to be the moſt ſhining and tranſparent. Its colours are various; ſome being aſh-coloured, others of a ſky-blue, ſome of a ferruginous colour, others yellow, others greyiſh white, and ſome almoſt perfectly white. The beſt for uſe are ſaid to be the ſky-coloured and the white. This ſtone is found in ſeveral parts of Italy, but eſpecially in the diſtrict of Bologna, towards the Apennine mountains, and on mount Paleino, or Paterno, about five Italian miles from Bologna. They are moſt commonly found after heavy rains, among the earth waſhed off from the neighbouring mountains. In this caſe the ſeveral maſſes of it appear, when the earth is waſhed away, as bright as burniſhed ſilver, or with the glittering of talc reſembling the gloſs of a looking-glaſs. This ſtone is the ponderous ſpar, or combination of vitriolic acid with ponderous earth. See Spar.

A chemiſt, whoſe name was Vincenzo Caſciarolo, having gathered ſome pieces in a river at the foot of mount Paterno, carried them home, in hopes by the fire to draw ſilver out of them; but inſtead of what he expected, found that admirable phenomenon they exhibit, which conſiſts in this, that having been expoſed to the light, they retain it, and ſhine in the dark. This diſcovery was made about the year 1630.

The property of this ſtone is, that though it has no lucid appearance in the dark, until it undergoes a particular calcination, it becomes capable, by previous preparation, of imbibing, when expoſed for a few minutes to the light of day, or even to the flame of a candle, ſuch a quantity of light, that it afterwards ſhines in the dark for an interval from eight to fifteen minutes, like a glowing coal, but without any ſenſible heat. The light it emits is ſufficient to read by, if the letters be placed near it. It does not retain its light long, but requires often renewing; and when well prepared, its virtue will laſt five or ſix years, but ſeldom longer. The method of uſing it to the greateſt advantage, is to remain for ſome time in a dark room, and to introduce the calcined ſubſtance immediately after its being expoſed to the light.

M. Homberg is ſaid to be the firſt perſon who taught us the true manner of preparing and calcining the Bononian ſtone, having made a journey to Italy on purpoſe to learn it. Though others allege, that the true art of preparing and calcining the ſtone is loſt; there having been but one, an eccleſiaſtic, who had the true ſecret, and who is ſince dead, without communicating it to any perſon. See Phil. Tranſ. N° 21.

M. Homberg, on his return from his travels in Italy, brought with him a great number of theſe ſtones, and calcined 200 of them in ſo many different ways, that he at laſt found out the ſecret. His method was as follows:—He firſt ſcraped the ſtone all over, till it appeared like talc; then, having ſoaked it thoroughly in brandy, and incloſed it in a paſte or cruſt made of other ſtones of the ſame kind pulverized, he calcined it in the fire, or a ſmall furnace. After this operation, he took off all the powder of the cruſt in which the ſtone was incloſed. Both the powder and the ſtone, when brought into the dark from the open air, make a luminous appearance; and the former, if kept in a ſtrong and well-ſtopped phial, when expoſed to the air, imbibes the light, and if ſprinkled on pictures and letters, illuminates them in the dark. In preparing the paſte, the ſtone muſt be pulverized in a braſs mortar. This circumſtance is mentioned by Lemery, who, in his "Cours de Chymie," deſcribes at large the whole proceſs of preparing this ſtone, which he acknowledges to have learnt from Homberg himſelf.

The whole art of preparing this ſtone, ſo as to make it ſhine in the dark, is deſcribed at large in Hook's "Philoſophical Collections," by ſir Marc Antonio Cellio; and in a book of the ſame author, publiſhed at Rome in 1680, on this ſubject: and the ſubſtance has hence been called "Il Fosforo de Marc Anton. Ceilio."

The following has been ſtated as an approved method of calcining this ſtone. Make a cylindric furnace of iron or copper plates, 7 inches in diameter, and as many in height. Line the inſide of it with a ſtrong lute, ſo that the inſide may be 6 inches wide in the clear hollow; at the top of this make four notches, $2\frac{1}{2}$ inches deep, and $1\frac{1}{2}$ inch wide; to this annex a cylindrical part of the ſame diameter, but a little higher; and at the bottom make two aſh-holes, or air-holes, big enough to admit the hand. Line this, like the other, with good lute, and give it a bottom of lute, that it may more powerfully reflect the heat; and line the cover for the top with lute. Into this furnace introduce an iron-wire grate near the bottom, for ſuſtaining the coals, and ſo as to admit of free acceſs of air. On this grate lay ſome pieces of lighted charcoal, and over theſe ſome pieces not lighted, all bruiſed to the ſize of about a walnut. Some of the ſtones muſt be powdered, and thoſe which are to be calcined muſt be dipped in ſtrong aqua vitæ, and while wet rolled in the powder, or the powder itſelf may be made up into thin cakes with mucilage of gum tragacanth. The ſtones, thus covered, or the cakes, muſt be laid upon the bed of charcoal cloſe to one another, and another bed of ſmall pieces of charcoal laid over them to the top of the furnace; the cover of the furnace is then to be put on, and the fire lighted. When the charcoal is entirely conſumed, and the whole is cold, take out the ſtones, and, ſeparating the cruſt from them, wrap them up in ſilk or cotton, and keep them cloſe in a box for uſe. Preſerve the cruſt taken off the ſtones;

for this ſhines as well as the ſtone; and being pulverized, may be rubbed over any ſurface for emitting light, the ſurface being firſt daubed over with the white of an egg in order to make it adhere; and this will ſhine like the ſtone. This kind of furnace is not abſolutely neceſſary to the operation; but it is convenient to know the quantity of charcoal requiſite for giving the ſhining quality to the ſtone; ſince an exceſs of heat deſtroys it, and too ſmall a degree is not ſufficient to produce it. The greateſt degree of phoſphorence ſeems to depend on a due application of the heat. An extreme degree of heat fuſes this ſtone. For other methods of preparing this kind of phoſphorus, ſee PHOSPHORUS. See alſo LIGHT.

This property of affording a phoſphorus by calcination, is common to the other gypſums, when pure from metallic or other heterogeneous mixtures; the artificial gypſums ſucceed equally with the natural, and it is found to belong to a variety of other ſubſtances. M. Margraaf obſerves, that all ſubſtances which have this property, contain a vitriolic acid, united to an alkaline or calcareous earth.

M. Elpigni obſerves, that one Zagonius had a method of making ſtatues and pictures of the Bononian ſtone, which would ſhine variouſly in the dark; but he adds, the perſon died without diſcovering his ſecret. See Phil. Tranſ. N° 134.

BONONIENSIS, in *Ornithology*, the ſpecific name of the greater lapwing, *tringa bononienſis* of Gmelin, and *vanellus bononienſis major* of Briſſon. The legs of this kind are ochraceous; head and upper part of the neck cheſnut; body above black, beneath white; throat and breaſt ſpotted with ferruginous. Gmel. *Obſ.* This is larger than the common lapwing (*tringa vanellus*); the beak is yellowiſh and black at the tip.

BONONIENSIS, *paſſerculus bononienſis* of Briſſon. This is *fringilla brachyura* of Gmelin, or ſhort-tailed ſparrow.

BONOSIANI, or BONOSIACI, in *Eccleſiaſtical Hiſtory*, an ancient branch of ADOPTIANI, in the fourth century, denominated from their leader Bonoſus, a biſhop of Macedonia.

BONPLANDIA, in *Botany*. Cavan. 532. Claſs, *pentandria monogynia*.

Gen. Char. *Cal.* tubular, five-toothed. *Cor.* monopetalous, almoſt labiate; tube longer than the calyx; border with fine emarginate diviſions; the two ſuperior long and ſtraight, the three inferior pendant. *Stam.* five inclining. *Piſt.* germ ſuperior; ſtyle capillary; ſtigma bifid; *Pericarp*, capſule ovate, three ſided; cells three; ſeeds three.

Species, B. *geminiflora*, an annual plant; leaves alternate, ſmooth, lanceolate, toothed; flowers violet, large, axillary, growing in pairs. A native of New Spain.

BONPOURNIKEL, a denomination given to a coarſe kind of bread uſed in Weſtphalia. See BREAD.

BONS-HOMMES, or BON-*Hommes*, in *Eccleſiaſtical Hiſtory*, a ſort of hermits of St. Auguſtin, founded by F. de Paula. They were brought over into England in 1283, by Edmund, earl of Cornwall, and ſettled at Aſhorng, in Bucks, beſides which they had only one houſe more at Edington in Wiltſhire. They followed the rule of St. Auſtin, and wore a blue habit.

The name is ſaid to have ariſen from Louis XI. of France, who uſed to call F. de Paula, prior of the order, *le bon homme*. Till then they had been called the *Minimi*, or order of Grammont. See ALBIGENSES.

BONSDORFII, in *Entomology*, a ſpecies of CURCULIO, of an oblong form. Colour white, with a black band and ſpots; ſnout ſulcated and brown. Bonſd. Curc. Suec. Inhabits Sweden, and is half the ſize of *curculio ſulciroſtris*.

BONTAIN, in *Geography*, a kingdom of the iſland of Celebes, ſituate on the ſouth coaſt, and on the eaſt ſhore of the bay of Boni. It is bounded on the weſt by the river Tino, which divides it from the kingdom of Tourattea; on the north, by the mountains which bear its own name; on the eaſt, by the river Kalekongang; and on the ſouth by the ſea. It was anciently conſidered among the dependent allies of Macaſſer, and governed by their kings; but it has been twice conquered by the arms of the Dutch Eaſt India company and their allies, and was ceded to them, in property, by the treaty of Boni. The country is pleaſant, and fertile in rice. It has a large bay, where ſhips may lie in perfect ſafety during both the monſoons. The ſoundings are good and regular, and the bottom ſoft mud; nor is there is any danger in coming in, except from a ridge of rocks, which are above water, and are a good mark for anchoring. The higheſt land in ſight is called "Bontain-hill." S. lat. 5° 30′; and when a ſhip is in the offing, at the diſtance of 2 or 3 miles from the land, ſhe ſhould bring this hill N. or N½W., and then run in with it and anchor. In this bay there are ſeveral ſmall towns; that which is called "Bontain," lies in the N.E. part of it (S. lat. 5° 10′. E. long. 117° 28′.); and here is a ſmall paliſadoed fort, on which are mounted eight guns, that carry a ball of about eight pounds weight; it is juſt ſufficient to keep the country people in ſubjection, and is intended for no other purpoſe; it lies on the ſouth ſide of a ſmall river, and there is water for a ſhip to come cloſe to it. Wood and water are to be procured here in great plenty; likewiſe plenty of freſh proviſions, at a reaſonable rate: the beef is excellent, but it would not be eaſy to procure enough of it for a ſquadron. Rice may be had in any quantity, and alſo fowls and fruit: in the woods there are herds of wild hogs, which may be purchaſed at a low price, as the natives, who are Mahometans, never eat them; and fiſh may be caught with the ſeine. The tides are very irregular; it is commonly but once high and once low water in 24 hours, and there is ſeldom a difference of ſix feet between them. The inhabitants of Bontain, and thoſe of Boele-Comba and Bera, are the beſt humoured, moſt peaceful, and moſt tractable of all the ſubjects belonging to the Dutch company, in the whole iſland of Celebes.

BONTEMPI, ANGELINI, in *Biography*, a native of Perugia, and author of the firſt hiſtory of muſic in the Italian language with which we are acquainted. He was an able profeſſor, of conſiderable learning, who flouriſhed about the middle of the 17th century. His work, which has for title "Hiſtoria Muſica di Gio. And. Angelmi Bontempi," was publiſhed at Perugia, in ſmall folio, 1695. It is become ſomewhat ſcarce, which enhances its value with collectors of books; and having been long unable to procure a copy, we imagined when one was found, from Broſſard's character of the work, that we were in poſſeſſion of a greater treaſure than on examination it proved to be. For with great parade of his learning, ſcience, and acquaintance with the Greek *theoriſts*, that are come down to us, he leaves us in as utter darkneſs concerning the *practice* of ancient muſic as ever; and, to ſay the truth, he has furniſhed us with but little information concerning the modern of his own time, with which, however, as a contrapuntiſt, he ſeems to have been perfectly well acquainted. Indeed, by the frequent uſe he makes of ſcientific terms, his book, when caſually opened, has more the appearance of a dry mathematical treatiſe, than the hiſtory of an elegant art.

The moſt curious and intereſting part of his work, is the account which he gives of the diſcipline of the college of ſingers in the ſervice of the pontifical chapel, and of the great maſters who then flouriſhed at Rome, who had diſtinguiſhed

guiſhed themſelves in writing "Alla Paleſtrina" for the church; ſecular muſic was then but little cultivated, and leſs reſpected there, till operas and oratorios had made ſome progreſs in poliſhing melody, and in the juſt accentuation and expreſſion of words.

BONTIA, in *Botany*, (in honour of Jacobus Bontius, a phyſician at Batavia, author of a treatiſe "De Medicina Indorum"). Linn. ſpecies 800. Syſt. 579. Reich. 3. 200. Willden. 1208. Schreb. 1062. Juſſieu 127. Claſs, *didynamia angioſpermia*. Nat. Ord. *perſonatæ*—allied to the *ſolaneæ?* Juſſ.

Gen. Char. *Per.* calyx one-leaved, five-parted; ſegments obtuſe, erect, permanent. *Cor.* one-petalled, ringent; tube long, cylindric; border gaping; upper lip erect, reflexed near the end, emarginate; lower ſemitrifid, the ſize of the upper. *Stam.* filaments ſubulate, bending to the upper lip, the length of the corolla; anthers ſimple. *Piſt.* germ ovate; ſtyle ſimple; ſtigma bifid, obtuſe. *Pericarp*, drupe ovate, with an oblique apex. *Seed*, nut oval, one-celled, germinating.

Eſſ. Char. *Cal.* five-parted. *Cor.* two-lipped; lower lip three-parted, revolute. *Drupe* ovate, one-ſeeded, with an oblique apex.

Species, B. *daphnoides*, Barbadoes wild olive. (La Marck Illuſt. Tab. 546.) "Leaves alternate; peduncles one-flowered." Linn. A ſhrub four or five feet high; leaves rather ſtiff, lanceolate, ſmooth, green on both ſides, lower ones ſerrate, upper ones entire. *Flowers* yellowiſh, with a line of duſky purple acroſs the lower lip; axillary ſingle, or in pairs; tube and lower lip hairy. It was cultivated by Mr. Bentick in 1690, and flowered with Dr. Sherard in June 1723.

Propagation and Culture. It is cultivated in Barbadoes for making hedges, and may be raiſed in England from ſeeds ſown on a hot-bed early in the ſpring. It muſt afterwards be tranſplanted into a ſmall pot filled with light earth, and plunged into a moderate tanner's bark hot-bed, with a large allowance of air and water in hot weather, but ſhould always remain in the ſtove. It may alſo be propagated by cuttings in the ſummer. Being evergreen, and growing in a pyramidal form, it makes a pretty variety in the ſtove.

BONTIA, (Brown Jamaic.) See AVICENNIA *germinans*.

BONTIA, (Pet.). See EPIDENDRON *carinatum*.

BONTIA, in *Conchology*, a ſpecies of HELIX, of which ſeveral varieties are deſcribed by Chemnitz. This ſhell is ſomewhat conic, ventricoſe, perforated, and pellucid, with the tip black; on the firſt whorl three yellowiſh bands; aperture ovate. *Helix bontia* is a native of Bengal; the ſhell is extremely fragile.

BONTIUS, JAMES, in *Biography*, a native of Leyden, was educated in philoſophy and medicine, under his father Gerard; and being ſent to the Eaſt Indies, practiſed phyſic at Batavia about the middle of the ſeventeenth century. On his return to Europe he wrote ſeveral valuable works on the diſeaſes and practice of medicine of India. Theſe are, "De conſervanda valetudine, ac dieta ſanis in India obſervandis;" "Methodus medendi, quâ oportet in India orientali uti;" "Obſervationes ſelectæ ex diſſectione cadaverum ac autopſia deſcriptæ." He alſo publiſhed curious obſervations relating to the botany and natural hiſtory of thoſe regions, more eſpecially the vegetables uſed in medicine and diet in his work entitled "De Medicina Indorum," in 1642, and afterwards, with Alpinus's work "De Medicina Ægyptiorum," 4to. 1718. He alſo publiſhed "Hiſtoria Nat. et Med. Indiæ orientalis," fol. in 1658. His brother Regnier was many years profeſſor of medicine at Leyden, and rector of the univerſity. He died in 1623. Haller. Bib. Med. Pract. et Botan.

BONTORY, in *Geography*, a town of Poland, in the palatinate of Braclaw, 20 miles eaſt of Braclaw.

BONVINCINO, ALESSANDRO, called *Le Moretto*, in *Biography*, an eminent painter of hiſtory and portrait, was born at Rovate in 1514, and ſtudied for ſome years under Titian; but he was enamoured with the deſigns of Raphael, which he accidentally ſaw; and devoting himſelf to the aſſiduous ſtudy of thoſe maſter-pieces of art and genius, he became an exceeding good painter. His works are eagerly bought, and much admired for the tenderneſs of the pencilling, the correctneſs and ſpirited expreſſion of the figures, the neatneſs of the finiſhing, and the rich variety of the draperies, conſiſting of velvets, damaſks, or ſatins, copied after nature, and wonderfully imitated. He was equally excellent in portrait, and placed by ſome perſons in competition with Titian. He died in 1564. Pilkington.

BONUS HENRICUS, in *Botany*, (Bauh. &c.) See CHENOPODIUM.

BONZES, or BONZUS, a name given to the prieſts and religious of China, Japan, and Tonquin. This is the appellation under which the prieſts, who are attached to the worſhip of Fo (ſee Fo), are generally known among Europeans. They are called "Talapoins" by the Siameſe, "Lamas" by the Tartars, "Ho-ſhang" in China, and "Bonzes" in Japan. They generally live in a ſort of community, in places apart, or aſſigned wholly to them. The iſland Pou-to, near Chuſan, is a famous ſeat of bonzes, being wholly inhabited by them, to the number of 3000, all of the ſect of Hoſhang, or unmarried bonzes.

They live a kind of Pythagorean life, and have not leſs than four hundred pagodas, or temples, in this little iſland. They have alſo females, called bonzeſſes, a ſort of nuns, who dedicate themſelves to the worſhip and ſervice of ſome temples or idols. They are obliged to abſtain from all converſe with men, and on that account are cloiſtered in large monaſteries, like thoſe of the Romiſh and Greek church. For incontinency theſe bonzeſſes are condemned by the mandarins to a kind of pillory called *Ranghi*, which ſee.

Theſe bonzes, or Chineſe prieſts of Fo, worſhip him under the forms of ſeveral animals, through which they pretend that he had tranſmigrated before he was deified; and ingroſſing the worſhip of this imaginary deity to themſelves, in the Chineſe temples, they ſupport and propagate it, with a view to their own perſonal emolument and influence, by the moſt unwarrantable impoſtures. They admit, however, the diſtinction between good and evil; and they declare, that, after death, rewards will be beſtowed on the good, and puniſhments inflicted on the wicked, in places deſtined for the ſouls of each. They teach, that the god Fo appeared on earth for the purpoſe of ſaving mankind, and of reſtoring to the paths of ſalvation thoſe who have ſtrayed; that it is by him their ſins are expiated; and that he alone can procure for them a happy regeneration in a future life. They enjoin the ſtrict obſervance of five precepts; of which the firſt forbids the killing of any living creature, of whatever nature it may be; the ſecond, the taking away of the goods of another; the third forbids men to pollute themſelves by uncleanneſs; the fourth, to lye; and the fifth to drink wine. They, above all, recommend the practice of certain acts of mercy; ſuch as, treating their bonzes well, building monaſteries and temples for them, and ſupplying them with every thing neceſſary for their maintenance, as the moſt effectual means of participating the benefit of their prayers, mortifications, penances, and other meritorious actions, towards the atonement of their own ſins, and for obtaining a happy tranſmigration in another life. On the other hand, they terrify thoſe who withhold their benefactions from them with menaces; aſſuring them, that they

ſhall hereafter revive in the form of dogs, rats, ſerpents, horſes, and mules; and that they ſhall be for ever expoſed to the moſt degrading and wretched tranſmigrations. Theſe menaces ſeldom fail of making a deep impreſſion on the minds of the credulous vulgar, inſomuch that they often perſuade them to burn, at the funerals of their deceaſed relatives, paper gilt, or waſhed with ſilver, ſilk, cloth, and other garments, which, they pretend, will be converted into ſubſtantial gold and ſilver, and ſuperb veſtments, for the uſe of their parents and friends. Le Compte relates a ſtory of an old man, who was led to believe, by the repreſentations of theſe bonzes, that his ſoul ſhould paſs into the body of one of the emperor's poſt-horſes. The poor man was ſo diſtreſſed, that he could neither eat nor ſleep, and his grief was ſuch as to threaten the ſpeedy termination of his life. He learned, however, that the ſouls of the Chriſtians were exempted from theſe dreadful metamorphoſes; upon which, he applied to one of the Jeſuits for Chriſtian baptiſm, aſſuring him, that he would rather be of that, or any religion, than tranſmigrate into a poſt-horſe. The Jeſuit complied with his requeſt, and made his mind eaſy. Theſe bonzes are perfectly acquainted with all the arts of hypocriſy and deceit; and dextrouſly practiſe them as occaſions occur. They addict themſelves to rigorous faſting, frequent watchings, and long prayers before the altars of Fo. When they cannot obtain gifts by cunning and addreſs, they endeavour to procure them by exciting compaſſion, and by ſubmitting to the ſevereſt penances, and practiſing the moſt rigorous auſterities. With this view they often appear in public places, as frightful ſpectacles of mortification. They often drag along the ſtreets heavy chains faſtened round their necks, arms, and legs: they beat their heads againſt the ſtones and poſts, and mangle their bodies, ſo that they are ſmeared with blood; they carry burning coals upon the tops of their naked heads; and ſome of them are carried about in a kind of ſedan, the inſide of which is ſtuck full of nails and ſpikes, ſo that they cannot ſtir without wounding themſelves; and theſe nails they ſell to the populace for a few pence, as amulets and preſervatives againſt all harm, and as efficacious means of bringing down bleſſings on the purchaſer and his family. By pretending to know the preſent ſtate of the dead, and the future condition of the living, they contrive to extort money from the ſurviving friends, in order to procure for the deceaſed a ſpeedy releaſe and paſſage into a better ſtate. Many other inſtances of their knavery are related by Du Halde, Le Compte, and other writers. Some of theſe are ſo atrocious in their nature, that the relation of them cannot be read without horror; and we are led to hope, that they are recited by the Jeſuit miſſionaries, to whom the bonzes have been great enemies, and againſt whom they have excited various perſecutions, with ſome exaggeration.

We read of their privately ſeizing men and women, and hurrying them away in a cloſe ſedan, where nothing is to be ſeen but the tops of their heads, and their eyes moving in a terrifying manner, to the next river or canal, and drowning them without mercy, before crowds of ſpectators, who are harangued by one of the fraternity into a firm belief that the perſons ſo treated had earneſtly requeſted to be thus diſpatched out of the world, in order to obtain immortality in a future ſtate. With all the external appearances of ſanctity and auſterity, theſe bonzes unite voluptuous manners and ſecret profligacy, of which various inſtances are recited. Notwithſtanding the infatuation which induces the vulgar to ſupport the popular ſuperſtition of the country, the condition and character of a bonze are generally deſpiſed in China. Moſt of theſe fanatical impoſtors are ſprung from the dregs of the people. Thoſe of Pegu, however, are ſaid to be generally gentlemen of the higheſt extraction. See PEGU. To recruit and perpetuate their ſect, they purchaſe young children, whom they betimes initiate in all their myſteries, and whom they inſtruct in every trick and deception which may render their profeſſion profitable; theſe afterwards ſucceed them, and tranſmit their arts to other young bonzes, who are educated in the ſame manner. They are, in general, very ignorant, and unable to give an exact account even of the true doctrine of their ſect. Although they have no regular hierarchy, they acknowledge ſuperiors, whom they call "ta-ho-ſhang," or grand bonzes. This rank ſecures to thoſe who have attained it particular diſtinction, and the firſt place in all religious aſſemblies at which they may be preſent. There are bonzes of all conditions; ſome deſtined only for collecting alms; others, better ſkilled in the art of ſpeaking, and who have acquired ſome knowledge of the Chineſe literature, are commiſſioned to viſit the literati, and to inſinuate themſelves into the houſes of the great; old men, rendered venerable by age, and by a grave deportment, are employed to exerciſe their talents among the female ſex; theſe preſide in all their aſſemblies, which, though not common, are held, however, in ſeveral provinces. Theſe religious clubs are very lucrative to the bonzes. One of theſe prieſts enters the chapel, where the female devotees are aſſembled, and ſings ſome anthems to the god Fo. At length, after having for ſome time repeated "Omito Fo," (Omito being the name of another deity more ancient than Fo, and worſhipped by the Japaneſe under the name of Amida, which ſee), and after being ſtunned with the tinkling noiſe of ſeveral ſmall kettles, upon which they beat, they place themſelves at table, and the noiſy devotion terminates with mirth and a good repaſt. On days of greater ſolemnity, the bonzes adorn their places of worſhip with ſeveral idols, and numerous paintings, exhibiting under various forms the different puniſhments inflicted on the wicked in hell. The prayers and faſting continue ſeven days, during which their chief buſineſs is to prepare and conſecrate treaſures for the other world. In every province of China there are temples, to which numerous votaries repair; ſome of them making pilgrimages thither from very remote places. The pilgrims climb theſe ſacred mountains with great difficulty, and are ſometimes dragged up on their bended knees. Thoſe, whoſe age or infirmities, or urgent buſineſs, will not allow of their joining theſe devout caravans, commiſſion ſome of their friends to bring them a large leaf, filled with characters, and ſtamped by the bonzes in a particular corner. The centre of this leaf is occupied by the image of the god Fo. On the veſtments of the god, and around his figure, are traced out a multitude of circles, intended for the following purpoſe.—The devotees of the god, whether male or female, wear hanging from their necks, or around their arms, a kind of chaplet, compoſed of 100 beads of moderate ſize, divided by three which are much larger; and a bead, ſtill bigger, in form of a ſmall gourd, ornaments the top of the chaplet. Theſe beads they roll between their fingers, pronouncing the myſterious words "O-mi-to, Fo!" and each of theſe invocations is accompanied by a genu-flection. When they have completed the number of 100, equal to that of the beads, they mark with a red ſtroke one of the circles which ſurround the figure of the god Fo, on the leaf ſtamped by the bonzes. This leaf becomes the regiſter of all the prayers which they have repeated in the courſe of their lives. To verify its authenticity, the bonzes are, from time to time, invited to their houſes, where they muſt atteſt the number of circles marked with red ſtrokes, and imprint their ſeals on the leaf. When any of them dies, this valuable memorial is carried at the funeral with the greateſt ſolemnity, and depoſited in a ſmall box cloſely ſhut and ſealed: this they call "lou-in," or a paſſport for the other world; and it

coſts

coſts a large ſum of money to have all theſe formalities obſerved.

It has been already hinted, that the bonzes are peculiarly inimical to the progreſs of the Chriſtian religion in China, Japan, &c.; and that they have excited a ſpirit of perſecution againſt the European miſſionaries, who have hitherto been chiefly Jeſuits of the church of Rome. Theſe ſtrangers, they ſay, have introduced themſelves into China for the purpoſe of invading it; the new doctrine they preach is calculated, as they pretend, to procure followers, and a number of partiſans, ſufficient to ſecond their efforts, when European troops and fleets ſhall be ready to attack them; and ſometimes they allege, that the miſſionaries perſuade people to embrace their doctrine merely by the aid of ſorcery, and that they gain converts, and fix their attachment by laviſhing gold and ſilver among them, of which they have great abundance, becauſe they poſſeſs the ſecret of imitating and counterfeiting theſe precious metals. By ſuch and ſimilar repreſentations, they have checked the zeal, and counteracted the efforts of Chriſtian miſſionaries. Le Compte, State of China. Du Halde's China, vol. i. Groſſiere's China, vol. ii.

It has been obſerved (ſee Embaſſy to China, vol. ii. p. 100.), that the likeneſs is ſo ſtrong between the apparent worſhip of many of the prieſts of Fo, and that which is exhibited in churches of the Roman faith, that a Chineſe, conveyed into one of the latter, might imagine the votaries he ſaw were then adoring the deities of his own country. On the altar of a Chineſe temple, behind a ſcreen, is frequently a repreſentation which might ſerve for that of the Virgin Mary, in the perſon of "Shin-moo," or the ſacred mother, ſitting in an alcove with a child in her arms, and rays proceeding from a circle, which are called a glory, round her head, with tapers burning conſtantly before her. The long coarſe gowns of the Ho-ſhangs, or prieſts of Fo, bound with cords round the waiſt, would almoſt equally ſuit the friars of the order of St. Francis. The former live, like the latter, in a ſtate of celibacy, reſide together in monaſteries, and impoſe occaſionally upon themſelves voluntary penance and rigorous abſtinence.

BOO-Hadjar, in *Geography*. See Agar.

Boo-*Jeemah*, a river of Africa, in the province of Conſtantina, which runs along the weſtern ſide of the marſh which ſeparates betwixt Bona and the ancient Hippo. Over this river is a bridge of Roman ſtructure.

Boo-*Shaater*, a town of Africa, in the kingdom of Tunis, ſaid by Shaw (Trav. p. 79.) to be built on the ruins of the ancient Utica, which ſee.

BOOBERAK, a river of Africa, in the kingdom of Algiers, formed by the junction of the Niſſah and Bugdourah. Its mouth, which is made up of a number of branches, is the eaſtern boundary of the province of Titterie.

BOOBY, a word of uncertain etymology, derived by Skinner from the Spaniſh *bobo*, fooliſh; but deduced by Junius from *bowbard*, an old Scottiſh word for a coward or contemptible fellow; denotes a dull, heavy, ſtupid perſon.

Booby *iſland*, in *Geography*, a ſmall iſland in the Weſt Indies, lying directly oppoſite to Moſquito bay, at the S.E. extremity of the iſland of St. Chriſtopher's, and more than half a league from it, off the north end of Nevis iſland.—Alſo, a ſmall iſland, ſuppoſed to be one of the iſlands called Prince of Wales's iſlands, extending from thence and Wallis's iſland, as far as New Guinea.

Booby, in *Ornithology*, the name of *pelecanus ſula* in Cateſby's Natural Hiſtory of Carolina. The *great booby* of Cateſby is a variety of *pelecanus baſſanus*. *Brown booby* of Latham, *pelecanus fiber*; *leſſer booby*, *pelecanus parvus*; *ſpotted booby*, *pelecanus maculatus*.

BOODGE-BOODGE, or Booge-booge, in *Geography*, a town of Hindoſtan, the preſent capital of the territory of Cutch, and reſidence of its rajah. It is alſo called Booz, and placed in a map, to which Mr. Rennell refers, about 34 geographical miles to the E. or E.S.E. of the eaſtern branch of the Indus: 120 miles S.E. of Tatta, and about 200 W. of Ahmedabad.

BOODH, *Bouddha*, *Budha*, or *Buddou*, in *Mythology*, a deity very anciently and very generally worſhipped in India. The name of this deity is variouſly expreſſed by different writers. In the Pali language, and among the Cingaleſe, his common name is Bouddha. Mr. Chambers, in the Aſiatic Reſearches, writes Buddou; and Paulinus (Muſ. Borg.), Budha; and from theſe two appellations we may eaſily deduce the Budda or Butta of Beauſobre and Bochart, the Bod of the Arabians, Bodda of Edriſi, Βούττα of Clemens Alexandrinus, and Baouth of M. Gentil. The name is ſaid to be an appellation, ſynonymous with ſage or philoſopher, and expreſſive of wiſdom. By Budha, ſays the learned Bryant, (Anal. Anc. Mythol. vol. iii. p. 573,) we are certainly to underſtand the idolatrous ſymbol, called by ſome nations Buddo; the ſame as Argus and Theba. In the mythology tranſmitted concerning it we may ſee a reference both to the machine itſelf, and to the perſon preſerved in it. In conſequence of which we find this perſon alſo ſtyled Bod, Budhu, and Buddo; and in the weſt Butus, Battus, and Bœotus. He was ſaid by the Indians not to have been born in the ordinary way; but to have come to light indirectly through the ſide of his mother. By Clemens of Alexandria, he is called Bouta; and in the hiſtory of this perſon, however varied, we may perceive a relation to the Arkite deity of the ſea, called Poſeidon; alſo to Arcalus and Dionuſus; ſtyled Bœotus and Thebanus. Different learned men have ſuppoſed Boudha to have been the ſame with Noah, Moſes, or Siphoas the 35th king of Egypt; and ſir William Jones ſuppoſed Bouddha to have been the ſame with Seſac or Seſoſtris, king of Egypt, who by conqueſt ſpread a new ſyſtem of religion and philoſophy from the Nile to the Ganges, about 1000 years before Chriſt. In order to reconcile ſome differences of opinion among the Hindoos, with regard to the time of Bouddha's appearance, this learned writer agrees with Giorgi in ſuppoſing, that they have confounded two Bouddha's; the younger of whom eſtabliſhed the new religion, which gave great offence to the bramins in India, and was introduced into China in the firſt century of our æra; whereas the more ancient Bouddha preceded him by many centuries, and is referred by ſir W. Jones, after a variety of computations, to the year 1027 before Chriſt. For want of adverting to this circumſtance, he confounded the latter Bouddha with the Woden of the Goths. Mr. Chambers alſo remarked, that Pood or Poaden, which is the Siameſe mode of pronouncing the Boodth of the Indians and Birmans, bears a ſtriking reſemblance to the Gothic Woden; and it is further ſuggeſted, that Boodh is the dies Mercurii, the Wedneſday, or Woden's day, of all Hindoos. But etymological reaſoning, more eſpecially when it interferes with chronology, is not ſufficient to eſtabliſh the identity of Boodh and Woden. According to the chronology of the Hindoos, which ſir W. Jones has minutely inveſtigated and detailed, Boudha was the ninth "Avatar," or deſcent of the deity, in his capacity of preſerver, or the ninth incarnation of Viſhnou, which was long antecedent to the exiſtence of the deified hero of Scandinavia, who, according to ſome writers, was a contemporary of Pompey and Julius Cæſar, and who is placed by the author of the Northern

Antiquities, 70 years after the Chriſtian æra. Beſides the attributes of Boodh and Odin are very different. The deity, whoſe doctrines were introduced into Scandinavia, was a god of terror, and his votaries carried deſolation and the ſword throughout whole regions; whereas the ninth Avatar (ſee Maurice's Hiſt. of Hindoſtan, vol. ii. part 3.) introduced the peaceful olive, and appeared in the world for the purpoſe of preventing ſanguinary acts. He ſeverely cenſured the ſacrifice of cattle, or depriving any being of life, and is denominated the author of happineſs. His place of reſidence is ſaid to have been diſcovered at Boodha Gaya in Bengal, by the illuſtrious Amara, renowned amongſt men; and according to an inſcription in Sanſcrit, found on a ſtone in this place, and tranſlated by Mr. Wilkins, (Aſiatic Reſearches, vol. i. p. 284,) he cauſed an image of the ſupreme ſpirit Bood-dha to be made, and worſhipped it according to the law, with perfumes, incenſe, and the like; and he thus glorified the name of that ſupreme being, the incarnation of a portion of Veeſhnoo: "Reverence be unto thee in the form of Bood-dha! reverence be unto the lord of the earth! reverence be unto thee, an incarnation of the deity and the eternal one! reverence be unto thee, O God, in the form of the God of mercy, the diſpeller of pain and trouble, the lord of all things, the deity who overcometh the ſins of the Kalee Yoog, the guardian of the univerſe, the emblem of mercy toward thoſe who ſerve thee!" &c. As the doctrines of Boodh and Woden are different, and their æras are very remote, they muſt of courſe be different perſons. The Buddha of the Hindoos is unqueſtionably, ſays ſir W. Jones, the Foe or Fo of China; and M. de Guignes, on the authority of four Chineſe hiſtorians, aſſerts, that Fo was born about the year before Chriſt 1027, in the kingdom of Caſhmir. Mr. Chambers, following M. Gentil, and followed by Paulinus, conceives, by a very forced train of etymology, the Fo or Fohi of the Chineſe to be a corruption of Bouddha. Nor is the derivation of Taautos, Toth, or Touth, the Egyptian name for Hermes from Bouddha, leſs fanciful; and yet Fo-hi, the progenitor of the Chineſe, a military tribe, whom the Hindoos call the Chandravanſa, or children of the moon, was, according to their Puranas or legends, Buddha, or the genius of the planet Mercury.

Among the various appellations by which the deity Buddha is known in ſeveral parts of the Eaſt, that of Godama is very common. This Godama, Gaudma, or Gotma, &c. as his name is differently expreſſed, is ſaid to have been a philoſopher, and is believed by the Birmans to have flouriſhed above 2300 years ago; he is ſaid to have taught in the Indian ſchools the heterodox religion and philoſophy of Boodh. See Godama. The image that repreſents Boodh is called Gaudma or Goutum, which is now a commonly received appellation of Boodh himſelf: this image is the primary object of worſhip in all countries ſituated between Bengal and China. The ſectaries of Boodh contend with thoſe of Brahma for the honours of antiquity, and are certainly far more numerous. The Cingaleſe in Ceylon are Boodhiſts of the pureſt ſource, and the Birmans acknowledge to have received their religion from that iſland, which they call Zehoo. From thence it was brought, as the Rhahaans ſay, to Arracan, and it was then introduced into Ava, and probably into China; for the Birmans confidently aſſert, that the Chineſe are Boodhiſts. Kæmpfer, ſpeaking of the Budz, or Seaka, (Shaka, Shakya, Sjaka, or Sakya, denoting, according to Paulinus, the cunning, or the god of good and bad fortune,) ſays, (Hiſt. Japan. b. iv. c. 6.) "I have ſtrong reaſons to believe, both from the affinity of the name, and the very nature of this religion, that its author and founder is the very ſame perſon whom the Bramins call Buddha, and believe to be the eſſential ſpirit of their Wiſhna (Viſhnou) or their deity, who made his ninth appearance in the world under this name: the Peguers call him Samana Khutama." Where he treats concerning the introduction of Boodh into China, he ſays, (id. ibid.) "about the year of Chriſt 518, one Darma, a great ſaint, and twenty-third ſucceſſor in the holy ſee of Seaka (Buddha), came over into China from Seitenſeku, as the Japaneſe writers explain it, that is, from that part of the world, which lies weſtward with regard to Japan, and laid, properly ſpeaking, the firſt firm foundation of the Budſdoiſm in that mighty empire." Others ſay, that the ſect of Boudha was introduced into China in the year of our æra 630, and that from China it extended itſelf to Japan, Tonquin, Cochinchina, and the moſt remote parts of Tartary.

Whatever may be the antiquity of the worſhip of Boodh or Buddha, we can entertain no doubt of the wide extent of its reception and prevalence. In the iſland of Ceylon, in the extenſive Birman empire, in the kingdoms of Siam and Cambodia, the prevailing religion is that of Bouddha or Godama, and Mr. Chambers (Aſiatic Reſearches, vol. i. p. 162, &c.) has given very good reaſons for believing that the worſhip of Bouddha extended all over India, and was not rooted out by the Bramins in the Deccan, ſo lately as the 9th, or even the 12th century of the Chriſtian æra. From the hiſtory of Caſhmire, preſented to the ſultan Acbar, on his firſt entrance into that kingdom, we learn, that Jelowk, one of its moſt powerful princes, tolerated the doctrine of Bouddh; and that it was not till the reign of Nerkh the 59th prince, A. D. 342, that the Brahmins acquired the aſcendency over the followers of Boodh, and burned down their temples. In Nepal the moſt ancient religion is that profeſſed by a ſect who call themſelves "Baryefu," and who ſeem to be worſhippers of Bouddha. In Narhoara or Nehrwaleh, the capital of the kingdom of Guzerat, we find that even after the Mahometan invaſion, in the 11th century of our æra, Edriſi, who wrote in the 12th century, informs us, that the people continued in the worſhip of the idol Bodda or Bud. This Arabian geographer adds, that the worſhip of the prince of this country, who reigned on the Malabar coaſt, with the title of Balhara, and whoſe dominions extended over Guzerat, and the greateſt part, if not the whole of Viſiapour, was addreſſed to Bodda, who, according to St. Jerome and Clemens Alexandrinus, was the founder of the ſect of the Gymnoſophiſts, in like manner, ſays M. d'Anville, as the Brahmins were uſed to attribute their inſtitution to Brahma. If the conjectures of ſir William Jones, relating to the inſcriptions found at Mongheer, and on the pillar of Buddal, be well founded, the governing powers on the banks of the Ganges, as late as about the time of the birth of Chriſt, were of the ſect of Bouddha; and however idle and ridiculous the legends and notions of the worſhippers of Bouddha may be, they have been in a great meaſure adopted by the Brahmins; but with all their defects and extravagances much aggravated, rajahs and heroes being converted into gods, and impoſſibilities accumulated on improbabilities. From various authorities, to which we might refer, it ſufficiently appears, that the worſhip of Bouddha, or Buddou, has prevailed in ſeveral parts of India at a period prior to that of the Brahmins; and that this has been the caſe even ſo late as the 9th and the 12th centuries of the Chriſtian æra; and that this ſyſtem forms the baſis of that religion which the Brahmins have brought with them into the ſouthern parts of the peninſula of Hindoſtan, into Madura, Tanjore, and Myſore. In thoſe parts of India, and chiefly on the coaſt of Coromandel, and in Ceylon, the god Baouth, ſays M. Gentil, of whom, at preſent, they know no more in India than the name, was the object of worſhip; but

But it is now totally aboliſhed; except that there may be found ſome families of Indians, who have remained faithful to Baouth, and do not acknowledge the religion of the Brahmins; and on that account ſeparated from and deſpiſed by the other caſts. It is generally allowed, that about the time of Chriſt the Brahmins gained a ſuperiority over the worſhippers of Bouddha; and about 900 years afterwards, we find them totally overthrowing his doctrine in its native country, and perſecuting his followers. The Vedas, which are commonly ſuppoſed to be the oldeſt books of the Brahmins, are of later date than the time of Bouddha, as is evident from the mention which they make of that perſonage. Aſiatic Reſearches, vols. i. ii. and iv. Symes's Embaſſy to Ava, vol. ii. ch. 13. For a further account of the votaries of Bouddha, as well as the principles and rites of his worſhip; ſee BRACHMANS, GODOMA, RAHANS, SAMANEANS, and TIRINANXES. See alſo BIRMAN *empire*, CEYLON, CHINA, COCHINCHINA, SIAM, &c.

BOODICOTTA, in *Geography*, a town of the peninſula of India, in the Myſore country; 87 miles E. N. E. of Seringapatam, and 33 E. S. E. of Bangalore. N. lat. 12° 50'. E. long. 78° 20'.

BOOG, or BOGOE, a ſmall iſland of Denmark, between the iſlands of Moen and Falſter.

BOOGOO, in *Zoology*, the ſpecies of BABOON called *Simia maimon*, by Linnæus. See MAIMON.

BOOK, a writing compoſed on ſome point of knowledge by a perſon intelligent therein, for the inſtruction or amuſement of the reader.

The word is formed from the Saxon *boc*, which comes from the Northern *buech*, of *buechaus*, a *beech* or *ſervice-tree*, on the bark of which our anceſtors uſed to write.

Book may be defined more preciſely, a compoſition of ſome man of wit or learning, deſigned to communicate, to prove, or illuſtrate ſome ſcience, art, truth, or invention.

Book is diſtinguiſhed from pamphlet, or ſingle paper, by its great length; and from tome or volume, by its containing the whole writing on the ſubject. Iſidore makes this diſtinction between *liber* and *codex*; that the former denotes a ſingle book, the latter a collection of ſeveral; though, according to Scipio Maffei, *codex* ſignifies a book in the ſquare form; *liber*, a book in the roll form. The primary diſtinction between *liber* and *codex* ſeems to have been derived, as Dr. Heylin has obſerved, from the different materials uſed for writing, among the ancients. From the innerſide of the bark of a tree, uſed for this purpoſe, and called in Latin *liber*, the name of liber applied to a book was deduced; and from tablet, formed from the main body of a tree, called *caudex*, was derived the appellation of *codex*.

We ſay an old book, a new book; a Latin, a Greek book; to read, to write, to publiſh a book; the preface, the title, the dedication, the index of a book. To collate a book, is to ſee that it be perfect, and that none of the ſheets be either wanting or tranſpoſed. Book-binders ſpeak of folding, ſewing, beating, preſſing, covering, gilding, and lettering of books. See BOOKBINDING.

A large collection of books is called a library. An inventory of a library, in order to the reader's finding any book, is called a catalogue.

The hiſtory or *notitia* of books makes the firſt part, according to ſome the whole, of the literary ſcience.—The principal points of the notitia of a book are, its author, date, printer, edition, verſions, comments, epitomes, ſucceſs, eulogies, cenſures, condemnation, ſuppreſſion, adverſaries, vindicators, continuators, and the like.

The hiſtory of a book is either of its contents, which is given by analyſing it, as is done by journaliſts and reviewers; or of its appendages, and accidents, which is the more immediate province of thoſe called literators, and bibliothecarians.

The contents of a book are the matters delivered in it; which make the province of the author. Of theſe there is one principal matter, called the ſubject; in reſpect of which the reſt are only incidents.

The appendages of a book are, the title, preface, epiſtle dedicatory, ſummaries, table of contents, index, and the like, which are the proper province of the editor, unleſs perhaps the title page, which is frequently uſurped by the bookſeller.

In the compoſition of a book, there occur ſentiments, which are alſo the materials of it; method, the order wherein theſe are diſpoſed; and ſtyle, or expreſſion, which is the language in which they are clothed.

The giving of hiſtories, catalogues, and bibliothecas of books, is ſaid to have been firſt introduced by the Germans: we may add, that they have beſt ſucceeded in them; and to them the chief works of this kind are owing. I. Alb. Fabricius has given us the hiſtory of the Greek and Latin books; Wolfius, that of the Hebrew books; Boecler, of the principal books in each ſcience and faculty; Struvius, of the books of hiſtory, law, and philoſophy; the abbot Fabricius, of the books of his own library; Lambecius, of thoſe in the Vienna library; Le Long, of the books of Scripture; Mattaire, of the books printed before the year 1550; and Morhoff, a general literary hiſtory of this kind, under the title of Polyhiſtor. The various catalogues of choice libraries are uſeful and neceſſary for the ſame purpoſes; ſo are likewiſe the relations, &c. and the reviews which have been periodically publiſhed. See BIBLIOTHECA.

BOOKS, as *to the materials of*, they were firſt written on ſtones, witneſs the Decalogue given to Moſes (which is the oldeſt book we have any warranted account of); then, on the parts of plants, e. gr. the leaves, chiefly of the palm-tree; the rinds and barks eſpecially of the tilia or philyra, and the Egyptian papyrus. By degrees, wax, then leather, were introduced, eſpecially the ſkins of goats and ſheep, of which, at length, parchment was prepared: then lead came in uſe: alſo linen, ſilk, horn, and, laſtly, paper itſelf. See PAPER.

The parts of vegetables continued long the common matter of books; inſomuch that moſt of the names and terms belonging to books, in moſt languages, are taken thence; as the Greek *biblos*, the Latin *liber*, *codex*, *folium*, *tabula*, and the Engliſh *book* itſelf. We may add, that vegetable barks appear ſtill in ſome meaſure retained for books in certain of the Northern countries, as among the Calmuc Tartars, where a library was diſcovered by the Ruſſians, of an unuſual form as well as matter: the books were exceedingly long, but of no breadth: the leaves very thick, and made of barks of trees, ſmeared over with a double varniſh; the ink, or writing, being white on a black ground. Hiſt. Acad. R. Inſcr. t. iii. p. 6.

Whatever were the materials uſed by the ancients for their books, they were liable to be eaſily deſtroyed by the damp, when hidden in the earth; and in times of war, deva ſtation, and rapacity, it was neceſſary to bury in the earth whatever they wiſhed to preſerve from the attacks of fraud and violence. Accordingly, it is well known, that perſons, whoſe property was thus expoſed, concealed in this manner, not only ſilver and gold, but wheat, barley, oil, and honey; and alſo their garments, and their writings. With this view, Jeremiah ordered the writings, which he delivered to Baruch, to be put in an earthen veſſel. See chap. xxxii. In the ſame manner the ancient Egyptians made uſe of earthen urns, or pots of a proper ſhape, for containing what-

whatever they wanted to inter in the earth, and which, without such care, would have been soon destroyed. We need not wonder then, that the prophet Jeremiah should think it necessary to enclose those writings in an earthen pot, which were to be buried in Judæa, in some place where they might be found without much difficulty on the return of the Jews from captivity. Accordingly two different writings, or small rolls of writing, called books in the original Hebrew, were designed to be enclosed in such an earthen vessel; but commentators have been much embarrassed in giving any probable account of the necessity of two writings, one sealed, the other open; or, as the passage has been commonly understood, the one *sealed up*, the other left *open* for any one to read: more especially, as both were to be alike buried in the earth and concealed from every eye, and both were to be examined at the return from the captivity. In order to solve this difficulty, the ingenious Mr. Harmer (Obs. on Script. vol. iv. p. 4.) remarks, that though one of them is said to be *sealed*, it doth not follow that it was sealed in such a manner as not to be opened. Like modern deeds for the conveyance of land, it might have been sealed, though not with wax, yet, according to the present eastern manner, with ink, so as to be valid. Moreover, the word translated *open*, in reference to the evidence, or book which was open, is not the same that is twice used by Nehemiah, ch. viii. 5.; but it is a word, which signifies (1 Sam. iii. 7. 21. Dan. ii. 19, 30. x. 1.) the revealing of future events to the minds of men by a divine agency; and it is particularly used in the book of Esther, (ch. viii. 13.) to express a book's making known the decree of an earthly king. Consequently the *open book* of Jeremiah seems to signify, not its being then lying open or unrolled before them, while the other was sealed up; but the book that had revealed the will of God, to bring back Israel into their own country, and to cause buying and selling of houses and lands again to take place among them. This was a *book of prophecy*, opening and revealing the future return of Israel; and the other little book, which was ordered to be buried along with it, was the purchase-deed. By adverting to the different modes of writing in the East, we obtain a satisfactory interpretation of a passage in the book of Job, (ch. xix. 23, 24.) and a distinct view of the beautiful gradation which is lost in our translation: "O that my words were now written! O that they were printed (written) in a book! that they were graven — in the rock for ever!" In the East there is a mode of writing, which is designed to fix words in the memory, but the writing is not intended for duration. Accordingly, we are informed by Dr. Shaw, (Trav. p. 194.) that children learn to write in Barbary by means of a smooth, thin board, slightly covered with whiting, which may be wiped off, or renewed at pleasure. As many occurrences were effaced from the memory of the Arabs in the time of Job, as well as from their writing-tables, as it now often happens in Barbary; Job expresses his wish not only that his words were written, and written in a book, from which they should not be blotted out, and graven in a rock, the most permanent mode of recording them, and much more effectual for perpetuating them than a book.

We find in Signior Castagnatta's account of the asbestos, a scheme for the making of a book, which from its imperishable nature, he is for calling the *book of eternity*. The leaves of this book were to be of the asbestos paper, the covers of a thicker sort of work of the same matter, and the whole sewed together with thread spun from the same substance. The things to be commemorated in this book were to be written in letters of gold, so that the whole matter of the book being incombustible and everlastingly permanent against the force of all the elements, and subject to no changes from fire, water, or air, must remain for ever, and always preserve the writing committed to it. See PAPER.

BOOKS, *form of*. The first books were in the form of blocks and tables, of which we find frequent mention in Scripture, under the appellation *sepher*, which the Septuagint render αξονες, q. d. *square tables*: of which form the book of the covenant, book of the law, book, or bill of divorce, book of curses, &c. appear to have been. As flexible matters came to be wrote on, they found it more convenient to make their books in form of rolls, called by the Greeks κοντακια, by the Latins *volumina*, which appear to have been in use among the ancient Jews as well as Grecians, Romans, Persians, and even Indians. And of such did the libraries chiefly consist, till some centuries after Christ. The form which obtains among us is the square, composed of separate leaves; which was also known, though little used, among the ancients; having been invented by Attalus, king of Pergamus, the same also who invented parchment: but it has now been so long in possession, that the oldest manuscripts are found in it. Montfaucon assures us, that of all the ancient Greek manuscripts he has seen, there are but two in the roll form; the rest being made up much after the manner of the modern books. See BOOK-BINDING.

The rolls, or volumes, were composed of several sheets, fastened to each other, and rolled upon a stick, or *umbilicus*; the whole making a kind of column, or cylinder, which was to be managed by the *umbilicus*, as a handle; it being reputed a kind of crime to take hold of the roll itself. The outside of the volume was called *front*; the ends of the *umbilicus*, were called *cornua*, *horns*; which were usually carved and adorned likewise with bits of silver, ivory, or even gold and precious stones. The title Συλλαβος was stuck on the outside. The whole volume, when extended, might make a yard and a half wide, and fifty long. Fabric. Bibl. Antiq. c. 19. § 7. p. 607.

Sir John Chardin informs us, in a note on Is. viii. 1. that the eastern people roll their papers, and do not fold them, because their paper is apt to fret. Whilst the Ægyptian papyrus was in common use, its brittle nature made it proper to roll up what they wrote: and as this had been a customary practice, many continued it when they used other materials, which might very safely have been treated in a different manner. This method of rolling up their books is referred to in the New Testament; and that they were of the same form much more anciently, we learn from Jer. xxxvi. 2. Ps. xl. 7, &c. &c.

It is customary not only to wrap up Oriental books and letters, which are rolled up, in an elegant and costly covering; but to inscribe words on these coverings, which give a general notion of their contents. This practice of writing on the outside of the case of a letter, or book rolled up, seems to be at least as ancient as the time of Chrysostom, as we learn from a note of Lambert Bos on Ps. xxxix. 7. as it occurs in the LXX. v. 40. in our version. Chrysostom remarks, that they call a wrapper (πλημα) the κεφαλις, which is the word the Septuagint translators make use of to express the Hebrew word we translate volume: "In the volume of the book it is written of me." The learned father seems to suppose, that there was written *in* or *on* the covering of the sacred volume, a word or words which signified the "coming of the Messiah." But Chrysostom would hardly have thought of such an interpretation, if it had not been frequently done at Constantinople in his time, or by the more eastern princes that had business to transact with the Greek emperors, or been known to have been practised

practiſed before thoſe times among the Jews. Chryſoſtom lived in the 4th century. Aquila, who is thought to have lived above 100 years ſooner, and is allowed to be a moſt cloſe tranſlator of the Hebrew, uſes, according to Bos, the ſame word σκεπασμα, or wrapper, to expreſs the Hebrew word we tranſlate volume. He therefore ſuppoſed that what was written, to which this paſſage refers, was written on the covering or wrapper of the ſacred books. This explanation ſuggeſts a much more agreeable mode of rendering the word than our Engliſh term *volume*; ſince every ancient Hebrew book was a volume, or roll, and conſequently the paſſage merely expreſſes; "In the book it is written of me." But if we underſtand it of the *caſe* in which their books were wrapped up, the thought is not only clear and diſtinct, but very energetic, and amounts to this, that the ſum and ſubſtance of the ſacred books is, that "the Meſſiah cometh;" and that thoſe words accordingly might be wrote or embroidered, with great propriety, on the wrapper, or caſe in in which they were kept.

Another tranſlation renders the word εν τομω, which intimates that the motto was inſcribed on the cylinder, round which books of this form were wont to be rolled. In this caſe, it was probably written on that part of the cylinder which reached beyond the parchment, linen, or whatever material was uſed, and which was convenient enough for exhibiting, in brief, what the purport of the volume was. Mr. Harmer (Obſ. on Script. vol. iv. p. 11) ſuggeſts, that the circle of gold, with the name of one of our Saxon princes upon it, and ornamented after the manner of thoſe times, might be deſigned to caſe the end of the cylinder, or one of the cylinders, on which ſome book belonging to that monarch, or relating to him, was rolled; of which ancient piece of gold an engraving is given in the ſeventh volume of the Archæologia, or Tranſactions of the Antiquarian Society. This ſort of capping to thoſe cylinders uſed to be called the "Aeſtel."

To the form of books belongs alſo the *economy of the inſide*, or the order and arrangement of points and letters into lines and pages, with margins, and other appurtenances. This has undergone many varieties: at firſt, the letters were only divided into lines, then into ſeparate words; which, by degrees, were noted with accents, and diſtributed, by points and ſtops into periods, paragraphs, chapters, and other diviſions. In ſome countries, as among the Orientals, the lines began from the right, and ran to the left; in others, as in Northern and Weſtern nations, from the left to right; others, as the Grecians, followed both directions alternately, going in the one, and returning in the other, called *bouſtrophedon*. In the Chineſe books, the lines ran from top to bottom. Again, the page in ſome is entire, and uniform; in others, divided into columns; in others, diſtinguiſhed into text and notes, either marginal, or at the bottom: uſually it is furniſhed with ſignatures and catch-words; alſo with a regiſter to diſcover whether the book be complete. To theſe are occaſionally added the apparatus of ſummaries, or ſide notes; the embelliſhments of red, gold, or figured initial letters, head-pieces, tail-pieces, effigies, ſchemes, maps, and the like. The end of the book, now denoted by *finis*, was anciently marked with a ≺, called *coronis*, and the whole frequently waſhed with an oil drawn from cedar, or citron chips, ſtrewed between the leaves to preſerve it from rotting. There alſo occur certain *formulæ* at the beginning and end of books; as among the Jews, the word חזק, *eſto fortis*, which we find at the end of the books of Exodus, Leviticus, Numbers, Ezekiel, &c. to exhort the reader to be courageous, and proceed on to the following book. The concluſions were alſo often guarded with imprecations againſt ſuch as ſhould falſify them; of which we have an inſtance in the Apocalypſe. The Mahometans, for the like reaſon, place the name of God at the beginning of all their books, which cannot fail to procure them protection, on account of the infinite regard had among them to that name, wherever found. For the like reaſon it is, that divers of the laws of the ancient emperors begin with the *formula*, *In nomine Dei*. At the end of each book the Jews alſo added the number of verſes contained in it, and at the end of the Pentateuch the number of ſections; that it might be tranſmitted to poſterity entire. The Maſoretes and Mahometan doctors have gone farther; ſo as to number the ſeveral words and letters in each book, chapter, verſe, &c. of the Old Teſtament, and the Alcoran. See ALCORAN, BIBLE, MASSORA, &c.

The kinds and denominations of books are various.

BOOKS, with regard to their *uſe and authority*, may be divided into *human* and *divine*, alſo called *ſacred* and *inſpired* books.

BOOKS, *Sibylline*, thoſe compoſed by certain pretended propheteſſes, depoſited in the Capitol, under the care of *duumviri*. See SIBYLS.

BOOKS, *Canonical*, thoſe received and allowed by the church as parts of holy ſcripture. Such are the books of the Old and New Teſtament, as commonly bound up together. See CANON, and BIBLE.

BOOKS, *Apocryphal*, thoſe excluded out of the canon, yet received and read in ſome churches. See APOCRYPHAL.

BOOKS, *Authentic*, thoſe which are deciſive, and of authority: ſuch, in the civil law, are the Code, Digeſt, &c. in our law, the Statutes, &c. Bacon de Augm. Sc. l. 8. c. 3.

BOOKS, *Auxiliary*, thoſe leſs eſſential, yet of uſe, as ſubſervient to the others: as in the ſtudy of the law, books of Inſtitutes, Formulæ, Maxims, Reports, &c.

BOOKS, *Elementary*, thoſe which deliver the firſt principles of ſciences: ſuch are thoſe under the titles of Rudiments, Methods, Grammars, &c. by which they ſtand contradiſtinguiſhed from books of a ſuperior order, which aim at making farther advances in the ſciences.

BOOKS, *Library*, ſuch as are not ordinarily read over, but turned to, and conſulted occaſionally; ſuch are dictionaries, &c.

BOOKS, *Exoteric*, thoſe intended for the uſe of popular and ordinary readers.

BOOKS, *Acroamatic*, thoſe containing more ſecret and ſublime matters, calculated for adepts and proficients in the ſubject.

BOOKS, *Public*, the records of paſt times and tranſactions kept by public authority.

BOOKS, *Church*, or *Eccleſiaſtical*, thoſe uſed in the public offices of religion.

BOOKS, again, with regard to their *ſcope and ſubject*, may be divided into *hiſtorical*, thoſe which relate facts, either by nature or mankind; *dogmatical*, thoſe which lay down doctrines, or general truths; *miſcellaneous*, thoſe of a neutral kind, containing both facts and doctrines; *hiſtorico-dogmatical*, thoſe which only rehearſe doctrines, or, at moſt, indicate the arguments by which they are proved, as Mallet's Geometry; *ſcientifico-dogmatical*, thoſe which not only recite the doctrines, but demonſtrate them, as Euclid's Elements. Wolf. Pnil. Rat. § 3. c. 1. § 744, 750, 751, &c.

BOOKS, *Pontifical*, among the Romans, were thoſe appointed by Numa to be kept by the *pontifex maximus*; deſcribing

ſcribing all the ceremonies, ſacrifices, feaſts, prayers, and other religious matters, with the manner, and circumſtances, wherewith each was to be celebrated; theſe were alſo called *indigitamenta*, as containing the names of all the gods, and the occaſions, and *formulæ* of invoking each. Liv. i. p. 23.

Books, *Ritual*, thoſe which directed the order and manner of founding, building, and conſecrating cities, temples, and altars; the ceremonies belonging to walls, gates, tribes, curiæ, camps, and the like.

Books, *Augural*, called by Cicero *recondiți*, were thoſe wherein the ſcience of foretelling futurity, from the flight and chattering of birds, was contained. Cicer. Orat. pro domo ſua ad pontiff. Serv. ad Æn. l. 5. v. 738. Lomei, de Bibl. c. 6.

Books, *Aruſpicine*, thoſe wherein the myſteries of divining from the entrails of victims are preſcribed.

Books, *Acherontic*, thoſe wherein the ceremonies and diſcipline of Acheron were contained; ſometimes alſo called *libri Etruſci*, as being ſuppoſed to have been compoſed by Tages the Hetrurian; though others pretend, that he had received them from Jupiter himſelf: ſome ſuppoſe theſe to have been the ſame with the *libri fatales*; others, with the *libri aruſpicini*. Serv. ad Æn. l. 8. v. 398. Lomei, ubi ſupra.

Books, *Fulgural*, thoſe written touching thunder and lightning, and their interpretation. As that compoſed by the Tuſcan nymph Bigois, preſerved in the temple of Apollo. Serv. ad Æn. l. 6. v. 72.

Books, *Fatal*, thoſe wherein the ages, or terms of the life of men were written, according to the Hetrurian diſcipline. Theſe were conſulted by the Romans in all public calamities; and inſtructions taken from them, how to expiate the offended deities. Cenſor. de Die. Natal. c. 14.

Books, *Black*, thoſe which treat of necromancy and witchcraft; or thoſe which are printed in the old black letter, the Celtic character, now only retained by the Germans. The ſame denomination is alſo given to ſome other books, on account of the colour of their backs, or the diſmalneſs of their contents; whence alſo *Red book*, and *Domeſday-book*.

Books, *Good*, in the common uſage, are thoſe of devotion and piety, as ſoliloquies, meditations, prayers, &c. Vide Shafteſb. Charact. tom. i. p. 165. idem. tom. iii. p. 327. A *good book*, in the bookſeller's language, is a ſaleable one; in the language of the curious, a ſcarce one; in that of men of ſenſe, an uſeful and inſtructive one.

Among five principal things which Rabbi Akiba recommended to his ſon, one was, that if he ſtudied the law, he ſhould take care to do it in a *good book*, leſt he ſhould be obliged to unlearn all again. Vide Cren. de Furib. Librar. See alſo farther, on the head of judging and chooſing of Books.

Books, *Spiritual*, thoſe which treat more expreſsly on the ſpiritual or Chriſtian life, and their exerciſes, as to contemplation, &c.

Books, *Prophane*, ſuch as do not treat of matters of religion.

Books, with regard to their *authors*, may be divided into *anonymous*, thoſe without any author's name; *cryptonymous*, thoſe whoſe authors' names are concealed in ſome anagram, or the like; *pſeudonymous*, thoſe which bear falſe names of authors; *poſthumous*, thoſe publiſhed after the author's death; *genuine*, thoſe really written by the perſons whom they pretend for their authors, and ſtill remaining in the ſtate wherein they were left by them; *ſpurious*, or *ſuppoſitious*, thoſe pretended to be written by others than their real authors; *interpolated*, thoſe which ſince their compoſition have been corrupted by ſpurious additions or inſertions.

Books, with regard to their *qualities*, may be divided into *clear* or *perſpicuous*, which, in the dogmatical kind, are thoſe where the authors define all their terms accurately, and keep ſtrictly to thoſe definitions in the courſe of their works: *obſcure*, thoſe where words are uſed vaguely, and without defining: *prolix*, thoſe which contain more things than were neceſſary to the author's deſign; as if in a book of ſurveying, a man ſhould give all Euclid; *uſeful*, thoſe which deliver things neceſſary to be known, either in other ſciences, or in the buſineſs of life: *complete*, thoſe which contain all that is known concerning the ſubject: *relatively complete*, thoſe which contain all that was known concerning the ſubject, at a certain time; or, if a book were written with any particular deſign, or view, it may be ſaid to be *complete*, if it contain neither more nor leſs than is neceſſary for the accompliſhing of that end: in contrary caſes, books are ſaid to be *incomplete*.

Books, with regard to the *matter* of which they conſiſt, may be divided into *paper-books*, thoſe written either on linen and cotton paper, or on the papyrus, of which laſt kind few are now remaining. Montfaucon Pal. Græc. l. i. c. 2. p. 13. *Parchment-books*, *libri in membrana*, thoſe written on ſkins, or pelts, chiefly of ſheep. *Linen-books*, *libri lintei*, among the Romans, were thoſe written on blocks, or tables, covered with a linen cloth. Such were the Sibylline books, and divers ancient laws, epiſtles of princes, leagues, annals, &c. Plin. Hiſt. Nat. l. xiii. c. 2. *Leathern books*, *libri in corio*, mentioned by Ulpian, are by Guilandinus taken for ſuch as were written on barks, different from that uſually written on; which was the *tilia*: by Scaliger, with more probability, for ſuch as were written on certain ſkins, or certain parts of ſkins, different from thoſe commonly uſed, which were the pelts, or back parts of ſheep. Ulp. l. 52. Guiland. Papyr. Membr. 3. n. 50. Scaliger, and Guiland. *Block-books*, *libri in ſchedis*, thoſe written on wooden planks, or tablets, ſmoothed for that purpoſe with an *aſcia*, and a plane. Such were the ordinary books among the Romans. *Waxen-books*, *libri in ceris*, mentioned by Pliny, have occaſioned ſome diſpute. Herm. Barbarus ſuſpects the term to be a corruption, and inclines to read *in ſchedis*, inſtead of *in ceris*, on the authority of ſome ancient MSS. Others ſee no need of the emendation, ſince it is known the Romans ſometimes covered their planks or *ſchedæ*, with a thin ſkin of wax, to make them ſuſceptible of eraſements and amendments, which the *libri in ſchedis* were not, and conſequently were leſs fit for works that required elegance and accuracy than the waxen ones, which are alſo called *ceræ* or *libri cerei*. *Elephantine books*, according to Turnebus, were thoſe written on thin ſlices, or leaves of ivory; according to Scaliger, thoſe made of the guts of elephants; according to others, thoſe wherein the acts of the ſenate, relating to the emperors, were written; according to others, certain huge or bulky books, conſiſting of 35 volumes, containing all the names of the 35 tribes. Salmuth. ad Pancirol. p. ii. p. 255. Guiland. Pap. Mem. 2. n. 48. Scal. ad Guil. p. 16. Calv. Lex. Jur. p. 534, Fabr. Deſcrip. Urb. c. 6.

Books, with regard to their *manufacture* and *commerce*, may be divided into *manuſcript*, thoſe written with the hand, whether originally by the authors, called *autographi*, or at ſecond hand by *librarii*, or *copyiſts*; *printed*, thoſe wrought off from the preſs; *books in quires*, or *ſheets*, thoſe not bound or ſtitched; *books in folio*, thoſe wherein a ſheet is folded but once, or makes two leaves, or four pages; *books in* 4°, where

where it makes four leaves; in 8°, where eight; *in duodecimo*, where twelve; in 16°, where ſixteen; in 24°, where twenty-four.

Books, with regard to *circumſtances* and *accidents*, may be divided into *loſt*, thoſe which have periſhed by the injuries of time, or the malice or zeal of enemies. Such are divers even of the ancient books of Scripture, written by Solomon, and others of the prophets. Fabr. Cod. Pſeud. Vet. Teſt. tom. ii. p. 171. p. 247. Books *promiſed*, thoſe which authors have given expectations of, which they have never accompliſhed. Janſ. ab Almeloveen has given a Bibliotheca of books promiſed, but ſtill latent, or not publiſhed. Books *fictitious*, thoſe which never exiſted: to which may be added divers feigned titles of books. Loeſcher has publiſhed a great number of plans, or projects of books, many of them good and uſeful enough, if there were but books written correſponding to them. M. Dugono has a whole volume of *ſchemes*, or *projects of books*, containing no leſs than 3000.

Books *in Ana*, *Anti*, &c. See Ana, Anti, &c.

Books, the *ſcope*, or *deſign of*, is various; that of ſome is to trace the origin of things diſcovered; of others, to fix and eſtabliſh ſome truth, or raiſe ſome doctrine to a higher pitch or ſubtilty; of others, to remove ſome ſcruple, or prejudice, which had before obtained, or fix more accurate and preciſe ideas of things: of others, to explain the names and words uſed in different nations, ages, and ſects; of others, to improve our knowledge of facts, and events, and ſhew the order and ways of Providence; laſtly, others aim at divers, or all of theſe ends.

Books, the *uſes of*, are numerous; they make one of the chief inſtruments, or means of acquiring knowledge: they are the repoſitories of laws, and the vehicles of learning of every kind: our religion itſelf is founded on books: "Without them," ſays Bartholin," "God is ſilent, juſtice dormant, phyſic at a ſtand, philoſophy lame, letters dumb, and all things involved in Cimmerian darkneſs." De Libr. Legend. Diſſ. i. p. 5.

The eulogiums which have been beſtowed on books are infinite: they are repreſented "as the refuge of truth, which is baniſhed out of converſation; as ſtanding counſellors, and preachers, always at hand, and always diſintereſted; having this advantage over oral inſtructors, that they are ready to repeat their leſſon, as oft as we pleaſe." Books ſupply the want of maſters, and even, in ſome meaſure, the want of genius and invention: and can raiſe the dulleſt perſons, who have memory, above the level of the brighteſt without them. An author who wrote not inelegantly, though in a barbarous age, ſums up all their praiſes. Vide Lucas de Penna ap. Morhoff. Polyhiſt. lib. i. cap. 3. p. 27. "Liber eſt lumen cordis, ſpeculum corporis, virtutum magiſter, vitiorum depulſor, corona prudentum, comes itineris, domeſticus amicus, congerro talentis, collega & conſiliarius præſidentis, myrothecium eloquentiæ, hortus plenus fructibus, pratum floribus diſtinctum, memoriæ penus, vita recordationis; vocatus properat, juſtus feſtinat, ſemper præſto eſt, nonquam non morigerus, rogatus confeſtim reſpondet; arcana revelat, obſcura illuſtrat, ambigua certiorat, perplexa reſolvit, contra adverſam fortunam defenſor, ſecundæ moderator, opes adauget, jacturam propulſat," &c.

Perhaps their greateſt glory is, the affection borne them by many of the greateſt men in all ages: M. Cato, the elder Pliny, the emperor Julian, and others, are on record for a very extraordinary devotion to books. This laſt has perpetuated his paſſion by ſome Greek epigrams in their praiſe. Richard Bury, biſhop of Durham, and lord chancellor of England, has a treatiſe expreſs on the love of books. Philobiblion, ſive de Amore Librorum. Vide Plin. Epiſt. vii. lib. iii. Cato's attachment to books may be obſerved in the following paragraph.

"M. Catonem vidi in bibliotheca ſedentem multis circumfuſum Stoicorum libris. Erat enim, ut ſcis, in eo inexhauſta aviditas legendi, nec ſatiari poterat: quippe qui, ne reprehenſionem vulgi inanem reformidans, in ipſa curia ſoleret legere, ſæpe dum ſenatus cogeretur, nihil operæ reipublicæ detrahens." Vide Cic. de Divin. lib. iii. n. 11. See alſo Cic. Orat. pro Arch. tom. iv. p. 2182.

Books, the *ill effects* objected to, are, that they employ too much of our time and attention; engage us in purſuits of no uſe to the commonwealth, and indiſpoſe us for the functions of civil life; that they render men lazy, and prevent their exerting their own talents, by furniſhing them, on every occaſion, with things that are the productions of others; and that our natural lights become weakened and extinguiſhed, by inuring ourſelves to ſee only with foreign lights: beſides, that ill men are hereby furniſhed with means of poiſoning the people, and propagating ſuperſtition, immorality, enthuſiaſm, or irreligion, which will always ſpread faſter, and be received more greedily, than leſſons of truth and virtue. Many other things are added concerning the emptineſs of books, and the errors, fables, and follies they are fraught with: which, together with the multitude and perplexity of them, are ſuch, that it may ſeem eaſier to diſcover truth in the nature and reaſon of things, than in the uncertainty and confuſion of books. Add, that books have turned the other inſtruments of knowledge out of doors, as experiments, obſervations, furnaces, and the like, without which the natural ſciences can never be cultivated to purpoſe; and that, in mathematics, books have ſo far ſuperſeded the exerciſe of invention, that the generality of mathematicians are now contented to learn the ſolution of problems from others; which is to relinquiſh the chief end of their ſcience; ſince what is contained in mathematical books is properly the hiſtory only of mathematics, not the ſcience, art, or talent of ſolving queſtions; which is hardly to be had from books, but only from nature and meditation.

Books, for the art of *writing*, or *compoſing*, we have much fewer helps and inſtructions than for the art of ſpeaking; though the former be the more difficult of the two; as a reader is not ſo eaſy to be impoſed upon, but has better opportunities of detecting faults than a hearer. A great cardinal, indeed, reduces an author's buſineſs to a few heads; were they but as eaſily practiſed as preſcribed; "Let him conſider who it is writes, what, how, why, and to whom." Auguſt. Valer. di Caut. in edend. lib. *The conditions required in a book* are, according to Salden, "ſolidity, perſpicuity, and brevity:" the firſt will be beſt attained, by keeping the piece long by us, often reviewing and correcting it by the advice of friends: the *ſecond*, by diſpoſing the ſentiments in a due order, and delivering them under proper and uſual expreſſions: the *third*, by throwing every thing aſide that does not immediately concern the ſubject. Were theſe rules obſerved, it would ſcarcely be poſſible for any, except an angel from heaven, to write many books. "Vix totidem quot Thebarum portæ vel divitiis oſtia Nili." The cuſtom is much altered ſince the times of the ancients, who carried their ſcrupulouſneſs into what relates to the compoſition of books beyond all that has been above expreſſed; ſo auguſt was the idea they formed of a book, that nothing would ſuffice leſs than its being a treaſure: "theſauros oportet eſſe, non libros:" no labour, no aſſiduity and exactneſs, were thought enough to fit a work for the public view: every ſentiment and expreſſion were to be maturely weighed, and turned on all ſides; and not ſuffered to paſs, unleſs every word were a pearl, and every page beſet with

gems. So that they put the reader in poſſeſſion in a ſingle hour, of what had coſt them perhaps ten years' intenſe thought and application. Such were thoſe books, which were reputed "cedro digni," fit to be anointed with cedar-juice, and thus rendered incorruptible, for the inſtruction of all future ages.

Books, *for the origin of*, we have nothing that is clear: the books of Moſes are doubtleſs the oldeſt of all that are extant; but there were books before them, for Moſes cites ſeveral. A book of Enoch is cited in the epiſtle of Jude, v. 14. and 15. from which ſome endeavour to prove the reality of antediluvian writings; but the book cited by that apoſtle is generally allowed both by ancient and modern writers to be ſpurious. See Bible.

Of prophane books, the oldeſt extant are Homer's poems, which were even ſo in the time of Sextus Empiricus; though we find mention in Greek writers, of about ſeventy others prior to Homer; as Hermes, Orpheus, Daphne, Horus, Linus, Muſæus, Palamedes, Zoroaſter, &c. but of the greater part of theſe, there is not the leaſt fragment remaining; and of the others, the pieces which go under their names are generally held by the learned ſuppoſititious. F. Hardouin goes farther; charging all the ancient books, both Greek and Latin, except Cicero, Pliny, Virgil's Georgics, Horace's Satires and Epiſtles, Herodotus, and Homer, as ſpurious, and forged in the thirteenth century, by a club of perſons under the direction of one Severus Arcontius. Fab. Bib. Græc. lib. i. cap. 1. § 1. § 6. tom. i. Hardouin de Num. Herod. in Proluſ. Act. Erud. Lipſ. an. 1710. p. 70.

Among the Greeks, it is to be obſerved, the oldeſt books were in verſe, which was prior to proſe; Herodotus's hiſtory is the oldeſt book extant of the proſaic kind. Strabo. Geog. lib. i. Heuman. Via ad Hiſt. Liter. § 20. p. 50. §. 21. p. 52.

Books, *the multitude of*, has been long complained of: the complaint is as old as Solomon, who lived three thouſand years ago: they are grown too numerous, not only to procure and read, but to ſee, to learn the names of, or even to number. England has more to fear on this ſcore, than other countries; ſince, beſides our own produce, we have, for ſome years paſt, drained our neighbours. However, as biſhop Caramuel's ſcheme miſcarried, which was, to write about a hundred volumes in folio, and then prevail on the civil and military powers to oblige all their ſubjects to read them, we need not much regret the multitude of books.

In reality, there are few of the immenſe number of books which deſerve ſeriouſly to be ſtudied: for the reſt, part of them, like this, are only to be occaſionally conſulted, and the reſt read for amuſement. A mathematician, for inſtance, ought not to be entirely ignorant of what is contained in the mathematical books; but then a general knowledge is ſufficient, which may eaſily be had by running over the chief authors; out of whom references may be made, directing to the places where they may be found, when wanted. For there are many things which are much better preſerved in books than in the memory; as aſtronomical obſervations, tables, rules, theorems, proportions, and in fine, whatever does not ſpontaneouſly adhere to the memory, when once known. For the leſs we croud that faculty, the readier and freer will the genius remain for inventing.

Other books may be valuable in themſelves, for ſome ſpecial purpoſe, or in ſome peculiar ſcience, but are not fit to be peruſed except by thoſe who are engaged in that particular ſcience, or buſineſs. To what uſe is it for a divine, or a phyſician, or a tradeſman, to read over the huge volumes of reports of adjudged caſes in the law? Or for a lawyer to learn Hebrew and read the Rabbins, unleſs his inclination leads him, and his leiſure allows him to employ himſelf in this way? For improvement of knowledge and ſaving of time, it is of great importance for young perſons to have the moſt proper books for his reading, recommended by a judicious friend.

Books of importance of any kind, and eſpecially complete treatiſes on any ſubject, ſhould be firſt read in a more general and curſory manner, to learn in ſome degree what the treatiſe promiſes, and what you may expect from the writer's manner and ſkill. For this purpoſe let the preface be read, and the table of contents, if there be any, before this firſt ſurvey of the book. By this means you will not only be better fitted to give the book a firſt reading, but be much aſſiſted in a ſecond peruſal of it, which ſhould be done with greater attention and deliberation, and you will learn with more eaſe and readineſs what the author profeſſes to teach. In reading it will be uſeful to mark what is new or unknown to you before, and to review thoſe chapters, pages, or paragraphs. Unleſs a reader has an uncommon and moſt retentive memory, we may venture to affirm, that there is ſcarcely any book or chapter worth reading once, that is not worthy of a ſecond peruſal. At leaſt it will be proper carefully to review all the lines or paragraphs which were previouſly marked, and to recollect the ſections which were thought truly valuable. There is another reaſon why it will be uſeful to take a ſuperficial and curſory ſurvey of a book, before we ſit down to read it, and to dwell upon it with ſtudious attention; and that is, that there may be ſeveral difficulties in it, which we cannot eaſily underſtand and reſolve at the firſt reading, for want of a fuller comprehenſion of the author's whole ſcheme. Many ſuch difficulties would be unravelled when we have proceeded farther in ſuch books, or would vaniſh themſelves upon a ſecond reading. What we cannot thoroughly underſtand at firſt may be noted down as matter of ſubſequent conſideration and inquiry, if the pages that follow do not happen to ſtrike a complete light on thoſe which went before. In peruſing books that treat of ſubjects of natural, moral, or divine ſcience, it ſhould be conſidered that it is our buſineſs, not merely to know the opinion of the author, for this is but the mere knowledge of hiſtory; but truly to reflect, whether his opinions are juſt or not, and to improve our own knowledge of the ſubject by a careful inveſtigation of it. With this view we ſhould deal freely with every author whoſe works we read, and yield our aſſent only to evidence and juſt reaſoning. If a writer on any particular ſubject, to which your attention is directed, maintains ſentiments ſimilar to your own, but does not explain his ideas, or prove his poſitions to your ſatisfaction, mark his defects, or faults, and endeavour to do it better, either in the margin of your book, or rather on ſome papers of your own. e. g. When the author is obſcure, enlighten him; where he is imperfect, ſupply his deficiencies; where he is too conciſe, amplify, and ſet his notion in a fairer view; where he is redundant, mark the paragraphs that ought to be retrenched; where he trifles and indulges to impertinence, abandon thoſe paſſages, or pages; where he argues, obſerve whether his reaſons be concluſive; if the concluſion be true, but the argument weak, endeavour to confirm it by better proofs; where he deduces any propoſitions obſcurely, or doubtfully, make the juſtneſs of the inference to appear, and add further inferences or corollaries, if ſuch occur to your mind; where you ſuppoſe he is miſtaken, propoſe your objections, and correct his errors; what he writes ſo well as to approve itſelf to your judgment, as both juſt and uſeful, treaſure up in your memory, and count it a part of your intellectual gains. If the method of a book be irregular, reduce it into form,

by an analyſis of your own, or by hints in the margin; if thoſe things are heaped together, which ſhould be ſeparated, diſtinguiſh and divide them. If ſeveral things relating to the ſame ſubject are ſcattered through various parts of the ſame treatiſe, let them be brought together into one view, by ſuitable references; or if the matter of a book be really valuable and deſerving the labour, you may arrange it in a better method, reduce it to a more logical ſcheme, or abridge it into a leſſer form. All theſe practices will have a tendency to advance your own ſkill in logic and method, to improve your judgment in general, and to give you a more comprehenſive ſurvey of that ſubject in particular. When you have finiſhed the treatiſe, with all your obſervations upon it, recollect and determine what real improvements you have made by reading that author. If a book have no index, or good table of contents, it is uſeful to make ſuch as you are reading it; taking notice merely of thoſe parts which are new and well written, and well worthy of remembrance, or review. If the writer be remarkable for any peculiar excellencies, or defects in his ſtyle, or manner of writing, attentively obſerve them, and whatever ornaments or blemiſhes occur in the language, or manner of the writer, you may make juſt remarks upon them. One book peruſed in the manner now propoſed, will tend more to enrich the underſtanding, than ſkimming over the ſurface of 20 authors. "There are many who read," ſays the excellent author of whoſe uſeful obſervations we are now availing ourſelves, (ſee Watts's Improvement of the Mind) "with conſtancy and diligence, and yet make no advances in true knowledge by it. They are delighted with the notions which they read, or hear, as they would be with ſtories that are told, but they do not weigh them in their minds as in a juſt balance, in order to determine their truth, or falſhood; they make no obſervations upon them, or inference from them. Perhaps their eye ſlides over the pages, or the words ſlide over their ears, and vaniſh like a rhapſody of evening tales, or the ſhadows of a cloud flying over a green field in a ſummer's day; or, if they review them ſufficiently to fix them in their remembrance, it is merely with a deſign to tell the tale over again, and to ſhew what men of learning they are. Thus they dream out their days in a courſe of reading without real advantage. As a man may be eating all day, and for want of digeſtion is never nouriſhed; ſo theſe endleſs readers may cram themſelves in vain with intellectual food, and without real improvement of their minds, for want of digeſting it by proper reflection."

"Never apply yourſelves," ſays the ſame writer, "to read any human author with a determination, before-hand, either for or againſt him, or with a ſettled reſolution to believe, or diſbelieve, to confirm, or oppoſe whatſoever he ſaith; but always read with a deſign to lay your mind open to truth, and to embrace it whereſoever you find it, as well as to reject every falſhood, though it appear under never ſo fair a diſguiſe. How unhappy are thoſe men, who ſeldom take an author in their hands, but they have determined before they begin, whether they will like or diſlike him! They have got ſome notion of his name, his character, his party, or his principles, by general converſation, or perhaps by ſome ſlight view of a few pages; and having all their own opinions adjuſted before-hand, they read all that he writes with a prepoſſeſſion either for or againſt him: unhappy thoſe who hunt and purvey for a party, and ſcrape together out of every author, all thoſe things, and thoſe only which favour their own tenets, while they deſpiſe and neglect all the reſt!" The author ſubjoins an uſeful caution; and wiſhes not to be underſtood, as perſuading a perſon to live without any ſettled principles, by which to judge of books, men, and things, or to be always doubting about his foundations. But having ſettled, upon good grounds, the moſt neceſſary and important principles of ſcience, prudence, and religion, we ſhould read, with a juſt freedom of thought, all thoſe books which treat of ſuch ſubjects as may admit of doubt, or reaſonable diſpute. When we peruſe thoſe authors who defend our own ſettled ſentiments, we ſhould not haſtily conclude that all their reaſonings are juſt and ſolid; nor eagerly embrace all their leſſer opinions, becauſe we agree with them in the greater. When we read thoſe authors who oppoſe our moſt certain and eſtabliſhed principles, we ſhould be ready to receive any information from them in other points, and not abandon every thing they ſay, though we are well fixed in oppoſition to their main object:

"Seize upon truth where-e'er 'tis found,
Amongſt your friends, amongſt your foes,
On Chriſtian, or on heathen ground;
The flower's divine where-e'er it grows;
Neglect the prickles, and aſſume the roſe."

Upon the plan of reading above ſtated and recommended, a few books well choſen, and thoroughly ſtudied, may ſuffice. It may be added, that as knowledge is naturally advantageous, and as every man ought to be in the way of information, even a ſuperfluity of books is not without its uſe, ſince hereby they are brought to obtrude themſelves on us, and engage us when we had leaſt deſign. This advantage, an ancient father obſerves, we owe to the multiplicity of books on the ſame ſubject, that one falls in the way of one man, and another beſt ſuits the level, or the apprehenſion, of another. "Every thing that is written," ſays he, "does not come into the hands of all perſons: perhaps ſome may meet with my books, who may hear nothing of others which have treated better of the ſame ſubject. It is of ſervice, therefore, that the ſame queſtions be handled by ſeveral perſons, and after different methods, though all on the ſame principles, that the explications of difficulties, and arguments for the truth, may come to the knowledge of every one, by one way or other." Add, that the multitude is the only ſecurity againſt the total loſs or deſtruction of books: it is this that has preſerved them againſt the injuries of time, the rage of tyrants, the zeal of perſecutors, and the ravages of barbarians; and handed them down, through long intervals of darkneſs and ignorance, ſafe to our days. "Solaque non norunt hæc monumenta mori." Bac. de Augm. Sc. lib. i. Auguſt. de Trin. lib. i. cap. 3. Barthol. lib. cit. Diff. i. p. 8, &c.

Books, *the ſcarcity of*, is an evil much more to be lamented, in the ſurvey of paſt ages, than their multitude at any later period. Before the art of printing was invented, the trouble and expence of procuring copies very much retarded the progreſs of literature. The univerſal ignorance that prevailed in Europe, from the ſeventh to the eleventh century, may be aſcribed to the ſcarcity of books during that period, and the difficulty of rendering them more common, concurring with other cauſes ariſing from the ſtate of government and manners. The Romans wrote their books either on parchment, or on paper made of the Egyptian papyrus. The latter, being the cheapeſt, was of courſe the moſt commonly uſed. But after the Saracens conquered Egypt, in the ſeventh century, the communication between that country and the people ſettled in Italy, or in other parts of Europe, was almoſt entirely broken off, and the papyrus was no longer in uſe among them. They were obliged on that account to write all their books upon parchment; and as the price of that was high, books became extremely rare and of great value. We may judge of the ſcarcity of materials for writing them from one circumſtance.

There ſtill remain ſeveral manuſcripts of the 8th, 9th, and following centuries, wrote on parchment, from which ſome former writing had been eraſed, in order to ſubſtitute a new compoſition in its place. Thus, it is probable, ſeveral of the works of the ancients periſhed. A book of Livy or of Tacitus might be eraſed, to make room for the legendary tale of a ſaint, or the ſuperſtitious prayers of a miſſal. As the want of materials for writing accounts for the loſs of many of the works of the ancients, and for the ſmall number of MSS. previous to the 11th century, many facts prove the ſcarcity of books at this period. Private perſons ſeldom poſſeſſed any books whatever; and even monaſteries of note had only one miſſal. Towards the end of the ſeventh century, even in the papal library at Rome, the number of books was ſo inconſiderable, that pope St. Martin requeſted Sanctamand, biſhop of Maeſtricht, if poſſible, to ſupply this defect from the remoteſt parts of Germany. In the year 855, Lupus, abbot of Ferrieres in France, ſent two of his monks to pope Benedict III. to beg a copy of Cicero de Oratore and Quintilian's Inſtitutes; "for," ſays the abbot, "although we have part of theſe books, there is no complete copy of them in all France." At the beginning of the tenth century books were ſo ſcarce in Spain, that one and the ſame copy of the bible, Jerome's epiſtles, and ſome volumes of eccleſiaſtical offices and martyrologies, often ſerved ſeveral different monaſteries. Among the conſtitutions given to the monks of England by archbiſhop Lanfranc, in 1072, the following injunction occurs: At the beginning of Lent, the librarian is ordered to deliver a book to each of the religious, for the peruſal of which a whole year was allowed; and at the returning Lent, thoſe monks who had neglected to read the books they had reſpectively received, are commanded to proſtrate themſelves before the abbot, and ſupplicate his forgiveneſs. In 1299, John de Pontiſſara, biſhop of Wincheſter, borrows of his cathedral convent of St. Swithin, at Wincheſter, "bibliam bene gloſſatam," that is, the bible, with marginal annotations, in two folio volumes; but gives a bond for the return of it, drawn up with great ſolemnity. For the bequeſt of this bible to the convent, and 100 marks, the monks founded a daily maſs for the ſoul of the donor. If any perſon gave a book to a religious houſe, he believed, that ſo valuable a donation merited eternal ſalvation, and he offered it on the altar with great ceremony. The prior and convent of Rocheſter declare, that they will every year pronounce the irrevocable ſentence of damnation on him, who ſhall purloin or conceal a Latin tranſlation of Ariſtotle's Poetics, or even obliterate the title. Sometimes a book was given to a monaſtery, on condition that the donor ſhould have the uſe of it for his life; and ſometimes to a private perſon, with the reſervation that he who receives it ſhould pray for the ſoul of his benefactor. In the year 1225, Roger de Inſula, dean of York, gave ſeveral Latin bibles to the univerſity of Oxford, on condition that the ſtudents who peruſed them, ſhould depoſit a cautionary pledge. The library of that univerſity, before the year 1300, conſiſted only of a few tracts, chained or kept in cheſts, in the choir of St. Mary's church. Among the ſtatutes of St. Mary's college at Oxford, in 1446, one is, that no ſcholar ſhould occupy a book in the library above one hour, or two hours at moſt, ſo that others ſhall be hindered from the uſe of the ſame. The famous library eſtabliſhed in the univerſity of Oxford by Humphrey duke of Glouceſter, a munificent patron of literature, contained only 600 volumes. About the beginning of the 14th century, there were only four claſſics in the univerſity of Paris, which were ſingle copies of Cicero, Ovid, Lucan, and Boethius.

The price of books became ſo high, that perſons of a moderate fortune could not afford to purchaſe them. In the year 1174, Walter, prior of St. Swithin's at Wincheſter, purchaſed of the monks of Dorcheſter, in Oxfordſhire, Bede's homilies and St. Auſtin's pſalter for twelve meaſures of barley and a pall, on which was embroidered in ſilver the hiſtory of St. Birinus converting a Saxon king. About the year 1400, a copy of John of Meun's "Roman de la Roſe" was ſold before the palace-gate at Paris for 40 crowns, or 33 l. 6 s. 6 d. The counteſs of Anjou paid, for a copy of the homilies of Haimon, biſhop of Halberſtadt, 200 ſheep, five quarters of wheat, and the ſame quantity of rye and millet. Even ſo late as the year 1471, when Louis XI. of France borrowed the works of Rhaſis, the Arabian phyſician, from the faculty of medicine at Paris, he not only depoſited by way of pledge a conſiderable quantity of plate, but he was obliged to procure a nobleman to join with him as ſurety in a deed, binding himſelf under a great forfeiture to reſtore it. Many other inſtances might be cited, in order to ſhew how ſcarce books were at the period to which we now refer, and with what difficulty, and at what extravagant prices, copies of them were procured; and therefore we can be at no loſs in accounting for the extreme ignorance that prevailed. But when, in the 11th century, the art of making paper was invented, and more eſpecially after the manufacture became general, the number of MSS. increaſed, and the ſtudy of the ſciences was wonderfully facilitated. Indeed, the invention of the art of making paper, and the invention of the art of printing, are two very memorable events in the hiſtory of literature and of human civilization. It is remarkable, that the former preceded the firſt dawning of letters and improvement in knowledge, towards the cloſe of the eleventh century; and the latter uſhered in the light which ſpread over Europe at the æra of the reformation. Murat. Antiq. Ital. vol. iii. vol. ix. Mem. de l'Acad. des Inſcript. tom. ix. Hiſt. Lit. de France, par des Religieux Benedictins, tom. vii. Naudé Addit. a l'hiſtoire de Louis XI. par Comines, ed. Freſnoy, tom. iv. Robertſon's Hiſt. Ch. v. vol. i. Wharton's Eng. Poetry, vol. i. diſſ. 2.

Books, *to form a judgment of.* Thoſe who have treated of the ſubject, direct us to obſerve the title, the author's or editor's name, the number of the edition, the place where, and the year when it is printed (which in old books is frequently marked at the end), and the printer's name, eſpecially if it be a celebrated one; proceed then to the preface, and index of contents, and look for the author's deſign, and the occaſion of his writing; conſider alſo his country (each nation having its peculiar genius), which may ſometimes be learned from the dedication; if his life be annexed, run it over, and note his profeſſion, what rank he was of, and any thing remarkable that attended his education, ſtudies, converſation, or correſpondences with learned men; not forgetting the elogies which have been given to the author, which often occur at the beginning, or even any critique or cenſure, eſpecially if made by a man of judgment. If the preface does not give an account of the method of the work, run briefly over the order and diſpoſition of it, and note what points the author has handled; obſerve whether the things and ſentiments he produces be trite and vulgar, or ſolid, and fetched from greater depths. Note, whether he go in the common road, or make any innovation, and introduce any new principle.

But it is a ſmall number of books we have opportunity of thus judging of by peruſing them; beſides, when we have read a book over, the judgment comes too late for many purpoſes. Life is too ſhort, and time is too precious, to read every new book quite over, in order to find that it is

not worth reading. It ſeems neceſſary, therefore, to have other indications, whereby to prevent our being at the charge of procuring, or the pains of peruſing a worthleſs book. Divers rules of this kind are given by Baillet, Struvius, Stollius, and others; which, though in reality no more than preſumptions, and frequently liable to be falſified, are not without their uſe. The journaliſts de Trevoux objected to them all: "The ſhorteſt way," ſay they, "to judge of a book is to read it, if you be qualified in the ſubject; otherwiſe to refer yourſelf to thoſe who are ſo." Heuman is ſomewhat more explicit; making it a mark that "a book is good, when it is eſteemed by perſons intelligent in the ſubject it treats of; and when thoſe who commend it receive no advantage from the applauſe they beſtow on it, nor are leagued with the author in any cabal, for eſpouſing any particular principle, ſyſtem, or party, in religion or learning." Baillet, Jugem. des Sçav. tom. i. b. ii. p. 121. Struv. Introd. ad Not. Rei Liter. cap. 5. § 3. p. 390. Stoll. Introd. Hiſt. Liter. p. i. § 11. p. 9. Budd. de Criteriis boni libri, paſſim. Mem. de Trev. an. 1712. Art. 17. Heuman. Conſp. Reipubl. Liter. cap. vi. § 11. p. 280.

But more particularly, it is an indication that a book is good; 1. If the author be known to excel in that talent more immediately neceſſary for ſuch a ſubject; or have already publiſhed any thing on the ſame that is eſteemed. Thus we may conclude, that Julius Cæſar will teach us the art of war better than Peter Ramus; Cato, Palladius, and Columella, agriculture better than Ariſtotle; and Cicero, oratory better than M. Varro: add, that it is not enough the author be ſkilled in the faculty, but that he be ſo in the particular branches of it, concerning which he treats; ſome, for inſtance, excel in the civil law, yet not in the public law; Salmaſius proved himſelf an excellent critic in his Exercitat. Plinian. but was much inferior to Milton in his Defenſio Regia. 2. If the book be on a ſubject that requires great reading, it may be preſumed good, if the author had a copious library, or could have acceſs to one; or if he lived in a place where books were not wanting; though here is danger too of running into exceſs of quotations; eſpecially, ſays Struvius, if the author be a lawyer. 3. A book which took up a long time in compoſing, cannot often fail of being good. 4. Books on points of doctrine by eclectic writers, are to be preſumed better than thoſe writ by the retainers to particular ſects. 5. The age of a writer may alſo give us ſome indication: books, which require labour, are uſually better performed by younger perſons than thoſe who are far advanced in years. 6. Another indication may be taken from the author's ſtate and condition: thus, hiſtory written by a perſon who was an eye-witneſs to what he relates, or is concerned in public affairs, or has acceſs to the public records, or other monuments, from whence intelligence may be drawn; who is not biaſſed by party, or any other indirect or ſiniſter motive, will be ſuppoſed to be good. Thus Salluſt and Cicero were well able to write the hiſtory of Cataline's conſpiracy. D'Avila, de Comines, Guicciardin, Clarendon, &c. were preſent in the civil wars they deſcribe; Xenophon, having an employment in the Spartan ſtate, has treated excellently of that commonwealth; and Amelot de la Houſſaye, by living long at Venice, was enabled to explain the ſecrets of their policy. Camden wrote annals of the affairs of his own time; Thuanus had correſpondence with the beſt writers in every country; and Puffendorf had acceſs to the public archives. So, in literary matters, we give credit to thoſe who have the direction of libraries. 7. The time or age wherein the author lived may give ſome light; every age having, according to Barclay, its peculiar genius and excellency. See Bartholin. Struv. Budd. Heuman. Baill. lib. cit.

Some judge by the bulk or ſize of books; following the grammarian Callimachus's rule, that every great book is of courſe an ill one, μεγα βιβλιον, μεγα κακον; a ſingle leaf of the Sybil was doubtleſs preferable to the vaſt annals of Voluſius: yet Pliny's obſervations will nevertheleſs hold true, that "a good book is ſo much the better by how much it is bigger." Plin. Epiſt. 20. lib. i. Martial preſcribes a remedy againſt the largeneſs of a book, when that is the only complaint, read but a little of it:

"Si nimius videar, ſeraque coronide longus
Eſſe liber, legito pauca, libellus ero."

Yet is the ſmallneſs of a book a real preſumption in its favour: he muſt be a poor author, who cannot furniſh a pamphlet, or looſe ſheet, with things curious, and written with ſpirit; but to ſupport the ſame through a volume in folio, requires very extraordinary abilities indeed. Addiſ. in Spec. N° 124.

There are ſome general miſtakes, which perſons are frequently guilty of in paſſing judgment on the books which they read. One is, when a treatiſe is written but tolerably well, we are ready to pronounce a favourable judgment of it, and ſometimes to exalt its character far beyond its merit, if it agree with our own principles and ſupport the opinions of our party. On the other hand, if the author be of different ſentiments, and eſpouſe contrary principles, we can find neither wit nor reaſon, good ſenſe, nor good language in it. For avoiding or correcting this error, it ſhould be conſidered, that books are never to be judged of merely by their ſubject, or the opinion they repreſent, but by the juſtneſs of their ſentiments, the beauty of their manner, the force of their expreſſion, or the ſtrength of reaſon, and the weight of juſt and proper argument, which appear in them. Another miſtake, which ſome perſons fall into, is this: When they read a treatiſe on any ſubject, with which they have but little acquaintance, they find almoſt every thing new and ſtrange to them, their underſtandings are much gratified and improved by many things unknown to them before; and hence they are led to admire the treatiſe, and commend the author: whereas, if they had previouſly attained a conſiderable degree of ſkill in that ſcience, perhaps they would have found that the author had written very indifferently, that neither his ſenſe nor his method was juſt and proper, and that he delivered nothing that was not very common or very trivial, in his diſcourſes on that ſubject. On the other hand, if we have made ourſelves maſters of any particular theme of knowledge, and ſurveyed it long on all ſides, there is ſcarcely any writer who much pleaſes us afterwards, becauſe we find little or nothing new in him; and yet in a true judgment perhaps his ſentiments are unexceptionably juſt, his illuſtrations clear, and his reaſonings forcible, and all the parts of the diſcourſe are well connected and ſet in a happy light; but we knew moſt of theſe things before, and therefore they do not ſtrike us, and we are in danger of diſcommending them. There are ſome other follies into which perſons are apt to be betrayed in forming their judgment of books. Some perſons, who are of a forward and lively temper, and who are fond of intermeddling with all appearances of knowledge, will give their judgment of a book as ſoon as the title of it is mentioned, for they would not ſeem ignorant of any thing that others know; and eſpecially, if they happen to have any ſuperior character or poſſeſſions, they fancy they have a right to talk freely and to pronounce magiſterially on every thing, even of a literary kind, that occurs. Thus, blind men will talk of the beauty

beauty of colours, and of the harmony or diſproportion of figures in painting; the deaf will prate of diſcords in muſic; and thoſe who have no pretenſions to literature, will pronounce, with an unpardonable preſumption, on books of ſcience; and thoſe who have little or no acquaintance with either the ſpeculative or practical principles of religion, will arraign the beſt treatiſe on divine ſubjects, though they do not underſtand the very language of the Scripture, nor the common terms or phraſes uſed in Chriſtianity. Judges of another deſcription ſet themſelves up to decide in favour of an author, or againſt him, according to the company they have kept, and the judgment pronounced concerning a book by others of their own ſtamp or ſize, though they have no knowledge or taſte of the ſubject themſelves. Theſe, with a fluent and voluble tongue, become mere echoes of the praiſes or cenſures of other men. Others, again, paſs judgment from the ſecret ſtimulations of vanity, pride, or envy; and in order to juſtify an unwarrantable and ſevere cenſure, they will allege a miſtake or two, which they have diſcovered, or a few ſentiments and expreſſions not ſuited to their capricious taſte and humour. It is, however, an indication of perverſeneſs and prejudice, to rail at any human performance becauſe it is not abſolutely perfect. Horace has given us a better example:

"Sunt delicta tamen, quibus ignoviſſe velimus:
Nam neque chorda ſonum reddit, quem vult manus, et mens.
Poſcentique gravem perſæpe remittit acutum;
Nec ſemper feriet quodcunque minabitur arcus
Verum, ubi plura nitent in carmine, non ego paucis
Offendar maculis, quas aut incuria fudit,
Aut humana parum cavit natura."— De Art. Poet.

"Be not too rigidly cenſorious:
A ſtring may jar in the beſt maſter's hand,
And the moſt ſkilful archer miſs his aim;
So in a poem elegantly writ,
I will not quarrel with a ſmall miſtake,
Such as our nature's frailty may excuſe." Roscommon.

Another, and very frequent fault in paſſing judgment upon books, is this, that perſons ſpread the ſame praiſes, or the ſame reproaches, over a whole treatiſe, which are juſtly applicable only to ſome detached parts of it. After all, when any perſon pretends to give his judgment of a book, we ſhould conſider whether he be a capable judge, or whether he may not lie under ſome unhappy bias or prejudice, for or againſt it, or whether he has made a ſufficient inquiry to enable him for forming a juſt opinion. Watts's Improvement of the Mind apud Works, vol. v. ch. 4—5.

The importation or ſale of maſs-books, or other popiſh books, is by ſtat. 3 Jac. I. c. 5. § 25. liable to a penalty of forty ſhillings.

The importation of books firſt printed in this kingdom, and reprinted abroad, is prohibited under a penalty of 5 l. and double the value of every book ſo imported and ſold. Vide ſtat. 12 Geo. II. c. 36. § 1.

There was a clauſe in the ſtatute of the 8th of queen Anne, c. 19. empowering the chancellor and ſome other great officers of ſtate, to ſet the price of books; but this is now repealed by 12 Geo. II. c. 36. § 2.

The ſole right of printing books bequeathed to the two univerſities of England, the four univerſities of Scotland, and the colleges of Eton, Weſtminſter, and Wincheſter, are ſecured to them by ſtat. 15 Geo. III. c. 53. See Literary *Property*.

Books, *burning of*, was a kind of puniſhment ſanctioned, both among the Greeks and Romans, by legal ſentence. At Athens, the works of Protagoras were prohibited; and all the copies of them which could be collected, were burnt by the public cryer. Diogenes Laert. l. ix. 52. At Rome, the writings of Numa, which had been found in his grave, were, by order of the ſenate, condemned to the fire, becauſe they were contrary to the religion which he had introduced. Liv. l. xl. c. 29. Plin. xiii. 13. Plutarch. in vit. Numæ. As the populace of Rome were, in times of public calamity, more addicted to ſuperſtition than ſeemed proper to the government, an order was iſſued that all ſuperſtitious and aſtrological books ſhould be delivered into the hands of the prætor. This order was often repeated; and the emperor Auguſtus cauſed more than 20,000 of theſe books to be burned at one time. Liv. l. xxv. c. 1. l. xxxix. 16. Tacit. Annal. vi. 12. Sueton. l. ii. c. 31. Sometimes the care of the execution of the ſentence for burning books was committed to *triumviri* appointed on purpoſe; ſometimes to the prætors; and ſometimes to the ædiles. Labienus, whom from his ſatirical ſpirit ſome have called *Rabienus*, is ſaid to have been the firſt who underwent the ſeverity of it, under the emperor Auguſtus. His enemies procured a *ſenatuſconſultum*, whereby all his books, publiſhed during ſeveral years, were ordered to be collected and burnt. The thing, ſays Seneca, (in the introduction to the 5th, or, as others reckon, the 10th book of his "Controverſiæ,") then appeared new and ſtrange to take revenge on learning! "Res nova et inſueta, ſupplicia de ſtudiis ſumi!" Caſſius Severus, a friend of Labienus, hearing the ſentence pronounced, cried aloud, that they muſt burn him too, ſince he had got all the books by heart; "Nunc me vivum uri oportet, qui illos edidici." Labienus could not ſurvive his books; but ſhutting himſelf up in the tomb of his anceſtors, pined away, and was buried alive. It is related as ſomewhat ſingular, that a few years after, the writings of the perſon, who had been the cauſe of the order for burning Labienus's books, ſhared the like fate, and were alſo publicly burned. In a manner ſomewhat ſimilar, the works of Ben-Arias Montanus, who aſſiſted to make the firſt catalogue of prohibited books, in the Netherlands,

therlands, were afterwards inſerted in a catalogue of the ſame kind. The expreſſion of Caſſius above cited gave occaſion to a law of Auguſtus againſt abuſive writings. Tacit. Annal. l. i. c. 72. When Cremutius Cordus, in his Hiſtory, called C. Caſſius the laſt of the Romans, the ſenate, in order to flatter Tiberius, cauſed the book to be burned; but a number of copies were concealed and preſerved from the flames. Tacit. Annal. l. iv. c. 35. Antiochus Epiphanes cauſed the books of the Jews to be burned; and in the firſt centuries of our æra, the books of the Chriſtians were treated with equal ſeverity, of which Arnobius (Adv. Gentes, l. iii. & iv.) bitterly complains. Euſebius informs us (Hiſt. Eccl. l. viii. c. 2.), that Diocleſian cauſed the ſacred Scriptures to be burned. After the ſpreading of the Chriſtian religion, the clergy exerciſed againſt books that were either unfavourable or diſagreeable to them, the ſame ſeverity which they had cenſured in the heathens as fooliſh and prejudicial to their own cauſe. Thus, were the writings of Arius condemned to the flames at the council of Nice; and Conſtantine threatened with the puniſhment of death thoſe who ſhould conceal them. Socrates, l. i. c. 6 The clergy aſſembled at the council of Epheſus, requeſted the emperor Theodoſius II. to cauſe the works of Neſtorius to be burned, and their requeſt was complied with. Cod. l. i. tit. 5, 6. The writings of Eutyches ſhared the like fate at the council of Chalcedon; and the ſame practice of burning books thought to be heretical with regard to religion, or injurious to the ſtate in a political view, has been imitated in ſubſequent ages, and in various nations even of the Chriſtian world.

Divers other ancient teſtimonies concerning the burning of books are given in Reimm. Idea Syſt. Antiq. Liter. p. 389.

Books, *Privilege of.* See Privilege.

Books, *whitening of.* The following proceſs for whitening prints, printed books, and paper, has been announced and deſcribed by M. Chaptal. Simple immerſion in oxygenated muriatic acid, for a longer or ſhorter ſpace of time, according to the ſtrength of the liquid, will ſuffice to whiten an engraving. But in whitening the paper of a bound book, it is neceſſary that all the leaves ſhould be moiſtened by the acid, and therefore the book muſt be well opened, and the leaves ſeparated; and the boards muſt be made to reſt on the edge of the veſſel containing the whitening liquor. This liquor in the proceſs aſſumes a yellow tint, and the paper becomes proportionably white. At the end of two or three hours, the book may be taken from the acid liquor and plunged into pure water; and the water ſhould be renewed every hour to extract the remaining acid, and to diſſipate the diſagreeable ſmell. In order to render this proceſs more effectual, the book-binders deſtroy the binding, unſew the book, and ſeparate its leaves; they then place theſe in caſes formed in a leaden tub, with very thin ſlips of wood or glaſs, ſo that the leaves may lie flat and ſeparate from one another at very ſmall intervals. The acid is then gently poured into the tub, without deranging the leaves. When the paper is become ſufficiently white, the acid liquor is drawn off by a cock at the bottom of the tub; and its place is ſupplied by clear, freſh water. The leaves are then dried, and, after being preſſed, re-bound. The leaves may with greater advantage be placed vertically in the tub. With this view, M. Chaptal conſtructed a wooden frame, adjuſted to the proper height, according to the ſize of the leaves propoſed to be whitened. This frame ſupported very thin ſlips of wood, at the diſtance from one another of half a line. In each of theſe intervals he placed two leaves, and kept them fixed in their place by two ſmall wooden wedges, puſhed in between the ſlips. When the paper was whitened, he lifted up the frame with the leaves, and plunged them into cold water, to take off the remaining acid, as well as the ſmell. By this operation books are not only cleaned, but the paper acquires a degree of whiteneſs ſuperior to what it poſſeſſed when firſt made. This acid will alſo ſerve to deſtroy ink ſpots; but it has no action upon ſpots of oil, or animal greaſe; however, a weak ſolution of pot-aſh will effectually remove ſtains of that kind. To oxygenate the muriatic acid, it is only neceſſary to dilute it, and mix it in a very ſtrong glaſs veſſel with manganeſe, in ſuch a manner that the mixture may not occupy the whole content of the glaſs. Air-bubbles are formed upon the ſurface of the liquor; the empty ſpace is filled with a greeniſh vapour; and, at the end of ſome hours, the acid may be further diluted with water, and then uſed. In order to remove ſpots of greaſe from books and prints, M. Deſchamps, member of the Philoſophical Society at Lyons, recommends to take out as much as poſſible of it by means of blotting paper; and then to dip a ſmall bruſh in the eſſential oil of well rectified ſpirit of turpentine, heated almoſt to ebullition, and draw it gently over both ſides of the paper, which muſt be carefully kept warm. This operation muſt be repeated as often as the quantity of greaſe imbibed by the paper, or the thickneſs of the paper, may render neceſſary. When the greaſe is entirely removed, the paper may be reſtored to its former whiteneſs, by dipping another bruſh in highly rectified ſpirit of wine, and drawing it, in like manner, over the place which was ſtained, and particularly round the edges, to remove the border that would ſtill preſent a ſtain. Bibliotheque Economique, vol. i. See Bleaching.

Book, *common-place.* See Common-Place.

Book, *text.* See Text.

Book, is alſo uſed for a part or diviſion of a volume, or large work.

In this ſenſe we ſay the book of Geneſis, the firſt book of Kings, the five books of Moſes, &c.—The Digeſt is contained in fifty books, the Code in twelve books.

Books are uſually ſubdivided into chapters, ſometimes into ſections, or paragraphs: accurate writers quote chapter and book.

Book is alſo uſed for a liſt or catalogue of perſons' names.—Such among the ancients were the *cenſorial* books, being tables or regiſters containing the names of all thoſe who were cenſed or taxed under Auguſtus. Tertullian aſſures us, that our Saviour's name was found in the cenſorial book of Auguſtus. Adv. Marcion. lib. iv. cap. 7. See Census.

Books, in *Matters of Commerce*, denote the ſeveral regiſters wherein merchants and other dealers keep their accounts. Hence *to book*, is to regiſter in a book.

We ſay, ſuch a perſon's books are in good order; merchants cannot poſſibly do without books; they are even obliged by the laws to keep books. But more or fewer are required, according to the nature or extent of their dealings, or the preciſion and exactneſs they deſire therein.

The ancients had alſo their books of accounts; witneſs the *codex accepti & expenſi*, ſo often mentioned in Roman writers; and the *patrimonial* books, which were rentals, containing an account of the lands, goods, and chattels, and other effects belonging to each perſon.

Among the defects to which the trial by jury is ſubject, one is the want of a compulſive power for the production of books and papers belonging to the parties. In the hands of third perſons, they can generally be obtained by rule of court, or by adding a clauſe of requiſition to the writ of "ſubpœna," which is then called a "ſubpœna duces tecum." But,

444045

But, in mercantile tranſactions eſpecially, the ſight of the party's own books is frequently deciſive; as the day-book of a trader, when the tranſaction was recently entered, as really underſtood at the time; though ſubſequent events may tempt him to give it a different colour. And, as this evidence may finally be obtained, and produced on a trial at law, by the circuitous courſe of filing a bill in equity, the want of an original power for the ſame purpoſes in the courts of law is a material defect.

Book-binding, the art of ſewing together the ſheets of a book, and ſecuring them with a back, and ſtrong paſte-board ſides, covered with leather, &c.

Binding is diſtinguiſhed from ſtitching, as in the latter the leaves are only ſewed, without bands or backs.

We ſay, French-*binding*, law-*binding*, marble-*binding*, *binding* in parchment, in ſheep, in calves leather, &c. alſo half-*binding*, wherein the leaves are generally left uncut, and only the back covered with leather, the paſteboard ſides being covered with marbled, or blue paper. Dutch-*binding* is where the backs are of vellum. The Italians are ſtill contented to bind in a coarſe, thick paper, called *binding alla ruſtica*, the inconvenience of which is its being liable to wear out without careful uſe. Without doubt, the art of binding is almoſt as ancient as the ſcience of compoſing books; and both the one and the other followed immediately the firſt invention of letters. Whatever the matter might be, on which men firſt wrote, there was a neceſſity of uniting the ſeveral parts together; as well for the making them of one piece, as for the better preſerving them; hence the origin of *book-binding*.

According to Olympiodorus (apud Phot.) it was one Phillatius, a learned man at Athens, who firſt taught the uſe of a kind of glue, to faſten the ſeveral leaves together; on which account a ſtatue was erected to him.

Books, *the manner of binding in volumes*, i.e. of gluing the leaves together; that of rolling them on round pieces, or cylinders of wood, appears the moſt ancient; though that of binding them ſquare, and of ſewing ſeveral quires one over another, lays claim to conſiderable antiquity. The firſt of the two, which we call *Egyptian* binding, held a long time after the age of Auguſtus; but it is now diſuſed, excepting in the Jewiſh ſynagogues, where they continue to write the books of the law on vellum ſewed together; making, as it were, only one long page, with two rollers and their claſps of gold and ſilver, at each extremity.

The form now in uſe is the *ſquare*-binding, which is ſaid to have been invented by one of the Attali, kings of Pergamus; to whom we likewiſe owe the manner of preparing parchment, called in Latin, from the name of his capital, *Pergamena*, or *Charta Pergamea*.

Books, *manner of binding*. The firſt operation is to fold the ſheets according to the form, viz. into two leaves for folios, four for quartos, eight for octavos, &c. which the workmen do with a ſlip of ivory or box, called a *folding-ſtick*; in this they are directed by the catch-words and ſignatures, which are the letters with the numbers annexed to them, at the bottom of the pages. The leaves thus folded, and laid over each other in the order of the ſignatures, are beaten on a ſtone with a heavy hammer to make them ſolid and ſmooth, and then preſſed. Being thus prepared, they are ſewed in a ſewing-preſs, upon pack-threads or cords, which are called bands, at a proper diſtance from each other, and in a convenient number; which is done by drawing a thread through the middle of each ſheet, and giving it a turn round each band, beginning with the firſt, and proceeding to the laſt. The common number of bands is ſix in folios, and five in quartos, octavos, &c. Sometimes they uſe a ſaw to make places for the bands, which are ſunk into the paper, ſo that the back of the book, when bound, is ſmooth, without any appearance of bands. After this the backs are glued, the ends of the bands being opened, and ſcraped with a knife, for the more convenient fixing of the paſte-boards; then the back is turned with a hammer, the book being fixed in a preſs between boards, called *backing-boards*, in order to make a groove for admitting the paſte-boards. The boards being then applied, holes are made for drawing the bands through, the ſuperfluous ends being cut off, and the parts hammered ſmooth. Then the book is preſſed in order for cutting; which is performed by a particular machine called a *plough*, to which is fixed a knife. After this the book is put into a preſs called the *cutting-preſs*, betwixt two boards, the one lying even with the preſs, for the knife to run upon; the other above it, for the knife to cut againſt.

The book being cut, the paſte-boards are ſquared with a proper pair of iron ſhears; and it is then ready for ſprinkling, gilding, blacking, or marbling the leaves. The colours with which is is ſprinkled, are uſually vermilion, or ſap-green; which is done with a bruſh made with hog's briſtles, holding the bruſh in one hand, and moving the hair with the other.

In the *French*-binding a book is put in parchment, i. e. a ſlip of parchment is applied over the back between each band, and the ends paſted on the inſide of each paſte-board. This preparation, called *indorſing*, ſeems peculiar to the French binders; who are enjoined by ordonnance to back their books with parchment on the penalty of 30 livres, and the re-binding of the book; it is done in the preſs, where the back being grated to make the paſte take hold, the parchment is applied; and they afterwards add glue to fortify it.

In 1799 a patent was granted to Mr. John Williams and Mr. Joſeph Williams, ſtationers, London, for an improved method of binding all ſorts of books. By the ſpecification it appears, that this invention conſiſts of a back, of a ſemi-circular, ſemi-oval, or any other curved form, turned a little at the edges, made of iron, ſteel, copper, braſs, tin, or any other metal, ivory, bone, wood, vellum, paper, leather, or any material capable of retaining a firm ſituation. This back, being put on the book before bound, ſo as juſt to cover but not to preſs the edges of the paper, will, when the book is opened, prevent its ſpreading on either ſide, and cauſe it to riſe in any part which is opened to nearly a level ſurface. This firm back, turned at the edges, ſo as to cauſe all ſorts of books to open freely, is the object of this patent. The method of binding, practiſed by the inventors, is as follows: they forward the paper in the uſual manner; ſew on vellum ſlips, glue, cut, clothe, and board, or half-board; and put on the firm back by faſtening it at the ſides, through holes, by vellum, or ſecuring it by incloſing it in vellum or ferret wrappers, or other matters, paſted down upon, or drawn through the boards. Mr. Ebeñezer Palmer, ſtationer of London, obtained a patent in 1800 for an improvement in the mode of binding books, particularly account books of merchants. This conſiſts in the addition of a certain metallic chain, which is made or applied in the following manner: firſt, provide ſeveral ſmall bars of metal, about the thickneſs of a ſhilling, or more, according to the ſize and thickneſs of the book; the length of each bar being from half an inch to ſeveral inches long, in proportion to the ſtrength required in the back of the book. At each end of every bar is made a pivot of different lengths, in proportion to the thickneſs of two links, which they are to receive. Each link is made in an oval form, and contains two holes, proportioned

portioned to the ſizes of the pivots; and theſe links are of the ſame metal as the hinge; each of them being nearly equal in length to the width of two bars. The links are then rivetted on the pivots, each pivot receiving two of them, and thus holding the hinge together, on the principle of a link-chain or hinge. There are further two holes or more of different ſizes, as required in each bar of the hinge or chain, by means of which each ſection of the book is ſtrongly faſtened to the ſame; which hinge, ſo faſtened, operates with the back of the book, when bound, in ſuch manner as to occaſion the ſeveral ſections to open ſo as to bring them on a parallel with each other, and conſequently admit the ruled lines being written into, without any inconvenience, cloſe to the back.

Manner of gilding books on the edges. The book, being put tight into the preſs, between two boards, is ſcraped with a knife called a *ſcraper;* and after that with another called a *ſmoother*, in order to take out all ſcratches. Being thus made ſmooth, they ſcrape a little yellow ochre upon the book, wet it with a little ſize-water, and rub it off with ſome clean ſhavings. The gilding ſize is made with the white of an egg, mixed with water, and beat well together. The leaves being wetted with the ſize-water, with a bruſh, the gold is then laid upon it, and afterwards dried before the fire. When dried, it is burniſhed off with a dog's tooth ſet in a handle. See GILDING on *paper*, &c. Blacking the leaves is done with fine antimony, the leaves being wet, and the antimony rubbed upon them until quite dry, when it is burniſhed like the gold.

The head-band is now added, which is an ornament of thread or ſilk, of two or three colours, placed at each extreme of the book, acroſs the leaves, and woven or twiſted, ſometimes about a ſingle, and ſometimes a double piece of rolled paper, or, what is more laſting, of glued paper-thread.

For the covers; the ſkins uſed undergo ſeveral preparations, which we ſhall explain in calf, as being the leather moſt uſed; and as being that to which all the reſt with a little variation may be referred. The calf-ſkin, being moiſtened in water, is cut to the ſize of the book, and the thickneſs of the edges pared off on a marble ſtone kept for that purpoſe. The cover is next ſmeared over with paſte, made of wheat-flour; then ſtretched over the paſte-board on the out-ſide, and doubled over the edges within-ſide. They then *cord the book*, or *bind* it firmly between two boards, to make the cover ſtick the ſtronger to the paſte-boards and the back; on the exact performance of which depends a great part of the truth and neatneſs of the book. The back is then warmed at the fire to ſoften the glue, and the leather of the back is rubbed down, with a folding-ſtick or bodkin, to ſet and fix it cloſe to the back of the book. It is now ſet to dry, and when dry, uncorded: the book is then waſhed over with a little paſte and water, the edges and ſquares blacked with ink, and then ſprinkled fine with a bruſh, by ſtriking it againſt the hand, or a ſtick; or with larger ſpots mixed with vitriol, which is called *marbling*. Two blank leaves, on each ſide, are then to be paſted down to the cover, and, when dry, the leaves are *burniſhed* in the preſs, and the cover rolled on the edges.

The cover is now glazed twice with the white of an egg; it is then filleted plain, or with gold; and at laſt poliſhed with a poliſhing iron, paſſed hot over the glazed colour. If the book be required to be lettered, they paſte a piece of red Morocco on the back, between the firſt and ſecond band to receive the title in gold letters; and ſometimes a ſecond between the next bands underneath, to receive the number of the volume.

The plain binding, properly ſo called, is now complete; the gilding on the back and cover, as it makes a part of the *book-binder's* buſineſs among us (though, with the French, &c. it is a diſtinct profeſſion), we ſhall here ſubjoin.

Manner of gilding books on the back and covers. In ordinary binding, they gild little elſe but the backs, and the outward edges of the cover. On the backs are gilt the title of the book, &c. with flowers, roſes, knots, ſtars, &c. between the bands: on the covers are ſometimes added compartments, arms, &c. All theſe ornaments are made with each its ſeveral gilding tool, engraved in *relievo;* either on the points of puncheons, as thoſe of letters, roſes, ſtars, &c. or around little cylinders of braſs, as the lines, embroideries, &c. The puncheons make their impreſſion, by being preſſed flat down; and the cylinders by being rolled along by a handle, to which they are fitted on an iron ſtay, or axis.

To apply the gold, they glaze thoſe parts of the leather, whereon the tools are to be applied, three or four times with a liquor made of the whites of eggs diluted with water by means of a ſponge; and, when nearly dry, they ſlightly oil them, and then lay on pieces of leaf-gold, and on theſe apply the tools, with a careful even preſſure of the hand, or roll the cylinders, both the one and the other, reaſonably hot. If the figures be large, and require a great *relievo*, as arms, &c. they are beat or preſſed down. The gilding thus finiſhed, they rub off the ſuperfluous gold, and poliſh the whole; the gloſs of which is greatly aſſiſted by a final preſſing between horns peculiar for the purpoſe.

Our book-binders, for gilding on rough leather, make uſe of reſin dried and powdered, inſtead of whites of eggs; and the gold leaf, firſt cut to a proper ſize, is laid on a hot ſomewhat oiled ſtamp, and preſſed down: and thus the reſin melts only in thoſe parts where the hot ſtamp is applied, and the gold fixes on it, whilſt the other parts of the leather remain rough as at firſt. Dr. Lewis's Com. Phil. Tech. p. 615. See GILDING.

Ahaſ. Fritſch, chancellor of the univerſity of Jena, has a diſſertation expreſs concerning book-binders, *De Bipliopegis;* wherein he treats of the laws preſcribed by theſe artificers, and the tax or price ſettled by the magiſtrate for binding books, of every ſort in ſheep-ſkin, vellum, &c.
